Deterministic Image-to-Image Translation via Denoising Brownian Bridge Models with Dual Approximators
Bohan Xiao, Peiyong Wang, Qisheng He, Ming Dong; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 28232-28241
Image-to-Image (I2I) translation involves converting an im- age from one domain to another. Deterministic I2I transla- tion, such as in image super-resolution, extends this con- cept by guaranteeing that each input generates a consistent and predictable output, closely matching the ground truth (GT) with high fidelity. In this paper, we propose a denois- ing Brownian bridge model with dual approximators (Dual- approx Bridge), a novel generative model that exploits the Brownian bridge dynamics and two neural network-based approximators (one for forward and one for reverse pro- cess) to produce faithful output with negligible variance and high image quality in I2I translations. Our extensive exper- iments on benchmark datasets including image generation and super-resolution demonstrate the consistent and supe- rior performance of Dual-approx Bridge in terms of im- age quality and faithfulness to GT when compared to both stochastic and deterministic baselines. Project page and code: https://github.com/bohan95/dual-app-bridge

Towards Source-Free Machine Unlearning
Sk Miraj Ahmed, Umit Yigit Basaran, Dripta S. Raychaudhuri, Arindam Dutta, Rohit Kundu, Fahim Faisal Niloy, Basak Guler, Amit K. Roy-Chowdhury; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 4948-4957
As machine learning become more pervasive and data privacy regulations evolve, the ability to remove private or copyrighted information from trained models is becoming an increasingly critical requirement. Existing unlearning methods often rely on the assumption of having access to the entire training dataset during the forgetting process. However, this assumption may not hold true in practical scenarios where the original training data may not be accessible, i.e., the source-free setting. To address this challenge, we focus on the source-free unlearning scenario, where an unlearning algorithm must be capable of removing specific data from a trained model without requiring access to the original training dataset. Building on recent work, we present a method that can estimate the Hessian of the unknown remaining training data, a crucial component required for efficient unlearning. Leveraging this estimation technique, our method enables efficient zero-shot unlearning while providing robust theoretical guarantees on the unlearning performance, while maintaining performance on the remaining data. Extensive experiments over a wide range of datasets verify the efficacy of our method.

Uni4D: Unifying Visual Foundation Models for 4D Modeling from a Single Video
David Yifan Yao, Albert J. Zhai, Shenlong Wang; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 1116-1126
This paper presents a unified approach to understanding dynamic scenes from casual videos. Large pretrained vision foundation models, such as vision-language, video depth prediction, motion tracking, and segmentation models, offer promising capabilities. However, training a single model for comprehensive 4D understanding remains challenging. We introduce Uni4D, a multi-stage optimization framework that harnesses multiple pretrained models to advance dynamic 3D modeling, including static/dynamic reconstruction, camera pose estimation, and dense 3D motion tracking. Our results show state-of-the-art performance in dynamic 4D modeling with superior visual quality. Notably, Uni4D requires no retraining or fine-tuning, highlighting the effectiveness of repurposing visual foundation models for 4D understanding. Code and more results are available at: https://davidyao99.github.io/uni4d.

DynScene: Scalable Generation of Dynamic Robotic Manipulation Scenes for Embodied AI
Sangmin Lee, Sungyong Park, Heewon Kim; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 12166-12175
Robotic manipulation in embodied AI critically depends on large-scale, high-qual

ity datasets that reflect realistic object interactions and physical dynamics. H
owever, existing data collection pipelines are often slow, expensive, and heavil
y reliant on manual efforts. We present DynScene, a diffusion-based framework fo
r generating dynamic robotic manipulation scenes directly from textual instructi
ons. Unlike prior methods that focus solely on static environments or isolated r
obot actions, DynScene decomposes the generation into two phases static scene sy
nthesis and action trajectory generation allowing fine-grained control and diver
sity. Our model enhances realism and physical feasibility through scene refineme
nt (layout sampling, quaternion quantization) and leverages residual action repr
esentation to enable action augmentation, generating multiple diverse trajectori
es from a single static configuration. Experiments show DynScene achieves 26.8x
faster generation, 1.84x higher accuracy, and 28% greater action diversity than
human-crafted data. Furthermore, agents trained with DynScene exhibit up to 19.4
% higher success rates across complex manipulation tasks. Our approach paves the
way for scalable, automated dataset generation in robot learning.

DiffLocks: Generating 3D Hair from a Single Image using Diffusion Models
Radu Alexandru Rosu, Keyu Wu, Yao Feng, Youyi Zheng, Michael J. Black; Proceedin
gs of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 1
0847-10857
We address the task of generating 3D hair geometry from a single image, which is
challenging due to the diversity of hairstyles and the lack of paired image-to-
3D hair data. Previous methods are primarily trained on synthetic data and cope
with the limited amount of such data by using low-dimensional intermediate repre
sentations, such as guide strands and scalp-level embeddings, that require post-
processing to decode, upsample, and add realism. These approaches fail to recons
truct detailed hair, struggle with curly hair, or are limited to handling only a
few hairstyles. To overcome these limitations, we propose DiffLocks, a novel fr
amework that enables detailed reconstruction of a wide variety of hairstyles dir
ectly from a single image. First, we address the lack of 3D hair data by automat
ing the creation of the largest synthetic hair dataset to date, containing 40K h
airstyles. Second, we leverage the synthetic hair dataset to learn an image-cond
itioned diffusion-transfomer model that generates accurate 3D strands from a sin
gle frontal image. By using a pretrained image backbone, our method generalizes
to in-the-wild images despite being trained only on synthetic data. Our diffusio
n model predicts a scalp texture map in which any point in the map contains the
latent code for an individual hair strand. These codes are directly decoded to 3
D strands without post-processing techniques. Representing individual strands, i
nstead of guide strands, enables the transformer to model the detailed spatial s
tructure of complex hairstyles. With this, DiffLocks can recover highly curled h
air, like afro hairstyles, from a single image for the first time. Data and code
is available at https://radualexandru.github.io/difflocks

Hyperbolic Category Discovery
Yuanpei Liu, Zhenqi He, Kai Han; Proceedings of the Computer Vision and Pattern
Recognition Conference (CVPR), 2025, pp. 9891-9900
Generalized Category Discovery (GCD) is an intriguing open-world problem that ha
s garnered increasing attention. Given a dataset that includes both labelled and
unlabelled images, GCD aims to categorize all images in the unlabelled subset,
regardless of whether they belong to known or unknown classes. In GCD, the commo
n practice typically involves applying a spherical projection operator at the en
d of the self-supervised pretrained backbone, operating within Euclidean or sphe
rical space. However, both of these spaces have been shown to be suboptimal for
encoding samples that possess hierarchical structures. In contrast, hyperbolic s
pace exhibits exponential volume growth relative to radius, making it inherently
strong at capturing the hierarchical structure of samples from both seen and un
seen categories. Therefore, we propose to tackle the category discovery challeng
e in the hyperbolic space. We introduce HypCD, a simple Hyperbolic framework for
learning hierarchy-aware representations and classifiers for generalized Catego
ry Discovery. HypCD first transforms the Euclidean embedding space of the backbo

ne network into hyperbolic space, facilitating subsequent representation and cla ssification learning by considering both hyperbolic distance and the angle betwe en samples. This approach is particularly helpful for knowledge transfer from kn own to unknown categories in GCD. We thoroughly evaluate HypCD on public GCD ben chmarks, by applying it to various baseline and state-of-the-art methods, consis tently achieving significant improvements.

The Language of Motion: Unifying Verbal and Non-verbal Language of 3D Human Moti on
Changan Chen, Juze Zhang, Shrinidhi K. Lakshmikanth, Yusu Fang, Ruizhi Shao, Gor don Wetzstein, Li Fei-Fei, Ehsan Adeli; Proceedings of the Computer Vision and P attern Recognition Conference (CVPR), 2025, pp. 6200-6211
Human communication is inherently multimodal, involving a combination of verbal and non-verbal cues such as speech, facial expressions, and body gestures. Model ing these behaviors is essential for understanding human interaction and for cre ating virtual characters that can communicate naturally in applications like gam es, films, and virtual reality. However, existing motion generation models are t ypically limited to specific input modalities--either speech, text, or motion da ta--and cannot fully leverage the diversity of available data. In this paper, we propose a novel framework that unifies verbal and non-verbal language using mul timodal language models for human motion understanding and generation. This mode l is flexible in taking text, speech, and motion or any combination of them as i nput. Coupled with our novel pre-training strategy, our model not only achieves state-of-the-art performance on co-speech gesture generation but also requires m uch less data for training. Our model also unlocks an array of novel tasks such as editable gesture generation and emotion prediction from motion. We believe un ifying the verbal and non-verbal language of human motion is essential for real- world applications, and language models offer a powerful approach to achieving t his goal.

CALICO: Part-Focused Semantic Co-Segmentation with Large Vision-Language Models
Kiet A. Nguyen, Adheesh Juvekar, Tianjiao Yu, Muntasir Wahed, Ismini Lourentzou; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2 025, pp. 4550-4561
Recent advances in Large Vision-Language Models (LVLMs) have enabled general-pur pose vision tasks through visual instruction tuning. While existing LVLMs can ge nerate segmentation masks from text prompts for single images, they struggle wit h segmentation-grounded reasoning across images, especially at finer granularit ies such as object parts. In this paper, we introduce the new task of part-focuse d semantic co-segmentation, which involves identifying and segmenting common obj ects and their constituent common and unique parts across images. To address thi s task, we present CALICO, the first LVLM designed for multi-image part-level re asoning segmentation. CALICO features two key components, a novel Correspondence Extraction Module that identifies semantic part-level correspondences, and Corr espondence Adaptation Modules that embed this information into the LVLM to facil itate multi-image understanding in a parameter-efficient manner. To support trai ning and evaluation, we curate MixedParts, a large-scale multi-image segmentatio n dataset containing 2.4M samples across 44K images spanning diverse object an d part categories. Experimental results demonstrate that CALICO, with just 0.3% of its parameters finetuned, achieves strong performance on this challenging tas k.

Task Preference Optimization: Improving Multimodal Large Language Models with Vi sion Task Alignment
Ziang Yan, Zhilin Li, Yinan He, Chenting Wang, Kunchang Li, Xinhao Li, Xiangyu Z eng, Zilei Wang, Yali Wang, Yu Qiao, Limin Wang, Yi Wang; Proceedings of the Com puter Vision and Pattern Recognition Conference (CVPR), 2025, pp. 29880-29892
Current multimodal large language models (MLLMs) struggle with fine-grained or p recise understanding of visuals although they give comprehensive perception and reasoning in a spectrum of vision applications. Recent studies either develop to

ol-using or unify specific visual tasks into the autoregressive framework, often at the expense of overall multimodal performance. To address this issue and enhance MLLMs with visual tasks in a scalable fashion, we propose Task Preference Optimization (TPO), a novel method that utilizes differentiable task preferences derived from typical fine-grained visual tasks. TPO introduces learnable task tokens that establish connections between multiple task-specific heads and the MLLM. By leveraging rich visual labels during training, TPO significantly enhances the MLLM's multimodal capabilities and task-specific performance. Through multi-task co-training within TPO, we observe synergistic benefits that elevate individual task performance beyond what is achievable through single-task training methodologies. Our instantiation of this approach with VideoChat and LLaVA demonstrates an overall 14.6% improvement in multimodal performance compared to baseline models. Additionally, MLLM-TPO demonstrates robust zero-shot capabilities across various tasks, performing comparably to state-of-the-art supervised models.

Cross-modal Causal Relation Alignment for Video Question Grounding

Weixing Chen, Yang Liu, Binglin Chen, Jiandong Su, Yongsen Zheng, Liang Lin; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 24087-24096

Video question grounding (VideoQG) requires models to answer the questions and simultaneously infer the relevant video segments to support the answers. However, existing VideoQG methods usually suffer from spurious cross-modal correlations, leading to a failure to identify the dominant visual scenes that align with the intended question. Moreover, vision-language models exhibit unfaithful generalization performance and lack robustness on challenging downstream tasks such as VideoQG. In this work, we propose a novel VideoQG framework named Cross-modal Causal Relation Alignment (CRA), to eliminate spurious correlations and improve the causal consistency between question-answering and video temporal grounding. Our CRA involves three essential components: i) Gaussian Smoothing Grounding (GSG) module for estimating the time interval via cross-modal attention, which is de-noised by an adaptive Gaussian filter, ii) Cross-Modal Alignment (CMA) enhances the performance of weakly supervised VideoQG by leveraging bidirectional contrastive learning between estimated video segments and QA features, iii) Explicit Causal Intervention (ECI) module for multimodal deconfounding, which involves front-door intervention for vision and back-door intervention for language. Extensive experiments on two VideoQG datasets demonstrate the superiority of our CRA in discovering visually grounded content and achieving robust question reasoning. Codes are available at https://github.com/WissingChen/CRA-GQA.

Words or Vision: Do Vision-Language Models Have Blind Faith in Text?

Ailin Deng, Tri Cao, Zhirui Chen, Bryan Hooi; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 3867-3876

Vision-Language Models (VLMs) excel in integrating visual and textual information for vision-centric tasks, but their handling of inconsistencies between modalities is underexplored. We investigate VLMs' modality preferences when faced with visual data and varied textual inputs in vision-centered settings.By introducing textual variations to four vision-centric tasks and evaluating ten Vision-Language Models (VLMs), we discover a "blind faith in text" phenomenon: VLMs disproportionately trust textual data over visual data when inconsistencies arise, leading to significant performance drops under corrupted text and raising safety concerns.We analyze factors influencing this text bias, including instruction prompts, language model size, text relevance, token order, and the interplay between visual and textual certainty. While certain factors, such as scaling up the language model size, slightly mitigate text bias, others like token order can exacerbate it due to positional biases inherited from language models. To address this issue, we explore supervised fine-tuning with text augmentation and demonstrate its effectiveness in reducing text bias. Additionally, we provide a theoretical analysis suggesting that the blind faith in text phenomenon may stem from an imbalance of pure text and multi-modal data during training.Our findings highlight the need for balanced training and careful consideration of modality interactio

ns in VLMs to enhance their robustness and reliability in handling multi-modal data inconsistencies.

Diffusion Renderer: Neural Inverse and Forward Rendering with Video Diffusion Models
Ruofan Liang, Zan Gojcic, Huan Ling, Jacob Munkberg, Jon Hasselgren, Chih-Hao Lin, Jun Gao, Alexander Keller, Nandita Vijaykumar, Sanja Fidler, Zian Wang; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 26069-26080
Understanding and modeling lighting effects are fundamental tasks in computer vision and graphics. Classic physically-based rendering (PBR) accurately simulates the light transport, but relies on precise scene representations--explicit 3D geometry, high-quality material properties, and lighting conditions--that are often impractical to obtain in real-world scenarios. Therefore, we introduce Diffusion Renderer, a neural approach that addresses the dual problem of inverse and forward rendering within a holistic framework. Leveraging powerful video diffusion model priors, the inverse rendering model accurately estimates G-buffers from real-world videos, providing an interface for image editing tasks, and training data for the rendering model. Conversely, our rendering model generates photorealistic images from G-buffers without explicit light transport simulation. Specifically, we first train a video diffusion model for inverse rendering on synthetic data, which generalizes well to real-world videos and allows us to auto-label diverse real-world videos. We then co-train our rendering model using both synthetic and auto-labeled real-world data. Experiments demonstrate that Diffusion Renderer effectively approximates inverse and forwards rendering, consistently outperforming the state-of-the-art. Our model enables practical applications from a single video input--including relighting, material editing, and realistic object insertion.

Harnessing Frequency Spectrum Insights for Image Copyright Protection Against Diffusion Models
Zhenguang Liu, Chao Shuai, Shaojing Fan, Ziping Dong, Jinwu Hu, Zhongjie Ba, Kui Ren; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 18653-18662
Diffusion models have achieved remarkable success in novel view synthesis, but their reliance on large, diverse, and often untraceable Web datasets has raised pressing concerns about image copyright protection. Current methods fall short in reliably identifying unauthorized image use, as they struggle to generalize across varied generation tasks and fail when the training dataset includes images from multiple sources with few identifiable (watermarked or poisoned) samples. In this paper, we present novel evidence that diffusion-generated images faithfully preserve the statistical properties of their training data, particularly reflected in their spectral features. Leveraging this insight, we introduce CoprGuard, a robust frequency domain watermarking framework to safeguard against unauthorized image usage in diffusion model training and fine-tuning. CoprGuard demonstrates remarkable effectiveness against a wide range of models, from naive diffusion models to sophisticated text-to-image models, and is robust even when watermarked images comprise a mere 1% of the training dataset. This robust and versatile approach empowers content owners to protect their intellectual property in the era of AI-driven image generation.

Learning to Detect Objects from Multi-Agent LiDAR Scans without Manual Labels
Qiming Xia, Wenkai Lin, Haoen Xiang, Xun Huang, Siheng Chen, Zhen Dong, Cheng Wang, Chenglu Wen; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 1418-1428
Unsupervised 3D object detection serves as an important solution for offline 3D object annotation. However, due to the data sparsity and limited views, the clustering-based label fitting in unsupervised object detection often generates low-quality pseudo-labels. Multi-agent collaborative dataset, which involves the sharing of complementary observations among agents, holds the potential to break th

rough this bottleneck. In this paper, we introduce a novel unsupervised method t hat learns to Detect Objects from Multi-Agent LiDAR scans, termed DOtA, without using labels from external. DOtA first uses the internally shared ego-pose and e go-shape of collaborative agents to initialize the detector, leveraging the gene ralization performance of neural networks to infer preliminary labels. Subsequen tly, DOtA uses the complementary observations between agents to perform multi-sc ale encoding on preliminary labels, then decodes high-quality and low-quality la bels. These labels are further used as prompts to guide a correct feature learni ng process, thereby enhancing the performance of the unsupervised object detecti on task. Extensive experiments on the V2V4Real and OPV2V datasets show that our DOtA outperforms state-of-the-art unsupervised 3D object detection methods. Addi tionally, we also validate the effectiveness of the DOtA labels under various co llaborative perception frameworks. The code is available at https://github.com/x muqimingxia/DOtA.

DeepLA-Net: Very Deep Local Aggregation Networks for Point Cloud Analysis

Ziyin Zeng, Mingyue Dong, Jian Zhou, Huan Qiu, Zhen Dong, Man Luo, Bijun Li; Pro ceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 1330-1341

Due to the irregular and disordered data structure in 3D point clouds, prior wor ks have focused on designing more sophisticated local representation methods to capture these complex local patterns. However, the recognition performance has s aturated over the past few years, indicating that increasingly complex and redun dant designs no longer make improvements to local learning. This phenomenon prom pts us to diverge from the trend in 3D vision and instead pursue an alternative and successful solution: deeper neural networks. In this paper, we propose DeepL A-Net, a series of very deep networks for point cloud analysis. The key insight of our approach is to exploit a small but mighty local learning block, which red uces 10xfewer FLOPs, enabling the construction of very deep networks. Furthermor e, we design a training supervision strategy to ensure smooth gradient backpropa gation and optimization in very deep networks. We construct the DeepLA-Net famil y with a depth of up to 120 blocks --- at least 5xdeeper than recent methods --- trained on a single RTX 3090. An ensemble of the DeepLA-Net achieves state-of-t he-art performance on classification and segmentation tasks of S3DIS Area5 (+2.2 % mIoU), ScanNet test set (+1.6% mIoU), ScanObjectNN (+2.1% OA), and ShapeNetPar t (+0.9% cls.mIoU).

Multi-Layer Visual Feature Fusion in Multimodal LLMs: Methods, Analysis, and Bes t Practices

Junyan Lin, Haoran Chen, Yue Fan, Yingqi Fan, Xin Jin, Hui Su, Jinlan Fu, Xiaoyu Shen; Proceedings of the Computer Vision and Pattern Recognition Conference (CV PR), 2025, pp. 4156-4166

Multimodal Large Language Models (MLLMs) have made significant advancements in r ecent years, with visual features playing an increasingly critical role in enhan cing model performance. However, the integration of multi-layer visual features in MLLMs remains underexplored, particularly with regard to optimal layer select ion and fusion strategies. Existing methods often rely on arbitrary design choic es, leading to suboptimal outcomes. In this paper, we systematically investigate two core aspects of multi-layer visual feature fusion: (1) selecting the most e ffective visual layers and (2) identifying the best fusion approach with the lan guage model. Our experiments reveal that while combining visual features from mu ltiple stages improves generalization, incorporating additional features from th e same stage typically leads to diminished performance. Furthermore, we find tha t direct fusion of multi-layer visual features at the input stage consistently y ields superior and more stable performance across various configurations.

APHQ-ViT: Post-Training Quantization with Average Perturbation Hessian Based Rec onstruction for Vision Transformers

Zhuguanyu Wu, Jiayi Zhang, Jiaxin Chen, Jinyang Guo, Di Huang, Yunhong Wang; Pro ceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025,

pp. 9686-9695
Vision Transformers (ViTs) have become one of the most commonly used backbones for vision tasks. Despite their remarkable performance, they often suffer significant accuracy drop when quantized for practical deployment, particularly by post-training quantization (PTQ) under ultra-low bits. Recently, reconstruction-based PTQ methods have shown promising performance in quantizing Convolutional Neural Networks (CNNs). However, they fail when applied to ViTs, primarily due to the inaccurate estimation of output importance and the substantial accuracy degradation in quantizing post-GELU activations. To address these issues, we propose APHQ-ViT, a novel PTQ approach based on importance estimation with Average Perturbation Hessian (APH). Specifically, we first thoroughly analyze the current approximation approaches with Hessian loss, and propose an improved average perturbation Hessian loss. To deal with the quantization of the post-GELU activations, we design an MLP-Reconstruction (MR) method by replacing the GELU function in MLP with ReLU and reconstructing it by the APH loss on a small unlabeled calibration set. Extensive experiments demonstrate that APHQ-ViT using linear quantizers outperforms existing PTQ methods by substantial margins in 3-bit and 4-bit across different vision tasks. The source code is available at https://github.com/GoatWu/APHQ-ViT.

AdaptCMVC: Robust Adaption to Incremental Views in Continual Multi-view Clustering

Jing Wang, Songhe Feng, Kristoffer Knutsen Wickstrøm, Michael C. Kampffmeyer; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 10285-10294

Most Multi-view Clustering approaches assume that all views are available for clustering. However, this assumption is often unrealistic as views are incrementally accumulated over time, leading to a need for continual multi-view clustering (CMVC) methods. Current approaches to CMVC leverage late fusion-based approaches, where a new model is typically learned individually for each view to obtain the corresponding partition matrix, and then used to update a consensus matrix via a moving average. These approaches are prone to view-specific noise and struggle to adapt to large gaps between different views. To address these shortcomings, we reconsider CMVC from the perspective of domain adaptation and propose AdaptCMVC, which learns how to incrementally accumulate knowledge of new views as they become available and prevents catastrophic forgetting. Specifically, a self-training framework is introduced to extend the model to new views, particularly designed to be robust to view-specific noise. Further, to combat catastrophic forgetting, a structure alignment mechanism is proposed to enable the model to explore the global group structure across multiple views. Experiments on several multi-view benchmarks demonstrate the effectiveness of our proposed method on the CMVC task. The code is available at: AdaptCMVC.

Omni-Scene: Omni-Gaussian Representation for Ego-Centric Sparse-View Scene Reconstruction

Dongxu Wei, Zhiqi Li, Peidong Liu; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 22317-22327

Prior works employing pixel-based Gaussian representation have demonstrated efficacy in feed-forward sparse-view reconstruction. However, such representation necessitates cross-view overlap for accurate depth estimation, and is challenged by object occlusions and frustum truncations. As a result, these methods require scene-centric data acquisition to maintain cross-view overlap and complete scene visibility to circumvent occlusions and truncations, which limits their applicability to scene-centric reconstruction. In contrast, in autonomous driving scenarios, a more practical paradigm is ego-centric reconstruction, which is characterized by minimal cross-view overlap and frequent occlusions and truncations. The limitations of pixel-based representation thus hinder the utility of prior works in this task. In light of this, this paper conducts an in-depth analysis of different representations, and introduces Omni-Gaussian representation with tailored network design to complement their strengths and mitigate their drawbacks. Ex

periments show that our method significantly surpasses state-of-the-art methods, pixelSplat and MVSplat, in ego-centric reconstruction, and achieves comparable performance to prior works in scene-centric reconstruction. Our code is availabl e at https://github.com/WU-CVGL/Omni-Scene.

3DTopia-XL: Scaling High-quality 3D Asset Generation via Primitive Diffusion

Zhaoxi Chen, Jiaxiang Tang, Yuhao Dong, Ziang Cao, Fangzhou Hong, Yushi Lan, Ten gfei Wang, Haozhe Xie, Tong Wu, Shunsuke Saito, Liang Pan, Dahua Lin, Ziwei Liu; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2 025, pp. 26576-26586

The increasing demand for high-quality 3D assets across various industries neces sitates efficient and automated 3D content creation. Despite recent advancements in 3D generative models, existing methods still face challenges with optimizati on speed, geometric fidelity, and the lack of assets for physically based render ing (PBR). In this paper, we introduce 3DTopia-XL, a scalable native 3D generati ve model designed to overcome these limitations. 3DTopia-XL leverages a novel pr imitive-based 3D representation, PrimX, which encodes detailed shape, albedo, an d material field into a compact tensorial format, facilitating the modeling of h igh-resolution geometry with PBR assets. On top of the novel representation, we propose a generative framework based on Diffusion Transformer (DiT), which compr ises 1) Primitive Patch Compression, 2) and Latent Primitive Diffusion. 3DTopia-XL learns to generate high-quality 3D assets from textual or visual inputs. Exte nsive qualitative and quantitative experiments are conducted to demonstrate that 3DTopia-XL significantly outperforms existing methods in generating high-qualit y 3D assets with fine-grained textures and materials, efficiently bridging the q uality gap between generative models and real-world applications.

UA-Pose: Uncertainty-Aware 6D Object Pose Estimation and Online Object Completio n with Partial References

Ming-Feng Li, Xin Yang, Fu-En Wang, Hritam Basak, Yuyin Sun, Shreekant Gayaka, M in Sun, Cheng-Hao Kuo; Proceedings of the Computer Vision and Pattern Recognitio n Conference (CVPR), 2025, pp. 1180-1189

6D object pose estimation has shown strong generalizability to novel objects. Ho wever, existing methods often require either a complete, well-reconstructed 3D m odel or numerous reference images that fully cover the object. Estimating 6D pos es from partial references, which capture only fragments of an object's appearan ce and geometry, remains challenging. To address this, we propose UA-Pose, an un certainty-aware approach for 6D object pose estimation and online object complet ion specifically designed for partial references. We assume access to either (1) a limited set of RGBD images with known poses or (2) a single 2D image. For the first case, we initialize a partial object 3D model based on the provided image s and poses, while for the second, we use image-to-3D techniques to generate an initial object 3D model. Our method integrates uncertainty into the incomplete 3 D model, distinguishing between seen and unseen regions. This uncertainty enable s confidence assessment in pose estimation and guides an uncertainty-aware sampl ing strategy for online object completion, enhancing robustness in pose estimati on accuracy and improving object completeness. We evaluate our method on the YCB -Video, YCBInEOAT, and HO3D datasets, including RGBD sequences of YCB objects ma nipulated by robots and human hands. Experimental results demonstrate significan t performance improvements over existing methods, particularly when object obser vations are incomplete or partially captured.

Missing Target-Relevant Information Prediction with World Model for Accurate Zer o-Shot Composed Image Retrieval

Yuanmin Tang, Jing Yu, Keke Gai, Jiamin Zhuang, Gang Xiong, Gaopeng Gou, Qi Wu; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 20 25, pp. 24785-24795

Zero-Shot Composed Image Retrieval (ZS-CIR) involves diverse tasks with a broad range of visual content manipulation intent across domain, scene, object, and at tribute. The key challenge for ZS-CIR tasks is to modify a reference image accor

ding to manipulation text to accurately retrieve a target image, especially when the reference image is missing essential target content. In this paper, we propose a novel prediction-based mapping network, named PrediCIR, to adaptively predict the missing target visual content in reference images in the latent space before mapping for accurate ZS-CIR. Specifically, a world view generation module first constructs a source view by omitting certain visual content of a target view, coupled with an action that includes the manipulation intent derived from existing image-caption pairs. Then, a target content prediction module trains a world model as a predictor to adaptively predict the missing visual information guided by user intention in manipulating text at the latent space. The two modules map an image with the predicted relevant information to a pseudo-word token without extra supervision. Our model shows strong generalization ability on six ZS-CIR tasks. It obtains consistent and significant performance boosts ranging from 1.73% to 4.45% over the best methods and achieves new state-of-the-art results on ZS-CIR. Our code is available at https://github.com/Pter61/predicir.

Binarized Mamba-Transformer for Lightweight Quad Bayer HybridEVS Demosaicing
Shiyang Zhou, Haijin Zeng, Yunfan Lu, Tong Shao, Ke Tang, Yongyong Chen, Jie Liu, Jingyong Su; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 8817-8827
Quad Bayer demosaicing is the central challenge for enabling the widespread application of Hybrid Event-based Vision Sensors (HybridEVS). Although existing learning-based methods that leverage long-range dependency modeling have achieved promising results, their complexity severely limits deployment on mobile devices for real-world applications. To address these limitations, we propose a lightweight Mamba-based binary neural network designed for efficient and high-performing demosaicing of HybridEVS RAW images. First, to effectively capture both global and local dependencies, we introduce a hybrid Binarized Mamba-Transformer architecture that combines the strengths of the Mamba and Swin Transformer architectures. Next, to significantly reduce computational complexity, we propose a binarized Mamba (Bi-Mamba), which binarizes all projections while retaining the core Selective Scan in full precision. Bi-Mamba also incorporates additional global visual information to enhance global context and mitigate precision loss. We conduct quantitative and qualitative experiments to demonstrate the effectiveness of BMTNet in both performance and computational efficiency, providing a lightweight demosaicing solution suited for real-world edge devices. Our codes and models are available at https://github.com/Clausy9/BMTNet.

DiffSensei: Bridging Multi-Modal LLMs and Diffusion Models for Customized Manga Generation
Jianzong Wu, Chao Tang, Jingbo Wang, Yanhong Zeng, Xiangtai Li, Yunhai Tong; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 28684-28693
Story visualization, the task of creating visual narratives from textual descriptions, has seen progress with text-to-image generation models. However, these models often lack effective control over character appearances and interactions, particularly in multi-character scenes. To address these limitations, we propose a new task: customized manga generation and introduce DiffSensei, an innovative framework specifically designed for generating manga with dynamic multi-character control. DiffSensei integrates a diffusion-based image generator with a multimodal large language model (MLLM) that acts as a text-compatible identity adapter. Our approach employs masked cross-attention to seamlessly incorporate character features, enabling precise layout control without direct pixel transfer. Additionally, the MLLM-based adapter adjusts character features to align with panel-specific text cues, allowing flexible adjustments in character expressions, poses, and actions. We also introduce MangaZero, a large-scale dataset tailored to this task, containing 43,264 manga pages and 427,147 annotated panels, supporting the visualization of varied character interactions and movements across sequential frames. Extensive experiments demonstrate that DiffSensei outperforms existing models, marking a significant advancement in manga generation by enabling text

-adaptable character customization. The code, model, and dataset will be open-so
urced to the community.

Narrating the Video: Boosting Text-Video Retrieval via Comprehensive Utilization
 of Frame-Level Captions
Chan Hur, Jeong-hun Hong, Dong-hun Lee, Dabin Kang, Semin Myeong, Sang-hyo Park,
 Hyeyoung Park; Proceedings of the Computer Vision and Pattern Recognition Confe
rence (CVPR), 2025, pp. 24077-24086
In recent text-video retrieval, the use of additional captions from vision-langu
age models has shown promising effects on the performance. However, existing mod
els using additional captions often have struggled to capture the rich semantics
, including temporal changes, inherent in the video. In addition, incorrect info
rmation caused by generative models can lead to inaccurate retrieval. To address
 these issues, we propose a new framework, Narrating the Video (NarVid), which s
trategically leverages the comprehensive information available from frame-level
captions, the narration. The proposed NarVid exploits narration in multiple ways
: 1) feature enhancement through cross-modal interactions between narration and
video, 2) query-aware adaptive filtering to suppress irrelevant or incorrect inf
ormation, 3) dual-modal matching score by adding query-video similarity and quer
y-narration similarity, and 4) hard-negative loss to learn discriminative featur
es from multiple perspectives using the two similarities from different views. E
xperimental results demonstrate that NarVid achieves state-of-the-art performanc
e on various benchmark datasets.

IDEA-Bench: How Far are Generative Models from Professional Designing?
Chen Liang, Lianghua Huang, Jingwu Fang, Huanzhang Dou, Wei Wang, Zhi-Fan Wu, Yu
peng Shi, Junge Zhang, Xin Zhao, Yu Liu; Proceedings of the Computer Vision and
Pattern Recognition Conference (CVPR), 2025, pp. 18541-18551
Recent advancements in image generation models enable the creation of high-quali
ty images and targeted modifications based on textual instructions. Some models
even support multimodal complex guidance and demonstrate robust task generalizat
ion capabilities. However, they still fall short of meeting the nuanced, profess
ional demands of designers. To bridge this gap, we introduce IDEA-Bench, a compr
ehensive benchmark designed to advance image generation models toward applicatio
ns with robust task generalization. IDEA-Bench comprises 100 professional image
generation tasks and 275 specific cases, categorized into five major types based
 on the current capabilities of existing models. Furthermore, we provide a repre
sentative subset of 18 tasks with enhanced evaluation criteria to facilitate mor
e nuanced and reliable evaluations using Multimodal Large Language Models (MLLMs
). By assessing models' ability to comprehend and execute novel, complex tasks,
IDEA-Bench paves the way toward the development of generative models with autono
mous and versatile visual generation capabilities.

Interpretable Image Classification via Non-parametric Part Prototype Learning
Zhijie Zhu, Lei Fan, Maurice Pagnucco, Yang Song; Proceedings of the Computer Vi
sion and Pattern Recognition Conference (CVPR), 2025, pp. 9762-9771
Classifying images with an interpretable decision-making process is a long-stand
ing problem in computer vision. In recent years, Prototypical Part Networks has
gained traction as an approach for self-explainable neural networks, due to thei
r ability to mimic human visual reasoning by providing explanations based on pro
totypical object parts. However, the quality of the explanations generated by th
ese methods leaves room for improvement, as the prototypes usually focus on repe
titive and redundant concepts. Leveraging recent advances in prototype learning,
 we present a framework for part-based interpretable image classification that l
earns a set of semantically distinctive object parts for each class, and provide
s diverse and comprehensive explanations. The core of our method is to learn the
 part-prototypes in a non-parametric fashion, through clustering deep features e
xtracted from foundation vision models that encode robust semantic information.
To quantitatively evaluate the quality of explanations provided by ProtoPNets, w
e introduce Distinctiveness Score and Comprehensiveness Score. Through evaluatio

n on CUB-200-2011, Stanford Cars and Stanford Dogs datasets, we show that our fr amework compares favourably against existing ProtoPNets while achieving better i nterpretability.

PhD: A ChatGPT-Prompted Visual Hallucination Evaluation Dataset
Jiazhen Liu, Yuhan Fu, Ruobing Xie, Runquan Xie, Xingwu Sun, Fengzong Lian, Zhan hui Kang, Xirong Li; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 19857-19866
Multimodal Large Language Models (MLLMs) hallucinate, resulting in an emerging t opic of visual hallucination evaluation (VHE). This paper contributes a ChatGPT-Prompted visual hallucination evaluation Dataset (PhD) for objective VHE at a la rge scale. The essence of VHE is to ask an MLLM questions about specific images to assess its susceptibility to hallucination. Depending on what to ask (objects , attributes, sentiment, etc.) and how the questions are asked, we structure PhD along two dimensions, i.e. task and mode. Five visual recognition tasks, rangin g from low-level (object / attribute recognition) to middle-level (sentiment / p osition recognition and counting), are considered. Besides a normal visual QA mo de, which we term PhD-base, PhD also asks questions with specious context (PhD-s ec) or with incorrect context (PhD-icc), or with AI-generated counter common sen se images (PhD-ccs). We construct PhD by a ChatGPT-assisted semi-automated pipel ine, encompassing four pivotal modules: task-specific hallucinatory item (hitem) selection, hitem-embedded question generation, specious / incorrect context gen eration, and counter-common-sense (CCS) image generation. With over 14k daily im ages, 750 CCS images and 102k VQA triplets in total, PhD reveals considerable va riability in MLLMs' performance across various modes and tasks, offering valuabl e insights into the nature of hallucination. As such, PhD stands as a potent too l not only for VHE but may also play a significant role in the refinement of MLL Ms.

CARL: A Framework for Equivariant Image Registration
Hastings Greer, Lin Tian, François-Xavier Vialard, Roland Kwitt, Raul San Jose E stepar, Marc Niethammer; Proceedings of the Computer Vision and Pattern Recognit ion Conference (CVPR), 2025, pp. 26014-26023
Image registration estimates spatial correspondences between image pairs. These estimates are typically obtained via numerical optimization or regression by a d eep network. A desirable property is that a correspondence estimate (e.g., the t rue oracle correspondence) for an image pair is maintained under deformations of the input images. Formally, the estimator should be equivariant to a desired cl ass of image transformations. In this work, we present careful analyses of equiv ariance properties in the context of multi-step deep registration networks. Base d on these analyses we 1) introduce the notions of [U,U] equivariance (network e quivariance to the same deformations of the input images) and [W,U] equivariance (where input images can undergo different deformations); we 2) show that in a s uitable multi-step registration setup it is sufficient for overall [W,U] equivar iance if the first step has [W,U] equivariance and all others have [U,U] equivar iance; we 3) show that common displacement-predicting networks only exhibit [U,U] equivariance to translations instead of the more powerful [W,U] equivariance; and we 4) show how to achieve multi-step [W,U] equivariance via a coordinate-att ention mechanism combined with displacement-predicting networks. Our approach ob tains excellent practical performance for 3D abdomen, lung, and brain medical im age registration. We match or outperform state-of-the-art (SOTA) registration ap proaches on all the datasets with a particularly strong performance for the chal lening abdomen registration.

ClimbingCap: Multi-Modal Dataset and Method for Rock Climbing in World Coordinat e
Ming Yan, Xincheng Lin, Yuhua Luo, Shuqi Fan, Yudi Dai, Qixin Zhong, Lincai Zhon g, Yuexin Ma, Lan Xu, Chenglu Wen, Siqi Shen, Cheng Wang; Proceedings of the Com puter Vision and Pattern Recognition Conference (CVPR), 2025, pp. 12312-12323
Human Motion Recovery (HMR) research mainly focuses on ground-based motions such

as running. The study on capturing climbing motion, an off-ground motion, is sparse. This is partly due to the limited availability of climbing motion datasets, especially large-scale and challenging 3D labeled datasets. To address the insufficiency of climbing motion datasets, we collect AscendMotion, a large-scale well-annotated, and challenging climbing motion dataset. It consists of 412k RGB, LiDAR frames, and IMU measurements, which includes the challenging climbing motions of 22 professional climbing coaches across 12 different rocks. Capturing the climbing motions is challenging as it requires precise recovery of not only the complex pose but also the global position of climbers. Although multiple global HMR methods have been proposed, they cannot faithfully capture climbing motions. To address the limitations of HMR methods for climbing, we propose ClimbingCap, a motion recovery method that reconstructs continuous 3D human climbing motion in a global coordinate system. One key insight is to use the RGB and the LiDAR modalities to separately reconstruct motions in camera coordinates and global coordinates and optimize them jointly. We demonstrate the quality of the AscendMotion dataset and present promising results from ClimbingCap. The AscendMotion dataset and the source code of ClimbingCap will be released publicly to the research community.

DAGSM: Disentangled Avatar Generation with GS-enhanced Mesh

Jingyu Zhuang, Di Kang, Linchao Bao, Liang Lin, Guanbin Li; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 292-303

Text-driven avatar generation has gained significant attention owing to its convenience. However, existing methods typically model the human body with all garments as a single 3D model, limiting its usability, such as clothing replacement, and reducing user control over the generation process. To overcome the limitations above, we propose DAGSM, a novel pipeline that generates disentangled human bodies and garments from the given text prompts. Specifically, we model each part (e.g., body, upper/lower clothes) of the clothed human as one GS-enhanced mesh (GSM), which is a traditional mesh attached with 2D Gaussians to better handle complicated textures (e.g., woolen, translucent clothes) and produce realistic cloth animations. During the generation, we first create the unclothed body, followed by a sequence of individual cloth generation based on the body, where we introduce a semantic-based algorithm to achieve better human-cloth and garment-garment separation. To improve texture quality, we propose a view-consistent texture refinement module, including a cross-view attention mechanism for texture style consistency and an incident-angle-weighted denoising (IAW-DE) strategy to update the appearance. Extensive experiments have demonstrated that DAGSM generates high-quality disentangled avatars, supports clothing replacement and realistic animation, and outperforms the baselines in visual quality.

Estimating Body and Hand Motion in an Ego-sensed World

Brent Yi, Vickie Ye, Maya Zheng, Yunqi Li, Lea Müller, Georgios Pavlakos, Yi Ma, Jitendra Malik, Angjoo Kanazawa; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 7072-7084

We present EgoAllo, a system for human motion estimation from a head-mounted device. Using only egocentric SLAM poses and images, EgoAllo guides sampling from a conditional diffusion model to estimate 3D body pose, height, and hand parameters that capture a device wearer's actions in the allocentric coordinate frame of the scene. To achieve this, our key insight is in representation: we propose spatial and temporal invariance criteria for improving model performance, from which we derive a head motion conditioning parameterization that improves estimation by up to 18%. We also show how the bodies estimated by our system can improve hand estimation: the resulting kinematic and temporal constraints can reduce world-frame errors in single-frame estimates by 40%.

A Bias-Free Training Paradigm for More General AI-generated Image Detection

Fabrizio Guillaro, Giada Zingarini, Ben Usman, Avneesh Sud, Davide Cozzolino, Luisa Verdoliva; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 18685-18694

Successful forensic detectors can produce excellent results in supervised learni
ng benchmarks but struggle to transfer to real-world applications. We believe th
is limitation is largely due to inadequate training data quality. While most res
earch focuses on developing new algorithms, less attention is given to training
 data selection, despite evidence that performance can be strongly impacted by sp
urious correlations such as content, format, or resolution. A well-designed fore
nsic detector should detect generator specific artifacts rather than reflect dat
a biases. To this end, we propose B-Free, a bias-free training paradigm, where f
ake images are generated from real ones using the conditioning procedure of stab
le diffusion models. This ensures semantic alignment between real and fake image
s, allowing any differences to stem solely from the subtle artifacts introduced
 by AI generation. Through content-based augmentation, we show significant improv
ements in both generalization and robustness over state-of-the-art detectors and
 more calibrated results across 27 different generative models, including recent
 releases, like FLUX and Stable Diffusion 3.5. Our findings emphasize the import
ance of a careful dataset design, highlighting the need for further research on
 this topic. Code and data are publicly available at https://grip-unina.github.io
/B-Free/.

FALCON: Fairness Learning via Contrastive Attention Approach to Continual Semant
ic Scene Understanding

Thanh-Dat Truong, Utsav Prabhu, Bhiksha Raj, Jackson Cothren, Khoa Luu; Proceedi
ngs of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp.
 15065-15075

Continual Learning in semantic scene segmentation aims to continually learn new
 unseen classes in dynamic environments while maintaining previously learned know
ledge. Prior studies focused on modeling the catastrophic forgetting and backgro
und shift challenges in continual learning. However, fairness, another major cha
llenge that causes unfair predictions leading to low performance among major and
 minor classes, still needs to be well addressed. In addition, prior methods hav
e yet to model the unknown classes well, thus resulting in producing non-discrim
inative features among unknown classes. This work presents a novel Fairness Lear
ning via Contrastive Attention Approach to continual learning in semantic scene
 understanding. In particular, we first introduce a new Fairness Contrastive Clus
tering loss to address the problems of catastrophic forgetting and fairness. The
n, we propose an attention-based visual grammar approach to effectively model th
e background shift problem and unknown classes, producing better feature represe
ntations for different unknown classes. Through our experiments, our proposed ap
proach achieves State-of-the-Art (SoTA) performance on different continual learn
ing benchmarks, i.e., ADE20K, Cityscapes, and Pascal VOC. It promotes the fairne
ss of the continual semantic segmentation model.

Certified Human Trajectory Prediction

Mohammadhossein Bahari, Saeed Saadatnejad, Amirhossein Askari Farsangi, Seyed-Mo
hsen Moosavi-Dezfooli, Alexandre Alahi; Proceedings of the Computer Vision and P
attern Recognition Conference (CVPR), 2025, pp. 12301-12311

Predicting human trajectories is essential for the safe operation of autonomous
 vehicles, yet current data-driven models often lack robustness in case of noisy
 inputs such as adversarial examples or imperfect observations. Although some tra
jectory prediction methods have been developed to provide empirical robustness,
 these methods are heuristic and do not offer guaranteed robustness. In this work
, we propose a certification approach tailored for trajectory prediction that pr
ovides guaranteed robustness. To this end, we address the unique challenges asso
ciated with trajectory prediction, such as unbounded outputs and multi-modality.
 To mitigate the inherent performance drop through certification, we propose a d
iffusion-based trajectory denoiser and integrate it into our method. Moreover, w
e introduce new certified performance metrics to reliably measure the trajectory
 prediction performance. Through comprehensive experiments, we demonstrate the a
ccuracy and robustness of the certified predictors and highlight their advantage
s over the non-certified ones. The code is available online: https://s-attack.gi

Evaluating Vision-Language Models as Evaluators in Path Planning
Mohamed Aghzal, Xiang Yue, Erion Plaku, Ziyu Yao; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 6886-6897
Despite their promise to perform complex reasoning, large language models (LLMs) have been shown to have limited effectiveness in end-to-end planning. This has inspired an intriguing question: if these models cannot plan well, can they still contribute to the planning framework as a helpful plan evaluator? In this work, we generalize this question to consider LLMs augmented with visual understanding, i.e., Vision-Language Models (VLMs). We introduce **PathEval**, a novel benchmark evaluating VLMs as plan evaluators in complex path-planning scenarios. Succeeding in the benchmark requires a VLM to be able to abstract traits of optimal paths from the scenario description, demonstrate precise low-level perception on each path, and integrate this information to decide the better path. Our analysis of state-of-the-art VLMs reveals that these models face significant challenges on the benchmark. We observe that the VLMs can precisely abstract given scenarios to identify the desired traits and exhibit mixed performance in integrating the provided information. Yet, their vision component presents a critical bottleneck, with models struggling to perceive low-level details about a path. Our experimental results show that this issue cannot be trivially addressed via end-to-end fine-tuning; rather, task-specific discriminative adaptation of these vision encoders is needed for these VLMs to become effective path evaluators.
****
Free on the Fly: Enhancing Flexibility in Test-Time Adaptation with Online EM
Qiyuan Dai, Sibei Yang; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 9538-9548
Vision-Language Models (VLMs) have become prominent in open-world image recognition for their strong generalization abilities. Yet, their effectiveness in practical applications is compromised by domain shifts and distributional changes, especially when test data distributions diverge from training data. Therefore, the paradigm of test-time adaptation (TTA) has emerged, enabling the use of online off-the-shelf data at test time, supporting independent sample predictions, and eliminating reliance on test annotations. Traditional TTA methods, however, often rely on costly training or optimization processes, or make unrealistic assumptions about accessing or storing historical training and test data.Instead, this study proposes FreeTTA, a training-free and universally available method that makes no assumptions, to enhance the flexibility of TTA. More importantly, FreeTTA is the first to explicitly model the test data distribution, enabling the use of intrinsic relationships among test samples to enhance predictions of individual samples without simultaneous access--a direction not previously explored. FreeTTA achieves these advantages by introducing an online EM algorithm that utilizes zero-shot predictions from VLMs as priors to iteratively compute the posterior probabilities of each online test sample and update parameters. Experiments demonstrate that FreeTTA achieves stable and significant improvements compared to state-of-the-art methods across 15 datasets in both cross-domain and out-of-distribution settings.

Transformers without Normalization
Jiachen Zhu, Xinlei Chen, Kaiming He, Yann LeCun, Zhuang Liu; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 14901-14911
Normalization layers are ubiquitous in modern neural networks and have long been considered essential. This work demonstrates that Transformers without normalization can achieve the same or better performance using a remarkably simple technique. We introduce Dynamic Tanh (DyT), an element-wise operation DyT(x)=tanh(ax), as a drop-in replacement for normalization layers in Transformers. DyT is inspired by the observation that layer normalization in Transformers often produces tanh-like, S-shaped input-output mappings. By incorporating DyT, Transformers without normalization can match or exceed the performance of their normalized coun

terparts, mostly without hyperparameter tuning. We validate the effectiveness of Transformers with DyT across diverse settings, ranging from recognition to generation, supervised to self-supervised learning, and computer vision to language models. These findings challenge the conventional understanding that normalization layers are indispensable in modern neural networks, and offer new insights into their role in deep networks.

SGC-Net: Stratified Granular Comparison Network for Open-Vocabulary HOI Detection

Xin Lin, Chong Shi, Zuopeng Yang, Haojin Tang, Zhili Zhou; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 4539-4549

Recent open-vocabulary human-object interaction (OV-HOI) detection methods primarily rely on large language model (LLM) for generating auxiliary descriptions and leverage knowledge distilled from CLIP to detect unseen interaction categories. Despite their effectiveness, these methods face two challenges: (1) feature granularity deficiency, due to reliance on last layer visual features for text alignment, leading to the neglect of crucial object-level details from intermediate layers; (2) semantic similarity confusion, resulting from CLIP's inherent biases toward certain classes, while LLM-generated descriptions based solely on labels fail to adequately capture inter-class similarities. To address these challenges, we propose a stratified granular comparison network. First, we introduce a granularity sensing alignment module that aggregates global semantic features with local details, refining interaction representations and ensuring robust alignment between intermediate visual features and text embeddings. Second, we develop a hierarchical group comparison module that recursively compares and groups classes using LLMs, generating fine-grained and discriminative descriptions for each interaction category. Experimental results on two widely-used benchmark datasets, SWIG-HOI and HICO-DET, demonstrate that our method achieves state-of-the-art results in OV-HOI detection. Codes is available at https://github.com/Phil0212/SGC-Net.

Galaxy Walker: Geometry-aware VLMs For Galaxy-scale Understanding

Tianyu Chen, Xingcheng Fu, Yisen Gao, Haodong Qian, Yuecen Wei, Kun Yan, Haoyi Zhou, Jianxin Li; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 4112-4121

Modern vision-language models (VLMs) develop patch embedding and convolution backbone within vector space, especially Euclidean ones, at the very founding. When expanding VLMs to a galaxy-scale for understanding astronomical phenomena, the integration of spherical space for planetary orbits and hyperbolic spaces for black holes raises two formidable challenges. a) The current pre-training model is confined to Euclidean space rather than a comprehensive geometric embedding. b) The predominant architecture lacks suitable backbones for anisotropic physical geometries. In this paper, we introduced Galaxy-Walker, a geometry-aware VLM, for the universe-level vision understanding tasks. We proposed the geometry prompt that generates geometry tokens by random walks across diverse spaces on a multi-scale physical graph, along with a geometry adapter that compresses and reshapes the space anisotropy in a mixture-of-experts manner. Extensive experiments demonstrate the effectiveness of our approach, with Galaxy-Walker achieving state-of-the-art performance in both galaxy property estimation (R2 scores up to 0.91) and morphology classification tasks (up to +0.17 F1 improvement in challenging features), significantly outperforming both domain-specific models and general-purpose VLMs.

HiPART: Hierarchical Pose AutoRegressive Transformer for Occluded 3D Human Pose Estimation

Hongwei Zheng, Han Li, Wenrui Dai, Ziyang Zheng, Chenglin Li, Junni Zou, Hongkai Xiong; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 16807-16817

Existing 2D-to-3D human pose estimation (HPE) methods struggle with the occlusion issue by enriching information like temporal and visual cues in the lifting st

age. In this paper, we argue that these methods ignore the limitation of the spa rse skeleton 2D input representation, which fundamentally restricts the 2D-to-3D lifting and worsens the occlusion issue. To address these, we propose a novel t wo-stage generative densification method, named Hierarchical Pose AutoRegressive Transformer (HiPART), to generate hierarchical 2D dense poses from the origina l sparse 2D pose. Specifically, we first develop a multi-scale skeleton tokeniza tion module to quantize the highly dense 2D pose into hierarchical tokens and pr opose a skeleton-aware alignment to strengthen token connections. We then develo p a hierarchical autoregressive modeling scheme for hierarchical 2D pose generat ion. With generated hierarchical poses as inputs for 2D-to-3D lifting, the propo sed method shows strong robustness in occluded scenarios and achieves state-of-t he-art performance on the single-frame-based 3D HPE. Moreover, it outperforms nu merous multi-frame methods while reducing parameter and computational complexity and can also complement them to further enhance performance and robustness.

SnowMaster: Comprehensive Real-world Image Desnowing via MLLM with Multi-Model F eedback Optimization

Jianyu Lai, Sixiang Chen, Yunlong Lin, Tian Ye, Yun Liu, Song Fei, Zhaohu Xing, Hongtao Wu, Weiming Wang, Lei Zhu; Proceedings of the Computer Vision and Patter n Recognition Conference (CVPR), 2025, pp. 4302-4312

Snowfall presents significant challenges for visual data processing, necessitati ng specialized desnowing algorithms. However, existing models often fail to gene ralize effectively due to their heavy reliance on synthetic datasets. Furthermor e, current real-world snowfall datasets are limited in scale and lack dedicated evaluation metrics designed specifically for snowfall degradation, thus hinderin g the effective integration of real snowy images into model training to reduce d omain gaps. To address these challenges, we first introduce RealSnow10K, a large -scale, high-quality dataset consisting of over 10,000 annotated real-world snow y images. In addition, we curate a preference dataset comprising 36,000 expert-r anked image pairs, enabling the adaptation of multimodal large language models (MLLMs) to better perceive snowy image quality through our innovative Multi-Model Preference Optimization (MMPO). Finally, we propose the SnowMaster, which emplo ys MMPO-enhanced MLLM to perform accurate snowy image evaluation and pseudo-labe l filtering for semi-supervised training. Experiments demonstrate that SnowMaste r delivers superior desnowing performance under real-world conditions.

From Faces to Voices: Learning Hierarchical Representations for High-quality Vid eo-to-Speech

Ji-Hoon Kim, Jeongsoo Choi, Jaehun Kim, Chaeyoung Jung, Joon Son Chung; Proceedi ngs of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 15874-15884

The objective of this study is to generate high-quality speech from silent talki ng face videos, a task also known as video-to-speech synthesis. A significant ch allenge in video-to-speech synthesis lies in the substantial modality gap betwee n silent video and multi-faceted speech. In this paper, we propose a novel vide o-to-speech system that effectively bridges this modality gap, significantly enh ancing the quality of synthesized speech. This is achieved by learning of hierar chical representations from video to speech. Specifically, we gradually transfor m silent video into acoustic feature spaces through three sequential stages -- c ontent, timbre, and prosody modeling. In each stage, we align visual factors -- lip movements, face identity, and facial expressions -- with corresponding acous tic counterparts to ensure the seamless transformation. Additionally, to generat e realistic and coherent speech from the visual representations, we employ a flo w matching model that estimates direct trajectories from a simple prior distribu tion to the target speech distribution. Extensive experiments demonstrate that o ur method achieves exceptional generation quality comparable to real utterances, outperforming existing methods by a significant margin.

DFM: Differentiable Feature Matching for Anomaly Detection

Sheng Wu, Yimi Wang, Xudong Liu, Yuguang Yang, Runqi Wang, Guodong Guo, David Do

ermann, Baochang Zhang; Proceedings of the Computer Vision and Pattern Recogniti on Conference (CVPR), 2025, pp. 15224-15233
Feature matching methods for unsupervised anomaly detection have demonstrated im pressive performance. Existing methods primarily rely on self-supervised trainin g and handcrafted matching schemes for task adaptation. However, they can only a chieve an inferior feature representation for anomaly detection because the feat ure extraction and matching modules are separately trained. To address these iss ues, we propose a Differentiable Feature Matching (DFM) framework for joint opt imization of the feature extractor and the matching head. DFM transforms nearest -neighbor matching into a pooling-based module and embeds it within a Feature Ma tching Network (FMN). This design enables end-to-end feature extraction and feat ure matching module training, thus providing better feature representation for a nomaly detection tasks. DFM is generic and can be incorporated into existing fea ture-matching methods. We implement DFM with various backbones and conduct exten sive experiments across various tasks and datasets, demonstrating its effectiven ess. Notably, we achieve state-of-the-art results in the continual anomaly detec tion task with instance-AUROC improvement of up to 3.9% and pixel-AP improvement of up to 5.5%.

FlashGS: Efficient 3D Gaussian Splatting for Large-scale and High-resolution Ren dering
Guofeng Feng, Siyan Chen, Rong Fu, Zimu Liao, Yi Wang, Tao Liu, Boni Hu, Linning Xu, Zhilin Pei, Hengjie Li, Xiuhong Li, Ninghui Sun, Xingcheng Zhang, Bo Dai; P roceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 202 5, pp. 26652-26662
Recent advances in 3D Gaussian Splatting (3DGS) have demonstrated significant po tential over traditional rendering techniques, attracting widespread attention f rom both industry and academia. However, real-time rendering with 3DGS remains a challenging problem, particularly in large-scale, high-resolution scenes due to the presence of numerous anisotropic Gaussian representations, and it has not b een extensively explored. To address this challenge, we introduce FlashGS, an op en-source CUDA library with Python bindings, featuring comprehensive algorithm d esign and optimizations, including redundancy elimination, adaptive scheduling, and efficient pipelining. First, we eliminate substantial redundant computations through precise Gaussian intersection tests, leveraging the intrinsic mechanism of the 3DGS rasterizer. During task partitioning, we propose an adaptive schedu ling strategy that accounts for variations in Gaussian size and shape. Additiona lly, we design a multi-stage pipelining strategy for color computation in the re ndering process, further accelerating performance. We conduct an extensive evalu ation of FlashGS across a diverse range of synthetic and real-world 3D scenes, e ncompassing scene sizes of up to 2.7 km^2 cityscape and resolutions of up to ove r 4K. Our approach improves 3DGS rendering performance by an order of magnitude, achieving an average speedup of 7.2x, and rendering at a minimum of 125.9 FPS, setting a new state-of-the-art in real-time 3DGS rendering. https://github.com/I nternLandMark/FlashGS.

PointSR: Self-Regularized Point Supervision for Drone-View Object Detection
Weizhuo Li, Yue Xi, Wenjing Jia, Zehao Zhang, Fei Li, Xiangzeng Liu, Qiguang Mia o; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 11707-11716
Point-Supervised Object Detection (PSOD) in a discriminative style has recently gained significant attention for its impressive detection performance and cost-e ffectiveness. However, accurately predicting high-quality pseudo-box labels for drone-view images, which often feature densely packed small objects, remains a c hallenge. This difficulty arises primarily from the limitation of rigid sampling strategies, which hinder the pseudo-box optimization process. To address this, we propose PointSR, an effective and robust point-supervised object detection fr amework with self-regularized sampling that integrates temporal and informative constraints throughout the pseudo-box generation process. Specifically, the fram ework comprises three key components: Temporal-Ensembling Encoder (TE Encoder),

Coarse Pseudo-box Prediction, and Pseudo-box Refinement. The TE Encoder builds a n anchor prototype library by aggregating temporal information for dynamic ancho r adjustment. In Coarse Pseudo-box Prediction, anchors are refined using the pro totype library, and a set of informative samples is collected for subsequent ref inement. During Pseudo-box Refinement, these informative negative samples are us ed to suppress low-confidence candidate positive samples, thereby improving the quality of the pseudo-boxes. Experimental results on benchmark datasets demonstr ate that PointSR significantly outperforms state-of-the-art methods, achieving u p to 2.6%~\mathbf 7.2% higher AP_ 50 using only point supervision. Additional ly, it exhibits strong robustness to perturbation in human-labeled points.

Exploring Timeline Control for Facial Motion Generation
Yifeng Ma, Jinwei Qi, Chaonan Ji, Peng Zhang, Bang Zhang, Zhidong Deng, Liefeng Bo; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR) , 2025, pp. 1940-1950
This paper introduces a new control signal for facial motion generation: timelin e control. Compared to audio and text signals, timelines provide more fine-grain ed control, such as generating specific facial motions with precise timing. User s can specify a multi-track timeline of facial actions arranged in temporal inte rvals, allowing precise control over the timing of each action. To model the tim eline control capability, We first annotate the time intervals of facial actions in natural facial motion sequences at a frame-level granularity. This process i s facilitated by Toeplitz Inverse Covariance-based Clustering to minimize human labor. Based on the annotations, we propose a diffusion-based generation model c apable of generating facial motions that are natural and accurately aligned with input timelines. Our method supports text-guided motion generation by using Cha tGPT to convert text into timelines. Experimental results show that our method c an annotate facial action intervals with satisfactory accuracy, and produces nat ural facial motions accurately aligned with timelines.

v-CLR: View-Consistent Learning for Open-World Instance Segmentation
Chang-Bin Zhang, Jinhong Ni, Yujie Zhong, Kai Han; Proceedings of the Computer V ision and Pattern Recognition Conference (CVPR), 2025, pp. 20307-20317
In this paper, we address the challenging problem of open-world instance segment ation. Existing works have shown that vanilla visual networks are biased toward learning appearance information, e.g. texture, to recognize objects. This implic it bias causes the model to fail in detecting novel objects with unseen textures in the open-world setting. To address this challenge, we propose a learning fra mework, called view-Consistent LeaRning (v-CLR), which aims to enforce the model to learn appearance-invariant representations for robust instance segmentation. In v-CLR, we first introduce additional views for each image, where the texture undergoes significant alterations while preserving the image's underlying struc ture. We then encourage the model to learn the appearance-invariant representati on by enforcing the consistency between object features across different views, for which we obtain class-agnostic object proposals using off-the-shelf unsuperv ised models that possess strong object-awareness. These proposals enable cross-v iew object feature matching, greatly reducing the appearance dependency while en hancing the object-awareness. We thoroughly evaluate our method on public benchm arks under both cross-class and cross-dataset settings, achieving state-of-the-a rt performance. Project page: https://visual-ai.github.io/vclr

Chat2SVG: Vector Graphics Generation with Large Language Models and Image Diffus ion Models
Ronghuan Wu, Wanchao Su, Jing Liao; Proceedings of the Computer Vision and Patte rn Recognition Conference (CVPR), 2025, pp. 23690-23700
Scalable Vector Graphics (SVG) has become the de facto standard for vector graph ics in digital design, offering resolution independence and precise control over individual elements. Despite their advantages, creating high-quality SVG conten t remains challenging, as it demands technical expertise with professional editi ng software and a considerable time investment to craft complex shapes. Recent t

ext-to-SVG generation methods aim to make vector graphics creation more accessib le, but they still encounter limitations in shape regularity, generalization abi lity, and expressiveness. To address these challenges, we introduce Chat2SVG, a hybrid framework that combines the strengths of Large Language Models (LLMs) and image diffusion models for text-to-SVG generation. Our approach first uses an L LM to generate semantically meaningful SVG templates from basic geometric primit ives. Guided by image diffusion models, a dual-stage optimization pipeline refin es paths in latent space and adjusts point coordinates to enhance geometric comp lexity. Extensive experiments show that Chat2SVG outperforms existing methods in visual fidelity, path regularity, and semantic alignment. Additionally, our sys tem enables intuitive editing through natural language instructions, making prof essional vector graphics creation accessible to all users. Our code is available at https://chat2svg.github.io/.

GAF: Gaussian Avatar Reconstruction from Monocular Videos via Multi-view Diffusi on

Jiapeng Tang, Davide Davoli, Tobias Kirschstein, Liam Schoneveld, Matthias Nießn er; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR) , 2025, pp. 5546-5558

We propose a novel approach for reconstructing animatable 3D Gaussian avatars fr om monocular videos captured by commodity devices like smartphones. Photorealist ic 3D head avatar reconstruction from such recordings is challenging due to limi ted observations, which leaves unobserved regions under-constrained and can lead to artifacts in novel views. To address this problem, we introduce a multi-view head diffusion model, leveraging its priors to fill in missing regions and ensu re view consistency in Gaussian splatting renderings. To enable precise viewpoin t control, we use normal maps rendered from FLAME-based head reconstruction, whi ch provides pixel-aligned inductive biases. We also condition the diffusion mode l on VAE features extracted from the input image to preserve facial identity and appearance details. For Gaussian avatar reconstruction, we distill multi-view d iffusion priors by using iteratively denoised images as pseudo-ground truths, ef fectively mitigating over-saturation issues. To further improve photorealism, w e apply latent upsampling priors to refine the denoised latent before decoding i t into an image. We evaluate our method on the NeRSemble dataset, showing that G AF outperforms previous state-of-the-art methods in novel view synthesis. Furthe rmore, we demonstrate higher-fidelity avatar reconstructions from monocular vide os captured on commodity devices.

Reloc3r: Large-Scale Training of Relative Camera Pose Regression for Generalizab le, Fast, and Accurate Visual Localization

Siyan Dong, Shuzhe Wang, Shaohui Liu, Lulu Cai, Qingnan Fan, Juho Kannala, Yanch ao Yang; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 16739-16752

Visual localization aims to determine the camera pose of a query image relative to a database of posed images. In recent years, deep neural networks that direct ly regress camera poses have gained popularity due to their fast inference capab ilities. However, existing methods struggle to either generalize well to new sce nes or provide accurate camera pose estimates. To address these issues, we prese nt Reloc3r, a simple yet effective visual localization framework. It consists of an elegantly designed relative pose regression network, and a minimalist motion averaging module for absolute pose estimation. Trained on approximately eight m illion posed image pairs, Reloc3r achieves surprisingly good performance and gen eralization ability. We conduct extensive experiments on six public datasets, co nsistently demonstrating the effectiveness and efficiency of the proposed method . It provides high-quality camera pose estimates in real time and generalizes to novel scenes. Code: https://github.com/ffrivera0/reloc3r.

AI-Face: A Million-Scale Demographically Annotated AI-Generated Face Dataset and Fairness Benchmark

Li Lin, Santosh Santosh, Mingyang Wu, Xin Wang, Shu Hu; Proceedings of the Compu

ter Vision and Pattern Recognition Conference (CVPR), 2025, pp. 3503-3515
AI-generated faces have enriched human life, such as entertainment, education, and art. However, they also pose misuse risks. Therefore, detecting AI-generated faces becomes crucial, yet current detectors show biased performance across different demographic groups. Mitigating biases can be done by designing algorithmic fairness methods, which usually require demographically annotated face datasets for model training. However, no existing dataset encompasses both demographic attributes and diverse generative methods simultaneously, which hinders the development of fair detectors for AI-generated faces. In this work, we introduce the AI-Face dataset, the first million-scale demographically annotated AI-generated face image dataset, including real faces, faces from deepfake videos, and faces generated by Generative Adversarial Networks and Diffusion Models. Based on this dataset, we conduct the first comprehensive fairness benchmark to assess various AI face detectors and provide valuable insights and findings to promote the future fair design of AI face detectors. Our AI-Face dataset and benchmark code are publicly available at https://github.com/Purdue-M2/AI-Face-FairnessBench.

Inference-Scale Complexity in ANN-SNN Conversion for High-Performance and Low-Power Applications
Tong Bu, Maohua Li, Zhaofei Yu; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 24387-24397
Spiking Neural Networks (SNNs) have emerged as a promising substitute for Artificial Neural Networks (ANNs) due to their advantages of fast inference and low power consumption. However, the lack of efficient training algorithms has hindered their widespread adoption. Even efficient ANN-SNN conversion methods necessitate quantized training of ANNs to enhance the effectiveness of the conversion, incurring additional training costs. To address these challenges, we propose an efficient ANN-SNN conversion framework with only inference scale complexity. The conversion framework includes a local threshold balancing algorithm, which enables efficient calculation of the optimal thresholds and fine-grained adjustment of the threshold value by channel-wise scaling. We also introduce an effective delayed evaluation strategy to mitigate the influence of the spike propagation delays. We demonstrate the scalability of our framework in typical computer vision tasks: image classification, semantic segmentation, object detection, and video classification. Our algorithm outperforms existing methods, highlighting its practical applicability and efficiency. Moreover, we have evaluated the energy consumption of the converted SNNs, demonstrating their superior low-power advantage compared to conventional ANNs. This approach simplifies the deployment of SNNs by leveraging open-source pre-trained ANN models, enabling fast, low-power inference with negligible performance reduction.

Janus: Decoupling Visual Encoding for Unified Multimodal Understanding and Generation
Chengyue Wu, Xiaokang Chen, Zhiyu Wu, Yiyang Ma, Xingchao Liu, Zizheng Pan, Wen Liu, Zhenda Xie, Xingkai Yu, Chong Ruan, Ping Luo; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 12966-12977
We introduce Janus, an autoregressive framework that unifies multimodal understanding and generation. Prior research often relies on a single visual encoder for both tasks, such as Chameleon. However, due to the differing levels of information granularity required by multimodal understanding and generation, this approach can lead to suboptimal performance, particularly in multimodal understanding. To address this issue, we decouple visual encoding into separate pathways, while still leveraging a single, unified transformer architecture for processing. The decoupling not only alleviates the conflict between the visual encoder's roles in understanding and generation, but also enhances the framework's flexibility. For instance, both the multimodal understanding and generation components can independently select their most suitable encoding methods. Experiments show that Janus surpasses previous unified model and matches or exceeds the performance of task-specific models. The simplicity, high flexibility, and effectiveness of Janus make it a strong candidate for next-generation unified multimodal models.

MVDoppler-Pose: Multi-Modal Multi-View mmWave Sensing for Long-Distance Self-Occluded Human Walking Pose Estimation
Jaeho Choi, Soheil Hor, Shubo Yang, Amin Arbabian; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 27750-27759
One of the main challenges in reliable camera-based 3D pose estimation for walking subjects is to deal with self-occlusions, especially in the case of using low-resolution cameras or at longer distance scenarios. In recent years, millimeter-wave (mmWave) radar has emerged as a promising alternative, offering inherent resilience to the effect of occlusions and distance variations. However, mmWave-based human walking pose estimation (HWPE) is still in the nascent development stages, primarily due to its unique set of practical challenges including the quality of the observed radar signal dependent on the subject's motion direction. This paper introduces the first comprehensive study comparing mmWave radar to camera systems for HWPE, highlighting its utility for distance-agnostic and occlusion-resilient pose estimation. Building upon mmWave's unique advantages, we address its intrinsic directionality issue through a new approach--the synergetic integration of multi-modal, multi-view mmWave signals, achieving robust HWPE against variations both in distance and walking direction. Extensive experiments on a newly curated dataset not only demonstrate the superior potential of mmWave technology over traditional camera-based HWPE systems, but also validate the effectiveness of our approach in overcoming the core limitations of mmWave HWPE.
****
TopNet: Transformer-Efficient Occupancy Prediction Network for Octree-Structured Point Cloud Geometry Compression
Xinjie Wang, Yifan Zhang, Ting Liu, Xinpu Liu, Ke Xu, Jianwei Wan, Yulan Guo, Hanyun Wang; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 27305-27314
Efficient Point Cloud Geometry Compression (PCGC) with a lower bits per point (BPP) and higher peak signal-to-noise ratio (PSNR) is essential for the transportation of large-scale 3D data. Although octree-based entropy models can reduce BPP without introducing geometry distortion, existing CNN-based models struggle with limited receptive fields to capture long-range dependencies, while Transformer-built architectures always neglect fine-grained details due to their reliance on global self-attention. In this paper, we propose a Transformer-efficient occupancy prediction Network, termed TopNet, to overcome these challenges by developing several novel components: Locally-enhanced Context Encoding (LeCE) for enhancing the translation-invariance of the octree nodes, Adaptive-Length Sliding Window Attention (AL-SWA) for capturing both global and local dependencies while adaptively adjusting attention weights based on the input window length, Spatial-Gated-enhanced Channel Mixer (SG-CM) for efficient feature aggregation from ancestors and siblings, and Latent-guided Node Occupancy Predictor (LNOP) for improving prediction accuracy of spatially adjacent octree nodes. Comprehensive experiments across both indoor and outdoor point cloud datasets demonstrate that our TopNet achieves state-of-the-art performance with fewer parameters, further advancing the reduction-efficiency boundaries of PCGC. The code is available at https://github.com/xinjiewang1995/TopNet.
****
MagicArticulate: Make Your 3D Models Articulation-Ready
Chaoyue Song, Jianfeng Zhang, Xiu Li, Fan Yang, Yiwen Chen, Zhongcong Xu, Jun Hao Liew, Xiaoyang Guo, Fayao Liu, Jiashi Feng, Guosheng Lin; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 15998-16007
With the explosive growth of 3D content creation, there is an increasing demand for automatically converting static 3D models into articulation-ready versions that support realistic animation. Traditional approaches rely heavily on manual annotation, which is both time-consuming and labor-intensive. Moreover, the lack of large-scale benchmarks has hindered the development of learning-based solutions. In this work, we present MagicArticulate, an effective framework that automatically transforms static 3D models into articulation-ready assets. Our key contributions are threefold. First, we introduce Articulation-XL, a large-scale benc

hmark containing over 33k 3D models with high-quality articulation annotations, carefully curated from Objaverse-XL. Second, we propose a novel skeleton generation method that formulates the task as a sequence modeling problem, leveraging an auto-regressive transformer to naturally handle varying numbers of bones or joints within skeletons and their inherent dependencies across different 3D models. Third, we predict skinning weights using a functional diffusion process that incorporates volumetric geodesic distance priors between vertices and joints. Extensive experiments demonstrate that MagicArticulate significantly outperforms existing methods across diverse object categories, achieving high-quality articulation that enables realistic animation. Project page: https://chaoyuesong.github.io/MagicArticulate.

Gain from Neighbors: Boosting Model Robustness in the Wild via Adversarial Perturbations Toward Neighboring Classes

Zhou Yang, Mingtao Feng, Tao Huang, Fangfang Wu, Weisheng Dong, Xin Li, Guangming Shi; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 25497-25507

Recent approaches, such as data augmentation, adversarial training, and transfer learning, have shown potential in addressing the issue of performance degradation caused by distributional shifts. However, they typically demand careful design in terms of data or models and lack awareness of the impact of distributional shifts. In this paper, we observe that classification errors arising from distribution shifts tend to cluster near the true values, suggesting that misclassifications commonly occur in semantically similar, neighboring categories. Furthermore, robust advanced vision foundation models maintain larger inter-class distances while preserving semantic consistency, making them less vulnerable to such shifts. Building on these findings, we propose a new method called GFN (Gain From Neighbors), which uses gradient priors from neighboring classes to perturb input images and incorporates an inter-class distance-weighted loss to improve class separation. This approach encourages the model to learn more resilient features from data prone to errors, enhancing its robustness against shifts in diverse settings. In extensive experiments across various model architectures and benchmark datasets, GFN consistently demonstrated superior performance. For instance, compared to the current state-of-the-art TAPADL method, our approach achieved a higher corruption robustness of 41.4% on ImageNet-C (+2.3%), without requiring additional parameters and using only minimal data.

****

Enhancing Video-LLM Reasoning via Agent-of-Thoughts Distillation

Yudi Shi, Shangzhe Di, Qirui Chen, Weidi Xie; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 8523-8533

This paper tackles the problem of video question answering (VideoQA), a task that often requires multi-step reasoning and a profound understanding of spatial-temporal dynamics. While large video-language models perform well on benchmarks, they often lack explainability and spatial-temporal grounding. In this paper, we propose **A**gent-**o**f-**T**houghts **D**istillation (**AoTD**), a method that enhances models by incorporating automatically generated Chain-of-Thoughts (CoTs) into the instruction-tuning process. Specifically, we leverage an agent-based system to decompose complex questions into sub-tasks, and address them with specialized vision models, the intermediate results are then treated as reasoning chains. We also introduce a verification mechanism using a large language model (LLM) to ensure the reliability of generated CoTs. Extensive experiments demonstrate that AoTD improves the performance on multiple-choice and open-ended benchmarks.

De^2Gaze: Deformable and Decoupled Representation Learning for 3D Gaze Estimation

Yunfeng Xiao, Xiaowei Bai, Baojun Chen, Hao Su, Hao He, Liang Xie, Erwei Yin; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 3091-3100

3D Gaze estimation is a challenging task due to two main issues. First, existing

methods focus on analyzing dense features (e.g., large pixel regions), which are sensitive to local noise (e.g., light spots, blurs) and result in increased computational complexity. Second, an eyeball model can correspond multiple gaze directions, and the entangled representation between gazes and models increases the learning difficulty. To address these issues, we propose De\textsuperscript 2Gaze , a lightweight and accurate model-aware 3D gaze estimation method. In De\textsuperscript 2 Gaze, we introduce two key innovations for deformable and decoupled representation learning. Specifically, first, we propose a deformable sparse attention mechanism that can adapt sparse sampling points to attention areas to avoid local noise influences. Second, we propose a spatial decoupling network with a dual-branch decoding architecture to disentangle invariant (e.g., eyeball radius, position) and variable (e.g., gaze, pupil, iris) features from the latent space. Compared to existing methods, De\textsuperscript 2 Gaze requires fewer sparse features, and achieves faster convergence speed, lower computational complexity, and higher accuracy in 3D gaze estimation.Qualitative and quantitative experiments demonstrate that De\textsuperscript 2 Gaze achieves state-of-the-art accuracy and high-quality semantic segmentation for 3D gaze estimation on the TEyeD dataset.

ReCapture: Generative Video Camera Controls for User-Provided Videos using Masked Video Fine-Tuning

David Junhao Zhang, Roni Paiss, Shiran Zada, Nikhil Karnad, David E. Jacobs, Yael Pritch, Inbar Mosseri, Mike Zheng Shou, Neal Wadhwa, Nataniel Ruiz; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 2050-2062

Recently, breakthroughs in video modeling have allowed for controllable camera trajectories in generated videos. However, these methods cannot be directly applied to user-provided videos that are not generated by a video model. In this paper, we present ReCapture, a method for generating new videos with novel camera trajectories from a single user-provided video. Our method allows us to re-generate the reference video, with all its existing scene motion, from vastly different angles and with cinematic camera motion. Notably, using our method we can also plausibly hallucinate parts of the scene that were not observable in the reference video. Our method works by (1) generating a noisy anchor video with a new camera trajectory using multiview diffusion models or depth-based point cloud rendering and then (2) regenerating the anchor video into a clean and temporally consistent reangled video using our proposed masked video fine-tuning technique.

M^3-VOS: Multi-Phase, Multi-Transition, and Multi-Scenery Video Object Segmentation

Zixuan Chen, Jiaxin Li, Junxuan Liang, Liming Tan, Yejie Guo, Cewu Lu, Yong-Lu Li; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 29193-29202

Intelligent robots need to interact with diverse objects across various environments. The appearance and state of objects frequently undergo complex transformations depending on the object properties, e.g., phase transitions. However, in the vision community, segmenting dynamic objects with phase transitions is overlooked. In light of this, we introduce the concept of phase in segmentation, which categorizes real-world objects based on their visual characteristics and potential morphological and appearance changes. Then, we present a new benchmark, Multi-Phase, Multi-Transition, and Multi-Scenery Video Object Segmentation (M^3-VOS), to verify the ability of models to understand object phases, which consists of 471 high-resolution videos spanning over 10 distinct everyday scenarios. It provides dense instance mask annotations that capture both object phases and their transitions. We evaluate state-of-the-art methods on M^3-VOS, yielding several key insights. Notably, current appearance-based approaches show significant room for improvement when handling objects with phase transitions. The inherent changes in disorder suggest that the predictive performance of the forward entropy-increasing process can be improved through a reverse entropy-reducing process. These findings lead us to propose ReVOS, a new plug-and-play model that improves its

performance by reversal refinement. Our data and code will be publicly availabl
e at https://zixuan-chen.github.io/M-cube-VOS.github.io/.

Self-Expansion of Pre-trained Models with Mixture of Adapters for Continual Lear
ning
Huiyi Wang, Haodong Lu, Lina Yao, Dong Gong; Proceedings of the Computer Vision
and Pattern Recognition Conference (CVPR), 2025, pp. 10087-10098
Continual learning (CL) aims to continually accumulate knowledge from a non-stat
ionary data stream without catastrophic forgetting of learned knowledge, requiri
ng a balance between stability and adaptability. Relying on the generalizable re
presentation in pre-trained models (PTMs), PTM-based CL methods perform effectiv
e continual adaptation on downstream tasks by adding learnable adapters or promp
ts upon the frozen PTMs. However, many existing PTM-based CL methods use restric
ted adaptation on a fixed set of these modules to avoid forgetting, suffering fr
om limited CL ability. Periodically adding task-specific modules results in line
ar model growth rate and impaired knowledge reuse. We propose Self-Expansion of
pre-trained models with Modularized Adaptation (SEMA), a novel approach to enhan
ce the control of stability-plasticity balance in PTM-based CL. SEMA automatical
ly decides to reuse or add adapter modules on demand in CL, depending on whether
significant distribution shift that cannot be handled is detected at different
representation levels. We design modular adapter consisting of a functional adap
ter and a representation descriptor. The representation descriptors are trained
as a distribution shift indicator and used to trigger self-expansion signals. Fo
r better composing the adapters, an expandable weighting router is learned joint
ly for mixture of adapter outputs. SEMA enables better knowledge reuse and sub-l
inear expansion rate. Extensive experiments demonstrate the effectiveness of the
proposed self-expansion method, achieving state-of-the-art performance compared
to PTM-based CL methods without memory rehearsal. Code is available at https://
github.com/huiyiwang01/SEMA-CL.

Dual Prompting Image Restoration with Diffusion Transformers
Dehong Kong, Fan Li, Zhixin Wang, Jiaqi Xu, Renjing Pei, Wenbo Li, WenQi Ren; Pr
oceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025
, pp. 12809-12819
Recent state-of-the-art image restoration methods mostly adopt latent diffusion
models with U-Net backbones, yet still facing challenges in achieving high-quali
ty restoration due to their limited capabilities. Diffusion transformers (DiTs),
like SD3, are emerging as a promising alternative because of their better quali
ty with scalability. However, previous conditional control methods for U-Net-bas
ed diffusion models, such as ControlNet, are not well-suited for DiTs. In this p
aper, we introduce DPIR (Dual Recent state-of-the-art image restoration methods
mostly adopt latent diffusion models with U-Net backbones, yet still facing chal
lenges in achieving high-quality restoration due to their limited capabilities.
Diffusion transformers (DiTs), like SD3, are emerging as a promising alternative
because of their better quality with scalability. In this paper, we introduce D
PIR (Dual Prompting Image Restoration), a novel image restoration method that ef
fectivly extracts conditional information of low-quality images from multiple pe
rspectives. Specifically, DPIR consits of two branches: a low-quality image cond
itioning branch and a dual prompting control branch. The first branch utilizes a
lightweight module to incorporate image priors into the DiT with high efficienc
y. More importantly, we believe that in image restoration, textual description a
lone cannot fully capture its rich visual characteristics. Therefore, a dual pro
mpting module is designed to provide DiT with additional visual cues, capturing
both global context and local appearance. The extracted global-local visual prom
pts as extra conditional control, alongside textual prompts to form dual prompts
, greatly enhance the quality of the restoration. Extensive experimental results
demonstrate that DPIR delivers superior image restoration performance.

Brain-Inspired Spiking Neural Networks for Energy-Efficient Object Detection
Ziqi Li, Tao Gao, Yisheng An, Ting Chen, Jing Zhang, Yuanbo Wen, Mengkun Liu, Qi

anxi Zhang; Proceedings of the Computer Vision and Pattern Recognition Conferenc e (CVPR), 2025, pp. 3552-3562
Brain-inspired spiking neural networks (SNNs) have the capability of energy-effi cient processing of temporal information. However, leveraging the rich dynamic c haracteristics of SNNs and prior works in artificial neural networks (ANNs) to c onstruct an effective object detection model for visual tasks remains an open qu estion for further exploration. To develop a directly-trained , low energy consu mption and high-performance multi-scale SNN model, we propose a novel interpreta ble object detection framework Multi-scale Spiking Detector (MSD). Initially, we propose a spiking convolutional neuron as a core component of the Optic Nerve N ucleus Block (ONNB), designed to significantly enhance the deep feature extracti on capabilities of SNNs. ONNB enables direct training with improved energy effic iency, demonstrating superior performance compared to state-of-the-art ANN-to-SN N conversion and SNN techniques. In addition, we propose a Multi-scale Spiking D etection Framework to emulate the biological response and comprehension of stimu li from different objects. Wherein, spiking multi-scale fusion and the spiking d etector are employed to integrate features across different depths and to detect response outcomes, respectively. Our method outperforms state-of-the-art ANN de tectors, with only 7.8 M parameters and 6.43 mJ energy consumption. MSD obtains the mean average precision (mAP) of 62.0% and 66.3% on COCO and Gen1 datasets, r espectively.

Medusa: A Multi-Scale High-order Contrastive Dual-Diffusion Approach for Multi-V iew Clustering
Liang Chen, Zhe Xue, Yawen Li, Meiyu Liang, Yan Wang, Anton van den Hengel, Yuan kai Qi; Proceedings of the Computer Vision and Pattern Recognition Conference (C VPR), 2025, pp. 10295-10304
Deep multi-view clustering methods utilize information from multiple views to ac hieve enhanced clustering results and have gained increasing popularity in recen t years. Most existing methods typically focus on either inter-view or intra-vie w relationships, aiming to align information across views or analyze structural patterns within individual views. However, they often incorporate inter-view com plementary information in a simplistic manner, while overlooking the complex, hi gh-order relationships within multi-view data and the interactions among samples , resulting in an incomplete utilization of the rich information available. Inst ead, we propose a multi-scale approach that exploits all of the available inform ation. We first introduce a dual graph diffusion module guided by a consensus gr aph. This module leverages inter-view information to enhance the representation of both nodes and edges within each view. Secondly, we propose a novel contrasti ve loss function based on hypergraphs to more effectively model and leverage com plex intra-view data relationships. Finally, we propose to adaptively learn fusi on weights at the sample level, which enables a more flexible and dynamic aggreg ation of multi-view information. Extensive experiments on eight datasets show fa vorable performance of the proposed method compared to state-of-the-art approach es, demonstrating its effectiveness across diverse scenarios.
****

MambaOut: Do We Really Need Mamba for Vision?
Weihao Yu, Xinchao Wang; Proceedings of the Computer Vision and Pattern Recognit ion Conference (CVPR), 2025, pp. 4484-4496
Mamba, an architecture with RNN-like token mixer of state space model (SSM), was recently introduced to address the quadratic complexity of the attention mechan ism and subsequently applied to vision tasks. Nevertheless, the performance of M amba for vision is often underwhelming when compared with convolutional and atte ntion-based models. In this paper, we delve into the essence of Mamba, and conce ptually conclude that Mamba is ideally suited for tasks with long-sequence and a utoregressive characteristics. For vision tasks, as image classification on Imag eNet does not align with either characteristic, we hypothesize that Mamba is not necessary for this task; Detection and segmentation tasks on COCO or ADE20K are also not autoregressive, yet they adhere to the long-sequence characteristic, s o we believe it is still worthwhile to explore Mamba's potential for these tasks

. To empirically verify our hypotheses, we construct a series of models named MambaOut through stacking Mamba blocks while removing their core token mixer, SSM. Experimental results strongly support our hypotheses. Specifically, our MambaOut model surpasses all visual Mamba models on ImageNet image classification, indicating that Mamba is indeed unnecessary for this task. As for detection and segmentation, MambaOut cannot match the performance of state-of-the-art visual Mamba models, demonstrating the potential of Mamba for long-sequence visual tasks.

Everything to the Synthetic: Diffusion-driven Test-time Adaptation via Synthetic-Domain Alignment

Jiayi Guo, Junhao Zhao, Chaoqun Du, Yulin Wang, Chunjiang Ge, Zanlin Ni, Shiji Song, Humphrey Shi, Gao Huang; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 30503-30513

Test-time adaptation (TTA) aims to improve the performance of source-domain pre-trained models on previously unseen, shifted target domains. Traditional TTA methods primarily adapt model weights based on target data streams, making model performance sensitive to the amount and order of target data. The recently proposed diffusion-driven TTA methods mitigate this by adapting model inputs instead of weights, where an unconditional diffusion model, trained on the source domain, transforms target-domain data into a synthetic domain that is expected to approximate the source domain. However, in this paper, we reveal that although the synthetic data in diffusion-driven TTA seems indistinguishable from the source data, it is unaligned with, or even markedly different from the latter for deep networks. To address this issue, we propose a Synthetic-Domain Alignment (SDA) framework. Our key insight is to fine-tune the source model with synthetic data to ensure better alignment. Specifically, we first employ a conditional diffusion model to generate labeled samples, creating a synthetic dataset. Subsequently, we use the aforementioned unconditional diffusion model to add noise to and denoise each sample before fine-tuning. This Mix of Diffusion (MoD) process mitigates the potential domain misalignment between the conditional and unconditional models. Extensive experiments across classifiers, segmenters, and multimodal large language models (MLLMs, e.g., LLaVA) demonstrate that SDA achieves superior domain alignment and consistently outperforms existing diffusion-driven TTA methods. Our code is available at https://github.com/SHI-Labs/Diffusion-Driven-Test-Time-Adaptation-via-Synthetic-Domain-Alignment.

Multi-Granularity Class Prototype Topology Distillation for Class-Incremental Source-Free Unsupervised Domain Adaptation

Peihua Deng, Jiehua Zhang, Xichun Sheng, Chenggang Yan, Yaoqi Sun, Ying Fu, Liang Li; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 30566-30576

This paper explores the Class-Incremental Source-Free Unsupervised Domain Adaptation (CI-SFUDA) problem, where the unlabeled target data come incrementally without access to labeled source instances. This problem poses two challenges, the interference of similar source-class knowledge in target-class representation learning and the shocks of new target knowledge to old ones. To address them, we propose the Multi-Granularity Class Prototype Topology Distillation (GROTO) algorithm, which effectively transfers the source knowledge to the class-incremental target domain. Concretely, we design the multi-granularity class prototype self-organization module and the prototype topology distillation module. First, we mine the positive classes by modeling accumulation distributions. Next, we introduce multi-granularity class prototypes to generate reliable pseudo-labels, and exploit them to promote the positive-class target feature self-organization. Second, the positive-class prototypes are leveraged to construct the topological structures of source and target feature spaces. Then, we perform the topology distillation to continually mitigate the shocks of new target knowledge to old ones. Extensive experiments demonstrate that our proposed method achieves state-of-the-art performance on three public datasets.

DepthCues: Evaluating Monocular Depth Perception in Large Vision Models

Duolikun Danier, Mehmet Aygün, Changjian Li, Hakan Bilen, Oisin Mac Aodha; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 20049-20059

Large-scale pre-trained vision models are becoming increasingly prevalent, offering expressive and generalizable visual representations that benefit various downstream tasks. Recent studies on the emergent properties of these models have revealed their high-level geometric understanding, in particular in the context of depth perception. However, it remains unclear how depth perception arises in these models without explicit depth supervision provided during pre-training. To investigate this, we examine whether the monocular depth cues, similar to those used by the human visual system, emerge in these models. We introduce a new benchmark, DepthCues, designed to evaluate depth cue understanding, and present findings across 20 diverse and representative pre-trained vision models. Our analysis shows that human-like depth cues emerge in more recent larger models. We also explore enhancing depth perception in large vision models by fine-tuning on DepthCues, and find that even without dense depth supervision, this improves depth estimation. To support further research, our benchmark and evaluation code will be made publicly available for studying depth perception in vision models.

A Polarization-Aided Transformer for Image Deblurring via Motion Vector Decomposition

Duosheng Chen, Shihao Zhou, Jinshan Pan, Jinglei Shi, Lishen Qu, Jufeng Yang; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 28061-28070

Effectively leveraging motion information is crucial for the image deblurring task. Existing methods typically build deep-learning models to restore a clean image by estimating blur patterns over the entire movement. This suggests that the blur caused by rotational motion components is processed together with the translational one. Exploring the movement without separation leads to limited performance for complex motion deblurring, especially rotational motion. In this paper, we propose Motion Decomposition Transformer (MDT), a transformer-based architecture augmented with polarized modules for deblurring via motion vector decomposition. MDT consists of a Motion Decomposition Module (MDM) for extracting hybrid rotation and translation features, and a Radial Stripe Attention Solver (RSAS) for sharp image reconstruction with enhanced rotational information. Specifically, the MDM uses a deformable Cartesian convolutional branch to capture translational motion, complemented by a polar-system branch to capture rotational motion. The RSAS employs radial stripe windows and angular relative positional encoding in the polar system to enhance rotational information. This design preserves translational details while keeping computational costs lower than dual-coordinate design. Experimental results on 6 image deblurring datasets show that MDT outperforms state-of-the-art methods, particularly in handling blur caused by complex motions with significant rotational components.

SpecTRe-GS: Modeling Highly Specular Surfaces with Reflected Nearby Objects by Tracing Rays in 3D Gaussian Splatting

Jiajun Tang, Fan Fei, Zhihao Li, Xiao Tang, Shiyong Liu, Youyu Chen, Binxiao Huang, Zhenyu Chen, Xiaofei Wu, Boxin Shi; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 16133-16142

3D Gaussian Splatting (3DGS), a recently emerged multi-view 3D reconstruction technique, has shown significant advantages in real-time rendering and explicit editing. However, 3DGS encounters challenges in the accurate modeling of both high-frequency view-dependent appearances and global illumination effects, including inter-reflection. This paper introduces SpecTRe-GS, which addresses these challenges and models highly Specular surfaces that reflect nearby objects through Tracing Rays in 3D Gaussian Splatting. SpecTRe-GS separately models reflections from highly specular and rough surfaces to leverage the distinctions between their reflective properties and integrates an efficient ray tracer within the 3DGS framework for querying secondary rays, thus achieving fast and accurate rendering. Also, it incorporates normal prior guidance and joint geometry optimization at

various stages of the training process to enhance geometry reconstruction for un
distorted reflections. Experiments on both synthetic and real-world scenes demon
strate the superiority of SpecTRe-GS compared to existing 3DGS-based methods in
capturing highly specular inter-reflections and also showcase its editing applic
ations.

Seurat: From Moving Points to Depth
Seokju Cho, Jiahui Huang, Seungryong Kim, Joon-Young Lee; Proceedings of the Com
puter Vision and Pattern Recognition Conference (CVPR), 2025, pp. 7211-7221
Accurate depth estimation from monocular videos remains challenging due to ambig
uities inherent in single-view geometry, as crucial depth cues like stereopsis a
re absent. However, humans often perceive relative depth intuitively by observin
g variations in the size and spacing of objects as they move. Inspired by this,
we propose a novel method that infers relative depth by examining the spatial re
lationships and temporal evolution of a set of tracked 2D trajectories. Specific
ally, we use off-the-shelf point tracking models to capture 2D trajectories. The
n, our approach employs spatial and temporal transformers to process these traje
ctories and directly infer depth changes over time. Evaluated on the TAPVid-3D b
enchmark, our method demonstrates robust zero-shot performance, generalizing eff
ectively from synthetic to real-world datasets. Results indicate that our approa
ch achieves temporally smooth, high-accuracy depth predictions across diverse do
mains.

AuraFusion360: Augmented Unseen Region Alignment for Reference-based 360deg Unbo
unded Scene Inpainting
Chung-Ho Wu, Yang-Jung Chen, Ying-Huan Chen, Jie-Ying Lee, Bo-Hsu Ke, Chun-Wei T
uan Mu, Yi-Chuan Huang, Chin-Yang Lin, Min-Hung Chen, Yen-Yu Lin, Yu-Lun Liu; Pr
oceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025
, pp. 16366-16376
Three-dimensional scene inpainting is crucial for applications from virtual real
ity to architectural visualization, yet existing methods struggle with view cons
istency and geometric accuracy in 360deg unbounded scenes. We present AuraFusion
360, a novel reference-based method that enables high-quality object removal and
 hole filling in 3D scenes represented by Gaussian Splatting. Our approach intro
duces (1) depth-aware unseen mask generation for accurate occlusion identificati
on, (2) Adaptive Guided Depth Diffusion, a zero-shot method for accurate initial
 point placement without requiring additional training, and (3) SDEdit-based det
ail enhancement for multi-view coherence. We also introduce 360-USID, the first
comprehensive dataset for 360deg unbounded scene inpainting with ground truth. E
xtensive experiments demonstrate that AuraFusion360 significantly outperforms ex
isting methods, achieving superior perceptual quality while maintaining geometri
c accuracy across dramatic viewpoint changes.

Language-Guided Image Tokenization for Generation
Kaiwen Zha, Lijun Yu, Alireza Fathi, David A. Ross, Cordelia Schmid, Dina Katabi
, Xiuye Gu; Proceedings of the Computer Vision and Pattern Recognition Conferenc
e (CVPR), 2025, pp. 15713-15722
Image tokenization, the process of transforming raw image pixels into a compact
low-dimensional latent representation, has proven crucial for scalable and effic
ient image generation. However, mainstream image tokenization methods generally
have limited compression rates, making high-resolution image generation computat
ionally expensive. To address this challenge, we propose to leverage language fo
r efficient image tokenization, and we call our method Text-Conditioned Image To
kenization (TexTok). TexTok is a simple yet effective tokenization framework tha
t leverages language to provide a compact, high-level semantic representation. B
y conditioning the tokenization process on descriptive text captions, TexTok sim
plifies semantic learning, allowing more learning capacity and token space to be
 allocated to capture fine-grained visual details, leading to enhanced reconstru
ction quality and higher compression rates. Compared to the conventional tokeniz
er without text conditioning, TexTok achieves average reconstruction FID improve

ments of 29.2% and 48.1% on ImageNet-256 and -512 benchmarks respectively, acros s varying numbers of tokens. These tokenization improvements consistently transl ate to 16.3% and 34.3% average improvements in generation FID. By simply replaci ng the tokenizer in Diffusion Transformer (DiT) with TexTok, our system can achi eve a 93.5x inference speedup while still outperforming the original DiT using o nly 32 tokens on ImageNet-512. TexTok with a vanilla DiT generator achieves stat e-of-the-art FID scores of 1.46 and 1.62 on ImageNet-256 and -512 respectively. Furthermore, we demonstrate TexTok's superiority on the text-to-image generation task, effectively utilizing the off-the-shelf text captions in tokenization.

Img-Diff: Contrastive Data Synthesis for Multimodal Large Language Models
Qirui Jiao, Daoyuan Chen, Yilun Huang, Bolin Ding, Yaliang Li, Ying Shen; Procee dings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp . 9296-9307
High-performance Multimodal Large Language Models (MLLMs) rely heavily on data q uality. This study introduces a novel data synthesis method, leveraging insights from contrastive learning and image difference captioning to enhance fine-grain ed image recognition in MLLMs. By analyzing object differences in detailed regio ns between similar images, we challenge the model to identify both matching and distinct components. Specifically, our method initially create pairs of similar images that highlight object variations. After that, we introduce a Difference A rea Generator for object differences identifying, followed by a Difference Capti ons Generator for differences describing. The outcome is a high-quality dataset of "object replacement" samples, named Img-Diff, which can be expanded as needed due to its automation. We use the generated dataset to finetune state-of-the-ar t (SOTA) MLLMs such as InternVL2, yielding comprehensive improvements across num erous image difference and Visual Question Answering tasks. For instance, the tr ained models notably surpass the SOTA models GPT-4V and Gemini on the MMVP bench mark. Additionally, we conduct thorough evaluations to confirm the dataset's div ersity, quality, and robustness, presenting several insights on the synthesis of such a contrastive dataset. We release our codes and dataset to encourage furth er research on multimodal data synthesis and MLLMs' fundamental capabilities for image understanding.

CocoER: Aligning Multi-Level Feature by Competition and Coordination for Emotio n Recognition
Xuli Shen, Hua Cai, Weilin Shen, Qing Xu, Dingding Yu, Weifeng Ge, Xiangyang Xue ; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 29591-29600
With the explosion of human-machine interaction, emotion recognition has reigni ted attention. Previous works focus on improving visual feature fusion and reas oning from multiple image levels. Although it is non-trivial to deduce a person 's emotion by integrating multi-level feature (head, body and context), the emo tion recognition results of each level is usually different from one another, wh ich creates inconsistency in the prevailing feature alignment method and decreas e recognition performance. In this work, we propose a multi-level image feature refinement method for emotion recognition (CocoER) to mitigate the impact caused by conflicting results from multi-level recognition. First, we leverage cross-level attention to improve visual feature consistency between hierarchically cr opped head, body and context windows. Then, vocabulary informed alignment is in corporated into the recognition framework to produce pseudo label and guide hier archical visual feature refinement. To effectively fuse multi-level feature, we elaborate on a competition process of eliminating irrelevant image level predic tions and a coordination process to enhance the feature across all levels. Exte nsive experiments are executed on two popular datasets, and our method achieves state-of-the-art performance with multi-level interpretation results.

Hyperbolic Uncertainty-Aware Few-Shot Incremental Point Cloud Segmentation
Tanuj Sur, Samrat Mukherjee, Kaizer Rahaman, Subhasis Chaudhuri, Muhammad Haris Khan, Biplab Banerjee; Proceedings of the Computer Vision and Pattern Recognitio

n Conference (CVPR), 2025, pp. 11810-11821
3D point cloud segmentation is essential across a range of applications; however, conventional methods often struggle in evolving environments, particularly when tasked with identifying novel categories under limited supervision. Few-Shot Learning (FSL) and Class Incremental Learning (CIL) have been adapted previously to address these challenges in isolation, yet the combined paradigm of Few-Shot Class Incremental Learning (FSCIL) remains largely unexplored for point cloud segmentation. To address this gap, we introduce Hyperbolic Ideal Prototypes Optimization (HIPO), a novel framework that harnesses hyperbolic embeddings for FSCIL in 3D point clouds. HIPO employs the Poincare Hyperbolic Sphere as its embedding space, integrating Ideal Prototypes enriched by CLIP-derived class semantics, to capture the hierarchical structure of 3D data. By enforcing orthogonality among prototypes and maximizing representational margins, HIPO constructs a resilient embedding space that mitigates forgetting and enables the seamless integration of new classes, thereby effectively countering overfitting. Extensive evaluations on S3DIS, ScanNetv2, and cross-dataset scenarios demonstrate HIPO's strong performance, significantly surpassing existing approaches in both in-domain and cross-dataset FSCIL tasks for 3D point cloud segmentation.

Enhancing Creative Generation on Stable Diffusion-based Models
Jiyeon Han, Dahee Kwon, Gayoung Lee, Junho Kim, Jaesik Choi; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 28609-28618
Recent text-to-image generative models, particularly Stable Diffusion and its distilled variants, have achieved impressive fidelity and strong text-image alignment. However, their creative generation capacity remains limited, as simply adding the term "creative" to prompts often fails to yield genuinely creative results. In this paper, we introduce C3 (Creative Concept Catalyst), a training-free approach designed to enhance creativity in Stable Diffusion-based models. C3 selectively amplifies features during the denoising process to foster more creative outputs. We offer practical guidelines for choosing amplification factors based on two main aspects of creativity. C3 allows user-friendly creativity control in image generation and is the first study to enhance creativity in diffusion models without extensive computational costs. We demonstrate its effectiveness across various Stable Diffusion-based models. Source codes will be publicly available.

The Devil is in the Prompts: Retrieval-Augmented Prompt Optimization for Text-to-Video Generation
Bingjie Gao, Xinyu Gao, Xiaoxue Wu, Yujie Zhou, Yu Qiao, Li Niu, Xinyuan Chen, Yaohui Wang; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 3173-3183
The evolution of Text-to-video (T2V) generative models, trained on large-scale datasets, has been marked by significant progress. However, the sensitivity of T2V generative models to input prompts highlights the critical role of prompt design in influencing generative outcomes. Prior research has predominantly relied on Large Language Models (LLMs) to align user-provided prompts with the distribution of training prompts, albeit without tailored guidance encompassing prompt vocabulary and sentence structure nuances. To this end, we introduce RAPO, a novel Retrieval-Augmented Prompt Optimization framework. In order to address potential inaccuracies and ambiguous details generated by LLM-generated prompts. RAPO refines the naive prompts through dual optimization branches, selecting the superior prompt for T2V generation. The first branch augments user prompts with diverse modifiers extracted from a learned relational graph, refining them to align with the format of training prompts via a fine-tuned LLM. Conversely, the second branch rewrites the naive prompt using a pre-trained LLM following a well-defined instruction set. Extensive experiments demonstrate that RAPO can effectively enhance both the static and dynamic dimensions of generated videos, demonstrating the significance of prompt optimization for user-provided prompts. Project website: \href https://whynothaha.github.io/Prompt_optimizer/RAPO.html GitHub .

Denoising Functional Maps: Diffusion Models for Shape Correspondence
Aleksei Zhuravlev, Zorah Lähner, Vladislav Golyanik; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 26899-26909
Estimating correspondences between pairs of deformable shapes remains a challenging problem. Despite substantial progress, existing methods lack broad generalization capabilities and require category-specific training data. To address these limitations, we propose a fundamentally new approach to shape correspondence based on denoising diffusion models. In our method, a diffusion model learns to directly predict the functional map, a low-dimensional representation of a point-wise map between shapes. We use a large dataset of synthetic human meshes for training and employ two steps to reduce the number of functional maps that need to be learned. First, the maps refer to a template rather than shape pairs. Second, the functional map is defined in a basis of eigenvectors of the Laplacian, which is not unique due to sign ambiguity. Therefore, we introduce an unsupervised approach to select a specific basis by correcting the signs of eigenvectors based on surface features. Our model achieves competitive performance on standard human datasets, meshes with anisotropic connectivity, non-isometric humanoid shapes, as well as animals compared to existing descriptor-based and large-scale shape deformation methods.

ProReflow: Progressive Reflow with Decomposed Velocity
Lei Ke, Haohang Xu, Xuefei Ning, Yu Li, Jiajun Li, Haoling Li, Yuxuan Lin, Dongsheng Jiang, Yujiu Yang, Linfeng Zhang; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 28029-28038
Diffusion models have achieved significant progress in both image and video generation while still suffering from huge computation costs. As an effective solution, rectified flow aims to rectify the diffusion process of diffusion models into a straight line for few-step and even one-step generation. However, in this paper, we suggest that the original training pipeline of reflow is not optimal and introduce two techniques to improve it. Firstly, we introduce progressive reflow, which progressively reflows the diffusion models in local timesteps until the whole diffusion progresses, reducing the difficulty of flow matching. Second, we introduce aligned v-prediction, which highlights the importance of direction matching in flow matching over magnitude matching. Experimental results on SDv1.5 and SDXL demonstrate the effectiveness of our method, for example, conducting on SDv1.5 achieves an FID of 10.70 on MSCOCO2014 validation set with only 4 sampling steps, close to our teacher model (32 DDIM steps, FID = 10.05). Our codes will be released at Github.
****

DnLUT: Ultra-Efficient Color Image Denoising via Channel-Aware Lookup Tables
Sidi Yang, Binxiao Huang, Yulun Zhang, Dahai Yu, Yujiu Yang, Ngai Wong; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 7582-7591
While deep neural networks have revolutionized image denoising capabilities, their deployment on edge devices remains challenging due to substantial computational and memory requirements. To this end, we present DnLUT, an ultra-efficient lookup table-based framework that achieves high-quality color image denoising with minimal resource consumption. Our key innovation lies in two complementary components: a Pairwise Channel Mixer (PCM) that effectively captures inter-channel correlations and spatial dependencies in parallel, and a novel L-shaped convolution design that maximizes receptive field coverage while minimizing storage overhead. By converting these components into optimized lookup tables post-training, DnLUT achieves remarkable efficiency - requiring only 500KB storage and 0.1% energy consumption compared to its CNN contestant DnCNN, while delivering 20x faster inference. Extensive experiments demonstrate that DnLUT outperforms all existing LUT-based methods by over 1dB in PSNR, establishing a new state-of-the-art in resource-efficient color image denoising.
****

Devil is in the Detail: Towards Injecting Fine Details of Image Prompt in Image Generation via Conflict-free Guidance and Stratified Attention

Kyungmin Jo, Jooyeol Yun, Jaegul Choo; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 23595-23603

While large-scale text-to-image diffusion models enable the generation of high-quality, diverse images from text prompts, these prompts struggle to capture intricate details, such as textures, preventing the user intent from being reflected. This limitation has led to efforts to generate images conditioned on user-provided images, referred to as image prompts. Recent work modifies the self-attention mechanism to impose image conditions in generated images by replacing or concatenating the keys and values from the image prompt. This enables the self-attention layer to work like a cross-attention layer, generally used to incorporate text prompts.In this paper, we identify two common issues in existing methods of modifying self-attention that hinder diffusion models from reflecting the image prompt. By addressing these issues, we propose a novel method that generates images that properly reflect the details of image prompts. First, existing approaches often neglect the importance of image prompts in classifier-free guidance, which directs the model towards the intended conditions and away from those undesirable. Specifically, current methods use image prompts as both desired and undesired conditions, causing conflicting signals. To resolve this, we propose conflict-free guidance by using image prompts only as desired conditions, ensuring that the generated image faithfully reflects the image prompt.In addition, we observe that the two most common self-attention modifications involve a trade-off between the realism of the generated image and alignment with the image prompt, achieved by selectively using keys and values from both images. Specifically, selecting more keys and values from the image prompt improves alignment, while selecting more from the generated image enhances realism. To balance both, we propose an alternative self-attention modification method, Stratified Attention, which jointly uses keys and values from both images rather than selecting between them. Through extensive experiments across three distinct image generation tasks, we demonstrate that the proposed method outperforms existing image-prompting models in faithfully reflecting the image prompt.

D^3-Human: Dynamic Disentangled Digital Human from Monocular Video

Honghu Chen, Bo Peng, Yunfan Tao, Juyong Zhang; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 10836-10846

We introduce \text D ^3\text -Human , a method for reconstructing Dynamic Disentangled Digital Human geometry from monocular videos. Past monocular video human reconstruction primarily focuses on reconstructing undecoupled clothed human bodies or only reconstructing clothing, making it difficult to apply directly in applications such as animation production. The challenge in reconstructing decoupled clothing and body lies in the occlusion caused by clothing over the body. To this end, the details of the visible area and the plausibility of the invisible area must be ensured during the reconstruction process. Our proposed method combines explicit and implicit representations to model the decoupled clothed human body, leveraging the robustness of explicit representations and the flexibility of implicit representations. Specifically, we reconstruct the visible region as SDF and propose a novel human manifold signed distance field (hmSDF) to segment the visible clothing and visible body, and then merge the visible and invisible body. Extensive experimental results demonstrate that, compared with existing reconstruction schemes, \text D ^3\text -Human can achieve high-quality decoupled reconstruction of the human body wearing different clothing, and can be directly applied to clothing transfer and animation production.

****

BiM-VFI: Bidirectional Motion Field-Guided Frame Interpolation for Video with Non-uniform Motions

Wonyong Seo, Jihyong Oh, Munchurl Kim; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 7244-7253

Existing Video Frame interpolation (VFI) models tend to suffer from time-to-location ambiguity when trained with video of non-uniform motions, such as accelerating, decelerating, and changing directions, which often yield blurred interpolated frames.In this paper, we propose (i) a novel motion description map, Bidirect

ional Motion field (BiM), to effectively describe non-uniform motions; (ii) a BiM-guided Flow Net (BiMFN) with Content-Aware Upsampling Network (CAUN) for precise optical flow estimation; and (iii) Knowledge Distillation for VFI-centric Flow supervision (KDVCF) to supervise the motion estimation of VFI model with VFI-centric teacher flows.The proposed VFI is called a Bidirectional Motion field-guided VFI (BiM-VFI) model.Extensive experiments show that our BiM-VFI model significantly surpasses the recent state-of-the-art VFI methods by 26% and 45% improvements in LPIPS and STLPIPS respectively, yielding interpolated frames with much fewer blurs at arbitrary time instances.

Curriculum Coarse-to-Fine Selection for High-IPC Dataset Distillation
Yanda Chen, Gongwei Chen, Miao Zhang, Weili Guan, Liqiang Nie; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 20437-20446
Dataset distillation (DD) excels in synthesizing a small number of images per class (IPC) but struggles to maintain its effectiveness in high-IPC settings. Recent works on dataset distillation demonstrate that combining distilled and real data can mitigate the effectiveness decay. However, our analysis of the combination paradigm reveals that the current one-shot and independent selection mechanism induces an incompatibility issue between distilled and real images. To address this issue, we introduce a novel curriculum coarse-to-fine selection (CCFS) method for efficient high-IPC dataset distillation. CCFS employs a curriculum selection framework for real data selection, where we leverage a coarse-to-fine strategy to select appropriate real data based on the current synthetic dataset in each curriculum. Extensive experiments validate CCFS, surpassing the state-of-the-art by +6.6% on CIFAR-10, +5.8% on CIFAR-100, and +3.4% on Tiny-ImageNet under high-IPC settings. Notably, CCFS achieves 60.2% test accuracy on ResNet-18 with a 20% compression ratio of Tiny-ImageNet, closely matching full-dataset training with only 0.3% degradation. Code: https://github.com/CYDaaa30/CCFS.

BADGR: Bundle Adjustment Diffusion Conditioned by Gradients for Wide-Baseline Floor Plan Reconstruction
Yuguang Li, Ivaylo Boyadzhiev, Zixuan Liu, Linda Shapiro, Alex Colburn; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 16785-16795
Reconstructing precise camera poses and floor plan layouts from wide-baseline RGB panoramas is a difficult and unsolved problem. We introduce BADGR, a novel diffusion model that jointly performs reconstruction and bundle adjustment (BA) to refine poses and layouts from a coarse state, using 1D floor boundary predictions from dozens of sparsely captured images. Unlike guided diffusion models, BADGR is conditioned on dense per-column outputs from a single-step Levenberg Marquardt (LM) optimizer and is trained to predict camera and wall positions, while minimizing reprojection errors for view consistency. The objective of layout generation from denoising diffusion process complements BA optimization by providing additional learned layout-structural constraints on top of the co-visible features across images. These constraints help BADGR make plausible guesses about spatial relationships, which constrain the pose graph, such as wall adjacency and collinearity, while also learning to mitigate errors from dense boundary observations using global context. BADGR trains exclusively on 2D floor plans, simplifying data acquisition, enabling robust augmentation, and supporting a variety of input densities. Our experiments validate our method, which significantly outperforms the state-of-the-art pose and floor plan layout reconstruction with different input densities.
****

Three Cars Approaching within 100m! Enhancing Distant Geometry by Tri-Axis Voxel Scanning for Camera-based Semantic Scene Completion
Jongseong Bae, Junwoo Ha, Ha Young Kim; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 11939-11948
Camera-based Semantic Scene Completion (SSC) is gaining attentions in the 3D perception field. However, properties such as perspective and occlusion lead to the

underestimation of the geometry in distant regions, posing a critical issue for safety-focused autonomous driving systems. To tackle this, we propose ScanSSC, a novel camera-based SSC model composed of a Scan Module and Scan Loss, both designed to enhance distant scenes by leveraging context from near-viewpoint scenes. The Scan Module uses axis-wise masked attention, where each axis employing a near-to-far cascade masking that enables distant voxels to capture relationships with preceding voxels. In addition, the Scan Loss computes the cross-entropy along each axis between cumulative logits and corresponding class distributions in a near-to-far direction, thereby propagating rich context-aware signals to distant voxels. Leveraging the synergy between these components, ScanSSC achieves state-of-the-art performance, with IoUs of 44.54 and 48.29, and mIoUs of 17.40 and 20.14 on the SemanticKITTI and SSCBench-KITTI-360 benchmarks.

MetaShadow: Object-Centered Shadow Detection, Removal, and Synthesis

Tianyu Wang, Jianming Zhang, Haitian Zheng, Zhihong Ding, Scott Cohen, Zhe Lin, Wei Xiong, Chi-Wing Fu, Luis Figueroa, Soo Ye Kim; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 28252-28262

Shadows are often underconsidered or even ignored in image editing applications, limiting the realism of the edited results. In this paper, we introduce MetaShadow, a three-in-one versatile framework that enables detection, removal, and controllable synthesis of shadows in natural images in an object-centered fashion. MetaShadow combines the strengths of two cooperative components: Shadow Analyzer, for object-centered shadow detection and removal, and Shadow Synthesizer, for reference-based controllable shadow synthesis. Notably, we optimize the learning of the intermediate features from Shadow Analyzer to guide Shadow Synthesizer to generate more realistic shadows that blend seamlessly with the scene. Extensive evaluations on multiple shadow benchmark datasets show significant improvements of MetaShadow over the existing state-of-the-art methods on object-centered shadow detection, removal, and synthesis. MetaShadow excels in supporting imageediting tasks such as object removal, relocation, and insertion, pushing the boundaries of object-centered image editing.

TANGO: Training-free Embodied AI Agents for Open-world Tasks

Filippo Ziliotto, Tommaso Campari, Luciano Serafini, Lamberto Ballan; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 24603-24613

Large Language Models (LLMs) have demonstrated excellent capabilities in composing various modules together to create programs that can perform complex reasoning tasks on images. In this paper, we propose TANGO, an approach that extends the program composition via LLMs already observed for images, aiming to integrate those capabilities into embodied agents capable of observing and acting in the world. Specifically, by employing a simple PointGoal Navigation model combined with a memory-based exploration policy as a foundational primitive for guiding an agent through the world, we show how a single model can address diverse tasks without additional training. We task an LLM with composing the provided primitives to solve a specific task, using only a few in-context examples in the prompt. We evaluate our approach on three key Embodied AI tasks: Open-Set ObjectGoal Navigation, Multi-Modal Lifelong Navigation, and Open Embodied Question Answering, achieving state-of-the-art results without any specific fine-tuning in challenging zero-shot scenarios.

****

SATA: Spatial Autocorrelation Token Analysis for Enhancing the Robustness of Vision Transformers

Nick Nikzad, Yi Liao, Yongsheng Gao, Jun Zhou; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 9730-9739

Over the past few years, vision transformers (ViTs) have consistently demonstrated remarkable performance across various visual recognition tasks. However, attempts to enhance their robustness have yielded limited success, mainly focusing on different training strategies, input patch augmentation, or network structural enhancements. These approaches often involve extensive training and fine-tuning

, which are time-consuming and resource-intensive. To tackle these obstacles, we introduce a novel approach named Spatial Autocorrelation Token Analysis (SATA). By harnessing spatial relationships between token features, SATA enhances both the representational capacity and robustness of ViT models. This is achieved through the analysis and grouping of tokens according to their spatial autocorrelation scores prior to their input into the Feed-Forward Network (FFN) block of the self-attention mechanism. Importantly, SATA seamlessly integrates into existing pre-trained ViT baselines without requiring retraining or additional fine-tuning, while concurrently improving efficiency by reducing the computational load of the FFN units. Experimental results show that the baseline ViTs enhanced with SATA not only achieve a new state-of-the-art top-1 accuracy on ImageNet-1K image classification (94.9%) but also establish new state-of-the-art performance across multiple robustness benchmarks, including ImageNet-A (top-1=63.6%), ImageNet-R (top-1=79.2%), and ImageNet-C (mCE=13.6%), all without requiring additional training or fine-tuning of baseline models. Availability: https://github.com/nick-nikzad/SATA

DViN: Dynamic Visual Routing Network for Weakly Supervised Referring Expression Comprehension

Xiaofu Chen, Yaxin Luo, Gen Luo, Jiayi Ji, Henghui Ding, Yiyi Zhou; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 14347-14357

In this paper, we focus on weakly supervised referring expression comprehension (REC), and identify that the lack of fine-grained visual capability greatly limits the upper performance bound of existing methods. To address this issue, we propose a novel framework for weakly supervised REC, namely Dynamic Visual routing Network (DViN), which overcomes the visual shortcomings from the perspective of feature combination and alignment. In particular, DViN is equipped with a novel sparse routing mechanism to efficiently combine features of multiple visual encoders in a dynamic manner, thus improving the visual descriptive power. Besides, we further propose an innovative weakly supervised objective, namely Routing-based Feature Alignment (RFA), which facilitates the visual understanding of routed features through the intra-modal and inter-modal alignment. To validate DViN, we conduct extensive experiments on four REC benchmark datasets. Experiments demonstrate that DViN achieves state-of-the-art results on four benchmarks while maintaining competitive inference efficiency. Besides, the strong generalization ability of DViN is also validated on weakly supervised referring expression segmentation. Source codes are anonymously released at: https://anonymous.4open.science/r/DViN-7736.

Nested Diffusion Models Using Hierarchical Latent Priors

Xiao Zhang, Ruoxi Jiang, Rebecca Willett, Michael Maire; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 2502-2512

We introduce nested diffusion models, an efficient and powerful hierarchical generative framework that substantially enhances the generation quality of diffusion models, particularly for images of complex scenes. Our approach employs a series of diffusion models to progressively generate latent variables at different semantic levels. Each model in this series is conditioned on the output of the preceding higher-level models, culminating in image generation. Hierarchical latent variables guide the generation process along predefined semantic pathways, allowing our approach to capture intricate structural details. To construct these latent variables, we leverage a pre-trained visual encoder, which learns strong semantic visual representations, and modulate its capacity via dimensionality reduction and noise injection. Across multiple datasets, our system demonstrates significant enhancements in image quality for both unconditional and class/text conditional generation. Moreover, our unconditional generation system substantially outperforms the baseline conditional system. These advancements incur minimal computational overhead as the more abstract levels of our hierarchy work with lower-dimensional representations.

A Theory of Learning Unified Model via Knowledge Integration from Label Space Varying Domains
Dexuan Zhang, Thomas Westfechtel, Tatsuya Harada; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 10142-10152
Existing domain adaptation systems can hardly be applied to real-world problems with new classes presenting at deployment time, especially regarding source-free scenarios where multiple source domains do not share the label space despite being given a few labeled target data. To address this, we consider a challenging problem: multi-source semi-supervised open-set domain adaptation and propose a learning theory via joint error, effectively tackling strong domain shift. To generalize the algorithm into source-free cases, we introdcue a computationally efficient and architecture-flexible attention-based feature generation module. Extensive experiments on various data sets demonstrate the significant improvement of our proposed algorithm over baselines.

HiLoTs: High-Low Temporal Sensitive Representation Learning for Semi-Supervised LiDAR Segmentation in Autonomous Driving
R.D. Lin, Pengcheng Weng, Yinqiao Wang, Han Ding, Jinsong Han, Fei Wang; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 1429-1438
LiDAR point cloud semantic segmentation plays a crucial role in autonomous driving. In recent years, semi-supervised methods have gained popularity due to their significant reduction in annotation labor and time costs. Current semi-supervised methods typically focus on point cloud spatial distribution or consider short-term temporal representations, e.g., only two adjacent frames, often overlooking the rich long-term temporal properties inherent in autonomous driving scenarios. In driving experience, we observe that nearby objects, such as roads and vehicles, remain stable while driving, whereas distant objects exhibit greater variability in category and shape. This natural phenomenon is also captured by LiDAR, which reflects lower temporal sensitivity for nearby objects and higher sensitivity for distant ones. To leverage these characteristics, we propose HiLoTs, which learns high-temporal sensitivity and low-temporal sensitivity representations from continuous LiDAR frames. These representations are further enhanced and fused using a cross-attention mechanism. Additionally, we employ a teacher-student framework to align the representations learned by the labeled and unlabeled branches, effectively utilizing the large amounts of unlabeled data. Experimental results on the SemanticKITTI and nuScenes datasets demonstrate that our proposed HiLoTs outperforms state-of-the-art semi-supervised methods, and achieves performance close to LiDAR+Camera multimodal approaches.

Spiking Transformer with Spatial-Temporal Attention
Donghyun Lee, Yuhang Li, Youngeun Kim, Shiting Xiao, Priyadarshini Panda; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 13948-13958
Spike-based Transformer presents a compelling and energy-efficient alternative to traditional Artificial Neural Network (ANN)-based Transformers, achieving impressive results through sparse binary computations. However, existing spike-based transformers predominantly focus on spatial attention while neglecting crucial temporal dependencies inherent in spike-based processing, leading to suboptimal feature representation and limited performance. To address this limitation, we propose Spiking Transformer with Spatial-Temporal Attention (STAtten), a simple and straightforward architecture that efficiently integrates both spatial and temporal information in the self-attention mechanism. STAtten introduces a block-wise computation strategy that processes information in spatial-temporal chunks, enabling comprehensive feature capture while maintaining the same computational complexity as previous spatial-only approaches. Our method can be seamlessly integrated into existing spike-based transformers without architectural overhaul. Extensive experiments demonstrate that STAtten significantly improves the performance of existing spike-based transformers across both static and neuromorphic datasets, including CIFAR10/100, ImageNet, CIFAR10-DVS, and N-Caltech101.

Perceptual Video Compression with Neural Wrapping
Muhammad Umar Karim Khan, Aaron Chadha, Mohammad Ashraful Anam, Yiannis Andreopoulos; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 17743-17754
Standard video codecs are rate-distortion optimization machines, where distortion is typically quantified using PSNR versus the source. However, it is now widely accepted that increasing PSNR does not necessarily translate to better visual quality. In this paper, a better balance between perception and fidelity is targeted, in order to provide for significant rate savings over state-of-the-art standards-based video codecs. Specifically, pre- and postprocessing neural networks are proposed that enhance the coding efficiency of standard video codecs when benchmarked with an array of well-established perceptual quality scores. These "neural wrapper" elements are end-to-end trained with a neural codec module serving as a differentiable proxy for standard video codecs. The codec proxy is jointly optimized with the pre- and post components, via a novel two-phase pretraining strategy and end-to-end iterative refinement with stop-gradient. This allows the neural pre- and postprocessor to learn to embed, remove and recover information in a codec-aware manner, thus improving its rate-quality performance. A single neural-wrapper model is thereby established and used for the entire rate-quality curve without needing any downscaling or upscaling. The trained model is tested with the AV1 and VVC standard codecs via an array of well-established objective quality scores (SSIM, MS-SSIM, VMAF, AVQT), as well as mean opinion scores (MOS) derived from ITU-T P.910 subjective testing. Experimental results show that the proposed approach improves all quality scores, with -18.5% average Bjontegaard Delta-rate (BD-rate) saving over all objective scores and MOS improvement over both standard codecs. This illustrates the significant potential of neural wrapper components over standards-based video coding.
****
ViKIENet: Towards Efficient 3D Object Detection with Virtual Key Instance Enhanced Network
Zhuochen Yu, Bijie Qiu, Andy W. H. Khong; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 11844-11853
The sparsity of point clouds and inadequacy of semantic information pose challenges to current LiDAR-only 3D object detection methods. Recent methods alleviate these challenges by converting RGB images into virtual points via depth completion to be fused with LiDAR points. Although these methods have shown outstanding results, they often introduce significant computation overhead due to the high density of virtual points and noise due to inaccurate depth completion. Besides, they do not thoroughly leverage semantic information from images. In this work, we propose the virtual key instance enhanced network (ViKIENet), a highly efficient and effective multi-modal feature fusion framework that fuses the features of virtual key instances (VKIs) and LiDAR points through multiple stages. Our contributions include three main components: semantic key instance selection (SKIS), virtual-instance-focused fusion (VIFF), and virtual-instance-to-real attention (VIRA). We also propose the extended version ViKIENet-R with VIFF-R which includes rotationally equivariant features. Experiment results show that ViKIENet and ViKIENet-R achieve significant improvements in detection performance on the KITTI, JRDB, and nuScenes datasets compared to existing works. On the KITTI dataset, ViKIENet and ViKIENet-R operate at 22.7 and 15.0 FPS, respectively. As of CVPR submission (Nov. 15th, 2024), ViKIENet ranks first on the car detection and orientation estimation leaderboard, while ViKIENet-R ranks second (compared with officially published papers) on the 3D car detection leaderboard.

DKDM: Data-Free Knowledge Distillation for Diffusion Models with Any Architecture
Qianlong Xiang, Miao Zhang, Yuzhang Shang, Jianlong Wu, Yan Yan, Liqiang Nie; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 2955-2965
Diffusion models (DMs) have demonstrated exceptional generative capabilities acr

oss various domains, including image, video, and so on. A key factor contributin g to their effectiveness is the high quantity and quality of data used during tr aining. However, mainstream DMs now consume increasingly large amounts of data. For example, training a Stable Diffusion model requires billions of image-text p airs. This enormous data requirement poses significant challenges for training l arge DMs due to high data acquisition costs and storage expenses. To alleviate t his data burden, we propose a novel scenario: using existing DMs as data sources to train new DMs with any architecture. We refer to this scenario as Data-Free Knowledge Distillation for Diffusion Models (DKDM), where the generative ability of DMs is transferred to new ones in a data-free manner. To tackle this challen ge, we make two main contributions. First, we introduce a DKDM objective that en ables the training of new DMs via distillation, without requiring access to the data. Second, we develop a dynamic iterative distillation method that efficientl y extracts time-domain knowledge from existing DMs, enabling direct retrieval of training data without the need for a prolonged generative process. To the best of our knowledge, we are the first to explore this scenario. Experimental result s demonstrate that our data-free approach not only achieves competitive generati ve performance but also, in some instances, outperforms models trained with the entire dataset.

SymDPO: Boosting In-Context Learning of Large Multimodal Models with Symbol Demo nstration Direct Preference Optimization

Hongrui Jia, Chaoya Jiang, Haiyang Xu, Wei Ye, Mengfan Dong, Ming Yan, Ji Zhang, Fei Huang, Shikun Zhang; Proceedings of the Computer Vision and Pattern Recogni tion Conference (CVPR), 2025, pp. 9361-9371

As language models continue to scale, Large Language Models (LLMs) have exhibite d emerging capabilities in In-Context Learning (ICL), enabling them to solve lan guage tasks by prefixing a few in-context demonstrations (ICDs) as context. Insp ired by these advancements, researchers have extended these techniques to develo p Large Multimodal Models (LMMs) with ICL capabilities. However, existing LMMs f ace a critical issue: they often fail to effectively leverage the visual context in multimodal demonstrations and instead simply follow textual patterns. This i ndicates that LMMs do not achieve effective alignment between multimodal demonst rations and model outputs. To address this problem, we propose Symbol Demonstrat ion Direct Preference Optimization (SymDPO). Specifically, SymDPO aims to break the traditional paradigm of constructing multimodal demonstrations by using rand om symbols to replace text answers within instances. This forces the model to ca refully understand the demonstration images and establish a relationship between the images and the symbols to answer questions correctly. We validate the effec tiveness of this method on multiple benchmarks, demonstrating that with SymDPO, LMMs can more effectively understand the multimodal context within examples and utilize this knowledge to answer questions better. Code is available at https:// github.com/APiaoG/SymDPO.

Stealthy Backdoor Attack in Self-Supervised Learning Vision Encoders for Large V ision Language Models

Zhaoyi Liu, Huan Zhang; Proceedings of the Computer Vision and Pattern Recogniti on Conference (CVPR), 2025, pp. 25060-25070

Self-supervised learning (SSL) vision encoders learn high-quality image represen tations and thus have become a vital part of developing vision modality of large vision language models (LVLMs). Due to the high cost of training such encoders, pre-trained encoders are widely shared and deployed into many LVLMs, which are security-critical or bear societal significance. Under this practical scenario, we reveal a new backdoor threat that significant visual hallucinations can be in duced into these LVLMs by merely compromising vision encoders. Because of the sh aring and reuse of these encoders, many downstream LVLMs may inherit backdoor be haviors from encoders, leading to widespread backdoors. In this work, we propose BadVision, the first method to exploit this vulnerability in SSL vision encoder s for LVLMs with novel trigger optimization and backdoor learning techniques. We evaluate BadVision on two types of SSL encoders and LVLMs across eight benchmar

ks. We show that BadVision effectively drives the LVLMs to attacker-chosen hallu cination with over 99% attack success rate, causing a 77.6% relative visual unde rstanding error while maintaining the stealthiness. SoTA backdoor detection meth ods cannot detect our attack effectively.

Data-free Universal Adversarial Perturbation with Pseudo-semantic Prior
Chanhui Lee, Yeonghwan Song, Jeany Son; Proceedings of the Computer Vision and P attern Recognition Conference (CVPR), 2025, pp. 13907-13916
Data-free Universal Adversarial Perturbation (UAP) is an image-agnostic adversar ial attack that deceives deep neural networks using a single perturbation genera ted solely from random noise without relying on data priors. However, traditiona l data-free UAP methods often suffer from limited transferability due to the abs ence of semantic content in random noise. To address this issue, we propose a no vel data-free universal attack method that recursively extracts pseudo-semantic priors directly from the UAPs during training to enrich the semantic content wit hin the data-free UAP framework. Our approach effectively leverages latent seman tic information within UAPs via region sampling, enabling successful input trans formations--typically ineffective in traditional data-free UAP methods due to th e lack of semantic cues--and significantly enhancing black-box transferability. Furthermore, we introduce a sample reweighting technique to mitigate potential i mbalances from random sampling and transformations, emphasizing hard examples le ss affected by the UAPs. Comprehensive experiments on ImageNet show that our met hod achieves state-of-the-art performance in average fooling rate by a substanti al margin, notably improves attack transferability across various CNN architectu res compared to existing data-free UAP methods, and even surpasses data-dependen t UAP methods. Code is available at: https://github.com/ChnanChan/PSP-UAP.

Debiasing Multimodal Large Language Models via Noise-Aware Preference Optimizati on
Zefeng Zhang, Hengzhu Tang, Jiawei Sheng, Zhenyu Zhang, Yiming Ren, Zhenyang Li, Dawei Yin, Duohe Ma, Tingwen Liu; Proceedings of the Computer Vision and Patter n Recognition Conference (CVPR), 2025, pp. 9423-9433
Multimodal Large Language Models (MLLMs) excel in various tasks, yet often strug gle with modality bias, tending to rely heavily on a single modality or prior kn owledge when generating responses. In this paper, we propose a debiased preferen ce optimization dataset, RLAIF-V-Bias, and introduce a Noise-Aware Preference Op timization (NAPO) algorithm. Specifically, we first construct the dataset by int roducing perturbations to reduce the informational content of certain modalities , prompting the model to overly rely on a specific modality when generating resp onses. To address the inevitable noise in automatically constructed data, we com bine the noise-robust Mean Absolute Error (MAE) with the Binary Cross-Entropy (B CE) in Direct Preference Optimization (DPO) using a negative Box-Cox transformat ion and dynamically adjust the algorithm's noise robustness based on the evaluat ed noise levels in the data.Extensive experiments validate our approach, demonst rating not only its effectiveness in mitigating modality bias but also its signi ficant role in minimizing hallucinations.

SAM2-LOVE: Segment Anything Model 2 in Language-aided Audio-Visual Scenes
Yuji Wang, Haoran Xu, Yong Liu, Jiaze Li, Yansong Tang; Proceedings of the Compu ter Vision and Pattern Recognition Conference (CVPR), 2025, pp. 28932-28941
Reference Audio-Visual Segmentation (Ref-AVS) aims to provide a pixel-wise scene understanding in Language-aided Audio-Visual Scenes (LAVS). This task requires the model to continuously segment objects referred to by text and audio from a v ideo. Previous dual-modality methods always fail due to the lack of a third moda lity and the existing triple-modality method struggles with spatio-temporal cons istency, leading to the target shift of different frames. In this work, we intro duce a novel framework, termed SAM2-LOVE, which integrates textual, audio, and v isual representations into a learnable token to prompt and align SAM2 for achiev ing Ref-AVS in the LAVS. Technically, our approach includes a multimodal fusion module aimed at improving multimodal understanding of SAM2, as well as token pro

pagation and accumulation strategies designed to enhance spatio-temporal consistency without forgetting historical information. We conducted extensive experiments to demonstrate that SAM2-LOVE outperforms the SOTA by 8.5% in J&F on the Ref-AVS benchmark and showcase the simplicity and effectiveness of the components. Our code will be available here.

GIVEPose: Gradual Intra-class Variation Elimination for RGB-based Category-Level Object Pose Estimation

Ziqin Huang, Gu Wang, Chenyangguang Zhang, Ruida Zhang, Xiu Li, Xiangyang Ji; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 22055-22066

Recent advances in RGBD-based category-level object pose estimation have been limited by their reliance on precise depth information, restricting their broader applicability. In response, RGB-based methods have been developed. Among these methods, geometry-guided pose regression that originated from instance-level tasks has demonstrated strong performance. However, we argue that the NOCS map is an inadequate intermediate representation for geometry-guided pose regression method, as its many-to-one correspondence with category-level pose introduces redundant instance-specific information, resulting in suboptimal results. This paper identifies the intra-class variation problem inherent in pose regression based solely on the NOCS map and proposes the Intra-class Variation-Free Consensus (IVFC) map, a novel coordinate representation generated from the category-level consensus model. By leveraging the complementary strengths of the NOCS map and the IVFC map, we introduce GIVEPose, a framework that implements Gradual Intra-class Variation Elimination for category-level object pose estimation. Extensive evaluations on both synthetic and real-world datasets demonstrate that GIVEPose significantly outperforms existing state-of-the-art RGB-based approaches, achieving substantial improvements in category-level object pose estimation. Our code is available at https://github.com/ziqin-h/GIVEPose.

FRAME: Floor-aligned Representation for Avatar Motion from Egocentric Video

Andrea Boscolo Camiletto, Jian Wang, Eduardo Alvarado, Rishabh Dabral, Thabo Beeler, Marc Habermann, Christian Theobalt; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 17497-17507

Egocentric motion capture with a head-mounted body-facing stereo camera is crucial for VR and AR applications but presents significant challenges such as heavy occlusions and limited annotated real-world data. Existing methods rely on synthetic pretraining and struggle to generate smooth and accurate predictions in real-world settings, particularly for lower limbs. Our work addresses these limitations by introducing a lightweight VR-based data collection setup with on-board, real-time 6D pose tracking. Using this setup, we collected the most extensive real-world dataset for ego-facing ego-mounted cameras to date in size and motion variability. Effectively integrating this multimodal input -- device pose and camera feeds -- is challenging due to the differing characteristics of each data source. To address this, we propose FRAME, a simple yet effective architecture that combines device pose and camera feeds for state-of-the-art body pose prediction through geometrically sound multimodal integration and can run at 300 FPS on modern hardware. Lastly, we showcase a novel training strategy to enhance the model's generalization capabilities. Our approach exploits the problem's geometric properties, yielding high-quality motion capture free from common artifacts in prior works. Qualitative and quantitative evaluations, along with extensive comparisons, demonstrate the effectiveness of our method. Data, code, and CAD designs will be available at https://vcai.mpi-inf.mpg.de/projects/FRAME/

Sketch Down the FLOPs: Towards Efficient Networks for Human Sketch

Aneeshan Sain, Subhajit Maity, Pinaki Nath Chowdhury, Shubhadeep Koley, Ayan Kumar Bhunia, Yi-Zhe Song; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 28383-28393

As sketch research has collectively matured over time, its adaptation for at-mass commercialisation emerges on the immediate horizon. Despite an already mature

research endeavour for photos, there is no research on the efficient inference specifically designed for sketch data. In this paper, we first demonstrate existing state-of-the-art efficient light-weight models designed for photos do not work on sketches. We then propose two sketch-specific components which work in a plug-n-play manner on any photo efficient network to adapt them to work on sketch data. We specifically chose fine-grained sketch-based image retrieval (FG-SBIR) as a demonstrator as the most recognised sketch problem with immediate commercial value. Technically speaking, we first propose a cross-modal knowledge distillation network to transfer existing photo efficient networks to be compatible with sketch, which brings down number of FLOPs and model parameters by 97.96% percent and 84.89% respectively. We then exploit the abstract trait of sketch to introduce a RL-based canvas selector that dynamically adjusts to the abstraction level which further cuts down number of FLOPs by two thirds. The end result is an overall reduction of 99.37% of FLOPs (from 40.18G to 0.254G) when compared with a full network, while retaining the accuracy (33.03% vs 32.77%) -- finally making an efficient network for the sparse sketch data that exhibit even fewer FLOPs than the best photo counterpart.

****

Generalized Zero-Shot Classification via Semantics-Free Inter-Class Feature Generation

Libiao Chen, Dong Nie, Junjun Pan, Jing Yan, Zhenyu Tang; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 20286-20295

Generalized Zero-Shot Learning (GZSL) addresses the challenge of classifying unseen classes in the presence of seen classes by leveraging semantic attributes to bridge the gap for unseen classes. However, in image based disease classification, such as glioma sub-typing, distinguishing between classes using image semantic attributes can be challenging. To address this challenge, we introduce a novel GZSL method that eliminates the dependency on semantic information. Specifically, we propose that the primary of most classification in clinic is risk stratification, and classes are inherently ordered rather than purely categorical. Based on this insight, we present an inter-class feature augmentation (IFA) module, where distributions of different classes are ordered by their risk levels in a learned feature space using pre-defined joint conditional Gaussian distribution model. This ordering enables the generation of unseen class features through feature mixing of adjacent seen classes, effectively transforming the zero-shot learning problem into a supervised learning task. Our method eliminates the need for explicit semantic information, avoiding the cross-modal alignment between visual and semantic features. Moreover, the IFA module for GZSL requires no structural modifications to the existing classification models. In the experiment, both in-house and public datasets are used to evaluate our method across different tasks, including glioma subtyping, Alzheimer's disease (AD) classification and diabetic retinopathy classification. Experimental results demonstrate that our method outperforms the state-of-the-art GZSL methods with statistical significance.

Feat2GS: Probing Visual Foundation Models with Gaussian Splatting

Yue Chen, Xingyu Chen, Anpei Chen, Gerard Pons-Moll, Yuliang Xiu; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 6348-6361

Given that visual foundation models (VFMs) are trained on extensive datasets but often limited to 2D images, a natural question arises: how well do they understand the 3D world? With the differences in architecture and training protocols (i.e., objectives, proxy tasks), a unified framework to fairly and comprehensively probe their 3D awareness is urgently needed. Existing works on 3D probing suggest single-view 2.5D estimation (e.g., depth and normal) or two-view sparse 2D correspondence (e.g., matching and tracking). Unfortunately, these tasks ignore texture awareness, and require 3D data as ground-truth, which limits the scale and diversity of their evaluation set. To address these issues, we introduce Feat2GS, which readout 3D Gaussians attributes from VFM features extracted from unposed images. This allows us to probe 3D awareness for geometry and texture via novel view synthesis, without requiring 3D data. Additionally, the disentanglement o

f 3DGS parameters - geometry (x, a, S) and texture (c) - enables separate analysis of texture and geometry awareness. Under Feat2GS, we conduct extensive experiments to probe the 3D awareness of several VFMs, and investigate the ingredients that lead to a 3D aware VFM. Building on these findings, we develop several variants that achieve state-of-the-art across diverse datasets. This makes Feat2GS useful for probing VFMs, and as a simple-yet-effective baseline for novel-view synthesis. Code and data will be made available at fanegg.github.io/Feat2GS.

Multi-Modal Aerial-Ground Cross-View Place Recognition with Neural ODEs
Sijie Wang, Rui She, Qiyu Kang, Siqi Li, Disheng Li, Tianyu Geng, Shangshu Yu, Wee Peng Tay; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 11717-11728
Place recognition (PR) aims at retrieving the query place from a database and plays a crucial role in various applications, including navigation, autonomous driving, and augmented reality. While previous multi-modal PR works have mainly focused on the same-view scenario in which ground-view descriptors are matched with a database of ground-view descriptors during inference, the multi-modal cross-view scenario, in which ground-view descriptors are matched with aerial-view descriptors in a database, remains under-explored. We propose AGPlace, a model that effectively integrates information from multi-modal ground sensors (cameras and LiDARs) to achieve accurate aerial-ground PR. AGPlace achieves effective aerial-ground cross-view PR by leveraging a manifold-based neural ordinary differential equation (ODE) framework with a multi-domain alignment loss. It outperforms existing state-of-the-art cross-view PR models on large-scale datasets. As most existing PR models are designed for ground-ground PR, we adapt these baselines into our cross-view pipeline. Experiments demonstrate that this direct adaptation performs worse than our overall model architecture AGPlace. AGPlace represents a significant advancement in multi-modal aerial-ground PR, with promising implications for real-world applications.

Rethinking Decoder Design: Improving Biomarker Segmentation Using Depth-to-Space Restoration and Residual Linear Attention
Saad Wazir, Daeyoung Kim; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 30861-30871
Segmenting biomarkers in medical images is crucial for various biotech applications. Despite advances, Transformer and CNN based methods often struggle with variations in staining and morphology, limiting feature extraction. In medical image segmentation, where datasets often have limited sample availability, recent state-of-the-art (SOTA) methods achieve higher accuracy by leveraging pre-trained encoders, whereas end-to-end methods tend to underperform. This is due to challenges in effectively transferring rich multiscale features from encoders to decoders, as well as limitations in decoder efficiency. To address these issues, we propose an architecture that captures multi-scale local and global contextual information and a novel decoder design, which effectively integrates features from the encoder, emphasizes important channels and regions, and reconstructs spatial dimensions to enhance segmentation accuracy. Our method, compatible with various encoders, outperforms SOTA methods, as demonstrated by experiments on four datasets and ablation studies. Specifically, our method achieves absolute performance gains of 2.76% on MoNuSeg, 3.12% on DSB, 2.87% on Electron Microscopy, and 4.03% on TNBC datasets compared to existing SOTA methods. Code: https://github.com/saadwazir/MCADS-Decoder

MaDCoW: Marginal Distortion Correction for Wide-Angle Photography with Arbitrary Objects
Kevin Zhang, Jia-Bin Huang, Jose Echevarria, Stephen DiVerdi, Aaron Hertzmann; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 10923-10932
We introduce MaDCoW, a method for correcting marginal distortion of arbitrary objects in wide-angle photography. People often use wide-angle photography to convey natural scenes--smartphones typically default to wide-angle photography--but

depicting very wide-field-of-view scenes produces distorted object appearance, particularly marginal distortion in linear projections. With MaDCoW, a user annotates regions-of-interest to correct, along with straight lines. For each region, MaDCoW solves for a local-linear perspective projection and then jointly solves for a projection for the whole photograph that minimizes distortion. We show that our method can produce good results in cases where previous methods yield visible distortions.

SynTab-LLaVA: Enhancing Multimodal Table Understanding with Decoupled Synthesis
Bangbang Zhou, Zuan Gao, Zixiao Wang, Boqiang Zhang, Yuxin Wang, Zhineng Chen, Hongtao Xie; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 24796-24806
Due to the limited scale of multimodal table understanding (MTU) data, model performance is constrained. A straightforward approach is to use multimodal large language models to obtain more samples, but this may cause hallucinations, generate incorrect sample pairs, and cost significantly.To address the above issues, we design a simple yet effective synthesis framework that consists of two independent steps: table image rendering and table question and answer (Q&A) pairs generation.We use table codes (HTML, LaTeX, Markdown) to synthesize images and generate Q&A pairs with large language model (LLM).This approach leverages LLM's high concurrency and low cost to boost annotation efficiency and reduce expenses. By inputting code instead of images, LLMs can directly access the content and structure of the table, reducing hallucinations in table understanding and improving the accuracy of generated Q&A pairs. Finally, we synthesize a large-scale MTU dataset, SynTab, containing 636K images and 1.8M samples costing within \200 in US dollars. We further introduce a generalist tabular multimodal model, SynTab-LLaVA. This model not only effectively extracts local textual content within the table but also enables global modeling of relationships between cells.SynTab-LLaVA achieves SOTA performance on 21 out of 24 in-domain and out-of-domain benchmarks, demonstrating the effectiveness and generalization of our method. The Code is available at \href https://github.com/bang123-box/SynTab-LLaVA SynTab-LLaVA .

Edit Away and My Face Will not Stay: Personal Biometric Defense against Malicious Generative Editing
Hanhui Wang, Yihua Zhang, Ruizheng Bai, Yue Zhao, Sijia Liu, Zhengzhong Tu; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 23806-23816
Recent advancements in diffusion models have made generative image editing more accessible than ever. While these developments allow users to generate creative edits with ease, they also raise significant ethical concerns, particularly regarding malicious edits to human portraits that threaten individuals' privacy and identity security. Existing general-purpose image protection methods primarily focus on generating adversarial perturbations to nullify edit effects. However, these approaches often exhibit instability to protect against diverse editing requests. In this work, we introduce a novel perspective to personal human portrait protection against malicious editing. Unlike traditional methods aiming to prevent edits from taking effect, our method, FaceLock, optimizes adversarial perturbations to ensure that original biometric information---such as facial features---is either destroyed or substantially altered post-editing, rendering the subject in the edited output biometrically unrecognizable. Our approach innovatively integrates facial recognition and visual perception factors into the perturbation optimization process, ensuring robust protection against a variety of editing attempts. Besides, we shed light on several critical issues with commonly used evaluation metrics in image editing and reveal cheating methods by which they can be easily manipulated, leading to deceptive assessments of protection. Through extensive experiments, we demonstrate that FaceLock significantly outperforms all baselines in defense performance against a wide range of malicious edits. Moreover, our method also exhibits strong robustness against purification techniques. Comprehensive ablation studies confirm the stability and broad applicability of our method across diverse diffusion-based editing algorithms. Our work not onl

y advances the state-of-the-art in biometric defense but also sets the foundatio
n for more secure and privacy-preserving practices in image editing.

Any6D: Model-free 6D Pose Estimation of Novel Objects
Taeyeop Lee, Bowen Wen, Minjun Kang, Gyuree Kang, In So Kweon, Kuk-Jin Yoon; Pro
ceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025,
 pp. 11633-11643
We introduce Any6D, a model-free framework for 6D object pose estimation that re
quires only a single RGB-D anchor image to estimate both the 6D pose and size of
 unknown objects in novel scenes. Unlike existing methods that rely on textured
3D models or multiple viewpoints, Any6D leverages a joint object alignment proce
ss to enhance 2D-3D alignment and metric scale estimation for improved pose accu
racy. Our approach integrates a render-and-compare strategy to generate and refi
ne pose hypotheses, enabling robust performance in scenarios with occlusions, no
n-overlapping views, diverse lighting conditions, and large cross-environment va
riations. We evaluate our method on five challenging datasets: REAL275, Toyota-L
ight, HO3D, YCBINEOAT, and LM-O, demonstrating its effectiveness in significantl
y outperforming state-of-the-art methods for novel object pose estimation. Proje

Improving Accuracy and Calibration via Differentiated Deep Mutual Learning
Han Liu, Peng Cui, Bingning Wang, Weipeng Chen, Yupeng Zhang, Jun Zhu, Xiaolin H
u; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR),
 2025, pp. 25812-25821
Deep Neural Networks (DNNs) have achieved remarkable success in a variety of tas
ks, particularly in terms of prediction accuracy. However, in real-world scenari
os, especially in safety-critical applications, accuracy alone is insufficient;
reliable uncertainty estimates are essential. Modern DNNs, often trained with cr
oss-entropy loss, tend to exhibit overconfidence, especially on ambiguous sample
s. Many techniques aim to improve uncertainty calibration, yet they often come a
t the cost of reduced accuracy or increased computational demands. To address th
is challenge, we propose Differentiated Deep Mutual Learning (Diff-DML), an effi
cient ensemble approach that simultaneously enhances accuracy and uncertainty ca
libration. Diff-DML draws inspiration from Deep Mutual Learning (DML) while intr
oducing two strategies to maintain prediction diversity: (1) Differentiated Trai
ning Strategy (DTS) and (2) Diversity-Preserving Learning Objective (DPLO). Our
theoretical analysis shows that Diff-DML's diversified learning framework not on
ly leverages ensemble benefits but also avoids the loss of prediction diversity
observed in traditional DML setups, which is crucial for improved calibration. E
xtensive evaluations on various benchmarks confirm the effectiveness of Diff-DML
. For instance, on the CIFAR-100 dataset, Diff-DML on ResNet34 model achieved su
bstantial improvements over the previous state-of-the-art method, MDCA, with abs
olute accuracy gains of 1.3%/3.1%, relative ECE reductions of 49.6%/43.8%, and r
elative classwise-ECE reductions of 7.7%/13.0%.

DrVideo: Document Retrieval Based Long Video Understanding
Ziyu Ma, Chenhui Gou, Hengcan Shi, Bin Sun, Shutao Li, Hamid Rezatofighi, Jianfe
i Cai; Proceedings of the Computer Vision and Pattern Recognition Conference (CV
PR), 2025, pp. 18936-18946
Most of the existing methods for video understanding primarily focus on videos o
nly lasting tens of seconds, with limited exploration of techniques for handling
 long videos. The increased number of frames in long videos poses two main chall
enges: difficulty in locating key information and performing long-range reasonin
g. Thus, we propose DrVideo, a document-retrieval-based system designed for long
 video understanding. Our key idea is to convert the long-video understanding pr
oblem into a long-document understanding task so as to effectively leverage the
power of large language models. Specifically, DrVideo first transforms a long vi
deo into a coarse text-based long document to initially retrieve key frames and
then updates the documents with the augmented key frame information. It then emp
loys an agent-based iterative loop to continuously search for missing informatio

n and augment the document until sufficient question-related information is gathered for making the final predictions in a chain-of-thought manner. Extensive experiments on long video benchmarks confirm the effectiveness of our method. DrVideo significantly outperforms existing LLM-based state-of-the-art methods on EgoSchema benchmark (3 minutes), MovieChat-1K benchmark (10 minutes), and the long split of Video-MME benchmark (average of 44 minutes). Code is available at https://github.com/Upper9527/DrVideo.

Infighting in the Dark: Multi-Label Backdoor Attack in Federated Learning
Ye Li, Yanchao Zhao, Chengcheng Zhu, Jiale Zhang; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 25770-25779
Federated Learning (FL), a privacy-preserving decentralized machine learning framework, has been shown to be vulnerable to backdoor attacks. Current research primarily focuses on the Single-Label Backdoor Attack (SBA), wherein adversaries share a consistent target. However, a critical fact is overlooked: adversaries may be non-cooperative, have distinct targets, and operate independently, which exhibits a more practical scenario called Multi-Label Backdoor Attack (MBA). Unfortunately, prior works are ineffective in the MBA scenario since non-cooperative attackers exclude each other. In this work, we conduct an in-depth investigation to uncover the inherent constraints of the exclusion: similar backdoor mappings are constructed for different targets, resulting in conflicts among backdoor functions. To address this limitation, we propose Mirage, the first non-cooperative MBA strategy in FL that allows attackers to inject effective and persistent backdoors into the global model without collusion by constructing in-distribution (ID) backdoor mapping. Specifically, we introduce an adversarial adaptation method to bridge the backdoor features and the target distribution in an ID manner. Additionally, we further leverage a constrained optimization method to ensure the ID mapping survives in the global training dynamics. Extensive evaluations demonstrate that Mirage outperforms various state-of-the-art attacks and bypasses existing defenses, achieving an average ASR greater than 97% and maintaining over 90% after 900 rounds. This work aims to alert researchers to this potential threat and inspire the design of effective defense mechanisms. Code has been made open-source.

Buffer Anytime: Zero-Shot Video Depth and Normal from Image Priors
Zhengfei Kuang, Tianyuan Zhang, Kai Zhang, Hao Tan, Sai Bi, Yiwei Hu, Zexiang Xu, Milos Hasan, Gordon Wetzstein, Fujun Luan; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 17660-17670
We present Buffer Anytime, a framework for estimation of depth and normal maps (which we call geometric buffers) from video that eliminates the need for paired video--depth and video--normal training data. Instead of relying on large-scale annotated video datasets, we demonstrate high-quality video buffer estimation by leveraging single-image priors with temporal consistency constraints. Our zero-shot training strategy combines state-of-the-art image estimation models based on optical flow smoothness through a hybrid loss function, implemented via a lightweight temporal attention architecture. Applied to leading image models like Depth Anything V2 and Marigold-E2E-FT, our approach significantly improves temporal consistency while maintaining accuracy. Experiments show that our method not only outperforms image-based approaches but also achieves results comparable to state-of-the-art video models trained on large-scale paired video datasets, despite using no such paired video data.

****

PSHuman: Photorealistic Single-image 3D Human Reconstruction using Cross-Scale Multiview Diffusion and Explicit Remeshing
Peng Li, Wangguandong Zheng, Yuan Liu, Tao Yu, Yangguang Li, Xingqun Qi, Xiaowei Chi, Siyu Xia, Yan-Pei Cao, Wei Xue, Wenhan Luo, Yike Guo; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 16008-16018
Photorealistic 3D human modeling is essential for various applications and has seen tremendous progress. However, existing methods for monocular full-body reconstruction, typically relying on front and/or predicted back view, still struggle

with satisfactory performance due to the ill-posed nature of the problem and so phisticated self-occlusions. In this paper, we propose PSHuman, a novel framewor k that explicitly reconstructs human meshes utilizing priors from the multiview diffusion model. It is found that directly applying multiview diffusion on singl e-view human images leads to severe geometric distortions, especially on genera ted faces. To address it, we propose a cross-scale diffusion that models the joi nt probability distribution of global full-body shape and local facial character istics, enabling identity-preserved novel-view generation without geometric dist ortion. Moreover, to enhance cross-view body shape consistency of varied human p oses, we condition the generative model on parametric models (SMPL-X), which pro vide body priors and prevent unnatural views inconsistent with human anatomy. Le veraging the generated multiview normal and color images, we present SMPLX-initi alized explicit human carving to recover realistic textured human meshes efficie ntly. Extensive experiments on CAPE and THuman2.1 demonstrate PSHuman's superior ity in geometry details, texture fidelity, and generalization capability.

LSNet: See Large, Focus Small

Ao Wang, Hui Chen, Zijia Lin, Jungong Han, Guiguang Ding; Proceedings of the Com puter Vision and Pattern Recognition Conference (CVPR), 2025, pp. 9718-9729

Vision network designs, including Convolutional Neural Networks and Vision Trans formers, have significantly advanced the field of computer vision. Yet, their co mplex computations pose challenges for practical deployments, particularly in re al-time applications. To tackle this issue, researchers have explored various li ghtweight and efficient network designs. However, existing lightweight models pr edominantly leverage self-attention mechanisms and convolutions for token mixing . This dependence brings limitations in effectiveness and efficiency in the perc eption and aggregation processes of lightweight networks, hindering the balance between performance and efficiency under limited computational budgets. In this paper, we draw inspiration from the dynamic heteroscale vision ability inherent in the efficient human vision system and propose a "See Large, Focus Small" stra tegy for lightweight vision network design. We introduce LS (Large-Small) convol ution, which combines large-kernel perception and small-kernel aggregation. It c an efficiently capture a wide range of perceptual information and achieve precis e feature aggregation for dynamic and complex visual representations, thus enabl ing proficient processing of visual information. Based on LS convolution, we pre sent LSNet, a new family of lightweight models. Extensive experiments demonstrat e that LSNet achieves superior performance and efficiency over existing lightwei ght networks in various vision tasks. Codes and models are available at https:// github.com/jameslahm/lsnet.

DynamicScaler: Seamless and Scalable Video Generation for Panoramic Scenes

Jinxiu Liu, Shaoheng Lin, Yinxiao Li, Ming-Hsuan Yang; Proceedings of the Comput er Vision and Pattern Recognition Conference (CVPR), 2025, pp. 6144-6153

The increasing demand for immersive AR/VR applications and spatial intelligence has heightened the need to generate high-quality scene-level and 360deg panorami c video. However, most video diffusion models are constrained by limited resolut ion and aspect ratio, which restricts their applicability to scene-level dynamic content synthesis. In this work, we propose DynamicScaler, addressing these cha llenges by enabling spatially scalable and panoramic dynamic scene synthesis tha t preserves coherence across panoramic scenes of arbitrary size. Specifically, w e introduce a Offset Shifting Denoiser, facilitating efficient, synchronous, and coherent denoising panoramic dynamic scenes via a diffusion model with fixed re solution through a seamless rotating Window, which ensures seamless boundary tra nsitions and consistency across the entire panoramic space, accommodating varyin g resolutions and aspect ratios. Additionally, we employ a Global Motion Guidanc e mechanism to ensure both local detail fidelity and global motion continuity. E xtensive experiments demonstrate our method achieves superior content and motion quality in panoramic scene-level video generation, offering a training-free, ef ficient, and scalable solution for immersive dynamic scene creation with constan t VRAM consumption regardless of the output video resolution. Project page is av

ailable at https://dynamic-scaler.pages.dev/new.

Tartan IMU: A Light Foundation Model for Inertial Positioning in Robotics
Shibo Zhao, Sifan Zhou, Raphael Blanchard, Yuheng Qiu, Wenshan Wang, Sebastian S
cherer; Proceedings of the Computer Vision and Pattern Recognition Conference (C
VPR), 2025, pp. 22520-22529
Despite recent advances in deep learning, most existing learning IMU odometry me
thods are trained on specific datasets, lack generalization, and are prone to ov
erfitting, which limits their real-world application. To address these challenge
s, we present Tartan IMU, a foundation model designed for generalizable, IMU-bas
ed state estimation across diverse robotic platforms. Our approach consists of t
hree-stage: First, a pre-trained foundation model leverages over 100 hours of mu
lti-platform data to establish general motion knowledge, achieving 36% improveme
nt in ATE over specialized models. Second, to adapt to previously unseen tasks,
we employ the Low-Rank Adaptation (LoRA), allowing positive transfer with only 1
.1 M trainable parameters. Finally, to support robotics deployment, we introduce
 online test-time adaptation, which eliminates the boundary between training and
 testing, allowing the model to continuously "learn as it operates" at 200 FPS i
n real-time.

Event Ellipsometer: Event-based Mueller-Matrix Video Imaging
Ryota Maeda, Yunseong Moon, Seung-Hwan Baek; Proceedings of the Computer Vision
and Pattern Recognition Conference (CVPR), 2025, pp. 21804-21813
Light-matter interactions modify both the intensity and polarization state of li
ght. Changes in polarization, represented by a Mueller matrix, encode detailed s
cene information. Existing optical ellipsometers capture Mueller-matrix images;
however, they are often limited to static scenes due to long acquisition times.
Here, we introduce Event Ellipsometer, a method for acquiring Mueller-matrix ima
ges of dynamic scenes. Our imaging system employs fast-rotating quarter-wave pla
tes (QWPs) in front of a light source and an event camera that asynchronously ca
ptures intensity changes induced by the rotating QWPs. We develop an ellipsometr
ic-event image formation model, a calibration method, and an ellipsometric-event
 reconstruction method. We experimentally demonstrate that Event Ellipsometer en
ables Mueller-matrix imaging at 30fps, extending ellipsometry to dynamic scenes.

DocLayLLM: An Efficient Multi-modal Extension of Large Language Models for Text-
rich Document Understanding
Wenhui Liao, Jiapeng Wang, Hongliang Li, Chengyu Wang, Jun Huang, Lianwen Jin; P
roceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 202
5, pp. 4038-4049
Text-rich document understanding (TDU) requires comprehensive analysis of docume
nts containing substantial textual content and complex layouts. While Multimodal
 Large Language Models (MLLMs) have achieved fast progress in this domain, exist
ing approaches either demand significant computational resources or struggle wit
h effective multi-modal integration. In this paper, we introduce DocLayLLM, an e
fficient multi-modal extension of LLMs specifically designed for TDU. By lightly
 integrating visual patch tokens and 2D positional tokens into LLMs' input and e
ncoding the document content using the LLMs themselves, we fully take advantage
of the document comprehension capability of LLMs and enhance their perception of
 OCR information. We have also deeply considered the role of chain-of-thought (C
oT) and innovatively proposed the techniques of CoT Pre-training and CoT Anneali
ng. Our DocLayLLM can achieve remarkable performances with lightweight training
settings, showcasing its efficiency and effectiveness. Experimental results demo
nstrate that our DocLayLLM outperforms existing OCR-dependent methods and OCR-fr
ee competitors. Code and model are available at https://github.com/whlscut/DocLa
yLLM.

EDEN: Enhanced Diffusion for High-quality Large-motion Video Frame Interpolation
Zihao Zhang, Haoran Chen, Haoyu Zhao, Guansong Lu, Yanwei Fu, Hang Xu, Zuxuan Wu
; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR),

2025, pp. 2105-2115
Handling complex or nonlinear motion patterns has long posed challenges for video frame interpolation. Although recent advances in diffusion-based methods offer improvements over traditional optical flow-based approaches, they still struggle to generate sharp, temporally consistent frames in scenarios with large motion. To address this limitation, we introduce EDEN, an Enhanced Diffusion for high-quality large-motion vidEo frame iNterpolation. Our approach first utilizes a transformer-based tokenizer to produce refined latent representations of the intermediate frames for diffusion models. We then enhance the diffusion transformer with temporal attention across the process and incorporate a start-end frame difference embedding to guide the generation of dynamic motion. Extensive experiments demonstrate that EDEN achieves state-of-the-art results across popular benchmarks, including nearly a 10% LPIPS reduction on DAVIS and SNU-FILM, and an 8% improvement on DAIN-HD.
****

Handling Spatial-Temporal Data Heterogeneity for Federated Continual Learning via Tail Anchor
Hao Yu, Xin Yang, Le Zhang, Hanlin Gu, Tianrui Li, Lixin Fan, Qiang Yang; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 4874-4883
Federated Continual Learning (FCL) allows each client to continually update its knowledge from task streams, enhancing the applicability of federated learning in real-world scenarios. However, FCL needs to address not only spatial data heterogeneity between clients but also temporal data heterogeneity between tasks. In this paper, empirical experiments demonstrate that such input-level heterogeneity significantly affects the model's internal parameters and outputs, leading to severe spatial-temporal catastrophic forgetting of local and previous knowledge. To this end, we propose Federated Tail Anchor (FedTA) to mix trainable Tail Anchor with the frozen output features to adjust their position in the feature space, thereby overcoming parameter-forgetting and output-forgetting. Three novel components are also included: Input Enhancement for improving the performance of pre-trained models on downstream tasks; Selective Input Knowledge Fusion for fusion of heterogeneous local knowledge on the server; and Best Global Prototype Selection for finding the best anchor point for each class in the feature space. Extensive experiments demonstrate that FedTA not only outperforms existing FCL methods but also effectively preserves the relative positions of features.
****

DeSiRe-GS: 4D Street Gaussians for Static-Dynamic Decomposition and Surface Reconstruction for Urban Driving Scenes
Chensheng Peng, Chengwei Zhang, Yixiao Wang, Chenfeng Xu, Yichen Xie, Wenzhao Zheng, Kurt Keutzer, Masayoshi Tomizuka, Wei Zhan; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 6782-6791
We present DeSiRe-GS, a self-supervised gaussian splatting representation, enabling effective static-dynamic decomposition and high-fidelity surface reconstruction in complex driving scenarios. Our approach employs a two-stage optimization pipeline of dynamic street Gaussians. In the first stage, we extract 2D motion masks based on the observation that 3D Gaussian Splatting inherently can reconstruct only the static regions in dynamic environments. These extracted 2D motion priors are then mapped into the Gaussian space in a differentiable manner, leveraging an efficient formulation of dynamic Gaussians in the second stage. Combined with the introduced geometric regularizations, our method are able to address the over-fitting issues caused by data sparsity in autonomous driving, reconstructing physically plausible Gaussians that align with object surfaces rather than floating in air. Furthermore, we introduce temporal cross-view consistency to ensure coherence across time and viewpoints, resulting in high-quality surface reconstruction. Comprehensive experiments demonstrate the efficiency and effectiveness of DeSiRe-GS, surpassing prior self-supervised arts and achieving accuracy comparable to methods relying on external 3D bounding box annotations.
****

End-to-End HOI Reconstruction Transformer with Graph-based Encoding

Zhenrong Wang, Qi Zheng, Sihan Ma, Maosheng Ye, Yibing Zhan, Dongjiang Li; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 27706-27715

Human-object interaction (HOI) reconstruction has garnered significant attention due to its diverse applications and the success of capturing human meshes. Existing HOI reconstruction methods often rely on explicitly modeling interactions between humans and objects. However, such a way leads to a natural conflict between 3D mesh reconstruction, which emphasizes global structure, and fine-grained contact reconstruction, which focuses on local details. To address the limitations of explicit modeling, we propose the End-to-End HOI Reconstruction Transformer with Graph-based Encoding (HOI-TG). It implicitly learns the interaction between humans and objects by leveraging self-attention mechanisms. Within the transformer architecture, we devise graph residual blocks to aggregate the topology among vertices of different spatial structures. This dual focus effectively balances global and local representations. Without bells and whistles, HOI-TG achieves state-of-the-art performance on BEHAVE and InterCap datasets. Particularly on the challenging InterCap dataset, our method improves the reconstruction results for human and object meshes by 8.9% and 8.6%, respectively.

REWIND: Real-Time Egocentric Whole-Body Motion Diffusion with Exemplar-Based Identity Conditioning

Jihyun Lee, Weipeng Xu, Alexander Richard, Shih-En Wei, Shunsuke Saito, Shaojie Bai, Te-Li Wang, Minhyuk Sung, Tae-Kyun Kim, Jason Saragih; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 7095-7104

We present REWIND (Real-Time Egocentric Whole-Body Motion Diffusion), a one-step diffusion model for real-time, high-fidelity human motion estimation from egocentric image inputs. While an existing method for egocentric whole-body (i.e., body and hands) motion estimation is non-real-time and acausal due to diffusion-based iterative motion refinement to capture correlations between body and hand poses, REWIND operates in a fully causal and real-time manner. To enable real-time inference, we introduce (1) cascaded body-hand denoising diffusion, which effectively models the correlation between egocentric body and hand motions in a fast, feed-forward manner, and (2) diffusion distillation, which enables high-quality motion estimation with a single denoising step. Our denoising diffusion model is based on a modified Transformer architecture, designed to causally model output motions while enhancing generalizability to unseen motion lengths. Additionally, REWIND optionally supports identity-conditioned motion estimation when identity prior is available. To this end, we propose a novel identity conditioning method based on a small set of pose exemplars of the target identity, which further enhances motion estimation quality. Through extensive experiments, we demonstrate that REWIND significantly outperforms the existing baselines both with and without exemplar-based identity conditioning.

Hiding Images in Diffusion Models by Editing Learned Score Functions

Haoyu Chen, Yunqiao Yang, Nan Zhong, Kede Ma; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 18663-18673

Hiding data using neural networks (i.e., neural steganography) has achieved remarkable success across both discriminative classifiers and generative adversarial networks. However, the potential of data hiding in diffusion models remains relatively unexplored. Current methods exhibit limitations in achieving high extraction accuracy, model fidelity, and hiding efficiency due primarily to the entanglement of the hiding and extraction processes with multiple denoising diffusion steps. To address these, we describe a simple yet effective approach that embeds images at specific timesteps in the reverse diffusion process by editing the learned score functions. Additionally, we introduce a parameter-efficient fine-tuning method that combines gradient-based parameter selection with low-rank adaptation to enhance model fidelity and hiding efficiency. Comprehensive experiments demonstrate that our method extracts high-quality images at human-indistinguishable levels, replicates the original model behaviors at both sample and population levels, and embeds images orders of magnitude faster than prior methods. Besid

es, our method naturally supports multi-recipient scenarios through independent extraction channels.

Disco4D: Disentangled 4D Human Generation and Animation from a Single Image
Hui En Pang, Shuai Liu, Zhongang Cai, Lei Yang, Tianwei Zhang, Ziwei Liu; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 26331-26344
We present Disco4D, a novel Gaussian Splatting framework for 4D human generation and animation from a single image. Different from existing methods, Disco4D distinctively disentangles clothings (with Gaussian models) from the human body (with SMPL-X model), significantly enhancing the generation details and flexibility. It has the following technical innovations. (1) Disco4D learns to efficiently fit the clothing Gaussians over the SMPL-X Gaussians. (2) It adopts diffusion models to enhance the 3D generation process, e.g. modeling occluded parts not visible in the input image. (3) It learns an identity encoding for each clothing Gaussian to facilitate the separation and extraction of clothing assets. Furthermore, Disco4D naturally supports 4D human animation with vivid dynamics. Extensive experiments demonstrate the superiority of Disco4D on 4D human generation and animation tasks.

DoraCycle: Domain-Oriented Adaptation of Unified Generative Model in Multimodal Cycles
Rui Zhao, Weijia Mao, Mike Zheng Shou; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 2835-2846
Adapting generative models to specific domains presents an effective solution for satisfying specialized requirements. However, adapting to some complex domains remains challenging, especially when these domains require substantial paired data to capture the targeted distributions. Since unpaired data from a single modality, such as vision or language, is more readily available, we utilize the bidirectional mappings between vision and language learned by the unified generative model to enable training on unpaired data for domain adaptation. Specifically, we propose DoraCycle, which integrates two multimodal cycles: text-to-image-to-text and image-to-text-to-image. The model is optimized through cross-entropy loss computed at the cycle endpoints, where both endpoints share the same modality. This facilitates self-evolution of the model without reliance on annotated text-image pairs. Experimental results demonstrate that for tasks independent of paired knowledge, such as stylization, DoraCycle can effectively adapt the unified model using only unpaired data. For tasks involving new paired knowledge, such as specific identities, a combination of a small set of paired image-text examples and larger-scale unpaired data is sufficient for effective domain-oriented adaptation. The code will be released at https://github.com/showlab/DoraCycle.

WeatherGen: A Unified Diverse Weather Generator for LiDAR Point Clouds via Spider Mamba Diffusion
Yang Wu, Yun Zhu, Kaihua Zhang, Jianjun Qian, Jin Xie, Jian Yang; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 17019-17028
3D scene perception demands a large amount of adverse-weather LiDAR data, yet the cost of LiDAR data collection presents a significant scaling-up challenge. To this end, a series of LiDAR simulators have been proposed. Yet, they can only simulate a single adverse weather with a single physical model, and the fidelity is quite limited. This paper presents **WeatherGen**, the first unified diverse-weather LiDAR data diffusion generation framework, significantly improving fidelity. Specifically, we first design a map-based data producer, which is capable of providing a vast amount of high-quality diverse-weather data for training purposes. Then, we utilize the diffusion-denoising paradigm to construct a diffusion model. Among them, we propose a spider mamba generator with the spider mamba scan to restore the disturbed diverse weather data gradually. The spider mamba models the feature interactions by scanning the LiDAR beam circle and central ray, excellently maintaining the physical structure of the LiDAR point cloud. Subsequ

ently, we design a latent domain aligner following the generator to transfer rea l-world knowledge. Afterward, we devise a contrastive learning-based controller, which equips weather control signals with compact semantic knowledge through la nguage supervision from CLIP, guiding the diffusion model in generating more dis criminative data. Finally, we fine-tune WeatherGen with small-scale real-world d ata to further enhance its performance. Extensive evaluations on KITTI-360 and S eeing Through Fog demonstrate the high generation quality of WeatherGen. Through WeatherGen, we construct the mini-weather dataset, promoting the performance of the downstream task under adverse weather conditions.

MUST: The First Dataset and Unified Framework for Multispectral UAV Single Objec t Tracking
Haolin Qin, Tingfa Xu, Tianhao Li, Zhenxiang Chen, Tao Feng, Jianan Li; Proceedi ngs of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 16882-16891
UAV tracking faces significant challenges in real-world scenarios, such as small -size targets and occlusions, which limit the performance of RGB-based trackers. Multispectral images (MSI), which capture additional spectral information, offe r a promising solution to these challenges. However, progress in this field has been hindered by the lack of relevant datasets. To address this gap, we introduc e the first large-scale Multispectral UAV Single Object Tracking dataset (MUST), which includes 250 video sequences spanning diverse environments and challenges , providing a comprehensive data foundation for multispectral UAV tracking. We a lso propose a novel tracking framework, UNTrack, which encodes unified spectral, spatial, and temporal features from spectrum prompts, initial templates, and se quential searches. UNTrack employs an asymmetric transformer with a spectral bac kground eliminate mechanism for optimal relationship modeling and an encoder tha t continuously updates the spectrum prompt to refine tracking, improving both ac curacy and efficiency. Extensive experiments show that our proposed UNTrack outp erforms state-of-the-art UAV trackers. We believe our dataset and framework will drive future research in this area. The dataset is available on https://github. com/q2479036243/MUST-Multispectral-UAV-Single-Object-Tracking.

IDOL: Instant Photorealistic 3D Human Creation from a Single Image
Yiyu Zhuang, Jiaxi Lv, Hao Wen, Qing Shuai, Ailing Zeng, Hao Zhu, Shifeng Chen, Yujiu Yang, Xun Cao, Wei Liu; Proceedings of the Computer Vision and Pattern Rec ognition Conference (CVPR), 2025, pp. 26308-26319
Creating a high-fidelity, animatable 3D full-body avatar from a single image is a challenging task due to the diverse appearance and poses of humans and the lim ited availability of high-quality training data. To achieve fast and high-qualit y human reconstruction, this work rethinks the task from the perspectives of dat aset, model, and representation. First, we introduce a large-scale HUman GEnerat ed training dataset, HuGe100K, consisting of 100K diverse, photorealistic human images with corresponding 24-view in a static pose or dynamic pose frames genera ted via a pose-controllable image-to-video model. Next, leveraging the diversity in views, poses, and appearances within HuGe100K, we develop a scalable feed-fo rward transformer model to predict a 3D human Gaussian representation in a unifo rm space of a given human image. This model is trained to disentangle human pose , shape, clothing geometry, and texture. Accordingly, the estimated Gaussians ca n be animated robustly without post-processing. We conduct comprehensive experim ents to validate the effectiveness of the proposed dataset and method. Our model demonstrates the generalizable ability to efficiently reconstruct photorealisti c humans in under 1 second using a single GPU. Additionally, it seamlessly suppo rts various applications, including animation, shape, and texture editing tasks.

Tightening Robustness Verification of MaxPool-based Neural Networks via Minimizi ng the Over-Approximation Zone
Yuan Xiao, Yuchen Chen, Shiqing Ma, Chunrong Fang, Tongtong Bai, Mingzheng Gu, Y uxin Cheng, Yanwei Chen, Zhenyu Chen; Proceedings of the Computer Vision and Pat tern Recognition Conference (CVPR), 2025, pp. 20695-20705

The robustness of neural network classifiers is important in the safety-critical domain and can be quantified by robustness verification. At present, efficient and scalable verification techniques are always sound but incomplete, and thus, the improvement of verified robustness results is the key criterion to evaluate the performance of incomplete verification approaches. The multi-variate function MaxPool is widely adopted yet challenging to verify. In this paper, we present Ti-Lin, a robustness verifier for MaxPool-based CNNs with Tight Linear Approximation. Following the sequel of minimizing the over-approximation zone of the non-linear function of CNNs, we are the first to propose the provably neuron-wise tightest linear bounds for the MaxPool function. By our proposed linear bounds, we can certify larger robustness results for CNNs. We evaluate the effectiveness of Ti-Lin on different verification frameworks with open-sourced benchmarks, including LeNet, PointNet, and networks trained on the MNIST, CIFAR-10, Tiny ImageNet and ModelNet40 datasets. Experimental results show that Ti-Lin significantly outperforms the state-of-the-art methods across all networks with up to 78.6% improvement in terms of the certified accuracy with almost the same time consumption as the fastest tool. Our code is available at https://anonymous.4open.science/r/Ti-Lin-cvpr-72EE.

SketchVideo: Sketch-based Video Generation and Editing

Feng-Lin Liu, Hongbo Fu, Xintao Wang, Weicai Ye, Pengfei Wan, Di Zhang, Lin Gao; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 23379-23390

Video generation and editing conditioned on text prompts or images have undergone significant advancements. However, challenges remain in accurately controlling global layout and geometry details solely by texts, and supporting motion control and local modification through images. In this paper, we aim to achieve sketch-based spatial and motion control for video generation and support fine-grained editing of real or synthetic videos. Based on the DiT video generation model, we propose a memory-efficient control structure with sketch control blocks that predict residual features of skipped DiT blocks. Sketches are drawn on one or two keyframes (at arbitrary time points) for easy interaction. To propagate such temporally sparse sketch conditions across all frames, we propose an inter-frame attention mechanism to analyze the relationship between the keyframes and each video frame. For sketch-based video editing, we design an additional video insertion module that maintains consistency between the newly edited content and the original video's spatial feature and dynamic motion. During inference, we use latent fusion for the accurate preservation of unedited regions. Extensive experiments demonstrate that our SketchVideo achieves superior performance in controllable video generation and editing.

PhysicsGen: Can Generative Models Learn from Images to Predict Complex Physical Relations?

Martin Spitznagel, Jan Vaillant, Janis Keuper; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 11125-11134

The image-to-image translation abilities of generative learning models have recently made significant progress in the estimation of complex (steered) mappings between image distributions. While appearance based tasks like image in-painting or style transfer have been studied at length, we propose to investigate the potential of generative models in the context of physical simulations. Providing a dataset of 300k image-pairs and baseline evaluations for three different physical simulation tasks, we propose a benchmark to investigate the following research questions: i) are generative models able to learn complex physical relations from input-output image pairs? ii) what speedups can be achieved by replacing differential equation based simulations? While baseline evaluations of different current models show the potential for high speedups (ii), these results also show strong limitations toward the physical correctness (i). This underlines the need for new methods to enforce physical correctness.

Taste More, Taste Better: Diverse Data and Strong Model Boost Semi-Supervised Cr

owd Counting
Maochen Yang, Zekun Li, Jian Zhang, Lei Qi, Yinghuan Shi; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 24440-24451
Semi-supervised crowd counting is crucial for addressing the high annotation costs of densely populated scenes. Although several methods based on pseudo-labeling have been proposed, it remains challenging to effectively and accurately utilize unlabeled data. In this paper, we propose a novel framework called Taste More Taste Better (TMTB), which emphasizes both data and model aspects. Firstly, we explore a data augmentation technique well-suited for the crowd counting task. By inpainting the background regions, this technique can effectively enhance data diversity while preserving the fidelity of the entire scenes. Secondly, we introduce the Visual State Space Model as backbone to capture the global context information from crowd scenes, which is crucial for extremely crowded, low-light, and adverse weather scenarios. In addition to the traditional regression head for exact prediction, we employ an Anti-Noise classification head to provide less exact but more accurate supervision, since the regression head is sensitive to noise in manual annotations. We conduct extensive experiments on four benchmark datasets and show that our method outperforms state-of-the-art methods by a large margin. Code is publicly available on https://github.com/syhien/taste_more_taste_better.

Gaussian Splashing: Unified Particles for Versatile Motion Synthesis and Rendering
Yutao Feng, Xiang Feng, Yintong Shang, Ying Jiang, Chang Yu, Zeshun Zong, Tianjia Shao, Hongzhi Wu, Kun Zhou, Chenfanfu Jiang, Yin Yang; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 518-529
We demonstrate the feasibility of integrating physics-based animations of solids and fluids with 3D Gaussian Splatting (3DGS) to create novel effects in virtual scenes reconstructed using 3DGS. Leveraging the coherence of the Gaussian Splatting and Position-Based Dynamics (PBD) in the underlying representation, we manage rendering, view synthesis, and the dynamics of solids and fluids in a cohesive manner. Similar to GaussianShader, we enhance each Gaussian kernel with an added normal, aligning the kernel's orientation with the surface normal to refine the PBD simulation. This approach effectively eliminates spiky noises that arise from rotational deformation in solids. It also allows us to integrate physically based rendering to augment the dynamic surface reflections on fluids. Consequently, our framework is capable of realistically reproducing surface highlights on dynamic fluids and facilitating interactions between scene objects and fluids from new views.

Improve Representation for Imbalanced Regression through Geometric Constraints
Zijian Dong, Yilei Wu, Chongyao Chen, Yingtian Zou, Yichi Zhang, Juan Helen Zhou; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 5082-5091
In representation learning, uniformity refers to the uniform feature distribution in the latent space (i.e., unit hypersphere). Previous work has shown that improving uniformity contributes to the learning of under-represented classes. However, most of the previous work focused on classification; the representation space of imbalanced regression remains unexplored. Classification-based methods are not suitable for regression tasks because they cluster features into distinct groups without considering the continuous and ordered nature essential for regression. In a geometric aspect, we uniquely focus on ensuring uniformity in the latent space for imbalanced regression through two key losses: enveloping and homogeneity. The enveloping loss encourages the induced trace to uniformly occupy the surface of a hypersphere, while the homogeneity loss ensures smoothness, with representations evenly spaced at consistent intervals. Our method integrates these geometric principles into the data representations via a Surrogate-driven Representation Learning (SRL) framework. Experiments with real-world regression and operator learning tasks highlight the importance of uniformity in imbalanced regression and validate the efficacy of our geometry-based loss functions.

AnyDressing: Customizable Multi-Garment Virtual Dressing via Latent Diffusion Models
Xinghui Li, Qichao Sun, Pengze Zhang, Fulong Ye, Zhichao Liao, Wanquan Feng, Songtao Zhao, Qian He; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 23723-23733
Recent advances in garment-centric image generation from text and image prompts based on diffusion models are impressive. However, existing methods lack support for various combinations of attire, and struggle to preserve the garment details while maintaining faithfulness to the text prompts, limiting their performance across diverse scenarios. In this paper, we focus on a new task, i.e., Multi-Garment Virtual Dressing, and we propose a novel AnyDressing method for customizing characters conditioned on any combination of garments and any personalized text prompts. AnyDressing primarily comprises two primary networks named GarmentsNet and DressingNet, which are respectively dedicated to extracting detailed clothing features and generating customized images. Specifically, we propose an efficient and scalable module called Garment-Specific Feature Extractor in GarmentsNet to individually encode garment textures in parallel. This design prevents garment confusion while ensuring network efficiency. Meanwhile, we design an adaptive Dressing-Attention mechanism and a novel Instance-Level Garment Localization Learning strategy in DressingNet to accurately inject multi-garment features into their corresponding regions. This approach efficiently integrates multi-garment texture cues into generated images and further enhances text-image consistency. Additionally, we introduce a Garment-Enhanced Texture Learning strategy to improve the fine-grained texture details of garments. Thanks to our well-craft design, AnyDressing can serve as a plug-in module to easily integrate with any community control extensions for diffusion models, improving the diversity and controllability of synthesized images. Extensive experiments show that AnyDressing achieves state-of-the-art results.

Spectral Informed Mamba for Robust Point Cloud Processing
Ali Bahri, Moslem Yazdanpanah, Mehrdad Noori, Sahar Dastani, Milad Cheraghalikhani, Gustavo Adolfo Vargas Hakim, David Osowiechi, Farzad Beizaee, Ismail Ben Ayed, Christian Desrosiers; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 11799-11809
State Space Models (SSMs) have shown significant promise in Natural Language Processing (NLP) and, more recently, computer vision. This paper introduces a new methodology leveraging Mamba and Masked Autoencoder (MAE) networks for point cloud data in both supervised and self-supervised learning. We propose three key contributions to enhance Mamba's capability in processing complex point cloud structures. First, we exploit the spectrum of a graph Laplacian to capture patch connectivity, defining an isometry-invariant traversal order that is robust to viewpoints and better captures shape manifolds than traditional 3D grid-based traversals. Second, we adapt segmentation via a recursive patch partitioning strategy informed by Laplacian spectral components, allowing finer integration and segment analysis. Third, we address token placement in MAE for Mamba by restoring tokens to their original positions, which preserves essential order and improves learning. Extensive experiments demonstrate our approach's improvements in classification, segmentation, and few-shot tasks over state-of-the-art (SOTA) baselines.

Latent Space Imaging
Matheus Souza, Yidan Zheng, Kaizhang Kang, Yogeshwar Nath Mishra, Qiang Fu, Wolfgang Heidrich; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 28295-28305
Digital imaging systems have traditionally relied on brute-force measurement and processing of pixels arranged on regular grids. In contrast, the human visual system performs significant data reduction from the large number of photoreceptors to the optic nerve, effectively encoding visual information into a low-bandwidth latent space representation optimized for brain processing. Inspired by this, we propose a similar approach to advance artificial vision systems. Latent Spac

e Imaging introduces a new paradigm that combines optics and software to encode image information directly into the semantically rich latent space of a generative model. This approach substantially reduces bandwidth and memory demands during image capture and enables a range of downstream tasks focused on the latent space.We validate this principle through an initial hardware prototype based on a single-pixel camera. By implementing an amplitude modulation scheme that encodes into the generative model's latent space, we achieve compression ratios ranging from 1:100 to 1:1000 during imaging, and up to 1:16384 for downstream applications. This approach leverages the model's intrinsic linear boundaries, demonstrating the potential of latent space imaging for highly efficient imaging hardware, adaptable future applications in high-speed imaging, and task-specific cameras with significantly reduced hardware complexity.

Balanced Direction from Multifarious Choices: Arithmetic Meta-Learning for Domain Generalization

Xiran Wang, Jian Zhang, Lei Qi, Yinghuan Shi; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 30577-30587

Domain generalization is proposed to address distribution shift, arising from statistical disparities between training source and unseen target domains. The widely used first-order meta-learning algorithms demonstrate strong performance for domain generalization by leveraging the gradient matching theory, which aims to establish balanced parameters across source domains to reduce overfitting to any particular domain. However, our analysis reveals that there are actually numerous directions to achieve gradient matching, with current methods representing just one possible path. These methods actually overlook another critical factor that the balanced parameters should be close to the centroid of optimal parameters of each source domain. To address this, we propose a simple yet effective arithmetic meta-learning with arithmetic-weighted gradients. This approach, while adhering to the principles of gradient matching, promotes a more precise balance by estimating the centroid between domain-specific optimal parameters. Experimental results validate the effectiveness of our strategy. Our code is available at https://github.com/zzwdx/ARITH.

Anatomical Consistency and Adaptive Prior-informed Transformation for Multi-contrast MR Image Synthesis via Diffusion Model

Yejee Shin, Yeeun Lee, Hanbyol Jang, Geonhui Son, Hyeongyu Kim, Dosik Hwang; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 30918-30927

Multi-contrast magnetic resonance (MR) images offer critical diagnostic information but are limited by long scan times and high cost. While diffusion models (DMs) excel in medical image synthesis, they often struggle to maintain anatomical consistency and utilize the diverse characteristics of multi-contrast MR images effectively. We propose APT, a unified diffusion model designed to generate accurate and anatomically consistent multi-contrast MR images. APT introduces a mutual information fusion module and an anatomical consistency loss to preserve critical anatomical structures across multiple contrast inputs. To enhance synthesis, APT incorporates a two-stage inference process: in the first stage, a prior codebook provides coarse anatomical structures by selecting appropriate guidance based on precomputed similarity mappings and Bezier curve transformations. The second stage applies iterative unrolling with weighted averaging to refine the initial output, enhancing fine anatomical details and ensuring structural consistency. This approach enables the preservation of both global structures and local details, resulting in realistic and diagnostically valuable synthesized images. Extensive experiments on public multi-contrast MR brain images demonstrate that our approach significantly outperforms state-of-the-art methods. The source codes are available at https://github.com/yejees/APT.

BlobGEN-Vid: Compositional Text-to-Video Generation with Blob Video Representations

Weixi Feng, Chao Liu, Sifei Liu, William Yang Wang, Arash Vahdat, Weili Nie; Pro

ceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 12989-12998

Existing video generation models struggle to follow complex text prompts and synthesize multiple objects, raising the need for additional grounding input for improved controllability. In this work, we propose to decompose videos into visual primitives -- blob video representation, a general representation for controllable video generation. Based on blob conditions, we develop a blob-grounded video diffusion model named BlobGEN-Vid that allows users to control object motions and fine-grained object appearance. In particular, we introduce a masked 3D attention module that effectively improves regional consistency across frames. In addition, we introduce a learnable module to interpolate text embeddings so that users can control semantics in specific frames and obtain smooth object transitions. We show that our framework is model-agnostic and build BlobGEN-Vid based on both U-Net and DiT-based video diffusion models. Extensive experimental results show that BlobGEN-Vid achieves superior zero-shot video generation ability and state-of-the-art layout controllability on multiple benchmarks. When combined with a Large Language Model for layout planning, our framework even outperforms proprietary text-to-video generators regarding compositional accuracy.

D2SP: Dynamic Dual-Stage Purification Framework for Dual Noise Mitigation in Vision-based Affective Recognition.

Haoran Wang, Xinji Mai, Zeng Tao, Xuan Tong, Junxiong Lin, Yan Wang, Jiawen Yu, Shaoqi Yan, Ziheng Zhou, Wenqiang Zhang; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 19218-19229

The current advancements in Dynamic Facial Expression Recognition (DFER) methods mainly focus on better capturing the spatial and temporal features of facial expressions. However, DFER datasets contain a substantial amount of noisy samples, and few have addressed the issue of handling this noise. We identified two types of noise: one is caused by low-quality data resulting from factors such as occlusion, dim lighting, and blurriness; the other arises from mislabeled data due to annotation bias by annotators. Addressing the two types of noise, we have meticulously crafted a Dynamic Dual-Stage Purification (D2SP) Framework. This initiative aims to dynamically purify the DFER datasets of these two types of noise, ensuring that only high-quality and correctly labeled data is used in the training process. To mitigate low-quality samples, we introduce the Coarse-Grained Pruning (CGP) stage, which computes sample weights and prunes those low-weight samples. After CGP, the Fine-Grained Correction (FGC) stage evaluates prediction stability to correct mislabeled data. Moreover, D2SP is conceived as a general and plug-and-play framework, tailored to integrate seamlessly with prevailing DFER methods. Extensive experiments covering prevalent DFER datasets and deploying multiple benchmark methods have substantiated D2SP's ability to significantly enhance performance metrics.

PartRM: Modeling Part-Level Dynamics with Large Cross-State Reconstruction Model

Mingju Gao, Yike Pan, Huan-ang Gao, Zongzheng Zhang, Wenyi Li, Hao Dong, Hao Tang, Li Yi, Hao Zhao; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 7004-7014

As interest grows in world models that predict future states from current observations and actions, accurately modeling part-level dynamics has become increasingly relevant for various applications. Existing approaches, such as Puppet-Master, rely on fine-tuning large-scale pre-trained video diffusion models, which are impractical for real-world use due to the limitations of 2D video representation and slow processing times. To overcome these challenges, we present PartRM, a novel 4D reconstruction framework that simultaneously models appearance, geometry, and part-level motion from multi-view images of a static object. PartRM builds upon large 3D Gaussian reconstruction models, leveraging their extensive knowledge of appearance and geometry in static objects. To address data scarcity in 4D, we introduce the PartDrag-4D dataset, providing multi-view observations of part-level dynamics across over 20,000 states. We enhance the model's understanding of interaction conditions with a multi-scale drag embedding module that captur

es dynamics at varying granularities. To prevent catastrophic forgetting during fine-tuning, we implement a two-stage training process that focuses sequentially on motion and appearance learning. Experimental results show that PartRM establishes a new state-of-the-art in part-level motion learning and can be applied in manipulation tasks in robotics. Our code, data, and models are publicly available to facilitate future research.

LaVin-DiT: Large Vision Diffusion Transformer

Zhaoqing Wang, Xiaobo Xia, Runnan Chen, Dongdong Yu, Changhu Wang, Mingming Gong, Tongliang Liu; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 20060-20070

This paper presents the Large Vision Diffusion Transformer (LaVin-DiT), a scalable and unified foundation model designed to tackle over 20 computer vision tasks in a generative framework. Unlike existing large vision models directly adapted from natural language processing architectures, which rely on less efficient autoregressive techniques and disrupt spatial relationships essential for vision data, LaVin-DiT introduces key innovations to optimize generative performance for vision tasks. First, to address the high dimensionality of visual data, we incorporate a spatial-temporal variational autoencoder that encodes data into a continuous latent space. Second, for generative modeling, we develop a joint diffusion transformer that progressively produces vision outputs. Third, for unified multi-task training, in-context learning is implemented. Input-target pairs serve as task context, which guides the diffusion transformer to align outputs with specific tasks within the latent space. During inference, a task-specific context set and test data as queries allow LaVin-DiT to generalize across tasks without fine-tuning. Trained on extensive vision datasets, the model is scaled from 0.1B to 3.4B parameters, demonstrating substantial scalability and state-of-the-art performance across diverse vision tasks. This work introduces a novel pathway for large vision foundation models, underscoring the promising potential of diffusion transformers. The code and models are available at https://derrickwang005.github.io/LaVin-DiT.

DiffFNO: Diffusion Fourier Neural Operator

Xiaoyi Liu, Hao Tang; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 150-160

We introduce DiffFNO, a novel diffusion framework for arbitrary-scale super-resolution strengthened by a Weighted Fourier Neural Operator (WFNO). Mode Rebalancing in WFNO effectively captures critical frequency components, significantly improving the reconstruction of high-frequency image details that are crucial for super-resolution tasks. Gated Fusion Mechanism (GFM) adaptively complements WFNO's spectral features with spatial features from an Attention-based Neural Operator (AttnNO). This enhances the network's capability to capture both global structures and local details. Adaptive Time-Step (ATS) ODE solver, a deterministic sampling strategy, accelerates inference without sacrificing output quality by dynamically adjusting integration step sizes ATS. Extensive experiments demonstrate that DiffFNO achieves state-of-the-art (SOTA) results, outperforming existing methods across various scaling factors by a margin of 2-4 dB in PSNR, including those beyond the training distribution. It also achieves this at lower inference time. Our approach sets a new standard in super-resolution, delivering both superior accuracy and computational efficiency.

****

CAP-Net: A Unified Network for 6D Pose and Size Estimation of Categorical Articulated Parts from a Single RGB-D Image

Jingshun Huang, Haitao Lin, Tianyu Wang, Yanwei Fu, Xiangyang Xue, Yi Zhu; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 11654-11664

This paper tackles category-level pose estimation of ar- ticulated objects in robotic manipulation tasks and intro- duces a new benchmark dataset. While recent methods es- timate part poses and sizes at the category level, they often rely on geometric cues and complex multi-stage pipelines that first segment parts from

the point cloud, followed by Normalized Part Coordinate Space (NPCS) estimation for 6D poses. These approaches overlook dense semantic cues from RGB images, leading to suboptimal accuracy, partic- ularly for objects with small parts. To address these limita- tions, we propose a single-stage Network, CAP-Net, for es- timating the 6D poses and sizes of Categorical Articulated Parts. This method combines RGB-D features to generate instance segmentation and NPCS representations for each part in an end-to-end manner. CAP-Net uses a unified net- work to simultaneously predict point-wise class labels, cen- troid offsets, and NPCS maps. A clustering algorithm then groups points of the same predicted class based on their es- timated centroid distances to isolate each part. Finally, the NPCS region of each part is aligned with the point cloud to recover its final pose and size. To bridge the sim-to-real do- main gap, we introduce the RGBD-Art dataset, the largest RGB-D articulated dataset to date, featuring photorealistic RGB images and depth noise simulated from real sensors. Experimental evaluations on the RGBD-Art dataset demon- strate that our method significantly outperforms the state-of-the-art approach. Real-world deployments of our model in robotic tasks underscore its robustness and exceptional sim-to-real transfer capabilities, confirming its substantial practical utility.

SeCap: Self-Calibrating and Adaptive Prompts for Cross-view Person Re-Identification in Aerial-Ground Networks

Shining Wang, Yunlong Wang, Ruiqi Wu, Bingliang Jiao, Wenxuan Wang, Peng Wang; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 22119-22128

When discussing the Aerial-Ground Person Re-identification (AGPReID) task, we face the main challenge of the significant appearance variations caused by different viewpoints, making identity matching difficult. To address this issue, previous methods attempt to reduce the differences between viewpoints by critical attributes and decoupling the viewpoints. While these methods can mitigate viewpoint differences to some extent, they still face two main issues: (1) difficulty in handling viewpoint diversity and (2) neglect of the contribution of local features. To effectively address these challenges, we design and implement the Self-Calibrating and Adaptive Prompt (SeCap) method for the AGPReID task. The core of this framework relies on the Prompt Re-calibration Module (PRM), which adaptively re-calibrates prompts based on the input. Combined with the Local Feature Refinement Module (LFRM), SeCap can extract view-invariant features from local features for AGPReID. Meanwhile, given the current scarcity of datasets in the AGPReID field, we further contribute two real-world Large-scale Aerial-Ground Person Re-Identification datasets, LAGPeR and G2APS-ReID. The former is collected and annotated by us independently, covering 4,231 unique identities and containing 63,841 high-quality images; the latter is reconstructed from the person search dataset G2APS. Through extensive experiments on AGPReID datasets, we demonstrate that SeCap is a feasible and effective solution for the AGPReID task.

Zero-Shot Styled Text Image Generation, but Make It Autoregressive

Vittorio Pippi, Fabio Quattrini, Silvia Cascianelli, Alessio Tonioni, Rita Cucchiara; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 7910-7919

Styled Handwritten Text Generation (HTG) has recently received attention from the computer vision and document analysis communities, which have developed several solutions, either GAN- or diffusion-based, that achieved promising results. Nonetheless, these strategies fail to generalize to novel styles and have technical constraints, particularly in terms of maximum output length and training efficiency. To overcome these limitations, in this work, we propose a novel framework for text-image generation, dubbed Emuru. Our approach leverages a powerful text-image representation model (a variational autoencoder) combined with an autoregressive Transformer. Our approach enables the generation of styled text images conditioned on textual content and style examples, such as specific fonts or handwriting styles. We train our model solely on a diverse, synthetic dataset of English text rendered in over 100,000 typewritten and calligraphy fonts, which give

s it the capability to reproduce unseen styles (both fonts and users' handwritin g) in zero-shot. To the best of our knowledge, Emuru is the first autoregressive model for HTG, and the first designed specifically for generalization to novel styles. Moreover, our model generates images without background artifacts, which are easier to use for downstream applications. Extensive evaluation on both typ ewritten and handwritten, any-length text image generation scenarios demonstrate s the effectiveness of our approach.

Don't Shake the Wheel: Momentum-Aware Planning in End-to-End Autonomous Driving
Ziying Song, Caiyan Jia, Lin Liu, Hongyu Pan, Yongchang Zhang, Junming Wang, Xin gyu Zhang, Shaoqing Xu, Lei Yang, Yadan Luo; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 22432-22441
End-to-end autonomous driving frameworks enable seamless integration of percepti on and planning but often rely on one-shot trajectory prediction, which may lead to unstable control and vulnerability to occlusions in single-frame perception. To address this, we propose the Momentum-Aware Driving (MomAD) framework, which introduces trajectory momentum and perception momentum to stabilize and refine trajectory predictions. MomAD comprises two core components: (1) Topological Tra jectory Matching (TTM) employs Hausdorff Distance to select the optimal planning query that aligns with prior paths to ensure coherence; (2) Momentum Planning I nteractor (MPI) cross-attends the selected planning query with historical querie s to expand static and dynamic perception files. This enriched query, in turn, h elps regenerate long-horizon trajectory and reduce collision risks. To mitigate noise arising from dynamic environments and detection errors, we introduce robus t instance denoising during training, enabling the planning model to focus on cr itical signals and improve its robustness. We also propose a novel Trajectory Pr ediction Consistency (TPC) metric to quantitatively assess planning stability. E xperiments on the nuScenes dataset demonstrate that MomAD achieves superior long -term consistency (>3s) compared to SOTA methods. Moreover, evaluations on the c urated Turning-nuScenes shows that MomAD reduces the collision rate by 26% and i mproves TPC by 0.97m (33.45%) over a 6s prediction horizon, while closed-loop on Bench2Drive demonstrates an up to 16.3% improvement in success rate.

Leveraging Perturbation Robustness to Enhance Out-of-Distribution Detection
Wenxi Chen, Raymond A. Yeh, Shaoshuai Mou, Yan Gu; Proceedings of the Computer V ision and Pattern Recognition Conference (CVPR), 2025, pp. 4724-4733
Out-of-distribution (OOD) detection is the task of identifying inputs that devia te from the training data distribution. This capability is essential for the saf e deployment of deep computer vision models in open-world environments. In this work, we propose a post-hoc method, Perturbation-Rectified OOD detection (PRO), based on the insight that prediction confidence for OOD inputs is more susceptib le to reduction under perturbation than IND inputs. From this observation, we pr oposed a meta-score function that searches for local minimum scores near origina l inputs by applying gradient descent. This procedure enhances the separability between in-distribution (IND) and OOD samples. Importantly, the approach improve s OOD detection performance without complex modifications to the underlying mode l architectures or training protocol. To validate our approach, we conduct exten sive experiments using the OpenOOD benchmark. Our approach further pushes the li mit of softmax-based OOD detection and is the leading post-hoc method for small- scale models. On a CIFAR-10 model with adversarial training, PRO effectively det ects near-OOD inputs, achieving a reduction of more than 10% on FPR@95 compared to state-of-the-art methods.

Neural Motion Simulator Pushing the Limit of World Models in Reinforcement Learn ing
Chenjie Hao, Weyl Lu, Yifan Xu, Yubei Chen; Proceedings of the Computer Vision a nd Pattern Recognition Conference (CVPR), 2025, pp. 27608-27617
An embodied system must not only model the patterns of the external world but al so understand its own motion dynamics. A motion dynamic model is essential for e fficient skill acquisition and effective planning. In this work, we introduce th

e neural motion simulator (MoSim), a world model that predicts the future physic al state of an embodied system based on current observations and actions. MoSim achieves state-of-the-art performance in physical state prediction and provides competitive performance across a range of downstream tasks. This works shows tha t when a world model is accurate enough and performs precise long-horizon predic tions, it can facilitate efficient skill acquisition in imagined worlds and even enable zero-shot reinforcement learning. Furthermore, MoSim can transform any m odel-free reinforcement learning (RL) algorithm into a model-based approach, eff ectively decoupling physical environment modeling from RL algorithm development. This separation allows for independent advancements in RL algorithms and world modeling, significantly improving sample efficiency and enhancing generalization capabilities. Our findings highlight that world models for motion dynamics is a promising direction for developing more versatile and capable embodied systems.

Aesthetic Post-Training Diffusion Models from Generic Preferences with Step-by-s tep Preference Optimization

Zhanhao Liang, Yuhui Yuan, Shuyang Gu, Bohan Chen, Tiankai Hang, Mingxi Cheng, J i Li, Liang Zheng; Proceedings of the Computer Vision and Pattern Recognition Co nference (CVPR), 2025, pp. 13199-13208

Generating visually appealing images is fundamental to modern text-to-image gene ration models. A potential solution to better aesthetics is direct preference op timization (DPO), which has been applied to diffusion models to improve general image quality including prompt alignment and aesthetics. Popular DPO methods pro pagate preference labels from clean image pairs to all the intermediate steps al ong the two generation trajectories. However, preference labels provided in exis ting datasets are blended with layout and aesthetic opinions, which would disagr ee with aesthetic preference. Even if aesthetic labels were provided (at substan tial cost), it would be hard for the two-trajectory methods to capture nuanced v isual differences at different steps. To improve aesthetics economically, this p aper uses existing generic preference data and introduces step-by-step preferenc e optimization (SPO) that discards the propagation strategy and allows fine-grai ned image details to be assessed. Specifically, at each denoising step, we 1) sa mple a pool of candidates by denoising from a shared noise latent, 2) use a step -aware preference model to find a suitable win-lose pair to supervise the diffus ion model, and 3) randomly select one from the pool to initialize the next denoi sing step. This strategy ensures that diffusion models focus on the subtle, fine -grained visual differences instead of layout aspect. We find that aesthetics ca n be significantly enhanced by accumulating these improved minor differences. Wh en fine-tuning Stable Diffusion v1.5 and SDXL, SPO yields significant improvemen ts in aesthetics compared with existing DPO methods while not sacrificing image-text alignment compared with vanilla models. Moreover, SPO converges much faster than DPO methods due to the use of more correct preference labels provided by t he step-aware preference model. Code and models are available at https://github. com/RockeyCoss/SPO.

Adversarial Diffusion Compression for Real-World Image Super-Resolution

Bin Chen, Gehui Li, Rongyuan Wu, Xindong Zhang, Jie Chen, Jian Zhang, Lei Zhang; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2 025, pp. 28208-28220

Real-world image super-resolution (Real-ISR) aims to reconstruct high-resolution images from low-resolution inputs degraded by complex, unknown processes. While many Stable Diffusion (SD)-based Real-ISR methods have achieved remarkable succ ess, their slow, multi-step inference hinders practical deployment. Recent SD-ba sed one-step networks like OSEDiff and S3Diff alleviate this issue but still inc ur high computational costs due to their reliance on large pretrained SD models. This paper proposes a novel Real-ISR method, AdcSR, by distilling the one-step diffusion network OSEDiff into a streamlined diffusion-GAN model under our Adver sarial Diffusion Compression (ADC) framework. We meticulously examine the module s of OSEDiff, categorizing them into two types: (1) Removable (VAE encoder, prom pt extractor, text encoder, etc.) and (2) Prunable (denoising UNet and VAE decod

er). Since direct removal and pruning can degrade the model's generation capabil ity, we pretrain our pruned VAE decoder to restore its ability to decode images and employ adversarial distillation to compensate for performance loss. This ADC -based diffusion-GAN hybrid design effectively reduces complexity by 73% in infe rence time, 78% in computation, and 74% in parameters, while preserving the mode l's generation capability. Experiments manifest that our proposed AdcSR achieves competitive recovery quality on both synthetic and real-world datasets, offerin g up to 9.3x speedup over previous one-step diffusion-based methods. Code and mo dels are available at https://github.com/Guaishou74851/AdcSR.

DiSciPLE: Learning Interpretable Programs for Scientific Visual Discovery

Utkarsh Mall, Cheng Perng Phoo, Mia Chiquier, Bharath Hariharan, Kavita Bala, Ca rl Vondrick; Proceedings of the Computer Vision and Pattern Recognition Conferen ce (CVPR), 2025, pp. 29258-29267

Visual data is used in numerous different scientific workflows ranging from remo te sensing to ecology. As the amount of observation data increases, the challeng e is not just to make accurate predictions but also to understand the underlying mechanisms for those predictions. Good interpretation is important in scientifi c workflows, as it allows for better decision-making by providing insights into the data. This paper introduces an automatic way of obtaining such interpretable -by-design models, by learning programs that interleave neural networks. We prop ose DiSciPLE (Discovering Scientific Programs using LLMs and Evolution) an evolu tionary algorithm that leverages common sense and prior knowledge of large langu age models (LLMs) to create Python programs explaining visual data. Additionally , we propose two improvements: a program critic and a program simplifier to impr ove our method further to synthesize good programs. On three different real worl d problems, DiSciPLE learns state-of-the-art programs on novel tasks with no pri or literature. For example, we can learn programs with 35% lower error than the closest non-interpretable baseline for population density estimation.

SOLAMI: Social Vision-Language-Action Modeling for Immersive Interaction with 3D Autonomous Characters

Jianping Jiang, Weiye Xiao, Zhengyu Lin, Huaizhong Zhang, Tianxiang Ren, Yang Ga o, Zhiqian Lin, Zhongang Cai, Lei Yang, Ziwei Liu; Proceedings of the Computer V ision and Pattern Recognition Conference (CVPR), 2025, pp. 26887-26898

Human beings are social animals. How to equip 3D autonomous characters with simi lar social intelligence that can perceive, understand and interact with humans r emains an open yet foundamental problem. In this paper, we introduce SOLAMI, the first end-to-end Social vision-Language-Action (VLA) Modeling framework for Imm ersive interaction with 3D autonomous characters. Specifically, SOLAMI builds 3D autonomous characters from three aspects: 1) Social VLA Architecture: We propos e a unified social VLA framework to generate multimodal response (speech and mot ion) based on the user's multimodal input to drive the character for social inte raction. 2) Interactive Multimodal Data: We present SynMSI, a synthetic multimo dal social interaction dataset generated by an automatic pipeline using only exi sting motion datasets to address the issue of data scarcity. 3) Immersive VR Int erface: We develop a VR interface that enables users to immersively interact wit h these characters driven by various architectures. Extensive quantitative exper iments and user studies demonstrate that our framework leads to more precise and natural character responses (in both speech and motion) that align with user ex pectations with lower latency.

EntropyMark: Towards More Harmless Backdoor Watermark via Entropy-based Constrai nt for Open-source Dataset Copyright Protection

Ming Sun, Rui Wang, Zixuan Zhu, Lihua Jing, Yuanfang Guo; Proceedings of the Com puter Vision and Pattern Recognition Conference (CVPR), 2025, pp. 30692-30701

High-quality open-source datasets are essential for advancing deep neural networ ks. However, the unauthorized commercial use of these datasets has raised signif icant concerns about copyright protection. One promising approach is backdoor wa termark-based dataset ownership verification (BW-DOV), in which dataset protecto

rs implant specific backdoors into illicit models through dataset watermarking, enabling the tracing of these models through abnormal prediction behaviors. Unfo rtunately, the targeted nature of these BW-DOV methods can be maliciously exploi ted, potentially leading to harmful side effects. While existing harmless method s attempt to mitigate these risks, watermarked datasets can still negatively aff ect prediction results, partially compromising dataset functionality. In this pa per, we propose a more harmless backdoor watermark, called EntropyMark, which im proves prediction confidence without altering the final prediction results. For this purpose, an entropy-based constraint is introduced to regulate the probabil ity distribution. Specifically, we design an iterative clean-label dataset water marking framework. Our framework employs gradient matching and adaptive data sel ection to optimize backdoor injection. In parallel, we introduce a hypothesis te st method grounded in entropy inconsistency to verify dataset ownership. Extensi ve experiments on benchmark datasets demonstrate the effectiveness, transferabil ity, and defense resistance of our approach.

Adaptive Markup Language Generation for Contextually-Grounded Visual Document Un derstanding

Han Xiao, Yina Xie, Guanxin Tan, Yinghao Chen, Rui Hu, Ke Wang, Aojun Zhou, Hao Li, Hao Shao, Xudong Lu, Peng Gao, Yafei Wen, Xiaoxin Chen, Shuai Ren, Hongsheng Li; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 29558-29568

Visual Document Understanding has become essential with the increase of text-ric h visual content. This field poses significant challenges due to the need for ef fective integration of visual perception and textual comprehension, particularly across diverse document types with complex layouts. Moreover, existing fine-tun ing datasets for this domain often fall short in providing the detailed contextu al information for robust understanding, leading to hallucinations and limited c omprehension of spatial relationships among visual elements. To address these ch allenges, we propose an innovative pipeline that utilizes adaptive generation of markup languages, such as Markdown, JSON, HTML, and TiKZ, to build highly struc tured document representations and deliver contextually-grounded responses. We i ntroduce two fine-grained structured datasets: DocMark-Pile, comprising approxim ately 3.8M pretraining data pairs for document parsing, and DocMark-Instruct, fe aturing 624k fine-tuning data annotations for grounded instruction following.Ext ensive experiments demonstrate that our proposed model significantly outperforms existing state-of-the-art MLLMs across a range of visual document understanding benchmarks, facilitating advanced reasoning and comprehension capabilities in c omplex visual scenarios.

BARD-GS: Blur-Aware Reconstruction of Dynamic Scenes via Gaussian Splatting

Yiren Lu, Yunlai Zhou, Disheng Liu, Tuo Liang, Yu Yin; Proceedings of the Comput er Vision and Pattern Recognition Conference (CVPR), 2025, pp. 16532-16542

3D Gaussian Splatting (3DGS) has shown remarkable potential for static scene rec onstruction, and recent advancements have extended its application to dynamic sc enes. However, the quality of reconstructions depends heavily on high-quality in put images and precise camera poses, which is not that trivial to fulfill in the real-world scenarios. Capturing dynamic scenes with handheld monocular cameras, for instance, typically involves simultaneous movement of both the camera and o bjects within a single exposure. This combined motion frequently results in imag e blur that existing methods cannot adequately handle. To address these challeng es, we introduce BARD-GS, a novel approach for robust dynamic scene reconstructi on that effectively handles blurry inputs and imprecise camera poses. Our method comprises two main components: 1) camera motion deblurring and 2) object motion deblurring. By explicitly decomposing motion blur into camera motion blur and o bject motion blur and modeling them separately, we achieve significantly improve d rendering results in dynamic regions. In addition, we collect a real-world mot ion blur dataset of dynamic scenes to evaluate our approach. Extensive experimen ts demonstrate that BARD-GS effectively reconstructs high-quality dynamic scenes under realistic conditions, significantly outperforming existing methods.

SALAD: Skeleton-aware Latent Diffusion for Text-driven Motion Generation and Editing
Seokhyeon Hong, Chaelin Kim, Serin Yoon, Junghyun Nam, Sihun Cha, Junyong Noh; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 7158-7168
Text-driven motion generation has advanced significantly with the rise of denoising diffusion models. However, previous methods often oversimplify representations for the skeletal joints, temporal frames, and textual words, limiting their ability to fully capture the information within each modality and their interactions. Moreover, when using pre-trained models for downstream tasks, such as editing, they typically require additional efforts, including manual interventions, optimization, or fine-tuning. In this paper, we introduce a skeleton-aware latent diffusion (SALAD), a model that explicitly captures the intricate inter-relationships between joints, frames, and words. Furthermore, by leveraging cross-attention maps produced during the generation process, we enable the attention-based zero-shot text-driven motion editing using a pre-trained SALAD model, requiring no additional user input beyond text prompts. Our approach significantly outperforms previous methods in terms of text-motion alignment without compromising generation quality, and demonstrates practical versatility by providing diverse editing capabilities beyond generation. Code is available at project page.

Towards Universal AI-Generated Image Detection by Variational Information Bottleneck Network
Haifeng Zhang, Qinghui He, Xiuli Bi, Weisheng Li, Bo Liu, Bin Xiao; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 23828-23837
The rapid advancement of generative models has significantly improved the quality of generated images. Meanwhile, it challenges information authenticity and credibility. Current generated image detection methods based on large-scale pre-trained multimodal models have achieved impressive results. Although these models provide abundant features, the authentication task-related features are often submerged. Consequently, those authentication task-irrelated features cause models to learn superficial biases, thereby harming their generalization performance across different model genera (e.g., GANs and Diffusion Models). To this end, we proposed VIB-Net, which uses Variational Information Bottlenecks to enforce authentication task-related feature learning. We tested and analyzed the proposed method and existing methods on samples generated by 17 different generative models. Compared to SOTA methods, VIB-Net achieved a 5.55% improvement in mAP and a 9.33% increase in accuracy. Notably, in generalization tests on unseen generative models from different series, VIB-Net improved mAP by 12.48% and accuracy by 23.59% over SOTA methods. The code is available at https://github.com/oceanzhf/VIBAIGCDetect.
****
HSI: A Holistic Style Injector for Arbitrary Style Transfer
Shuhao Zhang, Hui Kang, Yang Liu, Fang Mei, Hongjuan Li; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 23433-23442
Attention-based arbitrary style transfer methods have gained significant attention recently due to their impressive ability to synthesize style details. However, the point-wise matching within the attention mechanism may overly focus on local patterns such that neglect the remarkable global features of style images. Additionally, when processing large images, the quadratic complexity of the attention mechanism will bring high computational load. To alleviate above problems, we propose Holistic Style Injector (HSI), a novel attention-style transformation module to deliver artistic expression of target style. Specifically, HSI performs stylization only based on global style representation that is more in line with the characteristics of style transfer, to avoid generating local disharmonious patterns in stylized images. Moreover, we propose a dual relation learning mechanism inside the HSI to dynamically render images by leveraging semantic similarity in content and style, ensuring the stylized images preserve the original con

tent and improve style fidelity. Note that the proposed HSI achieves linear comp utational complexity because it establishes feature mapping through element-wise multiplication rather than matrix multiplication. Qualitative and quantitative results demonstrate that our method outperforms state-of-the-art approaches in b oth effectiveness and efficiency.

LookingGlass: Generative Anamorphoses via Laplacian Pyramid Warping
Pascal Chang, Sergio Sancho, Jingwei Tang, Markus Gross, Vinicius Azevedo; Proce edings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, p p. 24-33
Anamorphosis refers to a category of images that are intentionally distorted, ma king them unrecognizable when viewed directly. Their true form only reveals itse lf when seen from a specific viewpoint, which can be through some catadioptric d evice like a mirror or a lens. While the construction of these mathematical devi ces can be traced back to as early as the 17th century, they are only interpreta ble when viewed from a specific vantage point and tend to lose meaning when seen normally. In this paper, we revisit these famous optical illusions with a gener ative twist. With the help of latent rectified flow models, we propose a method to create anamorphic images that still retain a valid interpretation when viewed directly. To this end, we introduce Laplacian Pyramid Warping, a frequency-awar e image warping technique key to generating high-quality visuals. Our work exten ds Visual Anagrams (Geng et al. 2024) to latent space models and to a wider rang e of spatial transforms, enabling the creation of novel generative perceptual il lusions.

V2V3D: View-to-View Denoised 3D Reconstruction for Light Field Microscopy
Jiayin Zhao, Zhenqi Fu, Tao Yu, Hui Qiao; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 26451-26461
Light field microscopy (LFM) has gained significant attention due to its ability to capture snapshot-based, large-scale 3D fluorescence images. However, existin g LFM reconstruction algorithms are highly sensitive to sensor noise or require hard-to-get ground-truth annotated data for training. To address these challenge s, this paper introduces V2V3D, an unsupervised view2view-based framework that e stablishes a new paradigm for joint optimization of image denoising and 3D recon struction in a unified architecture. We assume that the LF images are derived fr om a consistent 3D signal, with the noise in each view being independent. This e nables V2V3D to incorporate the principle of noise2noise for effective denoising . To enhance the recovery of high-frequency details, we propose a novel wave-opt ics-based feature alignment technique, which transforms the point spread functio n, used for forward propagation in wave optics, into convolution kernels specifi cally designed for feature alignment. Moreover, we introduce an LFM dataset cont aining LF images and their corresponding 3D intensity volumes. Extensive experim ents demonstrate that our approach achieves high computational efficiency and ou tperforms the other state-of-the-art methods. These advancements position V2V3D as a promising solution for 3D imaging under challenging conditions. Our code an d dataset will be publicly accessible at https://joey1998hub.github.io/V2V3D/.

DiN: Diffusion Model for Robust Medical VQA with Semantic Noisy Labels
Erjian Guo, Zhen Zhao, Zicheng Wang, Tong Chen, Yunyi Liu, Luping Zhou; Proceedi ngs of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 14337-14346
Medical Visual Question Answering (Med-VQA) systems benefit the interpretation o f medical images containing critical clinical information. However, the challeng e of noisy labels and limited high-quality datasets remains underexplored. To ad dress this, we establish the first benchmark for noisy labels in Med-VQA by simu lating human mislabeling with semantically designed noise types. More important ly, we introduce the DiN framework, which leverages a diffusion model to handle noisy labels in Med-VQA. Unlike the dominant classification-based VQA approaches that directly predict answers, our Answer Diffuser (AD) module employs a coarse -to-fine process, refining answer candidates with a diffusion model for improved

accuracy. The Answer Condition Generator (ACG) further enhances this process by generating task-specific conditional information via integrating answer embeddings with fused image-question features. To address label noise, our Noisy Label Refinement(NLR) module introduces a robust loss function and dynamic answer adjustment to further boost the performance of the AD module. Our DiN framework consistently outperforms existing methods across multiple benchmarks with varying noise levels.

Splatter-360: Generalizable 360 Gaussian Splatting for Wide-baseline Panoramic Images
Zheng Chen, Chenming Wu, Zhelun Shen, Chen Zhao, Weicai Ye, Haocheng Feng, Errui Ding, Song-Hai Zhang; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 21590-21599
Wide-baseline panoramic images are frequently used in applications like VR and simulations to minimize capturing labor costs and storage needs. However, synthesizing novel views from these panoramic images in real time remains a significant challenge, especially due to panoramic imagery's high resolution and inherent distortions. Although existing 3D Gaussian splatting (3DGS) methods can produce photo-realistic views under narrow baselines, they often overfit the training views when dealing with wide-baseline panoramic images due to the difficulty in learning precise geometry from sparse 360^ \circ views. This paper presents Splatter-360, a novel end-to-end generalizable 3DGS framework designed to handle wide-baseline panoramic images. Unlike previous approaches, Splatter-360 performs multi-view matching directly in the spherical domain by constructing a spherical cost volume through a spherical sweep algorithm, enhancing the network's depth perception and geometry estimation. Additionally, we introduce a 3D-aware bi-projection encoder to mitigate the distortions inherent in panoramic images and integrate cross-view attention to improve feature interactions across multiple viewpoints. This enables robust 3D-aware feature representations and real-time rendering capabilities. Experimental results on the HM3D and Replica demonstrate that Splatter-360 significantly outperforms state-of-the-art NeRF and 3DGS methods (e.g., PanoGRF, MVSplat, DepthSplat, and HiSplat) in both synthesis quality and generalization performance for wide-baseline panoramic images. Code and trained models are available at https://3d-aigc.github.io/Splatter-360/.
****
ShowMak3r: Compositional TV Show Reconstruction
Sangmin Kim, Seunguk Do, Jaesik Park; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 864-874
Reconstructing dynamic radiance fields from video clips is challenging, especially when entertainment videos like TV shows are given. Many challenges make the reconstruction difficult due to (1) actors occluding with each other and having diverse facial expressions, (2) cluttered stages, and (3) small baseline views or sudden shot changes. To address these issues, we present ShowMak3r, a comprehensive reconstruction pipeline that allows the editing of scenes like how video clips are made in a production control room. In ShowMak3r, a 3DLocator module locates recovered actors on the stage using depth prior, and estimates unseen human poses via interpolation. The proposed ShotMatcher module then tracks the actors under shot changes. Furthermore, ShowMak3r introduces a face-fitting network that dynamically recovers the actors' expressions. Experiments on Sitcoms3D dataset show that our pipeline can reassemble TV show scenes with new cameras at different timestamps. We also demonstrate that ShowMak3r enables interesting applications such as synthetic shot-making, actor relocation, insertion, deletion, and pose manipulation. Project page : https://nstar1125.github.io/showmak3r

CADRef: Robust Out-of-Distribution Detection via Class-Aware Decoupled Relative Feature Leveraging
Zhiwei Ling, Yachen Chang, Hailiang Zhao, Xinkui Zhao, Kingsum Chow, Shuiguang Deng; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 4968-4977
Deep neural networks (DNNs) have been widely criticized for their overconfidence

when dealing with out-of-distribution (OOD) samples, highlighting the critical need for effective OOD detection to ensure the safe deployment of DNNs in real-world settings. Existing post-hoc OOD detection methods primarily enhance the discriminative power of logit-based approaches by reshaping sample features, yet they often neglect critical information inherent in the features themselves. In this paper, we propose the \underline C lass-\underline A ware \underline Re lative \underline F eature-based method (CARef), which utilizes the error between a sample's feature and its class-aware average feature as a discriminative criterion. To further refine this approach, we introduce the \underline C lass-\underline A ware \underline D ecoupled \underline Re lative \underline F eature-based method (CADRef), which decouples sample features based on the alignment of signs between the relative feature and corresponding model weights, enhancing the discriminative capabilities of CARef.Extensive experimental results across multiple datasets and models demonstrate that both proposed methods exhibit effectiveness and robustness in OOD detection compared to state-of-the-art methods. Specifically, our two methods outperform the best baseline by 2.82% and 3.27% in AUROC, with improvements of 4.03% and 6.32% in FPR95, respectively.

****

S^3-Face: SSS-Compliant Facial Reflectance Estimation via Diffusion Priors
Xingyu Ren, Jiankang Deng, Yuhao Cheng, Wenhan Zhu, Yichao Yan, Xiaokang Yang, Stefanos Zafeiriou, Chao Ma; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 16051-16060

Recent 3D face reconstruction methods have made remarkable advancements, yet achieving high-quality facial reflectance from monocular input remains challenging. Existing methods rely on the light-stage captured data to learn facial reflectance models. However, limited subject diversity in these datasets poses challenges in achieving good generalization and broad applicability. This motivates us to explore whether the extensive priors captured in recent generative diffusion models (e.g., Stable Diffusion) can enable more generalizable facial reflectance estimation as these models have been pre-trained on large-scale internet image collections containing rich visual patterns. In this paper, we introduce the use of Stable Diffusion as a prior for facial reflectance estimation, achieving robust results with minimal captured data for fine-tuning. We present S^3-Face, a comprehensive framework capable of producing SSS-compliant skin reflectance from in-the-wild images. Our method adopts a two-stage training approach: in the first stage, DSN-Net is trained to predict diffuse albedo, specular albedo, and normal maps from in-the-wild images using a novel joint reflectance attention module. In the second stage, HM-Net is trained to generate hemoglobin and melanin maps based on the diffuse albedo predicted in the first stage, yielding SSS-compliant and detailed reflectance maps. Extensive experiments demonstrate that our method achieves strong generalization and produces high-fidelity, SSS-compliant facial reflectance reconstructions.

FSBench: A Figure Skating Benchmark for Advancing Artistic Sports Understanding
Rong Gao, Xin Liu, Zhuozhao Hu, Bohao Xing, Baiqiang Xia, Zitong Yu, Heikki Kälviäinen; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 13595-13605

Figure skating, known as the "Art on Ice," is among the most artistic sports, challenging to understand due to its blend of technical elements (like jumps and spins) and overall artistic expression. Existing figure skating datasets mainly focus on single tasks, such as action recognition or scoring, lacking comprehensive annotations for both technical and artistic evaluation. Current sports research is largely centered on ball games, with limited relevance to artistic sports like figure skating. To address this, we introduce FSAnno, a large-scale dataset advancing artistic sports understanding through figure skating. FSAnno includes an open-access training and test dataset, alongside a benchmark dataset, FSBench, for fair model evaluation. FSBench consists of FSBench-Text, with multiple-choice questions and explanations, and FSBench-Motion, containing multimodal data and Question and Answer (QA) pairs, supporting tasks from technical analysis to performance commentary. Initial tests on FSBench reveal significant limitations

in existing models' understanding of artistic sports. We hope FSBench will become a key tool for evaluating and enhancing model comprehension of figure skating. All data, models, and more details are available at: https://github.com/Moomin-Fin/Ano.

Keep the Balance: A Parameter-Efficient Symmetrical Framework for RGB+X Semantic Segmentation
Jiaxin Cai, Jingze Su, Qi Li, Wenjie Yang, Shu Wang, Tiesong Zhao, Shengfeng He, Wenxi Liu; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 10587-10598
Multimodal semantic segmentation is a critical challenge in computer vision, with early methods suffering from high computational costs and limited transferability due to full fine-tuning of RGB-based pre-trained parameters. Recent studies, while leveraging additional modalities as supplementary prompts to RGB, still predominantly rely on RGB, which restricts the full potential of other modalities. To address these issues, we propose a novel symmetric parameter-efficient fine-tuning framework for multimodal segmentation, featuring with a modality-aware prompting and adaptation scheme, to simultaneously adapt the capabilities of a powerful pre-trained model to both RGB and X modalities. Furthermore, prevalent approaches use the global cross-modality correlations of attention mechanism for modality fusion, which inadvertently introduces noise across modalities. To mitigate this noise, we propose a dynamic sparse cross-modality fusion module to facilitate effective and efficient cross-modality fusion. To further strengthen the above two modules, we propose a training strategy that leverages accurately predicted dual-modality results to self-teach the single-modality outcomes. In comprehensive experiments, we demonstrate that our method outperforms previous state-of-the-art approaches across six multimodal segmentation scenarios with minimal computation cost.
****
VideoDirector: Precise Video Editing via Text-to-Video Models
Yukun Wang, Longguang Wang, Zhiyuan Ma, Qibin Hu, Kai Xu, Yulan Guo; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 2589-2598
Despite the typical inversion-then-editing paradigm using text-to-image (T2I) models has demonstrated promising results, directly extending it to text-to-video (T2V) models still suffers severe artifacts such as color flickering and content distortion. Consequently, current video editing methods primarily rely on T2I models, which inherently lack temporal-coherence generative ability, often resulting in inferior editing results. In this paper, we attribute the failure of the typical editing paradigm to: 1) Tightly Spatial-temporal Coupling. The vanilla pivotal-based inversion strategy struggles to disentangle spatial-temporal information in the video diffusion model; 2) Complicated Spatial-temporal Layout. The vanilla cross-attention control strategy is deficient in preserving the unedited content. To address these limitations, we propose a spatial-temporal decoupled guidance (STDG) and multi-frame null-text optimization strategy to provide pivotal temporal cues for more precise pivotal inversion. Furthermore, we introduce a self-attention control strategy to maintain higher fidelity for precise partial content editing. Experimental results demonstrate that our method (termed VideoDirector) effectively harnesses the powerful temporal generation capabilities of T2V models, producing edited videos with state-of-the-art performance in accuracy, motion smoothness, realism, and fidelity to unedited content.
****
LLM-driven Multimodal and Multi-Identity Listening Head Generation
Peiwen Lai, Weizhi Zhong, Yipeng Qin, Xiaohang Ren, Baoyuan Wang, Guanbin Li; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 10656-10666
Generating natural listener responses in conversational scenarios is crucial for creating engaging digital humans and avatars. Recent work has shown that large language models (LLMs) can be effectively leveraged for this task, demonstrating remarkable capabilities in generating contextually appropriate listener behavio

rs. However, current LLM-based methods face two critical limitations: they rely solely on speech content, overlooking other crucial communication signals, and they entangle listener identity with response generation, compromising output fidelity and generalization. In this work, we present a novel framework that addresses these limitations while maintaining the advantages of LLMs. Our approach introduces a Multimodal-LM architecture that jointly processes speech content, acoustics, and speaker emotion, capturing the full spectrum of communication cues. Additionally, we propose an identity disentanglement strategy using instance normalization and adaptive instance normalization in a VQ-VAE framework, enabling high-fidelity listening head synthesis with flexible identity control. Extensive experiments demonstrate that our method significantly outperforms existing approaches in terms of response naturalness and fidelity, while enabling effective identity control without retraining.

Towards Understanding How Knowledge Evolves in Large Vision-Language Models

Sudong Wang, Yunjian Zhang, Yao Zhu, Jianing Li, Zizhe Wang, Yanwei Liu, Xiangyang Ji; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 29858-29868

Large Vision-Language Models (LVLMs) are gradually becoming the foundation for many artificial intelligence applications. However, understanding their internal working mechanisms has continued to puzzle researchers, which in turn limits the further enhancement of their capabilities. In this paper, we seek to investigate how multimodal knowledge evolves and eventually induces natural languages in LVLMs. We design a series of novel strategies for analyzing internal knowledge within LVLMs, and delve into the evolution of multimodal knowledge from three levels, including single token probabilities, token probability distributions, and feature encodings. In this process, we identify two key nodes in knowledge evolution: the critical layers and the mutation layers, dividing the evolution process into three stages: rapid evolution, stabilization, and mutation. Our research is the first to reveal the trajectory of knowledge evolution in LVLMs, providing a fresh perspective for understanding their underlying mechanisms.

A Unified, Resilient, and Explainable Adversarial Patch Detector

Vishesh Kumar, Akshay Agarwal; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 30387-30397

Deep Neural Networks (DNNs), backbone architecture in `almost' every computer vision task, are vulnerable to adversarial attacks, particularly physical out-of-distribution (OOD) adversarial patches. Existing defense models often struggle with interpreting these attacks in ways that align with human visual perception. Our proposed AdvPatchXAI approach introduces a generalized, robust, and explainable defense algorithm designed to defend DNNs against physical adversarial threats. AdvPatchXAI employs a novel patch decorrelation loss that reduces feature redundancy and enhances the distinctiveness of patch representations, enabling better generalization across unseen adversarial scenarios. It learns prototypical parts self-supervised, enhancing interpretability and correlation with human vision. The model utilizes a sparse linear layer for classification, making the decision process globally interpretable through a set of learned prototypes and locally explainable by pinpointing relevant prototypes within an image. Our comprehensive evaluation shows that AdvPatchXAI closes the "semantic" gap between latent space and pixel space and effectively handles unseen adversarial patches even perturbed with unseen corruptions, thereby significantly advancing DNN robustness in practical settings(https://github.com/tbvl22/Unified-resilient-and-Explainable-Adversarial-Patch-detector).

****

VISTA: Enhancing Long-Duration and High-Resolution Video Understanding by Video Spatiotemporal Augmentation

Weiming Ren, Huan Yang, Jie Min, Cong Wei, Wenhu Chen; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 3804-3814

Current large multimodal models (LMMs) face significant challenges in processing and comprehending long-duration or high-resolution videos, which is mainly due

to the lack of high-quality datasets. To address this issue from a data-centric perspective, we propose VISTA, a simple yet effective video spatiotemporal augmentation framework that synthesizes long-duration and high-resolution video instruction-following pairs from existing video-caption datasets. VISTA spatially and temporally combines videos to create new synthetic videos with extended durations and enhanced resolutions, and subsequently produces question-answer pairs pertaining to these newly synthesized videos. Based on this paradigm, we develop seven video augmentation methods and curate VISTA-400K, a video instruction-following dataset aimed at enhancing long-duration and high-resolution video understanding. Finetuning various video LMMs on our data resulted in an average improvement of 3.3% across four challenging benchmarks for long-video understanding. Furthermore, we introduce the first comprehensive high-resolution video understanding benchmark HRVideoBench, on which our finetuned models achieve a 6.5% performance gain. These results highlight the effectiveness of our framework.

Structured 3D Latents for Scalable and Versatile 3D Generation

Jianfeng Xiang, Zelong Lv, Sicheng Xu, Yu Deng, Ruicheng Wang, Bowen Zhang, Dong Chen, Xin Tong, Jiaolong Yang; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 21469-21480

We introduce a novel 3D generation method for versatile and high-quality 3D asset creation.The cornerstone is a unified Structured LATent (SLAT) representation which allows decoding to different output formats, such as Radiance Fields, 3D Gaussians, and meshes. This is achieved by integrating a sparsely-populated 3D grid with dense multiview visual features extracted from a powerful vision foundation model, comprehensively capturing both structural (geometry) and textural (appearance) information while maintaining flexibility during decoding.We employ rectified flow transformers tailored for SLAT as our 3D generation models and train models with up to 2 billion parameters on a large 3D asset dataset of 500K diverse objects. Our model generates high-quality results with text or image conditions, significantly surpassing existing methods, including recent ones at similar scales. We showcase flexible output format selection and local 3D editing capabilities which were not offered by previous models. Code, model, and data will be released.

GA3CE: Unconstrained 3D Gaze Estimation with Gaze-Aware 3D Context Encoding

Yuki Kawana, Shintaro Shiba, Quan Kong, Norimasa Kobori; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 3081-3090

We propose a novel 3D gaze estimation approach that learns spatial relationships between the subject and objects in the scene, and outputs 3D gaze direction. Our method targets unconstrained settings, including cases where close-up views of the subject's eyes are unavailable, such as when the subject is distant or facing away. Previous approaches typically rely on either 2D appearance alone or incorporate limited spatial cues using depth maps in the non-learnable post-processing step. Estimating 3D gaze direction from 2D observations in these scenarios is challenging; variations in subject pose, scene layout, and gaze direction, combined with differing camera poses, yield diverse 2D appearances and 3D gaze directions even when targeting the same 3D scene. To address this issue, we propose GA3CE: Gaze-Aware 3D Context Encoding. Our method represents subject and scene using 3D poses and object positions, treating them as 3D context to learn spatial relationships in 3D space. Inspired by human vision, we align this context in an egocentric space, significantly reducing spatial complexity. Furthermore, we propose D^3 (direction-distance-decomposed) positional encoding to better capture the spatial relationship between 3D context and gaze direction in direction and distance space. Experiments demonstrate substantial improvements, reducing mean angle error by 13%-37% compared to leading baselines on benchmark datasets in single-frame settings.

Self-Cross Diffusion Guidance for Text-to-Image Synthesis of Similar Subjects

Weimin Qiu, Jieke Wang, Meng Tang; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 23528-23538

Diffusion models achieved unprecedented fidelity and diversity for synthesizing image, video, 3D assets, etc. However, subject mixing is an unresolved issue for diffusion-based image synthesis, particularly for synthesizing multiple similar-looking subjects. We propose Self-Cross Diffusion Guidance to penalize the overlap between cross-attention maps and the aggregated self-attention map. Compared to previous methods based on self-attention or cross-attention alone, our guidance is more effective in eliminating subject mixing. What's more, our guidance addresses subject mixing for all relevant patches beyond the most discriminant one, e.g., the beak of a bird. For each subject, we aggregate self-attention maps of patches with higher cross-attention values. Thus, the aggregated self-attention map forms a region that the whole subject attends to. Our training-free method boosts the performance of both Unet-based and Transformer-based diffusion models such as the Stable Diffusion series. We also release a similar subjects dataset (SSD), a challenging benchmark, and utilize GPT-4o for automatic and reliable evaluation. Extensive qualitative and quantitative results demonstrate the effectiveness of our self-cross diffusion guidance.

****

RigGS: Rigging of 3D Gaussians for Modeling Articulated Objects in Videos

Yuxin Yao, Zhi Deng, Junhui Hou; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 5592-5601

This paper considers the problem of modeling articulated objects captured in 2D videos to enable novel view synthesis, while also being easily editable, drivable, and reposable. To tackle this challenging problem, we propose RigGS, a new paradigm that leverages 3D Gaussian representation and skeleton-based motion representation to model dynamic objects without utilizing additional template priors. Specifically, we first propose skeleton-aware node-controlled deformation, which deforms a canonical 3D Gaussian representation over time to initialize the modeling process, producing candidate skeleton nodes that are further simplified into a sparse 3D skeleton according to their motion and semantic information. Subsequently, based on the resulting skeleton, we design learnable skin deformations and pose-dependent detailed deformations, thereby easily deforming the 3D Gaussian representation to generate new actions and render further high-quality images from novel views. Extensive experiments demonstrate that our method can generate realistic new actions easily for objects and achieve high-quality rendering.

****

Noise Modeling in One Hour: Minimizing Preparation Efforts for Self-supervised Low-Light RAW Image Denoising

Feiran Li, Haiyang Jiang, Daisuke Iso; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 5699-5708

Noise synthesis is a promising solution for addressing the data shortage problem in data-driven low-light RAW image denoising. However, accurate noise synthesis methods often necessitate labor-intensive calibration and profiling procedures during preparation, preventing them from landing to practice at scale. This work introduces a practically simple noise synthesis pipeline based on detailed analyses of noise properties and extensive justification of widespread techniques. Compared to other approaches, our proposed pipeline eliminates the cumbersome system gain calibration and signal-independent noise profiling steps, reducing the preparation time for noise synthesis from days to hours. Meanwhile, our method exhibits strong denoising performance, showing an up to 0.54dB PSNR improvement over the current state-of-the-art noise synthesis technique.

Adv-CPG: A Customized Portrait Generation Framework with Facial Adversarial Attacks

Junying Wang, Hongyuan Zhang, Yuan Yuan; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 21001-21010

Recent Customized Portrait Generation (CPG) methods, taking a facial image and a textual prompt as inputs, have attracted substantial attention. Although these methods generate high-fidelity portraits, they fail to prevent the generated portraits from being tracked and misused by malicious face recognition systems. To address this, this paper proposes a Customized Portrait Generation framework wit

h facial Adversarial attacks (Adv-CPG). Specifically, to achieve facial privacy protection, we devise a lightweight local ID encryptor and an encryption enhancer. They implement progressive double-layer encryption protection by directly injecting the target identity and adding additional identity guidance, respectively. Furthermore, to accomplish fine-grained and personalized portrait generation, we develop a multi-modal image customizer capable of generating controlled fine-grained facial features. To the best of our knowledge, Adv-CPG is the first study that introduces facial adversarial attacks into CPG. Extensive experiments demonstrate the superiority of Adv-CPG, e.g., the average attack success rate of the proposed Adv-CPG is 28.1% and 2.86% higher compared to the SOTA noise-based attack methods and unconstrained attack methods, respectively.

Fish-Vista: A Multi-Purpose Dataset for Understanding & Identification of Traits from Images

Kazi Sajeed Mehrab, M. Maruf, Arka Daw, Abhilash Neog, Harish Babu Manogaran, Mridul Khurana, Zhenyang Feng, Bahadir Altintas, Yasin Bakis, Elizabeth G Campolongo, Matthew J Thompson, Xiaojun Wang, Hilmar Lapp, Tanya Berger-Wolf, Paula Mabee, Henry Bart, Wei-Lun Chao, Wasila M Dahdul, Anuj Karpatne; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 24275-24285

We introduce Fish-Visual Trait Analysis (Fish-Vista), the first organismal image dataset designed for the analysis of visual traits of aquatic species directly from images using machine learning and computer vision methods. Fish-Vista contains 69,269 annotated images spanning 4,316 fish species, curated and organized to serve three downstream tasks: species classification, trait identification, and trait segmentation. Our work makes two key contributions. First, we provide a fully reproducible data processing pipeline to process fish images sourced from various museum collections, contributing to the advancement of AI in biodiversity science. We annotate the images with carefully curated labels from biological databases and manual annotations to create an AI-ready dataset of visual traits. Second, our work offers fertile grounds for researchers to develop novel methods for a variety of problems in computer vision such as handling long-tailed distributions, out-of-distribution generalization, learning with weak labels, explainable AI, and segmenting small objects. Dataset and code for Fish-Vista are available at https://github.com/Imageomics/Fish-Vista

High Dynamic Range Video Compression: A Large-Scale Benchmark Dataset and A Learned Bit-depth Scalable Compression Algorithm

Zhaoyi Tian, Feifeng Wang, Shiwei Wang, Zihao Zhou, Yao Zhu, Liquan Shen; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 7320-7330

Recently, learned video compression (LVC) is undergoing a period of rapid development. However, due to absence of large and high-quality high dynamic range (HDR) video training data, LVC on HDR video is still unexplored. In this paper, we are the first to collect a large-scale HDR video benchmark dataset, named HDRVD2K, featuring huge quantity, diverse scenes and multiple motion types. HDRVD2K fills gaps of video training data and facilitate the development of LVC on HDR videos. Based on HDRVD2K, we further propose the first learned bit-depth scalable video compression (LBSVC) network for HDR videos by effectively exploiting bit-depth redundancy between videos of multiple dynamic ranges. To achieve this, we first propose a compression-friendly bit-depth enhancement module (BEM) to effectively predict original HDR videos based on compressed tone-mapped low dynamic range (LDR) videos and dynamic range prior, instead of reducing redundancy only through spatio-temporal predictions. Our method greatly improves the reconstruction quality and compression performance on HDR videos. Extensive experiments demonstrate the effectiveness of HDRVD2K on learned HDR video compression and great compression performance of our proposed LBSVC network.

OffsetOPT: Explicit Surface Reconstruction without Normals

Huan Lei; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 11729-11738

Neural surface reconstruction has been dominated by implicit representations wit
h marching cubes for explicit surface extraction. However, those methods typical
ly require high-quality normals for accurate reconstruction. We propose OffsetOP
T, a method that reconstructs explicit surfaces directly from 3D point clouds
and eliminates the need for point normals. The approach comprises two stages: fi
rst, we train a neural network to predict surface triangles based on local point
geometry, given uniformly distributed training point clouds. Next, we apply the
frozen network to reconstruct surfaces from unseen point clouds by optimizing a
per-point offset to maximize the accuracy of triangle predictions. Compared to
state-of-the-art methods, OffsetOPT not only excels at reconstructing overall su
rfaces but also significantly preserves sharp surface features. We demonstrate i
ts accuracy on popular benchmarks, including small-scale shapes and large-scale
open surfaces.
****

PCM : Picard Consistency Model for Fast Parallel Sampling of Diffusion Models
Junhyuk So, Jiwoong Shin, Chaeyeon Jang, Eunhyeok Park; Proceedings of the Compu
ter Vision and Pattern Recognition Conference (CVPR), 2025, pp. 23313-23322
Recently, diffusion models have achieved significant advances in vision, text, a
nd robotics. However, they still face slow generation speeds due to sequential d
enoising processes. To address this, a parallel sampling method based on Picard
iteration was introduced, effectively reducing sequential steps while ensuring e
xact convergence to the original output. Nonetheless, Picard iteration does not
guarantee faster convergence, which can still result in slow generation in pract
ice. In this work, we propose a new parallelization scheme, the Picard Consisten
cy Model (PCM), which significantly reduces the number of generation steps in Pi
card iteration. Inspired by the consistency model, PCM is directly trained to pr
edict the fixed-point solution, or the final output, at any stage of the converg
ence trajectory. Additionally, we introduce a new concept called model switching
, which addresses PCM's limitations and ensures exact convergence. Extensive exp
eriments demonstrate that PCM achieves up to a 2.71x speedup over sequential sam
pling and a 1.77x speedup over Picard iteration across various tasks, including
image generation and robotic control.

CoMapGS: Covisibility Map-based Gaussian Splatting for Sparse Novel View Synthes
is
Youngkyoon Jang, Eduardo Pérez-Pellitero; Proceedings of the Computer Vision and
Pattern Recognition Conference (CVPR), 2025, pp. 26779-26788
We propose Covisibility Map-based Gaussian Splatting (CoMapGS), designed to reco
ver underrepresented sparse regions in sparse novel view synthesis. CoMapGS addr
esses both high- and low-uncertainty regions by constructing covisibility maps,
enhancing initial point clouds, and applying uncertainty-aware weighted supervis
ion using a proximity classifier. Our contributions are threefold: (1) CoMapGS r
eframes novel view synthesis by leveraging covisibility maps as a core component
to address region-specific uncertainty; (2) Enhanced initial point clouds for b
oth low- and high-uncertainty regions compensate for sparse COLMAP-derived point
clouds, improving reconstruction quality and benefiting few-shot 3DGS methods;
(3) Adaptive supervision with covisibility-score-based weighting and proximity c
lassification achieves consistent performance gains across scenes with varying s
parsity scores derived from covisibility maps. Experimental results demonstrate
that CoMapGS outperforms state-of-the-art methods on datasets including Mip-NeRF
360 and LLFF.

Any-Resolution AI-Generated Image Detection by Spectral Learning
Dimitrios Karageorgiou, Symeon Papadopoulos, Ioannis Kompatsiaris, Efstratios Ga
vves; Proceedings of the Computer Vision and Pattern Recognition Conference (CVP
R), 2025, pp. 18706-18717
Recent works have established that AI models introduce spectral artifacts into g
enerated images and propose approaches for learning to capture them using labele
d data. However, the significant differences in such artifacts among different g
enerative models hinder these approaches from generalizing to generators not see

n during training. In this work, we build upon the key idea that the spectral di
stribution of real images constitutes both an invariant and highly discriminativ
e pattern for AI-generated image detection. To model this under a self-supervise
d setup, we employ masked spectral learning using the pretext task of frequency
reconstruction. Since generated images constitute out-of-distribution samples fo
r this model, we propose spectral reconstruction similarity to capture this dive
rgence. Moreover, we introduce spectral context attention, which enables our app
roach to efficiently capture subtle spectral inconsistencies in images of any re
solution. Our spectral AI-generated image detection approach (SPAI) achieves a 5
.5% absolute improvement in AUC over the previous state-of-the-art across 13 rec
ent generative approaches, while exhibiting robustness against common online per
turbations. Code is available on https://mever-team.github.io/spai.

DivPrune: Diversity-based Visual Token Pruning for Large Multimodal Models
Saeed Ranjbar Alvar, Gursimran Singh, Mohammad Akbari, Yong Zhang; Proceedings o
f the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 9392-
9401
Large Multimodal Models (LMMs) have emerged as powerful models capable of unders
tanding various data modalities, including text, images, and videos. LMMs encode
 both text and visual data into tokens that are then combined and processed by a
n integrated Large Language Model (LLM). Including visual tokens substantially i
ncreases the total token count, often by thousands. The increased input length f
or LLM significantly raises the complexity of inference, resulting in high laten
cy in LMMs. To address this issue, token pruning methods, which remove part of t
he visual tokens, are proposed. The existing token pruning methods either requir
e extensive calibration and fine-tuning or rely on suboptimal importance metrics
 which results in increased redundancy among the retained tokens. In this paper,
 we first formulate token pruning as Max-Min Diversity Problem (MMDP) where the
goal is to select a subset such that the diversity among the selected tokens is
maximized. Then, we solve the MMDP to obtain the selected subset and prune the r
est. The proposed method, DivPrune, reduces redundancy and achieves the highest
diversity of the selected tokens. By ensuring high diversity, the selected token
s better represent the original tokens, enabling effective performance even at h
igh pruning ratios without requiring fine-tuning. Extensive experiments with var
ious LMMs show that DivPrune achieves state-of-the-art accuracy over 16 image- a
nd video-language datasets. Additionally, DivPrune reduces both the end-to-end l
atency and GPU memory usage for the tested models. The code is available here.

Training Data Provenance Verification: Did Your Model Use Synthetic Data from My
 Generative Model for Training?
Yuechen Xie, Jie Song, Huiqiong Wang, Mingli Song; Proceedings of the Computer V
ision and Pattern Recognition Conference (CVPR), 2025, pp. 23817-23827
High-quality open-source text-to-image models have lowered the threshold for obt
aining photorealistic images significantly, but also face potential risks of mis
use. Specifically, suspects may use synthetic data generated by these generative
 models to train models for specific tasks without permission, when lacking real
 data resources especially. Protecting these generative models is crucial for th
e well-being of their owners. In this work, we propose the first method to this
important yet unresolved issue, called Training data Provenance Verification (Tr
ainProVe). The rationale behind TrainProVe is grounded in the principle of gener
alization error bound, which suggests that, for two models with the same task, i
f the distance between their training data distributions is smaller, their gener
alization ability will be closer. We validate the efficacy of TrainProVe across
four text-to-image models (Stable Diffusion v1.4, latent consistency model, PixA
rt-\alpha, and Stable Cascade). The results show that TrainProVe achieves a veri
fication accuracy of over 99% in determining the provenance of suspicious model
training data, surpassing all previous methods. Code is available at https://git
hub.com/xieyc99/TrainProVe.

3D-AVS: LiDAR-based 3D Auto-Vocabulary Segmentation

Weijie Wei, Osman Ülger, Fatemeh Karimi Nejadasl, Theo Gevers, Martin R. Oswald; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 8910-8920

Open-vocabulary segmentation methods offer promising capabilities in detecting unseen object categories, but the category must be aware and needs to be provided by a human, either via a text prompt or pre-labeled datasets, thus limiting their scalability. We propose 3D-AVS, a method for Auto-Vocabulary Segmentation of 3D point clouds for which the vocabulary is unknown and auto-generated for each input at runtime, thus eliminating the human in the loop and typically providing a substantially larger vocabulary for richer annotations. 3D-AVS first recognizes semantic entities from image or point cloud data and then segments all points with the automatically generated vocabulary. Our method incorporates both image-based and point-based recognition, enhancing robustness under challenging lighting conditions where geometric information from LiDAR is especially valuable. Our point-based recognition features a Sparse Masked Attention Pooling (SMAP) module to enrich the diversity of recognized objects. To address the challenges of evaluating unknown vocabularies and avoid annotation biases from label synonyms, hierarchies, or semantic overlaps, we introduce the annotation-free Text-Point Semantic Similarity (TPSS) metric for assessing generated vocabulary quality. Our evaluations on nuScenes and ScanNet200 demonstrate 3D-AVS's ability to generate semantic classes with accurate point-wise segmentations.

STOP: Integrated Spatial-Temporal Dynamic Prompting for Video Understanding

Zichen Liu, Kunlun Xu, Bing Su, Xu Zou, Yuxin Peng, Jiahuan Zhou; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 13776-13786

Pre-trained on tremendous image-text pairs, vision-language models like CLIP have demonstrated promising zero-shot generalization across numerous image-based tasks. However, extending these capabilities to video tasks remains challenging due to limited labeled video data and high training costs. Recent video prompting methods attempt to adapt CLIP for video tasks by introducing learnable prompts, but they typically rely on a single static prompt for all video sequences, overlooking the diverse temporal dynamics and spatial variations that exist across frames. This limitation significantly hinders the model's ability to capture essential temporal information for effective video understanding. To address this, we propose an integrated Spatial-TempOral dynamic Prompting (STOP) model which consists of two complementary modules, the intra-frame spatial prompting and inter-frame temporal prompting. Our intra-frame spatial prompts are designed to adaptively highlight discriminative regions within each frame by leveraging intra-frame attention and temporal variation, allowing the model to focus on areas with substantial temporal dynamics and capture fine-grained spatial details. Additionally, to highlight the varying importance of frames for video understanding, we further introduce inter-frame temporal prompts, dynamically inserting prompts between frames with high temporal variance as measured by frame similarity. This enables the model to prioritize key frames and enhances its capacity to understand temporal dependencies across sequences. Extensive experiments on various video benchmarks demonstrate that STOP consistently achieves superior performance against state-of-the-art methods. The code is available at https://github.com/zhoujiahuan1991/CVPR2025-STOP

TimeTracker: Event-based Continuous Point Tracking for Video Frame Interpolation with Non-linear Motion

Haoyue Liu, Jinghan Xu, Yi Chang, Hanyu Zhou, Haozhi Zhao, Lin Wang, Luxin Yan; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 17649-17659

Video frame interpolation (VFI) that leverages the bio-inspired event cameras as guidance has recently shown better performance and memory efficiency than the frame-based methods, thanks to the event cameras' advantages, such as high temporal resolution. A hurdle for event-based VFI is how to effectively deal with non-linear motion, caused by the dynamic changes in motion direction and speed withi

n the scene. Existing methods either use events to estimate sparse optical flow or fuse events with image features to estimate dense optical flow. Unfortunately, motion errors often degrade the VFI quality as the continuous motion cues from events do not align with the dense spatial information of images in the temporal dimension. In this paper, we find that object motion is continuous in space, tracking local regions over continuous time enables more accurate identification of spatiotemporal feature correlations. In light of this, we propose a novel continuous point tracking-based VFI framework, named TimeTracker. Specifically, we first design a Scene-Aware Region Segmentation (SARS) module to divide the scene into similar patches. Then, a Continuous Trajectory guided Motion Estimation (CTME) module is proposed to track the continuous motion trajectory of each patch through events. Finally, intermediate frames at any given time are generated through global motion optimization and frame refinement. Moreover, we collect a real-world dataset that features fast non-linear motion. Extensive experiments show that our method outperforms prior arts in both motion estimation and frame interpolation quality.

Improving the Training of Data-Efficient GANs via Quality Aware Dynamic Discriminator Rejection Sampling

Zhaoyu Zhang, Yang Hua, Guanxiong Sun, Hui Wang, Seán McLoone; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 30682-30691

Data-Efficient Generative Adversarial Nets (DE-GANs) have become more and more popular in recent years. Existing methods apply data augmentation, noise injection and pre-trained models to maximumly increase the number of training samples thus improving the training of DE-GANs. However, none of these methods considers the sample quality during training, which can also significantly influence the training of DE-GANs. Focusing on sample quality during training, in this paper, we are the first to incorporate discriminator rejection sampling (DRS) into the training process and introduce a novel method, called quality aware dynamic discriminator rejection sampling (QADDRS). Specifically, QADDRS consists of two steps: (1) the sample quality aware step, which aims to obtain the sorted critic scores, i.e., the ordered discriminator outputs, on real/fake samples in the current training stage; (2) the dynamic rejection step that obtains dynamic rejection number N, where N is controlled by the overfitting degree of discriminator (D) during training. When updating the parameters of D, the N high critic score real samples and the N low critic score fake samples in the minibatch are rejected dynamically based on the overfitting degree of D. As a result, QADDRS can avoid D becoming overly confident in distinguishing both real and fake samples, thereby alleviating the overfitting of D issue during training. Extensive experiments on several datasets demonstrate that integrating QADDRS into different DE-GANs can achieve better performance and deliver state-of-the-art results. Codes are available at https://github.com/zzhang05/QADDRS.

Shading Meets Motion: Self-supervised Indoor 3D Reconstruction Via Simultaneous Shape-from-Shading and Structure-from-Motion

Guoyu Lu; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 16508-16519

Scene reconstruction has a wide range of applications in computer vision and robotics. To build practical constraints and feature Scene reconstruction has a wide range of applications in computer vision and robotics. To build practical constraints and feature correspondences, rich textures and distinguished gradient variations are particularly required in classic and learning-based SfM. When building low-texture regions with repeated patterns, especially mostly-white indoor rooms, there is a significant drop in performance. In this work, we propose Shading-SfM-Net, a novel framework for simultaneously learning a shape-from-shading network based on the inverse rendering constraint and a structure-from-motion framework based on warped keypoint and geometric consistency, to improve structure-from-motion and surface reconstruction for low-texture indoor scenes. Shading-SfM-Net tightly incorporates the surface shape consistency and 3D geometric regist

ration loss in order to dig into their mutual information and further overcome t
he instability on flat regions. We evaluate the proposed framework on texture-le
ss indoor scenes (NYUv2 and ScanNet), and show that by simultaneously learning s
hading, motion and shape, our pipeline is able to achieve state-of-the-art perfo
rmance with superior generalization capability for unseen texture-less datasets.

MotionStone: Decoupled Motion Intensity Modulation with Diffusion Transformer fo
r Image-to-Video Generation
Shuwei Shi, Biao Gong, Xi Chen, Dandan Zheng, Shuai Tan, Zizheng Yang, Yuyuan Li
, Jingwen He, Kecheng Zheng, Jingdong Chen, Ming Yang, Yinqiang Zheng; Proceedin
gs of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 2
2864-22874
The image-to-video (I2V) generation is conditioned on the static image, which ha
s been enhanced recently by the motion intensity as an additional control signal
. These motion-aware models are appealing to generate diverse motion patterns, y
et there lacks a reliable motion estimator for training such models on large-sca
le video set in the wild. Traditional metrics, e.g., SSIM or optical flow, are h
ard to generalize to arbitrary videos, while, it is very tough for human annotat
ors to label the abstract motion intensity neither. Furthermore, the motion inte
nsity shall reveal both local object motion and global camera movement, which ha
s not been studied before. This paper addresses the challenge with a new motion
estimator, capable of measuring the decoupled motion intensities of objects and
cameras in video. We leverage the contrastive learning on randomly paired videos
 and distinguish the video with greater motion intensity. Such a paradigm is fri
endly for annotation and easy to scale up to achieve stable performance on motio
n estimation. We then present a new I2V model, named MotionStone, developed with
 the decoupled motion estimator. Experimental results demonstrate the stability
of the proposed motion estimator and the state-of-the-art performance of MotionS
tone on I2V generation. These advantages warrant the decoupled motion estimator
to serve as a general plug-in enhancer for both data processing and video genera
tion training.

NLPrompt: Noise-Label Prompt Learning for Vision-Language Models
Bikang Pan, Qun Li, Xiaoying Tang, Wei Huang, Zhen Fang, Feng Liu, Jingya Wang,
Jingyi Yu, Ye Shi; Proceedings of the Computer Vision and Pattern Recognition Co
nference (CVPR), 2025, pp. 19963-19973
The emergence of vision-language foundation models, such as CLIP, has revolution
ized image-text representation, enabling a broad range of applications via promp
t learning. Despite its promise, real-world datasets often contain noisy labels
that can degrade prompt learning performance. In this paper, we demonstrate that
 using mean absolute error (MAE) loss in prompt learning, named PromptMAE, signi
ficantly enhances robustness against noisy labels while maintaining high accurac
y. Though MAE is straightforward and recognized for its robustness, it is rarely
 used in noisy-label learning due to its slow convergence and poor performance o
utside prompt learning scenarios. To elucidate the robustness of PromptMAE, we l

everage feature learning theory to show that MAE can suppress the influence of n
oisy samples, thereby improving the signal-to-noise ratio and enhancing overall
robustness. Additionally, we introduce PromptOT, a prompt-based optimal transpor
t data purification method to enhance the robustness further. PromptOT employs t
ext encoder representations in vision-language models as prototypes to construct
 an optimal transportation matrix. This matrix effectively partitions datasets i
nto clean and noisy subsets, allowing for the application of cross-entropy loss
to the clean subset and MAE loss to the noisy subset. Our Noise-Label Prompt Lea
rning method, named NLPrompt, offers a simple and efficient approach that levera
ges the expressive representation and precise alignment capabilities of vision-l
anguage models for robust prompt learning. We validate NLPrompt through extensi
ve experiments across various noise settings, demonstrating significant performa
nce improvements.

MEGA: Masked Generative Autoencoder for Human Mesh Recovery
Guénolé Fiche, Simon Leglaive, Xavier Alameda-Pineda, Francesc Moreno-Noguer; Pr
oceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025
, pp. 5366-5378
Human Mesh Recovery (HMR) from a single RGB image is a highly ambiguous problem,
 as an infinite set of 3D interpretations can explain the 2D observation equally
 well. Nevertheless, most HMR methods overlook this issue and make a single pred
iction without accounting for this ambiguity. A few approaches generate a distri
bution of human meshes, enabling the sampling of multiple predictions; however,
none of them is competitive with the latest single-output model when making a si
ngle prediction. This work proposes a new approach based on masked generative mo
deling. By tokenizing the human pose and shape, we formulate the HMR task as gen
erating a sequence of discrete tokens conditioned on an input image. We introduc
e MEGA, a MaskEd Generative Autoencoder trained to recover human meshes from ima
ges and partial human mesh token sequences. Given an image, our flexible generat
ion scheme allows us to predict a single human mesh in deterministic mode or to
generate multiple human meshes in stochastic mode. Experiments on in-the-wild be
nchmarks show that MEGA achieves state-of-the-art performance in deterministic a
nd stochastic modes, outperforming single-output and multi-output approaches.

PBR-NeRF: Inverse Rendering with Physics-Based Neural Fields
Sean Wu, Shamik Basu, Tim Broedermann, Luc Van Gool, Christos Sakaridis; Proceed
ings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp.
 10974-10984
We tackle the ill-posed inverse rendering problem in 3D reconstruction with a Ne
ural Radiance Field (NeRF) approach informed by Physics-Based Rendering (PBR) th
eory, named PBR-NeRF. Our method addresses a key limitation in most NeRF and 3D
Gaussian Splatting approaches: they estimate view-dependent appearance without m
odeling scene materials and illumination. To address this limitation, we present
 an inverse rendering (IR) model capable of jointly estimating scene geometry, m
aterials, and illumination. Our model builds upon recent NeRF-based IR approache
s, but crucially introduces two novel physics-based priors that better constrain
 the IR estimation. Our priors are rigorously formulated as intuitive loss terms
 and achieve state-of-the-art material estimation without compromising novel vie
w synthesis quality. Our method is easily adaptable to other inverse rendering a
nd 3D reconstruction frameworks that require material estimation. We demonstrate
 the importance of extending current neural rendering approaches to fully model
scene properties beyond geometry and view-dependent appearance. Code is publicly
 available at: https://github.com/s3anwu/pbrnerf.

Disentangling Safe and Unsafe Image Corruptions via Anisotropy and Locality
Ramchandran Muthukumar, Ambar Pal, Jeremias Sulam, Rene Vidal; Proceedings of th
e Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 9954-9963
State-of-the-art machine learning systems are vulnerable to small perturbations
to their input, where _small_ is defined according to a threat model that assign
s a positive threat to each perturbation. Most prior works define a task-agnosti

c, isotropic, and global threat, like the l_p norm, where the magnitude of the p erturbation fully determines the degree of the threat and neither the direction of the attack nor its position in space matter. However, common corruptions in c omputer vision, such as blur, compression, or occlusions, are not well captured by such treat models. This paper proposes a novel threat model called \texttt Pr ojected Displacement (PD) to study robustness beyond existing isotropic and glo bal threat models. The proposed threat model measures the threat of a perturbati on via its alignment with _unsafe directions_, defined as directions in the inpu t space along which a perturbation of sufficient magnitude changes the ground tr uth class label. Unsafe directions are identified locally for each input based o n observed training data. In this way, the PD-threat model exhibits anisotropy a nd locality. The PD-threat model is computationally efficient and can be easily integrated into existing robustness pipelines. Experiments on Imagenet-1k data i ndicate that, for any input, the set of perturbations with small PD threat inclu des _safe_ perturbations of large l_p norm that preserve the true label, such as noise, blur and compression, while simultaneously excluding _unsafe_ perturbati ons that alter the true label. Unlike perceptual threat models based on embeddin gs of large-vision models, the PD-threat model can be readily computed for arbit rary classification tasks without pre-training or finetuning. Further additional task information such as sensitivity to image regions or concept hierarchies ca n be easily integrated into the assessment of threat and thus the PD threat mode l presents practitioners a flexible, task-driven threat specification that allev iates the limitations of l_p-threat models.

Prometheus: 3D-Aware Latent Diffusion Models for Feed-Forward Text-to-3D Scene G eneration

Yuanbo Yang, Jiahao Shao, Xinyang Li, Yujun Shen, Andreas Geiger, Yiyi Liao; Pro ceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 2857-2869

In this work, we introduce Prometheus, a 3D-aware latent diffusion model for tex t-to-3D generation at both object and scene levels in seconds. We formulate 3D s cene generation as multi-view, feed-forward, pixel-aligned 3D Gaussian generatio n within the latent diffusion paradigm. To ensure generalizability, we build our model upon pre-trained text-to-image generation model with only minimal adjustm ents and further train it using a large number of images from both single-view a nd multi-view datasets. Furthermore, we introduce an RGB-D latent space into 3D Gaussian generation to disentangle appearance and geometry information, enabling efficient feed-forward generation of 3D Gaussians with better fidelity and geom etry. Extensive experimental results demonstrate the effectiveness of our method in both feed-forward 3D Gaussian reconstruction and text-to-3D generation.

No Pains, More Gains: Recycling Sub-Salient Patches for Efficient High-Resolutio n Image Recognition

Rong Qin, Xin Liu, Xingyu Liu, Jiaxuan Liu, Jinglei Shi, Liang Lin, Jufeng Yang; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2 025, pp. 14965-14975

Over the last decade, many notable methods have emerged to tackle the computatio nal resource challenge of the high resolution image recognition (HRIR). They typ ically focus on identifying and aggregating a few salient regions for classifica tion, discarding sub-salient areas for low training consumption. Nevertheless, m any HRIR tasks necessitate the exploration of wider regions to model objects and contexts, which limits their performance in such scenarios. To address this iss ue, we present a DBPS strategy to enable training with more patches at low consu mption. Specifically, in addition to a fundamental buffer that stores the embedd ings of most salient patches, DBPS further employs an auxiliary buffer to recycl e those sub-salient ones. To reduce the computational cost associated with gradi ents of sub-salient patches, these patches are primarily used in the forward pas s to provide sufficient information for classification. Meanwhile, only the grad ients of the salient patches are back-propagated to update the entire network. M oreover, we design a Multiple Instance Learning (MIL) architecture that leverage

s aggregated information from salient patches to filter out uninformative backgr ound within sub-salient patches for better accuracy. Besides, we introduce the r andom patch drop to accelerate training process and uncover informative regions. Experiment results demonstrate the superiority of our method in terms of both a ccuracy and training consumption against other advanced methods. The code is ava ilable in the https://github.com/Qinrong-NKU/DBPS.
****

SphereUFormer: A U-Shaped Transformer for Spherical 360 Perception
Yaniv Benny, Lior Wolf; Proceedings of the Computer Vision and Pattern Recogniti on Conference (CVPR), 2025, pp. 940-950
This paper proposes a novel method for omnidirectional 360\degree perception. Mo st common previous methods relied on equirectangular projection. This representa tion is easily applicable to 2D operation layers but introduces distortions into the image. Other methods attempted to remove the distortions by maintaining a s phere representation but relied on complicated convolution kernels that failed t o show competitive results. In this work, we introduce a transformer-based archi tecture that, by incorporating a novel "Spherical Local Self-Attention" and othe r spherically-oriented modules, successfully operates in the spherical domain an d outperforms the state-of-the-art in 360\degree perception benchmarks for depth estimation and semantic segmentation. Our code is available at https://github.c om/yanivbenny/sphere_uformer.

Advancing Generalizable Tumor Segmentation with Anomaly-Aware Open-Vocabulary At tention Maps and Frozen Foundation Diffusion Models
Yankai Jiang, Peng Zhang, Donglin Yang, Yuan Tian, Hai Lin, Xiaosong Wang; Proce edings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, p p. 25971-25981
We explore Generalizable Tumor Segmentation, aiming to train a single model for zero-shot tumor segmentation across diverse anatomical regions. Existing methods face limitations related to segmentation quality, scalability, and the range of applicable imaging modalities. In this paper, we uncover the potential of the i nternal representations within frozen medical foundation diffusion models as hig hly efficient zero-shot learners for tumor segmentation by introducing a novel f ramework named DiffuGTS. DiffuGTS creates anomaly-aware open-vocabulary attentio n maps based on text prompts to enable generalizable anomaly segmentation withou t being restricted by a predefined training category list. To further improve an d refine anomaly segmentation masks, DiffuGTS leverages the diffusion model, tra nsforming pathological regions into high-quality pseudo-healthy counterparts thr ough latent space inpainting, and applies a novel pixel-level and feature-level residual learning approach, resulting in segmentation masks with significantly e nhanced quality and generalization. Comprehensive experiments on four datasets a nd seven tumor categories demonstrate the superior performance of our method, su rpassing current state-of-the-art models across multiple zero-shot settings. Cod es are available at https://github.com/Yankai96/DiffuGTS.
****

Towards Generalizable Scene Change Detection
Jae-Woo Kim, Ue-Hwan Kim; Proceedings of the Computer Vision and Pattern Recogni tion Conference (CVPR), 2025, pp. 24463-24473
While current state-of-the-art Scene Change Detection (SCD) approaches achieve i mpressive results in well-trained research data, they become unreliable under un seen environments and different temporal conditions; in-domain performance drops from 77.6% to 8.0% in a previously unseen environment and to 4.6% under a diffe rent temporal condition---calling for generalizable SCD and benchmark. In this w ork, we propose the Generalizable Scene Change Detection Framework (GeSCF), whic h addresses unseen domain performance and temporal consistency---to meet the gro wing demand for anything SCD. Our method leverages the pre-trained Segment Anyth ing Model (SAM) in a zero-shot manner. For this, we design Initial Pseudo-mask G eneration and Geometric-Semantic Mask Matching---seamlessly turning user-guided prompt and single-image based segmentation into scene change detection for a pai r of inputs without guidance. Furthermore, we define the Generalizable Scene Cha

nge Detection (GeSCD) benchmark along with novel metrics and an evaluation proto col to facilitate SCD research in generalizability. In the process, we introduce the ChangeVPR dataset, a collection of challenging image pairs with diverse env ironmental scenarios---including urban, suburban, and rural settings. Extensive experiments across various datasets demonstrate that GeSCF achieves an average p erformance gain of 19.2% on existing SCD datasets and 30.0% on the ChangeVPR dat aset, nearly doubling the prior art performance. We believe our work can lay a s olid foundation for robust and generalizable SCD research.

Beyond Clean Training Data: A Versatile and Model-Agnostic Framework for Out-of-Distribution Detection with Contaminated Training Data

Yuchuan Li, Jae-Mo Kang, Il-Min Kim; Proceedings of the Computer Vision and Patt ern Recognition Conference (CVPR), 2025, pp. 10183-10192

In real-world AI applications, training datasets are often contaminated, contain ing a mix of in-distribution (ID) and out-of-distribution (OOD) samples without labels. This contamination poses a significant challenge for developing and trai ning OOD detection models, as nearly all existing methods assume access to a cle an training dataset of only ID samples--a condition rarely met in real-world sce narios. Customizing each existing OOD detection method to handle such contaminat ion is impractical, given the vast number of diverse methods designed for clean data. To address this issue, we propose a universal, model-agnostic framework th at integrates with nearly all existing OOD detection methods, enabling training on contaminated datasets while achieving high OOD detection accuracy on test dat asets. Additionally, our framework provides an accurate estimation of the unknow n proportion of OOD samples within the training dataset--an important and distin ct challenge in its own right. Our approach introduces a novel dynamic weighting function and transition mechanism within an iterative training structure, enabl ing both reliable estimation of the OOD sample proportion of the training data a nd precise OOD detection on test data. Extensive evaluations across diverse data sets, including ImageNet-1k, demonstrate that our framework accurately estimates OOD sample proportions of training data and substantially enhances OOD detectio n accuracy on test data.

Incomplete Multi-modal Brain Tumor Segmentation via Learnable Sorting State Spac e Model

Zheyu Zhang, Yayuan Lu, Feipeng Ma, Yueyi Zhang, Huanjing Yue, Xiaoyan Sun; Proc eedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 25982-25992

Brain tumor segmentation plays a crucial role in clinical diagnosis, yet the fre quent unavailability of certain MRI modalities poses a significant challenge. In this paper, we introduce the Learnable Sorting State Space Model (LS3M), a nove l framework designed to maximize the utilization of available modalities for bra in tumor segmentation. LS3M excels at efficiently modeling long-range dependenci es based on the Mamba design, while incorporating differentiable permutation mat rices that reorder input sequences based on modality-specific characteristics. T his dynamic reordering ensures that critical spatial inductive biases and long-r ange semantic correlations inherent in 3D brain MRI are preserved, which is cruc ial for imcomplete multi-modal brain tumor segmentation.Once the input sequences are reordered using the generated permutation matrix, the Series State Space Mo del (S3M) block models the relationships between them, capturing both local and long-range dependencies. This enables effective representation of intra-modal an d inter-modal relationships, significantly improving segmentation accuracy. Exte nsive experiments on the BraTS2018 and BraTS2020 datasets demonstrate that LS3M outperforms existing methods, offering a robust solution for brain tumor segment ation, particularly in scenarios with missing modalities.

FedAWA: Adaptive Optimization of Aggregation Weights in Federated Learning Using Client Vectors

Changlong Shi, He Zhao, Bingjie Zhang, Mingyuan Zhou, Dandan Guo, Yi Chang; Proc eedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025,

pp. 30651-30660
Federated Learning (FL) has emerged as a promising framework for distributed machine learning, enabling collaborative model training without sharing local data, thereby preserving privacy and enhancing security. However, data heterogeneity resulting from differences across user behaviors, preferences, and device characteristics poses a significant challenge for federated learning. Most previous works overlook the adjustment of aggregation weights, relying solely on dataset size for weight assignment, which often leads to unstable convergence and reduced model performance. Recently, several studies have sought to refine aggregation strategies by incorporating dataset characteristics and model alignment. However, adaptively adjusting aggregation weights while ensuring data security--without requiring additional proxy data--remains a significant challenge. In this work, we propose Federated learning with Adaptive Weight Aggregation (FedAWA), a novel method that adaptively adjusts aggregation weights based on client vectors during the learning process. The client vector captures the direction of model updates, reflecting local data variations, and is used to optimize the aggregation weight without requiring additional datasets or violating privacy. By assigning higher aggregation weights to local models whose updates align closely with the global optimization direction, FedAWA enhances the stability and generalization of the global model. Extensive experiments under diverse scenarios demonstrate the superiority of our method, providing a promising solution to the challenges of data heterogeneity in federated learning.

FreeUV: Ground-Truth-Free Realistic Facial UV Texture Recovery via Cross-Assembly Inference Strategy
Xingchao Yang, Takafumi Taketomi, Yuki Endo, Yoshihiro Kanamori; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 326-337
Recovering high-quality 3D facial textures from single-view 2D images is a challenging task, especially under constraints of limited data and complex facial details such as makeup, wrinkles, and occlusions. In this paper, we introduce FreeUV, a novel ground-truth-free UV texture recovery framework that eliminates the need for annotated or synthetic UV data. FreeUV leverages pre-trained stable diffusion model alongside a Cross-Assembly inference strategy to fulfill this objective. In FreeUV, separate networks are trained independently to focus on realistic appearance and structural consistency, and these networks are combined during inference to generate coherent textures. Our approach accurately captures intricate facial features and demonstrates robust performance across diverse poses and occlusions. Extensive experiments validate FreeUV's effectiveness, with results surpassing state-of-the-art methods in both quantitative and qualitative metrics. Additionally, FreeUV enables new applications, including local editing, facial feature interpolation, and multi-view texture recovery. By reducing data requirements, FreeUV offers a scalable solution for generating high-fidelity 3D facial textures suitable for real-world scenarios.

HarmonySet: A Comprehensive Dataset for Understanding Video-Music Semantic Alignment and Temporal Synchronization
Zitang Zhou, Ke Mei, Yu Lu, Tianyi Wang, Fengyun Rao; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 3152-3162
This paper introduces HarmonySet, a comprehensive dataset designed to advance video-music understanding. HarmonySet consists of 48,328 diverse video-music pairs, annotated with detailed information on rhythmic synchronization, emotional alignment, thematic coherence, and cultural relevance. We propose a multi-step human-machine collaborative framework for efficient annotation, combining human insights with machine-generated descriptions to identify key transitions and assess alignment across multiple dimensions. Additionally, we introduce a novel evaluation framework with tasks and metrics to assess the multi-dimensional alignment of video and music, including rhythm, emotion, theme, and cultural context. Our extensive experiments demonstrate that HarmonySet, along with the proposed evaluation framework, significantly improves the ability of multimodal models to capture and analyze the intricate relationships between video and music. Rethinking Diffusion for Text-Driven Human Motion Generation: Redundant Representations, Evaluation, and Masked Autoregression
Zichong Meng, Yiming Xie, Xiaogang Peng, Zeyu Han, Huaizu Jiang; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 27859-27871
Since 2023, Vector Quantization (VQ)-based discrete generation methods have rapidly dominated human motion generation, primarily surpassing diffusion-based continuous generation methods in standard performance metrics. However, VQ-based methods have inherent limitations. Representing continuous motion data as limited discrete tokens leads to inevitable information loss, reduces the diversity of generated motions, and restricts their ability to function effectively as motion priors or generation guidance. In contrast, the continuous space generation nature of diffusion-based methods makes them well-suited to address these limitations and with even potential for model scalability. In this work, we systematically investigate why current VQ-based methods perform well and explore the limitations of existing diffusion-based methods from the perspective of motion data representation and distribution. Drawing on these insights, we preserve the inherent strengths of a diffusion-based human motion generation model and gradually optimize it with inspiration from VQ-based approaches. Our approach introduces a human motion diffusion model enabled to perform masked autoregression, optimized with a reformed data representation and distribution. Additionally, we propose a more robust evaluation method to assess different approaches. Extensive experiments on various datasets demonstrate our method outperforms previous methods and achieves state-of-the-art performances.

StyleMaster: Stylize Your Video with Artistic Generation and Translation
Zixuan Ye, Huijuan Huang, Xintao Wang, Pengfei Wan, Di Zhang, Wenhan Luo; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 2630-2640
Style control has been popular in video generation models. Existing methods often generate videos far from the given style, cause content leakage, and struggle to transfer one video to the desired style. Our first observation is that the style extraction stage matters, whereas existing methods emphasize global style but ignore local textures. In order to bring texture features while preventing content leakage, we filter content-related patches while retaining style ones based on prompt-patch similarity; for global style extraction, we generate a paired style dataset through model illusion to facilitate contrastive learning, which greatly enhances the absolute style consistency. Moreover, to fill in the image-to-video gap, we train a lightweight motion adapter on still videos, which implicitly enhances stylization extent, and enables our image-trained model to be seamlessly applied to videos. Benefited from these efforts, our approach, StyleMaster, not only achieves significant improvement in both style resemblance and temporal coherence, but also can easily generalize to video style transfer with a gray tile ControlNet. Extensive experiments and visualizations demonstrate that StyleMaster significantly outperforms competitors, effectively generating high-quality stylized videos that align with textual content and closely resemble the style of reference images.

Unsupervised Continual Domain Shift Learning with Multi-Prototype Modeling
Haopeng Sun, Yingwei Zhang, Lumin Xu, Sheng Jin, Ping Luo, Chen Qian, Wentao Liu, Yiqiang Chen; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 10131-10141
In real-world applications, deep neural networks may encounter constantly changing environments, where the test data originates from continually shifting unlabeled target domains. This problem, known as Unsupervised Continual Domain Shift Learning (UCDSL), poses practical difficulties. Existing methods for UCDSL aim to learn domain-invariant representations for all target domains. However, due to the existence of adaptivity gap, the invariant representation may theoretically

lead to large joint errors. To overcome the limitation, we propose a novel UCDSL method, called Multi-Prototype Modeling (MPM). Our model comprises two key components: (1) Multi-Prototype Learning (MPL) for acquiring domain-specific representations using multiple domain-specific prototypes. MPL achieves domain-specific error minimization instead of enforcing feature alignment across different domains. (2) Bi-Level Graph Enhancer (BiGE) for enhancing domain-level and category-level representations, resulting in more accurate predictions. We provide theoretical and empirical analysis to demonstrate the effectiveness of our proposed method. We evaluate our approach on multiple benchmark datasets and show that our model surpasses state-of-the-art methods across all datasets, highlighting its effectiveness and robustness in handling unsupervised continual domain shift learning. Codes will be publicly accessible.

OmniGuard: Hybrid Manipulation Localization via Augmented Versatile Deep Image Watermarking

Xuanyu Zhang, Zecheng Tang, Zhipei Xu, Runyi Li, Youmin Xu, Bin Chen, Feng Gao, Jian Zhang; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 3008-3018

With the rapid growth of generative AI and its widespread application in image editing, new risks have emerged regarding the authenticity and integrity of digital content. Existing versatile watermarking approaches suffer from trade-offs between tamper localization precision and visual quality. Constrained by the limited flexibility of previous framework, their localized watermark must remain fixed across all images. Under AIGC-editing, their copyright extraction accuracy is also unsatisfactory. To address these challenges, we propose OmniGuard, a novel augmented versatile watermarking approach that integrates proactive embedding with passive, blind extraction for robust copyright protection and tamper localization. OmniGuard employs a hybrid forensic framework that enables flexible localization watermark selection and introduces a degradation-aware tamper extraction network for precise localization under challenging conditions. Additionally, a lightweight AIGC-editing simulation layer is designed to enhance robustness across global and local editing. Extensive experiments show that OmniGuard achieves superior fidelity, robustness, and flexibility. Compared to the recent state-of-the-art approach EditGuard, our method outperforms it by 4.25dB in PSNR of the container image, 20.7% in F1-Score under noisy conditions, and 14.8% in average bit accuracy.

Open-Canopy: Towards Very High Resolution Forest Monitoring

Fajwel Fogel, Yohann Perron, Nikola Besic, Laurent Saint-André, Agnès Pellissier-Tanon, Martin Schwartz, Thomas Boudras, Ibrahim Fayad, Alexandre d'Aspremont, Loic Landrieu, Philippe Ciais; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 1395-1406

Estimating canopy height and its changes at meter resolution from satellite imagery is a significant challenge in computer vision with critical environmental applications. However, the lack of open-access datasets at this resolution hinders the reproducibility and evaluation of models. We introduce Open-Canopy, the first open-access, country-scale benchmark for very high-resolution (1.5 m) canopy height estimation, covering over 87,000 km2 across France with 1.5 m resolution satellite imagery and aerial LiDAR data. Additionally, we present Open-Canopy-, a benchmark for canopy height change detection between images from different years at tree level--a challenging task for current computer vision models. We evaluate state-of-the-art architectures on these benchmarks, highlighting significant challenges and opportunities for improvement. Our datasets and code are publicly available at https://github.com/fajwel/Open-Canopy.

****

ClearSight: Visual Signal Enhancement for Object Hallucination Mitigation in Multimodal Large Language Models

Hao Yin, Guangzong Si, Zilei Wang; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 14625-14634

Contrastive decoding strategies are widely used to mitigate object hallucination

s in multimodal large language models (MLLMs). By reducing over-reliance on lang
uage priors, these strategies ensure that generated content remains closely grou
nded in visual inputs, producing contextually accurate outputs. Since contrastiv
e decoding requires no additional training or external tools, it offers both com
putational efficiency and versatility, making it highly attractive. However, the
se methods present two main limitations: (1) bluntly suppressing language priors
 can compromise coherence and accuracy of generated content, and (2) processing
contrastive inputs adds computational load, significantly slowing inference spee
d. To address these challenges, we propose Visual Amplification Fusion (VAF), a
plug-and-play technique that enhances attention to visual signals within the mod
el's middle layers, where modality fusion predominantly occurs. This approach en
ables more effective capture of visual features, reducing the model's bias towar
d language modality. Experimental results demonstrate that VAF significantly red
uces hallucinations across various MLLMs without affecting inference speed, whil
e maintaining coherence and accuracy in generated outputs.

Stretching Each Dollar: Diffusion Training from Scratch on a Micro-Budget
Vikash Sehwag, Xianghao Kong, Jingtao Li, Michael Spranger, Lingjuan Lyu; Procee
dings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp
. 28596-28608
As scaling laws in generative AI push performance, they simultaneously concentra
te the development of these models among actors with large computational resourc
es. With a focus on text-to-image (T2I) generative models, we aim to unlock this
 bottleneck by demonstrating very low-cost training of large-scale T2I diffusion
 transformer models. As the computational cost of transformers increases with th
e number of patches in each image, we propose randomly masking up to 75% of the
image patches during training. We propose a deferred masking strategy that prepr
ocesses all patches using a patch-mixer before masking, thus significantly reduc
ing the performance degradation with masking, making it superior to model downsc
aling in reducing computational cost. We also incorporate the latest improvement
s in transformer architecture, such as the use of mixture-of-experts layers, to
improve performance and further identify the critical benefit of using synthetic
 images in micro-budget training. Finally, using only 37M publicly available rea
l and synthetic images, we train a 1.16 billion parameter sparse transformer wit
h only 1,890 USD economical cost and achieve a 12.7 FID in zero-shot generation
on the COCO dataset. Notably, our model achieves competitive performance across
both automated and human-centric evaluations, as well as high-quality generation
s, while incurring 118xlower costs than Stable Diffusion models and 14xlower cos
ts than the current state-of-the-art approach, which costs \28,400. We also furt
her investigate the influence of synthetic images on performance and demonstrate
 that micro-budget training on only synthetic images is sufficient for achieving
 high-quality data generation. Our end-to-end training pipeline and model checkp
oints are available at https://github.com/SonyResearch/micro_diffusion.

Guiding Human-Object Interactions with Rich Geometry and Relations
Mengqing Xue, Yifei Liu, Ling Guo, Shaoli Huang, Changxing Ding; Proceedings of
the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 22714-2
2723
Human-object interaction (HOI) synthesis is crucial for creating immersive and r
ealistic experiences for applications such as virtual reality. Existing methods
often rely on simplified object representations, such as the object's centroid o
r the nearest point to a human, to achieve physically plausible motions. However
, these approaches may overlook geometric complexity, resulting in suboptimal in
teraction fidelity. To address this limitation, we introduce ROG, a novel diffus
ion-based framework that models the spatiotemporal relationships inherent in HOI
s with rich geometric detail. For efficient object representation, we select bou
ndary-focused and fine-detail key points from the object mesh, ensuring a compre
hensive depiction of the object's geometry. This representation is used to const
ruct an interactive distance field (IDF), capturing the robust HOI dynamics. Fur
thermore, we develop a diffusion-based relation model that integrates spatial an

d temporal attention mechanisms, enabling a better understanding of intricate HOI relationships. This relation model refines the generated motion's IDF, guiding the motion generation process to produce relation-aware and semantically aligned movements. Experimental evaluations demonstrate that ROG significantly outperforms state-of-the-art methods in the realism and semantic accuracy of synthesized HOIs. This paper's code will be released.

TacoDepth: Towards Efficient Radar-Camera Depth Estimation with One-stage Fusion
Yiran Wang, Jiaqi Li, Chaoyi Hong, Ruibo Li, Liusheng Sun, Xiao Song, Zhe Wang, Zhiguo Cao, Guosheng Lin; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 10523-10533
Radar-Camera depth estimation aims to predict dense and accurate metric depth by fusing input images and Radar data. Model efficiency is crucial for this task in pursuit of real-time processing on autonomous vehicles and robotic platforms. However, due to the sparsity of Radar returns, the prevailing methods adopt multi-stage frameworks with intermediate quasi-dense depth, which are time-consuming and not robust. To address these challenges, we propose TacoDepth, an efficient and accurate Radar-Camera depth estimation model with one-stage fusion. Specifically, the graph-based Radar structure extractor and the pyramid-based Radar fusion module are designed to capture and integrate the graph structures of Radar point clouds, delivering superior model efficiency and robustness without relying on the intermediate depth results. Moreover, TacoDepth can be flexible for different inference modes, providing a better balance of speed and accuracy. Extensive experiments are conducted to demonstrate the efficacy of our method. Compared with the previous state-of-the-art approach, TacoDepth improves depth accuracy and processing speed by 12.8% and 91.8%. Our work provides a new perspective on efficient Radar-Camera depth estimation.

Physical Plausibility-aware Trajectory Prediction via Locomotion Embodiment
Hiromu Taketsugu, Takeru Oba, Takahiro Maeda, Shohei Nobuhara, Norimichi Ukita; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 12324-12334
Humans can predict future human trajectories even from momentary observations by using human pose-related cues. However, previous Human Trajectory Prediction (HTP) methods leverage the pose cues implicitly, resulting in implausible predictions. To address this, we propose Locomotion Embodiment, a framework that explicitly evaluates the physical plausibility of the predicted trajectory by locomotion generation under the laws of physics. While the plausibility of locomotion is learned with an indifferentiable physics simulator, it is replaced by our differentiable Locomotion Value function to train an HTP network in a data-driven manner. In particular, our proposed Embodied Locomotion loss is beneficial for efficiently training a stochastic HTP network using multiple heads. Furthermore, the Locomotion Value filter is proposed to filter out implausible trajectories at inference. Experiments demonstrate that our method enhances even the state-of-the-art HTP methods across diverse datasets and problem settings. Our code is available at: https://github.com/ImIntheMiddle/EmLoco.
****

CADDreamer: CAD Object Generation from Single-view Images
Yuan Li, Cheng Lin, Yuan Liu, Xiaoxiao Long, Chenxu Zhang, Ningna Wang, Xin Li, Wenping Wang, Xiaohu Guo; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 21448-21457
The field of diffusion-based 3D generation has experienced tremendous progress in recent times. However, existing 3D generative models often produce overly dense and unstructured meshes, which are in stark contrast to the compact, structured and clear-edged CAD models created by human modelers. We introduce CADDreamer, a novel method for generating CAD objects from a single image. This method proposes a primitive-aware multi-view diffusion model, which perceives both local geometry and high-level structural semantics during the generation process. We encode primitive semantics into the color domain, and enforce the strong priors in pre-trained diffusion models to align with the well-defined primitives. As a res

ult, we can infer multi-view normal maps and semantic maps from a single image, thereby reconstructing a mesh with primitive labels. Correspondingly, we propose a set of fitting and optimization methods to deal with the inevitable noise and distortion in generated primitives, ultimately producing a complete and seamless Boundary Representation (B-rep) of a Computer-Aided Design (CAD) model. Experimental results demonstrate that our method can effectively recover high-quality CAD objects from single-view images. Compared to existing 3D generation methods, the models produced by CADDreamer are compact in representation, clear in structure, sharp in boundaries, and watertight in topology.

Vision-Language Model IP Protection via Prompt-based Learning
Lianyu Wang, Meng Wang, Huazhu Fu, Daoqiang Zhang; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 9497-9506
Vision-language models (VLMs) like CLIP (Contrastive Language-Image Pre-Training) have seen remarkable success in visual recognition, highlighting the increasing need to safeguard the intellectual property (IP) of well-trained models. Effective IP protection extends beyond ensuring authorized usage; it also necessitates restricting model deployment to authorized data domains, particularly when the model is fine-tuned for specific target domains. However, current IP protection methods often rely solely on the visual backbone, which may lack sufficient semantic richness. To bridge this gap, we introduce IP-CLIP, a lightweight IP protection strategy tailored to CLIP, employing a prompt-based learning approach. By leveraging the frozen visual backbone of CLIP, we extract both image style and content information, incorporating them into the learning of IP prompt. This strategy acts as a robust barrier, effectively preventing the unauthorized transfer of features from authorized domains to unauthorized ones. Additionally, we propose a style-enhancement branch that constructs feature banks for both authorized and unauthorized domains. This branch integrates self-enhanced and cross-domain features, further strengthening IP-CLIP's capability to block features from unauthorized domains. Finally, we present new three metrics designed to better balance the performance degradation of authorized and unauthorized domains. Comprehensive experiments in various scenarios demonstrate its promising potential for application in IP protection tasks for VLMs.

Where's the Liability in the Generative Era? Recovery-based Black-Box Detection of AI-Generated Content
Haoyue Bai, Yiyou Sun, Wei Cheng, Haifeng Chen; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 28821-28830
The recent proliferation of photorealistic images created by generative models has sparked both excitement and concern, as these images are increasingly indistinguishable from real ones to the human eye. While offering new creative and commercial possibilities, the potential for misuse, such as in misinformation and fraud, highlights the need for effective detection methods. Current detection approaches often rely on access to model weights or require extensive collections of real image datasets, limiting their scalability and practical application in real-world scenarios. In this work, we introduce a novel black-box detection framework that requires only API access, sidestepping the need for model weights or large auxiliary datasets. Our approach leverages a corrupt-and-recover strategy: by masking part of an image and assessing the model's ability to reconstruct it, we measure the likelihood that the image was generated by the model itself. For black-box models that do not support masked-image inputs, we incorporate a cost-efficient surrogate model trained to align with the target model's distribution, enhancing detection capability. Our framework demonstrates strong performance, outperforming baseline methods by 4.31% in mean average precision across eight diffusion model variant datasets.

Kiss3DGen: Repurposing Image Diffusion Models for 3D Asset Generation
Jiantao Lin, Xin Yang, Meixi Chen, Yingjie Xu, Dongyu Yan, Leyi Wu, Xinli Xu, Lie Xu, Shunsi Zhang, Ying-Cong Chen; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 5870-5880

Diffusion models have achieved great success in generating 2D images. However, t
he quality and generalizability of 3D content generation remain limited. State-o
f-the-art methods often require large-scale 3D assets for training, which are ch
allenging to collect. In this work, we introduce Kiss3DGen (Keep It Simple and S
traightforward in 3D Generation), an efficient framework for generating, editing
, and enhancing 3D objects by repurposing a well-trained 2D image diffusion mode
l for 3D generation. Specifically, we fine-tune a diffusion model to generate "3
D Bundle Image", a tiled representation composed of multi-view images and their
corresponding normal maps. The normal maps are then used to reconstruct a 3D mes
h, and the multi-view images provide texture mapping, resulting in a complete 3D
 model. This simple method effectively transforms the 3D generation problem into
 a 2D image generation task, maximizing the utilization of knowledge in pretrain
ed diffusion models. Furthermore, we demonstrate that our Kiss3DGen model is com
patible with various diffusion model techniques, enabling advanced features such
 as 3D editing, mesh and texture enhancement, etc. Through extensive experiments
, we demonstrate the effectiveness of our approach, showcasing its ability to pr
oduce high-quality 3D models efficiently.

DiTASK: Multi-Task Fine-Tuning with Diffeomorphic Transformations
Krishna Sri Ipsit Mantri, Carola-Bibiane Schönlieb, Bruno Ribeiro, Chaim Baskin,
 Moshe Eliasof; Proceedings of the Computer Vision and Pattern Recognition Confe
rence (CVPR), 2025, pp. 25218-25229
Pre-trained Vision Transformers now serve as powerful tools for computer vision.
 Yet, efficiently adapting them for multiple tasks remains a challenge that aris
es from the need to modify the rich hidden representations encoded by the learne
d weight matrices, without inducing interference between tasks. Current paramete
r-efficient methods like LoRA, which apply low-rank updates, force tasks to comp
ete within constrained subspaces, ultimately degrading performance. We introduce
 DiTASK, a novel Diffeomorphic Multi-Task Fine-Tuning approach that maintains pr
e-trained representations by preserving weight matrix singular vectors, while en
abling task-specific adaptations through neural diffeomorphic transformations of
 the singular values. By following this approach, DiTASK enables both shared and
 task-specific feature modulations with minimal added parameters. Our theoretic
al analysis shows that DiTASK achieves full-rank updates during optimization, pr
eserving the geometric structure of pre-trained features, and establishing a new
 paradigm for efficient multi-task learning (MTL). Our experiments on PASCAL MTL
 and NYUD show that DiTASK achieves state-of-the-art performance across four den
se prediction tasks, using 75% fewer parameters than existing methods.

OW-OVD: Unified Open World and Open Vocabulary Object Detection
Xing Xi, Yangyang Huang, Ronghua Luo, Yu Qiu; Proceedings of the Computer Vision
 and Pattern Recognition Conference (CVPR), 2025, pp. 25454-25464
Open world perception expands traditional closed-set frameworks, which assume a
predefined set of known categories, to encompass dynamic real-world environments
. Open World Object Detection (OWOD) and Open Vocabulary Object Detection (OVD)
are two main research directions, each addressing unique challenges in dynamic e
nvironments. However, existing studies often focus on only one of these tasks, l
eaving the combined challenges of OWOD and OVD largely underexplored. In this pa
per, we propose a novel detector, OW-OVD, which inherits the zero-shot generaliz
ation capability of OVD detectors while incorporating the ability to actively de
tect unknown objects and progressively optimize performance through incremental
learning, as seen in OWOD detectors. To achieve this, we start with a standard O
VD detector and adapt it for OWOD tasks. For attribute selection, we propose the
 Visual Similarity Attribute Selection (VSAS) method, which identifies the most
generalizable attributes by computing similarity distributions across annotated
and unannotated regions. Additionally, to ensure the diversity of attributes, we
 incorporate a similarity constraint in the iterative process. Finally, to prese
rve the standard inference process of OVD, we propose the Hybrid Attribute-Uncer
tainty Fusion (HAUF) method. This method combines attribute similarity with know
n class uncertainty to infer the likelihood of an object belonging to an unknown

class. We validated the effectiveness of OW-OVD through evaluations on two OWOD benchmarks, M-OWODB and S-OWODB. The results demonstrate that OW-OVD outperforms existing state-of-the-art models, achieving a +15.3 improvement in unknown object recall (U-Recall) and a +15.5 increase in unknown class average precision (U-mAP). Our code is available at: https://github.com/xxyzll/OW_OVD.

Improving Diffusion Inverse Problem Solving with Decoupled Noise Annealing
Bingliang Zhang, Wenda Chu, Julius Berner, Chenlin Meng, Anima Anandkumar, Yang Song; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 20895-20905
Diffusion models have recently achieved success in solving Bayesian inverse problems with learned data priors. Current methods build on top of the diffusion sampling process, where each denoising step makes small modifications to samples from the previous step. However, this process struggles to correct errors from earlier sampling steps, leading to worse performance in complicated nonlinear inverse problems, such as phase retrieval. To address this challenge, we propose a new method called Decoupled Annealing Posterior Sampling (DAPS) that relies on a novel noise annealing process. Specifically, we decouple consecutive steps in a diffusion sampling trajectory, allowing them to vary considerably from one another while ensuring their time-marginals anneal to the true posterior as we reduce noise levels. This approach enables the exploration of a larger solution space, improving the success rate for accurate reconstructions. We demonstrate that DAPS significantly improves sample quality and stability across multiple image restoration tasks, particularly in complicated nonlinear inverse problems.

AvatarArtist: Open-Domain 4D Avatarization
Hongyu Liu, Xuan Wang, Ziyu Wan, Yue Ma, Jingye Chen, Yanbo Fan, Yujun Shen, Yibing Song, Qifeng Chen; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 10758-10769
This work focuses on open-domain 4D avatarization, with the purpose of creating a 4D avatar from a portrait image in an arbitrary style. We select parametric triplanes as the intermediate 4D representation, and propose a practical training paradigm that takes advantage of both generative adversarial networks (GANs) and diffusion models. Our design stems from the observation that 4D GANs excel at bridging images and triplanes without supervision yet usually face challenges in handling diverse data distributions. A robust 2D diffusion prior emerges as the solution, assisting the GAN in transferring its expertise across various domains. The synergy between these experts permits the construction of a multi-domain image-triplane dataset, which drives the development of a general 4D avatar creator. Extensive experiments suggest that our model, termed AvatarArtist, is capable of producing high-quality 4D avatars with strong robustness to various source image domains. The code, the data, and the models will be made publicly available to facilitate future studies.
****

DesignDiffusion: High-Quality Text-to-Design Image Generation with Diffusion Models
Zhendong Wang, Jianmin Bao, Shuyang Gu, Dong Chen, Wengang Zhou, Houqiang Li; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 20906-20915
In this paper, we present DesignDiffusion, a simple yet effective framework for the novel task of synthesizing design images from textual descriptions. A primary challenge lies in generating accurate and style-consistent textual and visual content. Existing works in a related task of visual text generation often focus on generating text within given specific regions, which limits the creativity of generation models, resulting in style or color inconsistencies between textual and visual elements if applied to design image generation. To address this issue, we propose an end-to-end, one-stage diffusion-based framework that avoids intricate components like position and layout modeling. Specifically, the proposed framework directly synthesizes textual and visual design elements from user prompts. It utilizes a distinctive character embedding derived from the visual text t

o enhance the input prompt, along with a character localization loss for enhanced supervision during text generation. Furthermore, we employ a self-play Direct Preference Optimization fine-tuning strategy to improve the quality and accuracy of the synthesized visual text. Extensive experiments demonstrate that DesignDiffusion achieves state-of-the-art performance in design image generation.
****

Using Powerful Prior Knowledge of Diffusion Model in Deep Unfolding Networks for Image Compressive Sensing
Chen Liao, Yan Shen, Dan Li, Zhongli Wang; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 18000-18010
Recently, Deep Unfolding Networks (DUNs) have achieved impressive reconstruction quality in the field of image Compressive Sensing (CS) by unfolding iterative optimization algorithms into neural networks. The reconstruction quality of DUNs depends on the learned prior knowledge, so introducing stronger prior knowledge can further improve reconstruction quality. On the other hand, pre-trained diffusion models contain powerful prior knowledge and have a solid theoretical foundation and strong scalability, but it requires a large number of iterative steps to achieve reconstruction. In this paper, we propose to use the powerful prior knowledge of pre-trained diffusion model in DUNs to achieve high-quality reconstruction with less steps for image CS. Specifically, we first design an iterative optimization algorithm named Diffusion Message Passing (DMP), which embeds a pre-trained diffusion model into each iteration process of DMP. Then, we deeply unfold the DMP algorithm into a neural network named DMP-DUN. The proposed DMP-DUN can use lightweight neural networks to achieve mapping from measurement data to the intermediate steps of the reverse diffusion process and directly approximate the divergence of the diffusion model, thereby further improving reconstruction efficiency. Extensive experiments show that our proposed DMP-DUN achieves state-of-the-art performance and requires at least only 2 steps to reconstruct the image. Codes are available at https://github.com/FengodChen/DMP-DUN-CVPR2025.

Koala-36M: A Large-scale Video Dataset Improving Consistency between Fine-grained Conditions and Video Content
Qiuheng Wang, Yukai Shi, Jiarong Ou, Rui Chen, Ke Lin, Jiahao Wang, Boyuan Jiang, Haotian Yang, Mingwu Zheng, Xin Tao, Fei Yang, Pengfei Wan, Di Zhang; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 8428-8437
With the continuous progress of visual generation technologies, the scale of video datasets has grown exponentially. The quality of these datasets plays a pivotal role in the performance of video generation models. We assert that temporal splitting, detailed captions, and video quality filtering are three crucial determinants of dataset quality. However, existing datasets exhibit various limitations in these areas. To address these challenges, we introduce Koala-36M, a large-scale, high-quality video dataset featuring accurate temporal splitting, detailed captions, and superior video quality. The essence of our approach lies in improving the consistency between fine-grained conditions and video content. Specifically, we employ a linear classifier on probability distributions to enhance the accuracy of transition detection, ensuring better temporal consistency. We then provide structured captions for the splitted videos, with an average length of 200 words, to improve text-video alignment. Additionally, we develop a Video Training Suitability Score (VTSS) that integrates multiple sub-metrics, allowing us to filter high-quality videos from the original corpus. Finally, we incorporate several metrics into the training process of the generation model, further refining the fine-grained conditions. Our experiments demonstrate the effectiveness of our data processing pipeline and the quality of the proposed Koala-36M dataset. Our dataset and code have been released at https://koala36m.github.io/.

VASparse: Towards Efficient Visual Hallucination Mitigation via Visual-Aware Token Sparsification
Xianwei Zhuang, Zhihong Zhu, Yuxin Xie, Liming Liang, Yuexian Zou; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 4189-

4199
Large Vision-Language Models (LVLMs) may produce outputs that are unfaithful to reality, also known as visual hallucinations (VH), which significantly impedes their real-world usage. To alleviate VH, various decoding strategies have been proposed to enhance visual information. However, many of these methods may require secondary decoding and rollback, which significantly reduces inference speed. In this work, we propose an efficient plug-and-play decoding algorithm via Visual-Aware Sparsification (VASparse) from the perspective of token sparsity for mitigating VH. VASparse is inspired by empirical observations: (1) the sparse activation of attention in LVLMs, and (2) visual-agnostic tokens sparsification exacerbates VH. Based on these insights, we propose a novel token sparsification strategy that balances efficiency and trustworthiness. Specifically, VASparse implements a visual-aware token selection strategy during decoding to reduce redundant tokens while preserving visual context effectively. Additionally, we innovatively introduce a sparse-based visual contrastive decoding method to recalibrate the distribution of hallucinated outputs without the time overhead associated with secondary decoding. Subsequently, VASparse recalibrates attention scores to penalize attention sinking of LVLMs towards text tokens. Extensive experiments across four popular benchmarks confirm the effectiveness of VASparse in mitigating VH across different LVLM families without requiring additional training or post-processing. Impressively, VASparse achieves state-of-the-art performance for mitigating VH while maintaining competitive decoding speed. Code is available at https://github.com/mengchuang123/VASparse-github.

SPARC: Score Prompting and Adaptive Fusion for Zero-Shot Multi-Label Recognition in Vision-Language Models
Kevin Miller, Aditya Gangrade, Samarth Mishra, Kate Saenko, Venkatesh Saligrama; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 4313-4321
Zero-shot multi-label recognition (MLR) with Vision-Language Models (VLMs) faces significant challenges without training data, model tuning, or architectural modifications. Existing approaches require prompt tuning or architectural adaptations, limiting zero-shot applicability. Our work proposes a novel solution treating VLMs as black boxes, leveraging scores without training data or ground truth. We make two contributions. First, we find that VLM scores suffer from image- and prompt-specific biases, and that simple standardization is surprisingly effective at removing these and boosting MLR performance. And second, we introduce compound prompts grounded in realistic object combinations. Our analysis reveals "AND"/"OR" signal ambiguities that cause maximum compound scores to be surprisingly suboptimal compared to second-highest scores. We introduce an adaptive fusion method to address this issue. Our method enhances other zero-shot approaches, consistently improving their results. Experiments show superior mean Average Precision (mAP) compared to methods requiring training data, achieved through refined object ranking for robust zero-shot MLR. Code can be found at https://github.com/kjmillerCURIS/SPARC.
****

UniGoal: Towards Universal Zero-shot Goal-oriented Navigation
Hang Yin, Xiuwei Xu, Linqing Zhao, Ziwei Wang, Jie Zhou, Jiwen Lu; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 19057-19066
In this paper, we propose a general framework for universal zero-shot goal-oriented navigation. Existing zero-shot methods build inference framework upon large language models (LLM) for specific tasks, which differs a lot in overall pipeline and fails to generalize across different types of goal. Towards the aim of universal zero-shot navigation, we propose a uniform graph representation to unify different goals, including object category, instance image and text description. We also convert the observation of agent into an online maintained scene graph. With this consistent scene and goal representation, we preserve most structural information compared with pure text and are able to leverage LLM for explicit graph-based reasoning.Specifically, we conduct graph matching between the scene g

raph and goal graph at each time instant and propose different strategies to gen
erate long-term goal of exploration according to different matching states. The
agent first iteratively searches subgraph of goal when zero-matched. With partia
l matching, the agent then utilizes coordinate projection and anchor pair alignm
ent to infer the goal location. Finally scene graph correction and goal verifica
tion are applied for perfect matching. We also present a blacklist mechanism to
enable robust switch between stages.Extensive experiments on several benchmarks
show that our UniGoal achieves state-of-the-art zero-shot performance on three s
tudied navigation tasks with a single model, even outperforming task-specific ze
ro-shot methods and supervised universal methods.

Noise-Consistent Siamese-Diffusion for Medical Image Synthesis and Segmentation
Kunpeng Qiu, Zhiqiang Gao, Zhiying Zhou, Mingjie Sun, Yongxin Guo; Proceedings o
f the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 15672
-15681
Deep learning has revolutionized medical image segmentation, yet its full potent
ial remains constrained by the paucity of annotated datasets. While diffusion mo
dels have emerged as a promising approach for generating synthetic image-mask pa
irs to augment these datasets, they paradoxically suffer from the same data scar
city challenges they aim to mitigate. Traditional mask-only models frequently yi
eld low-fidelity images due to their inability to adequately capture morphologic
al intricacies, which can critically compromise the robustness and reliability o
f segmentation models. To alleviate this limitation, we introduce Siamese-Diffus
ion, a novel dual-component model comprising Mask-Diffusion and Image-Diffusion.
 During training, a Noise Consistency Loss is introduced between these component
s to enhance the morphological fidelity of Mask-Diffusion in the parameter space
. During sampling, only Mask-Diffusion is used, ensuring diversity and scalabili
ty. Comprehensive experiments demonstrate the superiority of our method. Siamese
-Diffusion boosts SANet's mDice and mIoU by 3.6% and 4.4% on the Polyps, while U
Net improves by 1.52% and 1.64% on the ISIC2018.

DefectFill: Realistic Defect Generation with Inpainting Diffusion Model for Visu
al Inspection
Jaewoo Song, Daemin Park, Kanghyun Baek, Sangyub Lee, Jooyoung Choi, Eunji Kim,
Sungroh Yoon; Proceedings of the Computer Vision and Pattern Recognition Confere
nce (CVPR), 2025, pp. 18718-18727
Developing effective visual inspection models remains challenging due to the sca
rcity of defect data. While image generation models have been used to synthesize
 defect images, producing highly realistic defects remains difficult. We propose
 DefectFill, a novel method for realistic defect generation that requires only a
 few reference defect images. It leverages a fine-tuned inpainting diffusion mod
el, optimized with our custom loss functions incorporating defect, object, and a
ttention terms. It enables precise capture of detailed, localized defect feature
s and their seamless integration into defect-free objects. Additionally, our Low
-Fidelity Selection method further enhances the defect sample quality. Experimen
ts show that DefectFill generates high-quality defect images, enabling visual in
spection models to achieve state-of-the-art performance on the MVTec AD dataset.

Less is More: Efficient Image Vectorization with Adaptive Parameterization
Kaibo Zhao, Liang Bao, Yufei Li, Xu Su, Ke Zhang, Xiaotian Qiao; Proceedings of
the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 18166-1
8175
Image vectorization aims to convert raster images to vector ones, allowing for e
asy scaling and editing.Existing works mainly rely on preset parameters (i.e., a
 fixed number of paths and control points), ignoring the complexity of the image
 and posing significant challenges to practical applications.We demonstrate that
 such an assumption is often incorrect, as the preset paths or control points ma
y be neither essential nor enough to achieve accurate and editable vectorization
 results.Based on this key insight, in this paper, we propose AdaVec, an efficie
nt image vectorization method with adaptive parametrization, where the paths and

control points can be adjusted dynamically based on the complexity of the input raster image.In particular, we first decompose the input raster image into a set of pure-colored layers that are aligned with human perception.For each layer with varying shape complexity, we propose a novel allocation mechanism to adaptively adjust the control point distribution.We further adopt a differentiable rendering process to compose and optimize the shape and color parameters of each layer iteratively.Extensive experiments demonstrate that AdaVec outperforms the baselines qualitatively and quantitatively, in terms of computational efficiency, vectorization accuracy, and editing flexibility.

FedMIA: An Effective Membership Inference Attack Exploiting "All for One" Principle in Federated Learning

Gongxi Zhu, Donghao Li, Hanlin Gu, Yuan Yao, Lixin Fan, Yuxing Han; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 20643-20653

Federated Learning (FL) is a promising approach for training machine learning models on decentralized data while preserving privacy. However, privacy risks, particularly Membership Inference Attacks (MIAs), which aim to determine whether a specific data point belongs to a target client's training set, remain a significant concern. Existing methods for implementing MIAs in FL primarily analyze updates from the target client, focusing on metrics such as loss, gradient norm, and gradient difference. However, these methods fail to leverage updates from non-target clients, potentially underutilizing available information.In this paper, we first formulate a one-tailed likelihood-ratio hypothesis test based on the likelihood of updates from non-target clients. Building upon this formulation, we introduce a three-stage Membership Inference Attack (MIA) method, called FedMIA, which follows the "all for one"--leveraging updates from all clients across multiple communication rounds to enhance MIA effectiveness. Both theoretical analysis and extensive experimental results demonstrate that FedMIA outperforms existing MIAs in both classification and generative tasks. Additionally, it can be integrated as an extension to existing methods and is robust against various defense strategies, Non-IID data, and different federated structures. Our code is available in https://github.com/Liar-Mask/FedMIA.

Erase Diffusion: Empowering Object Removal Through Calibrating Diffusion Pathways

Yi Liu, Hao Zhou, Benlei Cui, Wenxiang Shang, Ran Lin; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 2418-2427

Erase inpainting, or object removal, aims to precisely remove target objects within masked regions while preserving the overall consistency of the surrounding content. Despite diffusion-based methods have made significant strides in the field of image inpainting, challenges remain regarding the emergence of unexpected objects or artifacts. We assert that the inexact diffusion pathways established by existing standard optimization paradigms constrain the efficacy of object removal. To tackle these challenges, we propose a novel Erase Diffusion, termed EraDiff, aimed at unleashing the potential power of standard diffusion in the context of object removal. In contrast to standard diffusion, the EraDiff adapts both the optimization paradigm and the network to improve the coherence and elimination of the erasure results.We first introduce a Chain-Rectifying Optimization (CRO) paradigm, a sophisticated diffusion process specifically designed to align with the objectives of erasure. This paradigm establishes innovative diffusion transition pathways that simulate the gradual elimination of objects during optimization, allowing the model to accurately capture the intent of object removal. Furthermore, to mitigate deviations caused by artifacts during the sampling pathways, we develop a simple yet effective Self-Rectifying Attention (SRA) mechanism. The SRA calibrates the sampling pathways by altering self-attention activation, allowing the model to effectively bypass artifacts while further enhancing the coherence of the generated content. With this design, our proposed EraDiff achieves state-of-the-art performance on the OpenImages V5 dataset and demonstrates significant superiority in real-world scenarios.

Prompt-CAM: Making Vision Transformers Interpretable for Fine-Grained Analysis
Arpita Chowdhury, Dipanjyoti Paul, Zheda Mai, Jianyang Gu, Ziheng Zhang, Kazi Sajeed Mehrab, Elizabeth G. Campolongo, Daniel Rubenstein, Charles V. Stewart, Anuj Karpatne, Tanya Berger-Wolf, Yu Su, Wei-Lun Chao; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 4375-4385
We present a simple approach to make pre-trained Vision Transformers (ViTs) interpretable for fine-grained analysis, aiming to identify and localize the traits that distinguish visually similar categories, such as bird species. Pre-trained ViTs, such as DINO, have demonstrated remarkable capabilities in extracting localized, discriminative features. However, saliency maps like Grad-CAM often fail to identify these traits, producing blurred, coarse heatmaps that highlight entire objects instead. We propose a novel approach, Prompt Class Attention Map (Prompt-CAM), to address this limitation. Prompt-CAM learns class-specific prompts for a pre-trained ViT and uses the corresponding outputs for classification. To correctly classify an image, the true-class prompt must attend to unique image patches not present in other classes' images (i.e., traits). As a result, the true class's multi-head attention maps reveal traits and their locations. Implementation-wise, Prompt-CAM is almost a "free lunch," requiring only a modification to the prediction head of Visual Prompt Tuning (VPT). This makes Prompt-CAM easy to train and apply, in stark contrast to other interpretable methods that require designing specific models and training processes. Extensive empirical studies on a dozen datasets from various domains (e.g., birds, fishes, insects, fungi, flowers, food, and cars) validate the superior interpretation capability of Prompt-CAM. The source code and demo are available at https://github.com/Imageomics/Prompt_CAM.
****
Instruction-based Image Manipulation by Watching How Things Move
Mingdeng Cao, Xuaner Zhang, Yinqiang Zheng, Zhihao Xia; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 2704-2713
This paper introduces a novel dataset construction pipeline that samples pairs of frames from videos and uses multimodal large language models (MLLMs) to generate editing instructions for training instruction-based image manipulation models. Video frames inherently preserve the identity of subjects and scenes, ensuring consistent content preservation during editing. Additionally, video data captures diverse, natural dynamics--such as non-rigid subject motion and complex camera movements--that are difficult to model otherwise, making it an ideal source for scalable dataset construction. Using this approach, we create a new dataset to train InstructMove, a model capable of instruction-based complex manipulations that are difficult to achieve with synthetically generated datasets. Our model demonstrates state-of-the-art performance in tasks such as adjusting subject poses, rearranging elements, and altering camera perspectives.
****
DPFlow: Adaptive Optical Flow Estimation with a Dual-Pyramid Framework
Henrique Morimitsu, Xiaobin Zhu, Roberto M. Cesar, Xiangyang Ji, Xu-Cheng Yin; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 17810-17820
Optical flow estimation is essential for video processing tasks, such as restoration and action recognition. The quality of videos is constantly increasing, with current standards reaching 8K resolution. However, optical flow methods are usually designed for low resolution and do not generalize to large inputs due to their rigid architectures. They adopt downscaling or input tiling to reduce the input size, causing a loss of details and global information. There is also a lack of optical flow benchmarks to judge the actual performance of existing methods on high-resolution samples. Previous works only conducted qualitative high-resolution evaluations on hand-picked samples. This paper fills this gap in optical flow estimation in two ways. We propose DPFlow, an adaptive optical flow architecture capable of generalizing up to 8K resolution inputs while trained with only low-resolution samples. We also introduce Kubric-NK, a new benchmark for evaluating optical flow methods with input resolutions ranging from 1K to 8K. Our high

-resolution evaluation pushes the boundaries of existing methods and reveals new insights about their generalization capabilities. Extensive experimental results show that DPFlow achieves state-of-the-art results on the MPI-Sintel, KITTI 2015, Spring, and other high-resolution benchmarks. The code and dataset are available at https://github.com/hmorimitsu/ptlflow/tree/main/ptlflow/models/dpflow.

DocSAM: Unified Document Image Segmentation via Query Decomposition and Heterogeneous Mixed Learning
Xiao-Hui Li, Fei Yin, Cheng-Lin Liu; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 15021-15032
Document image segmentation is crucial in document analysis and recognition but remains challenging due to the heterogeneity of document formats and diverse segmentation tasks. Existing methods often treat these tasks separately, leading to limited generalization and resource wastage.This paper introduces DocSAM, a transformer-based unified framework for various document image segmentation tasks, including document layout analysis, multi-granularity text segmentation, and table structure recognition by modelling these tasks as a combination of instance and semantic segmentation.Specifically, DocSAM uses a Sentence BERT to map category names from each dataset into semantic queries of the same dimension as instance queries. These queries interact through attention mechanisms and are cross-attended with image features to predict instance and semantic segmentation masks. To predict instance categories, instance queries are dot-producted with semantic queries, and scores are normalized using softmax.As a result, DocSAM can be jointly trained on heterogeneous datasets, enhancing robustness and generalization while reducing computing and storage resources. Comprehensive evaluations show that DocSAM outperforms existing methods in accuracy, efficiency, and adaptability, highlighting its potential for advancing document image understanding and segmentation in various applications.

Ferret: An Efficient Online Continual Learning Framework under Varying Memory Constraints
Yuhao Zhou, Yuxin Tian, Jindi Lv, Mingjia Shi, Yuanxi Li, Qing Ye, Shuhao Zhang, Jiancheng Lv; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 4850-4861
In the realm of high-frequency data streams, achieving real-time learning within varying memory constraints is paramount. This paper presents Ferret, a comprehensive framework designed to enhance online accuracy of Online Continual Learning (OCL) algorithms while dynamically adapting to varying memory budgets.Ferret employs a fine-grained pipeline parallelism strategy combined with an iterative gradient compensation algorithm, ensuring seamless handling of high-frequency data with minimal latency, and effectively counteracting the challenge of stale gradients in parallel training. To adapt to varying memory budgets, its automated model partitioning and pipeline planning optimizes performance regardless of memory limitations. Extensive experiments across 20 benchmarks and 5 integrated OCL algorithms show Ferret's remarkable efficiency, achieving up to 3.7x lower memory overhead to reach the same online accuracy compared to competing methods.Furthermore, Ferret consistently outperforms these methods across diverse memory budgets, underscoring its superior adaptability. These findings position Ferret as a premier solution for efficient and adaptive OCL framework in real-time environments.

Spatiotemporal Skip Guidance for Enhanced Video Diffusion Sampling
Junha Hyung, Kinam Kim, Susung Hong, Min-Jung Kim, Jaegul Choo; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 11006-11015
Diffusion models have emerged as a powerful tool for generating high-quality images, videos, and 3D content. While sampling guidance techniques like CFG improve quality, they reduce diversity and motion. Autoguidance mitigates these issues but demands extra weak model training, limiting its practicality for large-scale models. In this work, we introduce Spatiotemporal Skip Guidance (STG), a simple

training-free sampling guidance method for enhancing transformer-based video diffusion models. STG employs an implicit weak model via self-perturbation, avoiding the need for external models or additional training. By selectively skipping spatiotemporal layers, STG produces an aligned, degraded version of the original model to boost sample quality without compromising diversity or dynamic degree. Our contributions include: (1) introducing STG as an efficient, high-performing guidance technique for video diffusion models, (2) eliminating the need for auxiliary models by simulating a weak model through layer skipping, and (3) ensuring quality-enhanced guidance without compromising sample diversity or dynamics unlike CFG. For additional results, visit https://junhahyung.github.io/STGuidance.

VidComposition: Can MLLMs Analyze Compositions in Compiled Videos?

Yunlong Tang, Junjia Guo, Hang Hua, Susan Liang, Mingqian Feng, Xinyang Li, Rui Mao, Chao Huang, Jing Bi, Zeliang Zhang, Pooyan Fazli, Chenliang Xu; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 8490-8500

The advancement of Multimodal Large Language Models (MLLMs) has enabled significant progress in multimodal understanding, expanding their capacity to analyze video content. However, existing evaluation benchmarks for MLLMs primarily focus on abstract video comprehension, lacking a detailed assessment of their ability to understand video compositions, the nuanced interpretation of how visual elements combine and interact within highly compiled video contexts. We introduce VidComposition, a new benchmark specifically designed to evaluate the video composition understanding capabilities of MLLMs using carefully curated compiled videos and cinematic-level annotations.VidComposition includes 982 videos with 1706 multiple-choice questions, covering various compositional aspects such as camera movement, angle, shot size, narrative structure, character actions and emotions, etc. Our comprehensive evaluation of 33 open-source and proprietary MLLMs reveals a significant performance gap between human and model capabilities. This highlights the limitations of current MLLMs in understanding complex, compiled video compositions and offers insights into areas for further improvement. Our benchmark is publicly available at https://yunlong10.github.io/VidComposition/

SAR3D: Autoregressive 3D Object Generation and Understanding via Multi-scale 3D VQVAE

Yongwei Chen, Yushi Lan, Shangchen Zhou, Tengfei Wang, Xingang Pan; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 28371-28382

Autoregressive models have demonstrated remarkable success across various fields, from large language models (LLMs) to large multimodal models (LMMs) and 2D content generation, moving closer to artificial general intelligence (AGI). Despite these advances, applying autoregressive approaches to 3D object generation and understanding remains largely unexplored. This paper introduces Scale AutoRegressive 3D (SAR3D), a novel framework that leverages a multi-scale 3D vector-quantized variational autoencoder (VQVAE) to tokenize 3D objects for efficient autoregressive generation and detailed understanding. By predicting the next scale in a multi-scale latent representation instead of the next single token, SAR3D reduces generation time significantly, achieving fast 3D object generation in just 0.82 seconds on an A6000 GPU. Additionally, given the tokens enriched with hierarchical 3D-aware information, we finetune a pretrained LLM on them, enabling multimodal comprehension of 3D content.Our experiments show that SAR3D surpasses current 3D generation methods in both speed and quality and allows LLMs to interpret and caption 3D models comprehensively.

Dual-Interrelated Diffusion Model for Few-Shot Anomaly Image Generation

Ying Jin, Jinlong Peng, Qingdong He, Teng Hu, Jiafu Wu, Hao Chen, Haoxuan Wang, Wenbing Zhu, Mingmin Chi, Jun Liu, Yabiao Wang; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 30420-30429

The performance of anomaly inspection in industrial manufacturing is constrained by the scarcity of anomaly data. To overcome this challenge, researchers have s

tarted employing anomaly generation approaches to augment the anomaly dataset. H
owever, existing anomaly generation methods suffer from limited diversity in the
 generated anomalies and struggle to achieve a seamless blending of this anomaly
 with the original image. Moreover, the generated mask is usually not aligned wi
th the generated anomaly. In this paper, we overcome these challenges from a new
 perspective, simultaneously generating a pair of the overall image and the corr
esponding anomaly part. We propose DualAnoDiff, a novel diffusion-based few-shot
 anomaly image generation model, which can generate diverse and realistic anomal
y images by using a dual-interrelated diffusion model, where one of them is empl
oyed to generate the whole image while the other one generates the anomaly part.
 Moreover, we extract background and shape information to mitigate the distortio
n and blurriness phenomenon in few-shot image generation. Extensive experiments
 demonstrate the superiority of our proposed model over state-of-the-art methods
 in terms of diversity, realism and the accuracy of mask. Overall, our approach
significantly improves the performance of downstream anomaly inspection tasks, i
ncluding anomaly detection, anomaly localization, and anomaly classification tas
ks. Code will be made available.

ODE: Open-Set Evaluation of Hallucinations in Multimodal Large Language Models
Yahan Tu, Rui Hu, Jitao Sang; Proceedings of the Computer Vision and Pattern Rec
ognition Conference (CVPR), 2025, pp. 19836-19845
Hallucination poses a persistent challenge for multimodal large language models
(MLLMs). However, existing benchmarks for evaluating hallucinations are generall
y static, which may overlook the potential risk of data contamination. To addres
s this issue, we propose ODE, an open-set, dynamic protocol designed to evaluate
 object hallucinations in MLLMs at both the existence and attribute levels. ODE
employs a graph-based structure to represent real-world object concepts, their a
ttributes, and the distributional associations between them. This structure faci
litates the extraction of concept combinations based on diverse distributional c
riteria, generating varied samples for structured queries that evaluate hallucin
ations in both generative and discriminative tasks. Through the generation of ne
w samples, dynamic concept combinations, and varied distribution frequencies, OD
E mitigates the risk of data contamination and broadens the scope of evaluation.
 This protocol is applicable to both general and specialized scenarios, includin
g those with limited data. Experimental results demonstrate the effectiveness of
 our protocol, revealing that MLLMs exhibit higher hallucination rates when eval
uated with ODE-generated samples, which indicates potential data contamination.
Furthermore, these generated samples aid in analyzing hallucination patterns and
 fine-tuning models, offering an effective approach to mitigating hallucinations
 in MLLMs.

Self-Supervised Learning for Color Spike Camera Reconstruction
Yanchen Dong, Ruiqin Xiong, Xiaopeng Fan, Zhaofei Yu, Yonghong Tian, Tiejun Huan
g; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR),
 2025, pp. 6231-6240
Spike camera is a kind of neuromorphic camera with ultra-high temporal resolutio
n, which can capture dynamic scenes by continuously firing spike signals. To cap
ture color information, a color filter array (CFA) is employed on the sensor of
the spike camera, resulting in Bayer-pattern spike streams. How to restore high-
quality color images from the binary spike signals remains challenging. In this
paper, we propose a motion-guided reconstruction method for spike cameras with C
FA, utilizing color layout and estimated motion information. Specifically, we de
velop a joint motion estimation pipeline for the Bayer-pattern spike stream, exp
loiting the motion consistency of channels. We propose to estimate the missing p
ixels of each color channel according to temporally neighboring pixels of the co
rresponding color along the motion trajectory. As the spike signals are read out
 at discrete time points, there is quantization noise that impacts the image qua
lity. Thus, we analyze the correlation of the noise in spatial and temporal doma
ins and propose a self-supervised network utilizing a masked spike encoder to ha
ndle the noise. Experiments on real-world captured Bayer-pattern spike streams s

how that our method can restore color images with better visual quality, compare d with state-of-the-art methods. The source codes are available at https://githu b.com/csycdong/SSL-CSC.

Interactive Medical Image Analysis with Concept-based Similarity Reasoning
Ta Duc Huy, Sen Kim Tran, Phan Nguyen, Nguyen Hoang Tran, Tran Bao Sam, Anton va n den Hengel, Zhibin Liao, Johan W. Verjans, Minh-Son To, Vu Minh Hieu Phan; Pro ceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 30797-30806
The ability to interpret and intervene model decisions is important for the adop tion of computer-aided diagnosis methods in clinical workflows. Recent concept-b ased methods link the model predictions with interpretable concepts and modify t heir activation scores to interact with the model. However, these concepts are a t the image level, which hinders the model from pinpointing the exact patches th e concepts are activated. Alternatively, prototype-based methods learn represent ations from training image patches and compare these with test image patches, us ing the similarity scores for final class prediction. However, interpreting the underlying concepts of these patches can be challenging and often necessitates p ost-hoc guesswork. To address this issue, this paper introduces the novel Concep t-based Similarity Reasoning network (CSR), which offers (i) patch-level prototy pe with intrinsic concept interpretation, and (ii) spatial interactivity. First, the proposed CSR provides localized explanation by grounding prototypes of each concept on image regions. Second, our model introduces novel spatial-level inte raction, allowing doctors to engage directly with specific image areas, making i t an intuitive and transparent tool for medical imaging. CSR improves upon prior state-of-the-art interpretable methods by up to 4.% across three biomedical dat asets.

From Elements to Design: A Layered Approach for Automatic Graphic Design Composi tion
Jiawei Lin, Shizhao Sun, Danqing Huang, Ting Liu, Ji Li, Jiang Bian; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 812 8-8137
In this work, we investigate automatic design composition from multimodal graphi c elements. Although recent studies have developed various generative models for graphic design, they usually face the following limitations: they only focus on certain subtasks and are far from achieving the design composition task; they d o not consider the hierarchical information of graphic designs during the genera tion process. To tackle these issues, we introduce the layered design principle into Large Multimodal Models (LMMs) and propose a novel approach, called LaDeCo, to accomplish this challenging task. Specifically, LaDeCo first performs layer planning for a given element set, dividing the input elements into different sem antic layers according to their contents. Based on the planning results, it subs equently predicts element attributes that control the design composition in a la yer-wise manner, and includes the rendered image of previously generated layers into the context. With this insightful design, LaDeCo decomposes the difficult t ask into smaller manageable steps, making the generation process smoother and cl earer. The experimental results demonstrate the effectiveness of LaDeCo in desig n composition. Furthermore, we show that LaDeCo enables some interesting applica tions in graphic design, such as resolution adjustment, design decoration, desig n variation, etc. In addition, it even outperforms the specialized models in som e design subtasks without any task-specific training.

h-Edit: Effective and Flexible Diffusion-Based Editing via Doob's h-Transform
Toan Nguyen, Kien Do, Duc Kieu, Thin Nguyen; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 28490-28501
We introduce a theoretical framework for diffusion-based image editing by formul ating it as a reverse-time bridge modeling problem. This approach modifies the b ackward process of a pretrained diffusion model to construct a bridge that conve rges to an implicit distribution associated with the editing target at time 0. B

uilding on this framework, we propose h-Edit, a novel editing method that utiliz es Doob's h-transform and Langevin Monte Carlo to decompose the update of an int ermediate edited sample into two components: a "reconstruction" term and an "edi ting" term. This decomposition provides flexibility, allowing the reconstruction term to be computed via existing inversion techniques and enabling the combinat ion of multiple editing terms to handle complex editing tasks. To our knowledge, h-Edit is the first training-free method capable of performing simultaneous tex t-guided and reward-model-based editing. Extensive experiments, both quantitativ e and qualitative, show that h-Edit outperforms state-of-the-art baselines in te rms of editing effectiveness and faithfulness.

Masking meets Supervision: A Strong Learning Alliance
Byeongho Heo, Taekyung Kim, Sangdoo Yun, Dongyoon Han; Proceedings of the Comput er Vision and Pattern Recognition Conference (CVPR), 2025, pp. 20447-20457
Pre-training with random masked inputs has emerged as a novel trend in self-supe rvised training. However, supervised learning still faces a challenge in adoptin g masking augmentations, primarily due to unstable training. In this paper, we p ropose a novel way to involve masking augmentations dubbed Masked Sub-branch (Ma skSub). MaskSub consists of the main-branch and sub-branch, the latter being a p art of the former. The main-branch undergoes conventional training recipes, whil e the sub-branch merits intensive masking augmentations, during training. MaskSu b tackles the challenge by mitigating adverse effects through a relaxed loss fun ction similar to a self-distillation loss. Our analysis shows that MaskSub impro ves performance, with the training loss converging faster than in standard train ing, which suggests our method stabilizes the training process. We further valid ate MaskSub across diverse training scenarios and models, including DeiT-III tra ining, MAE finetuning, CLIP finetuning, BERT training, and hierarchical architec tures (ResNet and Swin Transformer). Our results show that MaskSub consistently achieves impressive performance gains across all the cases. MaskSub provides a p ractical and effective solution for introducing additional regularization under various training recipes. Code available at https://github.com/naver-ai/augsub

DI-PCG: Diffusion-based Efficient Inverse Procedural Content Generation for High -quality 3D Asset Creation
Wang Zhao, Yan-Pei Cao, Jiale Xu, Yuejiang Dong, Ying Shan; Proceedings of the C omputer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 11061-11072
Procedural Content Generation (PCG) is powerful in creating high-quality 3D cont ents, yet controlling it to produce desired shapes is difficult and often requir es extensive parameter tuning. Inverse Procedural Content Generation aims to aut omatically find the best parameters under the input condition. However, existing sampling-based and neural network-based methods still suffer from numerous samp le iterations or limited controllability. In this work, we present DI-PCG, a nov el and efficient method for Inverse PCG from general image conditions. At its co re is a lightweight diffusion transformer model, where PCG parameters are direct ly treated as the denoising target and the observed images as conditions to cont rol parameter generation. DI-PCG is efficient and effective. With only 7.6M netw ork parameters and 30 GPU hours to train, it demonstrates superior performance i n recovering parameters accurately, and generalizing well to in-the-wild images. Quantitative and qualitative experiment results validate the effectiveness of D I-PCG in inverse PCG and image-to-3D generation tasks. DI-PCG offers a promising approach for efficient inverse PCG and represents a valuable exploration step t owards a 3D generation path that models how to construct a 3D asset using parame tric models.

SALOVA: Segment-Augmented Long Video Assistant for Targeted Retrieval and Routin g in Long-Form Video Analysis
Junho Kim, Hyunjun Kim, Hosu Lee, Yong Man Ro; Proceedings of the Computer Visio n and Pattern Recognition Conference (CVPR), 2025, pp. 3352-3362
Despite advances in Large Multi-modal Models, applying them to long and untrimme d video content remains challenging due to limitations in context length and sub

stantial memory overhead. These constraints often lead to significant informatio n loss and reduced relevance in the model responses. With the exponential growth of video data across web platforms, understanding long-form video is crucial fo r advancing generalized intelligence. In this paper, we introduce SALOVA: Segmen t-Augmented LOng Video Assistant, a novel video-LLM framework designed to enhanc e the comprehension of lengthy video content through targeted retrieval process. We address two main challenges to achieve it: (i) We present the SceneWalk data set, a high-quality collection of 87.8K long videos, each densely captioned at t he segment level to enable models to capture scene continuity and maintain rich descriptive context. (ii) We develop robust architectural designs integrating dy namic routing mechanism and spatio-temporal projector to efficiently retrieve an d process relevant video segments based on user queries. Our framework mitigates the limitations of current video-LMMs by allowing for precise identification an d retrieval of relevant video segments in response to queries, thereby improving the contextual relevance of the generated responses. Through extensive experime nts, SALOVA demonstrates enhanced capability in processing complex long-form vid eos, showing significant capability to maintain contextual integrity across exte nded sequences.

Notes-guided MLLM Reasoning: Enhancing MLLM with Knowledge and Visual Notes for Visual Question Answering

Wenlong Fang, Qiaofeng Wu, Jing Chen, Yun Xue; Proceedings of the Computer Visio n and Pattern Recognition Conference (CVPR), 2025, pp. 19597-19607

The knowledge-based visual question answering (KB-VQA) task involves using exter nal knowledge about the image to assist reasoning. Building on the impressive pe rformance of multimodal large language model (MLLM), recent methods have commenc ed leveraging MLLM as an implicit knowledge base for reasoning. However, the dir ect employment of MLLM with raw external knowledge might result in reasoning err ors due to misdirected knowledge information. Additionally, MLLM may lack fine-grained perception of visual features, which can result in hallucinations during reasoning. To address these challenges, we propose Notes-guided MLLM Reasoning (NoteMR), a novel framework that guides MLLM in better reasoning by utilizing kn owledge notes and visual notes. Specifically, we initially obtain explicit knowl edge from an external knowledge base. Then, this explicit knowledge, combined wi th images, is used to assist the MLLM in generating knowledge notes. These notes are designed to filter explicit knowledge and identify relevant internal implic it knowledge within the MLLM. We then identify highly correlated regions between the images and knowledge notes, retaining them as image notes to enhance the mo del's fine-grained perception, thereby mitigating MLLM induced hallucinations. F inally, both notes are fed into the MLLM, enabling a more comprehensive understa nding of the image-question pair and enhancing the model's reasoning capabilitie s. Our method achieves state-of-the-art performance on the OK-VQA and A-OKVQA da tasets, demonstrating its robustness and effectiveness across diverse VQA scenar ios.

Are Spatial-Temporal Graph Convolution Networks for Human Action Recognition Ove r-Parameterized?

Jianyang Xie, Yitian Zhao, Yanda Meng, He Zhao, Anh Nguyen, Yalin Zheng; Proceed ings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 24309-24319

Spatial-temporal graph convolutional networks (ST-GCNs) showcase impressive perf ormance in skeleton-based human action recognition (HAR). However, despite the d evelopment of numerous models, their recognition performance does not differ sig nificantly after aligning the input settings. With this observation, we hypothes ize that ST-GCNs are over-parameterized for HAR, a conjecture subsequently confi rmed through experiments employing the lottery ticket hypothesis. Additionally, a novel sparse ST-GCNs generator is proposed, which trains a sparse architecture from a randomly initialized dense network while maintaining comparable performa nce levels to the dense components. Moreover, we generate multi-level sparsity S T-GCNs by integrating sparse structures at various sparsity levels and demonstra

te that the assembled model yields a significant enhancement in HAR performance. Thorough experiments on four datasets, including NTU-RGB+D 60(120), Kinetics-400, and FineGYM, demonstrate that the proposed sparse ST-GCNs can achieve comparable performance to their dense components. Even with 95% fewer parameters, the sparse ST-GCNs exhibit a degradation of <1% in top-1 accuracy. Meanwhile, the multi-level sparsity ST-GCNs, which require only 66% of the parameters of the dense ST-GCNs, demonstrate an improvement of >1% in top-1 accuracy. The code is available at https://github.com/davelailai/Sparse-ST-GCN.
****

DA-VPT: Semantic-Guided Visual Prompt Tuning for Vision Transformers
Li Ren, Chen Chen, Liqiang Wang, Kien Hua; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 4353-4363
Visual Prompt Tuning (VPT) has become a promising solution for Parameter-Efficient Fine-Tuning (PEFT) approach for Vision Transformer (ViT) models by partially fine-tuning learnable tokens while keeping most model parameters frozen. Recent research has explored modifying the connection structures of the prompts. However, the fundamental correlation and distribution between the prompts and image tokens remain unexplored. In this paper, we leverage metric learning techniques to investigate how the distribution of prompts affects fine-tuning performance. Specifically, we propose a novel framework, Distribution Aware Visual Prompt Tuning (DA-VPT), to guide the distributions of the prompts by learning the distance metric from their class-related semantic data. Our method demonstrates that the prompts can serve as an effective bridge to share semantic information between image patches and the class token. We extensively evaluated our approach on popular benchmarks in both recognition and segmentation tasks. The results demonstrate that our approach enables more effective and efficient fine-tuning of ViT models by leveraging semantic information to guide the learning of the prompts, leading to improved performance on various downstream vision tasks.

Towards Lossless Implicit Neural Representation via Bit Plane Decomposition
Woo Kyoung Han, Byeonghun Lee, Hyunmin Cho, Sunghoon Im, Kyong Hwan Jin; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 2269-2278
We quantify the upper bound on the size of the implicit neural representation (INR) model from a digital perspective. The upper bound of the model size increases exponentially as the required bit-precision increases. To this end, we present a bit-plane decomposition method that makes INR predict bit-planes, producing the same effect as reducing the upper bound of the model size. We validate our hypothesis that reducing the upper bound leads to faster convergence with constant model size. Our method achieves lossless representation in 2D image and audio fitting, even for high bit-depth signals, such as 16-bit, which was previously unachievable. We pioneered the presence of bit bias, which INR prioritizes as the most significant bit (MSB). We expand the application of the INR task to bit depth expansion, lossless image compression, and extreme network quantization. Our source code is available at https://github.com/WooKyoungHan/LosslessINR.

Spectral State Space Model for Rotation-Invariant Visual Representation Learning
Sahar Dastani, Ali Bahri, Moslem Yazdanpanah, Mehrdad Noori, David Osowiechi, Gustavo Adolfo Vargas Hakim, Farzad Beizaee, Milad Cheraghalikhani, Arnab Kumar Mondal, Herve Lombaert, Christian Desrosiers; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 23881-23890
State Space Models (SSMs) have recently emerged as an alternative to Vision Transformers (ViTs) due to their unique ability of modeling global relationships with linear complexity. SSMs are specifically designed to capture spatially proximate relationships of image patches. However, they fail to identify relationships between conceptually related yet not adjacent patches. This limitation arises from the non-causal nature of image data, which lacks inherent directional relationships. Additionally, current vision-based SSMs are highly sensitive to transformations such as rotation. Their predefined scanning directions depend on the original image orientation, which can cause the model to produce inconsistent patch

-processing sequences after rotation.To address these limitations, we introduce Spectral VMamba, a novel approach that effectively captures the global structure within an image by leveraging spectral information derived from the graph Laplacian of image patches. Through spectral decomposition, our approach encodes patch relationships independently of image orientation, achieving rotation invariance with the aid of our Rotational Feature Normalizer (RFN) module. Our experiments on classification tasks show that Spectral VMamba outperforms the leading SSM models in vision, such as VMamba, while maintaining invariance to rotations and a providing a similar runtime efficiency.

iSegMan: Interactive Segment-and-Manipulate 3D Gaussians
Yian Zhao, Wanshi Xu, Ruochong Zheng, Pengchong Qiao, Chang Liu, Jie Chen; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 661-670
The efficient rendering and explicit nature of 3DGS promote the advancement of 3D scene manipulation.However, existing methods typically encounter challenges in controlling the manipulation region and are unable to furnish the user with interactive feedback, which inevitably leads to unexpected results.Intuitively, incorporating interactive 3D segmentation tools can compensate for this deficiency. Nevertheless, existing segmentation frameworks impose a pre-processing step of scene-specific parameter training, which limits the efficiency and flexibility of scene manipulation.To deliver a 3D region control module that is well-suited for scene manipulation with reliable efficiency, we propose **i**nteractive **Segment-and-**Man**ipulate 3D Gaussians (**iSegMan**), an interactive segmentation and manipulation framework that only requires simple 2D user interactions in any view.To propagate user interactions to other views, we propose Epipolar-guided Interaction Propagation (**EIP**), which innovatively exploits epipolar constraint for efficient and robust interaction matching.To avoid scene-specific training to maintain efficiency, we further propose the novel Visibility-based Gaussian Voting (**VGV**), which obtains 2D segmentations from SAM and models the region extraction as a voting game between 2D Pixels and 3D Gaussians based on Gaussian visibility.Taking advantage of the efficient and precise region control of EIP and VGV, we put forth a **Manipulation Toolbox** to implement various functions on selected regions, enhancing the controllability, flexibility and practicality of scene manipulation.Extensive results on 3D scene manipulation and segmentation tasks fully demonstrate the significant advantages of iSegMan.

BlueLM-V-3B: Algorithm and System Co-Design for Multimodal Large Language Models on Mobile Devices
Xudong Lu, Yinghao Chen, Cheng Chen, Hui Tan, Boheng Chen, Yina Xie, Rui Hu, Guanxin Tan, Renshou Wu, Yan Hu, Yi Zeng, Lei Wu, Liuyang Bian, Zhaoxiong Wang, Long Liu, Yanzhou Yang, Han Xiao, Aojun Zhou, Yafei Wen, Xiaoxin Chen, Shuai Ren, Hongsheng Li; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 4145-4155
The emergence and growing popularity of multimodal large language models (MLLMs) have significant potential to enhance various aspects of daily life, from improving communication to facilitating learning and problem-solving. Mobile phones, as essential daily companions, represent the most effective and accessible deployment platform for MLLMs, enabling seamless integration into everyday tasks. However, deploying MLLMs on mobile phones presents challenges due to limitations in memory size and computational capability, making it difficult to achieve smooth and real-time processing without extensive optimization. In this paper, we present BlueLM-V-3B, an algorithm and system co-design approach specifically tailored for the efficient deployment of MLLMs on mobile platforms. To be specific, we redesign the dynamic resolution scheme adopted by mainstream MLLMs and implement system optimization for hardware-aware deployment to optimize model inference on mobile phones. BlueLM-V-3B boasts the following key highlights: (1) Small Size: BlueLM-V-3B features a language model with 2.7B parameters and a vision encoder with 400M parameters. (2) Fast Speed: BlueLM-V-3B achieves a generation speed of 24.4 token/s on the MediaTek Dimensity 9300 processor with 4-bit LLM weight q

uantization. (3) Strong Performance: BlueLM-V-3B has attained the highest avera ge score of 66.1 on the OpenCompass benchmark among models with <= 4B parameters and surpassed a series of models with much larger parameter sizes (e.g., MiniCP M-V-2.6, InternVL2-8B).

Unraveling Normal Anatomy via Fluid-Driven Anomaly Randomization
Peirong Liu, Ana Lawry Aguila, Juan E. Iglesias; Proceedings of the Computer Vis ion and Pattern Recognition Conference (CVPR), 2025, pp. 10455-10465
Data-driven machine learning has made significant strides in medical image analy sis. However, most existing methods are tailored to specific modalities and assu me a particular resolution (often isotropic). This limits their generalizability in clinical settings, where variations in scan appearance arise from difference s in sequence parameters, resolution, and orientation. Furthermore, most general -purpose models are designed for healthy subjects and suffer from performance de gradation when pathology is present. We introduce UNA (Unraveling Normal Anatomy), the first modality-agnostic learning approach for normal brain anatomy recons truction that can handle both healthy scans and cases with pathology. We propose a fluid-driven anomaly randomization method that generates an unlimited number of realistic pathology profiles on-the-fly. UNA is trained on a combination of s ynthetic and real data, and can be applied directly to real images with potentia l pathology without the need for fine-tuning. We demonstrate UNA's effectiveness in reconstructing healthy brain anatomy and showcase its direct application to anomaly detection, using both simulated and real images from 3D healthy and stro ke datasets, including CT and MRI scans. By bridging the gap between healthy and diseased images, UNA enables the use of general-purpose models on diseased imag es, opening up new opportunities for large-scale analysis of uncurated clinical images in the presence of pathology.

Taming Teacher Forcing for Masked Autoregressive Video Generation
Deyu Zhou, Quan Sun, Yuang Peng, Kun Yan, Runpei Dong, Duomin Wang, Zheng Ge, Na n Duan, Xiangyu Zhang; Proceedings of the Computer Vision and Pattern Recognitio n Conference (CVPR), 2025, pp. 7374-7384
We introduce MAGI, a hybrid video generation framework that combines masked mode ling for intra-frame generation with causal modeling for next-frame generation. Our key innovation, Complete Teacher Forcing (CTF), conditions masked frames on complete observation frames rather than masked ones (namely Masked Teacher Forci ng, MTF), enabling a smooth transition from token-level (patch-level) to frame-l evel autoregressive generation. CTF significantly outperforms MTF, achieving a 2 3% improvement in FVD scores on first-frame conditioned video prediction. To add ress issues like exposure bias, we employ targeted training strategies, setting a new benchmark in autoregressive video generation. Experiments show that MAGI c an generate long, coherent video sequences exceeding 100 frames, even when train ed on as few as 16 frames, highlighting its potential for scalable, high-quality video generation.

UniRestore: Unified Perceptual and Task-Oriented Image Restoration Model Using D iffusion Prior
I-Hsiang Chen, Wei-Ting Chen, Yu-Wei Liu, Yuan-Chun Chiang, Sy-Yen Kuo, Ming-Hsu an Yang; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 17969-17979
Image restoration aims to recover content from inputs degraded by various factor s, such as adverse weather, blur, and noise. Perceptual Image Restoration (PIR) methods improve visual quality but often do not support downstream tasks effecti vely. On the other hand, Task-oriented Image Restoration (TIR) methods focus on enhancing image utility for high-level vision tasks, sometimes compromising visu al quality. This paper introduces UniRestore, a unified image restoration model that bridges the gap between PIR and TIR by using a diffusion prior. The diffusi on prior is designed to generate images that align with human visual quality pre ferences, but these images are often unsuitable for TIR scenarios. To solve this limitation, UniRestore utilizes encoder features from an autoencoder to adapt t

he diffusion prior to specific tasks. We propose a Complementary Feature Restoration Module (CFRM) to reconstruct degraded encoder features and a Task Feature Adapter (TFA) module to facilitate adaptive feature fusion in the decoder. This design allows UniRestore to optimize images for both human perception and downstream task requirements, addressing discrepancies between visual quality and functional needs. Integrating these modules also enhances UniRestore's adapability and efficiency across diverse tasks. Extensive expertments demonstrate the superior performance of UniRestore in both PIR and TIR scenarios.

Sharp-It: A Multi-view to Multi-view Diffusion Model for 3D Synthesis and Manipulation

Yiftach Edelstein, Or Patashnik, Dana Cohen-Bar, Lihi Zelnik-Manor; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 21458-21468

Advancements in text-to-image diffusion models have led to significant progress in fast 3D content creation. One common approach is to generate a set of multi-view images of an object, and then reconstruct it into a 3D model. However, this approach bypasses the use of a native 3D representation of the object and is hence prone to geometric artifacts and limited in controllability and manipulation capabilities. An alternative approach involves native 3D generative models that directly produce 3D representations. These models, however, are typically limited in their resolution, resulting in lower quality 3D objects. In this work, we bridge the quality gap between methods that directly generate 3D representations and ones that reconstruct 3D objects from multi-view images. We introduce a multi-view to multi-view diffusion model called Sharp-It, which takes a 3D consistent set of multi-view images rendered from a low-quality object and enriches its geometric details and texture. The diffusion model operates on the multi-view set in parallel, in the sense that it shares features across the generated views. A high-quality 3D model can then be reconstructed from the enriched multi-view set. By leveraging the advantages of both 2D and 3D approaches, our method offers an efficient and controllable method for high-quality 3D content creation. We demonstrate that Sharp-It enables various 3D applications, such as fast synthesis, editing, and controlled generation, while attaining high-quality assets.

URWKV: Unified RWKV Model with Multi-state Perspective for Low-light Image Restoration

Rui Xu, Yuzhen Niu, Yuezhou Li, Huangbiao Xu, Wenxi Liu, Yuzhong Chen; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 21267-21276

Existing low-light image enhancement (LLIE) and joint LLIE and deblurring (LLIE-deblur) models have made strides in addressing predefined degradations, yet they are often constrained by dynamically coupled degradations. To address these challenges, we introduce a Unified Receptance Weighted Key Value (URWKV) model with multi-state perspective, enabling flexible and effective degradation restoration for low-light images. Specifically, we customize the core URWKV block to perceive and analyze complex degradations by leveraging multiple intra- and inter-stage states. First, inspired by the pupil mechanism in the human visual system, we propose Luminance-adaptive Normalization (LAN) that adjusts normalization parameters based on rich inter-stage states, allowing for adaptive, scene-aware luminance modulation. Second, we aggregate multiple intra-stage states through exponential moving average approach, effectively capturing subtle variations while mitigating information loss inherent in the single-state mechanism. To reduce the degradation effects commonly associated with conventional skip connections, we propose the State-aware Selective Fusion (SSF) module, which dynamically aligns and integrates multi-state features across encoder stages, selectively fusing contextual information. In comparison to state-of-the-art models, our URWKV model achieves superior performance on various benchmarks, while requiring significantly fewer parameters and computational resources. Code is available at: https://github.com/FZU-N/URWKV.

Revisiting Backdoor Attacks against Large Vision-Language Models from Domain Shift

Siyuan Liang, Jiawei Liang, Tianyu Pang, Chao Du, Aishan Liu, Mingli Zhu, Xiaochun Cao, Dacheng Tao; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 9477-9486

Instruction tuning enhances large vision-language models (LVLMs) but increases their vulnerability to backdoor attacks due to their open design. Unlike prior studies in static settings, this paper explores backdoor attacks in LVLM instruction tuning across mismatched training and testing domains. We introduce a new evaluation dimension, backdoor domain generalization, to assess attack robustness under visual and text domain shifts. Our findings reveal two insights: (1) backdoor generalizability improves when distinctive trigger patterns are independent of specific data domains or model architectures, and (2) the competitive interaction between trigger patterns and clean semantic regions, where guiding the model to predict triggers enhances attack generalizability. Based on these insights, we propose a multimodal attribution backdoor attack (MABA) that injects domain-agnostic triggers into critical areas using attributional interpretation. Experiments with OpenFlamingo, Blip-2, and Otter show that MABA significantly boosts the attack success rate of generalization by 36.4% over the unimodal attack, achieving a 97% success rate at a 0.2% poisoning rate. This study reveals limitations in current evaluations and highlights how enhanced backdoor generalizability poses a security threat to LVLMs, even without test data access.

Condensing Action Segmentation Datasets via Generative Network Inversion

Guodong Ding, Rongyu Chen, Angela Yao; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 17733-17742

This work presents the first condensation approach for procedural video datasets used in temporal action segmentation. We propose a condensation framework that leverages generative prior learned from the dataset and network inversion to condense data into compact latent codes with significant storage reduced across temporal and channel aspects. Orthogonally, we propose sampling diverse and representative action sequences to minimize video-wise redundancy. Our evaluation on standard benchmarks demonstrates consistent effectiveness in condensing TAS datasets and achieving competitive performances. Specifically, on the Breakfast dataset, our approach reduces storage by over 500xwhile retaining 83% of the performance compared to training with the full dataset. Furthermore, when applied to a downstream incremental learning task, it yields superior performance compared to the state-of-the-art.

TCFG: Tangential Damping Classifier-free Guidance

Mingi Kwon, Shin seong Kim, Jaeseok Jeong, Yi Ting Hsiao, Youngjung Uh; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 2620-2629

Diffusion models have achieved remarkable success in text-to-image synthesis, largely attributed to the use of classifier-free guidance (CFG), which enables high-quality, condition-aligned image generation. CFG combines the conditional score (e.g., text-conditioned) with the unconditional score to control the output. However, the unconditional score is in charge of estimating the transition between manifolds of adjacent timesteps from x_t to x_{t-1}, which may inadvertently interfere with the trajectory toward the specific condition. In this work, we introduce a novel approach that leverages a geometric perspective on the unconditional score to enhance CFG performance when conditional scores are available. Specifically, we propose a method that filters the singular vectors of both conditional and unconditional scores using singular value decomposition. This filtering process aligns the unconditional score with the conditional score, thereby refining the sampling trajectory to stay closer to the manifold. Our approach improves image quality with negligible additional computation. We provide deeper insights into the score function behavior in diffusion models and present a practical technique for achieving more accurate and contextually coherent image synthesis.

MatAnyone: Stable Video Matting with Consistent Memory Propagation
Peiqing Yang, Shangchen Zhou, Jixin Zhao, Qingyi Tao, Chen Change Loy; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 7299-7308
Auxiliary-free human video matting methods, which rely solely on input frames, often struggle with complex or ambiguous backgrounds. To tackle this, we propose MatAnyone, a practical framework designed for target-assigned video matting. Specifically, building on a memory-based framework, we introduce a consistent memory propagation module via region-adaptive memory fusion, which adaptively combines memory from the previous frame. This ensures stable semantic consistency in core regions while maintaining fine details along object boundaries. For robust training, we present a larger, high-quality, and diverse dataset for video matting. Additionally, we incorporate a novel training strategy that efficiently leverages large-scale segmentation data, further improving matting stability. With this new network design, dataset, and training strategy, MatAnyone delivers robust, accurate video matting in diverse real-world scenarios, outperforming existing methods. The code and model will be publicly available.

Can Generative Video Models Help Pose Estimation?
Ruojin Cai, Jason Y. Zhang, Philipp Henzler, Zhengqi Li, Noah Snavely, Ricardo Martin-Brualla; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 16764-16773
Pairwise pose estimation from images with little or no overlap is an open challenge in computer vision. Existing methods, even those trained on large-scale datasets, struggle in these scenarios due to the lack of identifiable correspondences or visual overlap. Inspired by the human ability to infer spatial relationships from diverse scenes, we propose a novel approach, InterPose, that leverages the rich priors encoded within pre-trained generative video models. We propose to use a video model to hallucinate intermediate frames between two input images, effectively creating a dense, visual transition, which significantly simplifies the problem of pose estimation. Since current video models can still produce implausible motion or inconsistent geometry, we introduce a self-consistency score that evaluates the consistency of pose predictions from sampled videos. We demonstrate that our approach generalizes among three state-of-the-art video models and show consistent improvements over the state-of-the-art DUSt3R baseline on four diverse datasets encompassing indoor, outdoor, and object-centric scenes. Our findings suggest a promising avenue for improving pose estimation models by leveraging large generative models trained on vast amounts of video data, which is more readily available than 3D data. See our project page for results: Inter-Pose.github.io.

Molmo and PixMo: Open Weights and Open Data for State-of-the-Art Vision-Language Models
Matt Deitke, Christopher Clark, Sangho Lee, Rohun Tripathi, Yue Yang, Jae Sung Park, Mohammadreza Salehi, Niklas Muennighoff, Kyle Lo, Luca Soldaini, Jiasen Lu, Taira Anderson, Erin Bransom, Kiana Ehsani, Huong Ngo, YenSung Chen, Ajay Patel, Mark Yatskar, Chris Callison-Burch, Andrew Head, Rose Hendrix, Favyen Bastani, Eli VanderBilt, Nathan Lambert, Yvonne Chou, Arnavi Chheda, Jenna Sparks, Sam Skjonsberg, Michael Schmitz, Aaron Sarnat, Byron Bischoff, Pete Walsh, Chris Newell, Piper Wolters, Tanmay Gupta, Kuo-Hao Zeng, Jon Borchardt, Dirk Groeneveld, Crystal Nam, Sophie Lebrecht, Caitlin Wittlif, Carissa Schoenick, Oscar Michel, Ranjay Krishna, Luca Weihs, Noah A. Smith, Hannaneh Hajishirzi, Ross Girshick, Ali Farhadi, Aniruddha Kembhavi; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 91-104
Today's most advanced vision-language models (VLMs) remain proprietary. The strongest open-weight models rely heavily on synthetic data from proprietary VLMs to achieve good performance, effectively distilling these closed VLMs into open ones. As a result, the community has been missing foundational knowledge about how to build performant VLMs from scratch. We present Molmo, a new family of VLMs t

hat are state-of-the-art in their class of openness. Our key contribution is a c
ollection of new datasets called PixMo, including a dataset of highly detailed i
mage captions for pre-training, a free-form image Q&A dataset for fine-tuning, a
nd an innovative 2D pointing dataset, all collected without the use of external
VLMs. The success of our approach relies on careful modeling choices, a well-tun
ed training pipeline, and, most critically, the quality of our newly collected d
atasets. Our best-in-class 72B model not only outperforms others in the class of
 open weight and data models, but also outperforms larger proprietary models inc
luding Claude 3.5 Sonnet, and Gemini 1.5 Pro and Flash, second only to GPT-4o ba
sed on both academic benchmarks and on a large human evaluation. Our model weigh
ts, new datasets, and source code are available at https://molmo.allenai.org/blo
g.

DriveGPT4-V2: Harnessing Large Language Model Capabilities for Enhanced Closed-L
oop Autonomous Driving
Zhenhua Xu, Yan Bai, Yujia Zhang, Zhuoling Li, Fei Xia, Kwan-Yee K. Wong, Jianqi
ang Wang, Hengshuang Zhao; Proceedings of the Computer Vision and Pattern Recogn
ition Conference (CVPR), 2025, pp. 17261-17270
Multimodal large language models (MLLMs) possess the ability to comprehend visua
l images or videos, and show impressive reasoning ability thanks to the vast amo
unts of pretrained knowledge, making them highly suitable for autonomous driving
 applications. Unlike the previous work, DriveGPT4-V1, which focused on open-loo
p tasks, this study explores the capabilities of LLMs in enhancing closed-loop a
utonomous driving. DriveGPT4-V2 processes camera images and vehicle states as in
put to generate low-level control signals for end-to-end vehicle operation. A mu
lti-view visual tokenizer (MV-VT) is employed enabling DriveGPT4-V2 to perceive
the environment with an extensive range while maintaining critical details. The
model architecture has been refined to improve decision prediction and inference
 speed. To further enhance the performance, an additional expert LLM is trained
for online imitation learning. The expert LLM, sharing a similar structure with
DriveGPT4-V2, can access privileged information about surrounding objects for mo
re robust and reliable predictions. Experimental results show that DriveGPT4-V2
outperforms all baselines on the challenging CARLA Longest6 benchmark. The code
and data of DriveGPT4-V2 will be publicly available.

High-Fidelity Lightweight Mesh Reconstruction from Point Clouds
Chen Zhang, Wentao Wang, Ximeng Li, Xinyao Liao, Wanjuan Su, Wenbing Tao; Procee
dings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp
. 11739-11748
Recently, learning signed distance functions (SDFs) from point clouds has become
 popular for reconstruction. To ensure accuracy, most methods require using high
-resolution Marching Cubes for surface extraction. However, this results in redu
ndant mesh elements, making the mesh inconvenient to use. To solve the problem,
we propose an adaptive meshing method to extract resolution-adaptive meshes base
d on surface curvature, enabling the recovery of high-fidelity lightweight meshe
s. Specifically, we first use point-based representation to perceive implicit su
rfaces and calculate surface curvature. A vertex generator is designed to produc
e curvature-adaptive vertices with any specified number on the implicit surface,
 preserving the overall structure and high-curvature features. Then we develop a
 Delaunay meshing algorithm to generate meshes from vertices, ensuring geometric
 fidelity and correct topology. In addition, to obtain accurate SDFs for adaptiv
e meshing and achieve better lightweight reconstruction, we design a hybrid repr
esentation combining feature grid and feature tri-plane for better detail captur
e. Experiments demonstrate that our method can generate high-quality lightweight
 meshes from point clouds. Compared with methods from various categories, our ap
proach achieves superior results, especially in capturing more details with fewe
r elements.

MDP: Multidimensional Vision Model Pruning with Latency Constraint
Xinglong Sun, Barath Lakshmanan, Maying Shen, Shiyi Lan, Jingde Chen, Jose M. Al

varez; Proceedings of the Computer Vision and Pattern Recognition Conference (CV
PR), 2025, pp. 20113-20123
Current structural pruning methods face two significant limitations: (i) they of
ten limit pruning to finer-grained levels like channels, making aggressive param
eter reduction challenging, and (ii) they focus heavily on parameter and FLOP re
duction, with existing latency-aware methods frequently relying on simplistic, s
uboptimal linear models that fail to generalize well to transformers, where mult
iple interacting dimensions impact latency. In this paper, we address both limit
ations by introducing Multi-Dimensional Pruning(MDP), a novel paradigm that join
tly optimizes across a variety of pruning granularities--including channels, que
ry/key, heads, embeddings, and blocks. MDP employs an advanced latency modeling
technique to accurately capture latency variations across all prunable dimension
s, achieving an optimal balance between latency and accuracy. By reformulating p
runing as a Mixed-Integer Nonlinear Program (MINLP), MDP efficiently identifies
the optimal pruned structure across all prunable dimensions while respecting lat
ency constraints. This versatile framework supports both CNNs and transformers.
Extensive experiments demonstrate that MDP significantly outperforms previous me
thods, especially at high pruning ratios. On ImageNet, MDP achieves a 28% speed
increase with a +1.4 Top-1 accuracy improvement over prior work like HALP for Re
sNet50 pruning. Against the latest transformer pruning method, Isomorphic, MDP d
elivers an additional 37% acceleration with a +0.7 Top-1 accuracy improvement.

OSDFace: One-Step Diffusion Model for Face Restoration
Jingkai Wang, Jue Gong, Lin Zhang, Zheng Chen, Xing Liu, Hong Gu, Yutong Liu, Yu
lun Zhang, Xiaokang Yang; Proceedings of the Computer Vision and Pattern Recogni
tion Conference (CVPR), 2025, pp. 12626-12636
Diffusion models have demonstrated impressive performance in face restoration. Y
et, their multi-step inference process remains computationally intensive, limiti
ng their applicability in real-world scenarios. Moreover, existing methods often
 struggle to generate face images that are harmonious, realistic, and consistent
 with the subject's identity. In this work, we propose OSDFace, a novel one-step
 diffusion model for face restoration. Specifically, we propose a visual represe
ntation embedder (VRE) to better capture prior information and understand the in
put face. In VRE, low-quality faces are processed by a visual tokenizer and subs
equently embedded with a vector-quantized dictionary to generate visual prompts.
 Additionally, we incorporate a facial identity loss derived from face recogniti
on to further ensure identity consistency. We further employ a generative advers
arial network (GAN) as a guidance model to encourage distribution alignment betw
een the restored face and the ground truth. Experimental results demonstrate tha
t OSDFace surpasses current state-of-the-art (SOTA) methods in both visual quali
ty and quantitative metrics, generating high-fidelity, natural face images with
high identity consistency. The code and model will be released at https://github
.com/jkwang28/OSDFace.

Task Singular Vectors: Reducing Task Interference in Model Merging
Antonio Andrea Gargiulo, Donato Crisostomi, Maria Sofia Bucarelli, Simone Scarda
pane, Fabrizio Silvestri, Emanuele Rodolà; Proceedings of the Computer Vision an
d Pattern Recognition Conference (CVPR), 2025, pp. 18695-18705
Task Arithmetic has emerged as a simple yet effective method to merge models wit
hout additional training. However, by treating entire networks as flat parameter
 vectors, it overlooks key structural information and is susceptible to task int
erference. In this paper, we study task vectors at the layer level, focusing on
task layer matrices and their singular value decomposition. In particular, we co
ncentrate on the resulting singular vectors, which we refer to as Task Singular
Vectors (TSV). Recognizing that layer task matrices are often low-rank, we propo
se TSV-Compress, a simple procedure that compresses them to 10% of their origina
l size while retaining 99% of accuracy. We further leverage this low-rank space
to define a new measure of task interference based on the interaction of singula
r vectors from different tasks. Building on these findings, we introduce TSV-Mer
ge, a novel model merging approach that combines compression with interference r

eduction, significantly outperforming existing methods.

Functionality Understanding and Segmentation in 3D Scenes
Jaime Corsetti, Francesco Giuliari, Alice Fasoli, Davide Boscaini, Fabio Poiesi; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 24550-24559
Understanding functionalities in 3D scenes involves interpreting natural language descriptions to locate functional interactive objects, such as handles and buttons, in a 3D environment. Functionality understanding is highly challenging, as it requires both world knowledge to interpret language and spatial perception to identify fine-grained objects. For example, given a task like "turn on the ceiling light", an embodied AI agent must infer that it needs to locate the light switch, even though the switch is not explicitly mentioned in the task description.To date, no dedicated methods have been developed for this problem. In this paper, we introduce Fun3DU, the first approach designed for functionality understanding in 3D scenes. Fun3DU uses a language model to parse the task description through Chain-of-Thought reasoning in order to identify the object of interest. The identified object is segmented across multiple views of the captured scene by using a VLM. The segmentation results from each view are lifted in 3D and aggregated into the point cloud using geometric information. Fun3DU is training-free, relying entirely on pre-trained models. We evaluate Fun3DU on SceneFun3D, the most recent and only dataset to benchmark this task, which comprises over 3000 task descriptions on 230 scenes. Our method significantly outperforms state-of-the-art open-vocabulary 3D segmentation approaches. Project page: https://tev-fbk.github.io/fun3du
****
Dragin3D: Image Editing by Dragging in 3D Space
Weiran Guang, Xiaoguang Gu, Mengqi Huang, Zhendong Mao; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 21502-21512
Interactive drag editing of images is a valuable task that has gained considerable attention for its precision and controllability. However, existing approaches have primarily focused on manipulating the shape or movement of objects in 2D plane. We propose to extend this drag-based editing task to 3D space. Firstly, we utilize the trajectory of two points to represent the rotational trajectory of the object. Gaussian maps of a circle and a square are centered at these two points, respectively. We use distinct shapes to ensure that symmetric views produce different object representations. Secondly, we introduce a lightweight mapping network to embed the object features into two Gaussian maps to obtain a continuous control condition that guides the model in learning the correspondence between the trajectory and the object. Finally, to overcome the limitations of current 3D object reconstruction datasets, which typically consist of object maps with transparent backgrounds, we affix random backgrounds to them. This modification helps improve the model's ability to ignore background interference when editing real images with complex backgrounds. Experiments demonstrate that our approach successfully achieves object rotation within the drag framework and demonstrates strong generalization to real-world images.

MMTL-UniAD: A Unified Framework for Multimodal and Multi-Task Learning in Assistive Driving Perception
Wenzhuo Liu, Wenshuo Wang, Yicheng Qiao, Qiannan Guo, Jiayin Zhu, Pengfei Li, Zilong Chen, Huiming Yang, Zhiwei Li, Lening Wang, Tiao Tan, Huaping Liu; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 6864-6874
Advanced driver assistance systems require a comprehensive understanding of the driver's mental/physical state and traffic context but existing works often neglect the potential benefits of joint learning between these tasks. This paper proposes MMTL-UniAD, a unified multi-modal multi-task learning framework that simultaneously recognizes driver behavior (e.g., looking around, talking), driver emotion (e.g., anxiety, happiness), vehicle behavior (e.g., parking, turning), and traffic context (e.g., traffic jam, traffic smooth). A key challenge is avoiding

negative transfer between tasks, which can impair learning performance. To addr
ess this, we introduce two key components into the framework: one is the multi-a
xis region attention network to extract global context-sensitive features, and t
he other is the dual-branch multimodal embedding to learn multimodal embeddings
from both task-shared and task-specific features. The former uses a multi-attent
ion mechanism to extract task-relevant features, mitigating negative transfer ca
used by task-unrelated features. The latter employs a dual-branch structure to a
daptively adjust task-shared and task-specific parameters, enhancing cross-task
knowledge transfer while reducing task conflicts. We assess MMTL-UniAD on the AI
DE dataset, using a series of ablation studies, and show that it outperforms sta
te-of-the-art methods across all four tasks. The code is available on https://gi
thub.com/Wenzhuo-Liu/MMTL-UniAD.

T2V-CompBench: A Comprehensive Benchmark for Compositional Text-to-video Generat
ion
Kaiyue Sun, Kaiyi Huang, Xian Liu, Yue Wu, Zihan Xu, Zhenguo Li, Xihui Liu; Proc
eedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025,
pp. 8406-8416
Text-to-video (T2V) generative models have advanced significantly, yet their abi
lity to compose different objects, attributes, actions, and motions into a video
remains unexplored. Previous text-to-video benchmarks also neglect this importa
nt ability for evaluation. In this work, we conduct the first systematic study o
n compositional text-to-video generation. We propose T2V-CompBench, the first be
nchmark tailored for compositional text-to-video generation. T2V-CompBench encom
passes diverse aspects of compositionality, including consistent attribute bindi
ng, dynamic attribute binding, spatial relationships, motion binding, action bin
ding, object interactions, and generative numeracy. We further carefully design
evaluation metrics of multimodal large language model (MLLM)-based, detection-ba
sed, and tracking-based metrics, which can better reflect the compositional text
-to-video generation quality of seven proposed categories with 1400 text prompts
. The effectiveness of the proposed metrics is verified by correlation with huma
n evaluations. We also benchmark various text-to-video generative models and con
duct in-depth analysis across different models and various compositional categor
ies. We find that compositional text-to-video generation is highly challenging f
or current models, and we hope our attempt could shed light on future research i
n this direction.

Self-Evolving Visual Concept Library using Vision-Language Critics
Atharva Sehgal, Patrick Yuan, Ziniu Hu, Yisong Yue, Jennifer J. Sun, Swarat Chau
dhuri; Proceedings of the Computer Vision and Pattern Recognition Conference (CV
PR), 2025, pp. 13124-13134
We study the problem of building a visual concept library for visual recognition
. Building effective visual concept libraries is challenging, as manual definiti
on is labor-intensive, while relying solely on LLMs for concept generation can r
esult in concepts that lack discriminative power or fail to account for the comp
lex interactions between them. Our approach, ESCHER, takes a library learning pe
rspective to iteratively discover and improve visual concepts. ESCHER uses a vis
ion-language model (VLM) as a critic to iteratively refine the concept library,
including accounting for interactions between concepts and how they affect downs
tream classifiers. By leveraging the in-context learning abilities of LLMs and t
he history of performance using various concepts, ESCHER dynamically improves it
s concept generation strategy based on the VLM critic's feedback. Finally, ESCHE
R does not require any human annotations, and is thus an automated plug-and-play
framework. We empirically demonstrate the ability of ESCHER to learn a concept
library for zero-shot, few-shot, and fine-tuning visual classification tasks. Th
is work represents, to our knowledge, the first application of concept library l
earning to real-world visual tasks.

Multimodal Autoregressive Pre-training of Large Vision Encoders
Enrico Fini, Mustafa Shukor, Xiujun Li, Philipp Dufter, Michal Klein, David Hald

imann, Sai Aitharaju, Victor G. Turrisi da Costa, Louis Béthune, Zhe Gan, Alexander Toshev, Marcin Eichner, Moin Nabi, Yinfei Yang, Joshua Susskind, Alaaeldin El-Nouby; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 9641-9654
We introduce a novel method for pre-training of large-scale vision encoders. Building on recent advancements in autoregressive pre-training of vision models, we extend this framework to a multimodal setting, i.e., images and text. In this paper, we present AIMV2, a family of generalist vision encoders characterized by a straightforward pre-training process, scalability, and remarkable performance across a range of downstream tasks. This is achieved by pairing the vision encoder with a multimodal decoder that autoregressively generates raw image patches and text tokens. Our encoders excel not only in multimodal evaluations but also in vision benchmarks such as localization, grounding, and classification. Notably, our AIMV2-3B encoder achieves 89.5% accuracy on ImageNet-1k with a frozen trunk. Fur- thermore, AIMV2 consistently outperforms state-of-the-art contrastive models (e.g., CLIP, SigLIP) in multimodal im- age understanding across diverse settings.
****

AKiRa: Augmentation Kit on Rays for Optical Video Generation
Xi Wang, Robin Courant, Marc Christie, Vicky Kalogeiton; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 2609-2619
Recent advances in text-conditioned video diffusion have greatly improved video quality. However, these methods offer limited or sometimes no control to users on camera aspects, including dynamic camera motion, zoom, distorted lens and focus shifts. These motion and optical aspects are crucial for adding controllability and cinematic elements to generation frameworks, ultimately resulting in visual content that draws focus, enhances mood, and guides emotions according to film makers' controls. In this paper, we aim to close the gap between controllable video generation and camera optics. To achieve this, we propose AKiRa (Augmentation Kit on Rays), a novel augmentation framework that builds and trains a camera adapter with a complex camera model over an existing video generation backbone. It enables fine-tuned control over camera motion as well as complex optical parameters (focal length, distortion, aperture) to achieve cinematic effects such as zoom, fisheye effect, and bokeh. Extensive experiments demonstrate AKiRa's effectiveness in combining and composing camera optics while outperforming all state-of-the-art methods. This work sets a new landmark in controlled and optically enhanced video generation, paving the way for future camera diffusion methods.

Towards Stable and Storage-efficient Dataset Distillation: Matching Convexified Trajectory
Wenliang Zhong, Haoyu Tang, Qinghai Zheng, Mingzhu Xu, Yupeng Hu, Weili Guan; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 25581-25589
The rapid evolution of deep learning and large language models has led to an exponential growth in the demand for training data, prompting the development of Dataset Distillation methods to address the challenges of managing large datasets. Among these, Matching Training Trajectories (MTT) has been a prominent approach, which replicates the training trajectory of an expert network on real data with a synthetic dataset. However, our investigation found that this method suffers from three significant limitations: 1. Instability of expert trajectory generated by Stochastic Gradient Descent (SGD); 2. Low convergence speed of the distillation process; 3. High storage consumption of the expert trajectory. To address these issues, we offer a new perspective on understanding the essence of Dataset Distillation and MTT through a simple transformation of the objective function, and introduce a novel method called Matching Convexified Trajectory (MCT), which aims to provide better guidance for the student trajectory. MCT creates convex combinations of expert trajectories by selecting a few expert models, guiding student networks to converge quickly and stably. This trajectory is not only easier to store, but also enables continuous sampling strategies during the distillation process, ensuring thorough learning and fitting of the entire expert trajec

tory. The comprehensive experiment of three public datasets verified that MCT is superior to the traditional MTT method.
****

TSAM: Temporal SAM Augmented with Multimodal Prompts for Referring Audio-Visual Segmentation
Abduljalil Radman, Jorma Laaksonen; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 23947-23956
Referring audio-visual segmentation (Ref-AVS) aims to segment objects within audio-visual scenes using multimodal cues embedded in text expressions. While the Segment Anything Model (SAM) has revolutionized visual segmentation, its applicability to Ref-AVS, where multimodal cues act as novel prompts, remains unexplored. SAM's limitation to single-frame segmentation also hinders its ability to capture essential temporal context needed for multi-frame audio-visual segmentation. To address this gap, we propose TSAM, a novel extension of SAM designed to leverage multimodal cues for precise segmentation in dynamic audio-visual scenes. TSAM enhances SAM's image encoder with a temporal modeling branch, enabling spatio-temporal learning and deep multimodal fusion across video frames, while retaining SAM's pre-trained knowledge. Additionally, TSAM replaces SAM's user-interactive prompting mechanism with sparse and dense data-driven prompts, enabling more effective integration of audio-visual inputs and reference text expressions. Extensive experiments on the Ref-AVS dataset demonstrate TSAM's superiority over state-of-the-art methods. The results illustrate its effectiveness in segmenting objects in dynamic audio-visual scenes using text-based multimodal cues and its strong generalization to unseen objects.
****

TFCustom: Customized Image Generation with Time-Aware Frequency Feature Guidance
Mushui Liu, Dong She, Jingxuan Pang, Qihan Huang, Jiacheng Ying, Wanggui He, Yuanlei Hou, Siming Fu; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 2714-2723
Subject-driven image personalization has seen notable advancements, especially with the advent of the ReferenceNet paradigm. ReferenceNet excels in integrating image reference features, making it highly applicable in creative and commercial settings. However, current implementations of ReferenceNet primarily operate as latent-level feature extractors, which limit their potential. This constraint hinders the provision of appropriate features to the denoising backbone across different timesteps, leading to suboptimal image consistency. In this paper, we revisit the extraction of reference features and propose TFCustom, a model framework designed to focus on reference image features at different temporal steps and frequency levels. Specifically, we firstly propose synchronized ReferenceNet to extract reference image features while simultaneously optimizing noise injection and denoising for the reference image. We also propose a time-aware frequency feature refinement module that leverages high- and low-frequency filters, combined with time embeddings, to adaptively select the degree of reference feature injection. Additionally, to enhance the similarity between reference objects and the generated image, we introduce a novel reward-based loss that encourages greater alignment between the reference and generated images. Experimental results demonstrate state-of-the-art performance in both multi-object and single-object reference generation, with significant improvements in texture and textual detail generation over existing methods.
****

Boosting Point-Supervised Temporal Action Localization through Integrating Query Reformation and Optimal Transport
Mengnan Liu, Le Wang, Sanping Zhou, Kun Xia, Xiaolong Sun, Gang Hua; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 13865-13875
Point-supervised Temporal Action Localization poses significant challenges due to the difficulty of identifying complete actions with a single-point annotation per action. Existing methods typically employ Multiple Instance Learning, which struggles to capture global temporal context and requires heuristic post-processing. In research on fully-supervised tasks, DETR-based structures have effectiv

ely addressed these limitations. However, it is nontrivial to merely adapt DETR to this task, encountering two major bottlenecks. (1) How to integrate point label information into the model and (2) How to select optimal decoder proposals for training in the absence of complete action segment annotations. To address this issue, we introduce an end-to-end framework by integrating Query Reformation and Optimal Transport (QROT). Specifically, we encode point labels through a set of semantic consensus queries, enabling effective focus on action-relevant snippets. Furthermore, we integrate an optimal transport mechanism to generate high-quality pseudo labels. These pseudo-labels facilitate precise proposals selection based on Hungarian algorithm, significantly enhancing localization accuracy in point-supervised settings. Extensive experiments on the THUMOS14 and ActivityNet-v1.3 datasets demonstrate that our method outperforms existing MIL-based approaches, offering more stable and accurate temporal action localization in point-level supervision.

SketchFusion: Learning Universal Sketch Features through Fusing Foundation Models

Subhadeep Koley, Tapas Kumar Dutta, Aneeshan Sain, Pinaki Nath Chowdhury, Ayan Kumar Bhunia, Yi-Zhe Song; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 2556-2567

While foundation models have revolutionised computer vision, their effectiveness for sketch understanding remains limited by the unique challenges of abstract, sparse visual inputs. Through systematic analysis, we uncover two fundamental limitations: Stable Diffusion (SD) struggles to extract meaningful features from abstract sketches (unlike its success with photos), and exhibits a pronounced frequency-domain bias that suppresses essential low-frequency components needed for sketch understanding. Rather than costly retraining, we address these limitations by strategically combining SD with CLIP, whose strong semantic understanding naturally compensates for SD's spatial-frequency biases. By dynamically injecting CLIP features into SD's denoising process and adaptively aggregating features across semantic levels, our method achieves state-of-the-art performance in sketch retrieval (+3.35%), recognition (+1.06%), segmentation (+29.42%), and correspondence learning (+21.22%), demonstrating the first truly universal sketch feature representation in the era of foundation models.

Bridging the Vision-Brain Gap with an Uncertainty-Aware Blur Prior

Haitao Wu, Qing Li, Changqing Zhang, Zhen He, Xiaomin Ying; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 2246-2257

Can our brain signals faithfully reflect the original visual stimuli, even including high-frequency details? Although human perceptual and cognitive capacities enable us to process and remember visual information, these abilities are constrained by several factors, such as limited attentional resources and finite capacity of visual memory. When visual stimuli are processed by human visual system into brain signals, some information is inevitably lost, leading to a discrepancy known as the System GAP. Additionally, perceptual and cognitive dynamics, along with technical noise in signal acquisition, degrade the fidelity of brain signals relative to the visual stimuli, known as the Random GAP. When encoded brain representations are directly aligned with the corresponding pretrained image features, the System GAP and Random GAP between paired data challenge the model, requiring it to bridge these gaps. However, due to limited paired data, these gaps are difficult for the model to learn, leading to overfitting and poor generalization to new data. To address these GAPs, we propose a simple yet effective approach called the Uncertainty-aware Blur Prior (UBP). It estimates the uncertainty within the paired data, reflecting the mismatch between brain signals and visual stimuli. Based on uncertainty, UBP dynamically blurs the high-frequency details of the original images, reducing the impact of mismatch and improving alignment. Our method achieves a top-1 accuracy of 50.9% and a top-5 accuracy of 79.7% on the zero-shot brain-to-image retrieval task, surpassing previous state-of-the-art methods. Code is available at https://github.com/HaitaoWuTJU/Uncertainty-aware-Blur-Prior.

Invisible Backdoor Attack against Self-supervised Learning
Hanrong Zhang, Zhenting Wang, Boheng Li, Fulin Lin, Tingxu Han, Mingyu Jin, Chen lu Zhan, Mengnan Du, Hongwei Wang, Shiqing Ma; Proceedings of the Computer Visio n and Pattern Recognition Conference (CVPR), 2025, pp. 25790-25801
Self-supervised learning (SSL) models are vulnerable to backdoor attacks. Existi ng backdoor attacks that are effective in SSL often involve noticeable triggers, like colored patches or visible noise, which are vulnerable to human inspection . This paper proposes an imperceptible and effective backdoor attack against sel f-supervised models. We first find that existing imperceptible triggers designed for supervised learning are less effective in compromising self-supervised mode ls. We then identify this ineffectiveness is attributed to the overlap in distri butions between the backdoor and augmented samples used in SSL. Building on this insight, we design an attack using optimized triggers disentangled with the aug mented transformation in the SSL, while remaining imperceptible to human vision. Experiments on five datasets and six SSL algorithms demonstrate our attack is h ighly effective and stealthy. It also has strong resistance to existing backdoor defenses. Our code can be found at https://github.com/Zhang-Henry/INACTIVE.

Perceptually Accurate 3D Talking Head Generation: New Definitions, Speech-Mesh R epresentation, and Evaluation Metrics
Lee Chae-Yeon, Oh Hyun-Bin, Han EunGi, Kim Sung-Bin, Suekyeong Nam, Tae-Hyun Oh; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2 025, pp. 21065-21074
Recent advancements in speech-driven 3D talking head generation have made signif icant progress in lip synchronization. However, existing models still struggle t o capture the perceptual alignment between varying speech characteristics and co rresponding lip movements. In this work, we claim that three criteria--Temporal Synchronization, Lip Readability, and Expressiveness--are crucial for achieving perceptually accurate lip movements. Motivated by our hypothesis that a desirabl e representation space exists to meet these three criteria, we introduce a speec h-mesh synchronized representation that captures intricate correspondences betwe en speech signals and 3D face meshes. We found that our learned representation e xhibits desirable characteristics, and we plug it into existing models as a perc eptual loss to better align lip movements to the given speech. In addition, we u tilize this representation as a perceptual metric and introduce two other physic ally grounded lip synchronization metrics to assess how well the generated 3D ta lking heads align with these three criteria. Experiments show that training 3D t alking head generation models with our perceptual loss significantly improve all three aspects of perceptually accurate lip synchronization. Codes and datasets are available at https://perceptual-3d-talking-head.github.io/.

BWFormer: Building Wireframe Reconstruction from Airborne LiDAR Point Cloud with Transformer
Yuzhou Liu, Lingjie Zhu, Hanqiao Ye, Shangfeng Huang, Xiang Gao, Xianwei Zheng, Shuhan Shen; Proceedings of the Computer Vision and Pattern Recognition Conferen ce (CVPR), 2025, pp. 22215-22224
In this paper, we present BWFormer, a novel Transformer-based model for building wireframe reconstruction from airborne LiDAR point cloud. The problem is solve d in a ground-up manner here by detecting the building corners in 2D, lifting an d connecting them in 3D space afterwards with additional data augmentation.Due t o the 2.5D characteristic of the airborne LiDAR point cloud, we simplify the pr oblem by projecting the points on the ground plane to produce a 2D height map. W ith the height map, a heat map is first generated with pixel-wise corner likelih ood to predict the possible 2D corners.Then, 3D corners are predicted by a Trans former-based network with extra height embedding initialization. This 2D-to-3D c orner detection strategy reduces the search space significantly. To recover the topological connections among the corners, edges are finally predicted from the height map with the proposed edge attention mechanism, which extracts holistic f eatures and preserves local details simultaneously. In addition, due to the limi

ted datasets in the field and the irregularity of the point clouds, a conditiona l latent diffusion model for LiDAR scanning simulation is utilized for data augm entation. BWFormer surpasses other state-of-the-art methods, especially in recon struction completeness. Our code is available at: https://github.com/3dv-casia/ BWformer/.

Diffusion-4K: Ultra-High-Resolution Image Synthesis with Latent Diffusion Models
Jinjin Zhang, Qiuyu Huang, Junjie Liu, Xiefan Guo, Di Huang; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 23464-23473
In this paper, we present Diffusion-4K, a novel framework for direct ultra-high-resolution image synthesis using text-to-image diffusion models. The core advanc ements include: (1) Aesthetic-4K Benchmark: addressing the absence of a publicly available 4K image synthesis dataset, we construct Aesthetic-4K, a comprehensiv e benchmark for ultra-high-resolution image generation. We curated a high-qualit y 4K dataset with carefully selected images and captions generated by GPT-4o. Ad ditionally, we introduce GLCM Score and compression ratio metrics to evaluate fi ne details, combined with holistic measures such as FID, Aesthetics and CLIPScor e for a comprehensive assessment of ultra-high-resolution images. (2) Wavelet-ba sed Fine-tuning: we propose a wavelet-based fine-tuning approach for direct trai ning with photorealistic 4K images, applicable to various latent diffusion model s, demonstrating its effectiveness in synthesizing highly detailed 4K images. Co nsequently, Diffusion-4K achieves impressive performance in high-quality image s ynthesis and text prompt adherence, especially when powered by modern large-scal e diffusion models (e.g., SD3-2B and Flux-12B). Extensive experimental results f rom our benchmark demonstrate the superiority of Diffusion-4K in ultra-high-reso lution image synthesis. Code is available at https://github.com/zhang0jhon/diffu sion-4k.

AffordDP: Generalizable Diffusion Policy with Transferable Affordance
Shijie Wu, Yihang Zhu, Yunao Huang, Kaizhen Zhu, Jiayuan Gu, Jingyi Yu, Ye Shi, Jingya Wang; Proceedings of the Computer Vision and Pattern Recognition Conferen ce (CVPR), 2025, pp. 6971-6980
Diffusion-based policies have shown impressive performance in robotic manipulati on tasks while struggling with out-of-domain distributions. Recent efforts attem pted to enhance generalization by improving the visual feature encoding for diff usion policy. However, their generalization is typically limited to the same cat egory with similar appearances. Our key insight is that leveraging affordances--manipulation priors that define "where" and "how" an agent interacts with an obj ect--can substantially enhance generalization to entirely unseen object instance s and categories. We introduce the Diffusion Policy with transferable Affordance (AffordDP), designed for generalizable manipulation across novel categories. Af fordDP models affordances through 3D contact points and post-contact trajectorie s, capturing the essential static and dynamic information for complex tasks. The transferable affordance from in-domain data to unseen objects is achieved by es timating a 6D transformation matrix using foundational vision models and point c loud registration techniques. More importantly, we incorporate affordance guidan ce during diffusion sampling that can refine action sequence generation. This gu idance directs the generated action to gradually move towards the desired manipu lation for unseen objects while keeping the generated action within the manifold of action space. Experimental results from both simulated and real-world enviro nments demonstrate that AffordDP consistently outperforms previous diffusion-bas ed methods, successfully generalizing to unseen instances and categories where o thers fail.

HMAR: Efficient Hierarchical Masked Auto-Regressive Image Generation
Hermann Kumbong, Xian Liu, Tsung-Yi Lin, Ming-Yu Liu, Xihui Liu, Ziwei Liu, Dani el Y. Fu, Christopher Re, David W. Romero; Proceedings of the Computer Vision an d Pattern Recognition Conference (CVPR), 2025, pp. 2535-2544
Visual AutoRegressive modeling (VAR) shows promise in bridging the speed and qua lity gap between autoregressive image models and diffusion models. VAR reformula

tes autoregressive modeling by decomposing an image into successive resolution s cales. During inference, an image is generated by predicting all the tokens in t he next (higher-resolution) scale, conditioned on all tokens in all previous (lo wer-resolutions) scales. However, this formulation suffers from reduced image qu ality due to parallel generation of all tokens in a resolution scale; has sequen ce lengths scaling superlinearly in image resolution; and requires retraining to change the resolution sampling schedule.We introduce \underline H ierarchical \ underline M asked \underline A uto\underline R egressive modeling (HMAR), a new image generation algorithm that alleviates these issues using next-scale predict ion and masked prediction to generate high-quality images with fast sampling. HM AR reformulates next-scale prediction as a Markovian process, wherein prediction of each resolution scale is conditioned only on tokens in its immediate predece ssor instead of the tokens in all predecessor resolutions. When predicting a res olution scale, HMAR uses a controllable multi-step masked generation procedure t o generate a subset of the tokens in each step. On ImageNet 256 x 256 and 512 x 512 benchmarks, HMAR models match or outperform parameter-matched VAR, diffu sion, and autoregressive baselines. We develop efficient IO-aware block-sparse a ttention kernels that allow HMAR to achieve faster training and inference times over VAR by over 2.5xand 1.75 xrespectively, as well as over 3 xlower inference memory footprint. Finally, the Markovian formulation of HMAR yields additional f lexibility over VAR; we show that its sampling schedule can be changed without f urther training, and it can be applied to image editing tasks in a zero-shot man ner.

OmniDrive: A Holistic Vision-Language Dataset for Autonomous Driving with Counte rfactual Reasoning

Shihao Wang, Zhiding Yu, Xiaohui Jiang, Shiyi Lan, Min Shi, Nadine Chang, Jan Ka utz, Ying Li, Jose M. Alvarez; Proceedings of the Computer Vision and Pattern Re cognition Conference (CVPR), 2025, pp. 22442-22452

The advances in vision-language models (VLMs) have led to a growing interest in autonomous driving to leverage their strong reasoning capabilities. However, ext ending these capabilities from 2D to full 3D understanding is crucial for real-w orld applications. To address this challenge, we propose OmniDrive, a holistic v ision-language dataset that aligns agent models with 3D driving tasks through co unterfactual reasoning. This approach enhances decision-making by evaluating pot ential scenarios and their outcomes, similar to human drivers considering altern ative actions. Our counterfactual-based synthetic data annotation process genera tes large-scale, high-quality datasets, providing denser supervision signals tha t bridge planning trajectories and language-based reasoning. Futher, we explore two advanced OmniDrive-Agent frameworks, namely Omni-L and Omni-Q, to assess the importance of vision-language alignment versus 3D perception, revealing critica l insights into designing effective LLM-agents. Significant improvements on the DriveLM Q&A benchmark and nuScenes open-loop planning demonstrate the effectiven ess of our dataset and methods.

DKC: Differentiated Knowledge Consolidation for Cloth-Hybrid Lifelong Person Re-identification

Zhenyu Cui, Jiahuan Zhou, Yuxin Peng; Proceedings of the Computer Vision and Pat tern Recognition Conference (CVPR), 2025, pp. 3573-3582

Lifelong person re-identification (LReID) aims to match the same person using se quentially collected data. However, due to the long-term nature of lifelong lear ning, the inevitable changes in human clothes prevent the model from relying on unified discriminative information (e.g., clothing style) to match the same pers on in the streaming data, demanding differentiated cloth-irrelevant information. Unfortunately, existing LReID methods typically fail to leverage such knowledge resulting in the exacerbation of catastrophic forgetting issues. Therefore, in this paper, we focus on a challenging practical task called Cloth-Hybrid Lifelon g Person Re-identification (CH-LReID), which requires matching the same person w earing different clothes using sequentially collected data. A Differentiated Kno wledge Consolidation (DKC) framework is designed to unify and balance distinct k

nowledge across streaming data. The core idea is to adaptively balance different iated knowledge and compatibly consolidate cloth-relevant and cloth-irrelevant i nformation. To this end, a Differentiated Knowledge Transfer (DKT) module and a Latent Knowledge Consolidation (LKC) module are designed to adaptively discover differentiated new knowledge, while eliminating the derived domain shift of old knowledge via reconstructing the old latent feature space, respectively. Then, t o further alleviate the catastrophic conflict between differentiated new and old knowledge, we further propose a Dual-level Distribution Alignment (DDA) module to align the distribution of discriminative knowledge at both the instance level and the fine-grained level. Extensive experiments on multiple benchmarks demons trate the superiority of our method against existing methods in both CH-LReID an d traditional LReID tasks. The source code of this paper is available at https:/ /github.com/PKU-ICST-MIPL/DKC-CVPR2025.

Enhancing Facial Privacy Protection via Weakening Diffusion Purification
Ali Salar, Qing Liu, Yingli Tian, Guoying Zhao; Proceedings of the Computer Visi on and Pattern Recognition Conference (CVPR), 2025, pp. 8235-8244
The rapid growth of social media has led to the widespread sharing of individual portrait images, which pose serious privacy risks due to the capabilities of au tomatic face recognition (AFR) systems for mass surveillance. Hence, protecting facial privacy against unauthorized AFR systems is essential. Inspired by the ge neration capability of the emerging diffusion models, recent methods employ diff usion models to generate adversarial face images for privacy protection. However , they suffer from the diffusion purification effect, leading to a low protectio n success rate (PSR). In this paper, we first propose learning unconditional emb eddings to increase the learning capacity for adversarial modifications and then use them to guide the modification of the adversarial latent code to weaken the diffusion purification effect. Moreover, we integrate an identity-preserving st ructure to maintain structural consistency between the original and generated im ages, allowing human observers to recognize the generated image as having the sa me identity as the original. Extensive experiments conducted on two public datas ets, i.e., CelebA-HQ and LADN, demonstrate the superiority of our approach. The protected faces generated by our method outperform those produced by existing fa cial privacy protection approaches in terms of transferability and natural appea rance. The code is available at https://github.com/parham1998/Facial-Privacy-Pro tection

ORIDa: Object-centric Real-world Image Composition Dataset
Jinwoo Kim, Sangmin Han, Jinho Jeong, Jiwoo Choi, Dongyeoung Kim, Seon Joo Kim; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 20 25, pp. 3051-3060
Object compositing, the task of placing and harmonizing objects in images of div erse visual scenes, has become an important task in computer vision with the ris e of generative models.However, existing datasets lack the diversity and scale r equired to comprehensively explore real-world scenarios comprehensively. We intr oduce ORIDa (Object-centric Real-world Image Composition Dataset), a large-scale , real-captured dataset containing over 30,000 images featuring 200 unique objec ts, each of which is presented across varied positions and scenes. ORIDa has two types of data: factual-counterfactual sets and factual-only scenes. The factual -counterfactual sets consist of four factual images showing an object in differe nt positions within a scene and a single counterfactual (or background) image of the scene without the object, resulting in five images per scene. The factual-o nly scenes include a single image containing an object in a specific context, ex panding the variety of environments. To our knowledge, ORIDa is the first public ly available dataset with its scale and complexity for real-world image composit ion. Extensive analysis and experiments highlight the value of ORIDa as a resour ce for advancing further research in object compositing.

MeGA: Hybrid Mesh-Gaussian Head Avatar for High-Fidelity Rendering and Head Edit ing

Cong Wang, Di Kang, Heyi Sun, Shenhan Qian, Zixuan Wang, Linchao Bao, Song-Hai Zhang; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 26274-26284

Creating high-fidelity head avatars from multi-view videos is essential for many AR/VR applications. However, current methods often struggle to achieve high-quality renderings across all head components (e.g., skin vs. hair) due to the limitations of using one single representation for elements with varying characteristics. In this paper, we introduce a Hybrid Mesh-Gaussian Head Avatar (MeGA) that models different head components with more suitable representations. Specifically, we employ an enhanced FLAME mesh for the facial representation and predict a UV displacement map to provide per-vertex offsets for improved personalized geometric details. To achieve photorealistic rendering, we use deferred neural rendering to obtain facial colors and decompose neural textures into three meaningful parts. For hair modeling, we first build a static canonical hair using 3D Gaussian Splatting. A rigid transformation and an MLP-based deformation field are further applied to handle complex dynamic expressions. Combined with our occlusion-aware blending, MeGA generates higher-fidelity renderings for the whole head and naturally supports diverse downstream tasks. Experiments on the NeRSemble dataset validate the effectiveness of our designs, outperforming previous state-of-the-art methods and enabling versatile editing capabilities, including hairstyle alteration and texture editing.

Image Generation Diversity Issues and How to Tame Them

Mischa Dombrowski, Weitong Zhang, Sarah Cechnicka, Hadrien Reynaud, Bernhard Kainz; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 3029-3039

Generative methods have reached a level of quality that is almost indistinguishable from real data. However, while individual samples may appear unique, generative models often exhibit limitations in covering the full data distribution. Unlike quality issues, diversity problems within generative models are not easily detected by simply observing single images or generated datasets, which means we need a specific measure to assess the diversity of these models. In this paper, we draw attention to the current lack of diversity in generative models and the inability of common metrics to measure this. We achieve this by framing diversity as an image retrieval problem, where we measure how many real images can be retrieved using synthetic data as queries. This yields the Image Retrieval Score (IRS), an interpretable, hyperparameter-free metric that quantifies the diversity of a generative model's output. IRS requires only a subset of synthetic samples and provides a statistical measure of confidence. Our experiments indicate that current feature extractors commonly used in generative model assessment are inadequate for evaluating diversity effectively. Consequently, we perform an extensive search for the best feature extractors to assess diversity. Evaluation reveals that current diffusion models converge to limited subsets of the real distribution, with no current state-of-the-art models superpassing 77% of the diversity of the training data. To address this limitation, we introduce Diversity-Aware Diffusion Models (DiADM), a novel approach that improves diversity of unconditional diffusion models without loss of image quality. We do this by disentangling diversity from image quality by using a diversity aware module that uses pseudo-unconditional features as input. We provide a Python package offering unified feature extraction and metric computation to further facilitate the evaluation of generative models https://github.com/MischaD/beyondfid.

Annotation Ambiguity Aware Semi-Supervised Medical Image Segmentation

Suruchi Kumari, Pravendra Singh; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 10404-10413

Despite the remarkable progress of deep learning-based methods in medical image segmentation, their use in clinical practice remains limited for two main reasons. First, obtaining a large medical dataset with precise annotations to train segmentation models is challenging. Secondly, most current segmentation techniques generate a single deterministic segmentation mask for each image. However, in r

eal-world scenarios, there is often significant uncertainty regarding what defin es the "correct" segmentation, and various expert annotators might provide diffe rent segmentations for the same image. To tackle both of these problems, we prop ose Annotation Ambiguity Aware Semi-Supervised Medical Image Segmentation (AmbiS SL). AmbiSSL combines a small amount of multi-annotator labeled data and a large set of unlabeled data to generate diverse and plausible segmentation maps. Our method consists of three key components: (1) The Diverse Pseudo-Label Generation (DPG) module utilizes multiple decoders, created by performing randomized pruni ng on the original backbone decoder. These pruned decoders enable the generation of a diverse pseudo-label set; (2) a Semi-Supervised Latent Distribution Learni ng (SSLDL) module constructs a common latent space by utilizing both ground trut h annotations and pseudo-label set; and (3) a Cross-Decoder Supervision (CDS) mo dule, which enables pruned decoders to guide each other's learning. We evaluated the proposed method on two publicly available datasets. Extensive experiments d emonstrate that AmbiSSL can generate diverse segmentation maps using only a smal l amount of labeled data and abundant unlabeled data, offering a more practical solution for medical image segmentation by reducing reliance on large labeled da tasets.

Effective Cloud Removal for Remote Sensing Images by an Improved Mean-Reverting Denoising Model with Elucidated Design Space

Yi Liu, Wengen Li, Jihong Guan, Shuigeng Zhou, Yichao Zhang; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 17851-17861

Cloud removal (CR) remains a challenging task in remote sensing image processing . Although diffusion models (DM) exhibit strong generative capabilities, their d irect applications to CR are suboptimal, as they generate cloudless images from random noise, ignoring inherent information in cloudy inputs. To overcome this d rawback, we develop a new CR model EMRDM based on mean-reverting diffusion model s (MRDMs) to establish a direct diffusion process between cloudy and cloudless i mages. Compared to current MRDMs, EMRDM offers a modular framework with updatabl e modules and an elucidated design space, based on a reformulated forward proces s and a new ordinary differential equation (ODE)-based backward process. Leverag ing our framework, we redesign key MRDM modules to boost CR performance, includi ng restructuring the denoiser via a preconditioning technique, reorganizing the training process, and improving the sampling process by introducing determinisli c and stochastic samplers. To achieve multi-temporal CR, we further develop a de noising network for simultaneously denoising sequential images. Experiments on m ono-temporal and multi-temporal datasets demonstrate the superior performance of EMRDM. Our code is available at https://github.com/Ly403/EMRDM.

CAP4D: Creating Animatable 4D Portrait Avatars with Morphable Multi-View Diffusi on Models

Felix Taubner, Ruihang Zhang, Mathieu Tuli, David B. Lindell; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 5318-5330

Reconstructing photorealistic and dynamic portrait avatars from images is essent ial to many applications including advertising, visual effects, and virtual real ity. Depending on the application, avatar reconstruction involves different capt ure setups and constraints -- for example, visual effects studios use camera arr ays to capture hundreds of reference images, while content creators may seek to animate a single portrait image downloaded from the internet. As such, there is a large and heterogeneous ecosystem of methods for avatar reconstruction. Techni ques based on multi-view stereo or neural rendering achieve the highest quality results, but require hundreds of reference images. Recent generative models prod uce convincing avatars from a single reference image, but visual fidelity lags b ehind multi-view techniques. Here, we present CAP4D: an approach that uses a mor phable multi-view diffusion model to reconstruct photoreal 4D (dynamic 3D) portr ait avatars from any number of reference images (i.e., one to 100) and animate a nd render them in real time. Our approach demonstrates state-of-the-art performa nce for single-, few-, and multi-image 4D portrait avatar reconstruction, and ta kes steps to bridge the gap in visual fidelity between single-image and multi-vi

ew reconstruction techniques.

Comprehensive Information Bottleneck for Unveiling Universal Attribution to Interpret Vision Transformers
Jung-Ho Hong, Ho-Joong Kim, Kyu-Sung Jeon, Seong-Whan Lee; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 25166-25175
The feature attribution method reveals the contribution of input variables to the decision-making process to provide an attribution map for explanation. Existing methods grounded on the information bottleneck principle compute information in a specific layer to obtain attributions, compressing the features by injecting noise via a parametric damping ratio. However, the attribution obtained in a specific layer neglects evidence of the decision-making process distributed across layers. In this paper, we introduce a comprehensive information bottleneck (CoIBA), which discovers the relevant information in each targeted layer to explain the decision-making process. Our core idea is applying information bottleneck in multiple targeted layers to estimate the comprehensive information by sharing a parametric damping ratio across the layers. Leveraging this shared ratio complements the over-compressed information to discover the omitted clues of the decision by sharing the relevant information across the targeted layers. We suggest the variational approach to fairly reflect the relevant information of each layer by upper bounding layer-wise information. Therefore, CoIBA guarantees that the discarded activation is unnecessary in every targeted layer to make a decision. The extensive experimental results demonstrate the enhancement in faithfulness of the feature attributions provided by CoIBA.

OpticalNet: An Optical Imaging Dataset and Benchmark Beyond the Diffraction Limit
Benquan Wang, Ruyi An, Jin-Kyu So, Sergei Kurdiumov, Eng Aik Chan, Giorgio Adamo, Yuhan Peng, Yewen Li, Bo An; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 10900-10912
Optical imaging capable of resolving nanoscale features would revolutionize scientific research and engineering applications across biomedicine, smart manufacturing, and semiconductor quality control. However, due to the physical phenomenon of diffraction, the optical resolution is limited to approximately half the wavelength of light, which impedes the observation of subwavelength objects such as the native state coronavirus, typically smaller than 200 nm. Fortunately, deep learning methods have shown remarkable potential in uncovering underlying patterns within data, promising to overcome the diffraction limit by revealing the mapping pattern between diffraction images and their corresponding ground truth object images. However, the absence of suitable datasets has hindered progress in this field--collecting high-quality optical data of subwavelength objects is highly difficult as these objects are inherently invisible under conventional microscopy, making it impossible to perform standard visual calibration and drift correction. Therefore, we provide the first general optical imaging dataset based on the "building block" concept for challenging the diffraction limit. Drawing an analogy to modular construction principles, we construct a comprehensive optical imaging dataset comprising subwavelength fundamental elements, i.e., small square units that can be assembled into larger and more complex objects. We then frame the task as an image-to-image translation task and evaluate various vision methods. Experimental results validate our "building block" concept, demonstrating that models trained on basic square units can effectively generalize to realistic, more complex unseen objects. Most importantly, by highlighting this underexplored AI-for-science area and its potential, we aspire to advance optical science by fostering collaboration with the vision and machine learning communities.

Dataset Distillation with Neural Characteristic Function: A Minmax Perspective
Shaobo Wang, Yicun Yang, Zhiyuan Liu, Chenghao Sun, Xuming Hu, Conghui He, Linfeng Zhang; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 25570-25580
Dataset distillation has emerged as a powerful approach for reducing data requir

ements in deep learning. Among various methods, distribution matching-based appr oaches stand out for their balance of computational efficiency and strong perfor mance. However, existing distance metrics used in distribution matching often fa il to accurately capture distributional differences, leading to unreliable measu res of discrepancy. In this paper, we reformulate dataset distillation as a minm ax optimization problem and introduce Neural Characteristic Function Discrepancy (NCFD), a comprehensive and theoretically grounded metric for measuring distrib utional differences. NCFD leverages the Characteristic Function (CF) to encapsul ate full distributional information, employing a neural network to optimize the sampling strategy for the CF's frequency arguments, thereby maximizing the discr epancy to enhance distance estimation. Simultaneously, we minimize the differenc e between real and synthetic data under this optimized NCFD measure. Our approac h, termed Neural Characteristic Function Matching (NCFM), inherently aligns the phase and amplitude of neural features in the complex plane for both real and sy nthetic data, achieving a balance between realism and diversity in synthetic sam ples. Experiments demonstrate that our method achieves significant performance g ains over state-of-the-art methods on both low- and high-resolution datasets. No tably, we achieve a 22.9% accuracy boost on ImageSquawk. Our method also reduces GPU memory usage by over 300x and achieves 20x faster processing speeds compare d to state-of-the-art methods. To the best of our knowledge, this is the first w ork to achieve lossless compression of CIFAR-100 on a single NVIDIA 2080 Ti GPU using only 2.3 GB of memory. The code for this work is publicly available at: ht tps://github.com/gszfwsb/NCFM.

Free-viewpoint Human Animation with Pose-correlated Reference Selection

Fa-Ting Hong, Zhan Xu, Haiyang Liu, Qinjie Lin, Luchuan Song, Zhixin Shu, Yang Z hou, Duygu Ceylan, Dan Xu; Proceedings of the Computer Vision and Pattern Recogn ition Conference (CVPR), 2025, pp. 26253-26262

Diffusion-based human animation aims to animate a human character based on a sou rce human image as well as driving signals such as a sequence of poses. Leveragi ng the generative capacity of diffusion model, existing approaches are able to g enerate high-fidelity poses, but struggle with significant viewpoint changes, es pecially in zoom-in/zoom-out scenarios where camera-character distance varies. T his limits the applications such as cinematic shot type plan or camera control. We propose a pose-correlated reference selection diffusion network, supporting s ubstantial viewpoint variations in human animation. Our key idea is to enable th e network to utilize multiple reference images as input, since significant viewp oint changes often lead to missing appearance details on the human body. To elim inate the computational cost, we first introduce a novel pose correlation module to compute similarities between non-aligned target and source poses, and then p ropose an adaptive reference selection strategy, utilizing the attention map to identify key regions for animation generation. To train our model, we curated a large dataset from public TED talks featuring varied shots of the same character , helping the model learn synthesis for different perspectives. Our experimental results show that with the same number of reference images, our model performs favorably compared to the current SOTA methods under large viewpoint change. We further show that the adaptive reference selection is able to choose the most re levant reference regions to generate humans under free viewpoints.

CORE4D: A 4D Human-Object-Human Interaction Dataset for Collaborative Object REa rrangement

Yun Liu, Chengwen Zhang, Ruofan Xing, Bingda Tang, Bowen Yang, Li Yi; Proceeding s of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 17 69-1782

Understanding how humans cooperatively rearrange household objects is critical f or VR/AR and human-robot interaction. However, in-depth studies on modeling thes e behaviors are under-researched due to the lack of relevant datasets. We fill t his gap by presenting CORE4D, a novel large-scale 4D human-object-human interact ion dataset focusing on collaborative object rearrangement, which encompasses di verse compositions of various object geometries, collaboration modes, and 3D sce

nes. With 1K human-object-human motion sequences captured in the real world, we enrich CORE4D by contributing an iterative collaboration retargeting strategy to augment motions to a variety of novel objects. Leveraging this approach, CORE4D comprises a total of 11K collaboration sequences spanning 3K real and virtual object shapes. Benefiting from extensive motion patterns provided by CORE4D, we benchmark two tasks aiming at generating human-object interaction: human-object motion forecasting and interaction synthesis. Extensive experiments demonstrate the effectiveness of our collaboration retargeting strategy and indicate that CORE4D has posed new challenges to existing human-object interaction generation methodologies.

PillarHist: A Quantization-aware Pillar Feature Encoder based on Height-aware Histogram

Sifan Zhou, Zhihang Yuan, Dawei Yang, Xing Hu, Jian Qian, Ziyu Zhao; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 27336-27345

Real-time and high-performance 3D object detection plays a critical role in autonomous driving and robotics. Recent pillar-based 3D object detectors have gained significant attention due to their compact representation and low computational overhead, making them suitable for onboard deployment and quantization. However, existing pillar-based detectors still suffer from information loss along height dimension and large numerical distribution difference during pillar feature encoding (PFE), which severely limits their performance and quantization potential. To address above issue, we first unveil the importance of different input information during PFE and identify the height dimension as a key factor in enhancing 3D detection performance. Motivated by this observation, we propose a height-aware pillar feature encoder, called PillarHist. Specifically, PillarHist statistics the discrete distribution of points at different heights within one pillar. This simple yet effective design greatly preserves the information along the height dimension while significantly reducing the computation overhead of the PFE. Meanwhile, PillarHist also constrains the arithmetic distribution of PFE input to a stable range, making it quantization-friendly. Notably, PillarHist operates exclusively within the PFE stage to enhance performance, enabling seamless integration into existing pillar-based methods without introducing complex operations. Extensive experiments show the effectiveness of PillarHist in terms of both efficiency and performance.

POp-GS: Next Best View in 3D-Gaussian Splatting with P-Optimality

Joey Wilson, Marcelino Almeida, Sachit Mahajan, Martin Labrie, Maani Ghaffari, Omid Ghasemalizadeh, Min Sun, Cheng-Hao Kuo, Arnab Sen; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 3646-3655

In this paper, we present a novel algorithm for quantifying uncertainty and information gained within 3D Gaussian Splatting (3D-GS) through P-Optimality. While 3D-GS has proven to be a useful world model with high-quality rasterizations, it does not natively quantify uncertainty or information, posing a challenge for real-world applications such as 3D-GS SLAM. We propose to quantify information gain in 3D-GS by reformulating the problem through the lens of optimal experimental design, which is a classical solution widely used in literature. By restructuring information quantification of 3D-GS through optimal experimental design, we arrive at multiple solutions, of which T-Optimality and D-Optimality perform the best quantitatively and qualitatively as measured on two popular datasets. Additionally, we propose a block diagonal covariance approximation which provides a measure of correlation at the expense of a greater computation cost.

****

Empowering Vector Graphics with Consistently Arbitrary Viewing and View-dependent Visibility

Yidi Li, Jun Xiao, Zhengda Lu, Yiqun Wang, Haiyong Jiang; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 18531-18540

This work presents a novel text-to-vector graphics generation approach, Dream3DVG, allowing for arbitrary viewpoint viewing, progressive detail optimization, an

d view-dependent occlusion awareness. Our approach is a dual-branch optimizatio n framework, consisting of an auxiliary 3D Gaussian Splatting optimization branc h and a 3D vector graphics optimization branch. The introduced 3DGS branch can bridge the domain gaps between text prompts and vector graphics with more consis tent guidance. Moreover, 3DGS allows for progressive detail control by schedulin g classifier-free guidance, facilitating guiding vector graphics with coarse sha pes at the initial stages and finer details at later stages. We also improve th e view-dependent occlusions by devising a visibility-awareness rendering module. Extensive results on 3D sketches and 3D iconographies, demonstrate the superio rity of the method on different abstraction levels of details, cross-view consis tency, and occlusion-aware stroke culling.

Semantic and Expressive Variations in Image Captions Across Languages

Andre Ye, Sebastin Santy, Jena D. Hwang, Amy X. Zhang, Ranjay Krishna; Proceedin gs of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 2 9667-29679

Most vision-language models today are primarily trained on English image-text pa irs, with non-English pairs often filtered out. Evidence from cross-cultural psy chology suggests that this approach will bias models against perceptual modes ex hibited by people who speak other (non-English) languages. We investigate semant ic and expressive variation in image captions across different languages; we ana lyze both human-annotated datasets and model-produced captions. By analyzing cap tions across seven languages (English, French, German, Russian, Chinese, Japanes e, Korean) in high-quality image captioning datasets (Crossmodal and Visual Geno me), we find that multilingual caption sets tend to provide richer visual descri ptions than monolingual (including English-only) ones; multilingual sets contain 46.0% more objects, 66.1% more relationships, and 66.8% more attributes. We obs erve the same results with multilingual captions produced by LLaVA and the Googl e Vertex API: for example, compared to monolingual captions, they cover 21.9% mo re objects,18.8% more relations, and 20.1% more attributes. These suggest that, across a large number of samples, different languages bias people and models to focus on different visual concepts. Finally, we show that models trained on imag e-text data in one language perform distinctly better on that language's test se t. Our work points towards the potential value of training vision models on mult ilingual data sources to widen the range/variation of descriptive information th ose models are exposed to.

****

ATP-LLaVA: Adaptive Token Pruning for Large Vision Language Models

Xubing Ye, Yukang Gan, Yixiao Ge, Xiao-Ping Zhang, Yansong Tang; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 24972-2 4982

Large Vision Language Models (LVLMs) have achieved significant success across mu lti-modal tasks. However, the computational cost of processing long visual token s can be prohibitively expensive on resource-limited devices. Previous methods h ave identified redundancy in visual tokens within the Large Language Model (LLM) decoder layers and have mitigated this by pruning tokens using a pre-defined or fixed ratio, thereby reducing computational overhead. Nonetheless, we observe t hat the impact of pruning ratio varies across different LLM layers and instances (image-prompt pairs). Therefore, it is essential to develop a layer-wise and in stance-wise vision token pruning strategy to balance computational cost and mode l performance effectively. We propose ATP-LLaVA, a novel approach that adaptivel y determines instance-specific token pruning ratios for each LLM layer. Specific ally, we introduce an Adaptive Token Pruning (ATP) module, which computes the im portance score and pruning threshold based on input instance adaptively. The ATP module can be seamlessly integrated between any two LLM layers with negligible computational overhead. Additionally, we develop a Spatial Augmented Pruning (SA P) strategy that prunes visual tokens with both token redundancy and spatial mod eling perspectives. Our approach reduces the average token count by 75% while ma intaining performance, with only a minimal 1.9% degradation across seven widely used benchmarks.

ADD: Attribution-Driven Data Augmentation Framework for Boosting Image Super-Resolution
Ze-Yu Mi, Yu-Bin Yang; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 23101-23110
Data augmentation (DA) stands out as a powerful technique to enhance the generalization capabilities of deep neural networks across diverse tasks. However, in low-level vision tasks, DA remains rudimentary (i.e., vanilla DA), facing a critical bottleneck due to information loss. In this paper, we introduce a novel Calibrated Attribution Maps (CAM) to generate saliency masks, followed by two saliency-based DA methods-- Attribution-Driven Data augmentation (ADD) and ADD+--designed to address this issue. CAM leverages integrated gradients and incorporates two key innovations: a global feature detector and calibrated integrated gradients. Based on CAM and the proposed methods, we have two new insights for low-level vision tasks: (1) increasing pixel diversity, as seen in vanilla DA, can improve performance, and (2) focusing on salient features while minimizing the impact of irrelevant pixels, as seen in saliency-based DA, more effectively enhances model performance. Additionally, we find and highlight the key guiding principle for designing saliency-based DA: a wider spectrum of degradation patterns. Extensive experiments demonstrate the compatibility and consistency of our method, as well as the significant performance improvement across various SR tasks and networks.

DIFFER: Disentangling Identity Features via Semantic Cues for Clothes-Changing Person Re-ID
Xin Liang, Yogesh S Rawat; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 13980-13989
Clothes-changing person re-identification (CC-ReID) aims to recognize individuals under different clothing scenarios. Current CC-ReID approaches either concentrate on modeling body shape using additional modalities including silhouette, pose, and body mesh, potentially causing the model to overlook other critical biometric traits such as gender, age, and style, or they incorporate supervision through additional labels that the model tries to disregard or emphasize, such as clothing or personal attributes. However, these annotations are discrete in nature and do not capture comprehensive descriptions. In this work, we propose DIFFER: Disentangle Identity Features From Entangled Representations, a novel adversarial learning method that leverages textual descriptions to disentangle identity features. Recognizing that image features inherently mix inseparable information, DIFFER introduces NBDetach, a mechanism designed for feature disentanglement by leveraging the separable nature of text descriptions as supervision. It partitions the feature space into distinct subspaces and, through gradient reversal layers, effectively separates identity-related features from non-biometric features. We evaluate DIFFER on 4 different benchmark datasets (LTCC, PRCC, CelebreID-Light, and CCVID) to demonstrate its effectiveness and provide state-of-the-art performance across all the benchmarks. DIFFER consistently outperforms the baseline method, with improvements in top-1 accuracy of 3.6% on LTCC, 3.4% on PRCC, 2.5% on CelebReID-Light, and 1% on CCVID. Our code can be found at https://github.com/xliangp/DIFFER.git.
****
HyperPose: Hypernetwork-Infused Camera Pose Localization and an Extended Cambridge Landmarks Dataset
Ron Ferens, Yosi Keller; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 11547-11557
In this work, we propose HyperPose, which utilizes hypernetworks in absolute camera pose regressors. The inherent appearance variations in natural scenes, attributable to environmental conditions, perspective, and lighting, induce a significant domain disparity between the training and test datasets. This disparity degrades the precision of contemporary localization networks. To mitigate this, we advocate for incorporating hypernetworks into single-scene and multiscene camera pose regression models. During inference, the hypernetwork dynamically computes

adaptive weights for the localization regression heads based on the particular input image, effectively narrowing the domain gap. Using indoor and outdoor data sets, we evaluate the HyperPose methodology across multiple established absolute pose regression architectures. In particular, we introduce and share the Extended Cambridge Landmarks (ECL), which is a novel localization dataset, based on the Cambridge Landmarks dataset, showing it in multiple seasons with significantly varying appearance conditions. Our empirical experiments demonstrate that HyperPose yields notable performance enhancements for both single- and multi-scene architectures. We have made our source code, pre-trained models, and ECL dataset openly available.

Critic-V: VLM Critics Help Catch VLM Errors in Multimodal Reasoning

Di Zhang, Jingdi Lei, Junxian Li, Xunzhi Wang, Yujie Liu, Zonglin Yang, Jiatong Li, Weida Wang, Suorong Yang, Jianbo Wu, Peng Ye, Wanli Ouyang, Dongzhan Zhou; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 9050-9061

Vision-language models (VLMs) have shown remarkable advancements in multimodal reasoning tasks. However, they still often generate inaccurate or irrelevant responses due to issues like hallucinated image understandings or unrefined reasoning paths. To address these challenges, we introduce Critic-V, a novel framework inspired by the Actor-Critic paradigm to boost the reasoning capability of VLMs. This framework decouples the reasoning process and critic process by integrating two independent components: the Reasoner, which generates reasoning paths based on visual and textual inputs, and the Critic, which provides constructive critique to refine these paths. In this approach, the Reasoner generates reasoning responses according to text prompts, which can evolve iteratively as a policy based on feedback from the Critic. This interaction process was theoretically driven by a reinforcement learning framework where the Critic offers natural language critiques instead of scalar rewards, enabling more nuanced feedback to boost the Reasoner's capability on complex reasoning tasks. The Critic model is trained using Direct Preference Optimization (DPO), leveraging a preference dataset of critiques ranked by Rule-based Reward (RBR) to enhance its critic capabilities. Evaluation results show that the Critic-V framework significantly outperforms existing methods, including GPT-4V, on 5 out of 8 benchmarks, especially regarding reasoning accuracy and efficiency. Combining a dynamic text-based policy for the Reasoner and constructive feedback from the preference-optimized Critic enables a more reliable and context-sensitive multimodal reasoning process. Our approach provides a promising solution to enhance the reliability of VLMs, improving their performance in real-world reasoning-heavy multimodal applications such as autonomous driving and embodied intelligence.

Mono3DVLT: Monocular-Video-Based 3D Visual Language Tracking

Hongkai Wei, Yang Yang, Shijie Sun, Mingtao Feng, Xiangyu Song, Qi Lei, Hongli Hu, Rong Wang, Huansheng Song, Naveed Akhtar, Ajmal Saeed Mian; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 13886-13896

Visual-Language Tracking (VLT) is emerging as a promising paradigm to bridge the human-machine performance gap. For single objects, VLT broadens the problem scope to text-driven video comprehension. Yet, this direction is still confined to 2D spatial extents, currently lacking the ability to deal with 3D tracking in the confines of monocular video. Unfortunately, advances in 3D tracking mainly rely on expensive sensor inputs, e.g., point clouds, depth measurements, radar. Absence of language counterpart for the outputs of these mildly democratized sensors in the literature also hinders VLT expansion to 3D tracking. Addressing that, we make the first attempt towards extending VLT to 3D tracking based on monocular video. We present a comprehensive framework, introducing (i) the Monocular-Video-based 3D Visual Language Tracking (Mono3DVLT) task, (ii) a large-scale dataset for the task, called Mono3DVLT-V2X, and (iii) a customized neural model for the task. Our dataset is carefully curated, leveraging a Large Langauge Model (LLM) followed by human verification, composing natural language descriptions for 7

9,158 video sequences aiming at single object tracking, providing 2D and 3D boun ding box annotations. Our neural model, termed Mono3DVLT-MT, is the first target ed approach for the Mono3DVLT task. Comprising the pipeline of multi-modal feat ure extractor, visual-language encoder, tracking decoder and a tracking head, ou r model sets a strong baseline for the task on Mono3DVLT-V2X. Experimental resul ts show that our method significantly outperforms existing techniques on the Mon o3DVLT-V2X dataset. Our dataset and code are available in https://github.com/hon gkai-wei/Mono3DVLT.

Towards Universal Dataset Distillation via Task-Driven Diffusion
Ding Qi, Jian Li, Junyao Gao, Shuguang Dou, Ying Tai, Jianlong Hu, Bo Zhao, Yabi ao Wang, Chengjie Wang, Cairong Zhao; Proceedings of the Computer Vision and Pat tern Recognition Conference (CVPR), 2025, pp. 10557-10566
Dataset distillation (DD) condenses key information from large-scale datasets in to smaller synthetic datasets, reducing storage and computational costs for trai ning networks. However, recent research has primarily focused on image classific ation tasks, with limited expansion to detection and segmentation. Two key chall enges remain: (i) Task Optimization Heterogeneity, where existing methods focus on class-level information and fail to address the diverse needs of detection an d segmentation and (ii) Inflexible Image Generation, where current generation me thods rely on global updates for single-class targets and lack localized optimiz ation for specific object regions.To address these challenges, we propose a univ ersal dataset distillation framework, named UniDD, a task-driven diffusion model for diverse DD tasks, as illustrated in Fig.1. Our approach operates in two sta ges: Universal Task Knowledge Mining, which captures task-relevant information t hrough task-specific proxy model training, and Universal Task-Driven Diffusion, where these proxies guide the diffusion process to generate task-specific synthe tic images.Extensive experiments across ImageNet-1K, Pascal VOC, and MS COCO dem onstrate that UniDD consistently outperforms state-of-the-art methods. In partic ular, on ImageNet-1K with IPC-10, UniDD surpasses previous diffusion-based metho ds by 6.1%, while also reducing deployment costs.

Parametric Point Cloud Completion for Polygonal Surface Reconstruction
Zhaiyu Chen, Yuqing Wang, Liangliang Nan, Xiao Xiang Zhu; Proceedings of the Com puter Vision and Pattern Recognition Conference (CVPR), 2025, pp. 11749-11758
Existing polygonal surface reconstruction methods heavily depend on input comple teness and struggle with incomplete point clouds. We argue that while current po int cloud completion techniques may recover missing points, they are not optimiz ed for polygonal surface reconstruction, where the parametric representation of underlying surfaces remains overlooked. To address this gap, we introduce parame tric completion, a novel paradigm for point cloud completion, which recovers par ametric primitives instead of individual points to convey high-level geometric s tructures. Our presented approach, PaCo, enables high-quality polygonal surface reconstruction by leveraging plane proxies that encapsulate both plane parameter s and inlier points, proving particularly effective in challenging scenarios wit h highly incomplete data. Comprehensive evaluations of our approach on the ABC d ataset establish its effectiveness with superior performance and set a new stand ard for polygonal surface reconstruction from incomplete data. Project page: htt ps://parametric-completion.github.io.

SyncSDE: A Probabilistic Framework for Diffusion Synchronization
Hyunjun Lee, Hyunsoo Lee, Sookwan Han; Proceedings of the Computer Vision and Pa ttern Recognition Conference (CVPR), 2025, pp. 17508-17517
There have been many attempts to leverage multiple diffusion models for collabor ative generation, extending beyond the original domain. A prominent approach inv olves synchronizing multiple diffusion trajectories by mixing the estimated scor es to artificially correlate the generation processes. However, existing methods rely on naive heuristics, such as averaging, without considering task specifici ty. These approaches do not clarify why such methods work and often fail when a heuristic suitable for one task is blindly applied to others. In this paper, we

present a probabilistic framework for analyzing why diffusion synchronization wo rks and reveal where heuristics should be focused--modeling correlations between multiple trajectories and adapting them to each specific task. We further ident ify optimal correlation models per task, achieving better results than previous approaches that apply a single heuristic across all tasks without justification.
****

MaRI: Material Retrieval Integration across Domains
Jianhui Wang, Zhifei Yang, Yangfan He, Huixiong Zhang, Yuxuan Chen, Jingwei Huan g; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 5814-5823
Accurate material retrieval is critical for creating realistic 3D assets. Existi ng methods rely on datasets that capture shape-invariant and lighting-varied rep resentations of materials, which are scarce and face challenges due to limited d iversity and inadequate real-world generalization. Most current approaches adopt traditional image search techniques. They fall short in capturing the unique pr operties of material spaces, leading to suboptimal performance in retrieval task s. Addressing these challenges, we introduce MaRI, a framework designed to bridg e the feature space gap between synthetic and real-world materials. MaRI constru cts a shared embedding space that harmonizes visual and material attributes thro ugh a contrastive learning strategy by jointly training a image and a material e ncoder, bringing similar materials and images closer while separating dissimilar pairs within the feature space. To support this, we construct a comprehensive d ataset comprising high-quality synthetic materials rendered with controlled shap e variations and diverse lighting conditions, along with real-world materials pr ocessed and standardized using material transfer techniques. Extensive experimen ts demonstrate the superior performance, accuracy, and generalization capabiliti es of MaRI across diverse and complex material retrieval tasks, outperforming ex isting methods.

MCCD: Multi-Agent Collaboration-based Compositional Diffusion for Complex Text-t o-Image Generation
Mingcheng Li, Xiaolu Hou, Ziyang Liu, Dingkang Yang, Ziyun Qian, Jiawei Chen, Ji njie Wei, Yue Jiang, Qingyao Xu, Lihua Zhang; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 13263-13272
Diffusion models have shown excellent performance in text-to-image generation. H owever, existing methods often suffer from performance bottlenecks when dealing with complex prompts involving multiple objects, characteristics, and relations. Therefore, we propose a Multi-agent Collaboration-based Compositional Diffusio n (MCCD) for text-to-image generation for complex scenes. Specifically, we desig n a multi-agent collaboration based scene parsing module that generates an agent system containing multiple agents with different tasks using MLLMs to adequatel y extract multiple scene elements. In addition, Hierarchical Compositional diffu sion utilizes Gaussian mask and filtering to achieve the refinement of bounding box regions and highlights objects through region enhancement for accurate and h igh-fidelity generation of complex scenes. Comprehensive experiments demonstrate that our MCCD significantly improves the performance of the baseline models in a training-free manner, which has a large advantage in complex scene generation. The code will be open-source on github.
****

Dual Semantic Guidance for Open Vocabulary Semantic Segmentation
Zhengyang Wang, Tingliang Feng, Fan Lyu, Fanhua Shang, Wei Feng, Liang Wan; Proc eedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 20212-20222
Open-vocabulary semantic segmentation aims to enable models to segment arbitrary categories. Currently, though pre-trained Vision-Language Models (VLMs) like CL IP have established a robust foundation for this task by learning to match text and image representations from large-scale data, their lack of pixel-level recog nition necessitates further fine-tuning. Most existing methods leverage text as a guide to achieve pixel-level recognition. However, the inherent biases in text semantic descriptions and the lack of pixel-level supervisory information make

it challenging to fine-tune CLIP-based models effectively. This paper considers leveraging image-text data to simultaneously capture the semantic information contained in both image and text, thereby constructing Dual Semantic Guidance and corresponding pixel-level pseudo annotations. Particularly, the visual semantic guidance is enhanced via explicitly exploring foreground regions and minimizing the influence of background. The dual semantic guidance is then jointly utilized to fine-tune CLIP-based segmentation models, achieving decent fine-grained recognition capabilities. As the comprehensive evaluation shows, our method outperforms state-of-art results with large margins, on eight commonly used datasets with/without background.

****

CroCoDL: Cross-device Collaborative Dataset for Localization

Hermann Blum, Alessandro Mercurio, Joshua O'Reilly, Tim Engelbracht, Mihai Dusmanu, Marc Pollefeys, Zuria Bauer; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 27424-27434

Accurate localization plays a pivotal role in the autonomy of systems operating in unfamiliar environments, particularly when interaction with humans is expected. High-accuracy visual localization systems encompass various components, such as image retrievers, feature extractors, matchers, reconstruction and pose estimation methods. This complexity translates to the necessity of robust evaluation settings and pipelines. However, existing datasets and benchmarks primarily focus on single-agent scenarios, overlooking the critical issue of cross-device localization. Different agents with different sensors will show their own specific strengths and weaknesses, and the data they have available varies substantially. This work addresses this gap by enhancing an existing augmented reality visual localization benchmark with data from legged robots, and evaluating human-robot, cross-device mapping and localization. Our contributions extend beyond device diversity and include high environment variability, spanning ten distinct locations ranging from disaster sites to art exhibitions. Each scene in our dataset features recordings from robot agents, hand-held and head-mounted devices, and high-accuracy ground truth LiDAR scanners, resulting in a comprehensive multi-agent dataset and benchmark. This work represents a significant advancement in the field of visual localization benchmarking, with key insights into the performance of cross-device localization methods across diverse settings.

Q-Bench-Video: Benchmark the Video Quality Understanding of LMMs

Zicheng Zhang, Ziheng Jia, Haoning Wu, Chunyi Li, Zijian Chen, Yingjie Zhou, Wei Sun, Xiaohong Liu, Xiongkuo Min, Weisi Lin, Guangtao Zhai; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 3229-3239

With the rising interest in research on Large Multi-modal Models (LMMs) for video understanding, many studies have emphasized general video comprehension capabilities, neglecting the systematic exploration into video quality understanding. To address this oversight, we introduce Q-Bench-Video in this paper, a new benchmark specifically designed to evaluate LMMs' proficiency in discerning video quality. a) To ensure video source diversity, Q-Bench-Video encompasses videos from natural scenes, AI-generated Content (AIGC), and Computer Graphics (CG). b) Building on the traditional multiple-choice questions format with the Yes-or-No and What-How categories, we include Open-ended questions to better evaluate complex scenarios. Additionally, we incorporate the video pair quality comparison question to enhance comprehensiveness. c) Beyond the traditional Technical, Aesthetic, and Temporal distortions, we have expanded our evaluation aspects to include the dimension of AIGC distortions, which addresses the increasing demand for video generation. Finally, we collect a total of 2,378 question-answer pairs and test them on 12 open-source & 5 proprietary LMMs. Our findings indicate that while LMMs have a foundational understanding of video quality, their performance remains incomplete and imprecise, with a notable discrepancy compared to human performance. Through Q-Bench-Video, we seek to catalyze community interest, stimulate further research, and unlock the untapped potential of LMMs to close the gap in video quality understanding.

Glossy Object Reconstruction with Cost-effective Polarized Acquisition
Bojian Wu, Yifan Peng, Ruizhen Hu, Xiaowei Zhou; Proceedings of the Computer Vis ion and Pattern Recognition Conference (CVPR), 2025, pp. 422-431
The challenge of image-based 3D reconstruction for glossy objects lies in separa ting diffuse and specular components on glossy surfaces from captured images, a task complicated by the ambiguity in discerning lighting conditions and material properties using RGB data alone. While state-of-the-art methods rely on tailore d and/or high-end equipment for data acquisition, which can be cumbersome and t ime-consuming, this work introduces a scalable polarization-aided approach that employs cost-effective acquisition tools. By attaching a linear polarizer to rea dily available RGB cameras, multi-view polarization images can be captured witho ut the need for advance calibration or precise measurements of the polarizer ang le, substantially reducing system construction costs. The proposed approach repr esents polarimetric BRDF, Stokes vectors, and polarization states of object surf aces as neural implicit fields. These fields, combined with the polarizer angle, are retrieved by optimizing the rendering loss of input polarized images. By le veraging fundamental physical principles for the implicit representation of pola rization rendering, our method demonstrates superiority over existing techniques through experiments in public datasets and real captured images on both reconst ruction and novel view synthesis.

Generalizable Object Keypoint Localization from Generative Priors
Dongkai Wang, Jiang Duan, Liangjian Wen, Shiyu Xuan, Hao Chen, Shiliang Zhang; P roceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 202 5, pp. 20265-20274
Generalizable object keypoint localization is a fundamental computer vision task in understanding the object structure. It is challenging for existing keypoint localization methods because their limited training data cannot provide generali zable shape and semantic cues, leading to inferior performance and generalizatio n capability. Instead of relying on large scale training data, this work tackles this challenge by exploiting the rich priors from large generative models. We p ropose a data-efficient generalizable localization method named GenLoc. GenLoc e xtracts the generative priors from a pre-trained image generation model by calcu lating the correlation map between image latent feature and condition embedding. Those priors are hence optimized with our proposed heatmap expectation loss to perform object keypoint localization. Benefited by the rich knowledge of generat ive priors in understanding of object semantics and structures, GenLoc achieves superior performance on various object keypoint localization benchmarks. It show s more substantial performance enhancements in cross-domain, few-shot and zero-s hot evaluation settings, e.g., getting 20%+ AP enhancement over CLAMP in various zero-shot settings.

CLIP is Almost All You Need: Towards Parameter-Efficient Scene Text Retrieval wi thout OCR
Xugong Qin, Peng Zhang, Jun Jie Ou Yang, Gangyan Zeng, Yubo Li, Yuanyuan Wang, W anqian Zhang, Pengwen Dai; Proceedings of the Computer Vision and Pattern Recogn ition Conference (CVPR), 2025, pp. 24873-24883
Scene Text Retrieval (STR) seeks to identify all images containing a given query string. Existing methods typically rely on an explicit Optical Character Recogn ition (OCR) process of text spotting or localization, which is susceptible to co mplex pipelines and accumulated errors. To settle this, we resort to the Contras tive Language-Image Pre-training (CLIP) models, which have demonstrated the capa city to perceive and understand scene text, making it possible to achieve strict ly OCR-free STR. From the perspective of parameter-efficient transfer learning, a lightweight visual position adapter is proposed to provide a positional inform ation complement for the visual encoder. Besides, we introduce a visual context dropout technique to improve the alignment of local visual features. A novel, pa rameter-free cross-attention mechanism transfers the contrastive relationship be tween images and text to that between visual tokens and text, producing a rich c ross-modal representation, which can be utilized for efficient reranking with a

linear classifier. The resulting model, CAYN, which proves that CLIP is Almost a ll You Need for STR with no more than 0.50M additional parameters required, achi eves new state-of-the-art performance on the STR task, with 92.46%/89.49%/85.98% mAP on the SVT/IIIT-STR/TTR datasets. Our findings demonstrate that CLIP can se rve as a reliable and efficient solution for OCR-free STR.

L-SWAG: Layer-Sample Wise Activation with Gradients Information for Zero-Shot NA S on Vision Transformers
Sofia Casarin, Sergio Escalera, Oswald Lanz; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 4441-4451
Training-free Neural Architecture Search (NAS) efficiently identifies high-perfo rming neural networks using zero-cost (ZC) proxies. Unlike multi-shot and one-sh ot NAS approaches, ZC-NAS is both (i) time-efficient, eliminating the need for m odel training, and (ii) interpretable, with proxy designs often theoretically gr ounded. Despite rapid developments in the field, current SOTA ZC proxies are typ ically constrained to well-established convolutional search spaces. With the ris e of Large Language Models shaping the future of deep learning, this work extend s ZC proxy applicability to Vision Transformers (ViTs). We present a new benchma rk using the Autoformer search space evaluated on 6 distinct tasks, and propose Layer-Sample Wise Activation with Gradients information (L-SWAG), a novel, gener alizable metric that characterises both convolutional and transformer architectu res across 14 tasks. Additionally, previous works highlighted how different prox ies contain complementary information, motivating the need for a ML model to ide ntify useful combinations. To further enhance ZC-NAS, we therefore introduce LIB RA-NAS (Low Information gain and Bias Re-Alignment), a method that strategically combines proxies to best represent a specific benchmark. Integrated into the NA S search, LIBRA-NAS outperforms evolution and gradient-based NAS techniques by i dentifying an architecture with a 17.0% test error on ImageNet1k in just 0.1 GPU days.

Commonsense Video Question Answering through Video-Grounded Entailment Tree Reas oning
Huabin Liu, Filip Ilievski, Cees G. M. Snoek; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 3262-3271
This paper proposes the first video-grounded entailment tree reasoning method fo r commonsense video question answering (VQA). Despite the remarkable progress of large visual-language models (VLMs), there are growing concerns that they learn spurious correlations between videos and likely answers, reinforced by their bl ack-box nature and remaining benchmarking biases. Our method explicitly grounds VQA tasks to video fragments in four steps: entailment tree construction, video-language entailment verification, tree reasoning, and dynamic tree expansion. A vital benefit of the method is its generalizability to current video- and image-based VLMs across reasoning types.To support fair evaluation, we devise a de-bia sing procedure based on large-language models that rewrite VQA benchmark answer sets to enforce model reasoning. Systematic experiments on existing and de-biase d benchmarks highlight the impact of our method components across benchmarks, VL Ms, and reasoning types.

What Makes a Good Dataset for Knowledge Distillation?
Logan Frank, Jim Davis; Proceedings of the Computer Vision and Pattern Recogniti on Conference (CVPR), 2025, pp. 23755-23764
Knowledge distillation (KD) has been a popular and effective method for model co mpression. One important assumption of KD is that the teacher's original dataset will also be available when training the student. However, in situations such a s continual learning and distilling large models trained on company-withheld dat asets, having access to the original data may not always be possible. This leads practitioners towards utilizing other sources of supplemental data, which could yield mixed results. One must then ask: "what makes a good dataset for transfer ring knowledge from teacher to student?" Many would assume that only real in-dom ain imagery is viable, but is that the only option? In this work, we explore mul

tiple possible surrogate distillation datasets and demonstrate that many differe nt datasets, even unnatural synthetic imagery, can serve as a suitable alternati ve in KD. From examining these alternative datasets, we identify and present var ious criteria describing what makes a good dataset for distillation. Source code is available at https://github.com/osu-cvl/good-kd-dataset.

Lifelong Knowledge Editing for Vision Language Models with Low-Rank Mixture-of-E xperts

Qizhou Chen, Chengyu Wang, Dakan Wang, Taolin Zhang, Wangyue Li, Xiaofeng He; Pr oceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025 , pp. 9455-9466

Model editing aims to correct inaccurate knowledge, update outdated information, and incorporate new data into Large Language Models (LLMs) without the need for retraining. This task poses challenges in lifelong scenarios where edits must b e continuously applied for real-world applications. While some editors demonstra te strong robustness for lifelong editing in pure LLMs, Vision LLMs (VLLMs), whi ch incorporate an additional vision modality, are not directly adaptable to exis ting LLM editors. In this paper, we propose LiveEdit, a lifelong vision language model edit to bridge the gap between lifelong LLM editing and VLLMs. We begin b y training an editing expert generator to independently produce low-rank experts for each editing instance, with the goal of correcting the relevant responses o f the VLLM. A hard filtering mechanism is developed to utilize visual semantic k nowledge, thereby coarsely eliminating visually irrelevant experts for input que ries during the inference stage of the post-edited model. Finally, to integrate visually relevant experts, we introduce a soft routing mechanism based on textua l semantic relevance to achieve multi-expert fusion. For evaluation, we establis h a benchmark for lifelong VLLM editing. Extensive experiments demonstrate that LiveEdit offers significant advantages in lifelong VLLM editing scenarios. Furth er experiments validate the rationality and effectiveness of each module design in LiveEdit.

Rectification-specific Supervision and Constrained Estimator for Online Stereo R ectification

Rui Gong, Kim-Hui Yap, Weide Liu, Xulei Yang, Jun Cheng; Proceedings of the Comp uter Vision and Pattern Recognition Conference (CVPR), 2025, pp. 22348-22358

Online stereo rectification is critical for autonomous vehicles and robots in dy namic environments, where factors such as vibration, temperature fluctuations, a nd mechanical stress can affect rectification accuracy and severely degrade down stream stereo depth estimation. Current dominant approaches for online stereo re ctification involve estimating relative camera poses in real time to derive rect ification homographies. However, they do not directly optimize for rectification constraints. Additionally, the general-purpose correspondence matchers used in these methods are not trained for rectification, while training of these matcher s typically requires ground-truth correspondences which are not available in ste reo rectification datasets. To address these limitations, we propose a matching-based stereo rectification framework that is directly optimized for rectificatio n and does not require ground-truth correspondence annotations for training. We assume intrinsics are known as they are generally available on modern devices an d are relatively stable. Our framework incorporates a rectification-constrained estimator and applies multi-level, rectification-specific supervision that train s the matcher network for rectification without relying on ground-truth correspo ndences. Additionally, we create a new rectification dataset with ground-truth o ptical flow annotations, eliminating bias from evaluation metrics used in prior work that relied on pretrained keypoint matching or optical flow models. Extensi ve experiments show that our approach outperforms both state-of-the-art matching -based and matching-free methods in vertical flow metric by 10.7% on the Carla-F lowguided dataset and 21.3% on the Semi-Truck Highway dataset, offering superior rectification accuracy.

Shape and Texture: What Influences Reliable Optical Flow Estimation?

Libo Long, Xiao Hu, Jochen Lang; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 27894-27903

Recent methods have made significant progress in optical flow estimation. However, the evaluation of these methods focuses mainly on improved accuracy in benchmarks and often overlooks the analysis of network robustness, which may be important in safety-critical scenarios such as autonomous driving. In this paper, we propose a novel method for robustness evaluation by modifying data from original benchmarks. Unlike previous benchmarks that focus on complex scenes, we propose to modify shape and texture of objects from the original images in order to analyze the sensitivity to these changes observed in the output. Our aim is to identify common failure cases of state-of-the-art (SOTA) methods to evaluate their robustness and understand their behaviors. We show that: Optical flow methods are more sensitive to shape changes than to texture changes; and optical flow methods tend to "remember" objects seen during training and may "ignore" the motion of unseen objects. Our experimental results and findings provide a more in-depth understanding of the behavior of recent optical flow methods.

PartGen: Part-level 3D Generation and Reconstruction with Multi-view Diffusion Models

Minghao Chen, Roman Shapovalov, Iro Laina, Tom Monnier, Jianyuan Wang, David Novotny, Andrea Vedaldi; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 5881-5892

Text- or image-to-3D generators and 3D scanners can now produce 3D assets with high-quality shapes and textures, but as single, fused entities lacking meaningful structure. In contrast, most applications and creative workflows require 3D assets to be composed of distinct, meaningful parts that can be independently manipulated. To bridge this gap, we introduce PartGen, a novel approach for generating, from text, images, or unstructured 3D objects, 3D objects composed of meaningful parts. Our method leverages a multi-view diffusion model to extract plausible and view-consistent part segmentations from multiple views of a 3D object, dividing it into meaningful components. A second multi-view diffusion model then processes each part individually, filling in occlusions and generating completed views, which are subsequently passed to a 3D reconstruction network. The completion process ensures that the reconstructed parts integrate cohesively by considering the context of the entire object, compensating for missing information caused by occlusions and, in extreme cases, hallucinating entirely invisible parts based on contextual cues. We evaluate PartGen on both generated and real 3D assets, demonstrating significant improvements over segmentation and part completion baselines. We also showcase downstream applications such as text-guided 3D part editing.

FedCALM: Conflict-aware Layer-wise Mitigation for Selective Aggregation in Deeper Personalized Federated Learning

Hao Zheng, Zhigang Hu, Liu Yang, Meiguang Zheng, Aikun Xu, Boyu Wang; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 15444-15453

Server aggregation conflict is a key challenge in personalized federated learning (PFL). While existing PFL methods have achieved significant progress with shallow base models (e.g., four-layer CNNs), they often overlook the negative impacts of deeper base models on personalization mechanisms. In this paper, we identify the phenomenon of deep model degradation in PFL, where as base model depth increases, the model becomes more sensitive to local client data distributions, thereby exacerbating server aggregation conflicts and ultimately reducing overall model performance. Moreover, we show that these conflicts manifest in insufficient global average updates and mutual constraints between clients. Motivated by our analysis, we proposed a two-stage conflict-aware layer-wise mitigation algorithm (FedCALM), which first constructs a conflict-free global update to alleviate negative conflicts, and then maximizes the benefits of all clients through a conflict-aware strategy. Notably, our method naturally leads to a selective mechanism that balances the tradeoff between clients involved in aggregation and the to

lerance for conflicts. Consequently, it can boost the positive contribution to t
he clients even with the greatest conflicts with the global update. Extensive ex
periments across multiple datasets and deeper base models demonstrate that FedCA
LM outperforms four state-of-the-art (SOTA) methods by up to 9.88% and seamlessl
y integrates into existing PFL methods with performance improvements of up to 9.
01%.

SINR: Sparsity Driven Compressed Implicit Neural Representations
Dhananjaya Jayasundara, Sudarshan Rajagopalan, Yasiru Ranasinghe, Trac D. Tran,
Vishal M. Patel; Proceedings of the Computer Vision and Pattern Recognition Conf
erence (CVPR), 2025, pp. 3061-3070
Implicit Neural Representations (INRs) are increasingly recognized as a versatil
e data modality for representing discretized signals, offering benefits such as
infinite query resolution and reduced storage requirements. Existing signal comp
ression approaches for INRs typically employ one of two strategies: 1. direct qu
antization with entropy coding of the trained INR; 2. deriving a latent code on
top of the INR through a learnable transformation. Thus, their performance is he
avily dependent on the quantization and entropy coding schemes employed. In this
 paper, we introduce SINR, an innovative compression algorithm that leverages th
e patterns in the vector spaces formed by weights of INRs. We compress these vec
tor spaces using a high-dimensional sparse code within a dictionary. Further ana
lysis reveals that the atoms of the dictionary used to generate the sparse code
do not need to be learned or transmitted to successfully recover the INR weights
. We demonstrate that the proposed approach can be integrated with any existing
INR-based signal compression technique. Our results indicate that SINR achieves
substantial reductions in storage requirements for INRs across various configura
tions, outperforming conventional INR-based compression baselines. Furthermore,
SINR maintains high-quality decoding across diverse data modalities, including i
mages, occupancy fields, and Neural Radiance Fields.

CaricatureBooth: Data-Free Interactive Caricature Generation in a Photo Booth
Zhiyu Qu, Yunqi Miao, Zhensong Zhang, Jifei Song, Jiankang Deng, Yi-Zhe Song; Pr
oceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025
, pp. 10815-10824
We present CaricatureBooth, a system that transforms caricature creation into a
simple interactive experience -- as easy as using a photo booth! A key challenge
 in caricature generation is two-fold: the scarcity of high-quality caricature d
ata and the difficulty in enabling precise creative control over the exaggeratio
n process while maintaining identity. Prior approaches either require large-scal
e caricature and photo data or lack intuitive mechanisms for users to guide the
deformation without losing identity. We address the data scarcity by synthesisin
g training data through Thin Plate Spline (TPS) deformation of standard face ima
ges. For creative control, we design a Bezier curve interface where users can ea
sily manipulate facial features, with these edits then driving TPS transformatio
ns at inference time. When combined with a pre-trained ID-preserving diffusion m
odel, our system maintains both identity preservation and creative flexibility.
Through extensive experiments, we demonstrate that CaricatureBooth achieves stat
e-of-the-art quality while making the joy of caricature creation as accessible a
s taking a photo -- just walk in and walk out with your personalised caricature!
 Code is available at https://github.com/WinKawaks/CaricatureBooth.

FlexGS: Train Once, Deploy Everywhere with Many-in-One Flexible 3D Gaussian Spla
tting
Hengyu Liu, Yuehao Wang, Chenxin Li, Ruisi Cai, Kevin Wang, Wuyang Li, Pavlo Mol
chanov, Peihao Wang, Zhangyang Wang; Proceedings of the Computer Vision and Patt
ern Recognition Conference (CVPR), 2025, pp. 16336-16345
3D Gaussian splatting (3DGS) has enabled various applications in 3D scene repres
entation and novel view synthesis due to its efficient rendering capabilities. H
owever, 3DGS demands significant GPU memory, limiting its use on devices with re
stricted computational resources. Previous approaches have focused on pruning le

ss important Gaussians, effectively compressing 3DGS but often requiring a fine-tuning stage and lacking adaptability for the specific memory needs of different devices. In this work, we present an elastic inference method for 3DGS. Given an input for the desired model size, our method selects and transforms a subset of Gaussians, achieving substantial rendering performance without additional fine-tuning. We introduce a tiny learnable module that controls Gaussian selection based on the input percentage, along with a transformation module that adjusts the selected Gaussians to complement the performance of the reduced model. Comprehensive experiments on ZipNeRF, MipNeRF and Tanks&Temples scenes demonstrate the effectiveness of our approach. Code will be publicly available.

Generalizing Deepfake Video Detection with Plug-and-Play: Video-Level Blending and Spatiotemporal Adapter Tuning

Zhiyuan Yan, Yandan Zhao, Shen Chen, Mingyi Guo, Xinghe Fu, Taiping Yao, Shouhong Ding, Yunsheng Wu, Li Yuan; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 12615-12625

Three key challenges hinder the development of current deepfake video detection: (1) Temporal features can be complex and diverse: how can we identify general temporal artifacts to enhance model generalization? (2) Spatiotemporal models often lean heavily on one type of artifact and ignore the other: how can we ensure balanced learning from both? (3) Videos are naturally resource-intensive: how can we tackle efficiency without compromising accuracy? This paper attempts to tackle the three challenges jointly. First, inspired by the notable generality of using image-level blending data for image forgery detection, we investigate whether and how video-level blending can be effective in video. We then perform a thorough analysis and identify a previously underexplored temporal forgery artifact: Facial Feature Drift (FFD), which commonly exists across different forgeries. To reproduce FFD, we then propose a novel Video-level Blending data (VB), where VB is implemented by blending the original image and its warped version frame-by-frame, serving as a hard negative sample to mine more general artifacts. Second, we carefully design a lightweight Spatiotemporal Adapter (StA) to equip a pre-trained image model with the ability to capture both spatial and temporal features jointly and efficiently. StA is designed with two-stream 3D-Conv with varying kernel sizes, allowing it to process spatial and temporal features separately. This eliminates the need to design a new deepfake-specific video architecture from scratch. Extensive experiments validate the effectiveness of the proposed methods; and show our approach can generalize well to previously unseen forgery videos.

ManipTrans: Efficient Dexterous Bimanual Manipulation Transfer via Residual Learning

Kailin Li, Puhao Li, Tengyu Liu, Yuyang Li, Siyuan Huang; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 6991-7003

Human hands play a central role in interacting, motivating increasing research in dexterous robotic manipulation. Data-driven embodied AI algorithms demand precise, large-scale, human-like manipulation sequences, which are challenging to obtain with conventional reinforcement learning or real-world teleoperation. To address this, we introduce ManipTrans, a novel two-stage method for efficiently transferring human bimanual skills to dexterous robotic hands in simulation. ManipTrans first pre-trains a generalist trajectory imitator to mimic hand motion, then fine-tunes a specific residual module under interaction constraints, enabling efficient learning and accurate execution of complex bimanual tasks. Experiments show that ManipTrans surpasses state-of-the-art methods in success rate, fidelity, and efficiency. Leveraging ManipTrans, we transfer multiple hand-object datasets to robotic hands, creating DexManipNet, a large-scale dataset featuring previously unexplored tasks like pen capping and bottle unscrewing. DexManipNet comprises 3.3K episodes of robotic manipulation and is easily extensible, facilitating further policy training for dexterous hands and enabling real-world deployments.

Precise, Fast, and Low-cost Concept Erasure in Value Space: Orthogonal Complement Matters
Yuan Wang, Ouxiang Li, Tingting Mu, Yanbin Hao, Kuien Liu, Xiang Wang, Xiangnan He; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 28759-28768
The success of text-to-image generation enabled by diffusion models has imposed an urgent need to erase unwanted concepts, e.g., copyrighted, offensive, and unsafe ones, from the pre-trained models in a precise, timely, and low-cost manner. The twofold demand of concept erasure requires a precise removal of the target concept during generation (i.e., erasure efficacy), while a minimal impact on non-target content generation (i.e., prior preservation). Existing methods are either computationally costly or face challenges in maintaining an effective balance between erasure efficacy and prior preservation. To improve, we propose a precise, fast, and low-cost concept erasure method, called Adaptive Vaule Decomposer (AdaVD), which is training-free. This method is grounded in a classical linear algebraic orthogonal complement operation, implemented in the value space of each cross-attention layer within the UNet of diffusion models. An effective shift factor is designed to adaptively navigate the erasure strength, enhancing prior preservation without sacrificing erasure efficacy. Extensive experimental results show that the proposed AdaVD is effective at both single and multiple concept erasure, showing a 2- to 10-fold improvement in prior preservation as compared to the second best, meanwhile achieving the best or near best erasure efficacy, when comparing with both training-based and training-free state of the arts. AdaVD supports a series of diffusion models and downstream image generation tasks, with code to be publicly available.

HOIGen-1M: A Large-scale Dataset for Human-Object Interaction Video Generation
Kun Liu, Qi Liu, Xinchen Liu, Jie Li, Yongdong Zhang, Jiebo Luo, Xiaodong He, Wu Liu; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 24001-24010
Text-to-video (T2V) generation has made tremendous progress in generating complicated scenes based on texts. However, human-object interaction (HOI) often cannot be precisely generated by current T2V models due to the lack of large-scale videos with accurate captions for HOI. To address this issue, we introduce HOIGen-1M, the first large-scale dataset for HOI Generation, consisting of over one million high-quality videos collected from diverse sources. In particular, to guarantee the high quality of videos, we first design an efficient framework to automatically curate HOI videos using the powerful multimodal large language models (MLLMs), and then the videos are further cleaned by human annotators. Moreover, to obtain accurate textual captions for HOI videos, we design a novel video description method based on a Mixture-of-Multimodal-Experts (MoME) strategy that not only generates expressive captions but also eliminates the hallucination by individual MLLM. Furthermore, due to the lack of an evaluation framework for generated HOI videos, we propose two new metrics to assess the quality of generated videos in a coarse-to-fine manner. Extensive experiments reveal that current T2V models struggle to generate high-quality HOI videos and confirm that our HOIGen-1M dataset is instrumental for improving HOI video generation.
****
T2ISafety: Benchmark for Assessing Fairness, Toxicity, and Privacy in Image Generation
Lijun Li, Zhelun Shi, Xuhao Hu, Bowen Dong, Yiran Qin, Xihui Liu, Lu Sheng, Jing Shao; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 13381-13392
Text-to-image (T2I) models have rapidly advanced, enabling the generation of high-quality images from text prompts across various domains. However, these models present notable safety concerns, including the risk of generating harmful, biased, or private content. Current research on assessing T2I safety remains in its early stages. While some efforts have been made to evaluate models on specific safety dimensions, many critical risks remain unexplored. To address this gap, we introduce T2ISafety, a safety benchmark that evaluates T2I models across three

key domains: toxicity, fairness, and bias. We build a detailed hierarchy of 12 tasks and 44 categories based on these three domains, and meticulously collect 70K corresponding prompts. Based on this taxonomy and prompt set, we build a large-scale T2I dataset with 68K manually annotated images and train an evaluator capable of detecting critical risks that previous work has failed to identify, including risks that even ultra-large proprietary models like GPTs cannot correctly detect. We evaluate 15 prominent diffusion models on T2ISafety and reveal several concerns including persistent issues with racial fairness, a tendency to generate toxic content, and significant variation in privacy protection across the models, even with defense methods like concept erasing.

Order-One Rolling Shutter Cameras

Marvin Anas Hahn, Kathlén Kohn, Orlando Marigliano, Tomas Pajdla; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 27007-27016

Rolling shutter (RS) cameras dominate consumer and smartphone markets. Several methods for computing the absolute pose of RS cameras have appeared in the last 20 years, but the relative pose problem has not been fully solved yet. We provide a unified theory for the important class of order-one rolling shutter (RS_1) cameras. These cameras generalize the perspective projection to RS cameras, projecting a generic space point to exactly one image point via a rational map. We introduce a new back-projection RS camera model, characterize RS_1 cameras, construct explicit parameterizations of such cameras, and determine the image of a space line. We classify all minimal problems for solving the relative camera pose problem with linear RS_1 cameras and discover new practical cases. Finally, we show how the theory can be used to explain RS models previously used for absolute pose computation.

Animate and Sound an Image

Xihua Wang, Ruihua Song, Chongxuan Li, Xin Cheng, Boyuan Li, Yihan Wu, Yuyue Wang, Hongteng Xu, Yunfeng Wang; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 23369-23378

This paper addresses a promising yet underexplored task, Image-to-Sounding-Video (I2SV) generation, which animates a static image and generates synchronized sound simultaneously. Despite advances in video and audio generation models, challenges remain to develop a unified model for generating naturally sounding videos. In this work, we propose a novel approach that leverages two separate pretrained diffusion models and makes vision and audio influence each other during generation based on the Diffusion Transformer (DiT) architecture. First, the individual video and audio pretrained generation models are decomposed into input, output, and expert sub-modules. We propose using a unified joint DiT block to integrate the expert sub-modules to effectively model the interaction between the two modalities, resulting in high-quality I2SV generation. Then, we introduce a joint classifier-free guidance technique to boost the performance during joint generation. Finally, we conduct extensive experiments on three popular benchmark datasets, and in both objective and subjective evaluation our method surpass all the baseline methods in almost all metrics. Case studies show our generated sounding videos are high quality and synchronized between video and audio.

Shining Yourself: High-Fidelity Ornaments Virtual Try-on with Diffusion Model

Yingmao Miao, Zhanpeng Huang, Rui Han, Zibin Wang, Chenhao Lin, Chao Shen; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 359-368

While virtual try-on for clothes and shoes with diffusion models has gained attraction, virtual try-on for ornaments, such as bracelets, rings, earrings, and necklaces, remains largely unexplored. Due to the intricate tiny patterns and repeated geometric sub-structures in most ornaments, it is much more difficult to guarantee identity and appearance consistency under large pose and scale variances between ornaments and models. This paper proposes the task of virtual try-on for ornaments and presents a method to improve the geometric and appearance preser

vation of ornament virtual try-ons. Specifically, we estimate an accurate wearin g mask to improve the alignments between ornaments and models in an iterative sc heme alongside the denoising process. To preserve structure details, we further regularize attention layers to map the reference ornament mask to the wearing ma sk in an implicit way. Experiment results demonstrate that our method successful ly wears ornaments from reference images onto target models, handling substantia l differences in scale and pose while preserving identity and achieving realisti c visual effects.

Foveated Instance Segmentation
Hongyi Zeng, Wenxuan Liu, Tianhua Xia, Jinhui Chen, Ziyun Li, Sai Qian Zhang; Pr oceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025 , pp. 24496-24505
Instance segmentation is essential for augmented reality and virtual reality (AR /VR) as it enables precise object recognition and interaction, enhancing the int egration of virtual and real-world elements for an immersive experience. However , the high computational overhead of segmentation limits its application on reso urce-constrained AR/VR devices, causing large processing latency and degrading u ser experience. In contrast to conventional scenarios, AR/VR users typically fo cus on only a few regions within their field of view before shifting perspective , allowing segmentation to be concentrated on gaze-specific areas. This insight drives the need for efficient segmentation methods that prioritize processing in stance of interest, reducing computational load and enhancing real-time performa nce. In this paper, we present a foveated instance segmentation(FovealSeg) frame work that leverages real-time user gaze data to perform instance segmentation ex clusively on instance of interest, resulting in substantial computational saving s. Evaluation results show that FSNet achieves an IoU of 0.56 on ADE20K and 0.54 on LVIS, notably outperforming the baseline. The code is available at https://g ithub.com/SAI-Lab-NYU/Foveated-Instance-Segmentation.

Make It Count: Text-to-Image Generation with an Accurate Number of Objects
Lital Binyamin, Yoad Tewel, Hilit Segev, Eran Hirsch, Royi Rassin, Gal Chechik; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 20 25, pp. 13242-13251
Despite the unprecedented success of text-to-image diffusion models, controlling the number of depicted objects using text is surprisingly hard. This is importa nt for various applications from technical documents, to children's books to ill ustrating cooking recipes. Generating object-correct counts is fundamentally cha llenging because the generative model needs to keep a sense of separate identity for every instance of the object, even if several objects look identical or ove rlap, and then carry out a global computation implicitly during generation. It i s still unknown if such representations exist. To address count-correct generati on, we first identify features within the diffusion model that can carry the obj ect identity information. We then use them to separate and count instances of ob jects during the denoising process and detect over-generation and under-generati on. We fix the latter by training a model that predicts both the shape and locat ion of a missing object, based on the layout of existing ones, and show how it c an be used to guide denoising with correct object count. Our approach, CountGen, does not depend on external source to determine object layout, but rather uses the prior from the diffusion model itself, creating prompt-dependent and seed-de pendent layouts. Evaluated on two benchmark datasets, we find that CountGen stro ngly outperforms the count-accuracy of existing baselines.

Universal Domain Adaptation for Semantic Segmentation
Seun-An Choe, Keon-Hee Park, Jinwoo Choi, Gyeong-Moon Park; Proceedings of the C omputer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 4607-4617
Unsupervised domain adaptation for semantic segmentation (UDA-SS) aims to transf er knowledge from labeled synthetic data (source) to unlabeled real-world data (target). Traditional UDA-SS methods work on the assumption that the category set tings between the source and target domains are known in advance. However, in re

al-world scenarios, the category settings of the source and target are unknown d ue to the lack of labels in the target, resulting in the existence of target-pri vate or source-private classes. Traditional UDA-SS methods struggle with this ch ange, leading to negative transfer and performance degradation. To address these issues, we propose Universal Domain Adaptation for Semantic Segmentation (UniDA -SS) for the first time to achieve good performance even when the category setti ngs of source and target are unknown. We defined the problem in the UniDA-SS sce nario as that the confidence score of common Unsupervised domain adaptation for semantic segmentation (UDA-SS) aims to transfer knowledge from labeled source da ta to unlabeled target data. However, traditional UDA-SS methods assume that cat egory settings between source and target domains are known, which is unrealistic in real-world scenarios. This leads to performance degradation if private priva te classes exist. To address this limitation, we propose Universal Domain Adapta tion for Semantic Segmentation (UniDA-SS), achieving robust adaptation even with out prior knowledge of category settings. We define the problem in the UniDA-SS scenario as low confidence scores of common classes in the target domain, which leads to confusion with private classes. To solve this problem, we propose UniMA P: UniDA-SS with Image Ma tching and Prototype-based Distinction, a novel framew ork composed of two key components. First, Domain-Specific Prototype-based Disti nction (DSPD) divides each class into two domain-specific prototypes, enabling f iner separation of domain-specific features and enhancing the identification of common classes across domains. Second, Target-based Image Matching (TIM) selects a source image containing the most common-class pixels based on the target pseu do-label and pairs it in a batch to promote effective learning of common classes . We also introduce a new UniDA-SS benchmark and demonstrate through various exp eriments that UniMAP significantly outperforms baselines. The code is available at https://github.com/KU-VGI/UniDA-SS.

HyperGS: Hyperspectral 3D Gaussian Splatting

Christopher Thirgood, Oscar Mendez, Erin Ling, Jon Storey, Simon Hadfield; Proce edings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, p p. 5970-5979

We introduce HyperGS, a novel framework for Hyperspectral Novel View Synthesis (HNVS), based on a new latent 3D Gaussian Splatting (3DGS) technique. Our approac h enables simultaneous spatial and spectral renderings by encoding material prop erties from multi-view 3D hyperspectral datasets. HyperGS reconstructs high-fide lity views from arbitrary perspectives with improved accuracy and speed, outperf orming currently existing methods. To address the challenges of high-dimensional data, we perform view synthesis in a learned latent space, incorporating a pixe l-wise adaptive density function and a pruning technique for increased training stability and efficiency. Additionally, we introduce the first HNVS benchmark, i mplementing a number of new baselines based on recent SOTA RGB-NVS techniques, a longside the small number of prior works on HNVS. We demonstrate HyperGS's robus tness through extensive evaluation of real and simulated hyperspectral scenes wi th a 14dB accuracy improvement upon previously published models.

Emphasizing Discriminative Features for Dataset Distillation in Complex Scenario s

Kai Wang, Zekai Li, Zhi-Qi Cheng, Samir Khaki, Ahmad Sajedi, Ramakrishna Vedanta m, Konstantinos N Plataniotis, Alexander Hauptmann, Yang You; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 30451-3046 1

Dataset distillation has demonstrated strong performance on simple datasets like CIFAR, MNIST, and TinyImageNet but struggles to achieve similar results in more complex scenarios. In this paper, we propose EDF (emphasizes the discriminative features), a dataset distillation method that enhances key discriminative regio ns in synthetic images using Grad-CAM activation maps. Our approach is inspired by a key observation: in simple datasets, high-activation areas typically occupy most of the image, whereas in complex scenarios, the size of these areas is muc h smaller. Unlike previous methods that treat all pixels equally when synthesizi

ng images, EDF uses Grad-CAM activation maps to enhance high-activation areas. From a supervision perspective, we downplay supervision signals produced by lower trajectory-matching losses, as they contain common patterns. Additionally, to help the DD community better explore complex scenarios, we build the Complex Dataset Distillation (Comp-DD) benchmark by meticulously selecting sixteen subsets, eight easy and eight hard, from ImageNet-1K. In particular, EDF consistently outperforms SOTA results in complex scenarios, such as ImageNet-1K subsets. Hopefully, more researchers will be inspired and encouraged to improve the practicality and efficacy of DD. Our code and benchmark have been made public at NUS-HPC-AI-Lab/EDF.

LMO: Linear Mamba Operator for MRI Reconstruction

Wei Li, Jiawei Jiang, Jie Wu, Kaihao Yu, Jianwei Zheng; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 5112-5122

Interpretability and consistency have long been crucial factors in MRI reconstruction. While interpretability has been significantly innovated with the emerging deep unfolding networks, current solutions still suffer from inconsistency issues and produce inferior anatomical structures. Especially in out-of-distribution cases, e.g., when the acceleration rate (AR) varies, the generalization performance is often catastrophic. To counteract the dilemma, we propose an innovative Linear Mamba Operator (LMO) to ensure consistency and generalization, while still enjoying desirable interpretability. Theoretically, we argue that mapping between function spaces, rather than between signal instances, provides a solid foundation of high generalization. Technically, LMO achieves a good balance between global integration facilitated by a state space model that scans the whole function domain, and local integration engaged with an appealing property of continuous-discrete equivalence. On that basis, learning holistic features can be guaranteed, tapping the potential of maximizing data consistency. Quantitative and qualitative results demonstrate that LMO significantly outperforms other state-of-the-arts. More importantly, LMO is the unique model that, with AR changed, achieves retraining performance without retraining steps. Codes are available at https://github.com/ZhengJianwei2/LMO.

AnomalyNCD: Towards Novel Anomaly Class Discovery in Industrial Scenarios

Ziming Huang, Xurui Li, Haotian Liu, Feng Xue, Yuzhe Wang, Yu Zhou; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 4755-4765

Recently, multi-class anomaly classification has garnered increasing attention. Previous methods directly cluster anomalies but often struggle due to the lack of anomaly-prior knowledge. Acquiring this knowledge faces two issues: the non-prominent and weak-semantics anomalies. In this paper, we propose AnomalyNCD, a multi-class anomaly classification network compatible with different anomaly detection methods. To address the non-prominence of anomalies, we design main element binarization (MEBin) to obtain anomaly-centered images, ensuring anomalies are learned while avoiding the impact of incorrect detections. Next, to learn anomalies with weak semantics, we design mask-guided representation learning, which focuses on isolated anomalies guided by masks and reduces confusion from erroneous inputs through corrected pseudo labels. Finally, to enable flexible classification at both region and image levels, we develop a region merging strategy that determines the overall image category based on the classified anomaly regions. Our method outperforms the state-of-the-art works on the MVTec AD and MTD datasets. Compared with the current methods, AnomalyNCD combined with zero-shot anomaly detection method achieves a 10.8% F1 gain, 8.8% NMI gain, and 9.5% ARI gain on MVTec AD, and 12.8% F1 gain, 5.7% NMI gain, and 10.8% ARI gain on MTD. Code is available at https://github.com/HUST-SLOW/AnomalyNCD.

Segment This Thing: Foveated Tokenization for Efficient Point-Prompted Segmentation

Tanner Schmidt, Richard Newcombe; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 29428-29437

This paper presents Segment This Thing (STT), a new efficient image segmentation model designed to produce a single segment given a single point prompt. Instead of following prior work and increasing efficiency by decreasing model size, we gain efficiency by foveating input images. Given an image and a point prompt, we extract a crop centered on the prompt and apply a novel variable-resolution patch tokenization in which patches are downsampled at a rate that increases with increased distance from the prompt. This approach yields far fewer image tokens than uniform patch tokenization. As a result we can drastically reduce the computational cost of segmentation without reducing model size. Furthermore, the foveation focuses the model on the region of interest, a potentially useful inductive bias. We show that our Segment This Thing model is more efficient than prior work while remaining competitive on segmentation benchmarks. It can easily run at interactive frame rates on consumer hardware and is thus a promising tool for augmented reality or robotics applications.

Task-Specific Gradient Adaptation for Few-Shot One-Class Classification

Yunlong Li, Xiabi Liu, Liyuan Pan, Yuchen Ren; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 30556-30565

Optimization-based meta-learning methods for few-shot one-class classification (FS-OCC) aim to fine-tune a meta-trained model to classify the positive and negative samples using only a few positive samples by adaptation. However, recent approaches primarily focus on adjusting existing meta-learning algorithms for FS-OCC, while overlooking issues stemming from the misalignment between the cross-entropy loss and OCC tasks during adaptation. This misalignment, combined with the limited availability of one-class samples and the restricted diversity of task-specific adaptation, can significantly exacerbate the adverse effects of gradient instability and generalization. To address these challenges, we propose a novel Task-Specific Gradient Adaptation (TSGA) for FS-OCC. Without extra supervision, TSGA learns to generate appropriate, stable gradients by leveraging label prediction and feature representation details of one-class samples and refines the adaptation process by recalibrating task-specific gradients and regularization terms. We evaluate TSGA on three challenging datasets and a real-world CNC Milling Machine application and demonstrate consistent improvements over baseline methods. Furthermore, we illustrate the critical impact of gradient instability and task-agnostic adaptation. Notably, TSGA achieves state-of-the-art results by effectively addressing these issues.

****

TraF-Align: Trajectory-aware Feature Alignment for Asynchronous Multi-agent Perception

Zhiying Song, Lei Yang, Fuxi Wen, Jun Li; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 12048-12057

Cooperative perception presents significant potential for enhancing the sensing capabilities of individual vehicles, however, inter-agent latency remains a critical challenge. Latencies cause misalignments in both spatial and semantic features, complicating the fusion of real-time observations from the ego vehicle with delayed data from others. To address these issues, we propose TraF-Align, a novel framework that learns the flow path of features by predicting the feature-level trajectory of objects from past observations up to the ego vehicle's current time. By generating temporally ordered sampling points along these paths, TraF-Align directs attention from the current-time query to relevant historical features along each trajectory, supporting the reconstruction of current-time features and promoting semantic interaction across multiple frames. This approach corrects spatial misalignment and ensures semantic consistency across agents, effectively compensating for motion and achieving coherent feature fusion. Experiments on two real-world datasets, V2V4Real and DAIR-V2X-Seq, show that TraF-Align sets a new benchmark for asynchronous cooperative perception.

DreamCache: Finetuning-Free Lightweight Personalized Image Generation via Feature Caching

Emanuele Aiello, Umberto Michieli, Diego Valsesia, Mete Ozay, Enrico Magli; Proc

eedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 12480-12489
Personalized image generation requires text-to-image generative models that capture the core features of a reference subject to allow for controlled generation across different contexts. Existing methods face challenges due to complex training requirements, high inference costs, limited flexibility, or a combination of these issues. In this paper, we introduce DreamCache, a scalable approach for efficient and high-quality personalized image generation. By caching a small number of reference image features from a subset of layers and a single timestep of the pretrained diffusion denoiser, DreamCache enables dynamic modulation of the generated image features through lightweight, trained conditioning adapters. DreamCache achieves state-of-the-art image and text alignment, utilizing an order of magnitude fewer extra parameters, and is both more computationally effective and versatile than existing models.

3D Gaussian Inpainting with Depth-Guided Cross-View Consistency
Sheng-Yu Huang, Zi-Ting Chou, Yu-Chiang Frank Wang; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 26704-26713
When performing 3D inpainting using novel-view rendering methods like Neural Radiance Field (NeRF) or 3D Gussian Splatting (3DGS), how to achieve texture and geometry consistency across camera views has been a challenge. In this paper, we propose a framework of 3D Gaussian Inpainting with Depth-Guided Cross-View Consistency (3DGIC) for cross-view consistent 3D inpainting. Guided by the rendered depth information from each training view, our 3DGIC exploits background pixels visible across different views for updating the inpainting mask, allowing us to refine the 3DGS for inpainting purposes. Through extensive experiments on benchmark datasets, we confirm that our 3DGIC outperforms current state-of-the-art 3D inpainting methods quantitatively and qualitatively.

Your Large Vision-Language Model Only Needs A Few Attention Heads For Visual Grounding
Seil Kang, Jinyeong Kim, Junhyeok Kim, Seong Jae Hwang; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 9339-9350
Visual grounding seeks to localize the image region corresponding to a free-form text description. Recently, the strong multimodal capabilities of Large Vision-Language Models (LVLMs) have driven substantial improvements in visual grounding, though they inevitably require fine-tuning and additional model components to explicitly generate bounding boxes or segmentation masks. However, we discover that a few attention heads in frozen LVLMs demonstrate strong visual grounding capabilities. We refer to these heads, which consistently capture object locations related to text semantics, as localization heads. Using localization heads, we introduce a straightforward and effective training-free visual grounding framework that utilizes text-to-image attention maps from localization heads to identify the target objects. Surprisingly, only three out of thousands of attention heads are sufficient to achieve competitive localization performance compared to existing LVLM-based visual grounding methods that require fine-tuning. Our findings suggest that LVLMs can innately ground objects based on a deep comprehension of the text-image relationship, as they implicitly focus on relevant image regions to generate informative text outputs.

FlexUOD: The Answer to Real-world Unsupervised Image Outlier Detection
Zhonghang Liu, Kun Zhou, Changshuo Wang, Wen-Yan Lin, Jiangbo Lu; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 15183-15193
How many outliers are within an unlabeled and contaminated dataset? Despite a series of unsupervised outlier detection (UOD) approaches have been proposed, they cannot correctly answer this critical question, resulting in their performance instability across various real-world (varying contamination factor) scenarios. To address this problem, we propose FlexUOD, with a novel contamination factor estimation perspective. FlexUOD not only achieves its remarkable robustness but a

lso is a general and plug-and-play framework, which can significantly improve th e performance of existing UOD methods. Extensive experiments demonstrate that Fl exUOD achieves state-of-the-art results as well as high efficacy on diverse eval uation benchmarks.

Ges3ViG : Incorporating Pointing Gestures into Language-Based 3D Visual Groundin g for Embodied Reference Understanding
Atharv Mahesh Mane, Dulanga Weerakoon, Vigneshwaran Subbaraju, Sougata Sen, Sanj ay E. Sarma, Archan Misra; Proceedings of the Computer Vision and Pattern Recogn ition Conference (CVPR), 2025, pp. 9017-9026
3-Dimensional Embodied Reference Understanding (3DERU) combines a language descr iption and an accompanying pointing gesture to identify the most relevant target object in a 3D scene. Although prior work has explored pure language-based 3D g rounding, there has been limited exploration of 3D-ERU, which also incorporates human pointing gestures. To address this gap, we introduce a data augmentation f ramework-Imputer, and use it to curate a new benchmark dataset-ImputeRefer for 3 D-ERU, by incorporating human pointing gestures into existing 3D scene datasets that only contain language instructions. We also propose Ges3ViG, a novel model for 3D-ERU that achieves 30% improvement in accuracy as compared to other 3DERU models and 9% compared to other purely language-based 3D grounding models. Our code and dataset are available at https://github.com/AtharvMane/Ges3ViG.

Focusing on Tracks for Online Multi-Object Tracking
Kyujin Shim, Kangwook Ko, Yujin Yang, Changick Kim; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 11687-11696
Multi-object tracking (MOT) is a critical task in computer vision, requiring the accurate identification and continuous tracking of multiple objects across vide o frames. However, current state-of-the-art methods mainly rely on a global opti mization technique and multi-stage cascade association strategy, and those appro aches often overlook the specific characteristics of assignment task in MOT and useful detection results that may represent occluded objects. To address these c hallenges, we propose a novel Track-Focused Online Multi-Object Tracker (TrackTr ack) with two key strategies: Track-Perspective-Based Association (TPA) and Trac k-Aware Initialization (TAI). The TPA strategy associates each track with the mo st suitable detection result by choosing the one with the minimum distance from all available detection results in a track-perspective manner. On the other hand , TAI precludes the generation of spurious tracks in the track-aware aspect by s uppressing track initialization of detection results that heavily overlap with c urrent active tracks and more confident detection results. Extensive experiments on MOT17, MOT20, and DanceTrack demonstrate that our TrackTrack outperforms cur rent state-of-the-art trackers, offering improved robustness and accuracy across diverse and challenging tracking scenarios.

Floxels: Fast Unsupervised Voxel Based Scene Flow Estimation
David T. Hoffmann, Syed Haseeb Raza, Hanqiu Jiang, Denis Tananaev, Steffen Kling enhoefer, Martin Meinke; Proceedings of the Computer Vision and Pattern Recognit ion Conference (CVPR), 2025, pp. 22328-22337
Scene flow estimation is a foundational task for many robotic applications, incl uding robust dynamic object detection, automatic labeling, and sensor synchroniz ation. Two types of approaches to the problem have evolved: 1) Supervised and 2) optimization-based methods. Supervised methods are fast during inference and ac hieve high-quality results, however, they are limited by the need for large amou nts of labeled training data and are susceptible to domain gaps. In contrast, un supervised test-time optimization methods do not face the problem of domain gaps but usually suffer from substantial runtime, exhibit artifacts, or fail to conv erge to the right solution. In this work, we mitigate several limitations of exi sting optimization-based methods. To this end, we 1) introduce a simple voxel gr id-based model that improves over the standard MLP-based formulation in multiple dimensions and 2) introduce a new multi-frame loss formulation. 3) We combine b oth contributions in our new method, termed Floxels. On the Argoverse 2 benchmar

k, Floxels is surpassed only by EulerFlow among unsupervised methods while achie
ving comparable performance at a fraction of the computational cost. Floxels ach
ieves a massive speedup of more than 60-140x over EulerFlow, reducing the runti
me from a day to 10 minutes per sequence. Over the faster but low-quality baseli
ne, NSFP, Floxels achieves a speedup of 14x.

LiveCC: Learning Video LLM with Streaming Speech Transcription at Scale
Joya Chen, Ziyun Zeng, Yiqi Lin, Wei Li, Zejun Ma, Mike Zheng Shou; Proceedings
of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 2908
3-29095
Recent video large language models (Video LLMs) often depend on costly human ann
otations or proprietary APIs (e.g., GPT-4o) to produce training data, which limi
ts their training at scale. In this paper, we explore large-scale training for V
ideo LLM with cheap automatic speech recognition (ASR) transcripts. Specifically
, we propose a novel streaming training approach that densely interleaves the AS
R words and video frames according to their timestamps. Compared to previous stu
dies in vision-language representation with ASR, our method naturally fits the s
treaming characteristics of ASR, thus enabling the model to learn temporally-ali
gned, fine-grained vision-language modeling. To support the training algorithm,
we introduce a data pipeline for YouTube videos and their closed captions (CC),
resulting in \texttt Live-CC-10M pre-training set and \texttt Live-WhisperX-408
K high-quality supervised fine-tuning (SFT) set. Remarkably, even without SFT,
the pre-trained model \texttt LiveCC-7B demonstrates significant improvements i
n general video QA and exhibits a new capability in real-time video commentary.
To evaluate this, we carefully design a new benchmark \texttt LiveSports-3K , us
ing LLM-as-a-judge to measure the free-form commentary. Experiments show our fin
al model \texttt LiveCC-7B can surpass LLaVA-Video-72B in commentary quality ev
en working in a real-time mode. Meanwhile, it achieves state-of-the-art results
at the 7B scale on popular benchmarks such as VideoMME, demonstrating its broad
generalizability. All resources of this paper have been released at \href https:
//showlab.github.io/livecc showlab.github.io/livecc .

Identity-preserving Distillation Sampling by Fixed-Point Iterator
SeonHwa Kim, Jiwon Kim, Soobin Park, Donghoon Ahn, Jiwon Kang, Seungryong Kim, K
yong Hwan Jin, Eunju Cha; Proceedings of the Computer Vision and Pattern Recogni
tion Conference (CVPR), 2025, pp. 11115-11124
Score distillation sampling (SDS) demonstrates a powerful capability for text-co
nditioned 2D image and 3D object generation by distilling the knowledge from lea
rned score functions. However, SDS often suffers from blurriness caused by noisy
 gradients. When SDS meets the image editing, such degradations can be reduced b
y adjusting bias shifts using reference pairs, but the de-biasing techniques are
 still corrupted by erroneous gradients. To this end, we introduce Identity-pres
erving Distillation Sampling (IDS), which compensates for the gradient leading t
o undesired changes in the results. Based on the analysis that these errors come
 from the text-conditioned scores, a new regularization technique, called fixed-
point iterative regularization (FPR), is proposed to modify the score itself, dr
iving the preservation of the identity even including poses and structures. Than
ks to a self-correction by FPR, the proposed method provides clear and unambiguo
us representations corresponding to the given prompts in image-to-image editing
and editable neural radiance field (NeRF). The structural consistency between th
e source and the edited data is obviously maintained compared to other state-of-
the-art methods.

Progressive Focused Transformer for Single Image Super-Resolution
Wei Long, Xingyu Zhou, Leheng Zhang, Shuhang Gu; Proceedings of the Computer Vis
ion and Pattern Recognition Conference (CVPR), 2025, pp. 2279-2288
Transformer-based methods have achieved remarkable results in image super-resolu
tion tasks because they can capture non-local dependencies in low-quality input
images. However, this feature-intensive modeling approach is computationally exp
ensive because it calculates the similarities between numerous features that are

irrelevant to the query features when obtaining attention weights. These unnecessary similarity calculations not only degrade the reconstruction performance but also introduce significant computational overhead. How to accurately identify the features that are important to the current query features and avoid similarity calculations between irrelevant features remains an urgent problem. To address this issue, we propose a novel and effective Progressive Focused Transformer (PFT) that links all isolated attention maps in the network through Progressive Focused Attention (PFA) to focus attention on the most important tokens. PFA not only enables the network to capture more critical similar features, but also significantly reduces the computational cost of the overall network by filtering out irrelevant features before calculating similarities. Extensive experiments demonstrate the effectiveness of the proposed method, achieving state-of-the-art performance on various single image super-resolution benchmarks.
****

VladVA: Discriminative Fine-tuning of LVLMs
Yassine Ouali, Adrian Bulat, Alexandros Xenos, Anestis Zaganidis, Ioannis Maniadis Metaxas, Brais Martinez, Georgios Tzimiropoulos; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 4101-4111
Contrastively-trained Vision-Language Models (VLMs) like CLIP have become the de facto approach for discriminative vision-language representation learning. However, these models have limited language understanding, often exhibiting a "bag of words" behavior. At the same time, Large Vision-Language Models (LVLMs), which combine vision encoders with LLMs, have been shown to be capable of detailed vision-language reasoning, yet their autoregressive nature renders them less suitable for discriminative tasks. In this work, we propose to combine "the best of both worlds": a new training approach for discriminative fine-tuning of LVLMs that results in strong discriminative and compositional capabilities. Essentially, our approach converts a generative LVLM into a discriminative one, unlocking its capability for powerful image-text discrimination combined with enhanced language understanding. Our contributions include (1) A carefully designed training/optimization framework that utilizes image-text pairs of variable length and granularity for training the model with both contrastive and next-token prediction losses. This is accompanied by ablation studies that justify the necessity of our framework's components. (2) A parameter-efficient adaptation method using a combination of soft prompting and LoRA adapters. (3) Significant improvements over state-of-the-art CLIP-like models of similar size, including standard image-text retrieval benchmarks and notable gains in compositionality.
****

FlexiDiT: Your Diffusion Transformer Can Easily Generate High-Quality Samples with Less Compute
Sotiris Anagnostidis, Gregor Bachmann, Yeongmin Kim, Jonas Kohler, Markos Georgopoulos, Artsiom Sanakoyeu, Yuming Du, Albert Pumarola, Ali Thabet, Edgar Schönfeld; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 28316-28326
Despite their remarkable performance, modern Diffusion Transformers (DiTs) are hindered by substantial resource requirements during inference, stemming from the fixed and large amount of compute needed for each denoising step. In this work, we revisit the conventional static paradigm that allocates a fixed compute budget per denoising iteration and propose a dynamic strategy instead. Our simple and sample-efficient framework enables pre-trained DiT models to be converted into flexible ones --- dubbed FlexiDiT --- allowing them to process inputs at varying compute budgets. We demonstrate how a single flexible model can generate images without any drop in quality, while reducing the required FLOPs by more than 40% compared to their static counterparts, for both class-conditioned and text-conditioned image generation. Our method is general and agnostic to input and conditioning modalities. We show how our approach can be readily extended for video generation, where FlexiDiT models generate samples with up to 75% less compute without compromising performance.

WiLoR: End-to-end 3D Hand Localization and Reconstruction in-the-wild

Rolandos Alexandros Potamias, Jinglei Zhang, Jiankang Deng, Stefanos Zafeiriou; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 12242-12254

In recent years, 3D hand pose estimation methods have garnered significant attention due to their extensive applications in human-computer interaction, virtual reality, and robotics. In contrast, there has been a notable gap in hand detection pipelines, posing significant challenges in constructing effective real-world multi-hand reconstruction systems. In this work, we present a data-driven pipeline for efficient multi-hand reconstruction in the wild. The proposed pipeline is composed of two components: a real-time fully convolutional hand localization and a high-fidelity transformer-based 3D hand reconstruction model. To tackle the limitations of previous methods and build a robust and stable detection network, we introduce a large-scale dataset with over than 2M in-the-wild hand images with diverse lighting, illumination, and occlusion conditions. Our approach outperforms previous methods in both efficiency and accuracy on popular 2D and 3D benchmarks. Finally, we showcase the effectiveness of our pipeline to achieve smooth 3D hand tracking from monocular videos, without utilizing any temporal components. Code, models, and dataset are available at https://rolpotamias.github.io/WiLoR

HumanMM: Global Human Motion Recovery from Multi-shot Videos

Yuhong Zhang, Guanlin Wu, Ling-Hao Chen, Zhuokai Zhao, Jing Lin, Xiaoke Jiang, Jiamin Wu, Zhuoheng Li, Hao Frank Yang, Haoqian Wang, Lei Zhang; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 1973-1983

In this paper, we present a novel framework designed to reconstruct long-sequence 3D human motion in the world coordinates from in-the-wild videos with multiple shot transitions. Such long-sequence in-the-wild motions are highly valuable to applications such as motion generation and motion understanding, but are of great challenge to be recovered due to abrupt shot transitions, partial occlusions, and dynamic backgrounds presented in such videos. Existing methods primarily focus on single-shot videos, where continuity is maintained within a single camera view, or simplify multi-shot alignment in camera space only. In this work, we tackle the challenges by integrating an enhanced camera pose estimation with Human Motion Recovery (HMR) by incorporating a shot transition detector and a robust alignment module for accurate pose and orientation continuity across shots. By leveraging a custom motion integrator, we effectively mitigate the problem of foot sliding and ensure temporal consistency in human pose. Extensive evaluations on our created multi-shot dataset from public 3D human datasets demonstrate the robustness of our method in reconstructing realistic human motion in world coordinates.

Removing Reflections from RAW Photos

Eric Kee, Adam Pikielny, Kevin Blackburn-Matzen, Marc Levoy; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 161-171

We describe a system to remove real-world reflections from images for consumer photography. Our system operates on linear (RAW) photos, and accepts an optional contextual photo looking in the opposite direction (e.g., the "selfie" camera on a mobile device). This optional photo disambiguates what should be considered the reflection. The system is trained solely on synthetic mixtures of real RAW photos, which we combine using a reflection simulation that is photometrically and geometrically accurate. Our system comprises a base model that accepts the captured photo and optional context photo as input, and runs at 256p, followed by an up-sampling model that transforms 256p images to full resolution. The system produces preview images at 1K in 4.5-6.5s on a MacBook or iPhone 14 Pro. We show SOTA results on RAW photos that were captured in the field to embody typical consumer photos, and show that training on RAW simulation data improves performance more than the architectural variations among prior works.

BiomedCoOp: Learning to Prompt for Biomedical Vision-Language Models

Taha Koleilat, Hojat Asgariandehkordi, Hassan Rivaz, Yiming Xiao; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 14766-14776

Recent advancements in vision-language models (VLMs), such as CLIP, have demonstrated substantial success in self-supervised representation learning for vision tasks. However, effectively adapting VLMs to downstream applications remains challenging, as their accuracy often depends on time-intensive and expertise-demanding prompt engineering, while full model fine-tuning is costly. This is particularly true for biomedical images, which, unlike natural images, typically suffer from limited annotated datasets, unintuitive image contrasts, and nuanced visual features. Recent prompt learning techniques, such as Context Optimization (CoOp) intend to tackle these issues, but still fall short in generalizability. Meanwhile, explorations in prompt learning for biomedical image analysis are still highly limited. In this work, we propose BiomedCoOp, a novel prompt learning framework that enables efficient adaptation of BiomedCLIP for accurate and highly generalizable few-shot biomedical image classification. Our approach achieves effective prompt context learning by leveraging semantic consistency with average prompt ensembles from Large Language Models (LLMs) and knowledge distillation with a statistics-based prompt selection strategy. We conducted comprehensive validation of our proposed framework on 11 medical datasets across 9 modalities and 10 organs against existing state-of-the-art methods, demonstrating significant improvements in both accuracy and generalizability. The code is publicly available at https://github.com/HealthX-Lab/BiomedCoOp.

AMR-Transformer: Enabling Efficient Long-range Interaction for Complex Neural Fluid Simulation

Zeyi Xu, Jinfan Liu, Kuangxu Chen, Ye Chen, Zhangli Hu, Bingbing Ni; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 5804-5813

Accurately and efficiently simulating complex fluid dynamics is a challenging task that has traditionally relied on computationally intensive methods. Neural network-based approaches, such as convolutional and graph neural networks, have partially alleviated this burden by enabling efficient local feature extraction. However, they struggle to capture long-range dependencies due to limited receptive fields, and Transformer-based models, while providing global context, incur prohibitive computational costs. To tackle these challenges, we propose AMR-Transformer, an efficient and accurate neural CFD-solving pipeline that integrates a novel adaptive mesh refinement scheme with a Navier-Stokes constraint-aware fast pruning module. This design encourages long-range interactions between simulation cells and facilitates the modeling of global fluid wave patterns, such as turbulence and shockwaves. Experiments show that our approach achieves significant gains in efficiency while preserving critical details, making it suitable for high-resolution physical simulations with long-range dependencies. On CFDBench, PDEBench and a new shockwave dataset, our pipeline demonstrates up to an order-of-magnitude improvement in accuracy over baseline models. Additionally, compared to ViT, our approach achieves a reduction in FLOPs of up to 60 times.

****

MV-SSM: Multi-View State Space Modeling for 3D Human Pose Estimation

Aviral Chharia, Wenbo Gou, Haoye Dong; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 11590-11599

While significant progress has been made in single-view 3D human pose estimation, multi-view 3D human pose estimation remains challenging, particularly in terms of generalizing to new camera configurations. Existing attention-based transformers often struggle to accurately model the spatial arrangement of keypoints, especially in occluded scenarios. Additionally, they tend to overfit specific camera arrangements and visual scenes from training data, resulting in substantial performance drops in new settings. In this study, we introduce a novel Multi-View State Space Modeling framework, named MV-SSM, for robustly estimating 3D human keypoints. We explicitly model the joint spatial sequence at two distinct levels: the feature level from multi-view images and the person keypoint level. We pro

pose a Projective State Space (PSS) block to learn a generalized representation of joint spatial arrangements using state space modeling. Moreover, we modify Mamba's traditional scanning into an effective Grid Token-guided Bidirectional Scanning (GTBS), which is integral to the PSS block. Multiple experiments demonstrate that MV-SSM achieves strong generalization, outperforming state-of-the-art methods: +10.8 on AP25 on the challenging three-camera setting in CMU Panoptic, +7.0 on AP25 on varying camera arrangements, and +15.3 PCP on Campus A1 in cross-dataset evaluations. Project Website: https://aviralchharia.github.io/MV-SSM

HyperGLM: HyperGraph for Video Scene Graph Generation and Anticipation
Trong-Thuan Nguyen, Pha Nguyen, Jackson Cothren, Alper Yilmaz, Khoa Luu; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 29150-29160
Multimodal LLMs have advanced vision-language tasks but still struggle with understanding video scenes. To bridge this gap, Video Scene Graph Generation (VidSGG) has emerged to capture multi-object relationships across video frames. However, prior methods rely on pairwise connections, limiting their ability to handle complex multi-object interactions and reasoning. To this end, we propose Multimodal LLMs on a Scene HyperGraph (HyperGLM), promoting reasoning about multi-way interactions and higher-order relationships. Our approach uniquely integrates entity scene graphs, which capture spatial relationships between objects, with a procedural graph that models their causal transitions, forming a unified HyperGraph. Significantly, HyperGLM enables reasoning by injecting this unified HyperGraph into LLMs. Additionally, we introduce a new Video Scene Graph Reasoning (VSGR) dataset featuring 1.9M frames from third-person, egocentric, and drone views and supports five tasks: Scene Graph Generation, Scene Graph Anticipation, Video Question Answering, Video Captioning, and Relation Reasoning. Empirically, HyperGLM consistently outperforms state-of-the-art methods across five tasks, effectively modeling and reasoning complex relationships in diverse video scenes.

AnySat: One Earth Observation Model for Many Resolutions, Scales, and Modalities
Guillaume Astruc, Nicolas Gonthier, Clément Mallet, Loic Landrieu; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 19530-19540
Geospatial models must adapt to the diversity of Earth observation data in terms of resolutions, scales, and modalities. However, existing approaches expect fixed input configurations, which limits their practical applicability. We propose AnySat, a multimodal model based on joint embedding predictive architecture (JEPA) and scale-adaptive spatial encoders, allowing us to train a single model on highly heterogeneous data in a self-supervised manner. To demonstrate the advantages of this unified approach, we compile GeoPlex, a collection of 5 multimodal datasets with varying characteristics and 11 distinct sensors. We then train a single powerful model on these diverse datasets simultaneously. Once fine-tuned or probed, we achieve state-of-the-art results on the test sets of GeoPlex and for 6 external datasets across various environment monitoring tasks: land cover mapping, tree species identification, crop type classification, change detection, climate type classification, and segmentation of flood, burn scar, and deforestation. Our code and models are available at https://github.com/gastruc/AnySat.

FSFM: A Generalizable Face Security Foundation Model via Self-Supervised Facial Representation Learning
Gaojian Wang, Feng Lin, Tong Wu, Zhenguang Liu, Zhongjie Ba, Kui Ren; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 24364-24376
This work asks: with abundant, unlabeled real faces, how to learn a robust and transferable facial representation that boosts various face security tasks with respect to generalization performance? We make the first attempt and propose a self-supervised pretraining framework to learn fundamental representations of real face images, FSFM, that leverages the synergy between masked image modeling (MIM) and instance discrimination (ID). We explore various facial masking strategie

s for MIM and present a simple yet powerful CRFR-P masking, which explicitly for ces the model to capture meaningful intra-region Consistency and challenging int er-region Coherency. Furthermore, we devise an ID network that naturally couples with MIM to establish underlying local-to-global Correspondence through tailore d self-distillation. These three learning objectives, namely 3C, empower encodin g both local features and global semantics of real faces. After pretraining, a v anilla ViT serves as a universal vision Foundation Model for downstream Face Sec urity tasks: cross-dataset deepfake detection, cross-domain face anti-spoofing, and unseen diffusion facial forgery detection. Extensive experiments on 10 publi c datasets demonstrate that our model transfers better than supervised pretraini ng, visual and facial self-supervised learning arts, and even outperforms task-s pecialized SOTA methods.

OVO-Bench: How Far is Your Video-LLMs from Real-World Online Video Understanding ?

Junbo Niu, Yifei Li, Ziyang Miao, Chunjiang Ge, Yuanhang Zhou, Qihao He, Xiaoyi Dong, Haodong Duan, Shuangrui Ding, Rui Qian, Pan Zhang, Yuhang Zang, Yuhang Cao , Conghui He, Jiaqi Wang; Proceedings of the Computer Vision and Pattern Recogni tion Conference (CVPR), 2025, pp. 18902-18913

Temporal Awareness, the ability to reason dynamically based on the timestamp whe n a question is raised, is the key distinction between offline and online video LLMs. Unlike offline models, which rely on complete videos for static, post hoc analysis, online models process video streams incrementally and dynamically adap t their responses based on the timestamp at which the question is posed. Despite its significance, temporal awareness has not been adequately evaluated in exist ing benchmarks. To fill this gap, we present OVO-Bench (Online-VideO-Benchmark), a novel video benchmark that emphasizes the importance of timestamps for advanc ed online video understanding capability benchmarking. OVO-Bench evaluates the a bility of video LLMs to reason and respond to events occurring at specific times tamps under three distinct scenarios: (1) Backward tracing: trace back to past e vents to answer the question. (2) Real-time understanding: understand and respon d to events as they unfold at the current timestamp. (3) Forward active respondi ng: delay the response until sufficient future information becomes available to answer the question accurately. OVO-Bench comprises 12 tasks, featuring 644 uniq ue videos and approximately human-curated 2,800 fine-grained meta-annotations wi th precise timestamps. We combine automated generation pipelines with human cura tion. With these high-quality samples, we further developed an evaluation pipeli ne to systematically query video LLMs along the video timeline. Evaluations of n ine Video-LLMs reveal that, despite advancements on traditional benchmarks, curr ent models struggle with online video understanding, showing a significant gap c ompared to human agents. We hope OVO-Bench will drive progress in video LLMs and inspire future research in online video reasoning. Our benchmark and code can b e accessed at https://joeleelyf.github.io/OVO-Bench.

AlignMamba: Enhancing Multimodal Mamba with Local and Global Cross-modal Alignme nt

Yan Li, Yifei Xing, Xiangyuan Lan, Xin Li, Haifeng Chen, Dongmei Jiang; Proceedi ngs of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 24774-24784

Cross-modal alignment is crucial for multimodal representation fusion due to the inherent heterogeneity between modalities. While Transformer-based methods have shown promising results in modeling inter-modal relationships, their quadratic computational complexity limits their applicability to long-sequence or large-sc ale data. Although recent Mamba-based approaches achieve linear complexity, thei r sequential scanning mechanism poses fundamental challenges in comprehensively modeling cross-modal relationships. To address this limitation, we propose Align Mamba, an efficient and effective method for multimodal fusion. Specifically, gr ounded in Optimal Transport, we introduce a local cross-modal alignment module t hat explicitly learns token-level correspondences between different modalities. Moreover, we propose a global cross-modal alignment loss based on Maximum Mean D

iscrepancy to implicitly enforce the consistency between different modal distrib
utions. Finally, the unimodal representations after local and global alignment a
re passed to the Mamba backbone for further cross-modal interaction and multimod
al fusion. Extensive experiments on complete and incomplete multimodal fusion ta
sks demonstrate the effectiveness and efficiency of the proposed method. For ins
tance, on the CMU-MOSI dataset, AlignMamba improves classification accuracy by 0
.9%, reduces GPU memory usage by 20.3%, and decreases inference time by 83.3%.

Blurry-Edges: Photon-Limited Depth Estimation from Defocused Boundaries
Wei Xu, Charles James Wagner, Junjie Luo, Qi Guo; Proceedings of the Computer Vi
sion and Pattern Recognition Conference (CVPR), 2025, pp. 432-441
Extracting depth information from photon-limited, defocused images is challengin
g because depth from defocus (DfD) relies on accurate estimation of defocus blur
, which is fundamentally sensitive to image noise. We present a novel approach t
o robustly measure object depths from photon-limited images along the defocused
boundaries. It is based on a new image patch representation, Blurry-Edges, that
explicitly stores and visualizes a rich set of low-level patch information, incl
uding boundaries, color, and smoothness. We develop a deep neural network archit
ecture that predicts the Blurry-Edges representation from a pair of differently
defocused images, from which depth can be calculated using a closed-form DfD rel
ation we derive. The experimental results on synthetic and real data show that o
ur method achieves the highest depth estimation accuracy on photon-limited image
s compared to a broad range of state-of-the-art DfD methods.

VideoComp: Advancing Fine-Grained Compositional and Temporal Alignment in Video-
Text Models
Dahun Kim, AJ Piergiovanni, Ganesh Mallya, Anelia Angelova; Proceedings of the C
omputer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 29060-29070
We introduce VideoComp, a benchmark and learning framework for advancing video-t
ext compositionality understanding, aimed at improving vision-language models (V
LMs) in fine-grained temporal alignment. Unlike existing benchmarks focused on s
tatic image-text compositionality or isolated single-event videos, our benchmark
 targets alignment in continuous multi-event videos. Leveraging video-text datas
ets with temporally localized event captions (e.g. ActivityNet-Captions, YouCook
2), we construct two compositional benchmarks, ActivityNet-Comp and YouCook2-Com
p. We create challenging negative samples with subtle temporal disruptions such
as reordering, action word replacement, partial captioning, and combined disrupt
ions. These benchmarks comprehensively test models' compositional sensitivity ac
ross extended, cohesive video-text sequences. To improve model performance, we p
ropose a hierarchical pairwise preference loss that strengthens alignment with t
emporally accurate pairs and gradually penalizes increasingly disrupted ones, en
couraging fine-grained compositional learning. To mitigate the limited availabil
ity of densely annotated video data, we introduce a pretraining strategy that co
ncatenates short video-caption pairs to simulate multi-event sequences. We evalu
ate video-text foundational models and large multimodal models (LMMs) on our ben
chmark, identifying both strengths and areas for improvement in compositionality
. Overall, our work provides a comprehensive framework for evaluating and enhanc
ing model capabilities in achieving fine-grained, temporally coherent video-text
 alignment.
****

One Model for ALL: Low-Level Task Interaction Is a Key to Task-Agnostic Image Fu
sion
Chunyang Cheng, Tianyang Xu, Zhenhua Feng, Xiaojun Wu, Zhangyong Tang, Hui Li, Z
eyang Zhang, Sara Atito, Muhammad Awais, Josef Kittler; Proceedings of the Compu
ter Vision and Pattern Recognition Conference (CVPR), 2025, pp. 28102-28112
Advanced image fusion methods mostly prioritise high-level missions, where task
interaction struggles with semantic gaps, requiring complex bridging mechanisms.
 In contrast, we propose to leverage low-level vision tasks from digital photogr
aphy fusion, allowing for effective feature interaction through pixel-level supe
rvision. This new paradigm provides strong guidance for unsupervised multimodal

fusion without relying on abstract semantics, enhancing task-shared feature learning for broader applicability. Owning to the hybrid image features and enhanced universal representations, the proposed GIFNet supports diverse fusion tasks, achieving high performance across both seen and unseen scenarios with a single model. Uniquely, experimental results reveal that our framework also supports single-modality enhancement, offering superior flexibility for practical applications. Our code will be available at https://github.com/AWCXV/GIFNet.

MICAS: Multi-grained In-Context Adaptive Sampling for 3D Point Cloud Processing

Feifei Shao, Ping Liu, Zhao Wang, Yawei Luo, Hongwei Wang, Jun Xiao; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 6616-6626

Point cloud processing (PCP) encompasses tasks like reconstruction, denoising, registration, and segmentation, each often requiring specialized models to address unique task characteristics. While in-context learning (ICL) has shown promise across tasks by using a single model with task-specific demonstration prompts, its application to PCP reveals significant limitations. We identify inter-task and intra-task sensitivity issues in current ICL methods for PCP, which we attribute to inflexible sampling strategies lacking context adaptation at the point and prompt levels. To address these challenges, we propose MICAS, an advanced ICL framework featuring a multi-grained adaptive sampling mechanism tailored for PCP. MICAS introduces two core components: task-adaptive point sampling, which leverages inter-task cues for point-level sampling, and query-specific prompt sampling, which selects optimal prompts per query to mitigate intra-task sensitivity. To our knowledge, this is the first approach to introduce adaptive sampling tailored to the unique requirements of point clouds within an ICL framework. Extensive experiments show that MICAS not only efficiently handles various PCP tasks but also significantly outperforms existing methods. Notably, it achieves a remarkable 4.1% improvement in the part segmentation task and delivers consistent gains across various PCP applications.

****

Can Text-to-Video Generation help Video-Language Alignment?

Luca Zanella, Massimiliano Mancini, Willi Menapace, Sergey Tulyakov, Yiming Wang, Elisa Ricci; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 24097-24107

Recent video-language alignment models are trained on sets of videos, each with an associated positive caption and a negative caption generated by large language models. A problem with this procedure is that negative captions may introduce linguistic biases, i.e., concepts are seen only as negatives and never associated with a video. While a solution would be to collect videos for the negative captions, existing databases lack the fine-grained variations needed to cover all possible negatives. In this work, we study whether synthetic videos can help to overcome this issue. Our preliminary analysis with multiple generators shows that, while promising on some tasks, synthetic videos harm the performance of the model on others. We hypothesize this issue is linked to noise (semantic and visual) in the generated videos and develop a method, SynViTA, that accounts for those. SynViTA dynamically weights the contribution of each synthetic video based on how similar its target caption is w.r.t. the real counterpart. Moreover, a semantic consistency loss makes the model focus on fine-grained differences across captions, rather than differences in video appearance. Experiments show that, on average, SynViTA improves over existing methods on VideoCon test sets and SSv2-Temporal, SSv2-Events, and ATP-Hard benchmarks, being a first promising step for using synthetic videos when learning video-language models.

GoalFlow: Goal-Driven Flow Matching for Multimodal Trajectories Generation in End-to-End Autonomous Driving

Zebin Xing, Xingyu Zhang, Yang Hu, Bo Jiang, Tong He, Qian Zhang, Xiaoxiao Long, Wei Yin; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 1602-1611

We propose GoalFlow, an end-to-end autonomous driving method for generating high

-quality multimodal trajectories. In autonomous driving scenarios, there is rare ly a single suitable trajectory. Recent methods have increasingly focused on mod eling multimodal trajectory distributions. However, they suffer from trajectory selection complexity and reduced trajectory quality due to high trajectory diver gence and inconsistencies between guidance and scene information. To address the se issues, we introduce GoalFlow, a novel method that effectively constrains the generative process to produce high-quality, multimodal trajectories. To resolve the trajectory divergence problem inherent in diffusion-based methods, GoalFlow constrains the generated trajectories by introducing a goal point. GoalFlow est ablishes a novel scoring mechanism that selects the most appropriate goal point from the candidate points based on scene information. Furthermore, GoalFlow empl oys an efficient generative method, Flow Matching, to generate multimodal trajec tories, and incorporates a refined scoring mechanism to select the optimal traje ctory from the candidates. Our experimental results, validated on the Navsim, de monstrate that GoalFlow achieves state-of-the-art performance, delivering robust multimodal trajectories for autonomous driving. GoalFlow achieved PDMS of 90.3, significantly surpassing other methods. Compared with other diffusion-policy-ba sed methods, our approach requires only a single denoising step to obtain excell ent performance. The code is available at https://github.com/YvanYin/GoalFlow.

****

GuardSplat: Efficient and Robust Watermarking for 3D Gaussian Splatting

Zixuan Chen, Guangcong Wang, Jiahao Zhu, Jianhuang Lai, Xiaohua Xie; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 163 25-16335

3D Gaussian Splatting (3DGS) has recently created impressive 3D assets for vario us applications. However, considering security, capacity, invisibility, and trai ning efficiency, the copyright of 3DGS assets is not well protected as existing watermarking methods are unsuited for its rendering pipeline. In this paper, we propose GuardSplat, an innovative and efficient framework for watermarking 3DGS assets. Specifically, 1) We propose a CLIP-guided pipeline for optimizing the me ssage decoder with minimal costs. The key objective is to achieve high-accuracy extraction by leveraging CLIP's aligning capability and rich representations, de monstrating exceptional capacity and efficiency. 2) We tailor a Spherical-Harmon ic-aware (SH-aware) Message Embedding module for 3DGS, seamlessly embedding mess ages into the SH features of each 3D Gaussian while preserving the original 3D s tructure. This enables watermarking 3DGS assets with minimal fidelity trade-offs and prevents malicious users from removing the watermarks from the model files, meeting the demands for invisibility and security. 3) We present an Anti-distor tion Message Extraction module to improve robustness against various distortions . Experiments demonstrate that GuardSplat outperforms state-of-the-art and achie ves fast optimization speed.

Weakly Supervised Contrastive Adversarial Training for Learning Robust Features from Semi-supervised Data

Lilin Zhang, Chengpei Wu, Ning Yang; Proceedings of the Computer Vision and Patt ern Recognition Conference (CVPR), 2025, pp. 25718-25727

Existing adversarial training (AT) methods often suffer from incomplete perturba tion, meaning that not all non-robust features are perturbed when generating adv ersarial examples (AEs). This results in residual correlations between non-robus t features and labels, leading to suboptimal learning of robust features. Howeve r, achieving complete perturbation--perturbing as many non-robust features as po ssible--is challenging due to the difficulty in distinguishing robust and non-ro bust features and the sparsity of labeled data. To address these challenges, we propose a novel approach called Weakly Supervised Contrastive Adversarial Traini ng (WSCAT). WSCAT ensures complete perturbation for improved learning of robust features by disrupting correlations between non-robust features and labels throu gh complete AE generation over partially labeled data, grounded in information t heory. Extensive theoretical analysis and comprehensive experiments on widely ad opted benchmarks validate the superiority of WSCAT. Our code is available at htt ps://github.com/zhang-lilin/WSCAT.

****
From Poses to Identity: Training-Free Person Re-Identification via Feature Centralization
Chao Yuan, Guiwei Zhang, Changxiao Ma, Tianyi Zhang, Guanglin Niu; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 24409-24418
Person re-identification (ReID) aims to extract accurate identity representation features. However, during feature extraction, individual samples are inevitably affected by noise (background, occlusions, and model limitations). Considering that features from the same identity follow a normal distribution around identity centers after training, we propose a Training-Free Feature Centralization ReID framework (Pose2ID) by aggregating the same identity features to reduce individual noise and enhance the stability of identity representation, which preserves the feature's original distribution for following strategies such as re-ranking. Specifically, to obtain samples of the same identity, we introduce two components: Identity-Guided Pedestrian Generation: by leveraging identity features to guide the generation process, we obtain high-quality images with diverse poses, ensuring identity consistency even in complex scenarios such as infrared, and occlusion. Neighbor Feature Centralization: it explores each sample's potential positive samples from its neighborhood. Experiments demonstrate that our generative model exhibits strong generalization capabilities and maintains high identity consistency. With the Feature Centralization framework, we achieve impressive performance even with an ImageNet pre-trained model without ReID training, reaching mAP/Rank-1 of 52.81/78.92 on Market1501. Moreover, our method sets new state-of-the-art results across standard, cross-modality, and occluded ReID tasks, showcasing strong adaptability.
****
ColabSfM: Collaborative Structure-from-Motion by Point Cloud Registration
Johan Edstedt, André Mateus, Alberto Jaenal; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 6573-6583
Structure-from-Motion (SfM) is the task of estimating 3D structure and camera poses from images. We define Collaborative SfM (ColabSfM) as sharing distributed SfM reconstructions. Sharing maps requires estimating a joint reference frame, which is typically referred to as registration. However, there is a lack of scalable methods and training datasets for registering SfM reconstructions. In this paper, we tackle this challenge by proposing the scalable task of point cloud registration for SfM reconstructions. We find that current registration methods cannot register SfM point clouds when trained on existing datasets. To this end, we propose a SfM registration dataset generation pipeline, leveraging partial reconstructions from synthetically generated camera trajectories for each scene. Finally, we propose a simple but impactful neural refiner on top of the SotA registration method RoITr that yields significant improvements, which we call RefineRoITr. Our extensive experimental evaluation shows that our proposed pipeline and model enables ColabSfM. Code is available at https://github.com/EricssonResearch/ColabSfM.

RoadSocial: A Diverse VideoQA Dataset and Benchmark for Road Event Understanding from Social Video Narratives
Chirag Parikh, Deepti Rawat, Rakshitha R. T., Tathagata Ghosh, Ravi Kiran Sarvadevabhatla; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 19002-19011
We introduce RoadSocial, a large-scale, diverse VideoQA dataset tailored for generic road event understanding from social media narratives. Unlike existing datasets limited by regional bias, viewpoint bias and expert-driven annotations, RoadSocial captures the global complexity of road events with varied geographies, camera viewpoints (CCTV, handheld, drones) and rich social discourse. Our scalable semi-automatic annotation framework leverages Text LLMs and Video LLMs to generate comprehensive question-answer pairs across 12 challenging QA tasks, pushing the boundaries of road event understanding. RoadSocial is derived from social media videos spanning 14M frames and 414K social comments, resulting in a dataset

with 13.2K videos, 674 tags and 260K high-quality QA pairs. We evaluate 18 Video LLMs (open-source and proprietary, driving-specific and general-purpose) on our road event understanding benchmark. We also demonstrate RoadSocial's utility in improving road event understanding capabilities of general-purpose Video LLMs.

MangaNinja: Line Art Colorization with Precise Reference Following
Zhiheng Liu, Ka Leong Cheng, Xi Chen, Jie Xiao, Hao Ouyang, Kai Zhu, Yu Liu, Yujun Shen, Qifeng Chen, Ping Luo; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 5666-5677
Derived from diffusion models, MangaNinja specializes in the task of reference-guided line art colorization. We incorporate two thoughtful designs to ensure precise character detail transcription, including a patch shuffling module to facilitate correspondence learning between the reference color image and the target line art, and a point-driven control scheme to enable fine-grained color matching. Experiments on a self-collected benchmark demonstrate the superiority of our model over current solutions in terms of precise colorization. We further showcase the potential of the proposed interactive point control in handling challenging cases (*e.g.*, extreme poses and shadows), cross-character colorization, multi-reference harmonization, *etc.*, beyond the reach of existing algorithms.
****

Nonisotropic Gaussian Diffusion for Realistic 3D Human Motion Prediction
Cecilia Curreli, Dominik Muhle, Abhishek Saroha, Zhenzhang Ye, Riccardo Marin, Daniel Cremers; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 1871-1882
Probabilistic human motion prediction aims to forecast multiple possible future movements from past observations. While current approaches report high diversity and realism, they often generate motions with undetected limb stretching and jitter. To address this, we introduce SkeletonDiffusion, a latent diffusion model that embeds an explicit inductive bias on the human body within its architecture and training. We present a nonisotropic Gaussian diffusion formulation that aligns with the natural kinematic structure of the human skeleton and models relationships between body parts. Results show that our approach outperforms isotropic alternatives, consistently generating realistic predictions while avoiding artifacts such as limb distortion. Additionally, we identify a limitation in commonly used diversity metrics, which may favor models that produce inconsistent limb lengths within the same sequence. SkeletonDiffusion sets a new benchmark on three real-world datasets, outperforming various baselines across multiple evaluation metrics. We release the code on our \href https://ceveloper.github.io/publications/skeletondiffusion/ project page .

Is Your World Simulator a Good Story Presenter? A Consecutive Events-Based Benchmark for Future Long Video Generation
Yiping Wang, Xuehai He, Kuan Wang, Luyao Ma, Jianwei Yang, Shuohang Wang, Simon Shaolei Du, Yelong Shen; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 13629-13638
The current state-of-the-art video generative models can produce commercial-grade videos with highly realistic details. However, they still struggle to coherently present multiple sequential events in specific short stories, which is foreseeable an essential capability for future long video generation scenarios. For example, top T2V generative models still fail to generate a video of the short simple story "how to put an elephant into a refrigerator." While existing detail-oriented benchmarks primarily focus on fine-grained metrics like aesthetic quality and spatial-temporal consistency, they fall short of evaluating models' abilities to handle event-level story presentation. To address this gap, we introduce StoryEval, a story-oriented benchmark specifically designed to assess text-to-video (T2V) models' story-completion capabilities. StoryEval features 423 prompts spanning 7 classes, each representing short stories composed of 2-4 consecutive events. We employ Vision-Language Models, such as GPT-4o and LLaVA-OV-Chat-72B, to verify the completion of each event in the generated videos, applying a unanimous voting method to enhance reliability. Our methods ensure high alignment with

human evaluations, and the evaluation of 11 models reveals its challenge, with none exceeding an average story-completion rate of 50%. StoryEval provides a new benchmark for advancing T2V models and highlights the challenges and opportunities in developing next-generation solutions for coherent story-driven video generation. Project website is available at https://ypwang61.github.io/project/StoryEval.

LookCloser: Frequency-aware Radiance Field for Tiny-Detail Scene
Xiaoyu Zhang, Weihong Pan, Chong Bao, Xiyu Zhang, Xiaojun Xiang, Hanqing Jiang, Hujun Bao; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 16122-16132

Humans perceive and comprehend their surroundings through information spanning multiple frequencies. In immersive scenes, people naturally scan their environment to grasp its overall structure while examining fine details of objects that capture their attention. However, current NeRF frameworks primarily focus on modeling either high-frequency local views or the broad structure of scenes with low-frequency information, limited to balance both. We introduce FA-NeRF, a novel frequency-aware framework for view synthesis that simultaneously captures the overall scene structure and high-definition details within a single NeRF model. To achieve this, we propose a 3D frequency quantification method that analyzes the scene's frequency distribution, enabling frequency-aware rendering. Our framework incorporates a frequency grid for fast convergence and querying, a frequency-aware feature re-weighting strategy to balance features across different frequency contents. Extensive experiments show that our method significantly outperforms existing approaches in modeling entire scenes while preserving fine details.

PICO: Reconstructing 3D People In Contact with Objects
Alpár Cseke, Shashank Tripathi, Sai Kumar Dwivedi, Arjun S. Lakshmipathy, Agniv Chatterjee, Michael J. Black, Dimitrios Tzionas; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 1783-1794

Recovering 3D Human-Object Interaction (HOI) from single color images is challenging due to depth ambiguities, occlusions, and the huge variation in object shape and appearance. Thus, past work requires controlled settings such as known object shapes and contacts, and tackles only limited object classes. Instead, we need methods that generalize to natural images and novel object classes. We tackle this in two main ways:(1) We collect PICO-db, a new dataset of natural images uniquely paired with dense 3D contact correspondences on both body and object meshes. To this end, we use images from the recent DAMON dataset that are paired with annotated contacts, but only on a canonical 3D body. In contrast, we seek contact labels on both the body and the object. To infer these given an image, we retrieve an appropriate 3D object mesh from a database by leveraging vision foundation models. Then, we project DAMON's body contact patches onto the object via a novel method needing only 2 clicks per patch. This minimal human input establishes rich contact correspondences between bodies and objects. (2) We exploit our new dataset in a novel render-and-compare fitting method, called PICO-fit, to recover 3D body and object meshes in interaction. PICO-fit infers contact for the SMPL-X body, retrieves a likely 3D object mesh and contact from PICO-db for that object, and uses the contact to iteratively fit the 3D body and object meshes to image evidence via optimization. Uniquely, PICO-fit works well for many object categories that no existing method can tackle. This is crucial for scaling HOI understanding in the wild. Our data and code are available at https://pico.is.tue.mpg.de.

Convex Relaxation for Robust Vanishing Point Estimation in Manhattan World
Bangyan Liao, Zhenjun Zhao, Haoang Li, Yi Zhou, Yingping Zeng, Hao Li, Peidong Liu; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 15823-15832

Determining the vanishing points (VPs) in a Manhattan world, as a fundamental task in many 3D vision applications, consists of jointly inferring the line-VP association and locating each VP. Existing methods are, however, either sub-optimal

solvers or pursuing global optimality at a significant cost of computing time. In contrast to prior works, we introduce convex relaxation techniques to solve this task for the first time. Specifically, we employ a "soft" association scheme, realized via a truncated multi-selection error, that allows for joint estimation of VPs' locations and line-VP associations. This approach leads to a primal problem that can be reformulated into a quadratically constrained quadratic programming (QCQP) problem, which is then relaxed into a convex semidefinite programming (SDP) problem. To solve this SDP problem efficiently, we present a globally optimal outlier-robust iterative solver (called GlobustVP), which independently searches for one VP and its associated lines in each iteration, treating other lines as outliers. After each independent update of all VPs, the mutual orthogonality between the three VPs in a Manhattan world is reinforced via local refinement. Extensive experiments on both synthetic and real-world data demonstrate that GlobustVP achieves a favorable balance between efficiency, robustness, and global optimality compared to previous works. The code is publicly available at github.com/wu-cvgl/GlobustVP.

Linguistics-aware Masked Image Modeling for Self-supervised Scene Text Recognition

Yifei Zhang, Chang Liu, Jin Wei, Xiaomeng Yang, Yu Zhou, Can Ma, Xiangyang Ji; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 9318-9328

Text images are unique in their dual nature, encompassing both visual and linguistic information. The visual component encompasses structural and appearance-based features, while the linguistic dimension incorporates contextual and semantic elements. In scenarios with degraded visual quality, linguistic patterns serve as crucial supplements for comprehension, highlighting the necessity of integrating both aspects for robust scene text recognition (STR). Contemporary STR approaches often use language models or semantic reasoning modules to capture linguistic features, typically requiring large-scale annotated datasets. Self-supervised learning, which lacks annotations, presents challenges in disentangling linguistic features related to the global context. Typically, sequence contrastive learning emphasizes the alignment of local features, while masked image modeling (MIM) tends to exploit local structures to reconstruct visual patterns, resulting in limited linguistic knowledge. In this paper, we propose a Linguistics-aware Masked Image Modeling (LMIM) approach, which channels the linguistic information into the decoding process of MIM through a separate branch. Specifically, we design a linguistics alignment module to extract vision-independent features as linguistic guidance using inputs with different visual appearances. As features extend beyond mere visual structures, LMIM must consider the global context to achieve reconstruction. Extensive experiments on various benchmarks quantitatively demonstrate our state-of-the-art performance, and attention visualizations qualitatively show the simultaneous capture of both visual and linguistic information. The code is available at https://github.com/zhangyifei01/LMIM.

FruitNinja: 3D Object Interior Texture Generation with Gaussian Splatting

Fangyu Wu, Yuhao Chen; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 11051-11060

In the real world, objects reveal internal textures when sliced or cut, yet this behavior is not well-studied in 3D generation tasks today. For example, slicing a virtual 3D watermelon should reveal flesh and seeds. Given that no available dataset captures an object's full internal structure and collecting data from all slices is impractical, generative methods become the obvious approach. However, current 3D generation and inpainting methods often focus on visible appearance and overlook internal textures. To bridge this gap, we introduce FruitNinja, the first method to generate internal textures for 3D objects undergoing geometric and topological changes. Our approach produces objects via 3D Gaussian Splatting (3DGS) with both surface and interior textures synthesized, enabling real-time slicing and rendering without additional optimization. FruitNinja leverages a pre-trained diffusion model to progressively inpaint cross-sectional views and ap

plies voxel-grid-based smoothing to achieve cohesive textures throughout the obj
ect. Our OpaqueAtom GS strategy overcomes 3DGS limitations by employing densely
distributed opaque Gaussians, avoiding biases toward larger particles that desta
bilize training and sharp color transitions for fine-grained textures. Experime
ntal results show that FruitNinja substantially outperforms existing approaches,
 showcasing unmatched visual quality in real-time rendered internal views across
 arbitrary geometry manipulations. Project page: https://fanguw.github.io/FruitN
inja3D.

Scaling up Image Segmentation across Data and Tasks
Pei Wang, Zhaowei Cai, Hao Yang, Ashwin Swaminathan, R. Manmatha, Stefano Soatto
; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR),
2025, pp. 4573-4583
Traditional segmentation models, while effective in isolated tasks, often fail t
o generalize to more complex and open-ended segmentation problems, such as free-
form, open-vocabulary, and in-the-wild scenarios. To bridge this gap, we propose
 to scale up image segmentation across diverse datasets and tasks such that the
knowledge across different tasks and datasets can be integrated while improving
the generalization ability. QueryMeldNet, a novel segmentation framework, is int
roduced and designed to scale seamlessly across both data size and task diversit
y. It is built upon a dynamic object query mechanism called query meld, which fu
ses different types of queries using cross-attention. This hybrid approach enabl
es the model to balance between instance- and stuff-level segmentation, providin
g enhanced scalability for handling diverse object types. We further enhance sca
lability by leveraging synthetic data-generating segmentation masks and captions
 for pixel-level and open-vocabulary tasks-drastically reducing the need for cos
tly human annotations. By training on multiple datasets and tasks at scale, Quer
yMeldNet continuously improves performance as the volume and diversity of data a
nd tasks increase. It exhibits strong generalization capabilities, boosting perf
ormance in open-set segmentation tasks SeginW by 7 points. These advancements ma
rk a key step toward universal, scalable segmentation models capable of addressi
ng the demands of real-world applications.

Take the Bull by the Horns: Learning to Segment Hard Samples
Yuan Guo, Jingyu Kong, Yu Wang, Yuping Duan; Proceedings of the Computer Vision
and Pattern Recognition Conference (CVPR), 2025, pp. 15642-15652
Medical image segmentation is vital for clinical applications, with hard samples
 playing a key role in segmentation accuracy. We propose an effective image segm
entation framework that includes mechanisms for identifying and segmenting hard
samples. It derives a novel image segmentation paradigm: 1) Learning to identify
 hard samples: automatically selecting inherent hard samples from different data
sets, and 2) Learning to segment hard samples: achieving the segmentation of har
d samples through effective feature augmentation on dedicated networks. We name
our method `Learning to Segment hard samples' (L2S). The hard sample identificat
ion module comprises a backbone model and a classifier, which dynamically uncove
rs inherent dataset patterns. The hard sample segmentation module utilizes the d
iffusion process for feature augmentation and incorporates a more sophisticated
segmentation network to achieve precise segmentation. We justify our motivation
through solid theoretical analysis and extensive experiments. Evaluations across
 various modalities show that our L2S outperforms other SOTA methods, particular
ly by substantially improving the segmentation accuracy of hard samples. On ISIC
 dataset, our L2S improves the Dice score on hard samples and overall segmentati
on by 8.97% and 1.01%, respectively, compared to SOTA methods. The code is avail
able at \href https://github.com/TqlYuanGie/L2S https://github.com/TqlYuanGie/L
2S.

MIMO: A Medical Vision Language Model with Visual Referring Multimodal Input and
 Pixel Grounding Multimodal Output
Yanyuan Chen, Dexuan Xu, Yu Huang, Songkun Zhan, Hanpin Wang, Dongxue Chen, Xuep
ing Wang, Meikang Qiu, Hang Li; Proceedings of the Computer Vision and Pattern R

ecognition Conference (CVPR), 2025, pp. 24732-24741
Currently, medical vision language models are widely used in medical vision ques tion answering tasks. However, existing models are confronted with two issues: f or input, the model only relies on text instructions and lacks direct understand ing of visual clues in the image; for output, the model only gives text answers and lacks connection with key areas in the image. To address these issues, we pr opose a unified medical vision language model MIMO, with visual referring Multim odal Input and pixel grounding Multimodal Output. MIMO can not only combine visu al clues and textual instructions to understand complex medical images and seman tics, but can also ground medical terminologies in textual output within the ima ge. To overcome the scarcity of relevant data in the medical field, we propose M IMOSeg, a comprehensive medical multimodal dataset including 895K samples. MIMOS eg is constructed from four different perspectives, covering basic instruction f ollowing and complex question answering with multimodal input and multimodal out put. We conduct experiments on several downstream medical multimodal tasks. Exte nsive experimental results verify that MIMO can uniquely combine visual referrin g and pixel grounding capabilities, which are not available in previous models. Our project can be found in https://github.com/pkusixspace/MIMO.

Bias for Action: Video Implicit Neural Representations with Bias Modulation
Alper Kayabasi, Anil Kumar Vadathya, Guha Balakrishnan, Vishwanath Saragadam; Pr oceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025 , pp. 27999-28008
We propose a new continuous video modeling framework based on implicit neural re presentations (INRs) called ActINR. At the core of our approach is the observati on that INRs can be considered as a learnable dictionary, with the shapes of the basis functions governed by the weights of the INR, and their locations governe d by the biases. Given compact non-linear activation functions, we hypothesize t hat an INR's biases are suitable to capture motion across images, and facilitate compact representations for video sequences. Using these observations, we desig n ActINR to share INR weights across frames of a video sequence, while using uni que biases for each frame. We further model the biases as the output of a separa te INR conditioned on time index to promote smoothness. By training the video IN R and this bias INR together, we demonstrate unique capabilities, including 10x video slow motion, 4x spatial super resolution along with 2x slow motion, denois ing, and video inpainting. ActINR performs remarkably well across numerous video processing tasks (often achieving more than 6dB improvement), setting a new sta ndard for continuous modeling of videos.

Bridging Past and Future: End-to-End Autonomous Driving with Historical Predicti on and Planning
Bozhou Zhang, Nan Song, Xin Jin, Li Zhang; Proceedings of the Computer Vision an d Pattern Recognition Conference (CVPR), 2025, pp. 6854-6863
End-to-end autonomous driving unifies tasks in a differentiable framework, enabl ing planning-oriented optimization and attracting growing attention.Current meth ods aggregate historical information either through dense historical bird's-eye-view (BEV) features or by querying a sparse memory bank, following paradigms inh erited from detection.However, we argue that these paradigms either omit histori cal information in motion planning or fail to align with its multi-step nature, which requires predicting or planning multiple future time steps. In line with t he philosophy of "future is a continuation of past", we propose **BridgeAD**, wh ich reformulates motion and planning queries as multi-step queries to differenti ate the queries for each future time step. This design enables the effective use of historical prediction and planning by applying them to the appropriate parts of the end-to-end system based on the time steps, which improves both perceptio n and motion planning. Specifically, historical queries for the current frame ar e combined with perception, while queries for future frames are integrated with motion planning. In this way, we bridge the gap between past and future by aggre gating historical insights at every time step, enhancing the overall coherence a nd accuracy of the end-to-end autonomous driving pipeline. Extensive experiments

on the nuScenes dataset in both open-loop and closed-loop settings demonstrate that BridgeAD achieves state-of-the-art performance. We will make our code and models publicly available.

Blood Flow Speed Estimation with Optical Coherence Tomography Angiography Images
Wensheng Cheng, Zhenghong Li, Jiaxiang Ren, Hyomin Jeong, Congwu Du, Yingtian Pan, Haibin Ling; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 10466-10475
Estimating blood flow speed is essential in many medical and physiological applications, yet it is extremely challenging due to complex vascular structure and flow dynamics, particularly for cerebral cortex regions. Existing techniques, such as Optical Doppler Tomography (ODT), generally require complex hardware control and signal processing, and still suffer from inherent system-level artifacts. To address these challenges, we propose a new learning-based approach named OCTA-Flow, which directly estimates vascular blood flow speed from Optical Coherence Tomography Angiography (OCTA) images that are commonly used for vascular structure analysis. OCTA-Flow employs several novel components to achieve this goal. First, using an encoder-decoder architecture, OCTA-Flow leverages ODT data as pseudo labels during training, thus bypassing the difficulty of collecting ground truth data. Second, to capture the relationship between vessels of varying scales and their flow speed, we design an Adaptive Window Fusion module that employs multiscale window attention. Third, to mitigate ODT artifacts, we incorporate a Conditional Random Field Decoder that promotes smoothness and consistency in the estimated blood flow. Together, these innovations enable OCTA-Flow to effectively produce accurate flow estimation, suppress the artifacts in ODT, and enhance practicality, benefiting from the established techniques of OCTA data acquisition. The code and data are available at https://github.com/Spritea/OCTA-Flow.

DreamTrack: Dreaming the Future for Multimodal Visual Object Tracking
Mingzhe Guo, Weiping Tan, Wenyu Ran, Liping Jing, Zhipeng Zhang; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 7201-7210
Aiming to achieve class-agnostic perception in visual object tracking, current trackers commonly formulate tracking as a one-shot detection problem with the template-matching architecture. Despite the success, severe environmental variations in long-term tracking raise challenges to generalizing the tracker in novel situations. Temporal trackers try to fix it by preserving the time-validity of target information with historical predictions, e.g., updating the template. However, solely transmitting the previous observations instead of learning from them leads to an inferior capability of understanding the tracking scenario from past experience, which is critical for the generalization in new frames. To address this issue, we reformulate temporal learning in visual tracking as a History-to-Future process and propose a novel tracking framework DreamTrack. Our DreamTrack learns the temporal dynamics from past observations to dream the future variations of the environment, which boosts the generalization with the extended future information from history. Considering the uncertainty of future variation, multimodal prediction is designed to infer the target trajectory of each possible future situation. The experiments demonstrate that our DreamTrack achieves leading performance with real-time inference speed. In particular, DreamTrack obtains SUC scores of 76.6%/87.9% on LaSOT/TrackingNet, surpassing all recent SOTA trackers.

OmniStyle: Filtering High Quality Style Transfer Data at Scale
Ye Wang, Ruiqi Liu, Jiang Lin, Fei Liu, Zili Yi, Yilin Wang, Rui Ma; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 7847-7856
In this paper, we introduce OmniStyle-1M, a large-scale paired style transfer dataset comprising over one million content-style-stylized image triplets across 1,000 diverse style categories, each enhanced with textual descriptions and instruction prompts. We show that OmniStyle-1M can not only improve the generalizatio

n of style transfer models through supervised training but also facilitates prec
ise control over target stylization. Especially, to ensure the quality of the da
taset, we introduce OmniFilter, a comprehensive style transfer quality assessmen
t framework, which filters high-quality triplets based on content preservation,
style consistency, and aesthetic appeal. Building upon this foundation, we propo
se OmniStyle, a framework based on the Diffusion Transformer (DiT) architecture
designed for high-quality and efficient style transfer. This framework supports
both instruction-guided and image-guided style transfer, generating high resolut
ion outputs with exceptional detail. Extensive qualitative and quantitative eval
uations demonstrate OmniStyle's superior performance compared to existing approa
ches, highlighting its efficiency and versatility. OmniStyle-1M and its accompan
ying methodologies provide a significant contribution to advancing high-quality
style transfer, offering a valuable resource for the research community.

EIDT-V: Exploiting Intersections in Diffusion Trajectories for Model-Agnostic, Z
ero-Shot, Training-Free Text-to-Video Generation
Diljeet Jagpal, Xi Chen, Vinay P. Namboodiri; Proceedings of the Computer Vision
 and Pattern Recognition Conference (CVPR), 2025, pp. 18219-18228
Zero-shot, training-free, image-based text-to-video generation is an emerging ar
ea that aims to generate videos using existing image-based diffusion models. Cur
rent methods in this space require specific architectural changes to image-gener
ation models, which limit their adaptability and scalability.In contrast to such
 methods, we provide a model-agnostic approach. We use intersections in diffusio
n trajectories, working only with the latent values. We could not obtain localiz
ed frame-wise coherence and diversity using only the intersection of trajectorie
s. Thus, we instead use a grid-based approach. An in-context trained LLM is used
 to generate coherent frame-wise prompts; another is used to identify difference
s between frames. Based on these, we obtain a CLIP-based attention mask that con
trols the timing of switching the prompts for each grid cell. Earlier switching
results in higher variance, while later switching results in more coherence. The
refore, Our approach can ensure appropriate control between coherence and varian
ce for the frames.Our approach results in state-of-the-art performance while bei
ng more flexible when working with diverse image-generation models. The empirica
l analysis using quantitative metrics and user studies confirms our model's supe
rior temporal consistency, visual fidelity and user satisfaction, thus providing
 a novel way to obtain training-free, image-based text-to-video generation.

Multi-party Collaborative Attention Control for Image Customization
Han Yang, Chuanguang Yang, Qiuli Wang, Zhulin An, Weilun Feng, Libo Huang, Yongj
un Xu; Proceedings of the Computer Vision and Pattern Recognition Conference (CV
PR), 2025, pp. 7942-7951
The rapid development of diffusion models has fueled a growing demand for custom
ized image generation. However, current customization methods face several limit
ations: 1) typically accept either image or text conditions alone; 2) customizat
ion in complex visual scenarios often leads to subject leakage or confusion; 3)
image-conditioned outputs tend to suffer from inconsistent backgrounds; and 4) h
igh computational costs. To address these issues, this paper introduces Multi-pa
rty Collaborative Attention Control (MCA-Ctrl), a tuning-free approach that enab

les high-quality image customization under both text and complex visual conditio ns. Specifically, MCA-Ctrl leverages two key operations within the self-attentio n layer to coordinate multiple parallel diffusion processes and guide the target image generation. This approach allows MCA-Ctrl to capture the content and appe arance of specific subjects while maintaining semantic consistency with the cond itional input. Additionally, to mitigate subject leakage and confusion issues co mmon in complex visual scenarios, we introduce a Subject Localization Module tha t extracts precise subject and editable image layers based on user instructions. Extensive quantitative and human evaluation experiments demonstrate that MCA-Ct rl outperforms previous methods in zero-shot image customization, effectively ad dressing the aforementioned issues.

Reproducible Vision-Language Models Meet Concepts Out of Pre-Training

Ziliang Chen, Xin Huang, Xiaoxuan Fan, Keze Wang, Yuyu Zhou, Quanlong Guan, Lian g Lin; Proceedings of the Computer Vision and Pattern Recognition Conference (CV PR), 2025, pp. 14701-14711

Contrastive Language-Image Pre-training (CLIP) models as a milestone of modern m ultimodal intelligence, its generalization mechanism grasped massive research in terests in the community. While existing studies limited in the scope of pre-tra ining knowledge, hardly underpinned its generalization to countless open-world c oncepts absent from the pre-training regime. This paper dives into such Out-of-P re-training (OOP) generalization problem from a holistic perspective. We propose LAION-Beyond benchmark to isolate the evaluation of OOP concepts from pre-train ing knowledge, with regards to OpenCLIP and its reproducible variants derived fr om LAION datasets. Empirical analysis evidences that despite image features of O OP concepts born with significant category margins, their zero-shot transfer sig nificantly fails due to the poor image-text alignment. To this, we elaborate the "name-tuning" methodology with its theoretical merits in terms of OOP generaliz ation, then propose few-shot name learning (FSNL) and zero-shot name learning (Z SNL) algorithms to achieve OOP generalization in a data-efficient manner. Their superiority have been further verified in our comprehensive experiments.

Through-The-Mask: Mask-based Motion Trajectories for Image-to-Video Generation

Guy Yariv, Yuval Kirstain, Amit Zohar, Shelly Sheynin, Yaniv Taigman, Yossi Adi, Sagie Benaim, Adam Polyak; Proceedings of the Computer Vision and Pattern Recog nition Conference (CVPR), 2025, pp. 18198-18208

We consider the task of Image-to-Video (I2V) generation, which involves transfor ming static images into realistic video sequences based on a textual description . While recent advancements produce photorealistic outputs, they frequently stru ggle to create videos with accurate and consistent object motion, especially in multi-object scenarios. To address these limitations, we propose a two-stage com positional framework that decomposes I2V generation into: (i) An explicit interm ediate representation generation stage, followed by (ii) A video generation stag e that is conditioned on this representation. Our key innovation is the introduc tion of a mask-based motion trajectory as an intermediate representation, that c aptures both semantic object information and motion, enabling an expressive but compact representation of motion and semantics. To incorporate the learned repre sentation in the second stage, we utilize object-level attention objectives. Spe cifically, we consider a spatial, per-object, masked-cross attention objective, integrating object-specific prompts into corresponding latent space regions and a masked spatio-temporal self-attention objective, ensuring frame-to-frame consi stency for each object. We evaluate our method on challenging benchmarks with mu lti-object and high-motion scenarios and empirically demonstrate that the propos ed method achieves state-of-the-art results in temporal coherence, motion realis m, and text-prompt faithfulness. Additionally, we introduce SA-V-128, a new chal lenging benchmark for single-object and multi-object I2V generation, and demonst rate our method's superiority on this benchmark. Project page is available at ht tps://guyyariv.github.io/TTM/

MAGE : Single Image to Material-Aware 3D via the Multi-View G-Buffer Estimation

Model
Haoyuan Wang, Zhenwei Wang, Xiaoxiao Long, Cheng Lin, Gerhard Hancke, Rynson W.H. Lau; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 10985-10995
With advances in deep learning models and the availability of large-scale 3D datasets, we have recently witnessed significant progress in single-view 3D reconstruction. However, existing methods often fail to reconstruct physically based material properties given a single image, limiting their applicability in complicated scenarios. This paper presents a novel approach (named MAGE) for generating 3D geometry with realistic decomposed material properties given a single image as input. Our method leverages inspiration from traditional computer graphics deferred rendering pipelines to introduce a multi-view G-buffer estimation model. The proposed model estimates G-buffers for various views as multi-domain images, including XYZ coordinates, normals, albedo, roughness, and metallic properties from a single-view RGB image. To address the inherent ambiguity and inconsistency in generating G-buffers simultaneously, we also formulate a deterministic network from the pretrained diffusion models and propose a lighting response loss that enforces consistency across these domains using PBR principles. Finally, we propose a large-scale synthetic dataset rich in material diversity for our model training. Experimental results demonstrate the effectiveness of our method in producing high-quality 3D meshes with rich material properties. Our code and dataset can be found at https://www.whyy.site/paper/mage.

Segment Anything, Even Occluded
Wei-En Tai, Yu-Lin Shih, Cheng Sun, Yu-Chiang Frank Wang, Hwann-Tzong Chen; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 29385-29394
Amodal instance segmentation, which aims to detect and segment both visible and invisible parts of objects in images, plays a crucial role in various applications, including autonomous driving, robotic manipulation, and scene understanding. While existing methods require training both front-end detectors and mask decoders jointly, this approach lacks flexibility and fails to leverage the strengths of pre-existing modal detectors. To address this limitation, we propose SAMEO, a novel framework that adapts the Segment Anything Model (SAM) as a versatile mask decoder capable of interfacing with various front-end detectors to enable mask prediction even for partially occluded objects. Acknowledging the constraints of limited amodal segmentation datasets, we introduce Amodal-LVIS, a large-scale synthetic dataset comprising 300K images derived from the modal LVIS and LVVIS datasets. This dataset significantly expands the training data available for amodal segmentation research. Our experimental results demonstrate that our approach, when trained on the newly extended dataset, including Amodal-LVIS, achieves remarkable zero-shot performance on both COCOA-cls and D2SA benchmarks, highlighting its potential for generalization to unseen scenarios.

HOT3D: Hand and Object Tracking in 3D from Egocentric Multi-View Videos
Prithviraj Banerjee, Sindi Shkodrani, Pierre Moulon, Shreyas Hampali, Shangchen Han, Fan Zhang, Linguang Zhang, Jade Fountain, Edward Miller, Selen Basol, Richard Newcombe, Robert Wang, Jakob Julian Engel, Tomas Hodan; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 7061-7071
We introduce HOT3D, a publicly available dataset for egocentric hand and object tracking in 3D. The dataset offers over 833 minutes (3.7M+ images) of recordings that feature 19 subjects interacting with 33 diverse rigid objects. In addition to simple pick-up, observe, and put-down actions, the subjects perform actions typical for a kitchen, office, and living room environment. The recordings include multiple synchronized data streams containing egocentric multi-view RGB/monochrome images, eye gaze signal, scene point clouds, and 3D poses of cameras, hands, and objects. The dataset is recorded with two headsets from Meta: Project Aria, which is a research prototype of AI glasses, and Quest 3, a virtual-reality headset that has shipped millions of units. Ground-truth poses were obtained by a motion-capture system using small optical markers attached to hands and objects

. Hand annotations are provided in the UmeTrack and MANO formats, and objects ar e represented by 3D meshes with PBR materials obtained by an in-house scanner. I n our experiments, we demonstrate the effectiveness of multi-view egocentric dat a for three popular tasks: 3D hand tracking, model-based 6DoF object pose estima tion, and 3D lifting of unknown in-hand objects. The evaluated multi-view method s, whose benchmarking is uniquely enabled by HOT3D, significantly outperform the ir single-view counterparts.

DELT: A Simple Diversity-driven EarlyLate Training for Dataset Distillation
Zhiqiang Shen, Ammar Sherif, Zeyuan Yin, Shitong Shao; Proceedings of the Comput er Vision and Pattern Recognition Conference (CVPR), 2025, pp. 4797-4806
Recent advances in dataset distillation have led to solutions in two main direct ions. The conventional batch-to-batch matching mechanism is ideal for small-scal e datasets and includes bi-level optimization methods on models and syntheses, s uch as FRePo, RCIG, and RaT-BPTT, as well as other methods like distribution mat ching, gradient matching, and weight trajectory matching. Conversely, batch-to-g lobal matching typifies decoupled methods, which are particularly advantageous f or large-scale datasets. This approach has garnered substantial interest within the community, as seen in SRe^2L, G-VBSM, WMDD, and CDA. A primary challenge wit h the second approach is the lack of diversity among syntheses within each class since samples are optimized independently and the same global supervision signa ls are reused across different synthetic images. In this study, we propose a new Diversity-driven EarlyLate Training (DELT) scheme to enhance the diversity of i mages in batch-to-global matching with less computation. Our approach is concept ually simple yet effective, it partitions predefined IPC samples into smaller su btasks and employs local optimizations to distill each subset into distributions from distinct phases, reducing the uniformity induced by the unified optimizati on process. These distilled images from the subtasks demonstrate effective gener alization when applied to the entire task. We conduct extensive experiments on C IFAR, Tiny-ImageNet, ImageNet-1K, and its sub-datasets. Our approach outperforms the previous state-of-the-art by 2~5% on average across different datasets and IPCs (images per class), increasing diversity per class by more than 5% while re ducing synthesis time by up to 39.3% for enhancing the training efficiency.
****

MESC-3D:Mining Effective Semantic Cues for 3D Reconstruction from a Single Image
Shaoming Li, Qing Cai, Songqi Kong, Runqing Tan, Heng Tong, Shiji Qiu, Yongguo J iang, Zhi Liu; Proceedings of the Computer Vision and Pattern Recognition Confer ence (CVPR), 2025, pp. 16912-16921
Reconstructing 3D shapes from a single image plays an important role in computer vision. Many methods have been proposed and achieve impressive performance. How ever, existing methods mainly focus on extracting semantic information from imag es and then simply concatenating it with 3D point clouds without further explori ng the concatenated semantics. As a result, these entangled semantic features si gnificantly hinder the reconstruction performance. In this paper, we propose a n ovel single-image 3D reconstruction method called Mining Effective Semantic Cues for 3D Reconstruction from a Single Image (MESC-3D), which can actively mine ef fective semantic cues from entangled features. Specifically, we design an Effect ive Semantic Mining Module, which incorporates a point-selection map establish c onnections between point clouds and semantic attributes, enabling the point clou ds to autonomously select the necessary information. Furthermore, to address the potential insufficiencies in semantic information from a single image, such as occlusions, inspired by the human ability to represent 3D objects using prior kn owledge drawn from daily experiences, we introduce a 3D Semantic Prior Learning Module. This module employs contrastive learning paradigm along with a learnable text prompt to incorporates semantic understanding of spatial structures, enabl ing the model to interpret and reconstruct 3D objects with greater accuracy and realism, closely mirroring human perception of complex 3D environments. Extensiv e evaluations show that our method achieves significant improvements in reconstr uction quality and robustness compared to prior works. Additionally, further exp eriments validate the strong generalization capabilities and excels in zero-shot

preformance on unseen classes. Code is available at https://github.com/QINGQINGLE/MESC-3D.

RoboBrain: A Unified Brain Model for Robotic Manipulation from Abstract to Concrete

Yuheng Ji, Huajie Tan, Jiayu Shi, Xiaoshuai Hao, Yuan Zhang, Hengyuan Zhang, Pengwei Wang, Mengdi Zhao, Yao Mu, Pengju An, Xinda Xue, Qinghang Su, Huaihai Lyu, Xiaolong Zheng, Jiaming Liu, Zhongyuan Wang, Shanghang Zhang; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 1724-1734

Recent advancements in Multimodal Large Language Models (MLLMs) have shown remarkable capabilities across various multimodal contexts. However, their application in robotic scenarios, particularly for long-horizon manipulation tasks, reveals significant limitations. These limitations arise from the current MLLMs lacking three essential robotic brain capabilities: Planning Capability, which involves decomposing complex manipulation instructions into manageable sub-tasks; Affordance Perception, the ability to recognize and interpret the affordances of interactive objects; and Trajectory Prediction, the foresight to anticipate the complete manipulation trajectory necessary for successful execution. To enhance the robotic brain's core capabilities from abstract to concrete, we introduce ShareRobot, a high-quality heterogeneous dataset that labels multi-dimensional information such as task planning, object affordance, and end-effector trajectory. ShareRobot's diversity and accuracy have been meticulously refined by three human annotators. Building on this dataset, we developed RoboBrain, an MLLM-based model that combines robotic and general multi-modal data, utilizes a multi-stage training strategy, and incorporates long videos and high-resolution images to improve its robotic manipulation capabilities.Extensive experiments demonstrate that RoboBrain achieves state-of-the-art performance across various obotic tasks, highlighting its potential to advance robotic brain capabilities.

Advancing Multiple Instance Learning with Continual Learning for Whole Slide Imaging

Xianrui Li, Yufei Cui, Jun Li, Antoni B. Chan; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 20800-20809

Advances in medical imaging and deep learning have propelled progress in whole slide image (WSI) analysis, with multiple instance learning (MIL) showing promise for efficient and accurate diagnostics. However, conventional MIL models often lack adaptability to evolving datasets, as they rely on static training that cannot incorporate new information without extensive retraining. Applying continual learning (CL) to MIL models is a possible solution, but often sees limited improvements. In this paper, we analyze CL in the context of attention MIL models and find that the model forgetting is mainly concentrated in the attention layers of the MIL model. Using the results of this analysis we propose two components for improving CL on MIL:Attention Knowledge Distillation (AKD) and the Pseudo-Bag Memory Pool (PMP). AKD mitigates catastrophic forgetting by focusing on retaining attention layer knowledge between learning sessions, while PMP reduces the memory footprint by selectively storing only the most informative patches, or "pseudo-bags" from WSIs. Experimental evaluations demonstrate that our method significantly improves both accuracy and memory efficiency on diverse WSI datasets, outperforming current state-of-the-art CL methods. This work provides a foundation for CL in large-scale, weakly annotated clinical datasets, paving the way for more adaptable and resilient diagnostic models.

****

Beyond Image Classification: A Video Benchmark and Dual-Branch Hybrid Discrimination Framework for Compositional Zero-Shot Learning

Dongyao Jiang, Haodong Jing, Yongqiang Ma, Nanning Zheng; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 9860-9869

Human reasoning naturally combines concepts to identify unseen compositions, a capability that Compositional Zero-Shot Learning (CZSL) aims to replicate in machine learning models. However, we observe that focusing solely on typical image classification tasks in CZSL may limit models' compositional generalization poten

tial. To address this, we introduce C-EgoExo, a video-based benchmark, along wit h a compositional action recognition task to enable more comprehensive evaluatio ns. Inspired by human reasoning processes, we propose a Dual-branch Hybrid Discr imination (DHD) framework, featuring two branches that decode visual inputs in d istinct observation sequences. Through a cross-attention mechanism and a context ual dependency encoder, DHD effectively mitigates challenges posed by conditiona l variance. We further design a Copula-based orthogonal decoding loss to counter act contextual interference in primitive decoding. Our approach demonstrates out standing performance across diverse CZSL tasks, excelling in both image-based an d video-based modalities and in attribute-object and action-object compositions, setting a new benchmark for CZSL evaluation.

ABBSPO: Adaptive Bounding Box Scaling and Symmetric Prior based Orientation Pred iction for Detecting Aerial Image Objects

Woojin Lee, Hyugjae Chang, Jaeho Moon, Jaehyup Lee, Munchurl Kim; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 8848-8 858

Weakly supervised Oriented Object Detection (WS-OOD) has gained attention as a c ost-effective alternative to fully supervised methods, providing efficiency and high accuracy. Among weakly supervised approaches, horizontal bounding box (HBox) supervised OOD stands out for its ability to directly leverage existing HBox a nnotations while achieving the highest accuracy under weak supervision settings. This paper introduces adaptive bounding box scaling and symmetry-prior-based or ientation prediction, called ABBSPO that is a framework for WS-OOD. Our ABBSPO a ddresses the limitations of previous HBox-supervised OOD methods, which compare ground truth (GT) HBoxes directly with predicted RBoxes' minimum circumscribed r ectangles, often leading to inaccuracies. To overcome this, we propose: (i) Adap tive Bounding Box Scaling (ABBS) that appropriately scales the GT HBoxes to opti mize for the size of each predicted RBox, ensuring more accurate prediction for RBoxes' scales; and (ii) a Symmetric Prior Angle (SPA) loss that uses the inhere nt symmetry of aerial objects for self-supervised learning, addressing the issue in previous methods where learning fails if they consistently make incorrect pr edictions for all three augmented views (original, rotated, and flipped). Extens ive experimental results demonstrate that our ABBSPO achieves state-of-the-art r esults, outperforming existing methods.

Decoupled Distillation to Erase: A General Unlearning Method for Any Class-centr ic Tasks

Yu Zhou, Dian Zheng, Qijie Mo, Renjie Lu, Kun-Yu Lin, Wei-Shi Zheng; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 203 50-20359

In this work, we present DEcoupLEd Distillation To Erase (DELETE), a general and strong unlearning method for any class-centric tasks. To derive this, we first propose a theoretical framework to analyze the general form of unlearning loss a nd decompose it into forgetting and retention terms. Through the theoretical fra mework, we point out that a class of previous methods could be mainly formulated as a loss that implicitly optimizes the forgetting term while lacking supervisi on for the retention term, disturbing the distribution of pre-trained model and struggling to adequately preserve knowledge of the remaining classes. To address it, we refine the retention term using "dark knowledge" and propose a mask dist illation unlearning method. By applying a mask to separate forgetting logits fro m retention logits, our approach optimizes both the forgetting and refined reten tion components simultaneously, retaining knowledge of the remaining classes whi le ensuring thorough forgetting of the target class. Without access to the remai ning data or intervention (i.e., used in some works), we achieve state-of-the-ar t performance across various benchmarks. What's more, DELETE is a general soluti on that can be applied to various downstream tasks, including face recognition, backdoor defense, and semantic segmentation with great performance.

TAET: Two-Stage Adversarial Equalization Training on Long-Tailed Distributions

Wang Yu-Hang, Junkang Guo, Aolei Liu, Kaihao Wang, Zaitong Wu, Zhenyu Liu, Wenfe i Yin, Jian Liu; Proceedings of the Computer Vision and Pattern Recognition Conf erence (CVPR), 2025, pp. 15476-15485
Adversarial robustness remains a significant challenge in deploying deep neural networks for real-world applications. While adversarial training is widely ackno wledged as a promising defense strategy, most existing studies primarily focus o n balanced datasets, neglecting the fact that real-world data often exhibit a lo ng-tailed distribution, which introduces substantial challenges to robustness. I n this paper, we provide an in-depth analysis of adversarial training in the con text of long-tailed distributions and identify the limitations of the current st ate-of-the-art method, AT-BSL, in achieving robust performance under such condit ions. To address these challenges, we propose a novel training framework, TAET, which incorporates an initial stabilization phase followed by a stratified, equa lization adversarial training phase. Furthermore, prior work on long-tailed robu stness has largely overlooked a crucial evaluation metric--Balanced Accuracy. To fill this gap, we introduce the concept of Balanced Robustness, a comprehensive metric that measures robustness specifically under long-tailed distributions. E xtensive experiments demonstrate that our method outperforms existing advanced d efenses, yielding significant improvements in both memory and computational effi ciency. We believe this work represents a substantial step forward in tackling r obustness challenges in real-world applications. Our paper code can be found at https://github.com/BuhuiOK/TAET-Two-Stage-Adversarial-Equalization-Training-on-L ong-Tailed-Distributions

Few-shot Personalized Scanpath Prediction
Ruoyu Xue, Jingyi Xu, Sounak Mondal, Hieu Le, Greg Zelinsky, Minh Hoai, Dimitris Samaras; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 13497-13507
A personalized model for scanpath prediction provides insights into the visual p references and attention patterns of individual subjects. However, existing meth ods for training scanpath prediction models are data-intensive and cannot be eff ectively personalized to new individuals with only a few available examples. In this paper, we propose few-shot personalized scanpath prediction task (FS-PSP) a nd a novel method to address it, which aims to predict scanpaths for an unseen s ubject using minimal support data of that subject's scanpath behavior. The key t o our method's adaptability is the Subject-Embedding Network (SE-Net), specifica lly designed to capture unique, individualized representations for each subject' s scanpaths. SE-Net generates subject embeddings that effectively distinguish be tween subjects while minimizing variability among scanpaths from the same indivi dual. The personalized scanpath prediction model is then conditioned on these su bject embeddings to produce accurate, personalized results. Experiments on multi ple eye-tracking datasets demonstrate that our method excels in FS-PSP settings and does not require any fine-tuning steps at test time. Code is available at: h ttps://github.com/cvlab-stonybrook/few-shot-scanpath

Do Your Best and Get Enough Rest for Continual Learning
Hankyul Kang, Gregor Seifer, Donghyun Lee, Jongbin Ryu; Proceedings of the Compu ter Vision and Pattern Recognition Conference (CVPR), 2025, pp. 10077-10086
According to the forgetting curve theory, we can enhance memory retention by lea rning extensive data and taking adequate rest. This means that in order to effec tively retain new knowledge, it is essential to learn it thoroughly and ensure s ufficient rest so that our brain can memorize without forgetting. The main takea way from this theory is that learning extensive data at once necessitates suffic ient rest before learning the same data again. This aspect of human long-term me mory retention can be effectively utilized to address the continual learning of neural networks. Retaining new knowledge for a long period of time without catas trophic forgetting is the critical problem of continual learning. Therefore, bas ed on Ebbinghaus' theory, we introduce the view-batch model that adjusts the lea rning schedules to optimize the recall interval between retraining the same samp les. The proposed view-batch model allows the network to get enough rest to lear

n extensive knowledge from the same samples with a recall interval of sufficient length. To this end, we specifically present two approaches: 1) a replay method that guarantees the optimal recall interval, and 2) a self-supervised learning that acquires extensive knowledge from a single training sample at a time. We empirically show that these approaches of our method are aligned with the forgetting curve theory, which can enhance long-term memory. In our experiments, we also demonstrate that our method significantly improves many state-of-the-art continual learning methods in various protocols and scenarios. We open-source this project at https://github.com/hankyul2/ViewBatchModel.

Enhancing Few-Shot Class-Incremental Learning via Training-Free Bi-Level Modality Calibration
Yiyang Chen, Tianyu Ding, Lei Wang, Jing Huo, Yang Gao, Wenbin Li; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 9881-9890
Few-shot Class-Incremental Learning (FSCIL) challenges models to adapt to new classes with limited samples, presenting greater difficulties than traditional classincremental learning. While existing approaches rely heavily on visual models and require additional training during base or incremental phases, we propose a training-free framework that leverages pre-trained visual-language models like CLIP. At the core of our approach is a novel Bilevel Modality Calibration (BiMC) strategy. Our framework initially performs intra-modal calibration, combining LLM-generated fine-grained category descriptions with visual prototypes from the base session to achieve precise classifier estimation. This is further complemented by inter-modal calibration that fuses pre-trained linguistic knowledge with task-specific visual priors to mitigate modality-specific biases. To enhance prediction robustness, we introduce additional metrics and strategies that maximize the utilization of limited data. Extensive experimental results demonstrate that our approach significantly outperforms existing methods. Code is available at: https://github.com/yychen016/BiMC.

MUSt3R: Multi-view Network for Stereo 3D Reconstruction
Yohann Cabon, Lucas Stoffl, Leonid Antsfeld, Gabriela Csurka, Boris Chidlovskii, Jerome Revaud, Vincent Leroy; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 1050-1060
DUSt3R introduced a novel paradigm in geometric computer vision by proposing a model that can provide dense and unconstrained Stereo 3D Reconstruction of arbitrary image collections with no prior information about camera calibration nor viewpoint poses. Under the hood, however, DUSt3R processes image pairs, regressing local 3D reconstructions that need to be aligned in a global coordinate system. The number of pairs, growing quadratically, is an inherent limitation that becomes especially concerning for robust and fast optimization in the case of large image collections. In this paper, we propose an extension of DUSt3R from pairs to multiple views, that addresses all aforementioned concerns. Indeed, we propose a Multi-view Network for Stereo 3D Reconstruction, or MUSt3R, that modifies the DUSt3R architecture by making it symmetric and extending it to directly predict 3D structure for all views in a common coordinate frame. Second, we entail the model with a multi-layer memory mechanism which allows to reduce the computational complexity and to scale the reconstruction to large collections, inferring thousands of 3D pointmaps at high frame-rates with limited added complexity. The framework is designed to perform 3D reconstruction both offline and online, and hence can be seamlessly applied to SfM and visual SLAM scenarios showing state-of-the-art performance on various 3D downstream tasks, including uncalibrated Visual Odometry, relative camera pose, scale and focal estimation, 3D reconstruction and multi-view depth estimation.

Hybrid-Level Instruction Injection for Video Token Compression in Multi-modal Large Language Models
Zhihang Liu, Chen-Wei Xie, Pandeng Li, Liming Zhao, Longxiang Tang, Yun Zheng, Chuanbin Liu, Hongtao Xie; Proceedings of the Computer Vision and Pattern Recogni

tion Conference (CVPR), 2025, pp. 8568-8578
Recent Multi-modal Large Language Models (MLLMs) have been challenged by the computational overhead resulting from massive video frames, often alleviated through compression strategies. However, the visual content is not equally contributed to user instructions, existing strategies (e.g., average pool) inevitably lead to the loss of potentially useful information. To tackle this, we propose the Hybrid-level Instruction Injection Strategy for Conditional Token Compression in MLLMs (HICom), utilizing the instruction as a condition to guide the compression from both local and global levels. This encourages the compression to retain the maximum amount of user-focused information while reducing visual tokens to minimize computational burden. Specifically, the instruction condition is injected into the grouped visual tokens at the local level and the learnable tokens at the global level, and we conduct the attention mechanism to complete the conditional compression. From the hybrid-level compression, the instruction-relevant visual parts are highlighted while the temporal-spatial structure is also preserved for easier understanding of LLMs. To further unleash the potential of HICom, we introduce a new conditional pre-training stage with our proposed dataset HICom-248K. Experiments show that our HICom can obtain distinguished video understanding ability with fewer tokens, increasing the performance by 2.43% average on three multiple-choice QA benchmarks and saving 78.8% tokens compared with the SOTA method. The code is available at https://github.com/lntzm/HICom.

Mamba4D: Efficient 4D Point Cloud Video Understanding with Disentangled Spatial-Temporal State Space Models
Jiuming Liu, Jinru Han, Lihao Liu, Angelica I. Aviles-Rivero, Chaokang Jiang, Zhe Liu, Hesheng Wang; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 17626-17636
Point cloud videos can faithfully capture real-world spatial geometries and temporal dynamics, which are essential for enabling intelligent agents to understand the dynamically changing world. However, designing an effective 4D backbone remains challenging, mainly due to the irregular and unordered distribution of points and temporal inconsistencies across frames. Also, recent transformer-based 4D backbones commonly suffer from large computational costs due to their quadratic complexity, particularly for long video sequences. To address these challenges, we propose a novel point cloud video understanding backbone purely based on the State Space Models (SSMs). Specifically, we first disentangle space and time in 4D video sequences and then establish the spatio-temporal correlation with the unified spatial-temporal Mamba blocks. The Intra-frame Spatial Mamba module is developed to encode locally similar geometric structures within a certain temporal stride. Subsequently, locally correlated tokens are delivered to the Inter-frame Temporal Mamba module, which integrates long-term point features across the entire video with linear complexity. Our proposed Mamba4D achieves competitive performance on the MSR-Action3D action recognition (+10.4% accuracy), HOI4D action segmentation (+0.7 F1 Score), and Synthia4D semantic segmentation (+0.19 mIoU) datasets. Mamba4D also has a significant efficiency improvement, especially for long video sequences, with 87.5% GPU memory reduction and 5.36 times speed-up. Codes are released at https://github.com/IRMVLab/Mamba4D.

Mamba as a Bridge: Where Vision Foundation Models Meet Vision Language Models for Domain-Generalized Semantic Segmentation
Xin Zhang, Robby T. Tan; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 14527-14537
Vision Foundation Models (VFMs) and Vision-Language Models (VLMs) have gained traction in Domain Generalized Semantic Segmentation (DGSS) due to their strong generalization capabilities. However, existing DGSS methods often rely exclusively on either VFMs or VLMs, overlooking their complementary strengths. VFMs (e.g., DINOv2) excel at capturing fine-grained features, while VLMs (e.g., CLIP) provide robust text alignment but struggle with coarse granularity. Despite their complementary strengths, effectively integrating VFMs and VLMs with attention mechanisms is challenging, as the increased patch tokens complicate long-sequence mode

ling. To address this, we propose MFuser, a novel Mamba-based fusion framework t
hat efficiently combines the strengths of VFMs and VLMs while maintaining linear
 scalability in sequence length. MFuser consists of two key components: MVFuser,
 which acts as a co-adapter to jointly fine-tune the two models by capturing bot
h sequential and spatial dynamics; and MTEnhancer, a hybrid attention-Mamba modu
le that refines text embeddings by incorporating image priors. Our approach achi
eves precise feature locality and strong text alignment without incurring signif
icant computational overhead. Extensive experiments demonstrate that MFuser sign
ificantly outperforms state-of-the-art DGSS methods, achieving 68.20 mIoU on syn
thetic-to-real and 71.87 mIoU on real-to-real benchmarks. The code is available
at https://github.com/devinxzhang/MFuser.

Vision-Guided Action: Enhancing 3D Human Motion Prediction with Gaze-informed Af
fordance in 3D Scenes

Ting Yu, Yi Lin, Jun Yu, Zhenyu Lou, Qiongjie Cui; Proceedings of the Computer V
ision and Pattern Recognition Conference (CVPR), 2025, pp. 12335-12346

Recent advances in human motion prediction (HMP) have shifted focus from isolate
d motion data to integrating human-scene correlations. In particular, the latest
 methods leverage human gaze points, using their spatial coordinates to indicate
 intent--where a person might move within a 3D environment. Despite promising tr
ajectory results, these methods often produce inaccurate poses by overlooking th
e semantic implications of gaze, specifically the affordances of observed object
s, which indicate the possible interactions. To address this, we propose GAP3DS,
 an affordance-aware HMP model that utilizes gaze-informed object affordances to
 improve HMP in complex 3D environments. GAP3DS incorporates a gaze-guided affor
dance learner to identify relevant objects in the scene and infer their affordan
ces based on human gaze, thus contextualizing future human-object interactions.
This affordance information, enriched with visual features and gaze data, condit
ions the generation of multiple human-object interaction poses, which are subseq
uently decoded into final motion predictions. Extensive experiments on two real-
world datasets demonstrate that GAP3DS outperforms state-of-the-art methods in b
oth trajectory and pose accuracy, producing more physically consistent and conte
xtually grounded predictions. For more details and code, please refer to the pro
ject page.

LOGICZSL: Exploring Logic-induced Representation for Compositional Zero-shot Lea
rning

Peng Wu, Xiankai Lu, Hao Hu, Yongqin Xian, Jianbing Shen, Wenguan Wang; Proceedi
ngs of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp.
30301-30311

Compositional zero-shot learning (CZSL) aims to recognize unseen attribute-objec
t compositions by learning the primitive concepts (*i.e.*, attribute and object)
 from the training set. While recent works achieve impressive results in CZSL by
 leveraging large vision-language models like CLIP, they ignore the rich semanti
c relationships between primitive concepts and their compositions. In this work,
 we propose LOGICZSL, a novel logic-induced learning framework to explicitly mod
el the semantic relationships. Our logic-induced learning framework formulates t
he relational knowledge constructed from large language models as a set of logic
 rules, and grounds them onto the training data. Our logic-induced losses are co
mplementary to the widely used CZSL losses, therefore can be employed to inject
the semantic information into any existing CZSL methods. Extensive experimental
results show that our method brings significant performance improvements across
diverse datasets (*i.e.*, CGQA, UT-Zappos50K, MIT-States) with strong CLIP-based
 methods and settings (*i.e.*, Close World, Open World).

ChainHOI: Joint-based Kinematic Chain Modeling for Human-Object Interaction Gene
ration

Ling-An Zeng, Guohong Huang, Yi-Lin Wei, Shengbo Gu, Yu-Ming Tang, Jingke Meng,
Wei-Shi Zheng; Proceedings of the Computer Vision and Pattern Recognition Confer
ence (CVPR), 2025, pp. 12358-12369

We propose ChainHOI, a novel approach for text-driven human-object interaction (HOI) generation that explicitly models interactions at both the joint and kineti c chain levels. Unlike existing methods that implicitly model interactions us ing full-body poses as tokens, we argue that explicitly modeling joint-level int eractions is more natural and effective for generating realistic HOIs, as it dir ectly captures the geometric and semantic relationships between joints, rather t han modeling interactions in the latent pose space. To this end, ChainHOI int roduces a novel joint graph to capture potential interactions with objects, and a Generative Spatiotemporal Graph Convolution Network to explicitly model intera ctions at the joint level. Furthermore, we propose a Kinematics-based Intera ction Module that explicitly models interactions at the kinetic chain level, ens uring more realistic and biomechanically coherent motions. Evaluations on two public datasets demonstrate that ChainHOI significantly outperforms previous me thods, generating more realistic, and semantically consistent HOIs.

CLOC: Contrastive Learning for Ordinal Classification with Multi-Margin N-pair L oss

Dileepa Pitawela, Gustavo Carneiro, Hsiang-Ting Chen; Proceedings of the Compute r Vision and Pattern Recognition Conference (CVPR), 2025, pp. 15538-15548

In ordinal classification, misclassifying neighboring ranks is common, yet the c onsequences of these errors are not the same.For example, misclassifying benign tumor categories is less consequential, compared to an error at the pre-cancerou s to cancerous threshold, which could profoundly influence treatment choices. De spite this, existing ordinal classification methods do not account for the varyi ng importance of these margins, treating all neighboring classes as equally sign ificant. To address this limitation, we propose CLOC, a new margin-based contras tive learning method for ordinal classification that learns an ordered represent ation based on the optimization of multiple margins with a novel multi-margin n- pair loss (MMNP).CLOC enables flexible decision boundaries across key adjacent c ategories, facilitating smooth transitions between classes and reducing the risk of overfitting to biases present in the training data.We provide empirical disc ussion regarding the properties of MMNP and show experimental results on five re al-world image datasets (Adience, Historical Colour Image Dating, Knee Osteoarth ritis, Indian Diabetic Retinopathy Image, and Breast Carcinoma Subtyping) and on e synthetic dataset simulating clinical decision bias.Our results demonstrate th at CLOC outperforms existing ordinal classification methods and show the interpr etability and controllability of CLOC in learning meaningful, ordered representa tions that align with clinical and practical needs.

Universal Actions for Enhanced Embodied Foundation Models

Jinliang Zheng, Jianxiong Li, Dongxiu Liu, Yinan Zheng, Zhihao Wang, Zhonghong O u, Yu Liu, Jingjing Liu, Ya-Qin Zhang, Xianyuan Zhan; Proceedings of the Compute r Vision and Pattern Recognition Conference (CVPR), 2025, pp. 22508-22519

Training on diverse, internet-scale data is a key factor in the success of recen t large foundation models. Yet, using the same recipe for building embodied agen ts has faced noticeable difficulties. Despite the availability of many crowd-sou rced embodied datasets, their action spaces often exhibit significant heterogene ity due to distinct physical embodiment and control interfaces for different rob ots, causing substantial challenges in developing embodied foundation models usi ng cross-embodiment data. In this paper, we introduce UniAct, a new embodied fou ndation modeling framework operating in the Universal Action Space. Our learned universal actions capture the generic behaviors across diverse robots by exploit ing their shared structural features, and enable enhanced cross-domain data util ization and cross-embodiment generalizations by eliminating the notorious hetero geneity. Moreover, the universal actions can be efficiently translated back to h eterogeneous actionable commands by simply adding embodiment-specific details, f rom which fast adaptation to new robots becomes simple and straightforward. Our 0.5B instantiation of UniAct outperforms 14X larger SOTA embodied foundation mod els in extensive evaluations on various real-world and simulation robots, showca sing exceptional cross-embodiment control and adaptation capability, highlightin

g the crucial benefit of adopting universal actions.

ObjectMover: Generative Object Movement with Video Prior
Xin Yu, Tianyu Wang, Soo Ye Kim, Paul Guerrero, Xi Chen, Qing Liu, Zhe Lin, Xiaojuan Qi; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 17682-17691
Simple as it seems, moving an object to another location within an image is, in fact, a challenging image-editing task that requires re-harmonizing the lighting, adjusting the pose based on perspective, accurately filling occluded regions, and ensuring coherent synchronization of shadows and reflections while maintaining the object identity. In this paper, we present ObjectMover, a generative model that can perform object movement in highly challenging scenes. Our key insight is that we model this task as a sequence-to-sequence problem and fine-tune a video generation model to leverage its knowledge of consistent object generation across video frames. We show that with this approach, our model is able to adjust to complex real-world scenarios, handling extreme lighting harmonization and object effect movement. As large-scale data for object movement are unavailable, we construct a data generation pipeline using a modern game engine to synthesize high-quality data pairs. We further propose a multi-task learning strategy that enables training on real-world video data to improve the model generalization. Through extensive experiments, we demonstrate that ObjectMover achieves outstanding results and adapts well to real-world scenarios.
****

FaithDiff: Unleashing Diffusion Priors for Faithful Image Super-resolution
Junyang Chen, Jinshan Pan, Jiangxin Dong; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 28188-28197
Faithful image super-resolution (SR) not only needs to recover images that appear realistic, similar to image generation tasks, but also requires that the restored images maintain fidelity and structural consistency with the input. To this end, we propose a simple and effective method, named FaithDiff, to fully harness the impressive power of latent diffusion models (LDMs) for faithful image SR. In contrast to existing diffusion-based SR methods that freeze the diffusion model pre-trained on high-quality images, we propose to unleash the diffusion prior to identify useful information and recover faithful structures. As there exists a significant gap between the features of degraded inputs and the noisy latent from the diffusion model, we then develop an effective alignment module to explore useful features from degraded inputs to align well with the diffusion process. Considering the indispensable roles and interplay of the encoder and diffusion model in LDMs, we jointly fine-tune them in a unified optimization framework, facilitating the encoder to extract useful features that coincide with diffusion process. Extensive experimental results demonstrate that FaithDiff outperforms state-of-the-art methods, providing high-quality and faithful SR results.
****

MLLM-as-a-Judge for Image Safety without Human Labeling
Zhenting Wang, Shuming Hu, Shiyu Zhao, Xiaowen Lin, Felix Juefei-Xu, Zhuowei Li, Ligong Han, Harihar Subramanyam, Li Chen, Jianfa Chen, Nan Jiang, Lingjuan Lyu, Shiqing Ma, Dimitris N. Metaxas, Ankit Jain; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 14657-14666
Image content safety has become a significant challenge with the rise of visual media on online platforms. Meanwhile, in the age of AI-generated content (AIGC), many image generation models are capable of producing harmful content, such as images containing sexual or violent material. Thus, it becomes crucial to identify such unsafe images based on established safety rules. Pre-trained Multimodal Large Language Models (MLLMs) offer potential in this regard, given their strong pattern recognition abilities. Existing approaches typically fine-tune MLLMs with human-labeled datasets, which however brings a series of drawbacks. First, relying on human annotators to label data following intricate and detailed guidelines is both expensive and labor-intensive. Furthermore, users of safety judgment systems may need to frequently update safety rules, making fine-tuning on human-based annotation more challenging. This raises the research question: Can we de

tect unsafe images by querying MLLMs in a zero-shot setting using a predefined s afety constitution (a set of safety rules)? Our research showed that simply quer ying pre-trained MLLMs does not yield satisfactory results. This lack of effecti veness stems from factors such as the subjectivity of safety rules, the complexi ty of lengthy constitutions, and the inherent biases in the models. To address t hese challenges, we propose a MLLM-based method includes objectifying safety rul es, assessing the relevance between rules and images, making quick judgments bas ed on debiased token probabilities with logically complete yet simplified precon dition chains for safety rules, and conducting more in-depth reasoning with casc aded chain-of-thought processes if necessary. Experiment results demonstrate tha t our method is highly effective for zero-shot image safety judgment tasks.

A New Statistical Model of Star Speckles for Learning to Detect and Characterize Exoplanets in Direct Imaging Observations
Théo Bodrito, Olivier Flasseur, Julien Mairal, Jean Ponce, Maud Langlois, Anne-M arie Lagrange; Proceedings of the Computer Vision and Pattern Recognition Confer ence (CVPR), 2025, pp. 1230-1240
The search for exoplanets is an active field in astronomy, with direct imaging a s one of the most challenging methods due to faint exoplanet signals buried with in stronger residual starlight. Successful detection requires advanced image pr ocessing to separate the exoplanet signal from this nuisance component. This pap er presents a novel statistical model that captures nuisance fluctuations using a multi-scale approach, leveraging problem symmetries and a joint spectral chann el representation grounded in physical principles. Our model integrates into an interpretable, end-to-end learnable framework for simultaneous exoplanet detect ion and flux estimation. The proposed algorithm is evaluated against the state of the art using datasets from the SPHERE instrument operating at the Very Large Telescope (VLT). It significantly improves the precision-recall trade-off, not ably on challenging datasets that are otherwise unusable by astronomers. The pr oposed approach is computationally efficient, robust to varying data quality, an d well suited for large-scale observational surveys.

Scene-agnostic Pose Regression for Visual Localization
Junwei Zheng, Ruiping Liu, Yufan Chen, Zhenfang Chen, Kailun Yang, Jiaming Zhang , Rainer Stiefelhagen; Proceedings of the Computer Vision and Pattern Recognitio n Conference (CVPR), 2025, pp. 27092-27102
Absolute Pose Regression (APR) predicts 6D camera poses but lacks the adaptabili ty to unknown environments without retraining, while Relative Pose Regression (R PR) generalizes better yet requires a large image retrieval database. Visual Odo metry (VO) generalizes well in unseen environments but suffers from accumulated error in open trajectories. To address this dilemma, we introduce a new task, Sc ene-agnostic Pose Regression (SPR), which can achieve accurate pose regression i n a flexible way while eliminating the need for retraining or databases. To benc hmark SPR, we created a large-scale dataset, 360SPR, with over 200K photorealist ic panoramas, 3.6M pinhole images and camera poses in 270 scenes at three differ ent sensor heights. Furthermore, a SPR-Mamba model is initially proposed to addr ess SPR in a dual-branch manner. Extensive experiments and studies demonstrate t he effectiveness of our SPR paradigm, dataset, and model. In the unknown scenes of both 360SPR and 360Loc datasets, our method consistently outperforms APR, RPR and VO. The dataset and code are available at SPR.

Learning to Filter Outlier Edges in Global SfM
Nicole Damblon, Marc Pollefeys, Daniel Barath; Proceedings of the Computer Visio n and Pattern Recognition Conference (CVPR), 2025, pp. 11558-11568
We present a novel approach to enhance camera pose estimation in global Structur e-from-Motion (SfM) frameworks by filtering inaccurate pose graph edges - repres enting relative translation estimates - before applying translation averaging. I n SfM, pose graph vertices represent images, and edges represent relative poses (rotations and translations) between cameras. We reformulate the edge filtering problem as a vertex filtering in the dual graph, specifically, a line graph wher

e vertices correspond to edges in the original graph and edges correspond to cam
eras. Utilizing this representation, we frame the problem as a binary classifica
tion over nodes in the dual graph. To identify outlier edges, we employ a Transf
ormer-based architecture. To overcome the challenge of memory overflow caused by
 converting to a line graph, we introduce a clustering-based graph processing ap
proach, enabling our method to be applied to arbitrarily large pose graphs. Our
method outperforms existing relative translation filtering techniques in terms o
f camera position accuracy and can be seamlessly integrated with other filters.
The code is available at https://github.com/DmblnNicole/LFOE-GlobalSfM.

Divide and Conquer: Heterogeneous Noise Integration for Diffusion-based Adversar
ial Purification
Gaozheng Pei, Shaojie Lyu, Gong Chen, Ke Ma, Qianqian Xu, Yingfei Sun, Qingming
Huang; Proceedings of the Computer Vision and Pattern Recognition Conference (CV
PR), 2025, pp. 29268-29277
Existing diffusion-based purification methods aim to disrupt adversarial perturb
ations by introducing a certain amount of noise through a forward diffusion proc
ess, followed by a reverse process to recover clean examples. However, this appr
oach is fundamentally flawed: the uniform operation of the forward process acros
s all pixels compromises normal pixels while attempting to combat adversarial pe
rturbations, resulting in the target model producing incorrect predictions. Simp
ly relying on low-intensity noise is insufficient for effective defense. To addr
ess this critical issue, we implement a heterogeneous purification strategy grou
nded in the interpretability of neural networks. Our method decisively applies h
igher-intensity noise to specific pixels that the target model focuses on while
the remaining pixels are subjected to only low-intensity noise. This requirement
 motivates us to redesign the sampling process of the diffusion model, allowing
for the effective removal of varying noise levels. Furthermore, to evaluate our
method against strong adaptative attack, our proposed method sharply reduces tim
e cost and memory usage through a single-step resampling. The empirical evidence
 from extensive experiments across three datasets demonstrates that our method o
utperforms most current adversarial training and purification techniques by a su
bstantial margin.

SEC-Prompt:SEmantic Complementary Prompting for Few-Shot Class-Incremental Learn
ing
Ye Liu, Meng Yang; Proceedings of the Computer Vision and Pattern Recognition Co
nference (CVPR), 2025, pp. 25643-25656
Few-shot class-incremental learning (FSCIL) presents a significant challenge in
machine learning, requiring models to integrate new classes from limited example
s while preserving performance on previously learned classes. Recently, prompt-b
ased CIL approaches leverage ample data to train prompts, effectively mitigating
 catastrophic forgetting. However, these methods do not account for the semantic
 features embedded in prompts, exacerbating the plasticity-stability dilemma in
few-shot incremental learning. In this paper, we propose a novel and simple fram
ework named SEmantic Complementary Prompt(SEC-Prompt), which learns two sets of
semantically complementary prompts based on an adaptive query: discriminative pr
ompts(D-Prompt) and non-discriminative prompts(ND-Prompt). D-Prompt enhances the
 separation of class-specific feature distributions by strengthening key discrim
inative features, while ND-Prompt balances non-discriminative information to pro
mote generalization to novel classes. To efficiently learn high-quality knowledg
e from limited samples, we leverage ND-Prompt for data augmentation to increase
sample diversity and introduce Prompt Clustering Loss to prevent noise contamina
tion in D-Prompt, ensuring robust discriminative feature learning and improved g
eneralization. Our experimental results showcase state-of-the-art performance ac
ross three benchmark datasets, including CIFAR100, ImageNet-R and CUB datasets.

LiMoE: Mixture of LiDAR Representation Learners from Automotive Scenes
Xiang Xu, Lingdong Kong, Hui Shuai, Liang Pan, Ziwei Liu, Qingshan Liu; Proceedi
ngs of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp.

27368-27379
LiDAR data pretraining offers a promising approach to leveraging large-scale, readily available datasets for enhanced data utilization. However, existing methods predominantly focus on sparse voxel representation, overlooking the complementary attributes provided by other LiDAR representations. In this work, we propose LiMoE, a framework that integrates the Mixture of Experts (MoE) paradigm into LiDAR data representation learning to synergistically combine multiple representations, such as range images, sparse voxels, and raw points. Our approach consists of three stages: i) Image-to-LiDAR Pretraining, which transfers prior knowledge from images to point clouds across different representations; ii) Contrastive Mixture Learning (CML), which uses MoE to adaptively activate relevant attributes from each representation and distills these mixed features into a unified 3D network; iii) Semantic Mixture Supervision (SMS), which combines semantic logits from multiple representations to boost downstream segmentation performance. Extensive experiments across eleven large-scale LiDAR datasets demonstrate our effectiveness and superiority. The code has been made publicly accessible.

CoT-VLA: Visual Chain-of-Thought Reasoning for Vision-Language-Action Models
Qingqing Zhao, Yao Lu, Moo Jin Kim, Zipeng Fu, Zhuoyang Zhang, Yecheng Wu, Zhaoshuo Li, Qianli Ma, Song Han, Chelsea Finn, Ankur Handa, Tsung-Yi Lin, Gordon Wetzstein, Ming-Yu Liu, Donglai Xiang; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 1702-1713
Vision-language-action models (VLAs) have shown potential in leveraging pretrained vision-language models and diverse robot demonstrations for learning generalizable sensorimotor control. While this paradigm effectively utilizes large-scale data from both robotic and non-robotic sources, current VLAs primarily focus on direct input--output mappings, lacking the intermediate reasoning steps crucial for complex manipulation tasks. As a result, existing VLAs lack temporal planning or reasoning capabilities. In this paper, we introduce a method that incorporates explicit visual chain-of-thought (CoT) reasoning into vision-language-action models (VLAs) by predicting future image frames autoregressively as visual goals before generating a short action sequence to achieve these goals. We introduce CoT-VLA, a state-of-the-art 7B VLA that can understand and generate visual and action tokens. Our experimental results demonstrate that CoT-VLA achieves strong performance, outperforming the state-of-the-art VLA model by 17% in real-world manipulation tasks and 6% in simulation benchmarks. Videos are available at: https://cot-vla.github.io/.

WAVE: Weight Templates for Adaptive Initialization of Variable-sized Models
Fu Feng, Yucheng Xie, Jing Wang, Xin Geng; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 4819-4828
The growing complexity of model parameters underscores the significance of pre-trained models. However, deployment constraints often necessitate models of varying sizes, exposing limitations in the conventional pre-training and fine-tuning paradigm, particularly when target model sizes are incompatible with pre-trained ones. To address this challenge, we propose WAVE, a novel approach that reformulates variable-sized model initialization from a multi-task perspective, where initializing each model size is treated as a distinct task. WAVE employs shared, size-agnostic weight templates alongside size-specific weight scalers to achieve consistent initialization across various model sizes. These weight templates, constructed within the Learngene framework, integrate knowledge from pre-trained models through a distillation process constrained by Kronecker-based rules. Target models are then initialized by concatenating and weighting these templates, with adaptive connection rules established by lightweight weight scalers, whose parameters are learned from minimal training data. Extensive experiments demonstrate the efficiency of WAVE, achieving state-of-the-art performance in initializing models of various depth and width. The knowledge encapsulated in weight templates is also task-agnostic, allowing for seamless transfer across diverse downstream datasets. Code will be made available at https://github.com/fu-feng/WAVE.

Forensics Adapter: Adapting CLIP for Generalizable Face Forgery Detection
Xinjie Cui, Yuezun Li, Ao Luo, Jiaran Zhou, Junyu Dong; Proceedings of the Compu ter Vision and Pattern Recognition Conference (CVPR), 2025, pp. 19207-19217
We describe the Forensics Adapter, an adapter network designed to transform CLIP into an effective and generalizable face forgery detector. Although CLIP is hig hly versatile, adapting it for face forgery detection is non-trivial as forgery-related knowledge is entangled with a wide range of unrelated knowledge. Existin g methods treat CLIP merely as a feature extractor, lacking task-specific adapta tion, which limits their effectiveness. To address this, we introduce an adapter to learn face forgery traces -- the blending boundaries unique to forged faces, guided by task-specific objectives. Then we enhance the CLIP visual tokens with a dedicated interaction strategy that communicates knowledge across CLIP and th e adapter. Since the adapter is alongside CLIP, its versatility is highly retain ed, naturally ensuring strong generalizability in face forgery detection. With o nly 5.7M trainable parameters, our method achieves a significant performance boo st, improving by approximately 7% on average across five standard datasets. We b elieve the proposed method can serve as a baseline for future CLIP-based face fo rgery detection methods.

KAC: Kolmogorov-Arnold Classifier for Continual Learning
Yusong Hu, Zichen Liang, Fei Yang, Qibin Hou, Xialei Liu, Ming-Ming Cheng; Proce edings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, p p. 15297-15307
Continual learning requires models to train continuously across consecutive task s without forgetting. Most existing methods utilize linear classifiers, which st ruggle to maintain a stable classification space while learning new tasks. Inspi red by the success of Kolmogorov-Arnold Networks (KAN) in preserving learning st ability during simple continual regression tasks, we set out to explore their po tential in more complex continual learning scenarios. In this paper, we introduc e the Kolmogorov-Arnold Classifier (KAC), a novel classifier developed for conti nual learning based on the KAN structure. We delve into the impact of KAN's spli ne functions and introduce Radial Basis Functions (RBF) for improved compatibili ty with continual learning. We replace linear classifiers with KAC in several re cent approaches and conduct experiments across various continual learning benchm arks, all of which demonstrate performance improvements, highlighting the effect iveness and robustness of KAC in continual learning.
****
PI-HMR: Towards Robust In-bed Temporal Human Shape Reconstruction with Contact P ressure Sensing
Ziyu Wu, Yufan Xiong, Mengting Niu, Fangting Xie, Quan Wan, Qijun Ying, Boyan Li u, Xiaohui Cai; Proceedings of the Computer Vision and Pattern Recognition Confe rence (CVPR), 2025, pp. 27739-27749
Long-term in-bed monitoring benefits automatic and real-time health management w ithin healthcare, and the advancement of human shape reconstruction technologies further enhances the representation and visualization of users' activity patter ns. However, existing technologies are primarily based on visual cues, facing se rious challenges in non-light-of-sight and privacy-sensitive in-bed scenes. Pres sure-sensing bedsheets offer a promising solution for real-time motion reconstru ction. Yet, limited exploration in model designs and data have hindered its furt her development. To tackle these issues, we propose a general framework that bri dges gaps in data annotation and model design. Firstly, we introduce SMPLify-IB, an optimization method that overcomes the depth ambiguity issue in top-view sce narios through gravity constraints, enabling generating high-quality 3D human sh ape annotations for in-bed datasets. Then we present PI-HMR, a temporal-based hu man shape estimator to regress meshes from pressure sequences. By integrating mu lti-scale feature fusion with high-pressure distribution and spatial position pr iors, PI-HMR outperforms SOTA methods with 17.01mm Mean-Per-Joint-Error decrease . This work provides a whole tool-chain to support the development of in-bed mon itoring with pressure contact sensing.

BOOTPLACE: Bootstrapped Object Placement with Detection Transformers
Hang Zhou, Xinxin Zuo, Rui Ma, Li Cheng; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 19294-19303
In this paper, we tackle the copy-paste image-to-image composition problem with a focus on object placement learning. Prior methods have leveraged generative models to reduce the reliance for dense supervision. However, this often limits their capacity to model complex data distributions. Alternatively, transformer networks with a sparse contrastive loss have been explored, but their over-relaxed regularization often leads to imprecise object placement. We introduce BOOTPLACE, a novel paradigm that formulates object placement as a placement-by-detection problem. Our approach begins by identifying suitable regions of interest for object placement. This is achieved by training a specialized detection transformer on object-subtracted backgrounds, enhanced with multi-object supervisions. It then semantically associates each target compositing object with detected regions based on their complementary characteristics. Through a boostrapped training approach applied to randomly object-subtracted images, our model enforces meaningful placements through extensive paired data augmentation. Experimental results on established benchmarks demonstrate BOOTPLACE's superior performance in object repositioning, markedly surpassing state-of-the-art baselines on Cityscapes and OPA datasets with notable improvements in IOU scores. Additional ablation studies further showcase the compositionality and generalizability of our approach, supported by user study evaluations. Code is available at https://github.com/RyanHangZhou/BOOTPLACE

CheckManual: A New Challenge and Benchmark for Manual-based Appliance Manipulation
Yuxing Long, Jiyao Zhang, Mingjie Pan, Tianshu Wu, Taewhan Kim, Hao Dong; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 22595-22604
Correct use of electrical appliances has significantly improved human life quality. Unlike simple tools that can be manipulated with common sense, different parts of electrical appliances have specific functions defined by manufacturers. If we want the robot to heat bread by microwave, we should enable them to review the microwave's manual first. From the manual, it can learn about component functions, interaction methods, and representative task steps about appliances. However, previous manual-related works remain limited to question-answering tasks while existing manipulation researchers ignore the manual's important role and fail to comprehend multi-page manuals. In this paper, we propose the first manual-based appliance manipulation benchmark CheckManual. Specifically, we design a large model-assisted human-revised data generation pipeline to create manuals based on CAD appliance models. With these manuals, we establish novel manual-based manipulation challenges, metrics, and simulator environments for model performance evaluation. Furthermore, we propose the first manual-based manipulation planning model ManualPlan to set up a group of baselines for the CheckManual benchmark.

CXPMRG-Bench: Pre-training and Benchmarking for X-ray Medical Report Generation on CheXpert Plus Dataset
Xiao Wang, Fuling Wang, Yuehang Li, Qingchuan Ma, Shiao Wang, Bo Jiang, Jin Tang; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 5123-5133
X-ray image-based medical report generation (MRG) is a pivotal area in artificial intelligence that can significantly reduce diagnostic burdens and patient wait times. Despite significant progress, we believe that the task has reached a bottleneck due to the limited benchmark datasets and the existing large models' insufficient capability enhancements in this specialized domain. Specifically, the recently released CheXpert Plus dataset lacks comparative evaluation algorithms and their results, providing only the dataset itself. This situation makes the training, evaluation, and comparison of subsequent algorithms challenging. Thus, we conduct a comprehensive benchmarking of existing mainstream X-ray report generation models and large language models (LLMs), on the CheXpert Plus dataset. We

believe that the proposed benchmark can provide a solid comparative basis for subsequent algorithms and serve as a guide for researchers to quickly grasp the state-of-the-art models in this field. More importantly, we propose a large model for the X-ray image report generation using a multi-stage pre-training strategy, including self-supervised autoregressive generation and Xray-report contrastive learning, and supervised fine-tuning. Extensive experimental results indicate that the autoregressive pre-training based on Mamba effectively encodes X-ray images, and the image-text contrastive pre-training further aligns the feature spaces, achieving better experimental results.

FASTer: Focal token Acquiring-and-Scaling Transformer for Long-term 3D Objection Detection

Chenxu Dang, ZaiPeng Duan, Pei An, Xinmin Zhang, Xuzhong Hu, Jie Ma; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 17029-17038

Recent top-performing temporal 3D detectors based on Lidars have increasingly adopted region-based paradigms. They first generate coarse proposals, followed by encoding and fusing regional features. However, indiscriminate sampling and fusion often overlook the varying contributions of individual points and lead to exponentially increased complexity as the number of input frames grows. Moreover, arbitrary result-level concatenation limits the global information extraction. In this paper, we propose a Focal Token Acquring-and-Scaling Transformer (FASTer), which dynamically selects focal tokens and condenses token sequences in an adaptive and lightweight manner. Emphasizing the contribution of individual tokens, we propose a simple but effective Adaptive Scaling mechanism to capture geometric contexts while sifting out focal points. Adaptively storing and processing only focal points in historical frames dramatically reduces the overall complexity. Furthermore, a novel Grouped Hierarchical Fusion strategy is proposed, progressively performing sequence scaling and Intra-Group Fusion operations to facilitate the exchange of global spatial and temporal information. Experiments on the Waymo Open Dataset demonstrate that our FASTer significantly outperforms other state-of-the-art detectors in both performance and efficiency while also exhibiting improved flexibility and robustness. The code is available at https://github.com/MSunDYY/FASTer.git.

SEEN-DA: SEmantic ENtropy guided Domain-aware Attention for Domain Adaptive Object Detection

Haochen Li, Rui Zhang, Hantao Yao, Xin Zhang, Yifan Hao, Xinkai Song, Shaohui Peng, Yongwei Zhao, Chen Zhao, Yanjun Wu, Ling Li; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 25465-25475

Domain adaptive object detection (DAOD) aims to generalize detectors trained on an annotated source domain to an unlabelled target domain. Traditional works focus on aligning visual features between domains to extract domain-invariant knowledge, and recent VLM-based DAOD methods leverage semantic information provided by the textual encoder to supplement domain-specific features for each domain.However, they overlook the role of semantic information in guiding the learning of visual features that are beneficial for adaptation.To solve the problem, we propose semantic entropy to quantify the semantic information contained in visual features, and design SEmantic ENtropy guided Domain-aware Attention (SEEN-DA) to adaptively refine visual features with the semantic information of two domains.Semantic entropy reflects the importance of features based on semantic information, which can serve as attention to select discriminative visual features and suppress semantically irrelevant redundant information.Guided by semantic entropy, we introduce domain-aware attention modules into the visual encoder in SEEN-DA.It utilizes an inter-domain attention branch to extract domain-invariant features and eliminate redundant information, and an intra-domain attention branch to supplement the domain-specific semantic information discriminative on each domain.Comprehensive experiments validate the effectiveness of SEEN-DA, demonstrating significant improvements in cross-domain object detection performance.

Event-Equalized Dense Video Captioning
Kangyi Wu, Pengna Li, Jingwen Fu, Yizhe Li, Yang Wu, Yuhan Liu, Jinjun Wang, San ping Zhou; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 8417-8427
Dense video captioning aims to localize and caption all events in arbitrary untr immed videos. Although previous methods have achieved appealing results, they st ill face the issue of temporal bias, i.e, models tend to focus more on events wi th certain temporal characteristics. Specifically, 1) the temporal distribution of events in training datasets is uneven. Models trained on these datasets will pay less attention to out-of-distribution events. 2) long-duration events have m ore frame features than short ones and will attract more attention. To address t his, we argue that events, with varying temporal characteristics, should be trea ted equally when it comes to dense video captioning. Intuitively, different even ts tend to have distinct visual differences due to varied camera views, backgrou nds, or subjects. Inspired by that, we intend to utilize visual features to have an approximate perception of possible events and pay equal attention to them. I n this paper, we introduce a simple but effective framework, called Event-Equali zed Dense Video Captioning(E^2DVC) to overcome the temporal bias and treat all p ossible events equally. Specifically, an event perception module(EPM) is propose d to do uneven clustering on visual frame features to generate pseudo-events. We enforce the model's attention to these pseudo-events through the pseudo-event i nitialization module(PEI). A novel event-enhanced encoder(EEE) is also devised t o enhance the model's ability to explore frame-frame and frame-event relationshi ps. Experimental results validate the effectiveness of the proposed methods.

Geometry-guided Online 3D Video Synthesis with Multi-View Temporal Consistency
Hyunho Ha, Lei Xiao, Christian Richardt, Thu Nguyen-Phuoc, Changil Kim, Min H. K im, Douglas Lanman, Numair Khan; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 11275-11285
We introduce a novel geometry-guided online video view synthesis method with enh anced view and temporal consistency. Traditional approaches achieve high-quality synthesis from dense multi-view camera setups but require significant computati onal resources. In contrast, selective-input methods reduce this cost but often compromise quality, leading to multi-view and temporal inconsistencies such as f lickering artifacts. Our method addresses this challenge to deliver efficient, h igh-quality novel-view synthesis with view and temporal consistency. The key inn ovation of our approach lies in using global geometry to guide an image-based re ndering pipeline. To accomplish this, we progressively refine depth maps using c olor difference masks across time. These depth maps are then accumulated through truncated signed distance fields in the synthesized view's image space. This de pth representation is view and temporally consistent, and is used to guide a pre -trained blending network that fuses multiple forward-rendered input-view images . Thus, the network is encouraged to output geometrically consistent synthesis r esults across multiple views and time. Our approach achieves consistent, high-qu ality video synthesis, while running efficiently in an online manner.

EDCFlow: Exploring Temporally Dense Difference Maps for Event-based Optical Flow Estimation
Daikun Liu, Lei Cheng, Teng Wang, Changyin Sun; Proceedings of the Computer Visi on and Pattern Recognition Conference (CVPR), 2025, pp. 1984-1993
Recent learning-based methods for event-based optical flow estimation utilize co st volumes for pixel matching but suffer from redundant computations and limited scalability to higher resolutions for flow refinement. In this work, we take ad vantage of the complementarity between temporally dense feature differences of a djacent event frames and cost volume and present a lightweight event-based optic al flow network (EDCFlow) to achieve high-quality flow estimation at a higher re solution. Specifically, an attention-based multi-scale temporal feature differen ce layer is developed to capture diverse motion patterns at high resolution in a computation-efficient manner. An adaptive fusion of high-resolution difference motion features and low-resolution correlation motion features is performed to e

nhance motion representation and model generalization. Notably, EDCFlow can serv e as a plug-and-play refinement module for RAFT-like event-based methods to enha nce flow details. Extensive experiments demonstrate that EDCFlow achieves better performance with lower complexity compared to existing methods, offering superi or generalization. Codes and models will be available at here.

Point2RBox-v2: Rethinking Point-supervised Oriented Object Detection with Spatia l Layout Among Instances
Yi Yu, Botao Ren, Peiyuan Zhang, Mingxin Liu, Junwei Luo, Shaofeng Zhang, Feipen g Da, Junchi Yan, Xue Yang; Proceedings of the Computer Vision and Pattern Recog nition Conference (CVPR), 2025, pp. 19283-19293
With the rapidly increasing demand for oriented object detection (OOD), recent r esearch involving weakly-supervised detectors for learning OOD from point annota tions has gained great attention. In this paper, we rethink this challenging tas k setting with the layout among instances and present Point2RBox-v2. At the core are three principles: 1) Gaussian overlap loss. It learns an upper bound for ea ch instance by treating objects as 2D Gaussian distributions and minimizing thei r overlap. 2) Voronoi watershed loss. It learns a lower bound for each instance through watershed on Voronoi tessellation. 3) Consistency loss. It learns the si ze/rotation variation between two output sets with respect to an input image and its augmented view. Supplemented by a few devised techniques, e.g. edge loss an d copy-paste, the detector is further enhanced. To our best knowledge, Point2RBo x-v2 is the first approach to explore the spatial layout among instances for lea rning point-supervised OOD. Our solution is elegant and lightweight, yet it is e xpected to give a competitive performance especially in densely packed scenes: 6 2.61%/86.15%/34.71% on DOTA/HRSC/FAIR1M.

LibraGrad: Balancing Gradient Flow for Universally Better Vision Transformer Att ributions
Faridoun Mehri, Mahdieh Soleymani Baghshah, Mohammad Taher Pilehvar; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 67-78
Why do gradient-based explanations struggle with Transformers, and how can we im prove them? We identify gradient flow imbalances in Transformers that violate Fu llGrad-completeness, a critical property for attribution faithfulness that CNNs naturally possess. To address this issue, we introduce LibraGrad--a theoreticall y grounded post-hoc approach that corrects gradient imbalances through pruning a nd scaling of backward paths, without changing the forward pass or adding comput ational overhead. We evaluate LibraGrad using three metric families: Faithfulnes s, which quantifies prediction changes under perturbations of the most and least relevant features; Completeness Error, which measures attribution conservation relative to model outputs; and Segmentation AP, which assesses alignment with hu man perception. Extensive experiments across 8 architectures, 4 model sizes, and 5 datasets show that LibraGrad universally enhances gradient-based methods, out performing existing white-box methods--including Transformer-specific approaches --across all metrics. We demonstrate superior qualitative results through two co mplementary evaluations: precise text-prompted region highlighting on CLIP model s and accurate class discrimination between co-occurring animals on ImageNet-fin etuned models--two settings on which existing methods often struggle. LibraGrad is effective even on the attention-free MLP-Mixer architecture, indicating poten tial for extension to other modern architectures. Our code is freely available a t https://nightmachinery.github.io/LibraGrad/.

Blind Bitstream-corrupted Video Recovery via Metadata-guided Diffusion Model
Shuyun Wang, Hu Zhang, Xin Shen, Dadong Wang, Xin Yu; Proceedings of the Compute r Vision and Pattern Recognition Conference (CVPR), 2025, pp. 22975-22984
Bitstream-corrupted video recovery aims to fill in realistic video content due t o bitstream corruption during video storage or transmission. Most existing metho ds typically assume that the predefined masks of the corrupted regions are known in advance. However, manually annotating these masks is laborious and time-cons

uming, limiting the applicability of existing methods in real-world scenarios. T
herefore, we expect to relax this assumption by defining a new blind video recov
ery setting where the recovery of corrupted regions does not rely on predefined
masks. There are two significant challenges in this setting: (i) without predefi
ned masks, how accurately can a model identify the regions requiring recovery? (
ii) how to recover contents from extensive and irregular regions, especially whe
n large portions of frames are severely degraded? To address these challenges, w
e introduce a Metadata-Guided Diffusion Model, dubbed M-GDM. To enable a diffusi
on model focusing on the corrupted regions, we leverage intrinsic video metadata
as a corruption indicator and design a dual-stream metadata encoder. This encod
er first embeds the motion vectors and frame types of a video separately and the
n merges them into a unified metadata representation. The metadata representatio
n will interact with the corrupted latent feature through cross-attention mechan
isms at each diffusion step. Meanwhile, to preserve the intact regions, we propo
se a prior-driven mask predictor that generates pseudo masks for the corrupted r
egions by leveraging the metadata prior and diffusion prior. These pseudo masks
enable the separation and recombination of intact and recovered regions through
hard masking. However, imperfections in pseudo mask predictions and hard masking
processes often result in boundary artifacts. Thus, we introduce a post-refinem
ent module that refines the hard-masked outputs, enhancing the consistency betwe
en intact and recovered regions. Extensive experiment results validate the effec
tiveness of our method and demonstrate its superiority in the blind video recove
ry task.

Mind the Trojan Horse: Image Prompt Adapter Enabling Scalable and Deceptive Jail
breaking
Junxi Chen, Junhao Dong, Xiaohua Xie; Proceedings of the Computer Vision and Pat
tern Recognition Conference (CVPR), 2025, pp. 23785-23794
Recently, the Image Prompt Adapter (IP-Adapter) has been increasingly integrated
into text-to-image diffusion models (T2I-DMs) to improve controllability. Howev
er, in this paper, we reveal that T2I-DMs equipped with the IP-Adapter (T2I-IP-D
Ms) enable a new jailbreak attack named the hijacking attack. We demonstrate tha
t, by uploading imperceptible image-space adversarial examples (AEs), the advers
ary can hijack massive benign users to jailbreak an Image Generation Service (IG
S) driven by T2I-IP-DMs and mislead the public to discredit the service provider
. Worse still, the IP-Adapter's dependency on open-source image encoders reduces
the knowledge required to craft AEs. Extensive experiments verify the technical
feasibility of the hijacking attack. In light of the revealed threat, we invest
igate several existing defenses and explore combining the IP-Adapter with advers
arially trained models to overcome existing defenses' limitations. Our code is a
vailable at https://github.com/fhdnskfbeuv/attackIPA.

Lost in Translation, Found in Context: Sign Language Translation with Contextual
Cues
Youngjoon Jang, Haran Raajesh, Liliane Momeni, Gül Varol, Andrew Zisserman; Proc
eedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025,
pp. 8742-8752
Our objective is to translate continuous sign language into spoken language text
. Inspired by the way human interpreters rely on context for accurate translatio
n, we incorporate additional contextual cues together with the signing video, in
to a new translation framework. Specifically, besides visual sign recognition fe
atures that encode the input video, we integrate complementary textual informati
on from (i) captions describing the background show, (ii) translation of previou
s sentences, as well as (iii) pseudo-glosses transcribing the signing. These are
automatically extracted and inputted along with the visual features to a pre-tr
ained large language model (LLM), which we fine-tune to generate spoken language
translations in text form. Through extensive ablation studies, we show the posi
tive contribution of each input cue to the translation performance. We train and
evaluate our approach on BOBSL -- the largest British Sign Language dataset cur
rently available. We show that our contextual approach significantly enhances th

e quality of the translations compared to previously reported results on BOBSL, and also to state-of-the-art methods that we implement as baselines. Furthermore, we demonstrate the generality of our approach by applying it also to How2Sign, an American Sign Language dataset, and achieve competitive results.

CoCoGaussian: Leveraging Circle of Confusion for Gaussian Splatting from Defocused Images
Jungho Lee, Suhwan Cho, Taeoh Kim, Ho-Deok Jang, Minhyeok Lee, Geonho Cha, Dongyoon Wee, Dogyoon Lee, Sangyoun Lee; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 16101-16110
3D Gaussian Splatting (3DGS) has attracted significant attention for its high-quality novel view rendering, inspiring research to address real-world challenges. While conventional methods depend on sharp images for accurate scene reconstruction, real-world scenarios are often affected by defocus blur due to finite depth of field, making it essential to account for realistic 3D scene representation. In this study, we propose CoCoGaussian, a Circle of Confusion-aware Gaussian Splatting that enables precise 3D scene representation using only defocused images. CoCoGaussian addresses the challenge of defocus blur by modeling the Circle of Confusion (CoC) through a physically grounded approach based on the principles of photographic defocus. Exploiting 3D Gaussians, we compute the CoC diameter from depth and learnable aperture information, generating multiple Gaussians to precisely capture the CoC shape. Furthermore, we introduce a learnable scaling factor to enhance robustness and provide more flexibility in handling unreliable depth in scenes with reflective or refractive surfaces. Experiments on both synthetic and real-world datasets demonstrate that CoCoGaussian achieves state-of-the-art performance across multiple benchmarks.

Semantic and Sequential Alignment for Referring Video Object Segmentation
Feiyu Pan, Hao Fang, Fangkai Li, Yanyu Xu, Yawei Li, Luca Benini, Xiankai Lu; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 19067-19076
Referring video object segmentation (RVOS) seeks to segment the objects within a video referred by linguistic expressions. Existing RVOS solutions follow a "fuse then select" paradigm: establishing semantic correlation between visual and linguistic feature, and performing frame-level query interaction to select the instance mask per frame with instance segmentation module. This paradigm overlooks the challenge of semantic gap between the linguistic descriptor and the video object as well as the underlying clutters in the video. This paper proposes a novel Semantic and Sequential Alignment (SSA) paradigm to handle these challenges. We first insert a lightweight adapter after the vision language model (VLM) to perform the semantic alignment. Then, prior to selecting mask per frame, we exploit the trajectory-to-instance enhancement for each frame via sequential alignment. This paradigm leverages the visual-language alignment inherent in VLM during adaptation and tries to capture global information by ensembling trajectories. This helps understand videos and the corresponding descriptors by mitigating the discrepancy with intricate activity semantics, particularly when facing occlusion or similar interference. SSA demonstrates competitive performance while maintaining fewer learnable parameters.

Continual SFT Matches Multimodal RLHF with Negative Supervision
Ke Zhu, Yu Wang, Yanpeng Sun, Qiang Chen, Jiangjiang Liu, Gang Zhang, Jingdong W ang; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 14615-14624
Multimodal RLHF usually happens after supervised finetuning (SFT) stage to conti nually improve vision-language models' (VLMs) comprehension. Conventional wisdom holds its superiority over continual SFT during this preference alignment stage . In this paper, we observe that the inherent value of multimodal RLHF lies in i ts negative supervision, the logit of the rejected responses. We thus propose a novel negative supervised finetuning (nSFT) approach that fully excavates these information resided. Our nSFT disentangles this negative supervision in RLHF par adigm, and continually aligns VLMs with a simple SFT loss. This is more memory e fficient than multimodal RLHF where 2 (e.g., DPO) or 4 (e.g., PPO) large VLMs ar e strictly required. The effectiveness of nSFT is rigorously proved by comparing it with various multimodal RLHF approaches, across different dataset sources, b ase VLMs and evaluation metrics. Besides, fruitful of ablations are provided to support our hypothesis. Code will be found in https://github.com/Kevinz-code/nSF T/.

Semantic-guided Cross-Modal Prompt Learning for Skeleton-based Zero-shot Action Recognition
Anqi Zhu, Jingmin Zhu, James Bailey, Mingming Gong, Qiuhong Ke; Proceedings of t he Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 13876-13 885
Skeleton-based human action recognition is promising due to its privacy preserva tion, robustness to visual challenges, and computational efficiency. Especially, the practical necessity to recognize unseen actions has led to increased intere st in zero-shot skeleton-based action recognition (ZSSAR). Existing ZSSAR approa ches often rely on manually crafted action descriptions or visual assumptions to enhance knowledge transfer, which is limited in flexibility and prone to inaccu racies and noise. To overcome this, we introduce Semantic-guided Cross-Modal Pro mpt Learning (SCoPLe), a novel framework that replaces manual guidance with data -driven prompt learning for refinement and alignment of skeletal and textual fe atures. Specifically, we introduce a dual-stream language prompting module that preserves the original semantic context from the pre-trained text encoder while still effectively tuning its ouput for ZSSAR task adaptation. We also introduce a joint-shaped prompting module that learns tuning for skeleton features and inc orporate an adaptive visual representation sampler that leverages text semantics to strengthen the cross-modal prompting interactions during skeleton-to-text em bedding projection. Experimental results on the NTU-RGB+D and PKU-MMD datasets d emonstrate the state-of-the-art performance of our method in both ZSSAR and gene ralized ZSSAR scenarios.

FATE: Full-head Gaussian Avatar with Textural Editing from Monocular Video
Jiawei Zhang, Zijian Wu, Zhiyang Liang, Yicheng Gong, Dongfang Hu, Yao Yao, Xun Cao, Hao Zhu; Proceedings of the Computer Vision and Pattern Recognition Confere nce (CVPR), 2025, pp. 5535-5545
Reconstructing high-fidelity, animatable 3D head avatars from effortlessly captu red monocular videos is a pivotal yet formidable challenge. Although significant progress has been made in rendering performance and manipulation capabilities, notable challenges remain, including incomplete reconstruction and inefficient G aussian representation. To address these challenges, we introduce FATE -- a nove

l method for reconstructing an editable full-head avatar from a single monocular video. FATE integrates a sampling-based densification strategy to ensure optimal positional distribution of points, improving rendering efficiency. A neural baking technique is introduced to convert discrete Gaussian representations into continuous attribute maps, facilitating intuitive appearance editing. Furthermore, we propose a universal completion framework to recover non-frontal appearance, culminating in a 360^\circ-renderable 3D head avatar. FATE outperforms previous approaches in both qualitative and quantitative evaluations, achieving state-of-the-art performance. To the best of our knowledge, FATE is the first animatable and 360^\circ full-head monocular reconstruction method for a 3D head avatar. Project page and code are available at this \href https://zjwfufu.github.io/FATE-page/ link .

ChatGen: Automatic Text-to-Image Generation From FreeStyle Chatting

Chengyou Jia, Changliang Xia, Zhuohang Dang, Weijia Wu, Hangwei Qian, Minnan Luo ; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 13284-13293

Despite the significant advancements in text-to-image (T2I) generative models, users often face a trial-and-error challenge in practical scenarios. This challenge arises from the complexity and uncertainty of tedious steps such as crafting suitable prompts, selecting appropriate models, and configuring specific arguments, making users resort to labor-intensive attempts for desired images. This paper proposes Automatic T2I generation, which aims to automate these tedious steps, allowing users to simply describe their needs in a freestyle chatting way. To systematically study this problem, we first introduce ChatGenBench, a novel benchmark designed for Automatic T2I. It features high-quality paired data with diverse freestyle inputs, enabling comprehensive evaluation of automatic T2I models across all steps. Additionally, recognizing Automatic T2I as a complex multi-step reasoning task, we propose ChatGen-Evo, a multi-stage evolution strategy that progressively equips models with essential automation skills. Through extensive evaluation across step-wise accuracy and image quality, ChatGen-Evo significantly enhances performance over various baselines. Our evaluation also uncovers valuable insights for advancing automatic T2I. All our data, code and models will be publicly available.

GEM: A Generalizable Ego-Vision Multimodal World Model for Fine-Grained Ego-Motion, Object Dynamics, and Scene Composition Control

Mariam Hassan, Sebastian Stapf, Ahmad Rahimi, Pedro M B Rezende, Yasaman Haghighi, David Brüggemann, Isinsu Katircioglu, Lin Zhang, Xiaoran Chen, Suman Saha, Marco Cannici, Elie Aljalbout, Botao Ye, Xi Wang, Aram Davtyan, Mathieu Salzmann, Davide Scaramuzza, Marc Pollefeys, Paolo Favaro, Alexandre Alahi; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 22404-22415

We present GEM, a Generalizable Ego-vision Multimodal world model that predicts future frames using a reference frame, sparse features, human poses, and ego-trajectories. Hence, our model has precise control over object dynamics, ego-agent motion and human poses. GEM generates paired RGB and depth outputs for richer spatial understanding. We introduce autoregressive noise schedules to enable stable long-horizon generations. Our dataset is comprised of 4000+ hours of multimodal data across domains like autonomous driving, egocentric human activities, and drone flights. Pseudo-labels are used to get depth maps, ego-trajectories, and human poses. We use a comprehensive evaluation framework, including a new Control of Object Manipulation (COM) metric, to assess controllability. Experiments show GEM excels at generating diverse, controllable scenarios and temporal consistency over long generations. Code, models, and datasets are fully open-sourced.

VEU-Bench: Towards Comprehensive Understanding of Video Editing

Bozheng Li, Yongliang Wu, Yi Lu, Jiashuo Yu, Licheng Tang, Jiawang Cao, Wenqing Zhu, Yuyang Sun, Jay Wu, Wenbo Zhu; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 13671-13680

Widely shared videos on the internet are often edited. Recently, although Video Large Language Models (Vid-LLMs) have made great progress in general video understanding tasks, their capabilities in video editing understanding (VEU) tasks remain unexplored. To address this gap, in this paper, we introduce VEU-Bench (Video Editing Understanding Benchmark), a comprehensive benchmark that categorizes video editing components across various dimensions, from intra-frame features like shot size to inter-shot attributes such as cut types and transitions. Unlike previous video editing understanding benchmarks that focus mainly on editing element classification, VEU-Bench encompasses 19 fine-grained tasks across three stages: recognition, reasoning, and judging. To enhance the annotation of VEU automatically, we built an annotation pipeline integrated with an ontology-based knowledge base. Through extensive experiments with 11 state-of-the-art Vid-LLMs, our findings reveal that current Vid-LLMs face significant challenges in VEU tasks, with some performing worse than random choice. To alleviate this issue, we develop Oscars(Named after the Academy Awards.), a VEU expert model fine-tuned on the curated VEU-Bench dataset. It outperforms existing open-source Vid-LLMs on VEU-Bench by over 28.3% in accuracy and achieves performance comparable to commercial models like GPT-4o. We also demonstrate that incorporating VEU data significantly enhances the performance of Vid-LLMs on general video understanding benchmarks, with an average improvement of 8.3% across nine reasoning tasks. The code and data will be made available.

Decouple Distortion from Perception: Region Adaptive Diffusion for Extreme-low Bitrate Perception Image Compression

Jinchang Xu, Shaokang Wang, Jintao Chen, Zhe Li, Peidong Jia, Fei Zhao, Guoqing Xiang, Zhijian Hao, Shanghang Zhang, Xiaodong Xie; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 18051-18061

Leveraging the generative power of diffusion models, generative image compression has achieved impressive perceptual fidelity even at extremely low bitrates. However, current methods often neglect the non-uniform complexity of images, limiting their ability to balance global perceptual quality with local texture consistency and to allocate coding resources efficiently. To address this, we introduce the Map-guided Masking Realism Image Diffusion Codec(MRIDC), designed to optimize the trade-off between local distortion and global perceptual quality in extreme-low bitrate compression. MRIDC integrates a vector-quantized image encoder with a diffusion-based decoder. On the encoding side, we propose a Map-guided Latent Masking(MLM) module, which selectively masks elements in the latent space based on prior information, allowing adaptive resource allocation aligned with image complexity. On the decoding side, masked latents are completed using the Bidirectional Prediction Controllable Generation(BPCG) module, which guides the constrained generation process within the diffusion model to reconstruct the image. Experimental results show that MRIDC achieves state-of-the-art perceptual compression quality at extremely low bitrates, effectively preserving feature consistency in key regions and advancing the rate-distortion-perception performance curve, establishing new benchmarks in balancing compression efficiency with visual fidelity.

Yo'Chameleon: Personalized Vision and Language Generation

Thao Nguyen, Krishna Kumar Singh, Jing Shi, Trung Bui, Yong Jae Lee, Yuheng Li; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 14438-14448

Large Multimodal Models (e.g., GPT-4, Gemini, Chameleon) have evolved into powerful tools with millions of users. However, they remain generic models and lack personalized knowledge of specific user concepts. Previous work has explored personalization for text generation, yet it remains unclear how these methods can be adapted to new modalities, such as image generation. In this paper, we introduce Yo'Chameleon, the first attempt to study personalization for large multimodal models. Given 3-5 images of a particular concept, Yo'Chameleon leverages soft-prompt tuning to embed subject-specific information to (i) answer questions about the subject and (ii) recreate pixel-level details to produce images of the subje

ct in new contexts. Yo'Chameleon is trained with (i) a self-prompting optimizati on mechanism to balance performance across multiple modalities, and (ii) a "soft -positive" image generation approach to enhance image quality in a few-shot sett ing. Our qualitative and quantitative analyses reveal that Yo'Chameleon can lear n concepts more efficiently using fewer tokens and effectively encode visual att ributes, outperforming prompting baselines.

PatchVSR: Breaking Video Diffusion Resolution Limits with Patch-wise Video Super -Resolution
Shian Du, Menghan Xia, Chang Liu, Xintao Wang, Jing Wang, Pengfei Wan, Di Zhang, Xiangyang Ji; Proceedings of the Computer Vision and Pattern Recognition Confer ence (CVPR), 2025, pp. 17799-17809
Pre-trained video generation models hold great potential for generative video su per-resolution (VSR). However, adapting them for full-size VSR, as most existing methods do, suffers from unnecessary intensive full-attention computation and f ixed output resolution. To overcome these limitations, we make the first explora tion into utilizing video diffusion priors for patch-wise VSR.This is non-trivia l because pre-trained video diffusion models are not native for patch-level deta il generation. To mitigate this challenge, we propose an innovative approach, ca lled PatchVSR, which integrates a dual-stream adapter for conditional guidance. The patch branch extracts features from input patches to maintain content fideli ty while the global branch extracts context features from the resized full video to bridge the generation gap caused byincomplete semantics of patches.Particula rly, we also inject the patch's location information into the model to better co ntextualize patch synthesis within the global video frame.Experiments demonstrat e that our method can synthesize high-fidelity, high-resolution details at the p atch level. A tailor-made multi-patch joint modulation is proposed to ensure vis ual consistency across individually enhanced patches. Due to the flexibility of our patch-based paradigm, we can achieve highly competitive 4K VSR based on a 51 2x512 resolution base model, with extremely high efficiency.

FluxSpace: Disentangled Semantic Editing in Rectified Flow Models
Yusuf Dalva, Kavana Venkatesh, Pinar Yanardag; Proceedings of the Computer Visio n and Pattern Recognition Conference (CVPR), 2025, pp. 13083-13092
Rectified flow models have emerged as a dominant approach in image generation, s howcasing impressive capabilities in high-quality image synthesis. However, desp ite their effectiveness in visual generation, rectified flow models often strugg le with disentangled editing of images. This limitation prevents the ability to perform precise, attribute-specific modifications without affecting unrelated as pects of the image. In this paper, we introduce FluxSpace, a domain-agnostic ima ge editing method leveraging a representation space with the ability to control the semantics of images generated by rectified flow transformers, such as Flux. By leveraging the representations learned by the transformer blocks within the r ectified flow models, we propose a set of semantically interpretable representat ions that enable a wide range of image editing tasks, from fine-grained image ed iting to artistic creation. This work offers a scalable and effective image edit ing approach, along with its disentanglement capabilities.

Scene-Centric Unsupervised Panoptic Segmentation
Oliver Hahn, Christoph Reich, Nikita Araslanov, Daniel Cremers, Christian Ruppre cht, Stefan Roth; Proceedings of the Computer Vision and Pattern Recognition Con ference (CVPR), 2025, pp. 24485-24495
Unsupervised panoptic segmentation aims to partition an image into semantically meaningful regions and distinct object instances without training on manually an notated data. In contrast to prior work on unsupervised panoptic scene understan ding, we eliminate the need for object-centric training data, enabling the unsup ervised understanding of complex scenes. To that end, we present the first unsu pervised panoptic method that directly trains on scene-centric imagery. In parti cular, we propose an approach to obtain high-resolution panoptic pseudo labels o n complex scene-centric data, combining visual representations, depth, and motio

n cues. Utilizing both pseudo-label training and a panoptic self-training strategy yields a novel approach that accurately predicts panoptic segmentation of complex scenes without requiring any human annotations. Our approach significantly improves panoptic quality, e.g., surpassing the recent state of the art in unsupervised panoptic segmentation on Cityscapes by 9.4% points in PQ.

Touch2Shape: Touch-Conditioned 3D Diffusion for Shape Exploration and Reconstruction

Yuanbo Wang, Zhaoxuan Zhang, Jiajin Qiu, Dilong Sun, Zhengyu Meng, Xiaopeng Wei, Xin Yang; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 5656-5665

Diffusion models have made breakthroughs in 3D generation tasks. Current 3D diffusion models focus on reconstructing target shape from images or a set of partial observations. While excelling in global context understanding, they struggle to capture the local details of complex shapes and limited to the occlusion and lighting conditions. To overcome these limitations, we utilize tactile images to capture the local 3D information and propose a Touch2Shape model, which leverages a touch-conditioned diffusion model to explore and reconstruct the target shape from touch. For shape reconstruction, we have developed a touch embedding module to condition the diffusion model in creating a compact representation and a touch shape fusion module to refine the reconstructed shape. For shape exploration, we combine the diffusion model with reinforcement learning to train a policy. This involves using the generated latent vector from the diffusion model to guide the touch exploration policy training through a novel reward design. Experiments validate the reconstruction quality thorough both qualitatively and quantitative analysis, and our touch exploration policy further boosts reconstruction performance.

VITED: Video Temporal Evidence Distillation

Yujie Lu, Yale Song, William Wang, Lorenzo Torresani, Tushar Nagarajan; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 8501-8511

We investigate complex video question answering via chain-of-evidence reasoning --- identifying sequences of temporal spans from multiple relevant parts of the video, together with visual evidence within them.Existing models struggle with multi-step reasoning as they uniformly sample a fixed number of frames, which can miss critical evidence distributed nonuniformly throughout the video. Moreover, they lack the ability to temporally localize such evidence in the broader context of the full video, which is required for answering complex questions. We propose a framework to enhance existing VideoQA datasets with evidence reasoning chains, automatically constructed by searching for optimal intervals of interest in the video with supporting evidence, that maximizes the likelihood of answering a given question.We train our model (ViTED) to generate these evidence chains directly, enabling it to both localize evidence windows as well as perform multi-step reasoning across them in long-form video content.We show the value of our evidence-distilled models on a suite of long video QA benchmarks where we outperform state-of-the-art approaches that lack evidence reasoning capabilities.

Adversarial Domain Prompt Tuning and Generation for Single Domain Generalization

Zhipeng Xu, De Cheng, Xinyang Jiang, Nannan Wang, Dongsheng Li, Xinbo Gao; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 18584-18595

Single domain generalization (SDG) aims to learn a robust model, which could perform well on many unseen domains while there is only one single domain available for training. One of the promising directions for achieving single-domain generalization is to generate out-of-domain (OOD) training data through data augmentation or image generation. Given the rapid advancements in AI-generated content (AIGC), this paper is the first to propose leveraging powerful pre-trained text-to-image (T2I) foundation models to create the training data. However, manually designing textual prompts to generate images for all possible domains is often im

practical, and some domain characteristics may be too abstract to describe with words. To address these challenges, we propose a novel Progressive Adversarial Prompt Tuning (PAPT) framework for pre-trained diffusion models. Instead of relying on static textual domains, our approach learns two sets of abstract prompts as conditions for the diffusion model: one that captures domain-invariant category information and another that models domain-specific styles. This adversarial learning mechanism enables the T2I model to generate images in various domain styles while preserving key categorical features. Extensive experiments demonstrate the effectiveness of the proposed method, achieving superior performances to state-of-the-art single-domain generalization approaches.

Learning Physics From Video: Unsupervised Physical Parameter Estimation for Continuous Dynamical Systems
Alejandro Castañeda Garcia, Jan Warchocki, Jan van Gemert, Daan Brinks, Nergis Tomen; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 27924-27933
Extracting physical dynamical system parameters from recorded observations is key in natural science. Current methods for automatic parameter estimation from video train supervised deep networks on large datasets. Such datasets require labels, which are difficult to acquire. While some unsupervised techniques--which depend on frame prediction--exist, they suffer from long training times, initialization instabilities, only consider motion-based dynamical systems, and are evaluated mainly on synthetic data. In this work, we propose an unsupervised method to estimate the physical parameters of known, continuous governing equations from single videos suitable for different dynamical systems beyond motion and robust to initialization. Moreover, we remove the need for frame prediction by implementing a KL-divergence-based loss function in the latent space, which avoids convergence to trivial solutions and reduces model size and compute. We first evaluate our model on synthetic data, as commonly done. After which, we take the field closer to reality by recording Delfys75: our own real-world dataset of 75 videos for five different types of dynamical systems to evaluate our method and others. Our method compares favorably to others. Code and data are available online: https://github.com/Alejandro-neuro/Learning_physics_from_video.

Temporal Score Analysis for Understanding and Correcting Diffusion Artifacts
Yu Cao, Zengqun Zhao, Ioannis Patras, Shaogang Gong; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 7707-7716
Visual artifacts remain a persistent challenge in diffusion models, even with training on massive datasets. Current solutions primarily rely on supervised detectors, yet lack understanding of why these artifacts occur in the first place. In our analysis, we identify three distinct phases in the diffusion generative process: Profiling, Mutation, and Refinement. Artifacts typically emerge during the Mutation phase, where certain regions exhibit anomalous score dynamics over time, causing abrupt disruptions in the normal evolution pattern. This temporal nature explains why existing methods focusing only on spatial uncertainty of the final output fail at effective artifact localization. Based on these insights, we propose ASCED (Abnormal Score Correction for Enhancing Diffusion), that detects artifacts by monitoring abnormal score dynamics during the diffusion process, with a trajectory-aware on-the-fly mitigation strategy that appropriate generation of noise in the detected areas. Unlike most existing methods that apply post hoc corrections, e.g., by applying a noising-denoising scheme after generation, our mitigation strategy operates seamlessly within the existing diffusion process. Extensive experiments demonstrate that our proposed approach effectively reduces artifacts across diverse domains, matching or surpassing existing supervised methods without additional training.
****

ProAPO: Progressively Automatic Prompt Optimization for Visual Classification
Xiangyan Qu, Gaopeng Gou, Jiamin Zhuang, Jing Yu, Kun Song, Qihao Wang, Yili Li, Gang Xiong; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 25145-25155

Vision-language models (VLMs) have made significant progress in image classification by training with large-scale paired image-text data. Their performances largely depend on the prompt quality. While recent methods show that visual descriptions generated by large language models (LLMs) enhance the generalization of VLMs, class-specific prompts may be inaccurate or lack discrimination due to the hallucination in LLMs. In this paper, we aim to find visually discriminative prompts for fine-grained categories with minimal supervision and no human-in-the-loop. An evolution-based algorithm is proposed to progressively optimize language prompts from task-specific templates to class-specific descriptions. Unlike optimizing templates, the search space shows an explosion in class-specific candidate prompts. This increases prompt generation costs, iterative times, and the overfitting problem. To this end, we first introduce several simple yet effective edit-based and evolution-based operations to generate diverse candidate prompts by one-time query of LLMs. Then, two sampling strategies are proposed to find a better initial search point and reduce traversed categories, saving iteration costs. Moreover, we apply a novel fitness score with entropy constraints to mitigate overfitting. In a challenging one-shot image classification setting, our method outperforms existing textual prompt-based methods and improves LLM-generated description methods across 13 datasets. Meanwhile, we demonstrate that our optimal prompts improve adapter-based methods and transfer effectively across different backbones.

ShapeWords: Guiding Text-to-Image Synthesis with 3D Shape-Aware Prompts

Dmitry Petrov, Pradyumn Goyal, Divyansh Shivashok, Yuanming Tao, Melinos Averkiou, Evangelos Kalogerakis; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 13305-13314

We introduce ShapeWords, an approach for synthesizing images based on 3D shape guidance and text prompts.ShapeWords incorporates target 3D shape information within specialized tokens embedded together with the input text, effectively blending 3D shape awareness with textual context to guide the image synthesis process. Unlike conventional shape guidance methods that rely on depth maps restricted to fixed viewpoints and often overlook full 3D structure or textual context, ShapeWords generates diverse yet consistent images that reflect both the target shape's geometry and the textual description. Experimental results show that ShapeWords produces images that are more text-compliant, aesthetically plausible, while also maintaining 3D shape awareness.

Auto-Encoded Supervision for Perceptual Image Super-Resolution

MinKyu Lee, Sangeek Hyun, Woojin Jun, Jae-Pil Heo; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 17958-17968

This work tackles the fidelity objective in the perceptual super-resolution (SR) task. Specifically, we address the shortcomings of pixel-level $\mathcal L _\text p$ loss ($\mathcal L _\text pix$) in the GAN-based SR framework. Since $\mathcal L _\text pix$ is known to have a trade-off relationship against perceptual quality, prior methods often multiply a small scale factor or utilize low-pass filters. However, this work shows that these circumventions fail to address the fundamental factor that induces blurring. Accordingly, we focus on two points: 1) precisely discriminating the subcomponent of $\mathcal L _\text pix$ that contributes to blurring, and 2) guiding reconstruction only based on the factor that is free from this trade-off relationship. We show that this can be achieved in a surprisingly simple manner, with an Auto-Encoder (AE) pretrained using $\mathcal L _\text pix$. Based on this insight, we propose the Auto-Encoded Supervision for Optimal Penalization loss ($\mathcal L _\text AESOP$), a novel loss function that measures distance in the AE space (the space after the decoder, not the bottleneck), rather than in the raw pixel space. By simply substituting $\mathcal L _\text pix$ with $\mathcal L _\text AESOP$, we can provide effective reconstruction guidance without compromising perceptual quality. Designed for simplicity, our method enables easy integration into existing SR frameworks. Extensive experiments demonstrate the effectiveness of AESOP.

Black Swan: Abductive and Defeasible Video Reasoning in Unpredictable Events
Aditya Chinchure, Sahithya Ravi, Raymond Ng, Vered Shwartz, Boyang Li, Leonid Sigal; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 24201-24210
The commonsense reasoning capabilities of vision-language models (VLMs), especially in abductive reasoning and defeasible reasoning, remain poorly understood. Most benchmarks focus on typical visual scenarios, making it difficult to discern whether model performance stems from keen perception and reasoning skills, or reliance on pure statistical recall. We argue that by focusing on atypical events in videos, clearer insights can be gained on the core capabilities of VLMs. Explaining and understanding such out-of-distribution events requires models to extend beyond basic pattern recognition and regurgitation of their prior knowledge. To this end, we introduce BlackSwanSuite, a benchmark for evaluating VLMs' ability to reason about unexpected events through abductive and defeasible tasks. Our tasks artificially limit the amount of visual information provided to models while questioning them about hidden unexpected events, or provide new visual information that could change an existing hypothesis about the event. We curate a comprehensive benchmark suite comprising over 3,800 MCQ, 4,900 generative and 6,700 yes/no questions, spanning 1,655 videos. After extensively evaluating various state-of-the-art VLMs, including GPT-4o and Gemini 1.5 Pro, as well as open-source VLMs such as LLaVA-Video, we find significant performance gaps of up to 32% from humans on these tasks. Our findings reveal key limitations in current VLMs, emphasizing the need for enhanced model architectures and training strategies. Our data and leaderboard is available at blackswan.cs.ubc.ca.

Go-with-the-Flow: Motion-Controllable Video Diffusion Models Using Real-Time Warped Noise
Ryan Burgert, Yuancheng Xu, Wenqi Xian, Oliver Pilarski, Pascal Clausen, Mingming He, Li Ma, Yitong Deng, Lingxiao Li, Mohsen Mousavi, Michael Ryoo, Paul Debevec, Ning Yu; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 13-23
Generative modeling aims to transform random noise into structured outputs. In this work, we enhance video diffusion models by allowing motion control via structured latent noise sampling. This is achieved by just a change in data: we pre-process training videos to yield structured noise. Consequently, our method is agnostic to diffusion model design, requiring no changes to model architectures or training pipelines. Specifically, we propose a novel noise warping algorithm, fast enough to run in real time, that replaces random temporal Gaussianity with correlated warped noise derived from optical flow fields, while preserving the spatial Gaussianity. The efficiency of our algorithm enables us to fine-tune modern video diffusion base models using warped noise with minimal overhead, and provide a one-stop solution for a wide range of user-friendly motion control: local object motion control, global camera movement control, and motion transfer. The harmonization between temporal coherence and spatial Gaussianity in our warped noise leads to effective motion control while maintaining per-frame pixel quality. Extensive experiments and user studies demonstrate the advantages of our method, making it a robust and scalable approach for controlling motion in video diffusion models. Please see our project webpage: https://eyeline-research.github.io/Go-with-the-Flow/ ; source code and checkpoints are available on GitHub: https://github.com/Eyeline-Research/Go-with-the-Flow
****
Silence is Golden: Leveraging Adversarial Examples to Nullify Audio Control in LDM-based Talking-Head Generation
Yuan Gan, Jiaxu Miao, Yunze Wang, Yi Yang; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 13434-13444
Advances in talking-head animation based on Latent Diffusion Models (LDM) enable the creation of highly realistic, synchronized videos. These fabricated videos are indistinguishable from real ones, increasing the risk of potential misuse for scams, political manipulation, and misinformation. Hence, addressing these ethical concerns has become a pressing issue in AI security. Recent proactive defen

se studies focused on countering LDM-based models by adding perturbations to portraits. However, these methods are ineffective at protecting reference portraits from advanced image-to-video animation. The limitations are twofold: 1) they fail to prevent images from being manipulated by audio signals, and 2) diffusion-based purification techniques can effectively eliminate protective perturbations. To address these challenges, we propose Silencer, a two-stage method designed to proactively protect the privacy of portraits. First, a nullifying loss is proposed to ignore audio control in talking-head generation. Second, we apply anti-purification loss in LDM to optimize the inverted latent feature to generate robust perturbations. Extensive experiments demonstrate the effectiveness of Silencer in proactively protecting portrait privacy. We hope this work will raise awareness among the AI security community regarding critical ethical issues related to talking-head generation techniques. Code: https://github.com/yuangan/Silencer.

Iterative Predictor-Critic Code Decoding for Real-World Image Dehazing

Jiayi Fu, Siyu Liu, Zikun Liu, Chun-Le Guo, Hyunhee Park, Ruiqi Wu, Guoqing Wang, Chongyi Li; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 12700-12709

We propose a novel Iterative Predictor-Critic Code Decoding framework for real-world image dehazing, abbreviated as IPC-Dehaze, which leverages the high-quality codebook prior encapsulated in a pre-trained VQGAN. Apart from previous codebook-based methods that rely on one-shot decoding, our method utilizes high-quality codes obtained in the previous iteration to guide the prediction of the Code-Predictor in the subsequent iteration, improving code prediction accuracy and ensuring stable dehazing performance. Our idea stems from the observations that 1) the degradation of hazy images varies with haze density and scene depth, and 2) clear regions play crucial cues in restoring dense haze regions. However, it is nontrivial to progressively refine the obtained codes in subsequent iterations, owing to the difficulty in determining which codes should be retained or replaced at each iteration. Another key insight of our study is to propose Code-Critic to capture interrelations among codes. The Code-Critic is used to evaluate code correlations and then resample a set of codes with the highest mask scores, i.e., a higher score indicates that the code is more likely to be rejected, which helps retain more accurate codes and predict difficult ones. Extensive experiments demonstrate the superiority of our method over state-of-the-art methods in real-world dehazing. Our code will be made publicly available.

RNG: Relightable Neural Gaussians

Jiahui Fan, Fujun Luan, Jian Yang, Milos Hasan, Beibei Wang; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 26525-26534

3D Gaussian Splatting (3DGS) has shown impressive results for the novel view synthesis task, where lighting is assumed to be fixed. However, creating relightable 3D assets, especially for objects with ill-defined shapes (fur, fabric, etc.), remains a challenging task. The decomposition between light, geometry, and material is ambiguous, especially if either smooth surface assumptions or surface-based analytical shading models do not apply. We propose Relightable Neural Gaussians (RNG), a novel 3DGS-based framework that enables the relighting of objects with both hard surfaces or soft boundaries, while avoiding assumptions on the shading model. We condition the radiance at each point on both view and light directions. We also introduce a shadow cue, as well as a depth refinement network to improve shadow accuracy. Finally, we propose a hybrid forward-deferred fitting strategy to balance geometry and appearance quality. Our method achieves significantly faster training (1.3 hours) and rendering (60 frames per second) compared to a prior method based on neural radiance fields and produces higher-quality shadows than a concurrent 3DGS-based method.

Towards Realistic Example-based Modeling via 3D Gaussian Stitching

Xinyu Gao, Ziyi Yang, Bingchen Gong, Xiaoguang Han, Sipeng Yang, Xiaogang Jin; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 26597-26607

Using parts of existing models to rebuild new models, commonly termed as example-based modeling, is a classical methodology in the realm of computer graphics. Previous works mostly focus on shape composition, making them very hard to use for realistic composition of 3D objects captured from real-world scenes. This leads to combining multiple NeRFs into a single 3D scene to achieve seamless appearance blending. However, the current SeamlessNeRF method struggles to achieve interactive editing and harmonious stitching for real-world scenes due to its gradient-based strategy and grid-based representation. To this end, we present an example-based modeling method that combines multiple Gaussian fields in a point-based representation using sample-guided synthesis. Specifically, as for composition, we create a GUI to segment and transform multiple fields in real time, easily obtaining a semantically meaningful composition of models represented by 3D Gaussian Splatting (3DGS). For texture blending, due to the discrete and irregular nature of 3DGS, straightforwardly applying gradient propagation as SeamlssNeRF is not supported. Thus, a novel sampling-based cloning method is proposed to harmonize the blending while preserving the original rich texture and content. Our workflow consists of three steps: 1) real-time segmentation and transformation of a Gaussian model using a well-tailored GUI, 2) KNN analysis to identify boundary points in the intersecting area between the source and target models, and 3) two-phase optimization of the target model using sampling-based cloning and gradient constraints. Extensive experimental results validate that our approach significantly outperforms previous works in terms of realistic synthesis, demonstrating its practicality.

Filter Images First, Generate Instructions Later: Pre-Instruction Data Selection for Visual Instruction Tuning

Bardia Safaei, Faizan Siddiqui, Jiacong Xu, Vishal M. Patel, Shao-Yuan Lo; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 14247-14256

Visual instruction tuning (VIT) for large vision-language models (LVLMs) requires training on expansive datasets of image-instruction pairs, which can be costly. Recent efforts in VIT data selection aim to select a small subset of high-quality image-instruction pairs, reducing VIT runtime while maintaining performance comparable to full-scale training. However, a major challenge often overlooked is that generating instructions from unlabeled images for VIT is highly expensive. Most existing VIT datasets rely heavily on human annotations or paid services like the GPT API, which limits users with constrained resources from creating VIT datasets for custom applications. To address this, we introduce Pre-Instruction Data Selection (PreSel), a more practical data selection paradigm that directly selects the most beneficial unlabeled images and generates instructions only for the selected images. PreSel first estimates the relative importance of each vision task within VIT datasets to derive task-wise sampling budgets. It then clusters image features within each task, selecting the most representative images with the budget. This approach reduces computational overhead for both instruction generation during VIT data formation and LVLM fine-tuning. By generating instructions for only 15% of the images, PreSel achieves performance comparable to full-data VIT on the LLaVA-1.5 and Vision-Flan datasets. The link to our project page: https://bardisafa.github.io/PreSel

Gradient-Guided Annealing for Domain Generalization

Aristotelis Ballas, Christos Diou; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 20558-20568

Domain Generalization (DG) research has gained considerable traction as of late, since the ability to generalize to unseen data distributions is a requirement that eludes even state-of-the-art training algorithms. In this paper we observe that the initial iterations of model training play a key role in domain generalization effectiveness, since the loss landscape may be significantly different across the training and test distributions, contrary to the case of i.i.d. data. Conflicts between gradients of the loss components of each domain lead the optimization procedure to undesirable local minima that do not capture the domain-invar

iant features of the target classes. We propose alleviating domain conflicts in model optimization, by iteratively annealing the parameters of a model in the ea rly stages of training and searching for points where gradients align between do mains. By discovering a set of parameter values where gradients are updated towa rds the same direction for each data distribution present in the training set, t he proposed Gradient-Guided Annealing (GGA) algorithm encourages models to seek out minima that exhibit improved robustness against domain shifts. The efficacy of GGA is evaluated on five widely accepted and challenging image classification domain generalization benchmarks, where its use alone is able to establish high ly competitive or even state-of-the-art performance. Moreover, when combined wit h previously proposed domain-generalization algorithms it is able to consistentl y improve their effectiveness by significant margins.

Generative Sparse-View Gaussian Splatting

Hanyang Kong, Xingyi Yang, Xinchao Wang; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 26745-26755

Novel view synthesis from limited observations remains a significant challenge d ue to the lack of information in under-sampled regions, often resulting in notic eable artifacts. We introduce Generative Sparse-view Gaussian Splatting (GS-GS), a general pipeline designed to enhance the rendering quality of 3D/4D Gaussian Splatting (GS) when training views are sparse. Our method generates unseen views using generative models, specifically leveraging pre-trained image diffusion mo dels to iteratively refine view consistency and hallucinate additional images at pseudo views. This approach improves 3D/4D scene reconstruction by explicitly e nforcing semantic correspondences during the generation of unseen views, thereby enhancing geometric consistency--unlike purely generative methods that often fa il to maintain view consistency. Extensive evaluations on various 3D/4D datasets --including Blender, LLFF, Mip-NeRF360, and Neural 3D Video--demonstrate that ou r GS-GS outperforms existing state-of-the-art methods in rendering quality witho ut sacrificing efficiency.

MicroVQA: A Multimodal Reasoning Benchmark for Microscopy-Based Scientific Resea rch

James Burgess, Jeffrey J Nirschl, Laura Bravo-Sánchez, Alejandro Lozano, Sanket Rajan Gupte, Jesus G. Galaz-Montoya, Yuhui Zhang, Yuchang Su, Disha Bhowmik, Zac hary Coman, Sarina M Hasan, Alexandra Johannesson, William D. Leineweber, Malvik a G Nair, Ridhi Yarlagadda, Connor Zuraski, Wah Chiu, Sarah Cohen, Jan N. Hansen , Manuel D Leonetti, Chad Liu, Emma Lundberg, Serena Yeung-Levy; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 19552-1 9564

Scientific research demands sophisticated reasoning over multimodal data, a chal lenge especially prevalent in biology. Despite recent advances in multimodal lar ge language models (MLLMs) for AI-assisted research, existing multimodal reasoni ng benchmarks only target up to college-level difficulty, while research-level b enchmarks emphasize lower-level perception, falling short of the complex multimo dal reasoning needed for scientific discovery. To bridge this gap, we introduce MicroVQA, a visual-question answering (VQA) benchmark designed to assess three r easoning capabilities vital in research workflows: expert image understanding, h ypothesis generation, and experiment proposal. MicroVQA consists of 1,042 multip le-choice questions (MCQs) curated by biology experts across diverse microscopy modalities, ensuring VQA samples represent real scientific practice. In construc ting the benchmark, we find that standard MCQ generation methods induce language shortcuts, motivating a new two-stage pipeline: an optimized LLM prompt structu res question-answer pairs into MCQs; then, an agent-based 'RefineBot' updates th em to remove shortcuts. Benchmarking on state-of-the-art MLLMs reveal a peak per formance of 53%; models with smaller LLMs only slightly underperform top models, suggesting that language-based reasoning is less challenging than multimodal re asoning; and tuning with scientific articles enhances performance. Expert analys is of chain-of-thought responses shows that perception errors are the most frequ ent, followed by knowledge errors and then overgeneralization errors. These insi

ghts highlight the challenges in multimodal scientific reasoning, showing MicroVQA is a valuable resource advancing AI-driven biomedical research. MicroVQA is available at https://huggingface.co/datasets/jmhb/microvqa and project at https://jmhb0.github.io/microvqa.

Generative Inbetweening through Frame-wise Conditions-Driven Video Generation

Tianyi Zhu, Dongwei Ren, Qilong Wang, Xiaohe Wu, Wangmeng Zuo; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 27968-27978

Generative inbetweening aims to generate intermediate frame sequences by utilizing two key frames as input. Although remarkable progress has been made in video generation models, generative inbetweening still faces challenges in maintaining temporal stability due to the ambiguous interpolation path between two key frames. This issue becomes particularly severe when there is a large motion gap between input frames. In this paper, we propose a straightforward yet highly effective Frame-wise Conditions-driven Video Generation (FCVG) method that significantly enhances the temporal stability of interpolated video frames. Specifically, our FCVG provides an explicit condition for each frame, making it much easier to identify the interpolation path between two input frames and thus ensuring temporally stable production of visually plausible video frames. To achieve this, we suggest extracting matched lines from two input frames that can then be easily interpolated frame by frame, serving as frame-wise conditions seamlessly integrated into existing video generation models. In extensive evaluations covering diverse scenarios such as natural landscapes, complex human poses, camera movements and animations, existing methods often exhibit incoherent transitions across frames. In contrast, our FCVG demonstrates the capability to generate temporally stable videos using both linear and non-linear interpolation curves. Our project page and code are available at https://fcvg-inbetween.github.io/.

DexGrasp Anything: Towards Universal Robotic Dexterous Grasping with Physics Awareness

Yiming Zhong, Qi Jiang, Jingyi Yu, Yuexin Ma; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 22584-22594

A dexterous hand capable of grasping any object is essential for the development of general-purpose embodied intelligent robots. However, due to the high degree of freedom in dexterous hands and the vast diversity of objects, generating high-quality, usable grasping poses in a robust manner is a significant challenge. In this paper, we introduce DexGrasp Anything, a method that effectively integrates physical constraints into both the training and sampling phases of a diffusion-based generative model, achieving state-of-the-art performance across nearly all open datasets. Additionally, we present a new dexterous grasping dataset containing over 3.4 million diverse grasping poses for more than 15k different objects, demonstrating its potential to advance universal dexterous grasping. The code of our method and our dataset will be publicly released soon.

CustAny: Customizing Anything from A Single Example

Lingjie Kong, Kai Wu, Chengming Xu, Xiaobin Hu, Wenhui Han, Jinlong Peng, Donghao Luo, Mengtian Li, Jiangning Zhang, Chengjie Wang, Yanwei Fu; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 20916-20925

Recent advances in diffusion-based text-to-image models have simplified creating high-fidelity images, but preserving the identity (ID) of specific elements, like a personal dog, is still challenging.Object customization, using reference images and textual descriptions, is key to addressing this issue. Current object customization methods are either object-specific, requiring extensive fine-tuning, or object-agnostic, offering zero-shot customization but limited to specialized domains. The primary issue of promoting zero-shot object customization from specific domains to the general domain is to establish a large-scale general ID dataset for model pre-training, which is time-consuming and labor-intensive. In this paper, we propose a novel pipeline to construct a large dataset of general ob

jects and build the Multi-Category ID-Consistent (MC-IDC) dataset, featuring 315 k text-image samples across 10k categories. With the help of MC-IDC, we introduc e Customizing Anything (CustAny), a zero-shot framework that maintains ID fideli ty and supports flexible text editing for general objects. CustAny features thre e key components: a general ID extraction module, a dual-level ID injection modu le, and an ID-aware decoupling module, allowing it to customize any object from a single reference image and text prompt. Experiments demonstrate that CustAny o utperforms existing methods in both general object customization and specialized domains like human customization and virtual try-on. Our contributions include a large-scale dataset, the CustAny framework and novel ID processing to advance this field. The official project page is in https://lingjiekong-fdu.github.io.

Vision-Language Gradient Descent-driven All-in-One Deep Unfolding Networks
Haijin Zeng, Xiangming Wang, Yongyong Chen, Jingyong Su, Jie Liu; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 7524-7533
Dynamic image degradations, including noise, blur and lighting inconsistencies, pose significant challenges in image restoration, often due to sensor limitation s or adverse environmental conditions. Existing Deep Unfolding Networks (DUNs) o ffer stable restoration performance but require manual selection of degradation matrices for each degradation type, limiting their adaptability across diverse s cenarios.To address this issue, we propose the Vision-Language-guided Unfolding Network (VLU-Net), a unified DUN framework for handling multiple degradation typ es simultaneously.VLU-Net leverages a Vision-Language Model (VLM) refined on deg raded image-text pairs to align image features with degradation descriptions, se lecting the appropriate transform for target degradation.By integrating an autom atic VLM-based gradient estimation strategy into the Proximal Gradient Descent (PGD) algorithm, VLU-Net effectively tackles complex multi-degradation restoratio n tasks while maintaining interpretability. Furthermore, we design a hierarchica l feature unfolding structure to enhance VLU-Net framework, efficiently synthesi zing degradation patterns across various levels.VLU-Net is the first all-in-one DUN framework and outperforms current leading one-by-one and all-in-one end-to-e nd methods by 3.74 dB on the SOTS dehazing dataset and 1.70 dB on the Rain100L d eraining dataset.

3D-LLaVA: Towards Generalist 3D LMMs with Omni Superpoint Transformer
Jiajun Deng, Tianyu He, Li Jiang, Tianyu Wang, Feras Dayoub, Ian Reid; Proceedin gs of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 3 772-3782
Current 3D Large Multimodal Models (3D LMMs) have shown tremendous potential in 3D-vision-based dialogue and reasoning. However, how to further enhance 3D LMMs to achieve fine-grained scene understanding and facilitate flexible human-agent interaction remains a challenging problem. In this work, we introduce 3D-LLaVA, a simple yet highly powerful 3D LMM designed to act as an intelligent assistant in comprehending, reasoning, and interacting with the 3D world. Unlike existing top-performing methods that rely on complicated pipelines--such as offline multi -view feature extraction or additional task-specific heads--3D-LLaVA adopts a mi nimalist design with integrated architecture and only takes point clouds as inpu t. At the core of 3D-LLaVA is a new Omni Superpoint Transformer (OST), which int egrates three functionalities: (1) a visual feature selector that converts and s elects visual tokens, (2) a visual prompt encoder that embeds interactive visual prompts into the visual token space, and (3) a referring mask decoder that prod uces 3D masks based on text description. This versatile OST is empowered by the hybrid pretraining to obtain perception priors and leveraged as the visual conne ctor that bridges the 3D data to the LLM. After performing unified instruction t uning, our 3D-LLaVA reports impressive results on various benchmarks. The code a nd model will be released at https://github.com/djiajunustc/3D-LLaVA.

Event-based Video Super-Resolution via State Space Models
Zeyu Xiao, Xinchao Wang; Proceedings of the Computer Vision and Pattern Recognit

ion Conference (CVPR), 2025, pp. 12564-12574
Exploiting temporal correlations is crucial for video super-resolution (VSR). Recent approaches enhance this by incorporating event cameras. In this paper, we introduce MamEVSR, a Mamba-based network for event-based VSR that leverages the selective state space model, Mamba. MamEVSR stands out by offering global receptive field coverage with linear computational complexity, thus addressing the limitations of convolutional neural networks and Transformers. The key components of MamEVSR include: (1) The interleaved Mamba (iMamba) block, which interleaves tokens from adjacent frames and applies multidirectional selective state space modeling, enabling efficient feature fusion and propagation across bi-directional frames while maintaining linear complexity. (2) The crossmodality Mamba (cMamba) block facilitates further interaction and aggregation between event information and the output from the iMamba block. The cMamba block can leverage complementary spatio-temporal information from both modalities and allows MamEVSR to capture finermotion details. Experimental results show that the proposed MamEVSR achieves superior performance on various datasets quantitatively and qualitatively.

PoseTraj: Pose-Aware Trajectory Control in Video Diffusion
Longbin Ji, Lei Zhong, Pengfei Wei, Changjian Li; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 22776-22785
Recent advancements in trajectory-guided video generation have achieved notable progress. However, existing models still face challenges in generating object motions with potentially changing 6D poses under wide-range rotations, due to limited 3D understanding. To address this problem, we introduce PoseTraj, a pose-aware video dragging model for generating 3D-aligned motion from 2D trajectories. Our method adopts a novel two-stage pose-aware pretraining framework, improving 3D understanding across diverse trajectories. Specifically, we propose a large-scale synthetic dataset PoseTraj-10k, containing 10k videos of objects following rotational trajectories, and enhance the model perception of object pose changes by incorporating 3D bounding boxes as intermediate supervision signals. Following this, we fine-tune the trajectory-controlling module on real-world videos, applying an additional camera-disentanglement module to further refine motion accuracy. Experiments on various benchmark datasets demonstrate that our method not only excels in 3D pose-aligned dragging for rotational trajectories but also outperforms existing baselines in trajectory accuracy and video quality.

Masked Scene Modeling: Narrowing the Gap Between Supervised and Self-Supervised Learning in 3D Scene Understanding
Pedro Hermosilla, Christian Stippel, Leon Sick; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 14835-14844
Self-supervised learning has transformed 2D computer vision by enabling models trained on large, unannotated datasets to provide versatile off-the-shelf features that perform similarly to models trained with labels. However, in 3D scene understanding, self-supervised methods are typically only used as a weight initialization step for task-specific fine-tuning, limiting their utility for general-purpose feature extraction. This paper aims to address this shortcoming by proposing a robust evaluation protocol specifically designed to assess the quality of self-supervised features for 3D scene understanding. Our protocol uses multi-resolution feature sampling of hierarchical models to create rich point-level representations that capture the semantic capabilities of the model and, hence, are suitable for evaluation with linear probing and nearest-neighbor methods. Furthermore, we introduce the first self-supervised model that performs similarly to supervised models when only off-the-shelf features are used in a linear probing setup. In particular, our model is trained natively in 3D with a novel self-supervised approach based on a Masked Scene Modeling objective, which reconstructs deep features of masked patches in a bottom-up manner and is specifically tailored to hierarchical 3D models. Our experiments not only demonstrate that our method achieves competitive performance to supervised models, but also surpasses existing self-supervised approaches by a large margin.

VL2Lite: Task-Specific Knowledge Distillation from Large Vision-Language Models to Lightweight Networks
Jinseong Jang, Chunfei Ma, Byeongwon Lee; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 30073-30083
Deploying high-performing neural networks in resource-constrained environments poses a significant challenge due to the computational demands of large-scale models. We introduce VL2Lite, a knowledge distillation framework designed to enhance the performance of lightweight neural networks in image classification tasks by leveraging the rich representational knowledge from Vision-Language Models (VLMs). VL2Lite directly integrates multi-modal knowledge from VLMs into compact models during training, effectively compensating for the limited computational and modeling capabilities of smaller networks. By transferring high-level features and complex data representations, our approach improves the accuracy and efficiency of image classification tasks without increasing computational overhead during inference. Experimental evaluations demonstrate that VL2Lite achieves up to a 7% improvement in classification performance across various datasets. This method addresses the challenge of deploying accurate models in environments with constrained computational resources, offering a balanced solution between model complexity and operational efficiency.

Boost the Inference with Co-training: A Depth-guided Mutual Learning Framework for Semi-supervised Medical Polyp Segmentation
Yuxin Li, Zihao Zhu, Yuxiang Zhang, Yifan Chen, Zhibin Yu; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 10394-10403
Semi-supervised polyp segmentation has made significant progress in recent years as a potential solution for computer-assisted treatment. Since depth images can provide extra information other than RGB images to help segment these problematic areas, depth-assisted polyp segmentation has gained much attention. However, the utilization of depth information is still worth studying. The existing RGB-D segmentation methods rely on depth data in the inference stage, limiting their clinical applications. To tackle this problem, we propose a semi-supervised polyp segmentation framework based on the mean teacher architecture. We establish an auxiliary student network with depth images as input in the training stage, and we propose a depth-guided cross-modal mutual learning strategy to promote the learning of complementary information between different student networks. Meanwhile, we use the high-confidence pseudo-labels generated by the auxiliary student network to guide the learning progress of the main student network from different perspectives. Our model does not need depth data in the inference phase. In addition, we introduce a depth-guided patch augmentation method to improve the model's learning performance in difficult regions of unlabeled polyp images. Experimental results show that our method achieves state-of-the-art performance under different label conditions on five polyp datasets. The code is available at https://github.com/pingchuan/RD-Net.

VidHalluc: Evaluating Temporal Hallucinations in Multimodal Large Language Models for Video Understanding
Chaoyu Li, Eun Woo Im, Pooyan Fazli; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 13723-13733
Multimodal large language models (MLLMs) have recently shown significant advancements in video understanding, excelling in content reasoning and instruction-following tasks. However, hallucination, where models generate inaccurate or misleading content, remains underexplored in the video domain. Building on the observation that MLLM visual encoders often fail to distinguish visually different yet semantically similar video pairs, we introduce VidHalluc, the largest benchmark designed to examine hallucinations in MLLMs for video understanding. It consists of 5,002 videos, paired to highlight cases prone to hallucinations. VidHalluc assesses hallucinations across three critical dimensions: (1) action, (2) temporal sequence, and (3) scene transition. Comprehensive testing shows that most MLLMs are vulnerable to hallucinations across these dimensions. Furthermore, we propose DINO-HEAL, a training-free method that reduces hallucinations by incorporati

ng spatial saliency from DINOv2 to reweight visual features during inference. Our results show that DINO-HEAL consistently improves performance on VidHalluc, achieving an average improvement of 3.02% in mitigating hallucinations across all tasks. Both the VidHalluc benchmark and DINO-HEAL code are available at https://people-robots.github.io/vidhalluc.

StageDesigner: Artistic Stage Generation for Scenography via Theater Scripts
Zhaoxing Gan, Mengtian Li, Ruhua Chen, Zhongxia Ji, Sichen Guo, Huanling Hu, Guangnan Ye, Zuo Hu; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 28705-28714
In this work, we introduce StageDesigner, the first comprehensive framework for artistic stage generation using large language models combined with layout-controlled diffusion models. Given the professional requirements of stage scenography, StageDesigner simulates the workflows of seasoned artists to generate immersive 3D stage scenes. Specifically, our approach is divided into three primary modules: Script Analysis, which extracts thematic and spatial cues from input scripts; Foreground Generation, which constructs and arranges essential 3D objects; and Background Generation, which produces a harmonious background aligned with the narrative atmosphere and maintains spatial coherence by managing occlusions between foreground and background elements. Furthermore, we introduce the StagePro-V1 dataset, a dedicated dataset with 276 unique stage scenes spanning different historical styles and annotated with scripts, images, and detailed 3D layouts, specifically tailored for this task. Finally, evaluations using both standard and newly proposed metrics, along with extensive user studies, demonstrate the effectiveness of StageDesigner, showcasing its ability to produce visually and thematically cohesive stages that meet both artistic and spatial coherence standards. Project can be found at: https://deadsmither5.github.io/2025/01/03/StageDesigner/

From Laboratory to Real World: A New Benchmark Towards Privacy-Preserved Visible-Infrared Person Re-Identification
Yan Jiang, Hao Yu, Xu Cheng, Haoyu Chen, Zhaodong Sun, Guoying Zhao; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 8828-8837
Aiming to match pedestrian images captured under varying lighting conditions, visible-infrared person re-identification (VI-ReID) has drawn intensive research attention and achieved promising results. However, in real-world surveillance contexts, data is distributed across multiple devices/entities, raising privacy and ownership concerns that make existing centralized training impractical for VI-ReID. To tackle these challenges, we propose L2RW, a benchmark that brings VI-ReID closer to real-world applications. The rationale of L2RW is that integrating decentralized training into VI-ReID can address privacy concerns in scenarios with limited data-sharing regulation. Specifically, we design protocols and corresponding algorithms for different privacy sensitivity levels. In our new benchmark, we ensure the model training is done in the conditions that: 1) data from each camera remains completely isolated, or 2) different data entities (e.g., data controllers of a certain region) can selectively share the data. In this way, we simulate scenarios with strict privacy constraints which is closer to real-world conditions. Intensive experiments with various server-side federated algorithms are conducted, showing the feasibility of decentralized VI-ReID training. Notably, when evaluated in unseen domains (i.e., new data entities), our L2RW, trained with isolated data (privacy-preserved), achieves performance comparable to SOTAs trained with shared data (privacy-unrestricted). We hope this work offers a novel research entry for deploying VI-ReID that fits real-world scenarios and can benefit the community.
****

4Deform: Neural Surface Deformation for Robust Shape Interpolation
Lu Sang, Zehranaz Canfes, Dongliang Cao, Riccardo Marin, Florian Bernard, Daniel Cremers; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 6542-6551

Generating realistic intermediate shapes between non-rigidly deformed shapes is a challenging task in computer vision, especially with unstructured data (e.g., point clouds) where temporal consistency across frames is lacking, and topologies are changing. Most interpolation methods are designed for structured data (i.e., meshes) and do not apply to real-world point clouds. In contrast, our approach leverages neural implicit representation (NIR) to enable free-topology changing shape deformation. Unlike previous mesh-based methods, which model learns vertex-based deformation fields, our method learns a continuous velocity field in Euclidean space, making it suitable for less structured data such as point clouds. Additionally, our method does not require intermediate-shape supervision during training; instead, we incorporate physical and geometrical constraints to regularize the velocity field. We reconstruct intermediate surfaces using a modified level-set equation, directly linking our NIR with the velocity field. Experiments show that our method significantly outperforms previous NIR approaches across various scenarios (e.g., noisy, partial, topology-changing, non-isometric shapes) and, for the first time, enables new applications like 4D Kinect sequence upsampling and real-world high-resolution mesh deformation.

Dense Match Summarization for Faster Two-view Estimation

Jonathan Astermark, Anders Heyden, Viktor Larsson; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 1093-1102

In this paper, we speed up robust two-view relative pose from dense correspondences. Previous work has shown that dense matchers can significantly improve both accuracy and robustness in the resulting pose. However, the large number of matches comes with a significantly increased runtime during robust estimation in RANSAC. To avoid this, we propose an efficient match summarization scheme which provides comparable accuracy to using the full set of dense matches, while having 10-100x faster runtime. We validate our approach on standard benchmark datasets together with multiple state-of-the-art dense matchers.

****

Align-A-Video: Deterministic Reward Tuning of Image Diffusion Models for Consistent Video Editing

Shengzhi Wang, Yingkang Zhong, Jiangchuan Mu, Kai Wu, Mingliang Xiong, Wen Fang, Mingqing Liu, Hao Deng, Bin He, Gang Li, Qingwen Liu; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 2074-2083

Due to control limitations in the denoising process and the lack of training, zero-shot video editing methods often struggle to meet user instructions, resulting in generated videos that are visually unappealing and fail to fully satisfy expectations. To address this problem, we propose Align-A-Video, a video editing pipeline that incorporates human feedback through reward fine-tuning. Our approach consists of two key steps: 1) Deterministic Reward Fine-tuning. To reduce optimization costs for expected noise distributions, we propose a deterministic reward tuning strategy. This method improves tuning stability by increasing sample determinism, allowing the tuning process to be completed in minutes; 2) Feature Propagation Across Frames. We optimize a selected anchor frame and propagate its features to the remaining frames, improving both visual quality and semantic fidelity. This approach avoids temporal consistency degradation from reward optimization. Extensive qualitative and quantitative experiments confirm the effectiveness of using reward fine-tuning in Align-A-Video, significantly improving the overall quality of generated videos.

****

Interpreting Object-level Foundation Models via Visual Precision Search

Ruoyu Chen, Siyuan Liang, Jingzhi Li, Shiming Liu, Maosen Li, Zhen Huang, Hua Zhang, Xiaochun Cao; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 30042-30052

Advances in multimodal pre-training have propelled object-level foundation models, such as Grounding DINO and Florence-2, in tasks like visual grounding and object detection. However, interpreting these models' decisions has grown increasingly challenging. Existing interpretable attribution methods for object-level task interpretation have notable limitations: (1) gradient-based methods lack preci

se localization due to visual-textual fusion in foundation models, and (2) pertu rbation-based methods produce noisy saliency maps, limiting fine-grained interpr etability. To address these, we propose a Visual Precision Search method that ge nerates accurate attribution maps with fewer regions. Our method bypasses intern al model parameters to overcome attribution issues from multimodal fusion, divid ing inputs into sparse sub-regions and using consistency and collaboration score s to accurately identify critical decision-making regions. We also conducted a t heoretical analysis of the boundary guarantees and scope of applicability of our method. Experiments on RefCOCO, MS COCO, and LVIS show our approach enhances ob ject-level task interpretability over SOTA for Grounding DINO and Florence-2 acr oss various evaluation metrics, with faithfulness gains of 23.7%, 31.6%, and 20. 1% on MS COCO, LVIS, and RefCOCO for Grounding DINO, and 50.7% and 66.9% on MS C OCO and RefCOCO for Florence-2. Additionally, our method can interpret failures in visual grounding and object detection tasks, surpassing existing methods acro ss multiple evaluation metrics. The code is released at https://github.com/Ruoyu Chen10/VPS.

Foley-Flow: Coordinated Video-to-Audio Generation with Masked Audio-Visual Align ment and Dynamic Conditional Flows

Shentong Mo, Yibing Song; Proceedings of the Computer Vision and Pattern Recogni tion Conference (CVPR), 2025, pp. 28912-28921

Coordinated audio generation based on video inputs typically requires a strict a udio-visual (AV) alignment, where both semantics and rhythmics of the generated audio segments shall correspond to those in the video frames. Previous studies l everage a two-stage design where the AV encoders are firstly aligned via contras tive learning, then the encoded video representations guide the audio generation process. We observe that both contrastive learning and global video guidance ar e effective in aligning overall AV semantics while limiting temporally rhythmic synchronization. In this work, we propose Foley-Flow to first align unimodal AV encoders via masked modeling training, where the masked audio segments are recov ered under the guidance of the corresponding video segments. After training, the AV encoders which are separately pretrained using only unimodal data are aligne d with semantic and rhythmic consistency. Then, we develop a dynamic conditional flow for the final audio generation. Built upon the efficient velocity flow gen eration framework, our dynamic conditional flow utilizes temporally varying vide o features as the dynamic condition to guide corresponding audio segment generat ions. To this end, we extract coherent semantic and rhythmic representations dur ing masked AV alignment, and use this representation of video segments to guide audio generation temporally. Our audio results are evaluated on the standard ben chmarks and largely surpass existing results under several metrics. The superior performance indicates that Foley-Flow is effective in generating coordinated au dios that are both semantically and rhythmically coherent to various video seque nces.

LION-FS: Fast & Slow Video-Language Thinker as Online Video Assistant

Wei Li, Bing Hu, Rui Shao, Leyang Shen, Liqiang Nie; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 3240-3251

First-person video assistants are highly anticipated to enhance our daily life t hrough online video dialogue. However, existing online video assistants often sa crifice assistant efficacy for real-time efficiency by processing low-frame-rate videos with coarse-grained visual features. To overcome the trade-off between e fficacy and efficiency, we propose "**F**ast & **S**low Video-Language Thinker" as on**LI**ne vide**O** assista**N**t, **LION-FS**, achieving real-time, proacti ve, temporally accurate, and contextually precise responses. LION-FS adopts a tw o-stage optimization strategy: **1) Fast Path: Routing-Based Response Determinat ion** evaluates frame-by-frame whether a immediate response is necessary. To enh ance responses determination accuracy and handle higher frame-rate inputs effici ently, we employ Token Aggregation Routing to dynamically fuse spatiotemporal fe atures without increasing token numbers, while utilizing Token Dropping Routing to eliminate redundant features, and **2) Slow Path: Multi-granularity Keyframe

Augmentation** optimizes keyframes during response generation. To provide comprehensive and detailed responses beyond atomic actions constrained by training data, fine-grained spatial features and human-environment interaction features are extracted through multi-granular pooling. They are further integrated into a meticulously designed multimodal Thinking Template to guide more precise response generation. Comprehensive evaluations on online video tasks demonstrate that LION-FS achieves state-of-the-art efficacy and efficiency. The codes will be released soon.

CARE Transformer: Mobile-Friendly Linear Visual Transformer via Decoupled Dual Interaction

Yuan Zhou, Qingshan Xu, Jiequan Cui, Junbao Zhou, Jing Zhang, Richang Hong, Hanwang Zhang; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 20135-20145

Recently, large efforts have been made to design efficient linear-complexity visual Transformers. However, current linear attention models are generally unsuitable to be deployed in resource-constrained mobile devices, due to suffering from either few efficiency gains or significant accuracy drops. In this paper, we propose a new deCoupled duAl-interactive lineaR attEntion (CARE) mechanism, revealing that features' decoupling and interaction can fully unleash the power of linear attention. We first propose an asymmetrical feature decoupling strategy that asymmetrically decouples the learning process for local inductive bias and long-range dependencies, thereby preserving sufficient local and global information while effectively enhancing the efficiency of models. Then, a dynamic memory unit is employed to maintain critical information along the network pipeline. Moreover, we design a dual interaction module to effectively facilitate interaction between local inductive bias and long-range information as well as among features at different layers. By adopting a decoupled learning way and fully exploiting complementarity across features, our method can achieve both high efficiency and accuracy. Extensive experiments on ImageNet-1K, COCO, and ADE20K datasets demonstrate the effectiveness of our approach, e.g., achieving 78.4/82.1% top-1 accuracy on ImagegNet-1K at the cost of only 0.7/1.9 GMACs. Codes will be released on github.

Paint by Inpaint: Learning to Add Image Objects by Removing Them First

Navve Wasserman, Noam Rotstein, Roy Ganz, Ron Kimmel; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 18313-18324

Image editing has advanced significantly with the introduction of text-conditioned diffusion models. Despite this progress, seamlessly adding objects to images based on textual instructions without requiring user-provided input masks remains a challenge. We address this by leveraging the insight that removing objects (Inpaint) is significantly simpler than its inverse process of adding them (Paint), attributed to inpainting models that benefit from segmentation mask guidance. Capitalizing on this realization, by implementing an automated and extensive pipeline, we curate a filtered large-scale image dataset containing pairs of images and their corresponding object-removed versions. Using these pairs, we train a diffusion model to inverse the inpainting process, effectively adding objects into images. Unlike other editing datasets, ours features natural target images instead of synthetic ones while ensuring source-target consistency by construction. Additionally, we utilize a large Vision-Language Model to provide detailed descriptions of the removed objects and a Large Language Model to convert these descriptions into diverse, natural-language instructions. Our quantitative and qualitative results show that the trained model surpasses existing models in both object addition and general editing tasks. Visit our project page for the released dataset and trained models: https://rotsteinnoam.github.io/Paint-by-Inpaint/.

Motion-Grounded Video Reasoning: Understanding and Perceiving Motion at Pixel Level

Andong Deng, Tongjia Chen, Shoubin Yu, Taojiannan Yang, Lincoln Spencer, Yapeng Tian, Ajmal Saeed Mian, Mohit Bansal, Chen Chen; Proceedings of the Computer Vis

ion and Pattern Recognition Conference (CVPR), 2025, pp. 8625-8636
In this paper, we introduce Motion-Grounded Video Reasoning, a new motionunderstanding task that requires generating visual answers (video segmentationmasks) according to the input question, and hence needs implicit spatiotemporalreasoning and grounding. This task extends existing spatiotemporal groundingwork focusing on explicit action/motion grounding, to a more general format byenabling implicit reasoning via questions. To facilitate the development of the newtask, we collect a large-scale dataset called GROUNDMORE, which comprises1,715 video clips, 249K object masks that are deliberately designed with 4 questiontypes (Causal, Sequential, Counterfactual, and Descriptive) for benchmarkingdeep and comprehensive motion reasoning abilities. GROUNDMORE uniquelyrequires models to generate visual answers, providing a more concrete and visuallyinterpretable response than plain texts. It evaluates models on both spatiotemporalgrounding and reasoning, fostering to address complex challenges in motion-relatedvideo reasoning, temporal perception, and pixel-level understanding. Furthermore,we introduce a novel baseline model named Motion-Grounded Video ReasoningAssistant (MORA). MORA incorporates the multimodal reasoning ability from theMultimodal LLM, the pixel-level perception capability from the grounding model(SAM), and the temporal perception ability from a lightweight localization head.MORA achieves respectable performance on GROUNDMORE outperforming thebest existing visual grounding baseline model by an average of 21.5% relatively.We hope this novel and challenging task will pave the way for future advancementsin robust and general motion understanding via video reasoning segmentation.

PMA: Towards Parameter-Efficient Point Cloud Understanding via Point Mamba Adapter
Yaohua Zha, Yanzi Wang, Hang Guo, Jinpeng Wang, Tao Dai, Bin Chen, Zhihao Ouyang, Xue Yuerong, Ke Chen, Shu-Tao Xia; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 16976-16986
Applying pre-trained models to assist point cloud understanding has recently become a mainstream paradigm in 3D perception. However, existing application strategies are straightforward, utilizing only the final output of the pre-trained model for various task heads. It neglects the rich complementary information in the intermediate layer, thereby failing to fully unlock the potential of pre-trained models. To overcome this limitation, we propose an orthogonal solution: Point Mamba Adapter (PMA), which constructs an ordered feature sequence from all layers of the pre-trained model and leverages Mamba to fuse all complementary semantics, thereby promoting comprehensive point cloud understanding. Constructing this ordered sequence is non-trivial due to the inherent isotropy of 3D space. Therefore, we further propose a geometry-constrained gate prompt generator (G2PG) shared across different layers, which applies shared geometric constraints to the output gates of the Mamba and dynamically optimizes the spatial order, thus enabling more effective integration of multi-layer information. Extensive experiments conducted on challenging point cloud datasets across various tasks demonstrate that our PMA elevates the capability for point cloud understanding to a new level by fusing diverse complementary intermediate features. Code is available at https://github.com/zyh16143998882/PMA.

All-directional Disparity Estimation for Real-world QPD Images
Hongtao Yu, Shaohui Song, Lihu Sun, Wenkai Su, Xiaodong Yang, Chengming Liu; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 21836-21846
Quad Photodiode (QPD) sensors represent an evolution by providing four sub-views, whereas dual-pixel (DP) sensors are limited to two sub-views. In addition to enhancing auto-focus performance, QPD sensors also enable disparity estimation in horizontal and vertical directions. However, the characteristics of QPD sensors, including uneven illumination across sub-views and the narrow baseline, render algorithm design difficult. Furthermore, effectively utilizing the two-directional disparity of QPD sensors remains a challenge. The scarcity of QPD disparity datasets also limits the development of learning-based methods. In this work, we

address these challenges by first proposing a DPNet for DP disparity estimation. Specifically, we design an illumination-invariant module to reduce the impact of illumination, followed by a coarse-to-fine module to estimate sub-pixel disparity. Building upon the DPNet, we further propose a QuadNet, which integrates the two-directional disparity via an edge-aware fusion module. To facilitate the evaluation of our approaches, we propose the first QPD disparity dataset QPD2K, comprising 2,100 real-world QPD images and corresponding disparity maps. Experiments demonstrate that our approaches achieve state-of-the-art performance in DP and QPD disparity estimation.

LC-Mamba: Local and Continuous Mamba with Shifted Windows for Frame Interpolation

Min Wu Jeong, Chae Eun Rhee; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 17671-17681

In this paper, we propose LC-Mamba, a Mamba-based model that captures fine-grained spatiotemporal information in video frames, addressing limitations in current interpolation methods and enhancing performance. The main contributions are as follows: First, we apply a shifted local window technique to reduce historical decay and enhance local spatial features, allowing multiscale capture of detailed motion between frames. Second, we introduce a Hilbert curve-based selective state scan to maintain continuity across window boundaries, preserving spatial correlations both within and between windows. Third, we extend the Hilbert curve to enable voxel-level scanning to effectively capture spatiotemporal characteristics between frames. The proposed LC-Mamba achieves competitive results, with a PSNR of 36.53 dB on Vimeo-90k, outperforming prior models by +0.03 dB. The code and models are publicly available at https://github.com/Miinuuu/LC-Mamba.git

Zero-Shot Head Swapping in Real-World Scenarios

Taewoong Kang, Sohyun Jeong, Hyojin Jang, Jaegul Choo; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 10805-10814

With growing demand in media and social networks for personalized images, the need for advanced head-swapping techniques--integrating an entire head from the head image with the body from the body image--has increased. However, traditional head-swapping methods heavily rely on face-centered cropped data with primarily frontal-facing views, which limits their effectiveness in real-world applications. Additionally, their masking methods, designed to indicate regions requiring editing, are optimized for these types of dataset but struggle to achieve seamless blending in complex situations, such as when the original data includes features like long hair extending beyond the masked area. To overcome these limitations and enhance adaptability in diverse and complex scenarios, we propose a novel head swapping method, HID, that is robust to images including the full head and the upper body, and handles from frontal to side views, while automatically generating context-aware masks. For automatic mask generation, we introduce the IOMask, which enables seamless blending of the head and body, effectively addressing integration challenges. We further introduce the hair injection module to capture hair details with greater precision. Our experiments demonstrate that the proposed approach achieves state-of-the-art performance in head swapping, providing visually consistent and realistic results across a wide range of challenging conditions.

Toward Robust Neural Reconstruction from Sparse Point Sets

Amine Ouasfi, Shubhendu Jena, Eric Marchand, Adnane Boukhayma; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 6552-6562

We consider the challenging problem of learning Signed Distance Functions (SDF) from sparse and noisy 3D point clouds. In contrast to recent methods that depend on smoothness priors, our method, rooted in a distributionally robust optimization (DRO) framework, incorporates a regularization term that leverages samples from the uncertainty regions of the model to improve the learned SDFs. Thanks to tractable dual formulations, we show that this framework enables a stable and efficient optimization of SDFs in the absence of ground truth supervision. Using

a variety of synthetic and real data evaluations from different modalities, we s
how that of our DRO based learning framework can improve SDF learning with res
pect to baselines and the state-of-the-art.

GPAvatar: High-fidelity Head Avatars by Learning Efficient Gaussian Projections
Wei-Qi Feng, Dong Han, Ze-Kang Zhou, Shunkai Li, Xiaoqiang Liu, Pengfei Wan, Di
Zhang, Miao Wang; Proceedings of the Computer Vision and Pattern Recognition Con
ference (CVPR), 2025, pp. 250-259
Existing radiance field-based head avatar methods have mostly relied on pre-comp
uted explicit priors (e.g., mesh, point) or neural implicit representations, mak
ing it challenging to achieve high fidelity with both computational efficiency a
nd low memory consumption. To overcome this, we present GPAvatar, a novel and ef
ficient Gaussian splatting-based method for reconstructing high-fidelity dynamic
 3D head avatars from monocular videos. We extend Gaussians in 3D space to a hig
h-dimensional embedding space encompassing Gaussian's spatial position and avata
r expression, enabling the representation of the head avatar with arbitrary pose
 and expression. To enable splatting-based rasterization, a linear transformatio
n is learned to project each high-dimensional Gaussian back to the 3D space, whi
ch is sufficient to capture expression variations instead of using complex neura
l networks. Furthermore, we propose an adaptive densification strategy that dyna
mically allocates Gaussians to regions with high expression variance, improving
the facial detail representation. Experimental results on three datasets show t
hat our method outperforms existing state-of-the-art methods in rendering qualit
y and speed while reducing memory usage in training and rendering.

PIAD: Pose and Illumination agnostic Anomaly Detection
Kaichen Yang, Junjie Cao, Zeyu Bai, Zhixun Su, Andrea Tagliasacchi; Proceedings
of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 4734
-4743
We introduce the Pose and Illumination agnostic Anomaly Detection (PIAD) problem
, a generalization of pose-agnostic anomaly detection (PAD). Being illumination
agnostic is critical, as it relaxes the assumption that training data for an obj
ect has to be acquired in the same light configuration of the query images that
we want to test. Moreover, even if the object is placed within the same capture
environment, being illumination agnostic implies that we can relax the assumptio
n that the relative pose between environment light and query object has to match
 the one in the training data. We introduce a new dataset to study this problem,
 containing both synthetic and real-world examples, propose a new baseline for P
IAD, and demonstrate how our baseline provides state-of-the-art results in both
PAD and PIAD, not only in the new proposed dataset, but also in existing dataset
s that were designed for the simpler PAD problem. Project page: https://kaichen-
yang.github.io/piad/.

CAV-MAE Sync: Improving Contrastive Audio-Visual Mask Autoencoders via Fine-Grai
ned Alignment
Edson Araujo, Andrew Rouditchenko, Yuan Gong, Saurabhchand Bhati, Samuel Thomas,
 Brian Kingsbury, Leonid Karlinsky, Rogerio Feris, James R. Glass, Hilde Kuehne;
 Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2
025, pp. 18794-18803
Recent advances in audio-visual learning have shown promising results in learnin
g representations across modalities. However, most approaches rely on global au
dio representations that fail to capture fine-grained temporal correspondences w
ith visual frames.Additionally, existing methods often struggle with conflicting
 optimization objectives when trying to jointly learn reconstruction and cross-m
odal alignment. In this work, we propose CAV-MAE Sync as a simple yet effective
extension of the original CAV-MAE framework for self-supervised audio-visual lea
rning. We address three key challenges: First, we tackle the granularity mismatc
h between modalities by treating audio as a temporal sequence aligned with video
 frames, rather than using global representations. Second, we resolve conflictin
g optimization goals by separating contrastive and reconstruction objectives thr

ough dedicated global tokens. Third, we improve spatial localization by introduc ing learnable register tokens that reduce semantic load on patch tokens. We eval uate the proposed approach on AudioSet, VGG Sound, and the ADE20K Sound dataset on zero-shot retrieval, classification and localization tasks demonstrating stat e-of-the-art performance and outperforming more complex architectures. Code avai lable at https://github.com/edsonroteia/cav-mae-sync.

Two is Better than One: Efficient Ensemble Defense for Robust and Compact Model s

Yoojin Jung, Byung Cheol Song; Proceedings of the Computer Vision and Pattern Re cognition Conference (CVPR), 2025, pp. 9696-9706

Deep learning-based computer vision systems adopt complex and large architecture s to improve performance, yet they face challenges in deployment on resource-con strained mobile and edge devices. To address this issue, model compression techn iques such as pruning, quantization, and matrix factorization have been proposed ; however, these compressed models are often highly vulnerable to adversarial at tacks. We introduce the Efficient Ensemble Defense (EED) technique, which divers ifies the compression of a single base model based on different pruning importan ce scores and enhances ensemble diversity to achieve high adversarial robustness and resource efficiency. EED dynamically determines the number of necessary sub -models during the inference stage, minimizing unnecessary computations while ma intaining high robustness. On the CIFAR-10 and SVHN datasets, EED demonstrated s tate-of-the-art robustness performance compared to existing adversarial pruning techniques, along with an inference speed improvement of up to 1.86 times. This proves that EED is a powerful defense solution in resource-constrained environme nts.

Tiled Diffusion

Or Madar, Ohad Fried; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 7795-7804

Image tiling--the seamless connection of disparate images to create a coherent v isual field--is crucial for applications such as texture creation, video game as set development, and digital art. Traditionally, tiles have been constructed man ually, a method that poses significant limitations in scalability and flexibilit y. Recent research has attempted to automate this process using generative model s. However, current approaches primarily focus on tiling textures and manipulati ng models for single-image generation, without inherently supporting the creatio n of multiple interconnected tiles across diverse domains.This paper presents Ti led Diffusion, a novel approach that extends the capabilities of diffusion model s to accommodate the generation of cohesive tiling patterns across various domai ns of image synthesis that require tiling. Our method supports a wide range of t iling scenarios, from self-tiling to complex many-to-many connections, enabling seamless integration of multiple images.Tiled Diffusion automates the tiling pro cess, eliminating the need for manual intervention and enhancing creative possib ilities in various applications, such as seamlessly tiling of existing images, t iled texture creation, and 360deg synthesis.

Using Diffusion Priors for Video Amodal Segmentation

Kaihua Chen, Deva Ramanan, Tarasha Khurana; Proceedings of the Computer Vision a nd Pattern Recognition Conference (CVPR), 2025, pp. 22890-22900

Object permanence in humans is a fundamental cue that helps in understanding per sistence of objects, even when they are fully occluded in the scene. Present day methods in object segmentation do not account for this amodal nature of the wor ld, and only work for segmentation of visible or modal objects. Few amodal metho ds exist; single-image segmentation methods cannot handle high-levels of occlusi ons which are better inferred using temporal information, and multi-frame method s have focused solely on segmenting rigid objects. To this end, we propose to ta ckle video amodal segmentation by formulating it as a conditional generation tas k, thereby capitalizing on the foundational knowledge in video generative models . Our method is simple; we repurpose these models to condition on a sequence of

modal mask frames of an object along with contextual depth maps, to learn which object boundary may be occluded and therefore, extended to hallucinate the complete extent of an object. This is followed by a content completion stage which is able to inpaint the occluded regions of an object. We benchmark our approach alongside a wide array of state-of-the-art methods on four datasets and show a dramatic improvement of upto 13% for amodal segmentation in an object's occluded region.
****
COBRA: COmBinatorial Retrieval Augmentation for Few-Shot Adaptation
Arnav M. Das, Gantavya Bhatt, Lilly Kumari, Sahil Verma, Jeff Bilmes; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 20534-20546
Retrieval augmentation, the practice of retrieving additional data from large auxiliary pools, has emerged as an effective technique for enhancing model performance in the low-data regime. Prior approaches have employed only nearest-neighbor based strategies for data selection, which retrieve auxiliary samples with high similarity to instances in the target task. However, these approaches are prone to selecting highly redundant samples, since they fail to incorporate any notion of diversity. In our work, we first demonstrate that data selection strategies used in prior retrieval-augmented few-shot adaptation settings can be generalized using a class of functions known as Combinatorial Mutual Information (CMI) measures. We then propose COBRA (COmBinatorial Retrieval Augmentation), which employs an alternative CMI measure that considers both diversity and similarity to a target dataset. COBRA consistently outperforms previous retrieval approaches across image classification tasks and few-shot learning techniques when used to retrieve samples from LAION-2B. COBRA introduces negligible computational overhead to the cost of retrieval while providing significant gains in downstream model performance.
****
Dyn-HaMR: Recovering 4D Interacting Hand Motion from a Dynamic Camera
Zhengdi Yu, Stefanos Zafeiriou, Tolga Birdal; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 27716-27726
We propose Dyn-HaMR, to the best of our knowledge, the first approach to reconstruct 4D global hand motion from monocular videos recorded by dynamic cameras in the wild. Reconstructing accurate 3D hand meshes from monocular videos is a crucial task for understanding human behaviour, with significant applications in augmented and virtual reality (AR/VR). However, existing methods for monocular hand reconstruction typically rely on a weak perspective camera model, which simulates hand motion within a limited camera frustum. As a result, these approaches struggle to recover the full 3D global trajectory and often produce noisy or incorrect depth estimations, particularly when the video is captured by dynamic or moving cameras, which is common in egocentric scenarios. Our \name consists of a multi-stage, multi-objective optimization pipeline, that factors in (i) simultaneous localization and mapping (SLAM) to robustly estimate relative camera motion, (ii) an interacting-hand prior for generative infilling and to refine the interaction dynamics, ensuring plausible recovery under (self-)occlusions, and (iii) hierarchical initialization through a combination of state-of-the-art hand tracking methods.
****
The Scene Language: Representing Scenes with Programs, Words, and Embeddings
Yunzhi Zhang, Zizhang Li, Matt Zhou, Shangzhe Wu, Jiajun Wu; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 24625-24634
We introduce the Scene Language, a visual scene representation that concisely and precisely describes the structure, semantics, and identity of visual scenes. It represents a scene with three key components: a program that specifies the hierarchical and relational structure of entities in the scene, words in natural language that summarize the semantic class of each entity, and embeddings that capture the visual identity of each entity. This representation can be inferred from pre-trained language models via a training-free inference technique, given text or image inputs. The resulting scene can be rendered into images using traditi

onal, neural, or hybrid graphics renderers. Together, this forms an automated sy
stem for high-quality 3D and 4D scene generation. Compared with existing represe
ntations like scene graphs, our proposed Scene Language generates complex scenes
 with higher fidelity, while explicitly modeling the scene structures to enable
precise control and editing.
****

ProbeSDF: Light Field Probes For Neural Surface Reconstruction
Briac Toussaint, Diego Thomas, Jean-Sébastien Franco; Proceedings of the Compute
r Vision and Pattern Recognition Conference (CVPR), 2025, pp. 11026-11035
SDF-based differential rendering frameworks have achieved state-of-the-art multi
view 3D shape reconstruction. In this work, we re-examine this family of approac
hes by minimally reformulating its core appearance model in a way that simultane
ously yields faster computation and increased performance. To this goal, we exhi
bit a physically-inspired minimal radiance parametrization decoupling angular an
d spatial contributions, by encoding them with a small number of features stored
 in two respective volumetric grids of different resolutions. Requiring as littl
e as four parameters per voxel, and a tiny MLP call inside a single fully fused
kernel, our approach allows to enhance performance with both surface and image (
PSNR) metrics, while providing a significant training speedup and real-time rend
ering. We show this performance to be consistently achieved on real data over tw
o widely different and popular application fields, generic object and human subj
ect shape reconstruction, using four representative and challenging datasets.
****

Descriptor-In-Pixel : Point-Feature Tracking For Pixel Processor Arrays
Laurie Bose, Jianing Chen, Piotr Dudek; Proceedings of the Computer Vision and P
attern Recognition Conference (CVPR), 2025, pp. 5392-5400
This paper presents a novel approach for joint point-feature detection and track
ing, designed specifically for Pixel Processor Array (PPA) vision sensors. Inste
ad of standard pixels, PPA sensors consist of thousands of "pixel-processors", e
nabling massive parallel computation of visual data at the point of light captur
e. Our approach performs all computation entirely in-pixel, meaning no raw image
 data need ever leave the sensor for external processing. We introduce a Descrip
tor-In-Pixel paradigm, in which a feature descriptor is held within the memory o
f each pixel-processor. The PPA's architecture enables the response of every pro
cessor's descriptor, upon the current image, to be computed in parallel. This pr
oduces a "descriptor response map", which, by generating the correct layout of d
escriptors across the pixel-processors, can be used for both point-feature detec
tion and tracking. This reduces sensor output to just sparse feature locations a
nd descriptors, read-out via an address-event interface, giving a greater than 1
000X reduction in data transfer compared to raw image output. The sparse readout
 and complete utilization of all pixel-processors makes our approach very effici
ent. Our implementation upon the SCAMP-7 PPA prototype runs at over 3000 FPS (Fr
ames Per Second), tracking point-features reliably under violent motion. This is
 the first work performing point-feature detection and tracking entirely in-pixe
l.
****

Hybrid Concept Bottleneck Models
Yang Liu, Tianwei Zhang, Shi Gu; Proceedings of the Computer Vision and Pattern
Recognition Conference (CVPR), 2025, pp. 20179-20189
Concept Bottleneck Models (CBMs) provide an interpretable framework for neural n
etworks by mapping visual features to predefined, human-understandable concepts.
 However, the application of CBMs is often constrained by insufficient concept a
nnotations. Recently, multi-modal pre-trained models have shown promise in reduc
ing annotation costs by aligning visual representations with textual concept emb
eddings. Nevertheless, the quality and completeness of the predefined concepts s
ignificantly affect the performance of CBMs.In this work, we propose Hybrid Conc
ept Bottleneck Model (HybridCBM), a novel CBM framework to address the challenge
 of incomplete predefined concepts. Our method consists of two main components:
a Static Concept Bank and a Dynamic Concept Bank. The Static Concept Bank direct
ly leverages large language models (LLMs) for concept construction, while the Dy

namic Concept Bank employs learnable vectors to capture complementary and valuable concepts continuously during training. After training, a pre-trained translator converts these vectors into human-understandable concepts, further enhancing model interpretability. Notably, HybridCBM is highly flexible and can be easily applied to any CBM to improve performance. Experimental results across multiple datasets demonstrate that HybridCBM outperforms current state-of-the-art methods and achieves comparable results to black-box models. Additionally, we propose novel metrics to evaluate the quality of the learned concepts, showing that they perform comparably to predefined concepts.

UVGS: Reimagining Unstructured 3D Gaussian Splatting using UV Mapping
Aashish Rai, Dilin Wang, Mihir Jain, Nikolaos Sarafianos, Kefan Chen, Srinath Sridhar, Aayush Prakash; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 5927-5937
3D Gaussian Splatting (3DGS) has demonstrated superior quality in modeling 3D objects and scenes. However, generating 3DGS remains challenging due to their discrete, unstructured, and permutation-invariant nature. In this work, we present a simple yet effective method to overcome these challenges. We utilize spherical mapping to transform 3DGS into a structured 2D representation, termed UVGS. UVGS can be viewed as multi-channel images, with feature dimensions as a concatenation of Gaussian attributes such as position, scale, color, opacity, and rotation. We further find that these heterogeneous features can be compressed into a lower-dimensional (e.g., 3-channel) shared feature space using a carefully designed multi-branch network.The compressed UVGS can be treated as typical RGB images. Remarkably, we discover that typical VAEs trained with latent diffusion models can directly generalize to this new representation without additional training. Our novel representation makes it effortless to leverage foundational 2D models, such as diffusion models, to directly model 3DGS. Additionally, one can simply increase the 2D UV resolution to accommodate more Gaussians, making UVGS a scalable solution compared to typical 3D backbones. This approach immediately unlocks various novel generation applications of 3DGS by inherently utilizing the already developed superior 2D generation capabilities. In our experiments, we demonstrate various unconditional, conditional generation, and inpainting applications of 3DGS based on diffusion models, which were previously non-trivial.
****

Dual Consolidation for Pre-Trained Model-Based Domain-Incremental Learning
Da-Wei Zhou, Zi-Wen Cai, Han-Jia Ye, Lijun Zhang, De-Chuan Zhan; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 20547-20557
Domain-Incremental Learning (DIL) involves the progressive adaptation of a model to new concepts across different domains. While recent advances in pre-trained models provide a solid foundation for DIL, learning new concepts often results in the catastrophic forgetting of pre-trained knowledge. Specifically, sequential model updates can overwrite both the representation and the classifier with knowledge from the latest domain. Thus, it is crucial to develop a representation and corresponding classifier that accommodate all seen domains throughout the learning process. To this end, we propose DUal ConsolidaTion (Duct) to unify and consolidate historical knowledge at both the representation and classifier levels. By merging the backbone of different stages, we create a representation space suitable for multiple domains incrementally. The merged representation serves as a balanced intermediary that captures task-specific features from all seen domains. Additionally, to address the mismatch between consolidated embeddings and the classifier, we introduce an extra classifier consolidation process. Leveraging class-wise semantic information, we estimate the classifier weights of old domains within the latest embedding space. By merging historical and estimated classifiers, we align them with the consolidated embedding space, facilitating incremental classification. Extensive experimental results on four benchmark datasets demonstrate Duct's state-of-the-art performance. Code is available at: https://github.com/Estrella-fugaz/CVPR25-Duct.
****

Learning Physics-Based Full-Body Human Reaching and Grasping from Brief Walking References
Yitang Li, Mingxian Lin, Zhuo Lin, Yipeng Deng, Yue Cao, Li Yi; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 27673-27682
Existing motion generation methods based on mocap data are often limited by data quality and coverage. In this work, we propose a framework that generates diverse, physically feasible full-body human reaching and grasping motions using only brief walking mocap data. Base on the observation that walking data captures valuable movement patterns transferable across tasks and, on the other hand, the advanced kinematic methods can generate diverse grasping poses, which can then be interpolated into motions to serve as task-specific guidance. Our approach incorporates an active data generation strategy to maximize the utility of the generated motions, along with a local feature alignment mechanism that transfers natural movement patterns from walking data to enhance both the success rate and naturalness of the synthesized motions. By combining the fidelity and stability of natural walking with the flexibility and generalizability of task-specific generated data, our method demonstrates strong performance and robust adaptability in diverse scenes and with unseen objects.

EmoEdit: Evoking Emotions through Image Manipulation
Jingyuan Yang, Jiawei Feng, Weibin Luo, Dani Lischinski, Daniel Cohen-Or, Hui Huang; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 24690-24699
Affective Image Manipulation (AIM) seeks to modify user-provided images to evoke specific emotions. This task is inherently complex due to its twofold objective: evoking the intended emotion while preserving image composition. Existing AIM methods primarily adjust color and style, often failing to elicit precise, profound emotional shifts. Drawing on psychological insights, we introduce EmoEdit, which extends AIM by incorporating content modifications to enhance emotional impact. Specifically, we construct EmoEditSet, a large-scale AIM dataset of 40,120 paired data through emotion attribution and data construction. To make generative models emotion-aware, we design an Emotion Adapter and train it using EmoEditSet. We further propose an instruction loss to capture semantic variations in each data pair. Our method is evaluated both qualitatively and quantitatively, demonstrating superior performance over state-of-the-art techniques. Additionally, we showcase the portability of our Emotion Adapter to other diffusion-based models, enhancing their emotion knowledge with diverse semantics. Code is available at: https://github.com/JingyuanYY/EmoEdit.
****
RORem: Training a Robust Object Remover with Human-in-the-Loop
Ruibin Li, Tao Yang, Song Guo, Lei Zhang; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 14024-14035
Despite the significant advancements, existing object removal methods struggle with incomplete removal, incorrect content synthesis and blurry synthesized regions, resulting in low success rates. Such issues are mainly caused by the lack of high-quality paired training data, as well as the self-supervised training paradigm adopted in these methods, which forces the model to in-paint the masked regions, leading to ambiguity between synthesizing the masked objects and restoring the background. To address these issues, we propose a semi-supervised learning strategy with human-in-the-loop to create high-quality paired training data, aiming to train a Robust Object Remover (RORem). We first collect 60K training pairs from open-source datasets to train an initial object removal model for generating removal samples, and then utilize human feedback to select a set of high-quality object removal pairs, with which we train a discriminator to automate the following training data generation process. By iterating this process for several rounds, we finally obtain a substantial object removal dataset with over 200K pairs. Fine-tuning the pre-trained stable diffusion model with this dataset, we obtain our RORem, which demonstrates state-of-the-art object removal performance in terms of both reliability and image quality. Particularly, RORem improves the

object removal success rate over previous methods by more than 18%. The dataset, source code and trained model will be released.

All Languages Matter: Evaluating LMMs on Culturally Diverse 100 Languages

Ashmal Vayani, Dinura Dissanayake, Hasindri Watawana, Noor Ahsan, Nevasini Sasikumar, Omkar Thawakar, Henok Biadglign Ademtew, Yahya Hmaiti, Amandeep Kumar, Kartik Kukreja, Mykola Maslych, Wafa Al Ghallabi, Mihail Minkov Mihaylov, Chao Qin, Abdelrahman M. Shaker, Mike Zhang, Mahardika Krisna Ihsani, Amiel Gian Esplana, Monil Gokani, Shachar Mirkin, Harsh Singh, Ashay Srivastava, Endre Hamerlik, Fathinah Asma Izzati, Fadillah Adamsyah Maani, Sebastian Cavada, Jenny Chim, Rohit Gupta, Sanjay Manjunath, Kamila Zhumakhanova, Feno Heriniaina Rabevohitra, Azril Hafizi Amirudin, Muhammad Ridzuan, Daniya Najiha Abdul Kareem, Ketan Pravin More, Kunyang Li, Pramesh Shakya, Muhammad Saad, Amirpouya Ghasemaghaei, Amirbek Djanibekov, Dilshod Azizov, Branislava Jankovic, Naman Bhatia, Alvaro Cabrera, Johan Obando-Ceron, Olympiah Otieno, Febian Farestam, Muztoba Rabbani, Sanoojan Ballah, Santosh Sanjeev, Abduragim Shtanchaev, Maheen Fatima, Thao Nguyen, Amrin Kareem, Toluwani Aremu, Nathan Augusto Zacarias Xavier, Amit Bhatkal, Hawau Olamide Toyin, Aman Chadha, Hisham Cholakkal, Rao Muhammad Anwer, Michael Felsberg, Jorma Laaksonen, Thamar Solorio, Monojit Choudhury, Ivan Laptev, Mubarak Shah, Salman Khan, Fahad Shahbaz Khan; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 19565-19575

Existing Large Multimodal Models (LMMs) generally focus on only a few regions and languages. As LMMs continue to improve, it is increasingly important to ensure they understand cultural contexts, respect local sensitivities, and support low-resource languages, all while effectively integrating corresponding visual cues. In pursuit of culturally diverse global multimodal models, our proposed All Languages Matter Benchmark (ALM-bench) represents the largest and most comprehensive effort to date for evaluating LMMs across 100 languages. ALM-bench challenges existing models by testing their ability to understand and reason about culturally diverse images paired with text in various languages, including many low-resource languages traditionally underrepresented in multimodal research. The benchmark offers a robust and nuanced evaluation framework featuring various question formats, including True/False, multiple choice, and open-ended questions, which are further divided into short and long-answer categories. ALM-bench design ensures a comprehensive assessment of a model's ability to handle varied levels of difficulty in visual and linguistic reasoning. To capture the rich tapestry of global cultures, ALM-bench carefully curates content from 13 distinct cultural aspects, ranging from traditions and rituals to famous personalities and celebrations. Through this, ALM-bench not only provides a rigorous testing ground for state-of-the-art open and closed-source LMMs but also highlights the importance of cultural and linguistic inclusivity, encouraging the development of models that can serve diverse global populations effectively. Our benchmark will be publicly released.

SparseAlign: a Fully Sparse Framework for Cooperative Object Detection

Yunshuang Yuan, Yan Xia, Daniel Cremers, Monika Sester; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 22296-22305

Cooperative perception can increase the view field and decrease the occlusion of an ego vehicle, hence improving the perception performance and safety of autonomous driving. Despite the success of previous works on cooperative object detection, they mostly operate on dense Bird's Eye View (BEV) feature maps, which are computationally demanding and can hardly be extended to long-range detection problems. More efficient fully sparse frameworks are rarely explored. In this work, we design a fully sparse framework, SparseAlign, with three key features: an enhanced sparse 3D backbone, a query-based temporal context learning module, and a robust detection head specially tailored for sparse features. Extensive experimental results on both OPV2V and DairV2X datasets show that our framework, despite its sparsity, outperforms the state of the art with less communication bandwidth requirements. In addition, experiments on the OPV2Vt and DairV2Xt datasets for time-aligned cooperative object detection also show a significant performance

gain compared to the baseline works.

Video-Bench: Human-Aligned Video Generation Benchmark
Hui Han, Siyuan Li, Jiaqi Chen, Yiwen Yuan, Yuling Wu, Yufan Deng, Chak Tou Leong, Hanwen Du, Junchen Fu, Youhua Li, Jie Zhang, Chi Zhang, Li-jia Li, Yongxin Ni; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 18858-18868
Video generation assessment is essential for ensuring that generative models produce visually realistic, high-quality videos while aligning with human expectations. Current video generation benchmarks fall into two main categories: traditional benchmarks, which use metrics and embeddings to evaluate generated video quality across multiple dimensions but often lack alignment with human judgments; and large language model (LLM)-based benchmarks, though capable of human-like reasoning, are constrained by a limited understanding of video quality metrics and cross-modal consistency.To address these challenges and establish a benchmark that better aligns with human preferences, this paper introduces Video-Bench, a comprehensive benchmark featuring a rich prompt suite and extensive evaluation dimensions. This benchmark represents the first attempt to systematically leverage MLLMs across all dimensions relevant to video generation assessment in generative models. By incorporating few-shot scoring and chain-of-query techniques, Video-Bench provides a structured, scalable approach to generated video evaluation. Experimental results demonstrate that MLLMs achieve superior alignment with human preferences across all dimensions. Moreover, in instances where our framework's assessments diverge from human evaluations, it consistently offers more objective and accurate insights, suggesting an even greater potential advantage over traditional human judgment.

Data Distributional Properties As Inductive Bias for Systematic Generalization
Felipe del Rio, Alain Raymond-Saez, Daniel Florea, Rodrigo Toro Icarte, Julio Hurtado, Cristian B. Calderon, Alvaro Soto; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 25590-25601
Deep neural networks (DNNs) struggle at systematic generalization (SG). Several studies have evaluated the possibility of promoting SG through the proposal of novel architectures, loss functions, or training methodologies. Few studies, however, have focused on the role of training data properties in promoting SG. In this work, we investigate the impact of certain data distributional properties, as inductive biases for the SG ability of a multi-modal language model. To this end, we study three different properties. First, data diversity, instantiated as an increase in the possible values a latent property in the training distribution may take. Second, burstiness, where we probabilistically restrict the number of possible values of latent factors on particular inputs during training. Third, latent intervention, where a particular latent factor is altered randomly during training. We find that all three factors significantly enhance SG, with diversity contributing an 89% absolute increase in accuracy in the most affected property. Through a series of experiments, we test various hypotheses to understand why these properties promote SG. Finally, we find that Normalized Mutual Information (NMI) between latent attributes in the training distribution is strongly predictive of out-of-distribution generalization. We find that a mechanism by which lower NMI induces SG is in the geometry of representations. In particular, we find that NMI induces more parallelism in neural representations (i.e., input features coded in parallel neural vectors) of the model, a property related to the capacity of reasoning by analogy.

MergeVQ: A Unified Framework for Visual Generation and Representation with Disentangled Token Merging and Quantization
Siyuan Li, Luyuan Zhang, Zedong Wang, Juanxi Tian, Cheng Tan, Zicheng Liu, Chang Yu, Qingsong Xie, Haonan Lu, Haoqian Wang, Zhen Lei; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 19713-19723
Masked Image Modeling (MIM) with Vector Quantization (VQ) has achieved great success in both self-supervised pre-training and image generation. However, most ex

isting methods struggle to address the trade-off in the shared latent space for generation quality vs. representation learning and efficiency. To push the limits of this paradigm, we propose MergeVQ, which incorporates token merging techniques into VQ-based generative models to bridge the gap between image generation and visual representation learning in a unified architecture. During pre-training, MergeVQ decouples top-k semantics from latent space with the token merge module after self-attention blocks in the encoder for subsequent Look-up Free Quantization (LFQ) and global alignment and recovers their fine-grained details through cross-attention in the decoder for reconstruction. As for second-stage generation, we introduce MergeAR, which performs KV Cache compression for efficient raster-order prediction. Extensive experiments on ImageNet verify that MergeVQ as an AR generative model achieves competitive performance in both visual representation learning and image generation tasks while maintaining favorable token efficiency and inference speed. The code and model will be available at https://apexgen-x.github.io/MergeVQ.

InterAct: Advancing Large-Scale Versatile 3D Human-Object Interaction Generation
Sirui Xu, Dongting Li, Yucheng Zhang, Xiyan Xu, Qi Long, Ziyin Wang, Yunzhi Lu, Shuchang Dong, Hezi Jiang, Akshat Gupta, Yu-Xiong Wang, Liang-Yan Gui; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 7048-7060

While large-scale human motion capture datasets have advanced human motion generation, modeling and generating dynamic 3D human-object interactions (HOIs) remain challenging due to dataset limitations. Existing datasets often lack extensive, high-quality motion and annotation and exhibit artifacts such as contact penetration, floating, and incorrect hand motions. To address these issues, we introduce InterAct, a large-scale 3D HOI benchmark featuring dataset and methodological advancements. First, we consolidate and standardize 21.81 hours of HOI data from diverse sources, enriching it with detailed textual annotations. Second, we propose a unified optimization framework to enhance data quality by reducing artifacts and correcting hand motions. Leveraging the principle of contact invariance, we maintain human-object relationships while introducing motion variations, expanding the dataset to 30.70 hours. Third, we define six benchmarking tasks and develop a unified HOI generative modeling perspective, achieving state-of-the-art performance. Extensive experiments validate the utility of our dataset as a foundational resource for advancing 3D human-object interaction generation. The dataset will be publicly accessible to support further research in the field.

TopoCellGen: Generating Histopathology Cell Topology with a Diffusion Model
Meilong Xu, Saumya Gupta, Xiaoling Hu, Chen Li, Shahira Abousamra, Dimitris Samaras, Prateek Prasanna, Chao Chen; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 20979-20989

Accurately modeling multi-class cell topology is crucial in digital pathology, as it provides critical insights into tissue structure and pathology. The synthetic generation of cell topology enables realistic simulations of complex tissue environments, enhances downstream tasks by augmenting training data, aligns more closely with pathologists' domain knowledge, and offers new opportunities for controlling and generalizing the tumor microenvironment. In this paper, we propose a novel approach that integrates topological constraints into a diffusion model to improve the generation of realistic, contextually accurate cell topologies. Our method refines the simulation of cell distributions and interactions, increasing the precision and interpretability of results in downstream tasks such as cell detection and classification. To assess the topological fidelity of generated layouts, we introduce a new metric, Topological Frechet Distance (TopoFD), which overcomes the limitations of traditional metrics like FID in evaluating topological structure. Experimental results demonstrate the effectiveness of our approach in generating multi-class cell layouts that capture intricate topological relationships. Code is available at https://github.com/Melon-Xu/TopoCellGen.

Anyattack: Towards Large-scale Self-supervised Adversarial Attacks on Vision-lan

guage Models
Jiaming Zhang, Junhong Ye, Xingjun Ma, Yige Li, Yunfan Yang, Yunhao Chen, Jitao Sang, Dit-Yan Yeung; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 19900-19909
Due to their multimodal capabilities, Vision-Language Models (VLMs) have found numerous impactful applications in real-world scenarios. However, recent studies have revealed that VLMs are vulnerable to image-based adversarial attacks. Traditional targeted adversarial attacks require specific targets and labels, limiting their real-world impact. We present AnyAttack, a self-supervised framework that transcends the limitations of conventional attacks through a novel foundation model approach. By pre-training on the massive LAION-400M dataset without label supervision, AnyAttack achieves unprecedented flexibility - enabling any image to be transformed into an attack vector targeting any desired output across different VLMs. This approach fundamentally changes the threat landscape, making adversarial capabilities accessible at an unprecedented scale. Our extensive validation across five open-source VLMs (CLIP, BLIP, BLIP2, InstructBLIP, and MiniGPT-4) demonstrates AnyAttack's effectiveness across diverse multimodal tasks. Most concerning, AnyAttack seamlessly transfers to commercial systems including Google Gemini, Claude Sonnet, Microsoft Copilot and OpenAI GPT, revealing a systemic vulnerability requiring immediate attention.

Joint Optimization of Neural Radiance Fields and Continuous Camera Motion from a Monocular Video
Hoang Chuong Nguyen, Wei Mao, Jose M. Alvarez, Miaomiao Liu; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 11472-11481
Neural Radiance Fields (NeRF) has demonstrated its superior capability to represent 3D geometry but require accurately precomputed camera poses during training. To mitigate this requirement, existing methods jointly optimize camera poses and NeRF often relying on good pose initialisation or depth priors. However, these approaches struggle in challenging scenarios, such as large rotations, as they map each camera to a world coordinate system. We propose a novel method that eliminates prior dependencies by modeling continuous camera motions as time-dependent angular velocity and velocity. Relative motions between cameras are learned first via velocity integration, while camera poses can be obtained by aggregating such relative motions up to a world coordinate system defined at a single time step within the video. Specifically, accurate continuous camera movements are learned through a time-dependent NeRF, which captures local scene geometry and motion by training from neighboring frames for each time step. The learned motions enable fine-tuning the NeRF to represent the full scene geometry. Experiments on Co3D and Scannet show our approach achieves superior camera pose and depth estimation and comparable novel-view synthesis performance compared to state-of-the-art methods.

IRGS: Inter-Reflective Gaussian Splatting with 2D Gaussian Ray Tracing
Chun Gu, Xiaofei Wei, Zixuan Zeng, Yuxuan Yao, Li Zhang; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 10943-10952
In inverse rendering, accurately modeling visibility and indirect radiance for incident light is essential for capturing secondary effects. Due to the absence of a powerful Gaussian ray tracer, previous 3DGS-based methods have either adopted a simplified rendering equation or used learnable parameters to approximate incident light, resulting in inaccurate material and lighting estimations. To this end, we introduce the inter-reflective Gaussian splatting (IRGS) framework for inverse rendering. To capture inter-reflection, we apply the full rendering equation without simplification and compute incident radiance on the fly using the proposed differentiable 2D Gaussian ray tracing. Additionally, we present an efficient optimization scheme to handle the computational demands of Monte Carlo sampling for rendering equation evaluation. Furthermore, we introduce a novel strategy for querying the indirect radiance of incident light when relighting the optimized scenes. Extensive experiments on multiple standard benchmarks validate the effectiveness of IRGS, demonstrating its capability to accurately model comple

x inter-reflection effects.
****

InterMimic: Towards Universal Whole-Body Control for Physics-Based Human-Object Interactions
Sirui Xu, Hung Yu Ling, Yu-Xiong Wang, Liang-Yan Gui; Proceedings of the Compute r Vision and Pattern Recognition Conference (CVPR), 2025, pp. 12266-12277
Achieving realistic simulations of humans interacting with a wide range of objec ts has long been a fundamental goal. Extending physics-based motion imitation to complex human-object interactions (HOIs) is challenging due to intricate human- object coupling, variability in object geometries, and artifacts in motion captu re data, such as inaccurate contacts and limited hand detail. We introduce Inter Mimic, a framework that enables a single policy to robustly learn from hours of imperfect MoCap data covering diverse full-body interactions with dynamic and va ried objects. Our key insight is to employ a curriculum strategy -- perfect firs t, then scale up. We first train subject-specific teacher policies to mimic, ret arget, and refine motion capture data. Next, we distill these teachers into a st udent policy, with the teachers acting as online experts providing direct superv ision, as well as high-quality references. Notably, we incorporate RL fine-tunin g on the student policy to surpass mere demonstration replication and achieve hi gher-quality solutions. Our experiments demonstrate that InterMimic produces rea listic and diverse interactions across multiple HOI datasets. The learned policy generalizes in a zero-shot manner and seamlessly integrates with kinematic gene rators, elevating the framework from mere imitation to generative modeling of co mplex human-object interactions.

Meta-Learning Hyperparameters for Parameter Efficient Fine-Tuning
Zichen Tian, Yaoyao Liu, Qianru Sun; Proceedings of the Computer Vision and Patt ern Recognition Conference (CVPR), 2025, pp. 23037-23047
Training large foundation models from scratch for domain-specific applications i s almost impossible due to data limits and long-tailed distributions -- taking r emote sensing (RS) as an example. Fine-tuning natural image pre-trained models o n RS images is a straightforward solution. To reduce computational costs and imp rove performance on tail classes, existing methods apply parameter-efficient fin e-tuning (PEFT) techniques, such as LoRA and AdaptFormer. However, we observe th at fixed hyperparameters -- such as intra-layer positions, layer depth, and scal ing factors, can considerably hinder PEFT performance, as fine-tuning on RS imag es proves highly sensitive to these settings. To address this, we propose MetaPE FT, a method incorporating adaptive scalers that dynamically adjust module influ ence during fine-tuning. MetaPEFT dynamically adjusts three key factors of PEFT on RS images: module insertion, layer selection, and module-wise learning rates, which collectively control the influence of PEFT modules across the network. We conduct extensive experiments on three transfer-learning scenarios and five dat asets in both RS and natural image domains. The results show that MetaPEFT achie ves state-of-the-art performance in cross-spectral adaptation, requiring only a small amount of trainable parameters and improving tail-class accuracy significa ntly.
****

TriTex: Learning Texture from a Single Mesh via Triplane Semantic Features
Dana Cohen-Bar, Daniel Cohen-Or, Gal Chechik, Yoni Kasten; Proceedings of the Co mputer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 21403-21413
As 3D content creation continues to grow, transferring semantic textures between 3D meshes remains a significant challenge in computer graphics. While recent me thods leverage text-to-image diffusion models for texturing, they often struggle to preserve the appearance of the source texture during texture transfer. We pr esent TriTex, a novel approach that learns a volumetric texture field from a sin gle textured mesh by mapping semantic features to surface colors. Using an effic ient triplane-based architecture, our method enables semantic-aware texture tran sfer to a novel target mesh. Despite training on just one example, it generalize s effectively to diverse shapes within the same category. Extensive evaluation o n our newly created benchmark dataset shows that TriTex achieves superior textur

e transfer quality and fast inference times compared to existing methods. Our ap
proach advances single-example texture transfer, providing a practical solution
for maintaining visual coherence across related 3D models in applications like g
ame development and simulation.

Efficient Test-time Adaptive Object Detection via Sensitivity-Guided Pruning
Kunyu Wang, Xueyang Fu, Xin Lu, Chengjie Ge, Chengzhi Cao, Wei Zhai, Zheng-Jun Z
ha; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR)
, 2025, pp. 10577-10586
Continual test-time adaptive object detection (CTTA-OD) aims to online adapt a s
ource pre-trained detector to ever-changing environments during inference under
continuous domain shifts. Most existing CTTA-OD methods prioritize effectiveness
 while overlooking computational efficiency, which is crucial for resource-const
rained scenarios. In this paper, we propose an efficient CTTA-OD method via prun
ing. Our motivation stems from the observation that not all learned source featu
res are beneficial; certain domain-sensitive feature channels can adversely affe
ct target domain performance. Inspired by this, we introduce a sensitivity-guide
d channel pruning strategy that quantifies each channel based on its sensitivity
 to domain discrepancies at both image and instance levels. We apply weighted sp
arsity regularization to selectively suppress and prune these sensitive channels
, focusing adaptation efforts on invariant ones. Additionally, we introduce a st
ochastic channel reactivation mechanism to restore pruned channels, enabling rec
overy of potentially useful features and mitigating the risks of early pruning.
Extensive experiments on three benchmarks show that our method achieves superior
 adaptation performance while reducing computational overhead by 12% in FLOPs co
mpared to the recent SOTA method.

A Data-Centric Revisit of Pre-Trained Vision Models for Robot Learning
Xin Wen, Bingchen Zhao, Yilun Chen, Jiangmiao Pang, Xiaojuan Qi; Proceedings of
the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 12143-1
2154
Pre-trained vision models (PVMs) are fundamental to modern robotics, yet their o
ptimal configuration remains unclear. Through systematic evaluation, we find tha
t while DINO and iBOT outperform MAE across visuomotor control and perception ta
sks, they struggle when trained on non-(single-)object-centric (NOC) data--a lim
itation strongly correlated with their diminished ability to learn object-centri
c representations. This investigation indicates that the ability to form object-
centric representations from the non-object-centric robotics dataset is the key
to success for PVMs. Motivated by this discovery, we designed SlotMIM, a method
that induces object-centric representations by introducing a semantic bottleneck
 to reduce the number of prototypes to encourage the emergence of objectness as
well as cross-view consistency regularization for encouraging multiview invarian
ce. Our experiments encompass pre-training on object-centric, scene-centric, web
-crawled, and ego-centric data. Across all settings, our approach learns transfe
rrable representations and achieves significant improvements over prior work in
image recognition, scene understanding, and robot learning evaluations. When sca
led up with million-scale datasets, our method also demonstrates superior data e
fficiency and scalability. Our code and models are publicly available at https:/
/github.com/CVMI-Lab/SlotMIM.

Visual Agentic AI for Spatial Reasoning with a Dynamic API
Damiano Marsili, Rohun Agrawal, Yisong Yue, Georgia Gkioxari; Proceedings of the
 Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 19446-1945
5
Visual reasoning -- the ability to interpret the visual world -- is crucial for
embodied agents that operate within three-dimensional scenes. Progress in AI has
 led to vision and language models capable of answering questions from images. H
owever, their performance declines when tasked with 3D spatial reasoning. To tac
kle the complexity of such reasoning problems, we introduce an agentic program s
ynthesis approach where LLM agents collaboratively generate a Pythonic API with

new functions to solve common subproblems. Our method overcomes limitations of p
rior approaches that rely on a static, human-defined API, allowing it to handle
a wider range of queries. To assess AI capabilities for 3D understanding, we int
roduce a new benchmark of queries involving multiple steps of grounding and infe
rence. We show that our method outperforms prior zero-shot models for visual rea
soning in 3D and empirically validate the effectiveness of our agentic framework
for 3D spatial reasoning tasks. Project website: https://glab-caltech.github.io
/vadar/

TAMT: Temporal-Aware Model Tuning for Cross-Domain Few-Shot Action Recognition
Yilong Wang, Zilin Gao, Qilong Wang, Zhaofeng Chen, Peihua Li, Qinghua Hu; Proce
edings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, p
p. 3449-3459
Going beyond few-shot action recognition (FSAR), cross-domain FSAR (CDFSAR) has
attracted recent research interests by solving the domain gap lying in source-to
-target transfer learning. Existing CDFSAR methods mainly focus on joint trainin
g of source and target data to mitigate the side effect of domain gap. However,
such kind of methods suffer from two limitations: First, pair-wise joint trainin
g requires retraining deep models in case of one source data and multiple target
ones, which incurs heavy computation cost, especially for large source and smal
l target data. Second, pre-trained models after joint training are adopted to ta
rget domain in a straightforward manner, hardly taking full potential of pre-tra
ined models and then limiting recognition performance. To overcome above limitat
ions, this paper proposes a simple yet effective baseline, namely Temporal-Aware
Model Tuning (TAMT) for CDFSAR. Specifically, our TAMT involves a decoupled par
adigm by performing pre-training on source data and fine-tuning target data, whi
ch avoids retraining for multiple target data with single source. To effectively
and efficiently explore the potential of pre-trained models in transferring to
target domain, our TAMT proposes a Hierarchical Temporal Tuning Network (HTTN),
whose core involves local temporal-aware adapters (TAA) and a global temporal-aw
are moment tuning (GTMT). Particularly, TAA learns few parameters to recalibrate
the intermediate features of frozen pre-trained models, enabling efficient adap
tation to target domains. Furthermore, GTMT helps to generate powerful video rep
resentations, improving match performance on the target domain. Experiments on s
everal widely used video benchmarks show our TAMT outperforms the recently propo
sed counterparts by 13% 31%, achieving new state-of-the-art CDFSAR results.

Feature Spectrum Learning for Remote Sensing Change Detection
Qi Zang, Dong Zhao, Shuang Wang, Dou Quan, Zhun Zhong; Proceedings of the Comput
er Vision and Pattern Recognition Conference (CVPR), 2025, pp. 12647-12657
Change detection (CD) holds significant implications for Earth observation, in w
hich pseudo-changes between bitemporal images induced by imaging environmental f
actors are key challenges. Existing methods mainly regard pseudo-changes as a ki
nd of style shift and alleviate it by transforming bitemporal images into the sa
me style using generative adversarial networks (GANs). Nevertheless, their effor
ts are limited by the complexity of optimizing GANs and the absence of guidance
from physical properties. This paper finds that the spectrum transformation (ST)
has the potential to mitigate pseudo-changes by aligning in the frequency domai
n carrying the style. However, the benefit of ST is largely constrained by two d
rawbacks: 1) limited transformation space and 2) inefficient parameter search. T
o address these limitations, we propose a Feature Spectrum learning (FeaSpect) t
hat adaptively eliminate pseudo-changes in the latent space. For the drawback 1)
, FeaSpect directs the transformation towards style-aligned discriminative featu
res via feature spectrum transformation (FST). For the drawback 2), FeaSpect all
ows FST to be trainable, efficiently discovering optimal parameters via extracti
on box with adaptive attention and extraction box with learnable strides. Extens
ive experiments on challenging datasets demonstrate that our method remarkably o
utperforms existing methods and achieves a commendable trade-off between accurac
y and efficiency. Importantly, our method can be easily injected into other fram
eworks, achieving consistent improvements.

BioX-CPath: Biologically-driven Explainable Diagnostics for Multistain IHC Computational Pathology
Amaya Gallagher-Syed, Henry Senior, Omnia Alwazzan, Elena Pontarini, Michele Bombardieri, Costantino Pitzalis, Myles J. Lewis, Michael R. Barnes, Luca Rossi, Gregory Slabaugh; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 10372-10383
The development of biologically interpretable and explainable models remains a key challenge in computational pathology, particularly for multistain immunohistochemistry (IHC) analysis. We present BioX-CPath, an explainable graph neural network architecture for whole slide image (WSI) classification that leverages both spatial and semantic features across multiple stains. At its core, BioXCPath introduces a novel Stain-Aware Attention Pooling (SAAP) module that generates biologically meaningful, stain-aware patient embeddings. Our approach achieves state-of-the-art performance on both Rheumatoid Arthritis and Sjogren's Disease multistain datasets. Beyond performance metrics, BioX-CPath provides interpretable insights through stain attention scores, entropy measures, and stain interaction scores, that permit measuring model alignment with known pathological mechanisms. This biological grounding, combined with strong classification performance, makes BioX-CPath particularly suitable for clinical applications where interpretability is key. Source code and documentation can be found at: https://github.com/AmayaGS/BioX-CPath.

DriveDreamer4D: World Models Are Effective Data Machines for 4D Driving Scene Representation
Guosheng Zhao, Chaojun Ni, Xiaofeng Wang, Zheng Zhu, Xueyang Zhang, Yida Wang, Guan Huang, Xinze Chen, Boyuan Wang, Youyi Zhang, Wenjun Mei, Xingang Wang; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 12015-12026
Closed-loop simulation is essential for advancing end-to-end autonomous driving systems. Contemporary sensor simulation methods, such as NeRF and 3DGS, rely predominantly on conditions closely aligned with training data distributions, which are largely confined to forward-driving scenarios. Consequently, these methods face limitations when rendering complex maneuvers (e.g., lane change, acceleration, deceleration). Recent advancements in autonomous-driving world models have demonstrated the potential to generate diverse driving videos. However, these approaches remain constrained to 2D video generation, inherently lacking the spatiotemporal coherence required to capture intricacies of dynamic driving environments.In this paper, we introduce DriveDreamer4D, which enhances 4D driving scene representation leveraging world model priors. Specifically, we utilize the world model as a data machine to synthesize novel trajectory videos, where structured conditions are explicitly leveraged to control the spatial-temporal consistency of traffic elements. Besides, the cousin data training strategy is proposed to facilitate merging real and synthetic data for optimizing 4DGS. To our knowledge, DriveDreamer4D is the first to utilize video generation models for improving 4D reconstruction in driving scenarios.Experimental results reveal that DriveDreamer4D significantly enhances generation quality under novel trajectory views, achieving a relative improvement in FID by 32.1%, 46.4%, and 16.3% compared to PVG, S3Gaussian, and Deformable-GS. Moreover, DriveDreamer4D markedly enhances the spatiotemporal coherence of driving agents, which is verified by a comprehensive user study and the relative increases of 22.6%, 43.5%, and 15.6% in the NTA-IoU metric.

LoKi: Low-dimensional KAN for Efficient Fine-tuning Image Models
Xuan Cai, Renjie Pan, Hua Yang; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 14869-14880
'Pre-training + fine-tuning' has been widely used in various downstream tasks. Parameter-efficient fine-tuning (PEFT) has demonstrated higher efficiency and promising performance comapred to traditional full-tuning. The widely used adapter-based and prompt-based methods in PEFT can be uniformly represented as adding an

MLP structure to the pre-trained model. These methods are prone to over-fitting in downstream tasks, due to the difference in data scale and distribution. To address this issue, we propose a new adapter-based PEFT module, i.e., LoKi, which consists of an encoder, a learnable activation layer, and a decoder. To maintain the simplicity of LoKi, we use single-layer linear networks for the encoder and decoder, and for the learnable activation layer, we use a Kolmogorov-Arnold Network (KAN) with the minimal number of layers (only 2 KAN linear layers). With a bottleneck rate much lower than that of Adapter, LoKi is equipped with fewer parameters (only half of Adapter) and eliminates slow training speed and high memory usage of KAN. We conduct extensive experiments on LoKi under image classification and video action recognition across 9 datasets. LoKi demonstrates highly competitive generalization performance compared to other PEFT methods with fewer tunable parameters, ensuring both effectiveness and efficiency.

Dr. Splat: Directly Referring 3D Gaussian Splatting via Direct Language Embedding Registration

Kim Jun-Seong, GeonU Kim, Kim Yu-Ji, Yu-Chiang Frank Wang, Jaesung Choe, Tae-Hyun Oh; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 14137-14146

We introduce Dr. Splat, a novel approach for open-vocabulary 3D scene understanding leveraging 3D Gaussian Splatting. Unlike existing language-embedded 3DGS methods, which rely on a rendering process, our method directly associates language-aligned CLIP embeddings with 3D Gaussians for holistic 3D scene understanding. The key of our method is a language feature registration technique where CLIP embeddings are assigned to the dominant Gaussians intersected by each pixel-ray. Moreover, we integrate Product Quantization (PQ) trained on general large scale image data to compactly represent embeddings without per-scene optimization. Experiments demonstrate that our approach significantly outperforms existing approaches in 3D perception benchmarks, such as open-vocabulary 3D semantic segmentation, 3D object localization, and 3D object selection tasks.

Wavelet and Prototype Augmented Query-based Transformer for Pixel-level Surface Defect Detection

Feng Yan, Xiaoheng Jiang, Yang Lu, Jiale Cao, Dong Chen, Mingliang Xu; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 23860-23869

As an important part of intelligent manufacturing, pixel-level surface defect detection (SDD) aims to locate defect areas through mask prediction. Previous methods adopt the image-independent static convolution to indiscriminately classify per-pixel features for mask prediction, which leads to suboptimal results for some challenging scenes such as weak defects and cluttered backgrounds. In this paper, inspired by query-based methods, we propose a Wavelet and Prototype Augmented Query-based Transformer (WPFormer) for surface defect detection. Specifically, a set of dynamic queries for mask prediction is updated through the dual-domain transformer decoder. Firstly, a Wavelet-enhanced Cross-Attention (WCA) is proposed, which aggregates meaningful high- and low-frequency information of image features in the wavelet domain to refine queries. WCA enhances the representation of high-frequency components by capturing multi-scale relationships between different frequency components, enabling queries to focus more on defect details. Secondly, a Prototype-guided Cross-Attention (PCA) is proposed to refine queries through meta-prototypes in the spatial domain. The prototypes aggregate semantically meaningful tokens from image features, facilitating queries to aggregate crucial defect information under the cluttered backgrounds. Extensive experiments on three defect detection datasets (i.e., ESDIs-SOD, CrackSeg9k, and ZJU-Leaper) demonstrate that the proposed method achieves state-of-the-art performance in defect detection. The code will be available at https://github.com/yfhdm/WPFormer.

GauCho: Gaussian Distributions with Cholesky Decomposition for Oriented Object Detection

José Henrique Lima Marques, Jeffri Murrugarra-Llerena, Claudio R. Jung; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 3593-3602

Oriented Object Detection (OOD) has received increased attention in the past years, being a suitable solution for detecting elongated objects in remote sensing analysis. In particular, using regression loss functions based on Gaussian distributions has become attractive since they yield simple and differentiable terms. However, existing solutions are still based on regression heads that produce Oriented Bounding Boxes (OBBs), and the known problem of angular boundary discontinuity persists. In this work, we propose a regression head for OOD that directly produces Gaussian distributions based on the Cholesky matrix decomposition. The proposed head, named Gaucho, theoretically mitigates the boundary discontinuity problem and is fully compatible with recent Gaussian-based regression loss functions. Furthermore, we advocate using Oriented Ellipses (OEs) to represent oriented objects, which relates to GauCho through a bijective function and alleviates the encoding ambiguity problem for circular objects. Our experimental results show that GauCho can be a viable alternative to the traditional OBB head, achieving results comparable to or better than state-of-the-art detectors for the challenging dataset DOTA.

Alignment, Mining and Fusion: Representation Alignment with Hard Negative Mining and Selective Knowledge Fusion for Medical Visual Question Answering

Yuanhao Zou, Zhaozheng Yin; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 29623-29633

Medical Visual Question Answering (Med-VQA) is a challenging task that requires a deep understanding of both medical images and textual questions. Although recent works leveraging Medical Vision-Language Pre-training (Med-VLP) have shown strong performance on the Med-VQA task, there is still no unified solution for modality alignment, and the issue of hard negatives remains under-explored. Additionally, commonly used knowledge fusion techniques for Med-VQA may introduce irrelevant information. In this work, we propose a framework to address these challenges through three key contributions: (1) a unified solution for heterogeneous modality alignments across multiple levels, modalities, views, and stages, leveraging methods such as contrastive learning and optimal transport theory; (2) a hard negative mining method that employs soft labels for multi-modality alignments and enforces the hard negative pair discrimination; and (3) a Gated Cross-Attention Module for Med-VQA that integrates the answer vocabulary as prior knowledge and select relevant information from it. Our framework outperforms the previous state-of-the-art on widely used Med-VQA datasets like RAD-VQA, SLAKE, PathVQA and VQA-2019. The code will be publicly available.

No Thing, Nothing: Highlighting Safety-Critical Classes for Robust LiDAR Semantic Segmentation in Adverse Weather

Junsung Park, Hwijeong Lee, Inha Kang, Hyunjung Shim; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 6690-6699

Existing domain generalization methods for LiDAR semantic segmentation under adverse weather struggle to accurately predict "things" categories compared to "stuff" categories. In typical driving scenes, "things" categories can be dynamic and associated with higher collision risks, making them crucial for safe navigation and planning. Recognizing the importance of "things" categories, we identify their performance drop as a serious bottleneck in existing approaches. We observed that adverse weather induces degradation of semantic-level features and both corruption of local features, leading to a misprediction of "things" as "stuff". To mitigate these corruptions, we suggests our method, NTN - segmeNt Things for No-accident. To address semantic-level feature corruption, we bind each point feature to its superclass, preventing the misprediction of things classes into visually dissimilar categories. Additionally, to enhance robustness against local corruption caused by adverse weather, we define each LiDAR beam as a local region and propose a regularization term that aligns the clean data with its corrupted counterpart in feature space. NTN achieves state-of-the-art performance with a

+2.6 mIoU gain on the SemanticKITTI-to-SemanticSTF benchmark and +7.9 mIoU on th
e SemanticPOSS-to-SemanticSTF benchmark. Notably, NTN achieves a +4.8 and +7.9 m
IoU improvement on "things" classes, respectively, highlighting its effectivenes
s.

Mind the Gap: Detecting Black-box Adversarial Attacks in the Making through Quer
y Update Analysis
Jeonghwan Park, Niall McLaughlin, Ihsen Alouani; Proceedings of the Computer Vis
ion and Pattern Recognition Conference (CVPR), 2025, pp. 10235-10243
Adversarial attacks remain a significant threat that can jeopardize the integrit
y of Machine Learning (ML) models. In particular, query-based black-box attacks
can generate malicious noise without having access to the victim model's archite
cture, making them practical in real-world contexts. The community has proposed
several defenses against adversarial attacks, only to be broken by more advanced
 and adaptive attack strategies. In this paper, we propose a framework that det
ects if an adversarial noise instance is being generated. Unlike existing statef
ul defenses that detect adversarial noise generation by monitoring the input spa
ce, our approach learns adversarial patterns in the input update similarity spac
e. In fact, we propose to observe a new metric called Delta Similarity (DS), whi
ch we show it captures more efficiently the adversarial behavior.We evaluate our
 approach against 8 state-of-the-art attacks, including adaptive attacks, where
the adversary is aware of the defense and tries to evade detection. We find that
 our approach is significantly more robust than existing defenses both in terms
of specificity and sensitivity.

Consistent Normal Orientation for 3D Point Clouds via Least Squares on Delaunay
Graph
Rao Fu, Jianmin Zheng, Liang Yu; Proceedings of the Computer Vision and Pattern
Recognition Conference (CVPR), 2025, pp. 16932-16942
The orientation of surface normals in 3D point cloud is a fundamental problem in
 computer vision and graphics. Determining a globally consistent orientation sol
ely from the point cloud is however challenging due to the global scope of the p
roblem and the discrete nature of point cloud, particularly in the presence of n
oise, outliers, holes, thin structures, and complex topologies. This paper prese
nts an efficient, robust, and global algorithm for generating consistent normal
orientation of a dense 3D point cloud. The basic idea is to transform the origin
al binary normal orientation problem to finding a relaxed sign field on a Delaun
ay graph, which can be achieved by solving a sparse linear system. The Delaunay
graph is constructed by triangulating a level set of an implicit function define
d from the input point cloud. The shape diameter function is estimated to serve
as a prior for determining an appropriate level value such that the level set im
plicitly defines the inner and outer shells enclosing the input point clouds. As
 such, our algorithm leverages the strengths of the shape diameter function, Del
aunay triangulation, and the least-square techniques, making the underlying proc
esses take both geometry and topology into consideration, and thus provides an e
fficient and robust solution for handling point clouds with complicated geometry
 and topology. Extensive experiments on various shapes with noise and outliers c
onfirm the effectiveness and robustness of our algorithm.

GaussianWorld: Gaussian World Model for Streaming 3D Occupancy Prediction
Sicheng Zuo, Wenzhao Zheng, Yuanhui Huang, Jie Zhou, Jiwen Lu; Proceedings of th
e Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 6772-6781
3D occupancy prediction is important for autonomous driving due to its comprehen
sive perception of the surroundings. To incorporate sequential inputs, most exis
ting methods fuse representations from previous frames to infer the current 3D o
ccupancy. However, they fail to consider the continuity of driving scenarios and
 ignore the strong prior provided by the evolution of 3D scenes (e.g., only dyna
mic objects move). In this paper, we propose a world-modelbased framework to exp
loit the scene evolution for perception. We reformulate 3D occupancy prediction
as a 4D occupancy forecasting problem conditioned on the current sensor input. W

e decompose the scene evolution into three factors: 1) ego motion alignment of s
tatic scenes; 2) local movements of dynamic objects; and 3) completion of newly-
observed scenes. We then employ a Gaussian world model (GaussianWorld) to explic
itly exploit these priors and infer the scene evolution in the 3D Gaussian space
 considering the current RGB observation. We evaluate the effectiveness of our f
ramework on the widely used nuScenes dataset. Our GaussianWorld improves the per
formance of the single-frame counterpart by over 2% in mIoU without introducing
additional computations.

ICP: Immediate Compensation Pruning for Mid-to-high Sparsity
Xin Luo, Xueming Fu, Zihang Jiang, S. Kevin Zhou; Proceedings of the Computer Vi
sion and Pattern Recognition Conference (CVPR), 2025, pp. 9487-9496
The increasing adoption of large-scale models under 7 billion parameters in both
 language and vision domains enables inference tasks on a single consumer-grade
GPU but makes fine-tuning models of this scale, especially 7B models, challengin
g. This limits the applicability of pruning methods that require full fine-tunin
g. Meanwhile, pruning methods that do not require fine-tuning perform well at lo
w sparsity levels (10%-50%) but struggle at mid-to-high sparsity levels (50%-70%
), where the error behaves equivalently to that of semi-structured pruning. To a
ddress these issues, this paper introduces ICP, which finds a balance between fu
ll fine-tuning and zero fine-tuning. First, Sparsity Rearrange is used to reorga
nize the predefined sparsity levels, followed by Block-wise Compensate Pruning,
which alternates pruning and compensation on the model's backbone, fully utilizi
ng inference results while avoiding full model fine-tuning. Experiments show tha
t ICP improves performance at mid-to-high sparsity levels compared to baselines,
 with only a slight increase in pruning time and no additional peak memory overh
ead.

VinaBench: Benchmark for Faithful and Consistent Visual Narratives
Silin Gao, Sheryl Mathew, Li Mi, Sepideh Mamooler, Mengjie Zhao, Hiromi Wakaki,
Yuki Mitsufuji, Syrielle Montariol, Antoine Bosselut; Proceedings of the Compute
r Vision and Pattern Recognition Conference (CVPR), 2025, pp. 2870-2879
Visual narrative generation transforms textual narratives into sequences of imag
es illustrating the content of the text. However, generating visual narratives t
hat are faithful to the input text and self-consistent across generated images r
emains an open challenge, due to the lack of knowledge constraints used for plan
ning the stories. In this work, we propose a new benchmark, VinaBench, to addres
s this challenge. Our benchmark annotates the underlying commonsense and discour
se constraints in visual narrative samples, offering systematic scaffolds for le
arning the implicit strategies of visual storytelling. Based on the incorporated
 narrative constraints, we further propose novel metrics to closely evaluate the
 consistency of generated narrative images and the alignment of generations with
 the input textual narrative. Our results across three generative vision models
demonstrate that learning with VinaBench's knowledge constraints effectively imp
roves the faithfulness and cohesion of generated visual narratives.

ATA: Adaptive Transformation Agent for Text-Guided Subject-Position Variable Bac
kground Inpainting
Yizhe Tang, Zhimin Sun, Yuzhen Du, Ran Yi, Guangben Lu, Teng Hu, Luying Li, Lizh
uang Ma, Fangyuan Zou; Proceedings of the Computer Vision and Pattern Recognitio
n Conference (CVPR), 2025, pp. 18335-18345
Image inpainting aims to fill the missing region of an image.Recently, there has
 been a surge of interest in foreground-conditioned background inpainting, a sub
-task that fills the background of an image while the foreground subject and ass
ociated text prompt are provided.Existing background inpainting methods typicall
y strictly preserve the subject's original position from the source image,result
ing in inconsistencies between the subject and the generated background.To addre
ss this challenge, we propose a new task, the "Text-Guided Subject-Position Vari
able Background Inpainting", which aims to dynamically adjust the subject positi
on to achieve a harmonious relationship between the subject andthe inpainted bac

kground, and propose the Adaptive Transformation Agent (A^\text T A) for this ta sk.Firstly, we design a PosAgent Block that adaptively predicts an appropriate d isplacement based on given features to achieve variable subject-position.Secondl y, we design the Reverse Displacement Transform (RDT) module, which arranges mul tiple PosAgent blocks in a reverse structure, to transform hierarchical feature maps from deep to shallow based on semantic information.Thirdly, we equip A^\tex t T A with a Position Switch Embedding to control whether the subject's position in the generated image is adaptively predicted or fixed.Extensive comparative e xperiments validate the effectiveness of our A^\text T A approach, which not onl y demonstrates superior inpainting capabilities in subject-position variable inp ainting, but also ensures good performance on subject-position fixed inpainting.

Optimizing for the Shortest Path in Denoising Diffusion Model

Ping Chen, Xingpeng Zhang, Zhaoxiang Liu, Huan Hu, Xiang Liu, Kai Wang, Min Wang , Yanlin Qian, Shiguo Lian; Proceedings of the Computer Vision and Pattern Recog nition Conference (CVPR), 2025, pp. 18021-18030

In this research, we propose a novel denoising diffusion model based on shortest -path modeling that optimizes residual propagation to enhance both denoising eff iciency and quality. Drawing on Denoising Diffusion Implicit Models (DDIM) and i nsights from graph theory, our model, termed the Shortest Path Diffusion Model (ShortDF), treats the denoising process as a shortest-path problem aimed at minim izing reconstruction error. By optimizing the initial residuals, we improve the efficiency of the reverse diffusion process and the quality of the generated sam ples. Extensive experiments on multiple standard benchmarks demonstrate that Sho rtDF significantly reduces diffusion time (or steps) while enhancing the visual fidelity of generated samples compared to prior methods. This work, we suppose, paves the way for interactive diffusion-based applications and establishes a fou ndation for rapid data generation. Code is available at https://github.com/Unico mAI/ShortDF.

Antidote: A Unified Framework for Mitigating LVLM Hallucinations in Counterfactu al Presupposition and Object Perception

Yuanchen Wu, Lu Zhang, Hang Yao, Junlong Du, Ke Yan, Shouhong Ding, Yunsheng Wu, Xiaoqiang Li; Proceedings of the Computer Vision and Pattern Recognition Confer ence (CVPR), 2025, pp. 14646-14656

Large Vision-Language Models (LVLMs) have achieved impressive results across var ious cross-modal tasks. However, hallucinations, i.e., the models generating cou nterfactual responses, remain a challenge. Though recent studies have attempted to alleviate object perception hallucinations, they focus on the models' respons e generation, and overlook the task question itself. This paper discusses the vu lnerability of LVLMs in solving counterfactual presupposition questions (CPQs), where the models are prone to accept the presuppositions of counterfactual objec ts and produce severe hallucinatory responses. To this end, we introduce "Antido te", a unified, synthetic data-driven post-training framework for mitigating bot h types of hallucination above. It leverages synthetic data to incorporate factu al priors into questions to achieve self-correction, and decouples the mitigatio n process into a preference optimization problem. Furthermore, we construct "CP-Bench", a novel benchmark to evaluate LVLMs' ability to correctly handle CPQs an d produce factual responses. Applied to the LLaVA series, Antidote can simultane ously enhance performance on CP-Bench by over 50%, POPE by 1.8-3.3%, and CHAIR & SHR by 30-50%, all without relying on external supervision from stronger LVLMs or human feedback and without introducing noticeable catastrophic forgetting iss ues.

Language-Guided Audio-Visual Learning for Long-Term Sports Assessment

Huangbiao Xu, Xiao Ke, Huanqi Wu, Rui Xu, Yuezhou Li, Wenzhong Guo; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 2396 7-23977

Long-term sports assessment is a challenging task in video understanding since i t requires judging complex movement variations and action-music coordination. Ho

wever, there is no direct correlation between the diverse background music and m
ovements in sporting events. Previous works require a large number of model para
meters to learn potential associations between actions and music. To address thi
s issue, we propose a language-guided audio-visual learning (MLAVL) framework th
at models "audio-action-visual" correlations guided by low-cost language modalit
y. In our framework, multidimensional domain-based actions form action knowledge
 graphs, motivating audio-visual modalities to focus on task-relevant actions. W
e further design a shared-specific context encoder to integrate deep multimodal
semantics, and an audio-visual cross-modal fusion module to evaluate action-musi
c consistency. To match the sport's rules, we then propose a dual-branch prompt-
guided grading module to weigh both visual and audio-visual performance. Extensi
ve experiments demonstrate that our approach achieves state-of-the-art on four p
ublic long-term sports benchmarks while maintaining low parameters. Our code is
available at https://github.com/XuHuangbiao/MLAVL.

Dynamic Pseudo Labeling via Gradient Cutting for High-Low Entropy Exploration
Jae Hyeon Park, Joo Hyeon Jeon, Jae Yun Lee, Sangyeon Ahn, Min Hee Cha, Min Geol
 Kim, Hyeok Nam, Sung In Cho; Proceedings of the Computer Vision and Pattern Rec
ognition Conference (CVPR), 2025, pp. 20602-20611
This study addresses the limitations of existing dynamic pseudo-labeling (DPL) t
echniques, which often utilize static or dynamic thresholds for confident sample
 selection. The existing methods fail to capture the non-linear relationship bet
ween task accuracy and model confidence, particularly in the context of overconf
idence. This can limit the model's learning opportunities for high entropy sampl
es that significantly influence a model's generalization ability. To solve this,
 we propose a novel gradient pass-based DPL technique that incorporates the high
-entropy samples, which are typically overlooked. Our approach introduces two cl
assifiers--low gradient pass (LGP) and high gradient pass (HGP)--to derive over-
 and under-confident dynamic thresholds that indicate the class-wise overconfide
nce acceleration, respectively. By combining the under- and over-confident state
s from the GP classifiers, we create a more adaptive and accurate PL method. Our
 main contributions highlight the importance of considering both low and high-co
nfidence samples in enhancing the model's robustness and generalization for impr
oved PL performance.

VODiff: Controlling Object Visibility Order in Text-to-Image Generation
Dong Liang, Jinyuan Jia, Yuhao Liu, Zhanghan Ke, Hongbo Fu, Rynson W. H. Lau; Pr
oceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025
, pp. 18379-18389
Recent advancements in diffusion models have significantly enhanced the performa
nce of text-to-image models in image synthesis. To enable control over the the s
patial locations of the generated objects,diffusion-based methods typically util
izeobject layout as an auxiliary input. However, we observe that this approach t
reats all objects as being on the same layer and neglect their visibility order,
 leading to the synthesis of overlapping objects with incorrect occlusions.To ad
dress this limitation, we introduce in this paper a new training-free framework
that considers object visibility order explicitly and allows users to place over
lapping objects in a stack of layers. Our framework consists of two visibility-b
ased designs. First, we propose a novel Sequential Denoising Process (SDP) to di
vide the whole image generation into multiple stages for different objects, each
 stage primarily focuses on an object. Second, we propose a novel Visibility-Ord
er-Aware (VOA) Loss to transform the layout and occlusion constraints into an at
tention map optimization process to improve the accuracy of synthesizing object
occlusions in complex scenes. By merging these two novel components, our framewo
rk, dubbed VODiff, enables the generation of photorealistic images that satisfy
user-specified spatial constraints and object occlusion relationships. In additi
on, we introduce VOBench, a diverse benchmark dataset containing 200 curated sam
ples, each with a reference image, text prompts, object visibility orders and la
yout maps. We conduct extensive evaluations on this dataset to demonstrate the s
uperiority of our approach.

Dual Diffusion for Unified Image Generation and Understanding
Zijie Li, Henry Li, Yichun Shi, Amir Barati Farimani, Yuval Kluger, Linjie Yang, Peng Wang; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 2779-2790
Diffusion models have gained tremendous success in text-to-image generation, yet still struggle with visual understanding tasks, an area dominated by autoregressive vision-language models. We propose a large-scale and fully end-to-end diffusion model for multi-modal understanding and generation that significantly improves on existing diffusion-based multimodal models, and is the first of its kind to support the full suite of vision-language modeling capabilities. Inspired by the multimodal diffusion transformer (MM-DiT) and recent advances in discrete diffusion language modeling, we leverage a cross-modal maximum likelihood estimation framework that simultaneously trains the conditional likelihoods of both images and text jointly under a single loss function, which is back-propagated through both branches of the diffusion transformer. The resulting model is highly flexible and capable of a wide range of tasks including image generation, captioning, and visual question answering. Our model attained competitive performance compared to recent unified image understanding and generation models, demonstrating the potential of multimodal diffusion modeling as a promising alternative to autoregressive next-token prediction models.
****
WeakMCN: Multi-task Collaborative Network for Weakly Supervised Referring Expression Comprehension and Segmentation
Silin Cheng, Yang Liu, Xinwei He, Sebastien Ourselin, Lei Tan, Gen Luo; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 9175-9185
Weakly supervised referring expression comprehension (WREC) and segmentation (WRES) aim to learn object grounding based on a given expression using weak supervision signals like image-text pairs. While these tasks have traditionally been modeled separately, we argue that they can benefit from joint learning in a multi-task framework. To this end, we propose WeakMCN, a novel multi-task collaborative network that effectively combines WREC and WRES with a dual-branch architecture. Specifically, the WREC branch is formulated as anchor-based contrastive learning, which also acts as a teacher to supervise the WRES branch. In WeakMCN, we propose two innovative designs to facilitate multi-task collaboration, namely Dynamic Visual Feature Enhancement (DVFE) and Collaborative Consistency Module (CCM). DVFE dynamically combines various pre-trained visual knowledge to meet different task requirements, while CCM promotes cross-task consistency from the perspective of optimization. Extensive experimental results on three popular REC and RES benchmarks, i.e., RefCOCO, RefCOCO+, and RefCOCOg, consistently demonstrate performance gains of WeakMCN over state-of-the-art single-task alternatives, e.g., up to 3.91% and 13.11% on RefCOCO for WREC and WRES tasks, respectively. Furthermore, experiments also validate the strong generalization ability of WeakMCN in both semi-supervised REC and RES settings against existing methods, e.g., +8.94% for semi-REC and +7.71% for semi-RES on 1% RefCOCO.

CAD-Llama: Leveraging Large Language Models for Computer-Aided Design Parametric 3D Model Generation
Jiahao Li, Weijian Ma, Xueyang Li, Yunzhong Lou, Guichun Zhou, Xiangdong Zhou; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 18563-18573
Recently, Large Language Models (LLMs) have achieved significant success, prompting increased interest in expanding their generative capabilities beyond general text into domain-specific areas. This study investigates the generation of parametric sequences for computer-aided design (CAD) models using LLMs. This endeavor represents an initial step towards creating parametric 3D shapes with LLMs, as CAD model parameters directly correlate with shapes in three-dimensional space. Despite the formidable generative capacities of LLMs, this task remains challenging, as these models neither encounter parametric sequences during their pretra

ining phase nor possess direct awareness of 3D structures. To address this, we p
resent CAD-Llama, a framework designed to enhance pretrained LLMs for generating
 parametric 3D CAD models. Specifically, we develop a hierarchical annotation pi
peline and a code-like format to translate parametric 3D CAD command sequences i
nto Structured Parametric CAD Code (SPCC), incorporating hierarchical semantic d
escriptions. Furthermore, we propose an adaptive pretraining approach utilizing
 SPCC, followed by an instruction tuning process aligned with CAD-specific guidel
ines. This methodology aims to equip LLMs with the spatial knowledge inherent in
 parametric sequences. Experimental results demonstrate that our framework signi
ficantly outperforms prior autoregressive methods and existing LLM baselines.

Leveraging SD Map to Augment HD Map-based Trajectory Prediction
Zhiwei Dong, Ran Ding, Wei Li, Peng Zhang, Guobin Tang, Jia Guo; Proceedings of
 the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 17219-1
7228
Latest trajectory prediction models in real-world autonomous driving systems oft
en rely on online High-Definition (HD) maps to understand the road environment.H
owever, online HD maps suffer from perception errors and feature redundancy, whi
ch hinder the performance of HD map-based trajectory prediction models.To addres
s these issues, we introduce a framework, termed SD map-Augmented Trajectory Pre
diction (SATP), which leverages Standard-Definition (SD) maps to enhance HD map-
based trajectory prediction models.First, we propose an SD-HD fusion approach to
 leverage SD maps across the diverse range of HD map-based trajectory prediction
 models. Second, we design a novel AlignNet to align the SD map with the HD map,
 further improving the effectiveness of SD maps. Experiments on real-world auton
omous driving benchmarks demonstrate that SATP not only improves the performance
 of HD map-based trajectory prediction up to 25% in real-world scenarios using o
nline HD maps but also brings benefits in ideal scenarios with ground-truth HD m
aps.

4DGC: Rate-Aware 4D Gaussian Compression for Efficient Streamable Free-Viewpoint
 Video
Qiang Hu, Zihan Zheng, Houqiang Zhong, Sihua Fu, Li Song, Xiaoyun Zhang, Guangta
o Zhai, Yanfeng Wang; Proceedings of the Computer Vision and Pattern Recognition
 Conference (CVPR), 2025, pp. 875-885
3D Gaussian Splatting (3DGS) has substantial potential for enabling photorealist
ic Free-Viewpoint Video (FVV) experiences. However, the vast number of Gaussians
 and their associated attributes poses significant challenges for storage and tr
ansmission. Existing methods typically handle dynamic 3DGS representation and co
mpression separately, neglecting motion information and the rate-distortion (RD)
 trade-off during training, leading to performance degradation and increased mod
el redundancy. To address this gap, we propose 4DGC, a novel rate-aware 4D Gauss
ian compression framework that significantly reduces storage size while maintai
ning superior RD performance for FVV. Specifically, 4DGC introduces a motion-awa
re dynamic Gaussian representation that utilizes a compact motion grid combined
with sparse compensated Gaussians to exploit inter-frame similarities. This repr
esentation effectively handles large motions, preserving quality and reducing te
mporal redundancy. Furthermore, we present an end-to-end compression scheme that
 employs differentiable quantization and a tiny implicit entropy model to compre
ss the motion grid and compensated Gaussians efficiently. The entire framework i
s jointly optimized using a rate-distortion trade-off. Extensive experiments dem
onstrate that 4DGC supports variable bitrates and consistently outperforms exist
ing methods in RD performance across multiple datasets.

ONDA-Pose: Occlusion-Aware Neural Domain Adaptation for Self-Supervised 6D Objec
t Pose Estimation
Tao Tan, Qiulei Dong; Proceedings of the Computer Vision and Pattern Recognition
 Conference (CVPR), 2025, pp. 16829-16838
Self-supervised 6D object pose estimation has received increasing attention in c
omputer vision recently. Some typical works in literature attempt to translate t

he synthetic images with object pose labels generated by object CAD models into the real domain, and then use the translated data for training. However, their performance is generally limited, since (i) there still exists a domain gap between the translated images and the real images and (ii) the translated images cannot sufficiently reflect occlusions that exist in many real images. To address these problems, we propose an Occlusion-Aware Neural Domain Adaptation method for self-supervised 6D object Pose estimation, called ONDA-Pose. The proposed method comprises three main steps. Firstly, by utilizing both the training real images without pose labels and a CAD model, we explore a CAD-like radiance field for rendering corresponding synthetic images that have similar textures to those generated by the CAD model. Then, a backbone pose estimator trained on the synthetic data is employed to provide initial pose estimations for the synthetic images rendered from the CAD-like radiance field, and the initial object poses are refined by a global object pose refiner to generate pseudo object pose labels. Finally, the backbone pose estimator is further self-supervised as the final pose estimator by jointly utilizing the real images with pseudo object pose labels and the synthetic images rendered from the CAD-like radiance field. Experimental results on three public datasets demonstrate that ONDA-Pose significantly outperforms the comparative state-of-the-art methods in most cases.

Teller: Real-Time Streaming Audio-Driven Portrait Animation with Autoregressive Motion Generation

Dingcheng Zhen, Shunshun Yin, Shiyang Qin, Hou Yi, Ziwei Zhang, Siyuan Liu, Gan Qi, Ming Tao; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 21075-21085

In this work, we introduce the first autoregressive framework for real-time, audio-driven portrait animation, a.k.a, talking head. Beyond the challenge of lengthy animation times, a critical challenge in realistic talking head generation lies in preserving the natural movement of diverse body parts. To this end, we propose Teller, the first streaming audio-driven protrait animation framework with autoregressive motion generation. Specifically, Teller first decomposes facial and body detail animation into two components: Facial Motion Latent Generation (FMLG) based on an autoregressive transfromer, and movement authenticity refinement using a Efficient Temporal Module (ETM).Concretely, FMLG employs a Residual VQ model to map the facial motion latent from the implicit keypoint-based model into discrete motion tokens, which are then temporally sliced with audio embeddings. This enables the AR tranformer to learn real-time, stream-based mappings from audio to motion.Furthermore, Teller incorporate ETM to capture finer motion details. This module ensures the physical consistency of body parts and accessories, such as neck muscles and earrings, improving the realism of these movements.Teller is designed to be efficient, surpassing the inference speed of diffusion-based models (Hallo 20.93s vs. Teller 0.92s for one second video generation), and achieves a real-time streaming performance of up to 25 FPS. Extensive experiments demonstrate that our method outperforms recent audio-driven portrait animation models, especially in small movements, as validated by human evaluations with a significant margin in quality and realism.

GASP: Gaussian Avatars with Synthetic Priors

Jack Saunders, Charlie Hewitt, Yanan Jian, Marek Kowalski, Tadas Baltrusaitis, Yiye Chen, Darren Cosker, Virginia Estellers, Nicholas Gydé, Vinay P. Namboodiri, Benjamin E. Lundell; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 271-280

Gaussian Splatting has changed the game for real-time photo-realistic rendering. One of the most popular applications of Gaussian Splatting is to create animatable avatars, known as Gaussian Avatars. Recent works have pushed the boundaries of quality and rendering efficiency but suffer from two main limitations. Either they require expensive multi-camera rigs to produce avatars with free-view rendering, or they can be trained with a single camera but only rendered at high quality from this fixed viewpoint. An ideal model would be trained using a short monocular video or image from available hardware, such as a webcam, and rendered f

rom any view. To this end, we propose GASP: Gaussian Avatars with Synthetic Priors. To overcome the limitations of existing datasets, we exploit the pixel-perfect nature of synthetic data to train a Gaussian Avatar prior. By fitting this prior model to a single photo or videoand fine-tuning it, we get a high-quality Gaussian Avatar, which supports 360^\circ rendering. Our prior is only required for fitting, not inference, enabling real-time application. Through our method, we obtain high-quality, animatable Avatars from limited data which can be animated and rendered at 70fps on commercial hardware.

Q-PART: Quasi-Periodic Adaptive Regression with Test-time Training for Pediatric Left Ventricular Ejection Fraction Regression

Jie Liu, Tiexin Qin, Hui Liu, Yilei Shi, Lichao Mou, Xiao Xiang Zhu, Shiqi Wang, Haoliang Li; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 15560-15569

In this work, we address the challenge of adaptive pediatric Left Ventricular Ejection Fraction (LVEF) assessment. While Test-time Training (TTT) approaches show promise for this task, they suffer from two significant limitations. Existing TTT works are primarily designed for classification tasks rather than continuous value regression, and they lack mechanisms to handle the quasi-periodic nature of cardiac signals. To tackle these issues, we propose a novel Quasi-Periodic Adaptive Regression with Test-time Training (Q-PART) framework. In the training stage, the proposed Quasi-Period Network decomposes the echocardiogram into periodic and aperiodic components within latent space by combining parameterized helix trajectories with Neural Controlled Differential Equations. During inference, our framework further employs a variance minimization strategy across image augmentations that simulate common quality issues in echocardiogram acquisition, along with differential adaptation rates for periodic and aperiodic components. Theoretical analysis is provided to demonstrate that our variance minimization objective effectively bounds the regression error under mild conditions. Furthermore, extensive experiments across three pediatric age groups demonstrate that Q-PART not only significantly outperforms existing approaches in pediatric LVEF prediction, but also exhibits strong clinical screening capability with high mAUROC scores (up to 0.9747) and maintains gender-fair performance across all metrics, validating its robustness and practical utility in pediatric echocardiography analysis.

Composing Parts for Expressive Object Generation

Harsh Rangwani, Aishwarya Agarwal, Kuldeep Kulkarni, R. Venkatesh Babu, Srikrishna Karanam; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 13209-13219

Image composition and generation are processes where the artists need control over various parts of the generated images. However, the current state-of-the-art generation models, like Stable Diffusion, cannot handle fine-grained part-level attributes in the text prompts. Specifically, when additional attribute details are added to the base text prompt, these text-to-image models either generate an image vastly different from the image generated from the base prompt or ignore the attribute details. To mitigate these issues, we introduce PartComposer, a training-free method that enables image generation based on fine-grained part-level attributes specified for objects in the base text prompt. This allows more control for artists and enables novel object compositions by combining distinctive object parts. PartComposer first localizes object parts by denoising the object region from a specific diffusion process. This enables each part token to be localized to the right region. After obtaining part masks, we run a localized diffusion process in each part region based on fine-grained part attributes and combine them to produce the final image. All stages of PartComposer are based on repurposing a pre-trained diffusion model, which enables it to generalize across domains. We demonstrate the effectiveness of part-level control provided by PartComposer through qualitative visual examples and quantitative comparisons with contemporary baselines.

CarPlanner: Consistent Auto-regressive Trajectory Planning for Large-Scale Reinforcement Learning in Autonomous Driving

Dongkun Zhang, Jiaming Liang, Ke Guo, Sha Lu, Qi Wang, Rong Xiong, Zhenwei Miao, Yue Wang; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 17239-17248

Trajectory planning is vital for autonomous driving, ensuring safe and efficient navigation in complex environments. While recent learning-based methods, particularly reinforcement learning (RL), have shown promise in specific scenarios, RL planners struggle with training inefficiencies and managing large-scale, real-world driving scenarios.In this paper, we introduce CarPlanner, a Consistent auto-regressive Planner that uses RL to generate multi-modal trajectories. The auto-regressive structure enables efficient large-scale RL training, while the incorporation of consistency ensures stable policy learning by maintaining coherent temporal consistency across time steps. Moreover, CarPlanner employs a generation-selection framework with an expert-guided reward function and an invariant-view module, simplifying RL training and enhancing policy performance.Extensive analysis demonstrates that our proposed RL framework effectively addresses the challenges of training efficiency and performance enhancement, positioning CarPlanner as a promising solution for trajectory planning in autonomous driving.To the best of our knowledge, we are the first to demonstrate that the RL-based planner can surpass both IL- and rule-based state-of-the-arts (SOTAs) on the challenging large-scale real-world dataset nuPlan. Our proposed CarPlanner surpasses RL-, IL-, and rule-based SOTA approaches within this demanding dataset.

Apply Hierarchical-Chain-of-Generation to Complex Attributes Text-to-3D Generation

Yiming Qin, Zhu Xu, Yang Liu; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 18521-18530

Recent text-to-3D generation models have demonstrated remarkable abilities in producing high-quality 3D assets. Despite their great advancements, current models struggle to generate satisfying 3D objects with complex attributes. The difficulty for such complex attributes 3D generation arises from two aspects: (1) existing text-to-3D approaches typically lift text-to-image models to extract semantics via text encoders, while the text encoder exhibits limited comprehension ability for long descriptions, leading to deviated cross-attention focus, subsequently wrong attribute binding in generated results. (2) Objects with complex attributes often exhibit occlusion relationships between different parts, which demands a reasonable generation order as well as explicit disentanglement of different parts to enable structural coherent and attribute following results. Though some works introduce manual efforts to alleviate the above issues, their quality is unstable and highly reliant on manual information. To tackle above problems, we propose a automated method Hierarchical-Chain-of-Generation (HCoG). It leverages a large language model to analyze the long description, decomposes it into several blocks representing different object parts, and organizes an optimal generation order from in to out according to the occlusion relationship between parts, turning the whole generation process into a hierarchical chain. For optimization within each block, we first generate the necessary components coarsely, then bind their attributes precisely by target region localization and corresponding 3D Gaussian kernel optimization. For optimization between blocks, we introduce Gaussian Extension and Label Elimination to seamlessly generate new parts by extending new Gaussian kernels, re-assigning semantic labels, and eliminating unnecessary kernels, ensuring that only relevant parts are added without disrupting previously optimized parts. Experiments validate HCoG's effectiveness in handling complex attributes 3D assets and witnesses high-quality results. The code is available at https://github.com/Wakals/GASCOL.

PersonaHOI: Effortlessly Improving Face Personalization in Human-Object Interaction Generation

Xinting Hu, Haoran Wang, Jan Eric Lenssen, Bernt Schiele; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 23775-23784

We introduce PersonaHOI, a training- and tuning-free framework that fuses a general StableDiffusion model with a personalized face diffusion (PFD) model to generate identity-consistent human-object interaction (HOI) images. While existing PFD models have advanced significantly, they often overemphasize facial features at the expense of full-body coherence, PersonaHOI introduces an additional StableDiffusion (SD) branch guided by HOI-oriented text inputs. By incorporating cross-attention constraints in the PFD branch and spatial merging at both latent and residual levels, PersonaHOI preserves personalized facial details while ensuring interactive non-facial regions. Experiments, validated by a novel interaction alignment metric, demonstrate the superior realism and scalability of PersonaHOI, establishing a new standard for practical personalized face with HOI generation. Code is available at https://github.com/JoyHuYY1412/PersonaHOI.

Video-Panda: Parameter-efficient Alignment for Encoder-free Video-Language Models

Jinhui Yi, Syed Talal Wasim, Yanan Luo, Muzammal Naseer, Juergen Gall; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 24119-24128

We present an efficient encoder-free approach for video-language understanding that achieves competitive performance while significantly reducing computational overhead. Current video-language models typically rely on heavyweight image encoders (300M-1.1B parameters) or video encoders (1B-1.4B parameters), creating a substantial computational burden when processing multi-frame videos. Our method introduces a novel Spatio-Temporal Alignment Block (STAB) that directly processes video inputs without requiring pre-trained encoders while using only 45M parameters for visual processing - at least a 6.5x reduction compared to traditional approaches. The STAB architecture combines Local Spatio-Temporal Encoding for fine-grained feature extraction, efficient spatial downsampling through learned attention and separate mechanisms for modeling frame-level and video-level relationships. Our model achieves comparable or superior performance to encoder-based approaches for open-ended video question answering on standard benchmarks. The fine-grained video question-answering evaluation demonstrates our model's effectiveness, outperforming the encoder-based approaches Video-ChatGPT and Video-LLaVA in key aspects like correctness and temporal understanding. Extensive ablation studies validate our architectural choices and demonstrate the effectiveness of our spatio-temporal modeling approach while achieving 3-4x faster processing speeds than previous methods. Code is available at https://jh-yi.github.io/Video-Panda.

COSMIC: Clique-Oriented Semantic Multi-space Integration for Robust CLIP Test-Time Adaptation

Fanding Huang, Jingyan Jiang, Qinting Jiang, Hebei Li, Faisal Nadeem Khan, Zhi Wang; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 9772-9781

Recent vision-language models (VLMs) face significant challenges in test-time adaptation to novel domains. While cache-based methods show promise by leveraging historical information, they struggle with both caching unreliable feature-label pairs and indiscriminately using single-class information during querying, significantly compromising adaptation accuracy. To address these limitations, we propose COSMIC (\underline C lique-\underline O riented \underline S emantic \underline M ulti-space \underline I ntegration for \underline C LIP), a robust test-time adaptation framework that enhances adaptability through multi-granular, cross-modal semantic caching and graph-based querying mechanisms. Our framework introduces two key innovations: Dual Semantics Graph (DSG) and Clique Guided Hyper-class (CGH). The Dual Semantics Graph constructs complementary semantic spaces by incorporating textual features, coarse-grained CLIP features, and fine-grained DINOv2 features to capture rich semantic relationships. Building upon these dual graphs, the Clique Guided Hyper-class component leverages structured class relationships to enhance prediction robustness through correlated class selection. Extensive experiments demonstrate COSMIC's superior performance across multiple b

enchmarks, achieving significant improvements over state-of-the-art methods: 15.81% gain on out-of-distribution tasks and 5.33% on cross-domain generation with CLIP RN-50.

MonoSplat: Generalizable 3D Gaussian Splatting from Monocular Depth Foundation Models
Yifan Liu, Keyu Fan, Weihao Yu, Chenxin Li, Hao Lu, Yixuan Yuan; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 21570-21579
Recent advances in generalizable 3D Gaussian Splatting have demonstrated promising results in real-time high-fidelity rendering without per-scene optimization, yet existing approaches still struggle to handle unfamiliar visual content during inference on novel scenes due to limited generalizability. To address this challenge, we introduce MonoSplat, a novel framework that leverages rich visual priors from pre-trained monocular depth foundation models for robust Gaussian reconstruction. Our approach consists of two key components: a Mono-Multi Feature Adapter that transforms monocular features into multi-view representations, coupled with an Integrated Gaussian Prediction module that effectively fuses both feature types for precise Gaussian generation. Through the Adapter's lightweight attention mechanism, features are seamlessly aligned and aggregated across views while preserving valuable monocular priors, enabling the Prediction module to generate Gaussian primitives with accurate geometry and appearance. Through extensive experiments on diverse real-world datasets, we convincingly demonstrate that MonoSplat achieves superior reconstruction quality and generalization capability compared to existing methods while maintaining computational efficiency with minimal trainable parameters. Codes are available at \href https://github.com/CUHK-AIM-Group/MonoSplat https://github.com/CUHK-AIM-Group/MonoSplat .

Hybrid Global-Local Representation with Augmented Spatial Guidance for Zero-Shot Referring Image Segmentation
Ting Liu, Siyuan Li; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 29634-29643
Recent advances in zero-shot referring image segmentation (RIS), driven by models such as the Segment Anything Model (SAM) and CLIP, have made substantial progress in aligning visual and textual information. Despite these successes, the extraction of precise and high-quality mask region representations remains a critical challenge, limiting the full potential of RIS tasks. In this paper, we introduce a training-free, hybrid global-local feature extraction approach that integrates detailed mask-specific features with contextual information from the surrounding area, enhancing mask region representation. To further strengthen alignment between mask regions and referring expressions, we propose a spatial guidance augmentation strategy that improves spatial coherence, which is essential for accurately localizing described areas. By incorporating multiple spatial cues, this approach facilitates more robust and precise referring segmentation. Extensive experiments on standard RIS benchmarks demonstrate that our method significantly outperforms existing zero-shot referring segmentation models, achieving substantial performance gains. We believe our approach advances RIS tasks and establishes a versatile framework for region-text alignment, offering broader implications for cross-modal understanding and interaction. The code will be publicly available.

SOLVE: Synergy of Language-Vision and End-to-End Networks for Autonomous Driving
Xuesong Chen, Linjiang Huang, Tao Ma, Rongyao Fang, Shaoshuai Shi, Hongsheng Li; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 12068-12077
The integration of Vision-Language Models (VLMs) into autonomous driving systems has shown promise in addressing key challenges such as learning complexity, interpretability, and common-sense reasoning. However, existing approaches often struggle with efficient integration and real-time decision-making due to computational demands. In this paper, we introduce SOLVE, an innovative framework that sy

nergizes VLMs with end-to-end (E2E) models to enhance autonomous vehicle plannin
g. Our approach emphasizes knowledge sharing at the feature level through a shar
ed visual encoder, enabling comprehensive interaction between VLM and E2E compon
ents. We propose a Trajectory Chain-of-Thought (T-CoT) paradigm, which progressi
vely refines trajectory predictions, reducing uncertainty and improving accuracy
. By employing a temporal decoupling strategy, SOLVE achieves efficient asynchro
nous cooperation, aligning high-quality VLM outputs with E2E real-time performan
ce. Evaluated on the nuScenes dataset, our method demonstrates significant impro
vements in trajectory prediction accuracy, paving the way for more robust and re
liable autonomous driving systems.

Shift the Lens: Environment-Aware Unsupervised Camouflaged Object Detection
Ji Du, Fangwei Hao, Mingyang Yu, Desheng Kong, Jiesheng Wu, Bin Wang, Jing Xu, P
ing Li; Proceedings of the Computer Vision and Pattern Recognition Conference (C
VPR), 2025, pp. 19271-19282
Camouflaged Object Detection (COD) seeks to distinguish objects from their highl
y similar backgrounds. Existing work has essentially focused on isolating camouf
laged objects from the environment, demonstrating ever-improving performance but
 at the cost of extensive annotations and complex optimizations. In this paper,
we diverge from this paradigm and shift the lens to isolating the salient enviro
nment from the camouflaged object. We introduce EASE, an Environment-Aware unSup
Ervised COD framework that identifies the environment by referencing an environm
ent prototype library and detects camouflaged objects by inverting the retrieved
 environmental features. Specifically, our approach (DiffPro) uses large multimo
dal models, diffusion models, and vision-foundation models to construct the envi
ronment prototype library. To retrieve environments from the library and refrain
 from confusing foreground and background, we incorporate three retrieval scheme
s: Kernel Density Estimation-based Adaptive Threshold (KDE-AT), Global-to-Local
pixel-level retrieval (G2L), and Self-Retrieval (SR). Our experiments demonstrat
e significant improvements over current unsupervised methods, with EASE achievin
g an average gain of over 10% on the COD10K dataset. When integrated with SAM, E
ASE surpasses prompt-based segmentation approaches and performs competitively wi
th state-of-the-art fully-supervised methods. Code is available at https://githu
b.com/xiaohainku/EASE.

Probability Density Geodesics in Image Diffusion Latent Space
Qingtao Yu, Jaskirat Singh, Zhaoyuan Yang, Peter Henry Tu, Jing Zhang, Hongdong
Li, Richard Hartley, Dylan Campbell; Proceedings of the Computer Vision and Patt
ern Recognition Conference (CVPR), 2025, pp. 27989-27998
Diffusion models indirectly estimate the probability density over a data space,
which can be used to study its structure. In this work, we show that geodesics c
an be computed in diffusion latent space, where the norm induced by the spatiall
y-varying inner product is inversely proportional to the probability density. In
 this formulation, a path that traverses a high density (that is, probable) regi
on of image latent space is shorter than the equivalent path through a low densi
ty region. We present algorithms for solving the associated initial and boundary
 value problems and show how to compute the probability density along the path a
nd the geodesic distance between two points. Using these techniques, we analyze
how closely video clips approximate geodesics in a pre-trained image diffusion s
pace. Finally, we demonstrate how these techniques can be applied to training-fr
ee image sequence interpolation and extrapolation, given a pre-trained image dif
fusion model.

High-quality Point Cloud Oriented Normal Estimation via Hybrid Angular and Eucli
dean Distance Encoding
Yuanqi Li, Jingcheng Huang, Hongshen Wang, Peiyuan Lv, Yansong Liu, Jiuming Zhen
g, Jie Guo, Yanwen Guo; Proceedings of the Computer Vision and Pattern Recogniti
on Conference (CVPR), 2025, pp. 1287-1296
The proliferation of Light Detection and Ranging (LiDAR) technology has facilita
ted the acquisition of three-dimensional point clouds, which are integral to app

lications in VR, AR, and Digital Twin. Oriented normals, critical for 3D reconst ruction and scene analysis, cannot be directly extracted from scenes using LiDAR due to its operational principles. Previous traditional or learning-based metho ds are prone to inaccuracies due to uneven distribution and noise due to the dep endence on local geometry features. This paper addresses the challenge of estima ting oriented point normals by introducing a point cloud normal estimation frame work via hybrid angular and Euclidean distance encoding (HAE). Our method overco mes the limitations of local geometric information by combining angular and Eucl idean spaces to extract features from both point cloud coordinates and light ray s, leading to more accurate normal estimation. The core of our network consists of an angular distance encoding module, which leverages both ray directions and point coordinates for unoriented normal refinement, and a ray feature fusion mod ule for normal orientation, that is robust to noise. We also provide a point clo ud dataset with ground truth normals, generated a virtual scanner, which reflect s real scanning distributions and noise profiles.

DriveScape: High-Resolution Driving Video Generation by Multi-View Feature Fusio n

Wei Wu, Xi Guo, Weixuan Tang, Tingxuan Huang, Chiyu Wang, Chenjing Ding; Proceed ings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 17187-17196

Recent advancements in generative models offer promising solutions for synthesiz ing realistic driving videos, aiding in training autonomous driving perception m odels. However, existing methods often struggle with high-resolution multi-view generation, mainly due to the significant memory and computational overhead caus ed by simultaneously inputting multi-view videos into denoising diffusion models .In this paper, we propose a driving video generation framework based on multi-v iew feature fusion named DriveScape for multi-view 3D condition-guided video gen eration. We introduce a Bi-Directional Modulated Transformer (BiMoT) module to e ncode, fuse and inject multi-view features along with various 3D road structures and objects, which enables high-resolution multi-view generation. Consequently, our approach allows precise control over video generation, greatly enhancing re alism and providing a robust solution for creating high-quality, multi-view driv ing videos.Our framework achieves state-of-the-art results on the nuScenes datas et, demonstrating impressive generative quality metrics with an FID score of 8.3 4 and an FVD score of 76.39, as well as superior performance across various perc eption tasks. This lays the foundation for more accurate environment simulation in autonomous driving. We plan to make our code and pre-trained model publicly a vailable.Please refer to index.html webpage in the supplementary materials for m ore visualization results.

Training-free Neural Architecture Search through Variance of Knowledge of Deep N etwork Weights

Ondrej Tybl, Lukas Neumann; Proceedings of the Computer Vision and Pattern Recog nition Conference (CVPR), 2025, pp. 14881-14890

Deep learning has revolutionized computer vision, but it achieved its tremendous success using deep network architectures which are mostly hand-crafted and ther efore likely suboptimal. Neural Architecture Search (NAS) aims to bridge this ga p by following a well-defined optimization paradigm which systematically looks f or the best architecture, given objective criterion such as maximal classificati on accuracy. The main limitation of NAS is however its astronomical computationa l cost, as it typically requires training each candidate network architecture fr om scratch.In this paper, we aim to alleviate this limitation by proposing a nov el training-free proxy for image classification accuracy based on Fisher Informa tion. The proposed proxy has a strong theoretical background in statistics and i t allows estimating expected image classification accuracy of a given deep netwo rk without training the network, thus significantly reducing computational cost of standard NAS algorithms. Our training-free proxy achieves state-of-the-art re sults on three public datasets and in two search spaces, both when evaluated usi ng previously proposed metrics, as well as using a new metric that we propose wh

ich we demonstrate is more informative for practical NAS applications. The sourc
e code is publicly available.

Every SAM Drop Counts: Embracing Semantic Priors for Multi-Modality Image Fusion
 and Beyond
Guanyao Wu, Haoyu Liu, Hongming Fu, Yichuan Peng, Jinyuan Liu, Xin Fan, Risheng
Liu; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR
), 2025, pp. 17882-17891
Multi-modality image fusion, particularly infrared and visible, plays a crucial
role in integrating diverse modalities to enhance scene understanding. Although
early research prioritized visual quality, preserving fine details and adapting
to downstream tasks remains challenging. Recent approaches attempt task-specific
 design but rarely achieve "The Best of Both Worlds" due to inconsistent optimiz
ation goals. To address these issues, we propose a novel method that leverages t
he semantic knowledge from the Segment Anything Model (SAM) to grow the quality
of fusion results and enable downstream task adaptability, namely SAGE. Specific
ally, we design a Semantic Persistent Attention (SPA) Module that efficiently ma
intains source information via the persistent repository while extracting high-l
evel semantic priors from SAM. More importantly, to eliminate the impractical de
pendence on SAM during inference, we introduce a bi-level optimization-driven di
stillation mechanism with triplet losses, which allow the student network to eff
ectively extract knowledge. Extensive experiments show that our method achieves
a balance between high-quality visual results and downstream task adaptability w
hile maintaining practical deployment efficiency. The code is available at https
://github.com/RollingPlain/SAGE_IVIF.

EgoLife: Towards Egocentric Life Assistant
Jingkang Yang, Shuai Liu, Hongming Guo, Yuhao Dong, Xiamengwei Zhang, Sicheng Zh
ang, Pengyun Wang, Zitang Zhou, Binzhu Xie, Ziyue Wang, Bei Ouyang, Zhengyu Lin,
 Marco Cominelli, Zhongang Cai, Bo Li, Yuanhan Zhang, Peiyuan Zhang, Fangzhou Ho
ng, Joerg Widmer, Francesco Gringoli, Lei Yang, Ziwei Liu; Proceedings of the Co
mputer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 28885-28900
We introduce EgoLife, a project to develop an egocentric life assistant that acc
ompanies and enhances personal efficiency through AI-powered wearable glasses. T
o lay the foundation for this assistant, we conducted a comprehensive data colle
ction study where six participants lived together for one week, continuously rec
ording their daily activities - including discussions, shopping, cooking, social
izing, and entertainment - using AI glasses for multimodal egocentric video capt
ure, along with synchronized third-person-view video references. This effort res
ulted in the EgoLife Dataset, a comprehensive 300-hour egocentric, interpersonal
, multiview, and multimodal daily life dataset with intensive annotation. Levera
ging this dataset, we introduce EgoLifeQA, a suite of long-context, life-oriente
d question-answering tasks designed to provide meaningful assistance in daily li
fe by addressing practical questions such as recalling past relevant events, mon
itoring health habits, and offering personalized recommendations. To address the
 key technical challenges of (1) developing robust visual-audio models for egoce
ntric data, (2) enabling identity recognition, and (3) facilitating long-context
 question answering over extensive temporal information, we introduce EgoButler,
 an integrated system comprising EgoGPT and EgoRAG. EgoGPT is an omni-modal mode
l trained on egocentric datasets, achieving state-of-the-art performance on egoc
entric video understanding. EgoRAG is a retrieval-based component that supports
answering ultra-long-context questions. Our experimental studies verify their wo
rking mechanisms and reveal critical factors and bottlenecks, guiding future imp
rovements. By releasing our datasets, models, and benchmarks, we aim to stimulat
e further research in egocentric AI assistants.
****

RAEncoder: A Label-Free Reversible Adversarial Examples Encoder for Dataset Inte
llectual Property Protection
Fan Xing, Zhuo Tian, Xuefeng Fan, Xiaoyi Zhou; Proceedings of the Computer Visio
n and Pattern Recognition Conference (CVPR), 2025, pp. 20665-20674

Reversible Adversarial Examples (RAE) are designed to protect the intellectual p
roperty of datasets. Such examples can function as imperceptible adversarial exa
mples to erode the model performance of unauthorized users while allowing author
ized users to remove the adversarial perturbations and recover the original samp
les for normal model training. With the rise of Self-Supervised Learning (SSL),
an increasing number of unlabeled datasets and pre-trained encoders are availabl
e in the community. However, existing RAE methods not only rely on well-labeled
datasets for training Supervised Learning (SL) models but also exhibit poor adve
rsarial transferability when attacking SSL pre-trained encoders. To address thes
e challenges, we propose RAEncoder, the first framework for RAEs without the nee
d for labeled samples. RAEncoder aims to generate universal adversarial perturba
tions by targeting SSL pre-trained encoders. Unlike traditional RAE approaches,
the pre-trained encoder outputs the feature distribution of the protected datase
t rather than classification labels, enhancing both the attack success rate and
transferability of RAEs. Extensive experiments are conducted on six pre-trained
encoders and four SL models, covering aspects such as imperceptibility and trans
ferability. Our results demonstrate that RAEncoder effectively protects unlabele
d datasets from malicious infringements. Additional robustness experiments furth
er confirm the security of RAEncoder in practical application scenarios.

BrepGiff: Lightweight Generation of Complex B-rep with 3D GAT Diffusion
Hao Guo, Xiaoshui Huang, Hao jiacheng, Yunpeng Bai, Hongping Gan, Yilei Shi; Pro
ceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025,
 pp. 26587-26596
Despite advancements in Computer-Aided-Design (CAD) generation, direct generatio
n of complex Boundary Representation (B-rep) CAD models remains challenging. Thi
s difficulty arises from the parametric nature of B-rep data, complicating the e
ncoding and generation of its geometric and topological information. To address
this, we introduce BrepGiff, a lightweight generation approach for high-quality
and complex B-rep model based on 3D Graph Diffusion. First, we transfer B-rep mo
dels into 3D graphs representation. Specifically, BrepGiff extracts and integrat
es topological and geometric features to construct a 3D graph where nodes corres
pond to face centroids in 3D space, preserving adjacency and degree information.
 Geometric features are derived by sampling points in the UV domain and extracti
ng face and edge features. Then, BrepGiff applies a Graph Attention Network (GAT
) to enforce topological constraints from local to global during the degree-guid
ed diffusion process. With the 3D graph representation and efficient diffusion p
rocess, our method significantly reduces the computational cost and improves the
 quality, thus achieving lightweight generation of complex models. Experiments s
how that BrepGiff can generate complex B-rep models (>100 faces) using only 2 RT
X4090 GPUs, achieving state-of-the-art performance in B-rep generation.

Towards Fine-Grained Interpretability: Counterfactual Explanations for Misclassi
fication with Saliency Partition
Lintong Zhang, Kang Yin, Seong-Whan Lee; Proceedings of the Computer Vision and
Pattern Recognition Conference (CVPR), 2025, pp. 30053-30062
Attribution-based explanation techniques capture key patterns to enhance visual
interpretability. However, these patterns often lack the granularity needed for
insight in fine-grained tasks, particularly in cases of model misclassification,
 where explanations may be insufficiently detailed. To address this limitation,
we propose a fine-grained counterfactual explanation framework that generates bo
th object-level and part-level interpretability, addressing two fundamental ques
tions: (1) which fine-grained features contribute to model misclassification, an
d (2) where dominant local features influence counterfactual adjustments. Our ap
proach yields explainable counterfactuals in a non-generative manner by quantify
ing similarity and weighting component contributions within regions of interest
between correctly classified and misclassified samples. Furthermore, we introduc
e an importance-isolation module grounded in Shapley value contributions, isolat
ing features with region-specific relevance. Extensive experiments demonstrate t
he superiority of our approach in capturing more granular, intuitively meaningfu

l regions, surpassing fine-grained methods.

Prior-free 3D Object Tracking
Xiuqiang Song, Li Jin, Zhengxian Zhang, Jiachen Li, Fan Zhong, Guofeng Zhang, Xueying Qin; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 1200-1209
In this paper, we introduce a novel, truly prior-free 3D object tracking method that operates without given any model or training priors. Unlike existing methods that typically require pre-defined 3D models or specific training datasets as priors, which limit their applicability, our method is free from these constraints. Our method consists of a geometry generation module and a pose optimization module. Its core idea is to enable these two modules to automatically and iteratively enhance each other, thereby gradually building all the necessary information for the tracking task. We thus call the method as Bidirectional Iterative Tracking(BIT). The geometry generation module starts without priors and gradually generates high-precision mesh models for tracking, while the pose optimization module generates additional data during object tracking to further refine the generated models. Moreover, the generated 3D models can be stored and easily reused, allowing for seamless integration into various other tracking systems, not just our methods. Experimental results demonstrate that BIT outperforms many existing methods, even those that extensively utilize prior knowledge, while BIT does not rely on such information. Additionally, the generated 3D models deliver results comparable to actual 3D models, highlighting their superior and innovative qualities. The code is available at https://github.com/songxiuqiang/BIT.git.

LatentHOI: On the Generalizable Hand Object Motion Generation with Latent Hand Diffusion.
Muchen Li, Sammy Christen, Chengde Wan, Yujun Cai, Renjie Liao, Leonid Sigal, Shugao Ma; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 17416-17425
Current research on generating 3D hand-object interaction motion primarily focuses on in-domain objects. Generalization to unseen objects is essential for practical applications, yet it remains both challenging and largely unexplored.In this paper, we propose LatentHOI, a novel approach designed to tackle the challenges of generalizing hand-object interaction to unseen objects.Our main insight lies in decoupling high-level temporal motion from fine-grained spatial hand-object interactions with a latent diffusion model coupled with a Grasping Variational Autoencoder (GraspVAE). This configuration not only enhances the conditional dependency between spatial grasp and temporal motion but also improves data utilization and reduces overfitting through regularization in the latent space. We conducted extensive experiments in an unseen-object setting on both single-hand grasping and bi-manual motion datasets, including GRAB, DexYCB, and OakInk.Quantitative and qualitative evaluations demonstrate that our method significantly enhances the realism and physical plausibility of generated motions for unseen objects, both in single and bimanual manipulations, compared to the state-of-the-art.

Progressive Correspondence Regenerator for Robust 3D Registration
Guiyu Zhao, Sheng Ao, Ye Zhang, Kai Xu, Yulan Guo; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 1210-1219
Obtaining enough high-quality correspondences is crucial for robust registration. Existing correspondence refinement methods mostly follow the paradigm of outlier removal, which either fails to correctly identify the accurate correspondences under extreme outlier ratios, or select too few correct correspondences to support robust registration. To address this challenge, we propose a novel approach named Regor, which is a progressive correspondence regenerator that generates higher-quality matches whist sufficiently robust for numerous outliers. In each iteration, we first apply prior-guided local grouping and generalized mutual matching to generate the local region correspondences. A powerful center-aware three-point consistency is then presented to achieve local correspondence correction, instead of removal. Further, we employ global correspondence refinement to obta

in accurate correspondences from a global perspective. Through progressive itera tions, this process yields a large number of high-quality correspondences. Exten sive experiments on both indoor and outdoor datasets demonstrate that the propos ed Regor significantly outperforms existing outlier removal techniques. More cri tically, our approach obtain 10 times more correct correspondences than outlier removal methods. As a result, our method is able to achieve robust registration even with weak features. The code is available at https://github.com/GuiyuZhao/R egor.

Cross-Modal 3D Representation with Multi-View Images and Point Clouds
Ziyang Zhou, Pinghui Wang, Zi Liang, Haitao Bai, Ruofei Zhang; Proceedings of th e Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 3728-3739
The advancement of 3D understanding and representation is a crucial step for the next phase of autonomous driving, robotics, augmented and virtual reality, 3D g aming and 3D e-commerce products. However, existing 3D semantic representation r esearch has primarily focused on point clouds to perceive 3D objects and scenes, overlooking the rich visual details offered by multi-view images, thereby limit ing the potential of 3D semantic representation. This paper introduces OpenView, a novel representation method that integrates both point clouds and multi-view images to form a unified 3D representation. OpenView comprises a unique fusion f ramework, sequence-independent modeling, a cross-modal fusion encoder, and a pro gressive hard learning strategy. Our experiments demonstrate that OpenView outpe rforms the state-of-the-art by 11.5% and 5.5% on the R@1 metric for cross-modal retrieval and the Top-1 metric for zero-shot classification tasks, respectively. Furthermore, we showcase some applications of OpenView: 3D retrieval, 3D captio ning and hierarchical data clustering, highlighting its generality in the field of 3D representation learning.

Chapter-Llama: Efficient Chaptering in Hour-Long Videos with LLMs
Lucas Ventura, Antoine Yang, Cordelia Schmid, Gül Varol; Proceedings of the Comp uter Vision and Pattern Recognition Conference (CVPR), 2025, pp. 18947-18958
We address the task of video chaptering, i.e., partitioning a long video timelin e into semantic units and generating corresponding chapter titles. While relativ ely underexplored, automatic chaptering has the potential to enable efficient na vigation and content retrieval in long-form videos. In this paper, we achieve st rong chaptering performance on hour-long videos by efficiently addressing the pr oblem in the text domain with our "Chapter-Llama" framework. Specifically, we le verage a pre-trained large language model (LLM) with large context window, and f eed as input (i) speech transcripts and (ii) captions describing video frames, a long with their respective timestamps. Given the inefficiency of exhaustively ca ptioning all frames, we propose a lightweight speech-guided frame selection stra tegy based on speech transcript content, and experimentally demonstrate remarkab le advantages. We train the LLM to output timestamps for the chapter boundaries, as well as free-form chapter titles. This simple yet powerful approach scales t o processing one-hour long videos in a single forward pass. Our results demonstr ate substantial improvements (e.g., 45.3 vs 26.7 F1 score) over the state of the art on the recent VidChapters-7M benchmark. To promote further research, we rel ease our code and models at our project page.

Decompositional Neural Scene Reconstruction with Generative Diffusion Prior
Junfeng Ni, Yu Liu, Ruijie Lu, Zirui Zhou, Song-Chun Zhu, Yixin Chen, Siyuan Hua ng; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR) , 2025, pp. 6022-6033
Decompositional reconstruction of 3D scenes, with complete shapes and detailed t exture of all objects within, is intriguing for downstream applications but rema ins challenging, particularly with sparse views as input. Recent approaches inco rporate semantic or geometric regularization to address this issue, but they suf fer significant degradation in underconstrained areas and fail to recover occlud ed regions. We argue that the key to solving this problem lies in supplementing missing information for these areas. To this end, we propose DP-Recon, which emp

loys diffusion priors in the form of Score Distillation Sampling (SDS) to optimi ze the neural representation of each individual object under novel views. This p rovides additional information for the underconstrained areas, but directly inco rporating diffusion prior raises potential conflicts between the reconstruction and generative guidance. Therefore, we further introduce a visibility-guided app roach to dynamically adjust the per-pixel SDS loss weights. Together these compo nents enhance both geometry and appearance recovery while remaining faithful to input images. Extensive experiments across Replica and ScanNet++ demonstrate th at our method significantly outperforms state-of-the-art methods. Notably, it ac hieves better object reconstruction under 10 views than the baselines under 100 views. Our method enables seamless text-based editing for geometry and appearanc e through SDS optimization and produces decomposed object meshes with detailed U V maps that support photorealistic Visual effects (VFX) editing. The project pag e is available at https://dp-recon.github.io/.

Distribution Prototype Diffusion Learning for Open-set Supervised Anomaly Detect ion

Fuyun Wang, Tong Zhang, Yuanzhi Wang, Yide Qiu, Xin Liu, Xu Guo, Zhen Cui; Proce edings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, p p. 20416-20426

In Open-set Supervised Anomaly Detection (OSAD), the existing methods typically generate pseudo anomalies to compensate for the scarcity of observed anomaly s amples, while overlooking critical priors of normal samples, leading to less e ffective discriminative boundaries. To address this issue, we propose a Distri bution Prototype Diffusion Learning (DPDL) method aimed at enclosing normal samp les within a compact and discriminative distribution space. Specifically, we c onstruct multiple learnable Gaussian prototypes to create a latent representati on space for abundant and diverse normal samples and learn a Schr"odinger brid ge to facilitate a diffusive transition toward these prototypes for normal samp les while steering anomaly samples away. Moreover, to enhance inter-sample sep aration, we design a dispersion feature learning way in hyperspherical space, which benefits the identification of out-ofdistribution anomalies. Experimenta l results demonstrate the effectiveness and superiority of our proposed DPDL, achieving state-of-the-art performance on 9 public datasets.

Learning Visual Generative Priors without Text

Shuailei Ma, Kecheng Zheng, Ying Wei, Wei Wu, Fan Lu, Yifei Zhang, Chen-Wei Xie, Biao Gong, Jiapeng Zhu, Yujun Shen; Proceedings of the Computer Vision and Patt ern Recognition Conference (CVPR), 2025, pp. 8051-8061

Although text-to-image (T2I) models have recently thrived as visual generative p riors, their reliance on high-quality text-image pairs makes scaling up expensiv e. We argue that grasping the cross-modality alignment is not a necessity for a sound visual generative prior, whose focus should be on texture modeling. Such a philosophy inspires us to study image-to-image (I2I) generation, where models c an learn from in-the-wild images in a self-supervised manner. We first develop a pure vision-based training framework, Lumos, and confirm the feasibility and th e scalability of learning I2I models. We then find that, as an upstream task of T2I, our I2I model serves as a more foundational visual prior and achieves on-pa r or better performance than existing T2I models using only 1/10 text-image pair s for fine-tuning. We further demonstrate the superiority of I2I priors over T2I priors on some text-irrelevant vision tasks, like image-to-3D and image-to-vide o.

Joint Scheduling of Causal Prompts and Tasks for Multi-Task Learning

Chaoyang Li, Jianyang Qin, Jinhao Cui, Zeyu Liu, Ning Hu, Qing Liao; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 251 24-25134

Multi-task prompt learning has emerged as a promising technique for fine-tuning pre-trained Vision-Language Models (VLMs) to various downstream tasks. However, existing methods ignore challenges caused by spurious correlations and dynamic t

ask relationships, which may reduce the model performance. To tackle these chall enges, we propose JSCPT, a novel approach for Joint Scheduling of Causal Prompts and Tasks to enhance multi-task prompt learning. Specifically, we first design a Multi-Task Vison-Language Prompt (MTVLP) model, which learns task-shared and t ask-specific vison-language prompts and selects useful prompt features via causa l intervention, alleviating spurious correlations. Then, we propose the task-pro mpt scheduler that models inter-task affinities and assesses the causal effect o f prompt features to optimize the multi-task prompt learning process. Finally, w e formulate the scheduler and the multi-task prompt learning process as a bi-lev el optimization problem to optimize prompts and tasks adaptively. In the lower o ptimization, MTVLP is updated with the scheduled gradient, while in the upper op timization, the scheduler is updated with the implicit gradient. Extensive exper iments show the superiority of our proposed JSCPT approach over several baseline s in terms of multi-task prompt learning for pre-trained VLMs.

Full-DoF Egomotion Estimation for Event Cameras Using Geometric Solvers

Ji Zhao, Banglei Guan, Zibin Liu, Laurent Kneip; Proceedings of the Computer Vis ion and Pattern Recognition Conference (CVPR), 2025, pp. 11515-11524

For event cameras, current sparse geometric solvers for egomotion estimation ass ume that the rotational displacements are known, such as those provided by an IM U. Thus, they can only recover the translational motion parameters. Recovering f ull-DoF motion parameters using a sparse geometric solver is a more challenging task, and has not yet been investigated. In this paper, we propose several solve rs to estimate both rotational and translational velocities within a unified fra mework. Our method leverages event manifolds induced by line segments. The probl em formulations are based on either an incidence relation for lines or a novel c oplanarity relation for normal vectors. We demonstrate the possibility of recove ring full-DoF egomotion parameters for both angular and linear velocities withou t requiring extra sensor measurements or motion priors. To achieve efficient op timization, we exploit the Adam framework with a first-order approximation of ro tations for quick initialization. Experiments on both synthetic and real-world d ata demonstrate the effectiveness of our method. The code is available at https: //github.com/jizhaox/relpose-event.

3DGUT: Enabling Distorted Cameras and Secondary Rays in Gaussian Splatting

Qi Wu, Janick Martinez Esturo, Ashkan Mirzaei, Nicolas Moënne-Loccoz, Zan Gojcic ; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 26036-26046

3D Gaussian Splatting (3DGS) enables efficient reconstruction and high-fidelity real-time rendering of complex scenes on consumer hardware. However, due to its rasterization-based formulation, 3DGS is constrained to ideal pinhole cameras a nd lacks support for secondary lighting effects. Recent methods address these li mitations by tracing the particles instead, but, this comes at the cost of signi ficantly slower rendering. In this work, we propose 3D Gaussian Unscented Transf orm (3DGUT), replacing the EWA splatting formulation with the Unscented Transfor m that approximates the particles through sigma points, which can be projected e xactly under any nonlinear projection function. This modification enables trivia l support of distorted cameras with time dependent effects such as rolling shutt er, while retaining the efficiency of rasterization. Additionally, we align our rendering formulation with that of tracing-based methods, enabling secondary ray tracing required to represent phenomena such as reflections and refraction with in the same 3D representation. The source code is available at: https://github.c om/nv-tlabs/3dgrut.

Teaching Large Language Models to Regress Accurate Image Quality Scores Using Sc ore Distribution

Zhiyuan You, Xin Cai, Jinjin Gu, Tianfan Xue, Chao Dong; Proceedings of the Comp uter Vision and Pattern Recognition Conference (CVPR), 2025, pp. 14483-14494

With the rapid advancement of Multi-modal Large Language Models (MLLMs), MLLM-ba sed Image Quality Assessment (IQA) methods have shown promising performance in l

inguistic quality description. However, current methods still fall short in accu rately scoring image quality. In this work, we aim to leverage MLLMs to regress accurate quality scores. A key challenge is that the quality score is inherently continuous, typically modeled as a Gaussian distribution, whereas MLLMs generat e discrete token outputs. This mismatch necessitates score discretization. Previ ous approaches discretize the mean score into a one-hot label, resulting in info rmation loss and failing to capture inter-image relationships. We propose a dist ribution-based approach that discretizes the score distribution into a soft labe l. This method preserves the characteristics of the score distribution, achievin g high accuracy and maintaining inter-image relationships. Moreover, to address dataset variation, where different IQA datasets exhibit various distributions, w e introduce a fidelity loss based on Thurstone's model. This loss captures intra -dataset relationships, facilitating co-training across multiple IQA datasets. W ith these designs, we develop the distribution-based Depicted image Quality Asse ssment model for Score regression (DeQA-Score). Experiments across multiple benc hmarks show that DeQA-Score stably outperforms baselines in score regression. Al so, DeQA-Score can predict the score distribution that closely aligns with human annotations. Codes and model weights have been released in https://depictqa.git hub.io/deqa-score/.

Lifting the Veil on Visual Information Flow in MLLMs: Unlocking Pathways to Fast er Inference

Hao Yin, Guangzong Si, Zilei Wang; Proceedings of the Computer Vision and Patter n Recognition Conference (CVPR), 2025, pp. 9382-9391

Multimodal large language models (MLLMs) improve performance on vision-language tasks by integrating visual features from pre-trained vision encoders into large language models (LLMs). However, how MLLMs process and utilize visual informati on remains unclear. In this paper, a shift in the dominant flow of visual inform ation is uncovered: (1) in shallow layers, strong interactions are observed betw een image tokens and instruction tokens, where most visual information is inject ed into instruction tokens to form cross-modal semantic representations; (2) in deeper layers, image tokens primarily interact with each other, aggregating the remaining visual information to optimize semantic representations within the vis ual modality. Based on these insights, we propose Hierarchical Modality-Aware Pr uning (HiMAP), a plug-and-play inference acceleration method that dynamically pr unes image tokens at specific layers, reducing computational costs by approximat ely 65% without sacrificing performance. Our findings offer a new understanding of visual information processing in MLLMs and provide a state-of-the-art solutio n for efficient inference.

Your Scale Factors are My Weapon: Targeted Bit-Flip Attacks on Vision Transforme rs via Scale Factor Manipulation

Jialai Wang, Yuxiao Wu, Weiye Xu, Yating Huang, Chao Zhang, Zongpeng Li, Mingwei Xu, Zhenkai Liang; Proceedings of the Computer Vision and Pattern Recognition C onference (CVPR), 2025, pp. 20103-20112

Vision Transformers (ViTs) have experienced significant progress and are quantiz ed for deployment in resource-constrained applications. Quantized models are vul nerable to targeted bit-flip attacks (BFAs). A targeted BFA prepares a trigger a nd a corresponding Trojan/backdoor, inserting the latter (with RowHammer bit fli pping) into a victim model, to mislead its classification on samples containing the trigger. Existing targeted BFAs on quantized ViTs are limited in that: (1) t hey require numerous bit-flips, and (2) the separation between flipped bits is b elow 4 KB, making attacks infeasible with RowHammer in real-world scenarios. We propose a new and practical targeted attack Flip-S against quantized ViTs. The c ore insight is that in quantized models, a scale factor change ripples through a batch of model weights. Consequently, flipping bits in scale factors, rather th an solely in model weights, enables more cost-effective attacks. We design a Sca le-Factor-Search (SFS) algorithm to identify critical bits in scale factors for flipping, and adopt a mutual exclusion strategy to guarantee a 4 KB separation b etween flips. We evaluate Flip-S on CIFAR-10 and ImageNet datasets across five V

iT architectures and two quantization levels. Results show that Flip-S achieves attack success rate (ASR) exceeding 90.0% on all models with 50 bits flipped, outperforming baselines with ASR typically below 80.0%. Furthermore, compared to the SOTA, Flip-S reduces the number of required bit-flips by 8x-20xwhile reaching equal or higher ASR. Our source code is publicly available.

Marten: Visual Question Answering with Mask Generation for Multi-modal Document Understanding

Zining Wang, Tongkun Guan, Pei Fu, Chen Duan, Qianyi Jiang, Zhentao Guo, Shan Guo, Junfeng Luo, Wei Shen, Xiaokang Yang; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 14460-14471

Multi-modal Large Language Models (MLLMs) have introduced a novel dimension to document understanding, i.e., they endow large language models with visual comprehension capabilities; however, how to design a suitable image-text pre-training task for bridging the visual and language modality in document-level MLLMs remains underexplored. In this study, we introduce a novel visual-language alignment method that casts the key issue as a Visual Question Answering with Mask generation (VQAMask) task, optimizing two tasks simultaneously: VQA-based text parsing and mask generation. The former allows the model to implicitly align images and text at the semantic level. The latter introduces an additional mask generator (discarded during inference) to explicitly ensure alignment between visual texts within images and their corresponding image regions at a spatially-aware level. Together, they can prevent model hallucinations when parsing visual text and effectively promote spatially-aware feature representation learning. To support the proposed VQAMask task, we construct a comprehensive image-mask generation pipeline and provide a large-scale dataset with 6M data (MTMask6M). Subsequently, we demonstrate that introducing the proposed mask generation task yields competitive document-level understanding performance. Leveraging the proposed VQAMask, we introduce Marten, a training-efficient MLLM tailored for document-level understanding. Extensive experiments show that our Marten consistently achieves significant improvements among 8B-MLLMs in document-centric tasks. Code and datasets are available at https://github.com/PriNing/Marten.

Mamba-Reg: Vision Mamba Also Needs Registers

Feng Wang, Jiahao Wang, Sucheng Ren, Guoyizhe Wei, Jieru Mei, Wei Shao, Yuyin Zhou, Alan Yuille, Cihang Xie; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 14944-14953

Similar to Vision Transformers, this paper identifies artifacts also present within the feature maps of Vision Mamba. These artifacts, corresponding to high-norm tokens emerging in low-information background areas of images, appear much more severe in Vision Mamba---they exist prevalently even with the tiny-sized model and activate extensively across background regions. To mitigate this issue, we follow the prior solution of introducing register tokens into Vision Mamba. To better cope with Mamba blocks' uni-directional inference paradigm, two key modifications are introduced: 1) evenly inserting registers throughout the input token sequence, and 2) recycling registers for final decision predictions. We term this new architecture MambaReg. Qualitative observations suggest, compared to vanilla Vision Mamba, MambaReg's feature maps appear cleaner and more focused on semantically meaningful regions. Quantitatively, MambaReg attains stronger performance and scales better. For example, on the ImageNet benchmark, our MambaReg-B attains 83.0% accuracy, significantly outperforming Vim-B's 81.8%; furthermore, we provide the first successful scaling to the large model size (i.e., with 340M parameters), attaining a competitive accuracy of 83.6% (84.5% if finetuned with 384x384 inputs). Additional validation on the downstream semantic segmentation task also supports MambaReg's efficacy.

It's a (Blind) Match! Towards Vision-Language Correspondence without Parallel Data

Dominik Schnaus, Nikita Araslanov, Daniel Cremers; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 24983-24992

The platonic representation hypothesis suggests that vision and language embeddings become more homogeneous as model and dataset sizes increase. In particular, pairwise distances within each modality become more similar. This suggests that as foundation models mature, it may become possible to match vision and language embeddings in a fully unsupervised fashion, i.e. without parallel data. We present the first feasibility study, and investigate conformity of existing vision and language foundation models in the context of unsupervised, or "blind", matching. First, we formulate unsupervised matching as a quadratic assignment problem and introduce a novel heuristic that outperforms previous solvers. We also develop a technique to find optimal matching problems, for which a non-trivial match is very likely. Second, we conduct an extensive study deploying a range of vision and language models on four datasets. Our analysis reveals that for many problem instances, vision and language representations can be indeed matched without supervision. This finding opens up the exciting possibility of embedding semantic knowledge into other modalities virtually annotation-free. As a proof of concept, we showcase an unsupervised classifier, which achieves non-trivial classification accuracy without any image-text annotation.

****

Open Set Label Shift with Test Time Out-of-Distribution Reference

Changkun Ye, Russell Tsuchida, Lars Petersson, Nick Barnes; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 30619-30629

Open set label shift (OSLS) occurs when label distributions change from a source to a target distribution, and the target distribution has an additional out-of-distribution (OOD) class.In this work, we build estimators for both source and target open set label distributions using a source domain in-distribution (ID) classifier and an ID/OOD classifier. With reasonable assumptions on the ID/OOD classifier, the estimators are assembled into a sequence of three stages: 1) an estimate of the source label distribution of the OOD class, 2) an EM algorithm for Maximum Likelihood estimates (MLE) of the target label distribution, and 3) an estimate of the target label distribution of OOD class under relaxed assumptions on the OOD classifier.The sampling errors of estimates in 1) and 3) are quantified with a concentration inequality.The estimation result allows us to correct the ID classifier trained on the source distribution to the target distribution without retraining.Experiments on a variety of open set label shift settings demonstrate the effectiveness of our model.Our code is available at https://github.com/ChangkunYe/OpenSetLabelShift.

Visual Persona: Foundation Model for Full-Body Human Customization

Jisu Nam, Soowon Son, Zhan Xu, Jing Shi, Difan Liu, Feng Liu, Seungryong Kim, Yang Zhou; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 18630-18641

We introduce Visual Persona, a foundation model for text-to-image full-body human customization that, given a single in-the-wild human image, generates diverse images of the individual guided by text descriptions. Unlike prior methods that focus solely on preserving facial identity, our approach captures detailed full-body appearance, aligning with text descriptions for body structure and scene variations. Training this model requires large-scale paired human data, consisting of multiple images per individual with consistent full-body identities, which is notoriously difficult to obtain. To address this, we propose a data curation pipeline leveraging vision-language models to evaluate full-body appearance consistency, resulting in Visual Persona-500K--a dataset of 580k paired human images across 100k unique identities. For precise appearance transfer, we introduce a transformer encoder-decoder architecture adapted to a pre-trained text-to-image diffusion model, which augments the input image into distinct body regions, encodes these regions as local appearance features, and projects them into dense identity embeddings independently to condition the diffusion model for synthesizing customized images. Visual Persona consistently surpasses existing approaches, generating high-quality, customized images from in-the-wild inputs. Extensive ablation studies validate design choices, and we demonstrate the versatility of Visual Persona across various downstream tasks.

SOGS: Second-Order Anchor for Advanced 3D Gaussian Splatting
Jiahui Zhang, Fangneng Zhan, Ling Shao, Shijian Lu; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 11167-11176
Anchor-based 3D Gaussian splatting (3D-GS) exploits anchor features in 3D Gaussian prediction, which has achieved impressive 3D rendering quality with reduced Gaussian redundancy. On the other hand, it often encounters the dilemma among anchor features, model size, and rendering quality - large anchor features lead to large 3D models and high-quality rendering whereas reducing anchor features degrades Gaussian attribute prediction which leads to clear artifacts in the rendered textures and geometries. We design SOGS, an anchor-based 3D-GS technique that introduces second-order anchors to achieve superior rendering quality and reduced anchor features and model size simultaneously. Specifically, SOGS incorporates covariance-based second-order statistics and correlation across feature dimensions to augment features within each anchor, compensating for the reduced feature size and improving rendering quality effectively. In addition, it introduces a selective gradient loss to enhance the optimization of scene textures and scene geometries, leading to high-quality rendering with small anchor features. Extensive experiments over multiple widely adopted benchmarks show that SOGS achieves superior rendering quality in novel view synthesis with clearly reduced model size.

GaussianFormer-2: Probabilistic Gaussian Superposition for Efficient 3D Occupancy Prediction
Yuanhui Huang, Amonnut Thammatadatrakoon, Wenzhao Zheng, Yunpeng Zhang, Dalong Du, Jiwen Lu; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 27477-27486
3D semantic occupancy prediction has garnered attention as an important task for the robustness of vision-centric autonomous driving, which predicts fine-grained geometry and semantics of the surrounding scene. Most existing methods leverage dense grid-based scene representations, overlooking the spatial sparsity of the driving scenes, which leads to computational redundancy. Although 3D semantic Gaussian serves as an object-centric sparse alternative, most of the Gaussians still describe the empty region with low efficiency. To address this, we propose a probabilistic Gaussian superposition model which interprets each Gaussian as a probability distribution of its neighborhood being occupied and conforms to probabilistic multiplication to derive the overall geometry. Furthermore, we adopt the exact Gaussian mixture model for semantics calculation to avoid unnecessary overlapping of Gaussians. To effectively initialize Gaussians in non-empty region, we design a distribution-based initialization module which learns the pixel-aligned occupancy distribution instead of the depth of surfaces. We conduct extensive experiments on nuScenes and KITTI-360 datasets and our GaussianFormer-2 achieves state-of-the-art performance with high efficiency.
****
MExD: An Expert-Infused Diffusion Model for Whole-Slide Image Classification
Jianwei Zhao, Xin Li, Fan Yang, Qiang Zhai, Ao Luo, Yang Zhao, Hong Cheng, Huazhu Fu; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 20789-20799
Whole Slide Image (WSI) classification poses unique challenges due to the vast image size and numerous non-informative regions, which introduce noise and cause data imbalance during feature aggregation. To address these issues, we propose MExD, an Expert-Infused Diffusion Model that combines the strengths of a Mixture-of-Experts (MoE) mechanism with a diffusion model for enhanced classification. MExD balances patch feature distribution through a novel MoE-based aggregator that selectively emphasizes relevant information, effectively filtering noise, addressing data imbalance, and extracting essential features. These features are then integrated via a diffusion-based generative process to directly yield the class distribution for the WSI. Moving beyond conventional discriminative approaches, MExD represents the first generative strategy in WSI classification, capturing fine-grained details for robust and precise results. Our MExD is validated on t

hree widely-used benchmarks--Camelyon16, TCGA-NSCLC, and BRACS--consistently ach
ieving state-of-the-art performance in both binary and multi-class tasks.

Flexible Frame Selection for Efficient Video Reasoning
Shyamal Buch, Arsha Nagrani, Anurag Arnab, Cordelia Schmid; Proceedings of the C
omputer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 29071-29082
Video-language models have shown promise for addressing a range of multimodal ta
sks for video understanding, such as video question-answering. However, the inhe
rent computational challenges of processing long video data and increasing model
 sizes have led to standard approaches that are limited by the number of frames
they can process. In this work, we propose the Flexible Frame Selector (FFS), a
learnable policy model with a new flexible selection operation, that helps allev
iate input context restrictions by enabling video-language models to focus on th
e most informative frames for the downstream multimodal task, without adding und
ue processing cost. Our method differentiates from prior work due to its learnab
ility, efficiency, and flexibility. We verify the efficacy of our method on stan
dard video-question answering and reasoning benchmarks, and observe that our mod
el can improve base video-language model accuracy while reducing the number of d
ownstream processed frames.

EventGPT: Event Stream Understanding with Multimodal Large Language Models
Shaoyu Liu, Jianing Li, Guanghui Zhao, Yunjian Zhang, Xin Meng, Fei Richard Yu,
Xiangyang Ji, Ming Li; Proceedings of the Computer Vision and Pattern Recognitio
n Conference (CVPR), 2025, pp. 29139-29149
Event cameras capture visual information as asynchronous pixel change streams, e
xcelling in challenging lighting and high-dynamic scenarios. Existing multimodal
 large language models (MLLMs) concentrate on natural RGB images, failing in sce
narios where event data fits better. In this paper, we introduce EventGPT, the f
irst MLLM for event stream understanding, pioneering the integration of large la
nguage models (LLMs) with event-based vision. To bridge the huge domain gap, we
propose a three-stage optimization paradigm to progressively equip a pre-trained
 LLM with event understanding. Our EventGPT consists of an event encoder, a spat
io-temporal aggregator, a linear projector, an event-language adapter, and an LL
M. Firstly, GPT-generated RGB image-text pairs warm up the linear projector, fol
lowing LLaVA, as the gap between natural images and language is smaller. Secondl
y, we construct N-ImageNet-Chat, a large synthetic dataset of event data and cor
responding texts to enable the use of the spatio-temporal aggregator and to trai
n the event-language adapter, thereby aligning event features more closely with
the language space. Finally, we gather an instruction dataset, Event-Chat, which
 contains extensive real-world data to fine-tune the entire model, further enhan
cing its generalization ability. We construct a comprehensive benchmark, and exp
eriments show that EventGPT surpasses previous state-of-the-art MLLMs in generat
ion quality, descriptive accuracy, and reasoning capability.

Pixel-level and Semantic-level Adjustable Super-resolution: A Dual-LoRA Approach
Lingchen Sun, Rongyuan Wu, Zhiyuan Ma, Shuaizheng Liu, Qiaosi Yi, Lei Zhang; Pro
ceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025,
 pp. 2333-2343
Diffusion prior-based methods have shown impressive results in real-world image
super-resolution (SR). However, most existing methods entangle pixel-level and s
emantic-level SR objectives in the training process, struggling to balance pixel
-wise fidelity and perceptual quality. Meanwhile, users have varying preferences
 on SR results, thus it is demanded to develop an adjustable SR model that can b
e tailored to different fidelity-perception preferences during inference without
 re-training. We present Pixel-level and Semantic-level Adjustable SR (PiSA-SR),
 which learns two LoRA modules upon the pre-trained stable-diffusion (SD) model
to achieve improved and adjustable SR results. We first formulate the SD-based S
R problem as learning the residual between the low-quality input and the high-qu
ality output, then show that the learning objective can be decoupled into two di
stinct LoRA weight spaces: one is characterized by the l2-loss for pixel-level r

egression, and another is characterized by the LPIPS and classifier score distil lation losses to extract semantic information from pre-trained classification an d SD models. In its default setting, PiSA-SR can be performed in a single diffu sion step, achieving leading real-world SR results in both quality and efficienc y. By introducing two adjustable guidance scales on the two LoRA modules to cont rol the strengths of pixel-wise fidelity and semantic-level details during infer ence, PiSA-SR can offer flexible SR results according to user preference without re-training. The source code of our method can be found at https://github.com/c sslc/PiSA-SR.

Let Samples Speak: Mitigating Spurious Correlation by Exploiting the Clusterness of Samples
Weiwei Li, Junzhuo Liu, Yuanyuan Ren, Yuchen Zheng, Yahao Liu, Wen Li; Proceedin gs of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 1 5486-15496
Deep learning models are known to often learn features that spuriously correlate with the class label during training but are irrelevant to the prediction task. Existing methods typically address this issue by annotating potential spurious attributes, or filtering spurious features based on some empirical assumptions (e.g., simplicity of bias). However, these methods may yield unsatisfying perform ance due to the intricate and elusive nature of spurious correlations in real-wo rld data. In this paper, we propose a data-oriented approach to mitigate the spu rious correlation in deep learning models. We observe that samples that are infl uenced by spurious features tend to exhibit a dispersed distribution in the lear ned feature space. This allows us to identify the presence of spurious features. Subsequently, we obtain a bias-invariant representation by neutralizing the spu riousfeatures based on a simple grouping strategy. Then, we learn a feature tran sformation to eliminate the spuriousfeatures by aligning with this bias-invarian t representation. Finally, we update the classifier by incorporating the learned feature transformation and obtain an unbiased model. By integrating the aforeme ntioned identifying, neutralizing, eliminating and updating procedures, we build an effective pipeline for mitigating spurious correlation. Experiments on image and NLP debiasing benchmarks show an improvement in worst group accuracy of mor e than 20% compared to standard empirical risk minimization (ERM). Codes and ch eckpoints are available at https://github.com/davelee-uestc/nsf_debiasing.

Mr. DETR: Instructive Multi-Route Training for Detection Transformers
Chang-Bin Zhang, Yujie Zhong, Kai Han; Proceedings of the Computer Vision and Pa ttern Recognition Conference (CVPR), 2025, pp. 9933-9943
Existing methods enhance the training of detection transformers by incorporating an auxiliary one-to-many assignment. In this work, we treat the model as a mult i-task framework, simultaneously performing one-to-one and one-to-many predictio ns. We investigate the roles of each component in the transformer decoder across these two training targets, including self-attention, cross-attention, and feed -forward network. Our empirical results demonstrate that any independent compone nt in the decoder can effectively learn both targets simultaneously, even when o ther components are shared. This finding leads us to propose a multi-route train ing mechanism, featuring a primary route for one-to-one prediction and two auxil iary training routes for one-to-many prediction. We enhance the training mechani sm with a novel instructive self-attention that dynamically and flexibly guides object queries for one-to-many prediction. The auxiliary routes are removed duri ng inference, ensuring no impact on model architecture or inference cost. We con duct extensive experiments on various baselines, achieving consistent improvemen ts as shown in Fig. 1. Project page: https://visual-ai.github.io/mrdetr

MITracker: Multi-View Integration for Visual Object Tracking
Mengjie Xu, Yitao Zhu, Haotian Jiang, Jiaming Li, Zhenrong Shen, Sheng Wang, Hao lin Huang, Xinyu Wang, Han Zhang, Qing Yang, Qian Wang; Proceedings of the Compu ter Vision and Pattern Recognition Conference (CVPR), 2025, pp. 27176-27185
Multi-view object tracking (MVOT) offers promising solutions to challenges such

as occlusion and target loss, which are common in traditional single-view tracking. However, progress has been limited by the lack of comprehensive multi-view datasets and effective cross-view integration methods. To overcome these limitations, we compiled a Multi-View object Tracking (MVTrack) dataset of 234K high-quality annotated frames featuring 27 distinct objects across various scenes. In conjunction with this dataset, we introduce a novel MVOT method, Multi-View Integration Tracker (MITracker), to efficiently integrate multi-view object features and provide stable tracking outcomes. MITracker can track any object in video frames of arbitrary length from arbitrary viewpoints. The key advancements of our method over traditional single-view approaches come from two aspects: (1) MITracker transforms 2D image features into a 3D feature volume and compresses it into a bird's eye view (BEV) plane, facilitating inter-view information fusion; (2) we propose an attention mechanism that leverages geometric information from fused 3D feature volume to refine the tracking results at each view. MITracker outperforms existing methods on the MVTrack and GMTD datasets, achieving state-of-the-art performance.

****

Hearing Hands: Generating Sounds from Physical Interactions in 3D Scenes

Yiming Dou, Wonseok Oh, Yuqing Luo, Antonio Loquercio, Andrew Owens; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 1795-1804

We study the problem of making 3D scene reconstructions interactive by asking the following question: can we predict the sounds of human hands physically interacting with a scene? First, we record a video of a human manipulating objects within a 3D scene using their hands. We then use these action-sound pairs to train a rectified flow model to map 3D hand trajectories to their corresponding audio. At test time, a user can query the model for other actions, parameterized as sequences of hand poses, to estimate their corresponding sounds. In our experiments, we find that our generated sounds accurately convey material properties and actions, and that they are often indistinguishable to human observers from real sounds. Project page: https://www.yimingdou.com/hearing_hands/.

AirRoom: Objects Matter in Room Reidentification

Runmao Yao, Yi Du, Zhuoqun Chen, Haoze Zheng, Chen Wang; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 1385-1394

Room reidentification (ReID) is a challenging yet essential task with numerous applications in fields such as augmented reality (AR) and homecare robotics. Existing visual place recognition (VPR) methods, which typically rely on global descriptors or aggregate local features, often struggle in cluttered indoor environments densely populated with man-made objects. These methods tend to overlook the crucial role of object-oriented information. To address this, we propose AirRoom, an object-aware pipeline that integrates multi-level object-oriented information--from global context to object patches, object segmentation, and keypoints--utilizing a coarse-to-fine retrieval approach. Extensive experiments on four newly constructed datasets--MPReID, HMReID, GibsonReID, and ReplicaReID--demonstrate that AirRoom outperforms state-of-the-art (SOTA) models across nearly all evaluation metrics, with improvements ranging from 6% to 80%. Moreover, AirRoom exhibits significant flexibility, allowing various modules within the pipeline to be substituted with different alternatives without compromising overall performance. It also shows robust and consistent performance under diverse viewpoint variations.

Not Only Text: Exploring Compositionality of Visual Representations in Vision-Language Models

Davide Berasi, Matteo Farina, Massimiliano Mancini, Elisa Ricci, Nicola Strisciuglio; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 24917-24927

Vision-Language Models (VLMs) learn a shared feature space for text and images, enabling the comparison of inputs of different modalities. While prior works demonstrated that VLMs organize natural language representations into regular struc

tures encoding composite meanings, it remains unclear if compositional patterns also emerge in the visual embedding space. In this work, we investigate compositionality in the image domain, where the analysis of compositional properties is challenged by noise and sparsity of visual data. We address these problems and propose a framework, called Geodesically Decomposable Embeddings (GDE), that approximates image representations with geometry-aware compositional structures in the latent space. We demonstrate that visual embeddings of pre-trained VLMs exhibit a compositional arrangement, and evaluate the effectiveness of this property in the tasks of compositional classification and group robustness. GDE achieves stronger performance in compositional classification compared to its counterpart method that assumes linear geometry of the latent space. Notably, it is particularly effective for group robustness, where we achieve higher results than task-specific solutions. Our results indicate that VLMs can automatically develop a human-like form of compositional reasoning in the visual domain, making their underlying processes more interpretable. Code is available at https://github.com/BerasiDavide/vlm_image_compositionality.

DefMamba: Deformable Visual State Space Model

Leiye Liu, Miao Zhang, Jihao Yin, Tingwei Liu, Wei Ji, Yongri Piao, Huchuan Lu; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 8838-8847

Recently, state space models (SSM), particularly Mamba, have attracted significant attention from scholars due to their ability to effectively balance computational efficiency and performance. However, most existing visual Mamba methods flatten images into 1D sequences using predefined scan orders, which results the model being less capable of utilizing the spatial structural information of the image during the feature extraction process. To address this issue, we proposed a novel visual foundation model called DefMamba. This model includes a multi-scale backbone structure and deformable mamba (DM) blocks, which dynamically adjust the scanning path to prioritize important information, thus enhancing the capture and processing of relevant input features. By combining a deformable scanning (DS) strategy, this model significantly improves its ability to learn image structures and detects changes in object details. Numerous experiments have shown that DefMamba achieves state-of-the-art performance in various visual tasks, including image classification, object detection, instance segmentation, and semantic segmentation. The code is open source on DefMamba.

HOP: Heterogeneous Topology-based Multimodal Entanglement for Co-Speech Gesture Generation

Hongye Cheng, Tianyu Wang, Guangsi Shi, Zexing Zhao, Yanwei Fu; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 906-916

Co-speech gestures are crucial non-verbal cues that enhance speech clarity and expressiveness in human communication, which have attracted increasing attention in multimodal research. While the existing methods have made strides in gesture accuracy, challenges remain in generating diverse and coherent gestures, as most approaches assume independence among multimodal inputs and lack explicit modeling of their interactions. In this work, we propose a novel multimodal learning method named HOP for co-speech gesture generation that captures the heterogeneous entanglement between gesture motion, audio rhythm, and text semantics, enabling the generation of coordinated gestures. By leveraging spatiotemporal graph modeling, we achieve the alignment of audio and action. Moreover, to enhance modality coherence, we build the audio-text semantic representation based on a reprogramming module, which is beneficial for cross-modality adaptation. Our approach enables the trimodal system to learn each other's features and represent them in the form of topological entanglement. Extensive experiments demonstrate that HOP achieves state-of-the-art performance, offering more natural and expressive co-speech gesture generation. More information, codes, and demos are available here: https://star-uu-wang.github.io/HOP/.

VoxelSplat: Dynamic Gaussian Splatting as an Effective Loss for Occupancy and Fl

ow Prediction
Ziyue Zhu, Shenlong Wang, Jin Xie, Jiang-jiang Liu, Jingdong Wang, Jian Yang; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 6761-6771
Recent advancements in camera-based occupancy prediction have focused on the simultaneous prediction of 3D semantics and scene flow, a task that presents significant challenges due to specific difficulties, e.g., occlusions and unbalanced dynamic environments. In this paper, we analyze these challenges and their underlying causes. To address them, we propose a novel regularization framework called VoxelSplat. This framework leverages recent developments in 3D Gaussian Splatting to enhance model performance in two key ways: (i)Enhanced Semantics Supervision through 2D Projection: During training, our method decodes sparse semantic 3D Gaussians from 3D representations and projects them onto the 2D camera view. This provides additional supervision signals in the camera-visible space, allowing 2D labels to improve the learning of 3D semantics. (ii) Scene Flow Learning: Our framework uses the predicted scene flow to model the motion of Gaussians, and is thus able to learn the scene flow of moving objects in a self-supervised manner using the labels of adjacent frames. Our method can be seamlessly integrated into various existing occupancy models, enhancingperformance without increasing inference time. Extensive experiments on benchmark datasets demonstrate the effectiveness of VoxelSplat in improving the accuracy of both semantic occupancy and scene flow estimation. The project page and codes are available at https://zzy816.github.io/VoxelSplat-Demo/.

Exploring Scene Affinity for Semi-Supervised LiDAR Semantic Segmentation
Chuandong Liu, Xingxing Weng, Shuguo Jiang, Pengcheng Li, Lei Yu, Gui-Song Xia; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 27380-27389
This paper explores scene affinity (AIScene), namely intra-scene consistency and inter-scene correlation, for semi-supervised LiDAR semantic segmentation in driving scenes. Adopting teacher-student training, AIScene employs a teacher network to generate pseudo-labeled scenes from unlabeled data, which then supervise the student network's learning. Unlike most methods that include all points in pseudo-labeled scenes for forward propagation but only pseudo-labeled points for backpropagation, AIScene removes points without pseudo-labels, ensuring consistency in both forward and backward propagation within the scene. This simple point erasure strategy effectively prevents unsupervised, semantically ambiguous points (excluded in backpropagation) from affecting the learning of pseudo-labeled points. Moreover, AIScene incorporates patch-based data augmentation, mixing multiple scenes at both scene and instance levels. Compared to existing augmentation techniques that typically perform scene-level mixing between two scenes, our method enhances the semantic diversity of labeled (or pseudo-labeled) scenes, thereby improving the semi-supervised performance of segmentation models. Experiments show that AIScene outperforms previous methods on two popular benchmarks across four settings, achieving notable improvements of 1.9% and 2.1% in the most challenging 1% labeled data. The code will be released at https://github.com/azhuantou/AIScene.

ControlFace: Harnessing Facial Parametric Control for Face Rigging
Wooseok Jang, Youngjun Hong, Geonho Cha, Seungryong Kim; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 5614-5624
Manipulation of facial images to meet specific controls such as pose, expression, and lighting, also referred to as face rigging is a complex task in computer vision. Existing methods are limited by their reliance on image datasets, which necessitates individual-specific fine-tuning and limits their ability to retain fine-grained identity and semantic details, reducing practical usability. To overcome these limitations, we introduce ControlFace, a novel face rigging method conditioned on 3DMM renderings that enables flexible, high-fidelity control. ControlFace employs a dual-branch U-Nets: one, referred to as FaceNet, captures identity and fine details, while the other focuses on generation. To enhance control

precision, control mixer module encodes the correlated features between the target-aligned control and reference-aligned control, and a novel guidance method, reference control guidance, steers the generation process for better control adherence. By training on a facial video dataset, we fully utilize FaceNet's rich representations while ensuring control adherence. Extensive experiments demonstrate ControlFace's superior performance in identity preservation, and control precision, highlighting its practicality. Code and pre-trained weights will be publicly available.

Minority-Focused Text-to-Image Generation via Prompt Optimization
Soobin Um, Jong Chul Ye; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 20926-20936
We investigate the generation of minority samples using pretrained text-to-image (T2I) latent diffusion models. Minority instances, in the context of T2I generation, can be defined as ones living on low-density regions of text-conditional data distributions. They are valuable for various applications of modern T2I generators, such as data augmentation and creative AI. Unfortunately, existing pretrained T2I diffusion models primarily focus on high-density regions, largely due to the influence of guided samplers (like CFG) that are essential for high-quality generation. To address this, we present a novel framework to counter the high-density-focus of T2I diffusion models. Specifically, we first develop an online prompt optimization framework that encourages emergence of desired properties during inference while preserving semantic contents of user-provided prompts. We subsequently tailor this generic prompt optimizer into a specialized solver that promotes generation of minority features by incorporating a carefully-crafted likelihood objective. Extensive experiments conducted across various types of T2I models demonstrate that our approach significantly enhances the capability to produce high-quality minority instances compared to existing samplers. Code is available at https://github.com/soobin-um/MinorityPrompt.

Imputation-free and Alignment-free: Incomplete Multi-view Clustering Driven by Consensus Semantic Learning
Yuzhuo Dai, Jiaqi Jin, Zhibin Dong, Siwei Wang, Xinwang Liu, En Zhu, Xihong Yang, Xinbiao Gan, Yu Feng; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 5071-5081
In incomplete multi-view clustering (IMVC), missing data induce prototype shifts within views and semantic inconsistencies across views. A feasible solution is to explore cross-view consistency in paired complete observations, further imputing and aligning the similarity relationships inherently shared across views. Nevertheless, existing methods are constrained by two-tiered limitations: (1) Neither instance- nor cluster-level consistency learning construct a semantic space shared across views to learn consensus semantics. The former enforces cross-view instances alignment, and wrongly regards unpaired observations with semantic consistency as negative pairs; the latter focuses on cross-view cluster counterparts while coarsely handling fine-grained intra-cluster relationships within views. (2) Excessive reliance on consistency results in unreliable imputation and alignment without incorporating view-specific cluster information. Thus, we propose an IMVC framework, imputation- and alignment-free for consensus semantics learning (FreeCSL). To bridge semantic gaps across all observations, we learn consensus prototypes from available data to discover a shared space, where semantically similar observations are pulled closer for consensus semantics learning. To capture semantic relationships within specific views, we design a heuristic graph clustering based on modularity to recover cluster structure with intra-cluster compactness and inter-cluster separation for cluster semantics enhancement. Extensive experiments demonstrate, compared to state-of-the-art competitors, FreeCSL achieves more confident and robust assignments on IMVC task.

Sensitivity-Aware Efficient Fine-Tuning via Compact Dynamic-Rank Adaptation
Tianran Chen, Jiarui Chen, Baoquan Zhang, Zhehao Yu, Shidong Chen, Rui Ye, Xutao Li, Yunming Ye; Proceedings of the Computer Vision and Pattern Recognition Conf

erence (CVPR), 2025, pp. 9655-9664
Parameter-Efficient Fine-Tuning (PEFT) is a fundamental research problem in comp uter vision, which aims to tune a few of parameters for efficient storage and ad aptation of pre-trained vision models. Recently, sensitivity-aware parameter eff icient fine-tuning method (SPT) addresses this problem by identifying sensitive parameters and then leveraging its sparse characteristic to combine unstructured and structured tuning for PEFT. However, existing methods only focus on sparse characteristic of sensitive parameters but overlook its distribution characteris tic, which results in additional storage burden and limited performance improvem ent. In this paper, we find that the distribution of sensitive parameters is not chaotic, but concentrates in a small number of rows or columns in each paramete r matrix. Inspired by this fact, we propose a Compact Dynamic-Rank Adaptation-ba sed tuning method for Sensitivity-aware Parameter efficient fine-Tuning, called CDRA-SPT. Specifically, we first identify the sensitive parameters that require tuning for each downstream task. Then, we reorganize the sensitive parameters by following its row and column into a compact sub-parameter matrix. Finally, a dy namic-rank adaptation is designed and applied at sub-parameter matrix level for PEFT. Its advantage is that the dynamic-rank characteristic of sub-parameter mat rix can be fully exploited for PEFT. Extensive experiments show that our method achieves superior performance over previous state-of-the-art methods.

MoDec-GS: Global-to-Local Motion Decomposition and Temporal Interval Adjustment for Compact Dynamic 3D Gaussian Splatting
Sangwoon Kwak, Joonsoo Kim, Jun Young Jeong, Won-Sik Cheong, Jihyong Oh, Munchur l Kim; Proceedings of the Computer Vision and Pattern Recognition Conference (CV PR), 2025, pp. 11338-11348
3D Gaussian Splatting (3DGS) has made significant strides in scene representatio n and neural rendering, with intense efforts focused on adapting it for dynamic scenes. Despite delivering remarkable rendering quality and speed, existing meth ods struggle with storage demands and the representation of complex real-world m otions. To address these challenges, we propose MoDec-GS, a memory-efficient Gau ssian splatting framework designed to reconstruct novel views in challenging sce narios with complex motions. We introduce Global-to-Local Motion Decomposition (GLMD) to effectively capture dynamic motions in a coarse-to-fine manner. This ap proach leverages Global Canonical Scaffolds (Global CS) and Local Canonical Scaf folds (Local CS), which extend static Scaffold representation to dynamic video r econstruction. For Global CS, we propose Global Anchor Deformation (GAD) to effi ciently represent global dynamics along complex motions by directly deforming th e implicit Scaffold attributes, including anchor position, offset, and local con text features. Next, we finely adjust local motions via the Local Gaussian Defor mation (LGD) of Local CS explicitly. Additionally, we introduce Temporal Interva

l Adjustment (TIA) to automatically control the temporal coverage of each Local CS during training, enabling MoDec-GS to find optimal interval assignments based on the specified number of temporal segments. Extensive evaluations demonstrate that MoDec-GS achieves an average 70% reduction in model size over state-of-the-art methods for dynamic 3D Gaussians from real-world dynamic videos while maintaining or even improving rendering quality.

DaCapo: Score Distillation as Stacked Bridge for Fast and High-quality 3D Editing

Yufei Huang, Bangyan Liao, Yuqi Hu, Haitao Lin, Lirong Wu, Siyuan Li, Cheng Tan, Zicheng Liu, Yunfan Liu, Zelin Zang, Chang Yu, Zhen Lei; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 16304-16313

Score Distillation Sampling (SDS) has been successfully extended to text-driven 3D scene editing with 2D pretrained diffusion models. However, SDS-based editing methods suffer from lengthy optimization processes with slow inference and low quality. We attribute the issue of lengthy optimization to the stochastic optimization scheme used in SDS-based editing, where many steps may conflict with each other (e.g., the inherent trade-off between editing and preservation). To reduce this internal conflict and speed up the editing process, we propose to separate editing and preservation in time with a diffusion time schedule and frame the 3D editing optimization process as a diffusion bridge sampling process. Motivated by the analysis above, we introduce DaCapo, a fast diffusion sampling-like 3D editing method that incorporates a novel stacked bridge framework, which estimates a direct diffusion bridge between source and target distribution with only a pretrained 2D diffusion model. Specifically, It models the editing process as a combination of inversion and generation, where both processes happen simultaneously as a stack of Diffusion Bridges. DaCapo shows a 15x speed-up with comparable results to the state-of-the-art SDS-based method. It completes the process in just 2,500 steps on a single GPU and accommodates a variety of 3D representation methods.

A Selective Re-learning Mechanism for Hyperspectral Fusion Imaging

Yuanye Liu, Jinyang Liu, Renwei Dian, Shutao Li; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 7437-7446

Hyperspectral fusion imaging is challenged by high computational cost due to the abundant spectral information. We find that pixels in regions with smooth spatial-spectral structure can be reconstructed well using a shallow network, while only those in regions with complex spatial-spectral structure require a deeper network. However, existing methods process all pixels uniformly, which ignores this property. To leverage this property, we propose a Selective Re-learning Fusion Network (SRLF) that initially extracts features from all pixels uniformly and then selectively refines distorted feature points. Specifically, SRLF first employs a Preliminary Fusion Module with robust global modeling capability to generate a preliminary fusion feature. Afterward, it applies a Selective Re-learning Module to focus on improving distorted feature points in the preliminary fusion feature. To achieve targeted learning, we present a novel Spatial-Spectral Structure-Guided Selective Re-learning Mechanism (SSG-SRL) that integrates the observation model to identify the feature points with spatial or spectral distortions. Only these distorted points are sent to the corresponding re-learning blocks, reducing both computational cost and the risk of overfitting. Finally, we develop an SRLF-Net, composed of multiple cascaded SRLFs, which surpasses multiple state-of-the-art methods on several datasets with minimal computational cost.

****

SCSegamba: Lightweight Structure-Aware Vision Mamba for Crack Segmentation in Structures

Hui Liu, Chen Jia, Fan Shi, Xu Cheng, Shengyong Chen; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 29406-29416

Pixel-level segmentation of structural cracks across various scenarios remains a considerable challenge. Current methods encounter challenges in effectively modeling crack morphology and texture, facing challenges in balancing segmentation

quality with low computational resource usage. To overcome these limitations, we propose a lightweight Structure-Aware Vision Mamba Network (SCSegamba), capable of generating high-quality pixel-level segmentation maps by leveraging both the morphological information and texture cues of crack pixels with minimal computational cost. Specifically, we developed a Structure-Aware Visual State Space module (SAVSS), which incorporates a lightweight Gated Bottleneck Convolution (GBC) and a Structure-Aware Scanning Strategy (SASS). The key insight of GBC lies in its effectiveness in modeling the morphological information of cracks, while the SASS enhances the perception of crack topology and texture by strengthening the continuity of semantic information between crack pixels. Experiments on crack benchmark datasets demonstrate that our method outperforms other state-of-the-art (SOTA) methods, achieving the highest performance with only 2.8M parameters. On the multi-scenario dataset, our method reached 0.8390 in F1 score and 0.8479 in mIoU.

Autoregressive Sequential Pretraining for Visual Tracking

Shiyi Liang, Yifan Bai, Yihong Gong, Xing Wei; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 7254-7264

Recent advancements in visual object tracking have shifted towards a sequential generation paradigm, where object deformation and motion exhibit strong temporal dependencies. Despite the importance of these dependencies, widely adopted image-level pretrained backbones barely capture the dynamics in the consecutive video, which is the essence of tracking. Thus, we propose AutoRegressive Sequential Pretraining (ARP), an unsupervised spatio-temporal learner, via generating the evolution of object appearance and motion in video sequences.Our method leverages a diffusion model to autoregressively generate the future frame appearance, conditioned on historical embeddings extracted by a general encoder. Furthermore, to ensure trajectory coherence, the same encoder is employed to learn trajectory consistency by generating coordinate sequences in a reverse autoregressive fashion, a process we term back-tracking. Further, we integrate the pretrained ARP into ARTrackV2, creating ARPTrack, which is further fine-tuned for tracking tasks. ARPTrack achieves state-of-the-art performance across multiple benchmarks, becoming the first tracker to surpass 80% AO on GOT-10k, while maintaining high efficiency. These results demonstrate the effectiveness of our approach in capturing temporal dependencies for continuous video tracking.

****

Number it: Temporal Grounding Videos like Flipping Manga

Yongliang Wu, Xinting Hu, Yuyang Sun, Yizhou Zhou, Wenbo Zhu, Fengyun Rao, Bernt Schiele, Xu Yang; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 13754-13765

Video Large Language Models (Vid-LLMs) have made remarkable advancements in comprehending video content for QA dialogue. However, they struggle to extend this visual understanding to tasks requiring precise temporal localization, known as Video Temporal Grounding (VTG). To address this, we introduce Number-Prompt (NumPro), a novel method that empowers Vid-LLMs to bridge visual comprehension with temporal grounding by adding unique numerical identifiers to each video frame. Treating a video as a sequence of numbered frame images, NumPro transforms VTG into an intuitive process: flipping through manga panels in sequence. This allows Vid-LLMs to "read" event timelines, accurately linking visual content with corresponding temporal information. Our experiments demonstrate that NumPro significantly boosts VTG performance of top-tier Vid-LLMs without additional computational cost. Furthermore, fine-tuning on a NumPro-enhanced dataset defines a new state-of-the-art for VTG, surpassing previous top-performing methods by up to 6.9% in mIoU for moment retrieval and 8.5% in mAP for highlight detection. The code is available at https://github.com/yongliang-wu/NumPro.

Collaborative Tree Search for Enhancing Embodied Multi-Agent Collaboration

Lizheng Zu, Lin Lin, Song Fu, Na Zhao, Pan Zhou; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 29513-29522

Embodied agents based on large language models (LLMs) face significant challenge

s in collaborative tasks, requiring effective communication and reasonable divis
ion of labor to ensure efficient and correct task completion. Previous approache
s with simple communication patterns carry erroneous or incoherent agent actions
, which can lead to additional risks. To address these problems, we propose Coop
erative Tree Search (CoTS), a framework designed to significantly improve collab
orative planning and task execution efficiency among embodied agents. CoTS guide
s multi-agents to discuss long-term strategic plans within a modified Monte Carl
o tree, searching along LLM-driven reward functions to provide a more thoughtful
 and promising approach to cooperation. Another key feature of our method is the
 introduction of a plan evaluation module, which not only prevents agent action
confusion caused by frequent plan updates but also ensures plan updates when the
 current plan becomes unsuitable. Experimental results show that the proposed me
thod performs excellently in planning, communication, and collaboration on embod
ied environments (CWAH and TDW-MAT), efficiently completing long-term, complex t
asks and significantly outperforming existing methods.

PromptHMR: Promptable Human Mesh Recovery
Yufu Wang, Yu Sun, Priyanka Patel, Kostas Daniilidis, Michael J. Black, Muhammed
 Kocabas; Proceedings of the Computer Vision and Pattern Recognition Conference
(CVPR), 2025, pp. 1148-1159
Human pose and shape (HPS) estimation presents challenges in diverse scenarios s
uch as crowded scenes, person-person interactions, and single-view reconstructio
n. Existing approaches lack mechanisms to incorporate auxiliary "side informatio
n" that could enhance reconstruction accuracy in such challenging scenarios. Fur
thermore, the most accurate methods rely on cropped person detections and cannot
 exploit scene context while methods that process the whole image often fail to
detect people and are less accurate than methods that use crops. While recent la
nguage-based methods explore HPS reasoning through large language or vision-lang
uage models, their metric accuracy is well below the state of the art. In contra
st, we present PromptHMR, a transformer-based promptable method that reformulate
s HPS estimation through spatial and semantic prompts. Our method processes full
 images to maintain scene context and accepts multiple input modalities: spatial
 prompts like bounding boxes and masks, and semantic prompts like language descr
iptions or interaction labels. PromptHMR demonstrates robust performance across
challenging scenarios: estimating people from bounding boxes as small as faces i
n crowded scenes, improving body shape estimation through language descriptions,
 modeling person-person interactions, and producing temporally coherent motions
in videos. Experiments on benchmarks show that PromptHMR achieves state-of-the-a
rt performance while offering flexible prompt-based control over the HPS estimat
ion process.

SyncVP: Joint Diffusion for Synchronous Multi-Modal Video Prediction
Enrico Pallotta, Sina Mokhtarzadeh Azar, Shuai Li, Olga Zatsarynna, Juergen Gall
; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR),
2025, pp. 13787-13797
Predicting future video frames is essential for decision-making systems, yet RGB
 frames alone often lack the information needed to fully capture the underlying
complexities of the real world. To address this limitation, we propose a multi-m
odal framework for Synchronous Video Prediction (SyncVP) that incorporates compl
ementary data modalities, enhancing the richness and accuracy of future predicti
ons. SyncVP builds on pre-trained modality-specific diffusion models and introdu
ces an efficient spatio-temporal cross-attention module to enable effective info
rmation sharing across modalities. We evaluate SyncVP on standard benchmark data
sets, such as Cityscapes and BAIR, using depth as an additional modality. We fur
thermore demonstrate its generalization to other modalities on SYNTHIA with sema
ntic information and ERA5-Land with climate data. Notably, SyncVP achieves state
-of-the-art performance, even in scenarios where only one modality is present, d
emonstrating its robustness and potential for a wide range of applications.

HUSH: Holistic Panoramic 3D Scene Understanding using Spherical Harmonics

Jongsung Lee, Harin Park, Byeong-Uk Lee, Kyungdon Joo; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 16599-16608
Motivated by the efficiency of spherical harmonics (SH) in representing various physical phenomena, we propose a Holistic panoramic 3D scene Understanding framework using Spherical Harmonics, dubbed as HUSH. Our approach focuses on a unified framework adaptable to various 3D scene understanding tasks via SH bases. To achieve this, we first estimate SH coefficients, allowing for the adaptive configuration of the SH bases specific to each scene. HUSH then employs a hierarchical attention module that uses SH bases as queries to generate comprehensive scene features by integrating these scene-adaptive SH bases with image features. Additionally, we introduce an SH basis index module that adaptively emphasizes relevant SH bases to produce task-relevant features, enhancing the versatility of HUSH across different scene understanding tasks. Finally, by combining the scene features with task-relevant features in the task-specific heads, we perform various scene understanding tasks, including depth, surface normal and room layout estimation. Experiments demonstrate that HUSH achieves state-of-the-art performance on depth estimation benchmarks, highlighting the robustness and scalability of using SH in panoramic 3D scene understanding.

SkillMimic: Learning Basketball Interaction Skills from Demonstrations
Yinhuai Wang, Qihan Zhao, Runyi Yu, Hok Wai Tsui, Ailing Zeng, Jing Lin, Zhengyi Luo, Jiwen Yu, Xiu Li, Qifeng Chen, Jian Zhang, Lei Zhang, Ping Tan; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 17540-17549
Traditional reinforcement learning methods for human-object interaction (HOI) rely on labor-intensive, manually designed skill rewards that do not generalize well across different interactions. We introduce SkillMimic, a unified data-driven framework that fundamentally changes how agents learn interaction skills by eliminating the need for skill-specific rewards. Our key insight is that a unified HOI imitation reward can effectively capture the essence of diverse interaction patterns from HOI datasets. This enables SkillMimic to learn a single policy that not only masters multiple interaction skills but also facilitates skill transitions, with both diversity and generalization improving as the HOI dataset grows. For evaluation, we collect and introduce two basketball datasets containing approximately 35 minutes of diverse basketball skills. Extensive experiments show that SkillMimic successfully masters a wide range of basketball skills including stylistic variations in dribbling, layup, and shooting. Moreover, these learned skills can be effectively composed by a high-level controller to accomplish complex and long-horizon tasks such as consecutive scoring, opening new possibilities for scalable and generalizable interaction skill learning. Project page: https://ingrid789.github.io/SkillMimic/

VISTREAM: Improving Computation Efficiency of Visual Streaming Perception via Law-of-Charge-Conservation Inspired Spiking Neural Network
Kang You, Ziling Wei, Jing Yan, Boning Zhang, Qinghai Guo, Yaoyu Zhang, Zhezhi He; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 8796-8805
Visual streaming perception (VSP) involves online intelligent processing of sequential frames captured by vision sensors, enabling real-time decision-making in applications such as autonomous driving, UAVs, and AR/VR. However, the computational efficiency of VSP on edge devices remains a challenge due to power constraints and the underutilization of temporal dependencies between frames. While spiking neural networks (SNNs) offer biologically inspired event-driven processing with potential energy benefits, their practical advantage over artificial neural networks (ANNs) for VSP tasks remains unproven.In this work, we introduce a novel framework, VISTREAM, which leverages the Law of Charge Conservation (LoCC) property in ST-BIF neurons and a differential encoding (DiffEncode) scheme to optimize SNN inference for VSP. By encoding temporal differences between neighboring frames and eliminating frequent membrane resets, VISTREAM achieves significant computational efficiency while maintaining accuracy equivalent to its ANN counter

part. We provide theoretical proofs of equivalence and validate VISTREAM across diverse VSP tasks, including object detection, tracking, and segmentation, demonstrating substantial energy savings without compromising performance.

STPro: Spatial and Temporal Progressive Learning for Weakly Supervised Spatio-Temporal Grounding

Aaryan Garg, Akash Kumar, Yogesh S Rawat; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 3384-3394

In this work, we study Weakly Supervised Spatio-Temporal Video Grounding (WSTVG), a challenging task of localizing subjects spatio-temporally in videos using only textual queries and no bounding box supervision. Inspired by recent advances in vision-language foundation models, we investigate their utility for WSTVG, leveraging their zero-shot grounding capabilities. However, we find that a simple adaptation lacks essential spatio-temporal grounding abilities. To bridge this gap, we introduce Tubelet Referral Grounding (TRG), which connects textual queries to tubelets to enable spatio-temporal predictions. Despite its promise, TRG struggles with compositional action understanding and dense scene scenarios. To address these limitations, we propose STPro, a progressive learning framework with two key modules: Sub-Action Temporal Curriculum Learning (SA-TCL), which incrementally builds compositional action understanding, and Congestion-Guided Spatial Curriculum Learning (CG-SCL), which adapts the model to complex scenes by spatially increasing task difficulty. STPro achieves state-of-the-art results on three benchmark datasets, with improvements of 1.0% on VidSTG-Declarative and 3.0% on HCSTVG-v1.

RGBAvatar: Reduced Gaussian Blendshapes for Online Modeling of Head Avatars

Linzhou Li, Yumeng Li, Yanlin Weng, Youyi Zheng, Kun Zhou; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 10747-10757

We present Reduced Gaussian Blendshapes Avatar (RGBAvatar), a method for reconstructing photorealistic, animatable head avatars at speeds sufficient for on-the-fly reconstruction. Unlike prior approaches that utilize linear bases from 3D morphable models (3DMM) to model Gaussian blendshapes, our method maps tracked 3DMM parameters into reduced blendshape weights with an MLP, leading to a compact set of blendshape bases. The learned compact base composition effectively captures essential facial details for specific individuals, and does not rely on the fixed base composition weights of 3DMM, leading to enhanced reconstruction quality and higher efficiency. To further expedite the reconstruction process, we develop a novel color initialization estimation method and a batch-parallel Gaussian rasterization process, achieving state-of-the-art quality with training throughput of about 630 images per second. Moreover, we propose a local-global sampling strategy that enables direct on-the-fly reconstruction, immediately reconstructing the model as video streams in real time while achieving quality comparable to offline settings. Our source code is available at https://github.com/gapszju/RGBAvatar.

Rashomon Sets for Prototypical-Part Networks: Editing Interpretable Models in Real-Time

Jon Donnelly, Zhicheng Guo, Alina Jade Barnett, Hayden McTavish, Chaofan Chen, Cynthia Rudin; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 4528-4538

Interpretability is critical for machine learning models in high-stakes settings because it allows users to verify the model's reasoning. In computer vision, prototypical part models (ProtoPNets) have become the dominant model type to meet this need. Users can easily identify flaws in ProtoPNets, but fixing problems in a ProtoPNet requires slow, difficult retraining that is not guaranteed to resolve the issue. This problem is called the "interaction bottleneck." We solve the interaction bottleneck for ProtoPNets by simultaneously finding many equally good ProtoPNets (i.e., a draw from a "Rashomon set"). We show that our framework - called Proto-RSet - quickly produces many accurate, diverse ProtoPNets, allowing users to correct problems in real time while maintaining performance guarantees

with respect to the training set. We demonstrate the utility of this method in two settings: 1) removing synthetic bias introduced to a bird-identification model and 2) debugging a skin cancer identification model. This tool empowers non-machine-learning experts, such as clinicians or domain experts, to quickly refine and correct machine learning models without repeated retraining by machine learning experts.

EEE-Bench: A Comprehensive Multimodal Electrical And Electronics Engineering Benchmark

Ming Li, Jike Zhong, Tianle Chen, Yuxiang Lai, Konstantinos Psounis; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 13337-13349

Recent studies on large language models (LLMs) and large multimodal models (LMMs) have demonstrated promising skills in various domains including science and mathematics. However, their capability in more challenging and real-world related scenarios like engineering has not been systematically studied. To bridge this gap, we propose EEE-Bench, a multimodal benchmark aimed at assessing LMMs' capabilities in solving practical engineering tasks, using electrical and electronics engineering (EEE) as the testbed. Our benchmark consists of 2860 hand-picked and carefully curated problems spanning 10 essential subdomains such as analog circuits, control systems, etc. Compared to other domains, engineering problems are intrinsically 1) more visually complex and versatile and 2) less deterministic in solutions. Successful solutions to these problems often demand more-than-usual rigorous integration of visual and textual information as models need to understand intricate images like abstract circuits and system diagrams while taking professional instructions. Alongside EEE-Bench, we provide extensive quantitative evaluations, fine-grained analysis, and improvement methods using 17 widely-used open- and closed-sourced LLMs and LMMs and 7 popular prompting techniques. Our results reveal notable deficiencies in current foundation models for EEE, including an average performance ranging from 19.48% to 46.78% and a tendency toward "laziness" in overlooking essential visual context. In summary, we believe EEE-Bench not only reveals some noteworthy limitations of LMMs but also provides a valuable resource for advancing research on their application in practical engineering tasks, driving future improvements in their capability to handle complex, real-world scenarios.

Text-Driven Fashion Image Editing with Compositional Concept Learning and Counterfactual Abduction

Shanshan Huang, Haoxuan Li, Chunyuan Zheng, Mingyuan Ge, Wei Gao, Lei Wang, Li Liu; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 28726-28735

Fashion image editing is a valuable tool for designers to convey their creative ideas by visualizing design concepts. With the recent advances in text editing methods, significant progress has been made in fashion image editing. However, they face two key challenges: spurious correlations in training data often induce changes in other areas when editing an area representing the intended editing concept, and these models typically lack the ability to edit multiple concepts simultaneously. To address the above challenges, we propose a novel \underline T ext-driven \underline F ashion \underline I mage edi\underline T ing framework called T-FIT to mitigate the impact of spurious correlation by integrating counterfactual reasoning with compositional concept learning to precisely ensure compositional multi-concept fashion image editing relying solely on text descriptions. Specifically, T-FIT includes three key components. (i) Counterfactual abduction module, which learns an exogenous variable of the source image by a denoising U-Net model. (ii) Concept learning module, which identifies concepts in fashion image editing--such as clothing types and colors and projects a target concept into the space spanned from a series of textual prompts. (iii) Concept composition module, which enables simultaneous adjustments of multiple concepts by aggregating each concept's direction vector obtained from the concept learning module. Extensive experiments show that our method can achieve state-of-the-art performanc

e on various fashion image editing tasks, including single-concept editing (e.g. , sleeve length, clothing type) and multi-concept editing (e.g., color & sleeve length).

EnvPoser: Environment-aware Realistic Human Motion Estimation from Sparse Observ ations with Uncertainty Modeling
Songpengcheng Xia, Yu Zhang, Zhuo Su, Xiaozheng Zheng, Zheng Lv, Guidong Wang, Y ongjie Zhang, Qi Wu, Lei Chu, Ling Pei; Proceedings of the Computer Vision and P attern Recognition Conference (CVPR), 2025, pp. 1839-1849
Estimating full-body motion using the tracking signals of head and hands from VR devices holds great potential for various applications. However, the sparsity a nd unique distribution of observations present a significant challenge, resultin g in an ill-posed problem with multiple feasible solutions (i.e., hypotheses). T his amplifies uncertainty and ambiguity in full-body motion estimation, especial ly for the lower-body joints. Therefore, we propose a new method, EnvPoser, that employs a two-stage framework to perform full-body motion estimation using spar se tracking signals and pre-scanned environment from VR devices. EnvPoser models the multi-hypothesis nature of human motion through an uncertainty-aware estima tion module in the first stage. In the second stage, we refine these multi-hypot hesis estimates by integrating semantic and geometric environmental constraints, ensuring that the final motion estimation aligns realistically with both the en vironmental context and physical interactions.Qualitative and quantitative exper iments on two public datasets demonstrate that our method achieves state-of-the- art performance, highlighting significant improvements in human motion estimatio n within motion-environment interaction scenarios. Project page: https://xspc.gi thub.io/EnvPoser/.

A Unified Framework for Heterogeneous Semi-supervised Learning
Marzi Heidari, Abdullah Alchihabi, Hao Yan, Yuhong Guo; Proceedings of the Compu ter Vision and Pattern Recognition Conference (CVPR), 2025, pp. 15371-15380
In this work, we introduce a novel problem setup termed as Heterogeneous Semi-Su pervised Learning (HSSL), which presents unique challenges by bridging the semi- supervised learning (SSL) task and the unsupervised domain adaptation (UDA) task , and expanding standard semi-supervised learning to cope with heterogeneous tra ining data. At its core, HSSL aims to learn a prediction model using a combinati on of labeled and unlabeled training data drawn separately from heterogeneous do mains that share a common set of semantic categories; this model is intended to differentiate the semantic categories of test instances sampled from both the la beled and unlabeled domains. In particular, the labeled and unlabeled domains ha ve dissimilar label distributions and class feature distributions. This heteroge neity, coupled with the assorted sources of the test data, introduces significan t challenges to standard SSL and UDA methods. Therefore, we propose a novel meth od, Unified Framework for Heterogeneous Semi-supervised Learning (Uni-HSSL), to address HSSL by directly learning a fine-grained classifier from the heterogeneo us data, which adaptively handles the inter-domain heterogeneity while leveragin g both the unlabeled data and the inter-domain semantic class relationships for cross-domain knowledge transfer and adaptation. We conduct comprehensive experim ents and the experimental results validate the efficacy and superior performance of the proposed Uni-HSSL over state-of-the-art semi-supervised learning and uns upervised domain adaptation methods.

Adapting Text-to-Image Generation with Feature Difference Instruction for Generi c Image Restoration
Chao Wang, Hehe Fan, Huichen Yang, Sarvnaz Karimi, Lina Yao, Yi Yang; Proceeding s of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 23 539-23550
Diffusion-based Text-to-Image (T2I) models have demonstrated significant potenti al in image restoration. However, existing models continue to grapple with chall enges such as complex training and prompt design. We introduce a new perspective for improving image restoration by injecting knowledge from pretrained vision-l

anguage models into current T2I models. We empirically show that the degradation and content representations in BLIP-2 can be linearly separated, providing promising degradation guidance for image restoration. Specifically, the Feature Difference Instruction (FDI) is first extracted by Q-Formers through a simple subtraction operation based on reference image pairs. Then, we propose a multi-scale FDI adapter to decouple the degradation style and corrupted artifacts, and inject the styleflow exclusively into specific blocks through adapter-tuning, thereby preventing noise interference and eschewing the need for cumbersome weight retraining. In this way, we can train various task-specific adapters according to different degradations, achieving rich detail enhancement in the restoration results. Furthermore, the proposed FDI adapters have attractive properties of practical value, such as composability and generalization ability for all-in-one and mixed-degradation restoration. Extensive experiments under various settings demonstrate that our method has promising repairing quality over 10 image restoration tasks and a wide range of other applications.

****

ReCon: Enhancing True Correspondence Discrimination through Relation Consistency for Robust Noisy Correspondence Learning

Quanxing Zha, Xin Liu, Shu-Juan Peng, Yiu-ming Cheung, Xing Xu, Nannan Wang; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 29680-29689

Can we accurately identify the true correspondences from multimodal datasets containing mismatched data pairs? Existing methods primarily emphasize the similarity matching between the representations of objects across modalities, potentially neglecting the crucial relation consistency within modalities that are particularly important for distinguishing the true and false correspondences. Such an omission often runs the risk of misidentifying negatives as positives, thus leading to unanticipated performance degradation. To address this problem, we propose a general Relation Consistency learning framework, namely ReCon, to accurately discriminate the true correspondences among the multimodal data and thus effectively mitigate the adverse impact caused by mismatches. Specifically, ReCon leverages a novel relation consistency learning to ensure the dual-alignment, respectively of, the cross-modal relation consistency between different modalities and the intra-modal relation consistency within modalities. Thanks to such dual constrains on relations, ReCon significantly enhances its effectiveness for true correspondence discrimination and therefore reliably filters out the mismatched pairs to mitigate the risks of wrong supervisions. Extensive experiments on three widely-used benchmark datasets, including Flickr30K, MS-COCO, and Conceptual Captions, are conducted to demonstrate the effectiveness and superiority of ReCon compared with other SOTAs. The code is available at: https://anonymous.4open.science/r/ReCon-NCL.

Free360: Layered Gaussian Splatting for Unbounded 360-Degree View Synthesis from Extremely Sparse and Unposed Views

Chong Bao, Xiyu Zhang, Zehao Yu, Jiale Shi, Guofeng Zhang, Songyou Peng, Zhaopeng Cui; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 16377-16387

Neural rendering has demonstrated remarkable success in high-quality 3D neural reconstruction and novel view synthesis with dense input views and accurate poses. However, applying it to sparse, unposed views in unbounded 360* scenes remains a challenging problem. In this paper, we propose a novel neural rendering framework to accomplish the unposed and extremely sparse-view 3D reconstruction in unbounded 360* scenes. To resolve the spatial ambiguity inherent in unbounded scenes with sparse input views, we propose a layered Gaussian-based representation to effectively model the scene with distinct spatial layers. By employing a dense stereo reconstruction model to recover coarse geometry, we introduce a layer-specific bootstrap optimization to refine the noise and fill occluded regions in the reconstruction. Furthermore, we propose an iterative fusion of reconstruction and generation alongside an uncertainty-aware training approach to facilitate mutual conditioning and enhancement between these two processes. Comprehensive ex

periments show that our approach outperforms existing state-of-the-art methods i
n terms of rendering quality and surface reconstruction accuracy. Project page:
https://zju3dv.github.io/free360/

Tuning the Frequencies: Robust Training for Sinusoidal Neural Networks
Tiago Novello, Diana Aldana, Andre Araujo, Luiz Velho; Proceedings of the Comput
er Vision and Pattern Recognition Conference (CVPR), 2025, pp. 3071-3080
Sinusoidal neural networks have been shown effective as implicit neural represen
tations (INRs) of low-dimensional signals, due to their smoothness and high repr
esentation capacity. However, initializing and training them remain empirical ta
sks which lack on deeper understanding to guide the learning process. To fill th
is gap, our work introduces a theoretical framework that explains the capacity p
roperty of sinusoidal networks and offers robust control mechanisms for initiali
zation and training. Our analysis is based on a novel amplitude-phase expansion
of the sinusoidal multilayer perceptron, showing how its layer compositions prod
uce a large number of new frequencies expressed as integer combinations of the i
nput frequencies. This relationship can be directly used to initialize the input
neurons, as a form of spectral sampling, and to bound the network's spectrum wh
ile training. Our method, referred to as TUNER (TUNing sinusoidal nEtwoRks), gre
atly improves the stability and convergence of sinusoidal INR training, leading
to detailed reconstructions, while preventing overfitting.

Open Ad-hoc Categorization with Contextualized Feature Learning
Zilin Wang, Sangwoo Mo, Stella X. Yu, Sima Behpour, Liu Ren; Proceedings of the
Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 15108-15117
Adaptive categorization of visual scenes is essential for AI agents to handle ch
anging tasks. Unlike fixed common categories for plants or animals, ad-hoc cate
gories, such as things to sell at a garage sale, are created dynamically to achi
eve specific tasks. We study open ad-hoc categorization, where the goal is to i
nfer novel concepts and categorize images based on a given context, a small set
of labeled exemplars, and some unlabeled data. We have two key insights: 1) reco
gnizing ad-hoc categories relies on the same perceptual processes as common cate
gories; 2) novel concepts can be discovered semantically by expanding contextual
cues or visually by clustering similar patterns. We propose OAK, a simple mode
l that introduces a single learnable context token into CLIP, trained with CLIP'
s objective of aligning visual and textual features and GCD's objective of clust
ering similar images. On Stanford and Clevr-4 datasets, OAK consistently achieve
s the state-of-art in accuracy and concept discovery across multiple categorizat
ions, including 87.4% novel accuracy on Stanford Mood, surpassing CLIP and GCD b
y over 50%. Moreover, OAK generates interpretable saliency maps, focusing on han
ds for Action, faces for Mood, and backgrounds for Location, promoting transpare
ncy and trust while enabling accurate and flexible categorization.

Real-time Free-view Human Rendering from Sparse-view RGB Videos using Double Unp
rojected Textures
Guoxing Sun, Rishabh Dabral, Heming Zhu, Pascal Fua, Christian Theobalt, Marc Ha
bermann; Proceedings of the Computer Vision and Pattern Recognition Conference (

CVPR), 2025, pp. 562-573
Real-time free-view human rendering from sparse-view RGB inputs is a challenging task due to the sensor scarcity and the tight time budget. To ensure efficiency, recent methods leverage 2D CNNs operating in texture space to learn rendering primitives. However, they either jointly learn geometry and appearance, or completely ignore sparse image information for geometry estimation, significantly harming visual quality and robustness to unseen body poses. To address these issues, we present Double Unprojected Textures, which at the core disentangles coarse geometric deformation estimation from appearance synthesis, enabling robust and photorealistic 4K rendering in real-time. Specifically, we first introduce a novel image-conditioned template deformation network, which estimates the coarse deformation of the human template from a first unprojected texture. This updated geometry is then used to apply a second and more accurate texture unprojection. The resulting texture map has fewer artifacts and better alignment with input views, which benefits our learning of finer-level geometry and appearance represented by Gaussian splats. We validate the effectiveness and efficiency of the proposed method in quantitative and qualitative experiments, which significantly surpasses other state-of-the-art methods.
****
ECBench: Can Multi-modal Foundation Models Understand the Egocentric World? A Holistic Embodied Cognition Benchmark
Ronghao Dang, Yuqian Yuan, Wenqi Zhang, Yifei Xin, Boqiang Zhang, Long Li, Liuyi Wang, Qinyang Zeng, Xin Li, Lidong Bing; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 24593-24602
The enhancement of generalization in robots by large vision-language models (LVLMs) is increasingly evident. Therefore, the embodied cognitive abilities of LVLMs based on egocentric videos are of great interest. However, current datasets for embodied video question answering lack comprehensive and systematic evaluation frameworks. Critical embodied cognitive issues, such as robotic self-cognition, dynamic scene perception, and hallucination, are rarely addressed. To tackle these challenges, we propose ECBench, a high-quality benchmark designed to systematically evaluate the embodied cognitive abilities of LVLMs. ECBench features a diverse range of scene video sources, open and varied question formats, and 30 dimensions of embodied cognition. To ensure quality, balance, and high visual dependence, ECBench uses class-independent meticulous human annotation and multi-round question screening strategies. Additionally, we introduce ECEval, a comprehensive evaluation system that ensures the fairness and rationality of the indicators. Utilizing ECBench, we conduct extensive evaluations of proprietary, open-source, and task-specific LVLMs. ECBench is pivotal in advancing the embodied cognitive capabilities of LVLMs, laying a solid foundation for developing reliable core models for embodied agents. All data and code is available at https://github.com/Rh-Dang/ECBench.
****
SfM-Free 3D Gaussian Splatting via Hierarchical Training
Bo Ji, Angela Yao; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 21654-21663
Standard 3D Gaussian Splatting (3DGS) relies on known or pre-computed camera poses and a sparse point cloud, obtained from structure-from-motion (SfM) preprocessing, to initialize and grow 3D Gaussians. We propose a novel SfM-Free 3DGS (SFGS) method for video input, eliminating the need for known camera poses and SfM preprocessing. Our approach introduces a hierarchical training strategy that trains and merges multiple 3D Gaussian representations -- each optimized for specific scene regions -- into a single, unified 3DGS model representing the entire scene. To compensate for large camera motions, we leverage video frame interpolation models. Additionally, we incorporate multi-source supervision to reduce overfitting and enhance representation. Experimental results reveal that our approach significantly surpasses state-of-the-art SfM-free novel view synthesis methods. On the Tanks and Temples dataset, we improve PSNR by an average of 2.25dB, with a maximum gain of 3.72dB in the best scene. On the CO3D-V2 dataset, we achieve an average PSNR boost of 1.74dB, with a top gain of 3.90dB. The code is available

at \href https://github.com/jibo27/3DGS_Hierarchical_Training/ https://github.com/jibo27/3DGS_Hierarchical_Training .

Large Self-Supervised Models Bridge the Gap in Domain Adaptive Object Detection
Marc-Antoine Lavoie, Anas Mahmoud, Steven L. Waslander; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 4692-4702
The current state-of-the-art methods in domain adaptive object detection (DAOD) use Mean Teacher self-labelling, where a teacher model, directly derived as an exponential moving average of the student model, is used to generate labels on the target domain which are then used to improve both models in a positive loop. This couples learning and generating labels on the target domain, and other recent works also leverage the generated labels to add additional domain alignment losses. We believe this coupling is brittle and excessively constrained: there is no guarantee that a student trained only on source data can generate accurate target domain labels and initiate the positive feedback loop, and much better target domain labels can likely be generated by using a large pretrained network that has been exposed to much more data. Vision foundational models are exactly such models, and they have shown impressive task generalization capabilities even when frozen. We want to leverage these models for DAOD and introduce DINO Teacher, which consists of two components. First, we train a new labeller on source data only using a large frozen DINOv2 backbone and show it generates more accurate labels than Mean Teacher. Next, we align the student's source and target image patch features with those from a DINO encoder, driving source and target representations closer to the generalizable DINO representation. We obtain state-of-the-art performance on multiple DAOD datasets.

Dynamic Updates for Language Adaptation in Visual-Language Tracking
Xiaohai Li, Bineng Zhong, Qihua Liang, Zhiyi Mo, Jian Nong, Shuxiang Song; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 19165-19174
The consistency between the semantic information provided by the multi-modal reference and the tracked object is crucial for visual-language (VL) tracking. However, existing VL tracking frameworks rely on static multi-modal references to locate dynamic objects, which can lead to semantic discrepancies and reduce the robustness of the tracker. To address this issue, we propose a novel vision-language tracking framework, named DUTrack, which captures the latest state of the target by dynamically updating multi-modal references to maintain consistency.Specifically, we introduce a Dynamic Language Update Module, which leverages a large language model to generate dynamic language descriptions for the object based on visual features and object category information. Then, we design a Dynamic Template Capture Module, which captures the regions in the image that highly match the dynamic language descriptions. Furthermore, to ensure the efficiency of description generation, we design an update strategy that assesses changes in target displacement, scale, and other factors to decide on updates. Finally, the dynamic template and language descriptions that record the latest state of the target are used to update the multi-modal references, providing more accurate reference information for subsequent inference and enhancing the robustness of the tracker.DUTrack achieves new state-of-the-art performance on four mainstream vision-language and two vision-only tracking benchmarks, including LaSOT, LaSOT_ext, TNL2K, OTB99-Lang, GOT-10K, and UAV123.

Multi-focal Conditioned Latent Diffusion for Person Image Synthesis
Jiaqi Liu, Jichao Zhang, Paolo Rota, Nicu Sebe; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 16019-16028
The Latent Diffusion Model (LDM) has demonstrated strong capabilities in high-resolution image generation and has been widely employed for Pose-Guided Person Image Synthesis (PGPIS), yielding promising results. However, the compression process of LDM often results in the deterioration of details, particularly in sensitive areas such as facial features and clothing textures. In this paper, we propose a Multi-focal Conditioned Latent Diffusion (MCLD) method to address these lim

itations by conditioning the model on disentangled, pose-invariant features from these sensitive regions. Our approach utilizes a multi-focal condition aggregation module, which effectively integrates facial identity and texture-specific information, enhancing the model's ability to produce appearance realistic and identity-consistent images. Our method demonstrates consistent identity and appearance generation on the DeepFashion dataset and enables flexible person image editing due to its generation consistency. The code is available at https://github.com/jqliu09/mcld.

Uncertainty Meets Diversity: A Comprehensive Active Learning Framework for Indoor 3D Object Detection

Jiangyi Wang, Na Zhao; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 20329-20339

Active learning has emerged as a promising approach to reduce the substantial annotation burden in 3D object detection tasks, spurring several initiatives in outdoor environments. However, its application in indoor environments remains unexplored. Compared to outdoor 3D datasets, indoor datasets face significant challenges, including fewer training samples per class, a greater number of classes, more severe class imbalance, and more diverse scene types and intra-class variances.This paper presents the first study on active learning for indoor 3D object detection, where we propose a novel framework tailored for this task. Our method incorporates two key criteria - uncertainty and diversity - to actively select the most ambiguous and informative unlabeled samples for annotation. The uncertainty criterion accounts for both inaccurate detections and undetected objects, ensuring that the most ambiguous samples are prioritized. Meanwhile, the diversity criterion is formulated as a joint optimization problem that maximizes the diversity of both object class distributions and scene types, using a new Class-aware Adaptive Prototype (CAP) bank. The CAP bank dynamically allocates representative prototypes to each class, helping to capture varying intra-class diversity across different categories.We evaluate our method on SUN RGB-D and ScanNetV2, where it outperforms baselines by a significant margin, achieving over 85% of fully-supervised performance with just 10% of the annotation budget.

CASAGPT: Cuboid Arrangement and Scene Assembly for Interior Design

Weitao Feng, Hang Zhou, Jing Liao, Li Cheng, Wenbo Zhou; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 29173-29182

We present a novel approach for indoor scene synthesis, which learns to arrange decomposed cuboid primitives to represent 3D objects within a scene. Unlike conventional methods that use bounding boxes to determine the placement and scale of 3D objects, our approach leverages cuboids as a straightforward yet highly effective alternative for modeling objects. This allows for compact scene generation while minimizing object intersections. Our approach, coined CASAGPT for Cuboid Arrangement and Scene Assembly, employs an autoregressive model to sequentially arrange cuboids, producing physically plausible scenes. By applying rejection sampling during the fine-tuning stage to filter out scenes with object collisions, our model further reduces intersections and enhances scene quality. Additionally, we introduce a refined dataset, 3DFRONT-NC, which eliminates significant noise presented in the original dataset, 3D-FRONT. Extensive experiments on the 3D-FRONT dataset as well as our dataset demonstrate that our approach consistently outperforms the state-of-the-art methods, enhancing the realism of generated scenes, and providing a promising direction for 3D scene synthesis.

Identity-Clothing Similarity Modeling for Unsupervised Clothing Change Person Re-Identification

Zhiqi Pang, Junjie Wang, Lingling Zhao, Chunyu Wang; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 19251-19260

Clothing change person re-identification (CC-ReID) aims to match different images of the same person, even when the clothing varies across images. To reduce manual labeling costs, existing unsupervised CC-ReID methods employ clustering algorithms to generate pseudo-labels. However, they often fail to assign the same ps

eudo-label to two images with the same identity but different clothing--referred to as a clothing change positive pair--thus hindering clothing-invariant feature learning. To address this issue, we propose the identity-clothing similarity modeling (ICSM) framework. To effectively connect clothing change positive pairs, ICSM first performs clothing-aware learning to leverage all discriminative information, including clothing, to obtain compact clusters. It then extracts cluster-level identity and clothing features and performs inter-cluster similarity estimation to identify clothing change positive clusters, reliable negative clusters, and hard negative clusters for each compact cluster. During optimization, we design an adaptive version of existing optimization methods to enhance similarities of clothing change positive pairs, while also introducing text semantics as a supervisory signal to further promote clothing invariance. Extensive experimental results across multiple datasets validate the effectiveness of the proposed framework, demonstrating its superiority over existing unsupervised methods and its competitiveness with some supervised approaches.

Evaluating Model Perception of Color Illusions in Photorealistic Scenes

Lingjun Mao, Zineng Tang, Alane Suhr; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 7805-7814

We study the perception of color illusions by vision-language models. Color illusion, where a person's visual system perceives color differently from actual color, is well-studied in human vision. However, it remains underexplored whether vision-language models (VLMs), trained on large-scale human data, exhibit similar perceptual biases when confronted with such color illusions. We propose an automated framework for generating color illusion images, resulting in RCID (Realistic Color Illusion Dataset), a dataset of 19,000 realistic illusion images. Our experiments show that all studied VLMs exhibit perceptual biases similar human vision. Finally, we train a model to distinguish both human perception and actual pixel differences.

MINIMA: Modality Invariant Image Matching

Jiangwei Ren, Xingyu Jiang, Zizhuo Li, Dingkang Liang, Xin Zhou, Xiang Bai; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 23059-23068

Image matching for both cross-view and cross-modality plays a critical role in multimodal perception. In practice, the modality gap caused by different imaging systems/styles poses great challenges to the matching task. Existing works try to extract invariant features for specific modalities and train on limited datasets, showing poor generalization. In this paper, we present MINIMA, a unified image matching framework for multiple cross-modal cases. Without pursuing fancy modules, our MINIMA aims to enhance universal performance from the perspective of data scaling up. For such purpose, we propose a simple yet effective data engine that can freely produce a large dataset containing multiple modalities, rich scenarios, and accurate matching labels. Specifically, we scale up the modalities from cheap but rich RGB-only matching data, by means of generative models. Under this setting, the matching labels and rich diversity of the RGB dataset are well inherited by the generated multimodal data. Benefiting from this, we construct MD-syn, a new comprehensive dataset that fills the data gap for general multimodal image matching. With MD-syn, we can directly train any advanced matching pipeline on randomly selected modality pairs to obtain cross-modal ability. Extensive experiments on in-domain and zero-shot matching tasks, including 19 cross-modal cases, demonstrate that our MINIMA can significantly outperform the baselines and even surpass modality-specific methods. The dataset and code are available at https://github.com/LSXI7/MINIMA

OccMamba: Semantic Occupancy Prediction with State Space Models

Heng Li, Yuenan Hou, Xiaohan Xing, Yuexin Ma, Xiao Sun, Yanyong Zhang; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 11949-11959

Training deep learning models for semantic occupancy prediction is challenging d

ue to factors such as a large number of occupancy cells, severe occlusion, limit ed visual cues, complicated driving scenarios, etc. Recent methods often adopt t ransformer-based architectures given their strong capability in learning input-c onditioned weights and long-range relationships. However, transformer-based netw orks are notorious for their quadratic computation complexity, seriously undermi ning their efficacy and deployment in semantic occupancy prediction. Inspired by the global modeling and linear computation complexity of the Mamba architecture , we present the first Mamba-based network for semantic occupancy prediction, te rmed OccMamba. Specifically, we first design the hierarchical Mamba module and l ocal context processor to better aggregate global and local contextual informati on, respectively. Besides, to relieve the inherent domain gap between the lingui stic and 3D domains, we present a simple yet effective 3D-to-1D reordering schem e, i.e., height-prioritized 2D Hilbert expansion. It can maximally retain the sp atial structure of 3D voxels as well as facilitate the processing of Mamba block s. Endowed with the aforementioned designs, our OccMamba is capable of directly and efficiently processing large volumes of dense scene grids, achieving state-o f-the-art performance across three prevalent occupancy prediction benchmarks, in cluding OpenOccupancy, SemanticKITTI, and SemanticPOSS. Notably, on OpenOccupanc y, our OccMamba outperforms the previous state-of-the-art Co-Occ by 5.1% IoU and 4.3% mIoU, respectively. Our implementation is open-sourced and available at: h ttps://github.com/USTCLH/OccMamba.

3D Convex Splatting: Radiance Field Rendering with 3D Smooth Convexes

Jan Held, Renaud Vandeghen, Abdullah Hamdi, Adrien Deliege, Anthony Cioppa, Silv io Giancola, Andrea Vedaldi, Bernard Ghanem, Marc Van Droogenbroeck; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 213 60-21369

Recent advances in radiance field reconstruction, such as 3D Gaussian Splatting (3DGS), have achieved high-quality novel view synthesis and fast rendering by re presenting scenes with compositions of Gaussian primitives. However, 3D Gaussian s present several limitations for scene reconstruction. Accurately capturing har d edges is challenging without significantly increasing the number of Gaussians, creating a large memory footprint. Moreover, they struggle to represent flat su rfaces, as they are diffused in space. Without hand-crafted regularizers, they t end to disperse irregularly around the actual surface. To circumvent these issue s, we introduce a novel method, named 3D Convex Splatting (3DCS), which leverage s 3D smooth convexes as primitives for modeling geometrically-meaningful radianc e fields from multi-view images. Smooth convex shapes offer greater flexibility than Gaussians, allowing for a better representation of 3D scenes with hard edge s and dense volumes using fewer primitives. Powered by our efficient CUDA-based rasterizer, 3DCS achieves superior performance over 3DGS on benchmarks such as M ip-NeRF360, Tanks and Temples, and Deep Blending. Specifically, our method attai ns an improvement of up to 0.81 in PSNR and 0.026 in LPIPS compared to 3DGS whil e maintaining high rendering speeds and reducing the number of required primitiv es. Our results highlight the potential of 3D Convex Splatting to become the new standard for high-quality scene reconstruction and novel view synthesis. The pr oject page is https://convexsplatting.github.io/ .

3D Prior Is All You Need: Cross-Task Few-shot 2D Gaze Estimation

Yihua Cheng, Hengfei Wang, Zhongqun Zhang, Yang Yue, Boeun Kim, Feng Lu, Hyung J in Chang; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 23891-23900

3D and 2D gaze estimation share the fundamental objective of capturing eye movem ents but are traditionally treated as two distinct research domains. In this pap er, we introduce a novel cross-task few-shot 2D gaze estimation approach, aiming to adapt a pre-trained 3D gaze estimation network for 2D gaze prediction on uns een devices using only a few training images. This task is highly challenging du e to the domain gap between 3D and 2D gaze, unknown screen poses, and limited tr aining data. To address these challenges, we propose a novel framework that brid ges the gap between 3D and 2D gaze. Our framework contains a physics-based diffe

rentiable projection module with learnable parameters to model screen poses and project 3D gaze into 2D gaze. The framework is fully differentiable and can integrate into existing 3D gaze networks without modifying their original architecture. Additionally, we introduce a dynamic pseudo-labelling strategy for flipped images, which is particularly challenging for 2D labels due to unknown screen poses. To overcome this, we reverse the projection process by converting 2D labels to 3D space, where flipping is performed. Notably, this 3D space is not aligned with the camera coordinate system, so we learn a dynamic transformation matrix to compensate for this misalignment. We evaluate our method on MPIIGaze, EVE, and GazeCapture datasets, collected respectively on laptops, desktop computers, and mobile devices. The superior performance highlights the effectiveness of our approach, and demonstrates its strong potential for real-world applications.

Cheb-GR: Rethinking K-nearest Neighbor Search in Re-ranking for Person Re-identification

Jinxi Yang, He Li, Bo Du, Mang Ye; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 19261-19270

Person re-identification (ReID) is the task of matching individuals across different camera views. Existing approaches typically employ neural networks to extract discriminative features, ranking gallery images based on their similarities to probe images. While effective, these methods are often enhanced through re-ranking, a post-processing step that refines initial retrieval results without requiring additional model training. However, current re-ranking methods mostly rely on k-nearest neighbor search to extract similar images that might have the same identity as the query, which is time-consuming with a high computation burden, limiting their applications in reality. We rethink the effect of the k-nearest neighbor search and introduce the Chebyshev's Theorem-guided Graph Re-ranking (Cheb-GR) method, which adopts the adaptive neighbor search guided by Chebyshev's Theorem over the k-nearest neighbor search for efficient neighbor selection. Our method leverages graph convolution operations to refine image features and achieve robust re-ranking, leading to enhanced retrieval performance. Furthermore, we provide a theoretical analysis based on Chebyshev's Inequality to elucidate the factors contributing to the strong performance of the proposed method. Our method significantly reduces the computation costs while maintaining relatively strong performance. Through extensive experiments in both general and cross-domain settings, we demonstrate the effectiveness of Cheb-GR and its potential for real-world applications.

Spotting the Unexpected (STU): A 3D LiDAR Dataset for Anomaly Segmentation in Autonomous Driving

Alexey Nekrasov, Malcolm Burdorf, Stewart Worrall, Bastian Leibe, Julie Stephany Berrio Perez; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 11875-11885

To operate safely, autonomous vehicles (AVs) need to detect and handle unexpected objects or anomalies on the road. While significant research exists for anomaly detection and segmentation in 2D, research progress in 3D is underexplored. Existing datasets lack high-quality multimodal data that are typically found in AVs. This paper presents a novel dataset for anomaly segmentation in driving scenarios. To the best of our knowledge, it is the first publicly available dataset focused on road anomaly segmentation with dense 3D semantic labeling, incorporating both LiDAR and camera data, as well as sequential information to enable anomaly detection across various ranges. This capability is critical for the safe navigation of autonomous vehicles. We adapted and evaluated several baseline models for 3D segmentation, highlighting the challenges of 3D anomaly detection in driving environments. Our dataset and evaluation code will be openly available, facilitating the testing and performance comparison of different approaches.

Is `Right' Right? Enhancing Object Orientation Understanding in Multimodal Large Language Models through Egocentric Instruction Tuning

Ji Hyeok Jung, Eun Tae Kim, Seoyeon Kim, Joo Ho Lee, Bumsoo Kim, Buru Chang; Pro

ceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 14257-14267
Multimodal large language models (MLLMs) act as essential interfaces, connecting humans with AI technologies in multimodal applications. However, current MLLMs face challenges in accurately interpreting object orientation in images due to inconsistent orientation annotations in training data, hindering the development of a coherent orientation understanding. To overcome this, we propose egocentric instruction tuning, which aligns MLLMs' orientation understanding with the user's perspective, based on a consistent annotation standard derived from the user's egocentric viewpoint. We first generate egocentric instruction data that leverages MLLMs' ability to recognize object details and applies prior knowledge for orientation understanding. Using this data, we perform instruction tuning to enhance the model's capability for accurate orientation interpretation. In addition, we introduce EgoOrientBench, a benchmark that evaluates MLLMs' orientation understanding across three tasks using images collected from diverse domains. Experimental results on this benchmark show that egocentric instruction tuning significantly improves orientation understanding without compromising overall MLLM performance. The instruction data and benchmark dataset are available on our project page at https://github.com/jhCOR/EgoOrientBench.

GCC: Generative Color Constancy via Diffusing a Color Checker
Chen-Wei Chang, Cheng-De Fan, Chia-Che Chang, Yi-Chen Lo, Yu-Chee Tseng, Jiun-Long Huang, Yu-Lun Liu; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 10868-10878
Color constancy methods often struggle to generalize across different camera sensors due to varying spectral sensitivities. We present GCC, which leverages diffusion models to inpaint color checkers into images for illumination estimation. Our key innovations include (1) a single-step deterministic inference approach that inpaints color checkers reflecting scene illumination, (2) a Laplacian decomposition technique that preserves checker structure while allowing illumination-dependent color adaptation, and (3) a mask-based data augmentation strategy for handling imprecise color checker annotations. By harnessing rich priors from pre-trained diffusion models, GCC demonstrates strong robustness in challenging cross-camera scenarios. These results highlight our method's effective generalization capability across different camera characteristics without requiring sensor-specific training, making it a versatile and practical solution for real-world applications.
****

Do Visual Imaginations Improve Vision-and-Language Navigation Agents?
Akhil Perincherry, Jacob Krantz, Stefan Lee; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 3846-3855
Vision-and-Language Navigation (VLN) agents are tasked with navigating an unseen environment using natural language instructions. In this work, we study if visual representations of sub-goals implied by the instructions can serve as navigational cues and lead to increased navigation performance. To synthesize these visual representations or "imaginations", we leverage a text-to-image diffusion model on landmark references contained in segmented instructions. These imaginations are provided to VLN agents as an added modality to act as landmark cues and an auxiliary loss is added to explicitly encourage relating these with their corresponding referring expressions. Our findings reveal an increase in success rate (SR) of ~1 point and up to ~0.5 points in success scaled by inverse path length (SPL) across agents. These results suggest that the proposed approach reinforces visual understanding compared to relying on language instructions alone.

On Denoising Walking Videos for Gait Recognition
Dongyang Jin, Chao Fan, Jingzhe Ma, Jingkai Zhou, Weihua Chen, Shiqi Yu; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 12347-12357
To capture individual gait patterns, excluding identity-irrelevant cues in walking videos, such as clothing texture and color, remains a persistent challenge fo

r vision-based gait recognition. Traditional silhouette and pose-based methods, though theoretically effective at removing such distractions, often fall short of high accuracy due to their sparse and less informative inputs. To address this, emerging end-to-end methods focus on directly denoising RGB videos using global optimization and human-defined priors. Building on this trend, we propose a novel gait denoising method, DenosingGait. Inspired by the philosophy that "what I cannot create, I do not understand", we turn to generative diffusion models, uncovering how these models can partially filter out irrelevant factors for improved gait understanding. Based on this generation-driven denoising, we introduce feature matching, a kind of popular geometrical constraint in optical flow and depth estimation, to compact multi-channel float-encoded RGB information into two-channel direction vectors that represent local structural features, where within-frame matching captures spatial details and cross-frame matching conveys temporal dynamics. Experiments on the CCPG, CAISA-B*, and SUSTech1K datasets demonstrate that DenoisingGait achieves a new SoTA performance in most cases for both within-domain and cross-domain evaluations. Code is available at https://github.com/ShiqiYu/OpenGait.

Conformal Prediction for Zero-Shot Models
Julio Silva-Rodríguez, Ismail Ben Ayed, Jose Dolz; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 19931-19941
Vision-language models pre-trained at large scale have shown unprecedented adaptability and generalization to downstream tasks. Although its discriminative potential has been widely explored, its reliability and uncertainty are still overlooked. In this work, we investigate the capabilities of CLIP models under the split conformal prediction paradigm, which provides theoretical guarantees to black-box models based on a small, labeled calibration set. In contrast to the main body of literature on conformal predictors in vision classifiers, foundation models exhibit a particular characteristic: they are pre-trained on a one-time basis on an inaccessible source domain, different from the transferred task. This domain drift negatively affects the efficiency of the conformal sets and poses additional challenges. To alleviate this issue, we propose Conf-OT, a transfer learning setting that operates transductive over the combined calibration and query sets. Solving an optimal transport problem, the proposed method bridges the domain gap between pre-training and adaptation without requiring additional data splits but still maintaining coverage guarantees. We comprehensively explore this conformal prediction strategy on a broad span of 15 datasets and three non-conformity scores. Conf-OT provides consistent relative improvements of up to 20% on set efficiency while being 15 times faster than popular transductive approaches.

PhysAnimator: Physics-Guided Generative Cartoon Animation
Tianyi Xie, Yiwei Zhao, Ying Jiang, Chenfanfu Jiang; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 10793-10804
Creating hand-drawn animation sequences is labor-intensive and demands professional expertise. We introduce PhysAnimator, a novel approach for generating physically plausible meanwhile anime-stylized animation from static anime illustrations. Our method seamlessly integrates physics-based simulations with data-driven generative models to produce dynamic and visually compelling animations. To capture the fluidity and exaggeration characteristic of anime, we perform image-space deformable body simulations on extracted mesh geometries. We enhance artistic control by introducing customizable energy strokes and incorporating rigging point support, enabling the creation of tailored animation effects such as wind interactions. Finally, we extract and warp sketches from the simulation sequence, generating a texture-agnostic representation, and employ a sketch-guided video diffusion model to synthesize high-quality animation frames. The resulting animations exhibit temporal consistency and visual plausibility, demonstrating the effectiveness of our method in creating dynamic anime-style animations.
****

SeriesBench: A Benchmark for Narrative-Driven Drama Series Understanding
Chenkai Zhang, Yiming Lei, Zeming Liu, Haitao Leng, ShaoGuo Liu, Tingting Gao, Q

ingjie Liu, Yunhong Wang; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 28995-29004
With the rapid development of Multi-modal Large Language Models (MLLMs), an increasing number of benchmarks have been established to evaluate the video understanding capabilities of these models. However, these benchmarks focus on standalone videos and only assess "visual elements" like human actions and object states. In reality, contemporary videos often encompass complex and continuous narratives, typically presented as a series. To address this challenge, we propose SeriesBench, a benchmark consisting of 105 carefully curated narrative-driven series, covering 28 specialized tasks that require deep narrative understanding to solve. Specifically, we first select a diverse set of drama series spanning various genres. Then, we introduce a novel long-span narrative annotation method, combined with a full-information transformation approach to convert manual annotations into diverse task formats. To further enhance the model's capacity for detailed analysis of plot structures and character relationships within series, we propose a novel narrative reasoning framework, PC-DCoT. Extensive results on SeriesBench indicate that existing MLLMs still face significant challenges in understanding narrative-driven series, while PC-DCoT enables these MLLMs to achieve performance improvements. Overall, our SeriesBench and PC-DCoT highlight the critical necessity of advancing model capabilities for understanding narrative-driven series, guiding future MLLMs development. SeriesBench is publicly available at https://github.com/zackhxn/SeriesBench-CVPR2025.

Weakly Supervised Temporal Action Localization via Dual-Prior Collaborative Learning Guided by Multimodal Large Language Models
Quan Zhang, Jinwei Fang, Rui Yuan, Xi Tang, Yuxin Qi, Ke Zhang, Chun Yuan; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 24139-24148
Recent breakthroughs in Multimodal Large Language Models (MLLMs) have gained significant recognition within the deep learning community, where the fusion of the Video Foundation Models (VFMs) and Large Language Models(LLMs) has proven instrumental in constructing robust video understanding systems, effectively surmounting constraints associated with predefined visual tasks. These sophisticated MLLMs exhibit remarkable proficiency in comprehending videos, swiftly attaining unprecedented performance levels across diverse benchmarks. However, their operation demands substantial memory and computational resources, underscoring the continued importance of traditional models in video comprehension tasks. In this paper, we introduce a novel learning paradigm termed MLLM4WTAL. This paradigm harnesses the potential of MLLM to offer temporal action key semantics and complete semantic textual cues for conventional Weakly-supervised Temporal Action Localization (WTAL) methods. MLLM4WTAL facilitates the enhancement of WTAL by leveraging MLLM guidance. It achieves this by integrating two distinct modules: Key Semantic Matching (KSM) and Complete Semantic Reconstruction (CSR). These modules work in tandem to effectively address prevalent issues like incomplete and over-complete outcomes common in WTAL methods. Rigorous experiments are conducted to validate the efficacy of our proposed approach in augmenting the performance of various heterogeneous WTAL models.
****

FIMA-Q: Post-Training Quantization for Vision Transformers by Fisher Information Matrix Approximation
Zhuguanyu Wu, Shihe Wang, Jiayi Zhang, Jiaxin Chen, Yunhong Wang; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 14891-14900
Post-training quantization (PTQ) has stood out as a cost-effective and promising model compression approach over recent years, as it eliminates the need for retraining on the entire dataset. Unfortunately, most existing PTQ methods for Vision Transformers (ViTs) exhibit a notable drop in accuracy, especially in low-bit cases. To tackle these challenges, we analyze the extensively utilized Hessian-guided quantization loss, and uncover certain limitations within the approximated pre-activation Hessian. Following the block-by-block reconstruction paradigm o

f PTQ, we first derive a quantization loss based on the Fisher Information Matrix (FIM). Due to the large scale of the complete FIM, we establish the relationship between KL divergence and FIM in the PTQ scenario to enable fast computation of the quantization loss during reconstruction. Subsequently, we develop a Diagonal Plus Low-Rank (DPLR) estimation on FIM to achieve a more nuanced quantization loss. Our extensive experiments, conducted across various vision tasks with distinct representative ViT-based architectures on public benchmark datasets, demonstrate that our method outperforms the state-of-the-art approaches, especially in the case of low-bit quantization. The source code is available at https://github.com/ShiheWang/FIMA-Q.

HotSpot: Signed Distance Function Optimization with an Asymptotically Sufficient Condition

Zimo Wang, Cheng Wang, Taiki Yoshino, Sirui Tao, Ziyang Fu, Tzu-Mao Li; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 1276-1286

We propose a method, HotSpot, for optimizing neural signed distance functions. Existing losses, such as the eikonal loss, act as necessary but insufficient constraints and cannot guarantee that the recovered implicit function represents a true distance function, even if the output minimizes these losses almost everywhere. Furthermore, the eikonal loss suffers from stability issues in optimization. Finally, in conventional methods, regularization losses that penalize surface area distort the reconstructed signed distance function. We address these challenges by designing a loss function using the solution of a screened Poisson equation. Our loss, when minimized, provides an asymptotically sufficient condition to ensure the output converges to a true distance function. Our loss also leads to stable optimization and naturally penalizes large surface areas. We present theoretical analysis and experiments on both challenging 2D and 3D datasets and show that our method provides better surface reconstruction and a more accurate distance approximation.

****

GliaNet: Adaptive Neural Network Structure Learning with Glia-Driven

Mengqiao Han, Liyuan Pan, Xiabi Liu; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 25240-25249

Neural networks derived from the M-P model have excelled in various visual tasks. However, as a simplified simulation version of the brain neural pathway, their structures are locked during training, causing over-fitting and over-parameterization. Although recent models have begun using the biomimetic concept and empirical pruning, they still result in irrational pruning, potentially affecting the accuracy of the model. In this paper, we introduce the Glia unit, composed of oligodendrocytes (Oli) and astrocytes (Ast), to emulate the exact workflow of the mammalian brain, thereby enhancing the biological plausibility of neural functions. Oli selects neurons involved in signal transmission during neural communication and, together with Ast, adaptively optimizes the neural structure. Specifically, we first construct the artificial Glia-Neuron (G-N) model, which is formulated at the instance, group, and interaction levels with adaptive and collaborative mechanisms. Then, we construct GliaNet based on our G-N model, whose structure and connections can be continuously optimized during training. Experiments show that our GliaNet advances state-of-the-art on multiple tasks while significantly reducing its parameters.

BACON: Improving Clarity of Image Captions via Bag-of-Concept Graphs

Zhantao Yang, Ruili Feng, Keyu Yan, Huangji Wang, Zhicai Wang, Shangwen Zhu, Han Zhang, Jie Xiao, Pingyu Wu, Kai Zhu, Jixuan Chen, Chen-Wei Xie, Yue Yang, Hongyang Zhang, Yu Liu, Fan Cheng; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 14380-14389

Advancements in large Vision-Language Models have brought precise, accurate image captioning, vital for advancing multi-modal image understanding and processing. Yet these captions often carry lengthy, intertwined contexts that are difficult to parse and frequently overlook essential cues, posing a great barrier for mo

dels like GroundingDINO and SDXL, which lack the strong text encoding and syntax analysis needed to fully leverage dense captions.To address this, we propose BACON, a prompting method that breaks down VLM-generated captions into disentangled, structured elements such as objects, relationships, styles, and themes. This approach not only minimizes confusion from handling complex contexts but also allows for efficient transfer into a JSON dictionary, enabling models without linguistic processing capabilities to easily access key information.We annotated 100,000 image-caption pairs using BACON with GPT-4V and trained an LLaVA captioner on this dataset, enabling it to produce BACON-style captions without relying on costly GPT-4V resources. Evaluations of overall quality, precision, and recall--as well as user studies--demonstrate that the resulting caption model consistently outperforms other state-of-the-art VLM models in generating high-quality captions.Additionally, we show that BACON-style captions exhibit better clarity when applied to various models, enabling them to accomplish previously unattainable tasks or surpass existing SOTA solutions without training. For example, BACON-style captions help groundingDINO achieve 1.51 times higher recall scores on open-vocabulary object detection tasks compared to leading methods.

EntitySAM: Segment Everything in Video
Mingqiao Ye, Seoung Wug Oh, Lei Ke, Joon-Young Lee; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 24234-24243
Automatically tracking and segmenting every video entity remains a significant challenge. Despite rapid advancements in video segmentation, even state-of-the-art models like SAM 2 struggle to consistently track all entities across a video--a task we refer to as Video Entity Segmentation.We propose EntitySAM, a framework for zero-shot video entity segmentation. EntitySAM extends SAM 2 by removing the need for explicit prompts, allowing automatic discovery and tracking of all entities, including those appearing in later frames. We incorporate query-based entity discovery and association into SAM 2, inspired by transformer-based object detectors. Specifically, we introduce an entity decoder to facilitate inter-object communication and an automatic prompt generator using learnable object queries. Additionally, we add a semantic encoder to enhance SAM 2's semantic awareness, improving segmentation quality. Trained on image-level mask annotations without category information from the COCO dataset, EntitySAM demonstrates strong generalization on four zero-shot video segmentation tasks: Video Entity, Panoptic, Instance, and Semantic Segmentation. Results on six popular benchmarks show that EntitySAM outperforms previous unified video segmentation methods and strong baselines, setting new standards for zero-shot video segmentation.

GS-2DGS: Geometrically Supervised 2DGS for Reflective Object Reconstruction
Jinguang Tong, Xuesong Li, Fahira Afzal Maken, Sundaram Muthu, Lars Petersson, Chuong Nguyen, Hongdong Li; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 21547-21557
3D modeling of highly reflective objects remains challenging due to strong view-dependent appearances. While previous SDF-based methods can recover high-quality meshes, they are often time-consuming and tend to produce over-smoothed surfaces. In contrast, 3D Gaussian Splatting (3DGS) offers the advantage of high speed and detailed real-time rendering, but extracting surfaces from the Gaussians can be noisy due to the lack of geometric constraints. To bridge the gap between these approaches, we propose a novel reconstruction method called GS-2DGS for reflective objects based on 2D Gaussian Splatting (2DGS). Our approach combines the rapid rendering capabilities of Gaussian Splatting with additional geometric information from a foundation model. Experimental results on synthetic and real datasets demonstrate that our method significantly outperforms Gaussian-based techniques in terms of reconstruction and relighting and achieves performance comparable to SDF-based methods while being an order of magnitude faster.

Libra-Merging: Importance-redundancy and Pruning-merging Trade-off for Acceleration Plug-in in Large Vision-Language Model
Longrong Yang, Dong Shen, Chaoxiang Cai, Kaibing Chen, Fan Yang, Tingting Gao, D

i Zhang, Xi Li; Proceedings of the Computer Vision and Pattern Recognition Confe rence (CVPR), 2025, pp. 9402-9412
Large Vision-Language Models (LVLMs) have achieved significant progress in recen t years. However, the expensive inference cost limits the realistic deployment o f LVLMs. Some works find that visual tokens are redundant and compress tokens to reduce the inference cost. These works identify important non-redundant tokens as target tokens, then prune the remaining tokens (non-target tokens) or merge t hem into target tokens. However, target token identification faces the token imp ortance-redundancy dilemma. Besides, token merging and pruning face a dilemma be tween disrupting target token information and losing non-target token informatio n. To solve these problems, we propose a novel visual token compression scheme, named Libra-Merging. In target token identification, Libra-Merging selects the m ost important tokens from spatially discrete intervals, achieving a more robust token importance-redundancy trade-off than relying on a hyper-parameter. In toke n compression, when non-target tokens are dissimilar to target tokens, Libra-Mer ging does not merge them into the target tokens, thus avoiding disrupting target token information. Meanwhile, Libra-Merging condenses these non-target tokens i nto an information compensation token to prevent losing important non-target tok en information. Our method can serve as a plug-in for diverse LVLMs, and extensi ve experimental results demonstrate its effectiveness. The code will be publicly available at https://github.com/longrongyang/Libra-Merging.

VasTSD: Learning 3D Vascular Tree-state Space Diffusion Model for Angiography Sy nthesis
Zhifeng Wang, Renjiao Yi, Xin Wen, Chenyang Zhu, Kai Xu; Proceedings of the Comp uter Vision and Pattern Recognition Conference (CVPR), 2025, pp. 15693-15702
Angiography imaging is a medical imaging technique that enhances the visibility of blood vessels within the body by using contrast agents. Angiographic images c an effectively assist in the diagnosis of vascular diseases. However, contrast a gents may bring extra radiation exposure which is harmful to patients with healt h risks. To mitigate these concerns, in this paper, we aim to automatically gene rate angiography from non-angiographic inputs, by leveraging and enhancing the i nherent physical properties of vascular structures. Previous methods relying on 2D slice-based angiography synthesis struggle with maintaining continuity in 3D vascular structures and exhibit limited effectiveness across different imaging m odalities. We propose VasTSD, a 3D vascular tree-state space diffusion model to synthesize angiography from 3D non-angiographic volumes, with a novel state spac e serialization approach that dynamically constructs vascular tree topologies, i ntegrating these with a diffusion-based generative model to ensure the generatio n of anatomically continuous vasculature in 3D volumes. A pre-trained vision emb edder is employed to construct vascular state space representations, enabling co nsistent modeling of vascular structures across multiple modalities. Extensive e xperiments on various angiographic datasets demonstrate the superiority of VasTS D over prior works, achieving enhanced continuity of blood vessels in synthesize d angiographic synthesis in multiple modalities and anatomical regions.

PanSplat: 4K Panorama Synthesis with Feed-Forward Gaussian Splatting
Cheng Zhang, Haofei Xu, Qianyi Wu, Camilo Cruz Gambardella, Dinh Phung, Jianfei Cai; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 11437-11447
With the advent of portable 360deg cameras, panorama has gained significant atte ntion in applications like virtual reality (VR), virtual tours, robotics, and au tonomous driving. As a result, wide-baseline panorama view synthesis has emerged as a vital task, where high resolution, fast inference, and memory efficiency a re essential. Nevertheless, existing methods typically focus on lower resolution s (512 x1024) due to demanding memory and computational requirements. In this pa per, we present PanSplat, a generalizable, feed-forward approach that efficientl y supports resolution up to 4K (2048 x4096). Our approach features a tailored sp herical 3D Gaussian pyramid with a Fibonacci lattice arrangement, enhancing imag e quality while reducing information redundancy. To accommodate the demands of h

igh resolution, we propose a pipeline that integrates a hierarchical spherical c ost volume and localized Gaussian heads, enabling two-step deferred backpropagat ion for memory-efficient training on a single A100 GPU. Experiments demonstrate that PanSplat achieves state-of-the-art results with superior efficiency and ima ge quality across both synthetic and real-world datasets.

WISNet: Pseudo Label Generation on Unbalanced and Patch Annotated Waste Images
Shifan Zhang, Hongzi Zhu, Yinan He, Minyi Guo, Ziyang Lou, Shan Chang; Proceedin gs of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 1 5076-15085
Computer-vision-based assessment on waste sorting is desired to replace manpower supervision in Shanghai city. Due to the hardness of labeling a multitude of wa ste images, it is infeasible to train a semantic segmentation model for this pur pose directly. In this work, we construct a new dataset consisting of 12,208 was te images, upon which seed regions (i.e., patches) are annotated and classified into 21 categories in a crowdsourcing fashion. To obtain pixel-level labels to t rain an effective segmentation model, we propose a weakly-supervised waste image pseudo label generation scheme, called WISNet. Specifically, we train a cohesiv e feature extractor with contrastive prototype learning, incorporating an unsupe rvised classification pretext task to help the extractor focus on more discrimin ative regions even with the same category. Furthermore, we propose an effective iterative patch expansion method to generate accurate pixel-level pseudo labels. Given these generated pseudo labels, a few-shot segmentation model can be train ed to segment waste images. We implement and deploy WISNet in two real-world sce narios and conduct intensive experiments. Results show that WISNet can achieve a state-of-the-art 40.2% final segmentation mIoU on our waste benchmark, outperfo rming all other baselines and demonstrating the efficacy of WISNet.

MixerMDM: Learnable Composition of Human Motion Diffusion Models
Pablo Ruiz-Ponce, German Barquero, Cristina Palmero, Sergio Escalera, José Garcí a-Rodríguez; Proceedings of the Computer Vision and Pattern Recognition Conferen ce (CVPR), 2025, pp. 12380-12390
Generating human motion guided by conditions such as textual descriptions is cha llenging due to the need for datasets with pairs of high-quality motion and thei r corresponding conditions. The difficulty increases when aiming for finer contr ol in the generation. To that end, prior works have proposed to combine several motion diffusion models pre-trained on datasets with different types of conditio ns, thus allowing control with multiple conditions. However, the proposed mergin g strategies overlook that the optimal way to combine the generation processes m ight depend on the particularities of each pre-trained generative model and also the specific textual descriptions. In this context, we introduce MixerMDM, the first learnable model composition technique for combining pre-trained text-condi tioned human motion diffusion models. Unlike previous approaches, MixerMDM provi des a dynamic mixing strategy that is trained in an adversarial fashion to learn to combine the denoising process of each model depending on the set of conditio ns driving the generation. By using MixerMDM to combine single- and multi-person motion diffusion models, we achieve fine-grained control on the dynamics of eve ry person individually, and also on the overall interaction. Furthermore, we pro pose a new evaluation technique that, for the first time in this task, measures the interaction and individual quality by computing the alignment between the mi xed generated motions and their conditions as well as the capabilities of MixerM DM to adapt the mixing throughout the denoising process depending on the motions to mix.

Hand-held Object Reconstruction from RGB Video with Dynamic Interaction
Shijian Jiang, Qi Ye, Rengan Xie, Yuchi Huo, Jiming Chen; Proceedings of the Com puter Vision and Pattern Recognition Conference (CVPR), 2025, pp. 12220-12230
This work aims to reconstruct the 3D geometry of a rigid object manipulated by o ne or both hands using monocular RGB video. Previous methods rely on Structure-f rom-Motion or hand priors to estimate relative motion between the object and cam

era, which typically assume textured objects or single-hand interactions. To acc
urately recover object geometry in dynamic interactions, we incorporate priors f
rom 3D generation model into object pose estimation and propose semantic consist
ency constraints to solve the challenge of shape and texture discrepancy between
 the generated priors and observations. The poses are initialized, followed by j
oint optimization of the object poses and implicit neural representation. During
 optimization, a novel pose outlier voting strategy with inter-view consistency
is proposed to correct large pose errors. Experiments on three datasets demonstr
ate that our method significantly outperforms the state-of-the-art in reconstruc
tion quality for both single- and two-hand scenarios. Our project page: https://
east-j.github.io/dynhor/

LEDiff: Latent Exposure Diffusion for HDR Generation
Chao Wang, Zhihao Xia, Thomas Leimkuhler, Karol Myszkowski, Xuaner Zhang; Procee
dings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp
. 453-464
While consumer displays increasingly support more than 10 stops of dynamic range
, most image assets -- such as internet photographs and generative AI content --
 remain limited to 8-bit low dynamic range (LDR), constraining their utility acr
oss high dynamic range (HDR) applications. Currently, no generative model can pr
oduce high-bit, high-dynamic range content in a generalizable way. Existing LDR-
to-HDR conversion methods often struggle to produce photorealistic details and p
hysically-plausible dynamic range in the clipped areas. We introduce LEDiff, a m
ethod that enables a generative model with HDR content generation through latent
 space fusion inspired by image-space exposure fusion techniques. It also functi
ons as an LDR-to-HDR converter, expanding the dynamic range of existing low-dyna
mic range images. Our approach uses a small HDR dataset to enable a pretrained d
iffusion model to recover detail and dynamic range in clipped highlights and sha
dows. LEDiff brings HDR capabilities to existing generative models and converts
any LDR image to HDR, creating photorealistic HDR outputs for image generation,
image-based lighting (HDR environment map generation), and photographic effects
such as depth of field simulation, where linear HDR data is essential for realis
tic quality.

Video Depth Anything: Consistent Depth Estimation for Super-Long Videos
Sili Chen, Hengkai Guo, Shengnan Zhu, Feihu Zhang, Zilong Huang, Jiashi Feng, Bi
ngyi Kang; Proceedings of the Computer Vision and Pattern Recognition Conference
 (CVPR), 2025, pp. 22831-22840
Depth Anything has achieved remarkable success in monocular depth estimation wit
h strong generalization ability. However, it suffers from temporal inconsistency
 in videos, hindering its practical applications. Various methods have been prop
osed to alleviate this issue by leveraging video generation models or introducin
g priors from optical flow and camera poses. Nonetheless, these methods are only
 applicable to short videos (10 seconds) and require a trade-off between quality
 and computational efficiency. We propose Video Depth Anything for high-quality,
 consistent depth estimation in super-long videos (over several minutes) without
 sacrificing efficiency. We base our model on Depth Anything V2 and replace its
head with an efficient spatial-temporal head. We design a straightforward yet ef
fective temporal consistency loss by constraining the temporal depth gradient, e
liminating the need for additional geometric priors. The model is trained on a j
oint dataset of video depth and unlabeled images, similar to Depth Anything V2.
Moreover, a novel key-frame-based strategy is developed for long video inference
. Experiments show that our model can be applied to arbitrarily long videos wit
hout compromising quality, consistency, or generalization ability. Comprehensive
 evaluations on multiple video benchmarks demonstrate that our approach sets a n
ew state-of-the-art in zero-shot video depth estimation. We offer models of diff
erent scales to support a range of scenarios, with our smallest model capable of
 real-time performance at 30 FPS.

VideoAutoArena: An Automated Arena for Evaluating Large Multimodal Models in Vid

eo Analysis through User Simulation
Ziyang Luo, Haoning Wu, Dongxu Li, Jing Ma, Mohan Kankanhalli, Junnan Li; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 8461-8474
Large multimodal models (LMMs) with advanced video analysis capabilities have recently garnered significant attention. However, most evaluations rely on traditional methods like multiple-choice question answering in benchmarks such as VideoMME and LongVideoBench, which are prone to lack the depth needed to capture the complex demands of real-world users. To address this limitation--and due to the prohibitive cost and slow pace of human annotation for video tasks--we introduce VideoAutoArena, an arena-style benchmark inspired by LMSYS Chatbot Arena's framework, designed to automatically assess LMMs' video analysis abilities. VideoAutoArena utilizes user simulation to generate open-ended, adaptive questions that rigorously assess model performance in video understanding. The benchmark features an automated, scalable evaluation framework, incorporating a modified ELO Rating System for fair and continuous comparisons across multiple LMMs. To validate our automated judging system, we construct a "gold standard" using a carefully curated subset of human annotations, demonstrating that our arena strongly aligns with human judgment while maintaining scalability. Additionally, we introduce a fault-driven evolution strategy, progressively increasing question complexity to push models toward handling more challenging video analysis scenarios. Experimental results demonstrate that VideoAutoArena effectively differentiates among state-of-the-art LMMs, providing insights into model strengths and areas for improvement. To further streamline our evaluation, we introduce VideoAutoBench as an auxiliary benchmark, where human annotators label winners in a subset of VideoAutoArena battles. We use GPT-4o as a judge to compare responses against these human-validated answers. Together, VideoAutoArena and VideoAutoBench offer a cost-effective, and scalable framework for evaluating LMMs in user-centric video analysis.

InstanceCap: Improving Text-to-Video Generation via Instance-aware Structured Caption
Tiehan Fan, Kepan Nan, Rui Xie, Penghao Zhou, Zhenheng Yang, Chaoyou Fu, Xiang Li, Jian Yang, Ying Tai; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 28974-28983
Text-to-video generation has evolved rapidly in recent years, delivering remarkable results. Training typically relies on video-caption paired data, which plays a crucial role in enhancing generation performance. However, current video captions often suffer from insufficient details, hallucinations and imprecise motion depiction, affecting the fidelity and consistency of generated videos. In this work, we propose a novel instance-aware structured caption framework, termed \mathtt InstanceCap , to achieve instance-level and fine-grained video caption for the first time. Based on this scheme, we design an auxiliary models cluster to convert original video into instances to enhance instance fidelity. Video instances are further used to refine dense prompts into structured phrases, achieving concise yet precise descriptions. Furthermore, a 22K \mathtt InstanceVid dataset is curated for training, and an enhancement pipeline that tailored to \mathtt InstanceCap structure is proposed for inference. Experimental results demonstrate that our proposed \mathtt InstanceCap significantly outperform previous models, ensuring high fidelity between captions and videos while reducing hallucinations.

AudCast: Audio-Driven Human Video Generation by Cascaded Diffusion Transformers
Jiazhi Guan, Kaisiyuan Wang, Zhiliang Xu, Quanwei Yang, Yasheng Sun, Shengyi He, Borong Liang, Yukang Cao, Yingying Li, Haocheng Feng, Errui Ding, Jingdong Wang, Youjian Zhao, Hang Zhou, Ziwei Liu; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 10678-10689
Despite the recent progress of audio-driven video generation, existing methods mostly focus on driving facial movements, leading to non-coherent head and body dynamics. Moving forward, it is desirable yet challenging to generate holistic hu

man videos with both accurate lip-sync and delicate co-speech gestures w.r.t. gi ven audio. In this work, we propose AudCast, a generalized audio-driven human vi deo generation framework adopting a cascade Diffusion-Transformers (DiTs) paradi gm, which synthesizes holistic human videos based on a reference image and a giv en audio. 1) Firstly, an audio-conditioned Holistic Human DiT architecture is pr oposed to directly drive the movements of any human body with vivid gesture dyna mics. 2) Then to enhance hand and face details that are well-knownly difficult t o handle, a Regional Refinement DiT leverages regional 3D fitting as the bridge to reform the signals, producing the final results. Extensive experiments demon strate that our framework generates high-fidelity audio-driven holistic human vi deos with temporal coherence and fine facial and hand details.
****

Luminance-GS: Adapting 3D Gaussian Splatting to Challenging Lighting Conditions with View-Adaptive Curve Adjustment

Ziteng Cui, Xuangeng Chu, Tatsuya Harada; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 26472-26482

Capturing high-quality photographs under diverse real-world lighting conditions is challenging, as both natural lighting (e.g., low-light) and camera exposure s ettings (e.g., exposure time) significantly impact image quality. This challenge becomes more pronounced in multi-view scenarios, where variations in lighting a nd image signal processor (ISP) settings across viewpoints introduce photometric inconsistencies. Such lighting degradations and view-dependent variations pose substantial challenges to novel view synthesis (NVS) frameworks based on Neural Radiance Fields (NeRF) and 3D Gaussian Splatting (3DGS). To address this, we int roduce Luminance-GS, a novel approach to achieving high-quality novel view synth esis results under diverse challenging lighting conditions using 3DGS. By adopti ng per-view color matrix mapping and view adaptive curve adjustments, Luminance- GS achieves state-of-the-art (SOTA) results across various lighting conditions-- including low-light, overexposure, and varying exposure--while not altering the original 3DGS explicit representation. Compared to previous NeRF- and 3DGS-based baselines, Luminance-GS provides real-time rendering speed with improved recons truction quality. The source code is available at https://github.com/cuiziteng/L uminance-GS.

EventSplat: 3D Gaussian Splatting from Moving Event Cameras for Real-time Render ing

Toshiya Yura, Ashkan Mirzaei, Igor Gilitschenski; Proceedings of the Computer Vi sion and Pattern Recognition Conference (CVPR), 2025, pp. 26876-26886

We introduce a method for using event camera data in novel view synthesis via Ga ussian Splatting. Event cameras offer exceptional temporal resolution and a high dynamic range. Leveraging these capabilities allows us to effectively address t he novel view synthesis challenge in the presence of fast camera motion. For ini tialization of the optimization process, our approach uses prior knowledge encod ed in an event-to-video model. We also use spline interpolation for obtaining hi gh quality poses along the event camera trajectory. This enhances the reconstruc tion quality from fast-moving cameras while overcoming the computational limitat ions traditionally associated with event-based Neural Radiance Field (NeRF) meth ods. Our experimental evaluation demonstrates that our results achieve higher vi sual fidelity and better performance than existing event-based NeRF approaches w hile being an order of magnitude faster to render.

Thinking in Space: How Multimodal Large Language Models See, Remember, and Recal l Spaces

Jihan Yang, Shusheng Yang, Anjali W. Gupta, Rilyn Han, Li Fei-Fei, Saining Xie; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 20 25, pp. 10632-10643

Humans possess the visual-spatial intelligence to remember spaces from sequentia l visual observations. However, can Multimodal Large Language Models (MLLMs) tra ined on million-scale video datasets also "think in space" from videos? We prese nt a novel video-based visual-spatial intelligence benchmark (VSI-Bench) of over

5,000 question-answer pairs, and find that MLLMs exhibit competitive--though subhuman--visual-spatial intelligence. We probe models to express how they think in space both linguistically and visually and find that while spatial reasoning capabilities remain the primary bottleneck for MLLMs to reach higher benchmark performance, local world models and spatial awareness do emerge within these models. Notably, prevailing linguistic reasoning techniques (e.g., chain-of-thought, self-consistency, tree-of-thoughts) fail to improve performance, whereas explicitly generating cognitive maps during question-answering enhances MLLMs' spatial distance awareness.

3D Student Splatting and Scooping

Jialin Zhu, Jiangbei Yue, Feixiang He, He Wang; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 21045-21054

Recently, 3D Gaussian Splatting (3DGS) provides a new framework for novel view synthesis, and has spiked a new wave of research in neural rendering and related applications. As 3DGS is becoming a foundational component of many models, any improvement on 3DGS itself can bring huge benefits. To this end, we aim to improve the fundamental paradigm and formulation of 3DGS. We argue that as an unnormalized mixture model, it needs to be neither Gaussians nor splatting. We subsequently propose a new mixture model consisting of flexible Student's t distributions, with both positive (splatting) and negative (scooping) densities. We name our model Student Splatting and Scooping, or SSS. When providing better expressivity, SSS also poses new challenges in learning. Therefore, we also propose a new principled sampling approach for optimization. Through exhaustive evaluation and comparison, across multiple datasets, settings, and metrics, we demonstrate that SSS outperforms existing methods in terms of quality and parameter efficiency, e.g. achieving matching or better quality with similar numbers of components, and obtaining comparable results while reducing the component number by as much as 82%.

World-consistent Video Diffusion with Explicit 3D Modeling

Qihang Zhang, Shuangfei Zhai, Miguel Ángel Bautista Martin, Kevin Miao, Alexander Toshev, Joshua Susskind, Jiatao Gu; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 21685-21695

Recent advancements in diffusion models have set new benchmarks in image and video generation, enabling realistic visual synthesis across single- and multi-frame contexts. However, these models still struggle with efficiently and explicitly generating 3D-consistent content. To address this, we propose World-consistent Video Diffusion (WVD), a novel framework that incorporates explicit 3D supervision using XYZ images, which encode global 3D coordinates for each image pixel. More specifically, we train a diffusion transformer to learn the joint distribution of RGB and XYZ frames. This approach supports multi-task adaptability via a flexible inpainting strategy. For example, WVD can estimate XYZ frames from ground-truth RGB or generate novel RGB frames using XYZ projections along a specified camera trajectory. In doing so, WVD unifies tasks like single-image-to-3D generation, multi-view stereo, and camera-controlled video generation. Our approach demonstrates competitive performance across multiple benchmarks, providing a scalable solution for 3D-consistent video and image generation with a single pretrained model.

A Stitch in Time Saves Nine: Small VLM is a Precise Guidance for Accelerating Large VLMs

Wangbo Zhao, Yizeng Han, Jiasheng Tang, Zhikai Li, Yibing Song, Kai Wang, Zhangyang Wang, Yang You; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 19814-19824

Vision-language models (VLMs) have shown remarkable success across various multi-modal tasks, yet large VLMs encounter significant efficiency challenges due to processing numerous visual tokens. A promising approach to accelerating large VLM inference is using partial information, such as attention maps from specific layers, to assess token importance and prune less essential tokens. However, our

study reveals three key insights: (i) Partial attention information is insufficient for accurately identifying critical visual tokens, resulting in suboptimal performance, especially at low token retention ratios; (ii) Global attention information, such as the attention map aggregated across all layers, more effectively preserves essential tokens and maintains performance under aggressive pruning. However, it requires a full inference pass, which increases computational load and is therefore impractical in existing methods; and (iii) The global attention map aggregated from a small VLM closely resembles that of a large VLM, suggesting an efficient alternative. Based on these findings, we introduce \underline S mall VLM \underline G uidance for \underline L arge VLMs (SGL). Specifically, we employ the aggregated attention map from a small VLM guide the pruning of visual tokens in a large VLM. Additionally, we develop a small VLM early exiting mechanism to make full use of the small VLM's predictions, dynamically invoking the larger VLM only when necessary, yielding a superior trade-off between accuracy and computational cost. Extensive evaluations across 11 benchmarks demonstrate the effectiveness and generalizability of our method, achieving up to 91% pruning ratio for visual tokens while retaining competitive performance.

Zero-Shot Novel View and Depth Synthesis with Multi-View Geometric Diffusion
Vitor Guizilini, Muhammad Zubair Irshad, Dian Chen, Greg Shakhnarovich, Rares Ambrus; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 764-776
Current methods for 3D scene reconstruction from sparse posed images employ intermediate 3D representations such as neural fields, voxel grids, or 3D Gaussians, to achieve multi-view consistent scene appearance and geometry. In this paper we introduce MVGD, a diffusion-based architecture capable of direct pixel-level generation of images and depth maps from novel viewpoints, given an arbitrary number of input views. Our method uses raymap conditioning to both augment visual features with spatial information from different viewpoints, as well as to guide the generation of images and depth maps from novel views. A key aspect of our approach is the multi-task generation of images and depth maps, using learnable task embeddings to guide the diffusion process towards specific modalities. We train this model on a collection of more than 60 million multi-view samples from publicly available datasets, and propose techniques to enable efficient and consistent learning in such diverse conditions. We also propose a novel strategy that enables the efficient training of larger models by incrementally fine-tuning smaller ones, with promising scaling behavior. Through extensive experiments, we report state-of-the-art results in multiple novel view synthesis benchmarks, as well as multi-view stereo and video depth estimation.
****

Unveiling Visual Perception in Language Models: An Attention Head Analysis Approach
Jing Bi, Junjia Guo, Yunlong Tang, Lianggong Bruce Wen, Zhang Liu, Bingjie Wang, Chenliang Xu; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 4135-4144
Recent advancements in Multimodal Large Language Models (MLLMs) have demonstrated remarkable progress in visual understanding. This impressive leap raises a compelling question: how can language models, initially trained solely on linguistic data, effectively interpret and process visual content? This paper aims to address this question with systematic investigation across 4 model families and 4 model scales, uncovering a unique class of attention heads that focus specifically on visual content. Our analysis reveals a strong correlation between the behavior of these attention heads, the distribution of attention weights, and their concentration on visual tokens within the input. These findings enhance our understanding of how LLMs adapt to multimodal tasks, demonstrating their potential to bridge the gap between textual and visual understanding. This work paves the way for the development of AI systems capable of engaging with diverse modalities.

SemanticDraw: Towards Real-Time Interactive Content Creation from Image Diffusion Models

Jaerin Lee, Daniel Sungho Jung, Kanggeon Lee, Kyoung Mu Lee; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 13021-13030
We introduce SemanticDraw, a new paradigm of interactive content creation where high-quality images are generated in near real-time from given multiple hand-drawn regions, each encoding prescribed semantic meaning. In order to maximize the productivity of content creators and to fully realize their artistic imagination, it requires both quick interactive interfaces and fine-grained regional controls in their tools. Despite astonishing generation quality from recent diffusion models, we find that existing approaches for regional controllability are very slow (52 seconds for 512 x 512 image) while not compatible with acceleration methods such as LCM, blocking their huge potential in interactive content creation. From this observation, we build our solution for interactive content creation in two steps: (1) we establish compatibility between region-based controls and acceleration techniques for diffusion models, maintaining high fidelity of multi-prompt image generation with x 10 reduced number of inference steps, (2) we increase the generation throughput with our new multi-prompt stream batch pipeline, enabling low-latency generation from multiple, region-based text prompts on a single RTX 2080 Ti GPU. Our proposed framework is generalizable to any existing diffusion models and acceleration schedulers, allowing sub-second (0.64 seconds) image content creation application upon well-established image diffusion models.

SemiDAViL: Semi-supervised Domain Adaptation with Vision-Language Guidance for Semantic Segmentation
Hritam Basak, Zhaozheng Yin; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 9816-9828
Domain Adaptation (DA) and Semi-supervised Learning (SSL) converge in Semi-supervised Domain Adaptation (SSDA), where the objective is to transfer knowledge from a source domain to a target domain using a combination of limited labeled target samples and abundant unlabeled target data. Although intuitive, a simple amalgamation of DA and SSL is suboptimal in semantic segmentation due to two major reasons: (1) previous methods, while able to learn good segmentation boundaries, are prone to confuse classes with similar visual appearance due to limited supervision; and (2) skewed and imbalanced training data distribution preferring source representation learning whereas impeding from exploring limited information about tailed classes. Language guidance can serve as a pivotal semantic bridge, facilitating robust class discrimination and mitigating visual ambiguities by leveraging the rich semantic relationships encoded in pre-trained language models to enhance feature representations across domains. Therefore, we propose the first language-guided SSDA setting for semantic segmentation in this work. Specifically, we harness the semantic generalization capabilities inherent in vision-language models (VLMs) to establish a synergistic framework within the SSDA paradigm. To address the inherent class-imbalance challenges in long-tailed distributions, we introduce class-balanced segmentation loss formulations that effectively regularize the learning process. Through extensive experimentation across diverse domain adaptation scenarios, our approach demonstrates substantial performance improvements over contemporary state-of-the-art (SoTA) methodologies.

Learning Partonomic 3D Reconstruction from Image Collections
Xiaoqian Ruan, Pei Yu, Dian Jia, Hyeonjeong Park, Peixi Xiong, Wei Tang; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 26734-26744
Reconstructing the 3D shape of an object from a single-view image is a fundamental task in computer vision. Recent advances in differentiable rendering have enabled 3D reconstruction from image collections using only 2D annotations. However, these methods mainly focus on whole-object reconstruction and overlook object partonomy, which is essential for intelligent agents interacting with physical environments. This paper aims at learning partonomic 3D reconstruction from collections of images with only 2D annotations. Our goal is not only to reconstruct the shape of an object from a single-view image but also to decompose the shape into meaningful semantic parts. To handle the expanded solution space and frequen

t part occlusions in single-view images, we introduce a novel approach that repr
esents, parses, and learns the structural compositionality of 3D objects. This a
pproach comprises: (1) a compact and expressive compositional representation of
object geometry, achieved through disentangled modeling of large shape variation
s, constituent parts, and detailed part deformations as multi-granularity neural
 fields; (2) a part transformer that recovers precise partonomic geometry and ha
ndles occlusions, through effective part-to-pixel grounding and part-to-part rel
ational modeling; and (3) a 2D-supervised learning method that jointly learns th
e compositional representation and part transformer, by bridging object shape an
d parts, image synthesis, and differentiable rendering. Extensive experiments on
 ShapeNetPart, PartNet, and CUB-200-2011 demonstrate the effectiveness of our ap
proach on both overall and partonomic reconstruction. Code, models, and data are
 avaliable at https://github.com/XiaoqianRuan1/Partonomic_Reconstruction.

Arc2Avatar: Generating Expressive 3D Avatars from a Single Image via ID Guidance
Dimitrios Gerogiannis, Foivos Paraperas Papantoniou, Rolandos Alexandros Potamia
s, Alexandros Lattas, Stefanos Zafeiriou; Proceedings of the Computer Vision and
 Pattern Recognition Conference (CVPR), 2025, pp. 10770-10782
Inspired by the effectiveness of 3D Gaussian Splatting (3DGS) in reconstructing
detailed 3D scenes within multi-view setups and the emergence of large 2D human
foundation models, we introduce Arc2Avatar, the first SDS-based method utilizing
 a human face foundation model as guidance with just a single image as input. To
 achieve that, we extend such a model for diverse-view human head generation by
fine-tuning on synthetic data and modifying its conditioning. Our avatars mainta
in a dense correspondence with a human face mesh template, allowing blendshape-b
ased expression generation. This is achieved through a modified 3DGS approach, c
onnectivity regularizers, and a strategic initialization tailored for our task.
Additionally, we propose an optional efficient SDS-based correction step to refi
ne the blendshape expressions, enhancing realism and diversity. Experiments demo
nstrate that Arc2Avatar achieves state-of-the-art realism and identity preservat
ion, effectively addressing color issues by allowing the use of very low guidanc
e, enabled by our strong identity prior and initialization strategy, without com
promising detail.

Seeing Speech and Sound: Distinguishing and Locating Audio Sources in Visual Sce
nes
Hyeonggon Ryu, Seongyu Kim, Joon Son Chung, Arda Senocak; Proceedings of the Com
puter Vision and Pattern Recognition Conference (CVPR), 2025, pp. 13540-13549
We present a unified model capable of simultaneously grounding both spoken langu
age and non-speech sounds within a visual scene, addressing key limitations in c
urrent audio-visual grounding models. Existing approaches are typically limited
to handling either speech or non-speech sounds independently, or at best, togeth
er but sequentially without mixing. This limitation prevents them from capturing
 the complexity of real-world audio sources that are often mixed. Our approach i
ntroduces a "mix-and-separate" framework with audio-visual alignment objectives
that jointly learn correspondence and disentanglement using mixed audio. Through
 these objectives, our model learns to produce distinct embeddings for each audi
o type, enabling effective disentanglement and grounding across mixed audio sour
ces.Additionally, we created a new dataset to evaluate simultaneous grounding of
 mixed audio sources, demonstrating that our model outperforms prior methods. Ou
r approach also achieves state-of-the-art performance in standard segmentation a
nd cross-modal retrieval tasks, highlighting the benefits of our mix-and-separat
e approach.
****

Structure from Collision
Takuhiro Kaneko; Proceedings of the Computer Vision and Pattern Recognition Conf
erence (CVPR), 2025, pp. 16314-16324
Recent advancements in neural 3D representations, such as neural radiance fields
 (NeRF) and 3D Gaussian splatting (3DGS), have made accurate estimation of the 3
D structure from multiview images possible. However, this capability is limited

to estimating the visible external structure, and it is still difficult to identify the invisible internal structure hidden behind the surface. To overcome this limitation, we address a new task called structure from collision (SfC), which aims to estimate the structure (including the invisible internal one) of an object from the appearance changes at collision. To solve this task, we propose a novel model called SfC-NeRF, which optimizes the invisible internal structure of the object through a video sequence under physical, appearance (i.e., visible external structure)-preserving, and keyframe constraints. In particular, to avoid falling into undesirable local optima owing to its ill-posed nature, we propose volume annealing, i.e., searching for the global optima by repeatedly reducing and expanding the volume. Extensive experiments on 115 objects involving diverse structures (i.e., various cavity shapes, locations, and sizes) and various material properties reveal the properties of SfC and demonstrate the effectiveness of the proposed SfC-NeRF.

ODA-GAN: Orthogonal Decoupling Alignment GAN Assisted by Weakly-supervised Learning for Virtual Immunohistochemistry Staining

Tong Wang, Mingkang Wang, Zhongze Wang, Hongkai Wang, Qi Xu, Fengyu Cong, Hongming Xu; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 25920-25929

Recently, virtual staining has emerged as a promising alternative to revolutionize histological staining by digitally generating stains. However, most existing methods suffer from the curse of staining unreality and unreliability. In this paper, we propose the Orthogonal Decoupling Alignment Generative Adversarial Network (ODA-GAN) for unpaired virtual immunohistochemistry (IHC) staining. Our approach is based on the assumption that an image consists of IHC staining-related features, which influence staining distribution and intensity, and staining-unrelated features, such as tissue morphology. Leveraging a pathology foundation model, we first develop a weakly-supervised segmentation pipeline as an alternative to expert annotations. We introduce an Orthogonal MLP (O-MLP) module to project image features into an orthogonal space, decoupling them into staining-related and unrelated components. Additionally, we propose a Dual-stream PatchNCE (DPNCE) loss to resolve contrastive learning contradictions in the staining-related space, thereby enhancing staining accuracy. To further improve realism, we introduce a Multi-layer Domain Alignment (MDA) module to bridge the domain gap between generated and real IHC images. Evaluations on three benchmark datasets show that our ODA-GAN reaches state-of-the-art (SOTA) performance. Our source code is available at https://github.com/ittong/ODA-GAN.

EVOS: Efficient Implicit Neural Training via EVOlutionary Selector

Weixiang Zhang, Shuzhao Xie, Chengwei Ren, Siyi Xie, Chen Tang, Shijia Ge, Mingzi Wang, Zhi Wang; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 30472-30482

We propose EVOlutionary Selector (EVOS), an efficient training paradigm for accelerating Implicit Neural Representation (INR). Unlike conventional INR training that feeds all samples through the neural network in each iteration, our approach restricts training to strategically selected points, reducing computational overhead by eliminating redundant forward passes.Specifically, we treat each sample as an individual in an evolutionary process, where only those fittest ones survive and merit inclusion in training, adaptively evolving with the neural network dynamics. While this is conceptually similar to Evolutionary Algorithms, their distinct objectives (selection for acceleration vs. iterative solution optimization) require a fundamental redefinition of evolutionary mechanisms for our context.In response, we design sparse fitness evaluation, frequency-guided crossover, and augmented unbiased mutation to comprise EVOS. These components respectively guide sample selection with reduced computational cost, enhance performance through frequency-domain balance, and mitigate selection bias from cached evaluation. Extensive experiments demonstrate that our method achieves approximately 48%-66% reduction in training time while ensuring superior convergence without additional cost, establishing state-of-the-art acceleration among recent sampling-ba

sed strategies.

Crab: A Unified Audio-Visual Scene Understanding Model with Explicit Cooperation
Henghui Du, Guangyao Li, Chang Zhou, Chunjie Zhang, Alan Zhao, Di Hu; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 18804-18814
In recent years, numerous tasks have been proposed to encourage model to develop specified capability in understanding audio-visual scene, primarily categorized into temporal localization, spatial localization, spatio-temporal reasoning, and pixel-level understanding. Instead, human possesses a unified understanding ability for diversified tasks. Therefore, designing an audio-visual model with general capability to unify these tasks is of great value. However, simply joint training for all tasks can lead to interference due to the heterogeneity of audiovisual data and complex relationship among tasks. We argue that this problem can be solved through explicit cooperation among tasks. To achieve this goal, we propose a unified learning method which achieves explicit inter-task cooperation from both the perspectives of data and model thoroughly. Specifically, considering the labels of existing datasets are simple words, we carefully refine these datasets and construct an Audio-Visual Unified Instruction-tuning dataset with Explicit reasoning process (AV-UIE), which clarifies the cooperative relationship among tasks. Subsequently, to facilitate concrete cooperation in learning stage, an interaction-aware LoRA structure with multiple LoRA heads is designed to learn different aspects of audiovisual data interaction. By unifying the explicit cooperation across the data and model aspect, our method not only surpasses existing unified audio-visual model on multiple tasks, but also outperforms most specialized models for certain tasks. Furthermore, we also visualize the process of explicit cooperation and surprisingly find that each LoRA head has certain audio-visual understanding ability. Code and dataset: https://github.com/GeWu-Lab/Crab

Nullu: Mitigating Object Hallucinations in Large Vision-Language Models via HalluSpace Projection
Le Yang, Ziwei Zheng, Boxu Chen, Zhengyu Zhao, Chenhao Lin, Chao Shen; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 14635-14645
Recent studies have shown that large vision-language models (LVLMs) often suffer from the issue of object hallucinations (OH). To mitigate this issue, we introduce an efficient method that edits the model weights based on an unsafe subspace, which we call HalluSpace in this paper. With truthful and hallucinated text prompts accompanying the visual content as inputs, the HalluSpace can be identified by extracting the hallucinated embedding features and removing the truthful representations in LVLMs. By orthogonalizing the model weights, input features will be projected into the Null space of the HalluSpace to reduce OH, based on which we name our method Nullu. We reveal that HalluSpaces generally contain prior information in the large language models (LLMs) applied to build LVLMs, which have been shown as essential causes of OH in previous studies. Therefore, null space projection suppresses the LLMs' priors to filter out the hallucinated features, resulting in contextually accurate outputs. Experiments show that our method can effectively mitigate OH across different LVLM families without extra inference costs and also show strong performance in general LVLM benchmarks. Code is released at https://github.com/Ziwei-Zheng/Nullu.

OralXrays-9: Towards Hospital-Scale Panoramic X-ray Anomaly Detection via Personalized Multi-Object Query-Aware Mining
Bingzhi Chen, Sisi Fu, Xiaocheng Fang, Jieyi Cai, Boya Zhang, Minhua Lu, Yishu Liu; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 15570-15579
In clinical practice, panoramic dental radiography is a widely employed imaging technique that can provide a detailed and comprehensive view of dental structures and surrounding tissues for identifying various oral anomalies. However, due to the complexity of oral anomalies and the scarcity of available data, existing

research still suffers from substantial challenges in automated oral anomaly det
ection. To this end, this paper presents a new hospital-scale panoramic X-ray be
nchmark, namely "OralXrays-9", which consists of 12,688 panoramic X-ray images w
ith 84,113 meticulously annotated instances across nine common oral anomalies. C
orrespondingly, we propose a personalized Multi-Object Query-Aware Mining (MOQAM
) paradigm, which jointly incorporates the Distribution-IoU Region Proposal Netw
ork (DI-RPN) and Class-Balanced Spherical Contrastive Regularization (CB-SCR) me
chanisms to address the challenges posed by multi-scale variations and class-imb
alanced distributions. To the best of our knowledge, this is the first attempt t
o develop AI-driven diagnostic systems specifically designed for multi-object or
al anomaly detection, utilizing publicly available data resources. Extensive exp
eriments on the newly-published OralXrays-9 dataset and real-world nature scenar
ios consistently demonstrate the superiority of our MOQAM in revolutionizing ora
l healthcare practices.

MEET: Towards Memory-Efficient Temporal Sparse Deep Neural Networks
Zeqi Zhu, Ibrahim Batuhan Akkaya, Luc Waeijen, Egor Bondarev, Arash Pourtaherian
, Orlando Moreira; Proceedings of the Computer Vision and Pattern Recognition Co
nference (CVPR), 2025, pp. 29309-29320
Deep Neural Networks (DNNs) are accurate but compute-intensive, leading to subst
antial energy consumption during inference. Exploiting temporal redundancy throu
gh \Delta-\Sigma convolution in video processing has proven to greatly enhance c
omputation efficiency. However, temporal \Delta-\Sigma DNNs typically require su
bstantial memory for storing neuron states to compute inter-frame differences, h
indering their on-chip deployment. To mitigate this memory cost, directly compre
ssing the states can disrupt the linearity of temporal \Delta-\Sigma convolution
, causing accumulated errors in long-term \Delta-\Sigma processing. Thus, we pro
pose MEET, an optimization framework for MEmory-Efficient Temporal \Delta-\Sigma
 DNNs. MEET transfers the state compression challenge to a well-established weig
ht compression problem by trading fewer activations for more weights and introdu
ces a co-design of network architecture and suppression method to optimize for m
ixed spatial-temporal execution. Evaluations on three vision applications demons
trate a reduction of 5.1~13.3 xin total memory compared to the most computation-
efficient temporal DNNs, while preserving the computation efficiency and model a
ccuracy in long-term \Delta-\Sigma processing. MEET facilitates the deployment o
f temporal \Delta-\Sigma DNNs within on-chip memory of embedded event-driven pla
tforms, empowering low-power edge processing.

SplatAD: Real-Time Lidar and Camera Rendering with 3D Gaussian Splatting for Aut
onomous Driving
Georg Hess, Carl Lindström, Maryam Fatemi, Christoffer Petersson, Lennart Svenss
on; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR)
, 2025, pp. 11982-11992
Ensuring the safety of autonomous robots, such as self-driving vehicles, require
s extensive testing across diverse driving scenarios. Simulation is a key ingred
ient for conducting such testing in a cost-effective and scalable way. Neural re
ndering methods have gained popularity, as they can build simulation environment
s from collected logs in a data-driven manner. However, existing neural radiance
 field (NeRF) methods for sensor-realistic rendering of camera and lidar data su
ffer from low rendering speeds, limiting their applicability for large-scale tes
ting. While 3D Gaussian Splatting (3DGS) enables real-time rendering, current me
thods are limited to camera data and are unable to render lidar data essential f
or autonomous driving. To address these limitations, we propose SplatAD, the fir
st 3DGS-based method for realistic, real-time rendering of dynamic scenes for bo
th camera and lidar data. SplatAD accurately models key sensor-specific phenomen
a such as rolling shutter effects, lidar intensity, and lidar ray dropouts, usin
g purpose-built algorithms to optimize rendering efficiency. Evaluation across t
hree autonomous driving datasets demonstrates that SplatAD achieves state-of-the
-art rendering quality with up to +2 PSNR for NVS and +3 PSNR for reconstruction
 while increasing rendering speed over NeRF-based methods by an order of magnitu

de. Code to be released upon publication.

Audio-Visual Instance Segmentation
Ruohao Guo, Xianghua Ying, Yaru Chen, Dantong Niu, Guangyao Li, Liao Qu, Yanyu Qi, Jinxing Zhou, Bowei Xing, Wenzhen Yue, Ji Shi, Qixun Wang, Peiliang Zhang, Buwen Liang; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 13550-13560
In this paper, we propose a new multi-modal task, termed audio-visual instance segmentation (AVIS), which aims to simultaneously identify, segment and track individual sounding object instances in audible videos. To facilitate this research, we introduce a high-quality benchmark named AVISeg, containing over 90K instance masks from 26 semantic categories in 926 long videos. Additionally, we propose a strong baseline model for this task. Our model first localizes sound source within each frame, and condenses object-specific contexts into concise tokens. Then it builds long-range audio-visual dependencies between these tokens using window-based attention, and tracks sounding objects among the entire video sequences. Extensive experiments reveal that our method performs best on AVISeg, surpassing the existing methods from related tasks. We further conduct the evaluation on several multi-modal large models. Unfortunately, they exhibits subpar performance on instance-level sound source localization and temporal perception. We expect that AVIS will inspire the community towards a more comprehensive multi-modal understanding. Dataset and code is available at https://github.com/ruohaoguo/avis.
****

Probabilistic Prompt Distribution Learning for Animal Pose Estimation
Jiyong Rao, Brian Nlong Zhao, Yu Wang; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 29438-29447
Multi-species animal pose estimation has emerged as a challenging yet critical task, hindered by substantial visual diversity and uncertainty. This paper challenges the problem by efficient prompt learning for Vision-Language Pretrained (VLP) models, e.g. CLIP, aiming to resolve the cross-species generalization problem. At the core of the solution lies in the prompt designing, probabilistic prompt modeling and cross-modal adaptation, thereby enabling prompts to compensate for cross-modal information and effectively overcome large data variances under unbalanced data distribution. To this end, we propose a novel probabilistic prompting approach to fully explore textual descriptions, which could alleviate the diversity issues caused by long-tail property and increase the adaptability of prompts on unseen category instance. Specifically, we first introduce a set of learnable prompts and propose a diversity loss to maintain distinctiveness among prompts, thus representing diverse image attributes. Diverse textual probabilistic representations are sampled and used as the guidance for the pose estimation. Subsequently, we explore three different cross-modal fusion strategies at spatial level to alleviate the adverse impacts of visual uncertainty. Extensive experiments on multi-species animal pose benchmarks show that our method achieves the state-of-the-art performance under both supervised and zero-shot settings.

dFLMoE: Decentralized Federated Learning via Mixture of Experts for Medical Data Analysis
Luyuan Xie, Tianyu Luan, Wenyuan Cai, Guochen Yan, Zhaoyu Chen, Nan Xi, Yuejian Fang, Qingni Shen, Zhonghai Wu, Junsong Yuan; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 10203-10213
Federated learning has wide applications in the medical field. It enables knowledge sharing among different healthcare institutes while protecting patients' privacy. However, existing federated learning systems are typically centralized, requiring clients to upload client-specific knowledge to a central server for aggregation. This centralized approach would integrate the knowledge from each client into a centralized server, and the knowledge would be already undermined during the centralized integration before it reaches back to each client. Besides, the centralized approach also creates a dependency on the central server, which may affect training stability if the server malfunctions or connections are unstab

le. To address these issues, we propose a decentralized federated learning frame work named dFLMoE. In our framework, clients directly exchange lightweight head models with each other. After exchanging, each client treats both local and rece ived head models as individual experts, and utilizes a client-specific Mixture o f Experts (MoE) approach to make collective decisions. This design not only redu ces the knowledge damage with client-specific aggregations but also removes the dependency on the central server to enhance the robustness of the framework. We validate our framework on multiple medical tasks, demonstrating that our method evidently outperforms state-of-the-art approaches under both model homogeneity a nd heterogeneity settings.

Reconstructing Humans with a Biomechanically Accurate Skeleton
Yan Xia, Xiaowei Zhou, Etienne Vouga, Qixing Huang, Georgios Pavlakos; Proceedin gs of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 5 355-5365
In this paper, we introduce a method for reconstructing 3D humans from a single image using a biomechanically accurate skeleton model. To achieve this, we train a transformer that takes an image as input and estimates the parameters of the model. Due to the lack of training data for this task, we build a pipeline to pr oduce pseudo ground truth model parameters for single images and implement a tra ining procedure that iteratively refines these pseudo labels. Compared to state- of-the-art methods for 3D human mesh recovery, our model achieves competitive pe rformance on standard benchmarks, while it significantly outperforms them in set tings with extreme 3D poses and viewpoints. Additionally, we show that previous reconstruction methods frequently violate joint angle limits, leading to unnatur al rotations. In contrast, our approach leverages the biomechanically plausible degrees of freedom making more realistic joint rotation estimates. We validate o ur approach across multiple human pose estimation benchmarks. We make the code, models and data available at: https://isshikihugh.github.io/HSMR/

AdaCM^2: On Understanding Extremely Long-Term Video with Adaptive Cross-Modality Memory Reduction
Yuanbin Man, Ying Huang, Chengming Zhang, Bingzhe Li, Wei Niu, Miao Yin; Proceed ings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 8534-8544
The advancements in large language models (LLMs) have propelled the improvement of video understanding tasks by incorporating LLMs with visual models. However, most existing LLM-based models (e.g., VideoLLaMA, VideoChat) are constrained to processing short-duration videos. Recent attempts to understand long-term videos by extracting and compressing visual features into a fixed memory size. Neverth eless, those methods leverage only visual modality to merge video tokens and ove rlook the correlation between visual and textual queries, leading to difficultie s in effectively handling complex question-answering tasks. To address the chall enges of long videos and complex prompts, we propose AdaCM^2, which, for the fir st time, introduces an adaptive cross-modality memory reduction approach to vide o-text alignment in an auto-regressive manner on video streams. Our extensive ex periments on various video understanding tasks, such as video captioning, video question answering, and video classification, demonstrate that AdaCM^2 achieves state-of-the-art performance across multiple datasets while significantly reduci ng memory usage. Notably, it achieves a 4.5% improvement across multiple tasks i n the LVU dataset with a GPU memory consumption reduction of up to 65%.

Mitigating Object Hallucinations in Large Vision-Language Models with Assembly o f Global and Local Attention
Wenbin An, Feng Tian, Sicong Leng, Jiahao Nie, Haonan Lin, Qianying Wang, Ping C hen, Xiaoqin Zhang, Shijian Lu; Proceedings of the Computer Vision and Pattern R ecognition Conference (CVPR), 2025, pp. 29915-29926
Despite great success across various multimodal tasks, Large Vision-Language Mod els (LVLMs) often encounter object hallucinations with generated textual respons es being inconsistent with the actual objects in images. We examine different LV

LMs and pinpoint that one root cause of object hallucinations lies with deficien t attention on discriminative image features. Specifically, LVLMs often predomin antly attend to prompt-irrelevant global features instead of prompt-relevant loc al features, undermining their visual grounding capacity and leading to object h allucinations. We propose Assembly of Global and Local Attention (AGLA) , a trai ning-free and plug-and-play approach that mitigates hallucinations by assembling global features for response generation and local features for visual discrimin ation simultaneously. Specifically, we introduce an image-prompt matching schem e that captures prompt-relevant local features from images, leading to an augmen ted view of the input image where prompt-relevant content is highlighted while i rrelevant distractions are suppressed. Hallucinations can thus be mitigated wit h a calibrated logit distribution that is from generative global features of the original image and discriminative local features of the augmented image. Extens ive experiments show the superiority of AGLA in LVLM hallucination mitigation, d emonstrating its wide applicability across both discriminative and generative ta sks. Our code is available at https://github.com/Lackel/AGLA.

Silent Branding Attack: Trigger-free Data Poisoning Attack on Text-to-Image Diff usion Models

Sangwon Jang, June Suk Choi, Jaehyeong Jo, Kimin Lee, Sung Ju Hwang; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 820 3-8212

Text-to-image diffusion models have achieved remarkable success in generating hi gh-quality contents from text prompts. However, their reliance on publicly avail able data and the growing trend of data sharing for fine-tuning make these model s particularly vulnerable to data poisoning attacks. In this work, we introduce the Silent Branding Attack, a novel data poisoning method that manipulates text- to-image diffusion models to generate images containing specific brand logos or symbols without any text triggers. We find that when certain visual patterns are repeatedly in the training data, the model learns to reproduce them naturally i n its outputs, even without prompt mentions. Leveraging this, we develop an auto mated data poisoning algorithm that unobtrusively injects logos into original im ages, ensuring they blend naturally and remain undetected. Models trained on thi s poisoned dataset generate images containing logos without degrading image qual ity or text alignment. We experimentally validate our silent branding attack acr oss two realistic settings on large-scale high-quality image datasets and style personalization datasets, achieving high success rates even without a specific t ext trigger. Human evaluation and quantitative metrics including logo detection show that our method can stealthily embed logos.

UniSTD: Towards Unified Spatio-Temporal Learning across Diverse Disciplines

Chen Tang, Xinzhu Ma, Encheng Su, Xiufeng Song, Xiaohong Liu, Wei-Hong Li, Lei B

ai, Wanli Ouyang, Xiangyu Yue; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 29213-29224
Traditional spatiotemporal models generally rely on task-specific architectures, which limit their generalizability and scalability across diverse tasks due to domain-specific design requirements. In this paper, we introduce UniSTD, a unified Transformer-based framework for spatiotemporal modeling, which is inspired by advances in recent foundation models with the two-stage pretraining-then-adaption paradigm. Specifically, our work demonstrates that task-agnostic pretraining on 2D vision and vision-text datasets can build a generalizable model foundation for spatiotemporal learning, followed by specialized joint training on spatiotemporal datasets to enhance task-specific adaptability. To improve the learning capabilities across domains, our framework employs a rank-adaptive mixture-of-expert adaptation by using fractional interpolation to relax the discrete variables so that can be optimized in the continuous space. Additionally, we introduce a temporal module to incorporate temporal dynamics explicitly. We evaluate our approach on a large-scale dataset covering 10 tasks across 4 disciplines, demonstrating that a unified spatiotemporal model can achieve scalable, cross-task learning and support up to 10 tasks simultaneously within one model while reducing training costs in multi-domain applications. Code will be available at https://github.com/1hunters/UniSTD.
****

Visual Consensus Prompting for Co-Salient Object Detection
Jie Wang, Nana Yu, Zihao Zhang, Yahong Han; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 9591-9600
Existing co-salient object detection (CoSOD) methods generally employ a three-stage architecture (i.e., encoding, consensus extraction & dispersion, and prediction) along with a typical full fine-tuning paradigm. Although they yield certain benefits, they exhibit two notable limitations: 1) This architecture relies on encoded features to facilitate consensus extraction, but the meticulously extracted consensus does not provide timely guidance to the encoding stage. 2) This paradigm involves globally updating all parameters of the model, which is parameter-inefficient and hinders the effective representation of knowledge within the foundation model for this task. Therefore, in this paper, we propose an interaction-effective and parameter-efficient concise architecture for the CoSOD task, addressing two key limitations. It introduces, for the first time, a parameter-efficient prompt tuning paradigm and seamlessly embeds consensus into the prompts to formulate task-specific Visual Consensus Prompts (VCP). Our VCP aims to induce the frozen foundation model to perform better on CoSOD tasks by formulating task-specific visual consensus prompts with minimized tunable parameters. Concretely, the primary insight of the purposeful Consensus Prompt Generator (CPG) is to enforce limited tunable parameters to focus on co-salient representations and generate consensus prompts. The formulated Consensus Prompt Disperser (CPD) leverages consensus prompts to form task-specific visual consensus prompts, thereby arousing the powerful potential of pre-trained models in addressing CoSOD tasks. Extensive experiments demonstrate that our concise VCP outperforms 13 cutting-edge full fine-tuning models, achieving the new state of the art (with 6.8% improvement in F_m metrics on the most challenging CoCA dataset). Source code has been available at https://github.com/WJ-CV/VCP.

Mani-GS: Gaussian Splatting Manipulation with Triangular Mesh
Xiangjun Gao, Xiaoyu Li, Yiyu Zhuang, Qi Zhang, Wenbo Hu, Chaopeng Zhang, Yao Yao, Ying Shan, Long Quan; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 21392-21402
Neural 3D representations, such as Neural Radiation Fields (NeRF), excel at producing photorealistic rendering results but lack the flexibility for manipulation and editing which is crucial for content creation. However, manipulating NeRF is not highly controllable and requires a long training and inference time. With the emergence of 3D Gaussian Splatting (3DGS), extremely high-fidelity novel view synthesis can be achieved using an explicit point-based 3D representation with much faster training and rendering speed. However, there is still a lack of eff

ective means to manipulate 3DGS freely while maintaining rendering quality. In t
his work, we aim to tackle the challenge of achieving manipulable photo-realisti
c rendering. We propose to utilize a triangular mesh to manipulate 3DGS directly
 with self-adaptation. This approach reduces the need to design various algorith
ms for different types of 3DGS manipulation. By utilizing a triangle shape-aware
 Gaussian binding and adapting method, we can achieve 3DGS manipulation and pres
erve high-fidelity rendering. In addition, our method is also effective with ina
ccurate meshes extracted from 3DGS. Experiments demonstrate our method's effecti
veness and superiority over baseline approaches.

UniHOPE: A Unified Approach for Hand-Only and Hand-Object Pose Estimation
Yinqiao Wang, Hao Xu, Pheng-Ann Heng, Chi-Wing Fu; Proceedings of the Computer V
ision and Pattern Recognition Conference (CVPR), 2025, pp. 12231-12241
Estimating the 3D pose of hand and potential hand-held object from monocular ima
ges is a longstanding challenge. Yet, existing methods are specialized, focusing
 on either bare-hand or hand interacting with object. No method can flexibly han
dle both scenarios and their performance degrades when applied to the other scen
ario. In this paper, we propose UniHOPE, a unified approach for general 3D hand-
object pose estimation, flexibly adapting both scenarios. Technically, we design
 a grasp-aware feature fusion module to integrate hand-object features with an o
bject switcher to dynamically control the hand-object pose estimation according
to grasping status. Further, to uplift the robustness of hand pose estimation re
gardless of object presence, we generate realistic de-occluded image pairs to tr
ain the model to learn object-induced hand occlusions, and formulate multi-level
 feature enhancement techniques for learning occlusion-invariant features. Exten
sive experiments on three commonly-used benchmarks demonstrate UniHOPE's SOTA pe
rformance in addressing hand-only and hand-object scenarios. Code will be releas
ed on https://github.com/JoyboyWang/UniHOPE_Pytorch.

RL-RC-DoT: A Block-level RL agent for Task-Aware Video Compression
Uri Gadot, Assaf Shocher, Shie Mannor, Gal Chechik, Assaf Hallak; Proceedings of
 the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 12533-
12542
Video encoders optimize compression for human perception by minimizing reconstru
ction error under bit-rate constraints. In many modern applications such as auto
nomous driving, an overwhelming majority of videos serve as input for AI systems
 performing tasks like object recognition or segmentation, rather than being wat
ched by humans. It is therefore useful to optimize the encoder for a downstream
task instead of for perceptual image quality. However, a major challenge is how
to combine such downstream optimization with existing standard video encoders, w
hich are highly efficient and popular. Here, we address this challenge by contro
lling the Quantization Parameters (QPs) at the macro-block level to optimize the
 downstream task. This granular control allows us to prioritize encoding for tas
k-relevant regions within each frame. We formulate this optimization problem as
a Reinforcement Learning (RL) task, where the agent learns to balance long-term
implications of choosing QPs on both task performance and bit-rate constraints.
Notably, our policy does not require the downstream task as an input during infe
rence, making it suitable for streaming applications and edge devices such as ve
hicles. We demonstrate significant improvements in two tasks, car detection, and
 ROI (saliency) encoding. Our approach improves task performance for a given bit
 rate compared to traditional task agnostic encoding methods, paving the way for
 more efficient task-aware video compression.

Quantization without Tears
Minghao Fu, Hao Yu, Jie Shao, Junjie Zhou, Ke Zhu, Jianxin Wu; Proceedings of th
e Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 4462-4472
Deep neural networks, while achieving remarkable success across diverse tasks, d
emand significant resources, including computation, GPU memory, bandwidth, stora
ge, and energy. Network quantization, as a standard compression and acceleration
 technique, reduces storage costs and enables potential inference acceleration b

y discretizing network weights and activations into a finite set of integer valu
es. However, current quantization methods are often complex and sensitive, requi
ring extensive task-specific hyperparameters, where even a single misconfigurati
on can impair model performance, limiting generality across different models and
 tasks. In this paper, we propose Quantization without Tears (QwT), a method tha
t simultaneously achieves quantization speed, accuracy, simplicity, and generali
ty. The key insight of QwT is to incorporate a lightweight additional structure
into the quantized network to mitigate information loss during quantization. Thi
s structure consists solely of a small set of linear layers, keeping the method
simple and efficient. More importantly, it provides a closed-form solution, allo
wing us to improve accuracy effortlessly under 2 minutes. Extensive experiments
across various vision, language, and multimodal tasks demonstrate that QwT is bo
th highly effective and versatile. In fact, our approach offers a robust solutio
n for network quantization that combines simplicity, accuracy, and adaptability,
 which provides new insights for the design of novel quantization paradigms.

PHGC: Procedural Heterogeneous Graph Completion for Natural Language Task Verifi
cation in Egocentric Videos

Xun Jiang, Zhiyi Huang, Xing Xu, Jingkuan Song, Fumin Shen, Heng Tao Shen; Proce
edings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, p
p. 8615-8624

Natural Language-based Egocentric Task Verification (NLETV) aims to equip agents
 to determine if operation flows of procedural tasks in egocentric videos align
with natural language instructions. Describing rules with natural language provi
des generalizable applications, but also raises cross-modal heterogeneity and hi
erarchical misalignment challenges. In this paper, we proposed a novel approach
termed Procedural Heterogeneous Graph Completion (PHGC), which addresses these c
hallenges with heterogeneous graphs representing the logic in rules and operatio
n flows. Specifically, our PHGC method mainly consists of three key components:
(1) Heterogeneous Graph Construction module that defines objective states and op
eration flows as vertices, with temporal and sequential relations as edges. (2)
Cross-Modal Path Finding module that aligns semantic relations between hierarchi
cal video and text elements. (3) Discriminative Entity Representation module exc
avates hidden entities that integrate general logical relations and discriminati
ve cues to reveal final verification results. Additionally, we further construct
ed a new dataset called CSV-NL comprised of realistic videos. Extensive experime
nts on the two benchmark datasets covering both digital and physical scenarios,
i.e., EgoTV and CSV-NL, demonstrate that our proposed PHGC establishes state-of-
the-art performance across different settings. Our code and dataset are availabl
e at https://github.com/XunCHN/PHGC.

Recognition-Synergistic Scene Text Editing

Zhengyao Fang, Pengyuan Lyu, Jingjing Wu, Chengquan Zhang, Jun Yu, Guangming Lu,
 Wenjie Pei; Proceedings of the Computer Vision and Pattern Recognition Conferen
ce (CVPR), 2025, pp. 13104-13113

Scene text editing aims to modify text content within scene images while maintai
ning style consistency. Traditional methods achieve this by explicitly disentang
ling style and content from the source image and then fusing the style with the
target content, while ensuring content consistency using a pre-trained recogniti
on model. Despite notable progress, these methods suffer from complex pipelines,
 leading to suboptimal performance in complex scenarios. In this work, we introd
uce Recognition-Synergistic Scene Text Editing (RS-STE), a novel approach that f
ully exploits the intrinsic synergy of text recognition for editing. Our model s
eamlessly integrates text recognition with text editing within a unified framewo
rk, and leverages the recognition model's ability to implicitly disentangle styl
e and content while ensuring content consistency. Specifically, our approach emp
loys a multi-modal parallel decoder based on transformer architecture, which pre
dicts both text content and stylized images in parallel. Additionally, our cycli
c self-supervised fine-tuning strategy enables effective training on unpaired re
al-world data without ground truth, enhancing style and content consistency thro

ugh a twice-cyclic generation process. Built on a relatively simple architecture, RS-STE achieves state-of-the-art performance on both synthetic and real-world benchmarks, and further demonstrates the effectiveness of leveraging the generated hard cases to boost the performance of downstream recognition tasks. Code will be made publicly available.

****

Towards Consistent Multi-Task Learning: Unlocking the Potential of Task-Specific Parameters

Xiaohan Qin, Xiaoxing Wang, Junchi Yan; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 10067-10076

Multi-task learning (MTL) has gained widespread application for its ability to transfer knowledge across tasks, improving resource efficiency and generalization. However, gradient conflicts from different tasks remain a major challenge in MTL. Previous gradient-based and loss-based methods primarily focus on gradient optimization in shared parameters, often overlooking the potential of task-specific parameters. This work points out that task-specific parameters not only capture task-specific information but also influence the gradients propagated to shared parameters, which in turn affects gradient conflicts. Motivated by this insight, we propose ConsMTL, which models MTL as a bi-level optimization problem: in the upper-level optimization, we perform gradient aggregation on shared parameters to find a joint update vector that minimizes gradient conflicts; in the lower-level optimization, we introduce an additional loss for task-specific parameters guiding the k gradients of shared parameters to gradually converge towards the joint update vector. Our design enables the optimization of both shared and task-specific parameters to consistently alleviate gradient conflicts. Extensive experiments show that ConsMTL achieves state-of-the-art performance across various benchmarks with task numbers ranging from 2 to 40, demonstrating its superior performance.

WildAvatar: Learning In-the-wild 3D Avatars from the Web

Zihao Huang, Shoukang Hu, Guangcong Wang, Tianqi Liu, Yuhang Zang, Zhiguo Cao, Wei Li, Ziwei Liu; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 15963-15975

Existing research on avatar creation is typically limited to laboratory datasets, which require high costs against scalability and exhibit insufficient representation of the real world. On the other hand, the web abounds with off-the-shelf real-world human videos, but these videos vary in quality and require accurate annotations for avatar creation. To this end, we propose an automatic annotating pipeline with filtering protocols to curate these humans from the web. Our pipeline surpasses state-of-the-art methods on the EMDB benchmark, and the filtering protocols boost verification metrics on web videos. We then curate WildAvatar, a web-scale in-the-wild human avatar creation dataset extracted from YouTube, with 10,000+ different human subjects and scenes. WildAvatar is at least 10xricher than previous datasets for 3D human avatar creation and closer to the real world. To explore its potential, we demonstrate the quality and generalizability of avatar creation methods on WildAvatar. We will publicly release our code, data source links and annotations to push forward 3D human avatar creation and other related fields for real-world applications.

BooW-VTON: Boosting In-the-Wild Virtual Try-On via Mask-Free Pseudo Data Training

Xuanpu Zhang, Dan Song, Pengxin Zhan, Tianyu Chang, Jianhao Zeng, Qingguo Chen, Weihua Luo, An-An Liu; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 26399-26408

Image-based virtual try-on is an increasingly popular and important task to generate realistic try-on images of the specific person.Recent methods model virtual try-on as image mask-inpaint task, which requires masking the person image and results in significant loss of spatial information. Especially, for in-the-wild try-on scenarios with complex poses and occlusions, mask-based methods often introduce noticeable artifacts. Our research found that a mask-free approach can fu

lly leverage spatial and lighting information from the original person image, en
abling high-quality virtual try-on. Consequently, we propose a novel training pa
radigm for a mask-free try-on diffusion model. We ensure the model's mask-free t
ry-on capability by creating high-quality pseudo-data and further enhance its ha
ndling of complex spatial information through effective in-the-wild data augment
ation. Besides, a try-on localization loss is designed to concentrate on try-on
area while suppressing garment features in non-try-on areas, ensuring precise re
ndering of garments and preservation of fore/back-ground. In the end, we introdu
ce BooW-VTON, the mask-free virtual try-on diffusion model, which delivers SOTA
try-on quality without parsing cost. Extensive qualitative and quantitative expe
riments have demonstrated superior performance in wild scenarios with such a low
-demand input.

Rectified Diffusion Guidance for Conditional Generation
Mengfei Xia, Nan Xue, Yujun Shen, Ran Yi, Tieliang Gong, Yong-Jin Liu; Proceedin
gs of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 1
3371-13380
Classifier-Free Guidance (CFG), which combines the conditional and unconditional
score functions with two coefficients summing to one, serves as a practical tec
hnique for diffusion model sampling. Theoretically, however, denoising with CFG
cannot be expressed as a reciprocal diffusion process, which may consequently le
ave some hidden risks during use. In this work, we revisit the theory behind CFG
and rigorously confirm that the improper configuration of the combination coeff
icients (*i.e.*, the widely used summing-to-one version) brings about expectatio
n shift of the generative distribution. To rectify this issue, we propose ReCFG
with a relaxation on the guidance coefficients such that denoising with ReCFG st
rictly aligns with the diffusion theory. We further show that our approach enjoy
s a **closed-form** solution given the guidance strength. That way, the rectifie
d coefficients can be readily pre-computed via traversing the observed data, lea
ving the sampling speed barely affected. Empirical evidence on real-world data d
emonstrate the compatibility of our post-hoc design with existing state-of-the-a
rt diffusion models, including both class-conditioned ones (*e.g.*, EDM2 on Imag
eNet) and text-conditioned ones (*e.g.*, SD3 on CC12M), without any retraining.
Code is available at https://github.com/thuxmf/recfg.

SceneFactor: Factored Latent 3D Diffusion for Controllable 3D Scene Generation
Aleksey Bokhovkin, Quan Meng, Shubham Tulsiani, Angela Dai; Proceedings of the C
omputer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 628-639
We present SceneFactor, a diffusion-based approach for large-scale 3D scene gene
ration that enables controllable generation and effortless editing. SceneFactor
enables text-guided 3D scene synthesis through our factored diffusion formulatio
n, leveraging latent semantic and geometric manifolds for generation of arbitrar
y-sized 3D scenes. While text input enables easy, controllable generation, text
guidance remains imprecise for intuitive, localized editing and manipulation of
the generated 3D scenes. Our factored semantic diffusion generates a proxy seman
tic space composed of semantic 3D boxes that enables controllable editing of gen
erated scenes by adding, removing, changing the size of the semantic 3D proxy bo
xes that guides high-fidelity, consistent 3D geometric editing. Extensive experi
ments demonstrate that our approach enables high-fidelity 3D scene synthesis wit
h effective controllable editing through our factored diffusion approach.
****

HiFi-Portrait: Zero-shot Identity-preserved Portrait Generation with High-fideli
ty Multi-face Fusion
Yifang Xu, Benxiang Zhai, Yunzhuo Sun, Ming Li, Yang Li, Sidan Du; Proceedings o
f the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 5625-
5635
Recent advancements in diffusion-based technologies have made significant stride
s, particularly in identity-preserved portrait generation (IPG). However, when u
sing multiple reference images from the same ID, existing methods typically prod
uce lower-fidelity portraits and struggle to customize face attributes precisely

. To address these issues, this paper presents HiFi-Portrait, a high-fidelity method for zero-shot portrait generation. Specifically, we first introduce the face refiner and landmark generator to obtain fine-grained multi-face features and 3D-aware face landmarks. The landmarks include the reference ID and the target attributes. Then, we design HiFi-Net to fuse multi-face features and align them with landmarks, which improves ID fidelity and face control. In addition, we devise an automated pipeline to construct an ID-based dataset for training HiFi-Portrait. Extensive experimental results demonstrate that our method surpasses the SOTA approaches in face similarity and controllability. Furthermore, our method is also compatible with previous SDXL-based works.

IAAO: Interactive Affordance Learning for Articulated Objects in 3D Environments

Can Zhang, Gim Hee Lee; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 12132-12142

This work presents IAAO, a novel framework that builds an explicit 3D model for intelligent agents to gain understanding of articulated objects in their environment through interaction. Unlike prior methods that rely on task-specific networks and assumptions about movable parts, our IAAO leverages large foundation models to estimate interactive affordances and part articulations in three stages. We first build hierarchical features and label fields for each object state using 3D Gaussian Splatting (3DGS) by distilling mask features and view-consistent labels from multi-view images. We then perform object- and part-level queries on the 3D Gaussian primitives to identify static and articulated elements, estimating global transformations and local articulation parameters along with affordances. Finally, scenes from different states are merged and refined based on the estimated transformations, enabling robust affordance-based interaction and manipulation of objects. Experimental results demonstrate the effectiveness of our method.

FloVD: Optical Flow Meets Video Diffusion Model for Enhanced Camera-Controlled Video Synthesis

Wonjoon Jin, Qi Dai, Chong Luo, Seung-Hwan Baek, Sunghyun Cho; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 2040-2049

We present FloVD, a novel video diffusion model for camera-controllable video generation. FloVD leverages optical flow to represent the motions of the camera and moving objects. This approach offers two key benefits. Since optical flow can be directly estimated from videos, our approach allows for the use of arbitrary training videos without ground-truth camera parameters. Moreover, as background optical flow encodes 3D correlation across different viewpoints, our method enables detailed camera control by leveraging the background motion. To synthesize natural object motion while supporting detailed camera control, our framework adopts a two-stage video synthesis pipeline consisting of optical flow generation and flow-conditioned video synthesis. Extensive experiments demonstrate the superiority of our method over previous approaches in terms of accurate camera control and natural object motion synthesis.

****

RAD: Region-Aware Diffusion Models for Image Inpainting

Sora Kim, Sungho Suh, Minsik Lee; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 2439-2448

Diffusion models have achieved remarkable success in image generation, with applications broadening across various domains.Inpainting is one such application that can benefit significantly from diffusion models. Existing methods either hijack the reverse process of a pretrained diffusion model or cast the problem into a larger framework, i.e., conditioned generation. However, these approaches often require nested loops in the generation process or additional components for conditioning. In this paper, we present region-aware diffusion models (RAD) for inpainting with a simple yet effective reformulation of the vanilla diffusion models. RAD utilizes a different noise schedule for each pixel, which allows local regions to be generated asynchronously while considering the global image context. A plain reverse process requires no additional components, enabling RAD to ach

ieve inference time up to 100 times faster than the state-of-the-art approaches. Moreover, we employ low-rank adaptation (LoRA) to fine-tune RAD based on other pretrained diffusion models, reducing computational burdens in training as well. Experiments demonstrated that RAD provides state-of-the-art results both qualitatively and quantitatively, on the FFHQ, LSUN Bedroom, and ImageNet datasets.
****

RaSS: Improving Denoising Diffusion Samplers with Reinforced Active Sampling Scheduler

Xin Ding, Lei Yu, Xin Li, Zhijun Tu, Hanting Chen, Jie Hu, Zhibo Chen; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 12923-12933

Recent years have witnessed the great success of denoising diffusion samplers in improving the generative capability and sampling efficiency given a pre-trained diffusion model. However, most sampling schedulers in diffusion models lack the sampling dynamics and planning capability for future generation results, leading to suboptimal solutions. To overcome this, we propose the Reinforced Active Sampling Scheduler, termed RaSS, intending to find the optimal sampling trajectory by actively planning and adjusting the sampling steps for each sampling process in time. Concretely, RaSS divides the whole sampling process into five stages and introduces a reinforcement learning (RL) agent to continuously monitor the generated instance and perceive the potential generation results, thereby achieving optimal instance- and state-adaptive sampling steps decision. Meanwhile, a sampling reward is designed to assist the planning capability of the RL agent by balancing the sampling efficiency and generation quality. The RaSS is a plug-and-play module, which is applicable to multiple denoising diffusion samplers of diffusion models. Extensive experiments on different benchmarks have shown that our RaSS can consistently improve the generation quality and efficiency across various tasks, without introducing significant computational overhead.

Supervising Sound Localization by In-the-wild Egomotion

Anna Min, Ziyang Chen, Hang Zhao, Andrew Owens; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 23936-23946

We present a method for learning binaural sound localization from ego-motion in videos. When the camera moves in a video, the direction of sound sources will change along with it. We train an audio model to predict sound directions that are consistent with visual estimates of camera motion, which we obtain using methods from multi-view geometry. This provides a weak but plentiful form of supervision that we combine with traditional binaural cues. To evaluate this idea, we propose a dataset of real-world audio-visual videos with ego-motion. We show that our model can successfully learn from this real-world data, and that it obtains strong performance on sound localization tasks.
****

AutoLUT: LUT-Based Image Super-Resolution with Automatic Sampling and Adaptive Residual Learning

Yuheng Xu, Shijie Yang, Xin Liu, Jie Liu, Jie Tang, Gangshan Wu; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 23131-23140

In recent years, the increasing popularity of Hi-DPI screens has driven a rising demand for high-resolution images. However, the limited computational power of edge devices poses a challenge in deploying complex super-resolution neural networks, highlighting the need for efficient methods. While prior works have made significant progress, they have not fully exploited pixel-level information. Moreover, their reliance on fixed sampling patterns limits both accuracy and the ability to capture fine details in low-resolution images. To address these challenges, we introduce two plug-and-play modules designed to capture and leverage pixel information effectively in Look-Up Table (LUT) based super-resolution networks. Our method introduces Automatic Sampling (AutoSample), a flexible LUT sampling approach where sampling weights are dynamically learned during training to adapt to pixel variations and expand the receptive field without added inference cost. We also incorporate Adaptive Residual Learning (AdaRL) to enhance inter-layer

connections, enabling detailed information flow and improving the network's abi
lity to reconstruct fine details. Our method achieves significant performance im
provements on both MuLUT and SPF-LUT while maintaining similar storage sizes. Sp
ecifically, for MuLUT, we achieve a PSNR improvement of approximately +0.20 dB i
mprovement on average across five datasets . For SPF-LUT, with more than a 50% r
eduction in storage space and about a 2/3 reduction in inference time, our metho
d still maintains performance comparable to the original.
****
Understanding Fine-tuning CLIP for Open-vocabulary Semantic Segmentation in Hype
rbolic Space
Zelin Peng, Zhengqin Xu, Zhilin Zeng, Changsong Wen, Yu Huang, Menglin Yang, Fei
long Tang, Wei Shen; Proceedings of the Computer Vision and Pattern Recognition
Conference (CVPR), 2025, pp. 4562-4572
CLIP, a foundational vision-language model, has emerged as a powerful tool for o
pen-vocabulary semantic segmentation. While freezing the text encoder preserves
its powerful embeddings, recent studies show that fine-tuning both the text and
image encoders jointly significantly enhances segmentation performance, especial
ly for classes from open sets. In this work, we explain this phenomenon from the
perspective of hierarchical alignment, since during fine-tuning, the hierarchy
level of image embeddings shifts from image-level to pixel-level. We achieve thi
s by leveraging hyperbolic space, which naturally encoders hierarchical structur
es. Our key observation is that, during fine-tuning, the hyperbolic radius of CL
IP's text embeddings decreases, facilitating better alignment with the pixel-lev
el hierarchical structure of visual data. Building on this insight, we propose H
yperCLIP, a novel fine-tuning strategy that adjusts the hyperbolic radius of the
text embeddings through scaling transformations. By doing so, HyperCLIP equips
CLIP with segmentation capability while introducing only a small number of learn
able parameters. Our experiments demonstrate that HyperCLIP achieves state-of-th
e-art performance on open-vocabulary semantic segmentation tasks across three be
nchmarks, while fine-tuning only approximately 4% of the total parameters of CLI
P. More importantly, we observe that after adjustment, CLIP's text embeddings ex
hibit a relatively fixed hyperbolic radius across datasets, suggesting that the
segmentation task has a characteristic level in hyperbolic space.
****
TexGaussian: Generating High-quality PBR Material via Octree-based 3D Gaussian S
platting
Bojun Xiong, Jialun Liu, Jiakui Hu, Chenming Wu, Jinbo Wu, Xing Liu, Chen Zhao,
Errui Ding, Zhouhui Lian; Proceedings of the Computer Vision and Pattern Recogni
tion Conference (CVPR), 2025, pp. 551-561
Physically Based Rendering (PBR) materials play a crucial role in modern graphic
s, enabling photorealistic rendering across diverse environment maps. Developing
an effective and efficient algorithm that is capable of automatically generatin
g high-quality PBR materials rather than RGB texture for 3D meshes can significa
ntly streamline the 3D content creation. Most existing methods leverage pre-trai
ned 2D diffusion models for multi-view image synthesis, which often leads to sev
ere inconsistency between the generated textures and input 3D meshes. This paper
presents TexGaussian, a novel method that uses octant-aligned 3D Gaussian Splat
ting for rapid PBR material generation. Specifically, we place each 3D Gaussian
on the finest leaf node of the octree built from the input 3D mesh to render the
multi-view images not only for the albedo map but also for roughness and metall
ic. Moreover, our model is trained in a regression manner instead of diffusion d
enoising, capable of generating the PBR material for a 3D mesh in a single feed-
forward process. Extensive experiments on publicly available benchmarks demonstr
ate that our method synthesizes more visually pleasing PBR materials and runs fa
ster than previous methods in both unconditional and text-conditional scenarios,
exhibiting better consistency with the given geometry. Our code and trained mod
els are available at https://3d-aigc.github.io/TexGaussian.

OSV: One Step is Enough for High-Quality Image to Video Generation
Xiaofeng Mao, Zhengkai Jiang, Fu-yun Wang, Jiangning Zhang, Hao Chen, Mingmin Ch

i, Yabiao Wang, Wenhan Luo; Proceedings of the Computer Vision and Pattern Recog nition Conference (CVPR), 2025, pp. 12585-12594

Video diffusion models have shown great potential in generating high-quality vid eos, making them an increasingly popular focus. However, their inherent iterativ e nature leads to substantial computational and time costs. Although techniques such as consistency distillation and adversarial training have been employed to accelerate video diffusion by reducing inference steps, these methods often simp ly transfer the generation approaches from Image diffusion models to video diffu sion models. As a result, these methods frequently fall short in terms of both p erformance and training stability. In this work, we introduce a two-stage traini ng framework that effectively combines consistency distillation with adversarial training to address these challenges. Additionally, we propose a novel video di scriminator design, which eliminates the need for decoding the video latents and improves the final performance. Our model is capable of producing high-quality videos in merely one-step, with the flexibility to perform multi-step refinement for further performance enhancement. Our quantitative evaluation on the OpenVid -1M benchmark shows that our model significantly outperforms existing methods. N otably, our 1-step performance (FVD 171.15) exceeds the 8-step performance of th e consistency distillation based method, AnimateLCM (FVD 184.79), and approache s the 25-step performance of advanced Stable Video Diffusion (FVD 156.94).

Fuzzy Multimodal Learning for Trusted Cross-modal Retrieval

Siyuan Duan, Yuan Sun, Dezhong Peng, Zheng Liu, Xiaomin Song, Peng Hu; Proceedin gs of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 2 0747-20756

Cross-modal retrieval aims to match related samples across distinct modalities, facilitating the retrieval and discovery of heterogeneous information. Although existing methods show promising performance, most are deterministic models and a re unable to capture the uncertainty inherent in the retrieval outputs, leading to potentially unreliable results. To address this issue, we propose a novel fra mework called FUzzy Multimodal lEarning (FUME), which is able to self-estimate e pistemic uncertainty, thereby embracing trusted cross-modal retrieval. Specifica lly, our FUME leverages the Fuzzy Set Theory to view the outputs of the classifi cation network as a set of membership degrees and quantify category credibility by incorporating both possibility and necessity measures. However, directly opti mizing the category credibility could mislead the model by over-optimizing the n ecessity for unmatched categories. To overcome this challenge, we present a nove l fuzzy multimodal learning strategy, which utilizes label information to guide necessity optimization in the right direction, thereby indirectly optimizing cat egory credibility and achieving accurate decision uncertainty quantification. Fu rthermore, we design an uncertainty merging scheme that accounts for decision un certainties, thus further refining uncertainty estimates and boosting the trustw orthiness of retrieval results. Extensive experiments on five benchmark datasets demonstrate that FUME remarkably improves both retrieval performance and reliab ility, offering a prospective solution for cross-modal retrieval in high-stakes applications. Code is available at https://github.com/siyuancncd/FUME .

AniGS: Animatable Gaussian Avatar from a Single Image with Inconsistent Gaussian Reconstruction

Lingteng Qiu, Shenhao Zhu, Qi Zuo, Xiaodong Gu, Yuan Dong, Junfei Zhang, Chao Xu , Zhe Li, Weihao Yuan, Liefeng Bo, Guanying Chen, Zilong Dong; Proceedings of th e Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 21148-211 58

Generating animatable human avatars from a single image is essential for various digital human modeling applications. Existing 3D reconstruction methods often s truggle to capture fine details in animatable models, while generative approache s for controllable animation, though avoiding explicit 3D modeling, suffer from viewpoint inconsistencies in extreme poses and computational inefficiencies. In this paper, we address these challenges by leveraging the power of generative mo dels to produce detailed multi-view canonical pose images, which help resolve am

biguities in animatable human reconstruction. We then propose a robust method fo r 3D reconstruction of inconsistent images, enabling real-time rendering during inference. Specifically, we adapt a transformer-based Text-to-Video model to gen erate multi-view canonical pose images and normal maps, pretraining on a large-s cale monocular video dataset to improve generalization. To handle view inconsist encies, we recast the reconstruction problem as a 4D task and introduce an effic ient 3D modeling approach using 4D Gaussian Splatting. Experiments demonstrate t hat our method achieves photorealistic, real-time animation of 3D human avatars from in-the-wild images, showcasing its effectiveness and generalization capabil ity.

Few-Shot Recognition via Stage-Wise Retrieval-Augmented Finetuning
Tian Liu, Huixin Zhang, Shubham Parashar, Shu Kong; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 15086-15097
Few-shot recognition (FSR) aims to train a classification model with only a few labeled examples of each concept concerned by a downstream task, where data anno tation cost can be prohibitively high. We develop methods to solve FSR by levera ging a pretrained Vision-Language Model (VLM). We particularly explore retrieval -augmented learning (RAL), which retrieves open data, e.g., the VLM's pretrainin g dataset, to learn models for better serving downstream tasks. RAL has been stu died in zero-shot recognition but remains under-explored in FSR. Although applyi ng RAL to FSR may seem straightforward, we observe interesting and novel challen ges and opportunities. First, somewhat surprisingly, finetuning a VLM on a large amount of retrieved data underperforms state-of-the-art zero-shot methods. This is due to the imbalanced distribution of retrieved data and its domain gaps wit h the few-shot examples in the downstream task. Second, more surprisingly, we fi nd that simply finetuning a VLM solely on few-shot examples significantly outper forms previous FSR methods, and finetuning on the mix of retrieved and few-shot data yields even better results. Third, to mitigate the imbalanced distribution and domain gap issues, we propose Stage-Wise retrieval-Augmented fineTuning (SWA T), which involves end-to-end finetuning on mixed data in the first stage and re training the classifier on the few-shot data in the second stage. Extensive expe riments on nine popular benchmarks demonstrate that SWAT significantly outperfor ms previous methods by >6% accuracy.

Concept Replacer: Replacing Sensitive Concepts in Diffusion Models via Precision Localization

Lingyun Zhang, Yu Xie, Yanwei Fu, Ping Chen; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 8172-8181
As large-scale diffusion models continue to advance, they excel at producing high-quality images but often generate unwanted content, such as sexually explicit or violent content. Existing methods for concept removal generally guide the image generation process but can unintentionally modify unrelated regions, leading to inconsistencies with the original model. We propose a novel approach for targeted concept replacing in diffusion models, enabling specific concepts to be removed without affecting non-target areas. Our method introduces a dedicated concept localizer for precisely identifying the target concept during the denoising process, trained with few-shot learning to require minimal labeled data. Within the identified region, we introduce a training-free Dual Prompts Cross-Attention (DPCA) module to substitute the target concept, ensuring minimal disruption to surrounding content. We evaluate our method on concept localization precision and replacement efficiency. Experimental results demonstrate that our method achieves superior precision in localizing target concepts and performs coherent concept replacement with minimal impact on non-target areas, outperforming existing approaches.

A Regularization-Guided Equivariant Approach for Image Restoration
Yulu Bai, Jiahong Fu, Qi Xie, Deyu Meng; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 2300-2310
Equivariant and invariant deep learning models have been developed to exploit intrinsic symmetries in data, demonstrating significant effectiveness in certain scenarios. However, these methods often suffer from limited representation accuracy and rely on strict symmetry assumptions that may not hold in practice. These limitations pose a significant drawback for image restoration tasks, which demands high accuracy and precise symmetry representation. To address these challenges, we propose a rotation-equivariant regularization strategy that adaptively enforces the appropriate symmetry constraints on the data while preserving the network's representational accuracy. Specifically, we introduce EQ-Reg, a regularizer designed to enhance rotation equivariance, which innovatively extends the insights of data-augmentation-based and equivariant-based methodologies. This is achieved through self-supervised learning and the spatial rotation and cyclic channel shift of feature maps deduce in the equivariant framework. Our approach firstly enables a non-strictly equivariant network suitable for image restoration, providing a simple and adaptive mechanism for adjusting equivariance based on task. Extensive experiments across three low-level tasks demonstrate the superior accuracy and generalization capability of our method, outperforming state-of-the-art approaches.

RestorGS: Depth-aware Gaussian Splatting for Efficient 3D Scene Restoration
Yuanjian Qiao, Mingwen Shao, Lingzhuang Meng, Kai Xu; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 11177-11186
3D Gaussian Splatting (3DGS) has recently achieved remarkable progress in novel view synthesis. However, existing methods rely heavily on high-quality data for rendering and struggle to handle degraded scenes with multi-view inconsistency, leading to inferior rendering quality. To address this challenge, we propose a novel Depth-aware Gaussian Splatting for efficient 3D scene Restoration, called RestorGS, which flexibly restores multiple degraded scenes using a unified framework. Specifically, RestorGS consists of two core designs: Appearance Decoupling and Depth-Guided Modeling. The former exploits appearance learning over spherical harmonics to decouple clear and degraded Gaussian, thus separating the clear views from the degraded ones. Collaboratively, the latter leverages the depth information to guide the degradation modeling, thereby facilitating the decoupling process. Benefiting from the above optimization strategy, our method achieves high-quality restoration while enabling real-time rendering speed. Extensive experiments show that our RestorGS outperforms existing methods significantly in underwater, nighttime, and hazy scenes.

IM-Portrait: Learning 3D-aware Video Diffusion for Photorealistic Talking Heads from Monocular VideosC
Yuan Li, Ziqian Bai, Feitong Tan, Zhaopeng Cui, Sean Fanello, Yinda Zhang; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 21107-21116
We propose a novel 3D-aware diffusion-based method for generating photorealistic talking head videos directly from a single identity image and explicit control signals (e.g., expressions). Our method generates Multiplane Images (MPIs) that ensure geometric consistency, making them ideal for immersive viewing experiences like binocular videos for VR headsets.Unlike existing methods that often require a separate stage or joint optimization to reconstruct a 3D representation (such as NeRF or 3D Gaussians), our approach directly generates the final output through a single denoising process, eliminating the need for post-processing steps to render novel views efficiently.To effectively learn from monocular videos, we introduce a training mechanism that reconstructs the output MPI randomly in either the target or the reference camera space. This approach enables the model to simultaneously learn sharp image details and underlying 3D information.Extensive experiments demonstrate the effectiveness of our method, which achieves competitive avatar quality and novel-view rendering capabilities, even without explicit 3D reconstruction or high-quality multi-view training data.
****
Deep Fair Multi-View Clustering with Attention KAN
HaiMing Xu, Qianqian Wang, Boyue Wang, Quanxue Gao; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 5061-5070
Multi-view clustering is effective in unsupervised multi-view data analysis and has received considerable attention. However, most existing methods excessively emphasize certain attributes, resulting in unfair clustering outcomes, i.e., certain sensitive attributes dominate the clustering results. Moreover, existing methods struggle to effectively capture complex nonlinear relationships and interactions across views, limiting their ability to achieve optimal clustering performance. Therefore, in this work, we propose a novel method, Deep Fair Multi-View Clustering with Attention Kolmogorov-Arnold Network (DFMVC-AKAN), to generate fair clustering results while maintaining robust performance. DFMVC-AKAN integrates attention mechanisms into Kolmogorov-Arnold Networks (KAN) to exploit the complex nonlinear inter-view relationships. Specifically, KAN provides a nonlinear feature representation capable of efficiently approximating arbitrary multivariate continuous functions, augmented by a hybrid attention mechanism which enables the model to dynamically focus on the most relevant features. Finally, we refine the clustering assignments with a distribution alignment module to ensure fair outcomes across diverse groups while maintaining discriminative ability. Experimental results on four datasets containing sensitive attributes demonstrate that DFMVC-AKAN significantly improves fairness and clustering performance compared to state-of-the-art methods.
****
LineArt: A Knowledge-guided Training-free High-quality Appearance Transfer for Design Drawing with Diffusion Model
Xi Wang, Hongzhen Li, Heng Fang, Yichen Peng, Haoran Xie, Xi Yang, Chuntao Li; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 2912-2923
Image rendering from line drawings is vital in design and image generation technologies reduce costs, yet professional line drawings demand preserving complex details. Text prompts struggle with accuracy, and image translation struggles with consistency and fine-grained control. We present LineArt, a framework that transfers complex appearance onto detailed design drawings, facilitating design and artistic creation. It generates high-fidelity appearance while preserving structural accuracy by simulating hierarchical visual cognition and integrating human artistic experience to guide the diffusion process. LineArt overcomes the limitations of current methods in terms of difficulty in fine-grained control and style degradation in design drawings. It requires no precise 3D modeling, physical property specifications, or network training, making it more convenient for desi

gn tasks. LineArt consists of two stages: a multi-frequency lines fusion module to supplement the input design drawing with detailed structural information and a two-part painting process for Base Layer Shaping and Surface Layer Coloring. We also present a new design drawing dataset, ProLines, for evaluation. The experiments show that LineArt performs better in accuracy, realism, and material precision compared to SOTAs.

4Real-Video: Learning Generalizable Photo-Realistic 4D Video Diffusion

Chaoyang Wang, Peiye Zhuang, Tuan Duc Ngo, Willi Menapace, Aliaksandr Siarohin, Michael Vasilkovsky, Ivan Skorokhodov, Sergey Tulyakov, Peter Wonka, Hsin-Ying Lee; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 17723-17732

We propose 4Real-Video, a novel framework for generating 4D videos, organized as a grid of video frames with both time and viewpoint axes. In this grid, each row contains frames sharing the same timestep, while each column contains frames from the same viewpoint. One stream performs viewpoint updates on columns, and the other stream performs temporal updates on rows. After each diffusion transformer layer, a newly designed synchronization layer exchanges information between the two token streams. We propose two implementations of the synchronization layer, using either hard or soft synchronization.This feedforward architecture improves upon previous work in three ways: higher inference speed, enhanced visual quality (measured by FVD, CLIP, and VideoScore), and improved temporal and viewpoint consistency (measured by VideoScore, GIM-Confidence, and Dust3R-Confidence).

****

DynaMoDe-NeRF: Motion-aware Deblurring Neural Radiance Field for Dynamic Scenes

Ashish Kumar, Rajagopalan A. N.; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 21728-21738

Neural Radiance Fields (NeRFs) have made significant advances in rendering novel photorealistic views for both static and dynamic scenes. However, most prior works assume ideal conditions of artifact-free visual inputs i.e., images and videos. In real scenarios, artifacts such as object motion blur, camera motion blur, or lens defocus blur are ubiquitous. Some recent studies have explored novel view synthesis using blurred input frames by examining either camera motion blur, defocus blur, or both. However, these studies are limited to static scenes. In this work, we enable NeRFs to deal with object motion blur whose local nature stems from the interplay between object velocity and camera exposure time. Often, the object motion is unknown and time varying, and this adds to the complexity of scene reconstruction. Sports videos are a prime example of how rapid object motion can significantly degrade video quality for static cameras by introducing motion blur. We present an approach for realizing motion blur-free novel views of dynamic scenes from input videos with object motion blur captured from static cameras spanning multiple poses. We propose a NeRF-based analytical framework that elegantly correlates object three-dimensional (3D) motion across views as well as time to the observed blurry videos. Our proposed method DynaMoDe-NeRF (Dynamic Motion-aware Deblurring NeRF) is self-supervised and reconstructs the dynamic 3D scene, renders sharp novel views by blind deblurring, and recovers the underlying 3D motion and blur parameters. We provide comprehensive experimental analysis on synthetic and real data to validate our approach. To the best of our knowledge, this is the first work to address localized object motion blur in the NeRF domain.

****

VideoICL: Confidence-based Iterative In-context Learning for Out-of-Distribution Video Understanding

Kangsan Kim, Geon Park, Youngwan Lee, Woongyeong Yeo, Sung Ju Hwang; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 3295-3305

Recent advancements in video large multimodal models (LMMs) have significantly improved their video understanding and reasoning capabilities. However, their performance drops on out-of-distribution (OOD) tasks that are underrepresented in training data. Traditional methods like fine-tuning on OOD datasets are impractic

al due to high computational costs. While In-context learning (ICL) with demonstration examples has shown promising generalization performance in language tasks and image-language tasks without fine-tuning, applying ICL to video-language tasks faces challenges due to the limited context length in Video LMMs, as videos require longer token lengths. To address these issues, we propose VideoICL, a novel video in-context learning framework for OOD tasks that introduces a similarity-based relevant example selection strategy and a confidence-based iterative inference approach. This allows to select the most relevant examples and rank them based on similarity, to be used for inference. If the generated response has low confidence, our framework selects new examples and performs inference again, iteratively refining the results until a high-confidence response is obtained. This approach improves OOD video understanding performance by extending effective context length without incurring high costs. The experimental results on multiple benchmarks demonstrate significant performance gains, especially in domain-specific scenarios, laying the groundwork for broader video comprehension applications.

Zero-Shot Image Restoration Using Few-Step Guidance of Consistency Models (and Beyond)

Tomer Garber, Tom Tirer; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 2398-2407

In recent years, it has become popular to tackle image restoration tasks with a single pretrained diffusion model (DM) and data-fidelity guidance, instead of training a dedicated deep neural network per task. However, such "zero-shot" restoration schemes currently require many Neural Function Evaluations (NFEs) for performing well, which may be attributed to the many NFEs needed in the original generative functionality of the DMs. Recently, faster variants of DMs have been explored for image generation. These include Consistency Models (CMs), which can generate samples via a couple of NFEs. However, existing works that use guided CMs for restoration still require tens of NFEs or fine-tuning of the model per task that leads to performance drop if the assumptions during the fine-tuning are not accurate. In this paper, we propose a zero-shot restoration scheme that uses CMs and operates well with as little as 4 NFEs. It is based on a wise combination of several ingredients: better initialization, back-projection guidance, and above all a novel noise injection mechanism. We demonstrate the advantages of our approach for image super-resolution and inpainting. Interestingly, we show that the usefulness of our noise injection technique goes beyond CMs: it can also mitigate the performance degradation of existing guided DM methods when reducing their NFE count.

Similarity-Guided Layer-Adaptive Vision Transformer for UAV Tracking

Chaocan Xue, Bineng Zhong, Qihua Liang, Yaozong Zheng, Ning Li, Yuanliang Xue, Shuxiang Song; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 6730-6740

Vision transformers (ViTs) have emerged as a popular backbone for visual tracking. However, complete ViT architectures are too cumbersome to deploy for unmanned aerial vehicle (UAV) tracking which extremely emphasizes efficiency. In this study, we discover that many layers within lightweight ViT-based trackers tend to learn relatively redundant and repetitive target representations. Based on this observation, we propose a similarity-guided layer adaptation approach to optimize the structure of ViTs. Our approach dynamically disables a large number of representation-similar layers and selectively retains only a single optimal layer among them, aiming to achieve a better accuracy-speed trade-off. By incorporating this approach into existing ViTs, we tailor previously complete ViT architectures into an efficient similarity-guided layer-adaptive framework, namely SGLATrack, for real-time UAV tracking. Extensive experiments on six tracking benchmarks verify the effectiveness of the proposed approach, and show that our SGLATrack achieves a state-of-the-art real-time speed while maintaining competitive tracking precision. Codes and models are available at https://github.com/GXNU-ZhongLab/SGLATrack.

LidarGait++: Learning Local Features and Size Awareness from LiDAR Point Clouds for 3D Gait Recognition
Chuanfu Shen, Rui Wang, Lixin Duan, Shiqi Yu; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 6627-6636
Point clouds have gained growing interest in gait recognition. However, current methods, which typically convert point clouds into 3D voxels, often fail to extract essential gait-specific features. In this paper, we explore gait recognition within 3D point clouds from the perspectives of architectural designs and gait representation modeling. We indicate the significance of local and body size features in 3D gait recognition and introduce LidarGait++, a novel framework combining advanced local representation learning techniques with a novel size-aware learning mechanism. Specifically, LidarGait++ utilizes Set Abstraction (SA) layer and Pyramid Point Pooling (P^3) layer for learning locally fine-grained gait representations from 3D point clouds directly. Both the SA and P^3 layers can be further enhanced with size-aware learning to make the model aware of the actual size of the subjects. In the end, LidarGait++ not only outperforms current state-of-the-art methods, but it also consistently demonstrates robust performance and great generalizability on two benchmarks. Our extensive experiments validate the effectiveness of size and local features in 3D gait recognition.
****
UrbanCAD: Towards Highly Controllable and Photorealistic 3D Vehicles for Urban Scene Simulation
Yichong Lu, Yichi Cai, Shangzhan Zhang, Hongyu Zhou, Haoji Hu, Huimin Yu, Andreas Geiger, Yiyi Liao; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 27519-27530
Photorealistic 3D vehicle models with high controllability are essential for autonomous driving simulation and data augmentation. While handcrafted CAD models provide flexible controllability, free CAD libraries often lack the high-quality materials necessary for photorealistic rendering. Conversely, reconstructed 3D models offer high-fidelity rendering but lack controllability. In this work, we introduce UrbanCAD, a framework that generates highly controllable and photorealistic 3D vehicle digital twins from a single urban image, leveraging a large collection of free 3D CAD models and handcrafted materials. To achieve this, we propose a novel pipeline that follows a retrieval-optimization manner, adapting to observational data while preserving fine-grained expert-designed priors for both geometry and material. This enables vehicles' realistic 360-degree rendering, background insertion, material transfer, relighting, and component manipulation. Furthermore, given multi-view background perspective and fisheye images, we approximate environment lighting using fisheye images and reconstruct the background with 3DGS, enabling the photorealistic insertion of optimized CAD models into rendered novel view backgrounds. Experimental results demonstrate that UrbanCAD outperforms baselines in terms of photorealism. Additionally, we show that various perception models maintain their accuracy when evaluated on UrbanCAD with in-distribution configurations but degrade when applied to realistic out-of-distribution data generated by our method. This suggests that UrbanCAD is a significant advancement in creating photorealistic, safety-critical driving scenarios for downstream applications.

Coarse Correspondences Boost Spatial-Temporal Reasoning in Multimodal Language Model
Benlin Liu, Yuhao Dong, Yiqin Wang, Zixian Ma, Yansong Tang, Luming Tang, Yongming Rao, Wei-Chiu Ma, Ranjay Krishna; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 3783-3792
Multimodal language models (MLLMs) are increasingly being applied in real-world environments, necessitating their ability to interpret 3D spaces and comprehend temporal dynamics. Current methods often rely on specialized architectural designs or task-specific fine-tuning to achieve this. We introduce Coarse Correspondences, a simple lightweight method that enhances MLLMs' spatial-temporal reasoning with 2D images as input, without modifying the architecture or requiring task-

specific fine-tuning. Our method uses a lightweight tracking model to identify p
rimary object correspondences between frames in a video or across different imag
e viewpoints, and then conveys this information to MLLMs through visual promptin
g. We demonstrate that this simple training-free approach brings substantial gai
ns to GPT4-V/O consistently on four benchmarks that require spatial-temporal rea
soning, including +20.5% improvement on ScanQA, +9.7% on OpenEQA's episodic memo
ry subset, +6.0% on the long-form video benchmark EgoSchema, and +11% on the R2R
 navigation benchmark. Additionally, we show that Coarse Correspondences can al
so enhance open-source MLLMs' spatial reasoning (by +6.9% on ScanQA) when applie
d in both training and inference and that the improvement can generalize to unse
en datasets such as SQA3D (+3.1%). Taken together, we show that Coarse Correspon
dences effectively and efficiently boosts models' performance on downstream tas
ks requiring spatial-temporal reasoning.

Diff-Palm: Realistic Palmprint Generation with Polynomial Creases and Intra-Clas
s Variation Controllable Diffusion Models

Jianlong Jin, Chenglong Zhao, Ruixin Zhang, Sheng Shang, Jianqing Xu, Jingyun Zh
ang, ShaoMing Wang, Yang Zhao, Shouhong Ding, Wei Jia, Yunsheng Wu; Proceedings
of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 2636
7-26376

Palmprint recognition is significantly limited by the lack of large-scale public
ly available datasets. Previous methods have adopted Bezier curves to simulate t
he palm creases, which then serve as input for conditional GANs to generate real
istic palmprints.However, without employing real data fine-tuning, the performan
ce of the recognition model trained on these synthetic datasets would drasticall
y decline, indicating a large gap between generated and real palmprints.This is
primarily due to the utilization of an inaccurate palm crease representation and
 challenges in balancing intra-class variation with identity consistency.To addr
ess this, we introduce a polynomial-based palm crease representation that provid
es a new palm crease generation mechanism more closely aligned with the real dis
tribution. We also propose the palm creases conditioned diffusion model with a n
ovel intra-class variation control method.By applying our proposed K-step noise-
sharing sampling, we are able to synthesize palmprint datasets with large intra-
class variation and high identity consistency.Experimental results show that, fo
r the first time, recognition models trained solely on our synthetic datasets, w
ithout any fine-tuning, outperform those trained on real datasets.Furthermore, o
ur approach achieves superior recognition performance as the number of generated
 identities increases.Our code and pre-trained models will be released.

FoundationStereo: Zero-Shot Stereo Matching

Bowen Wen, Matthew Trepte, Joseph Aribido, Jan Kautz, Orazio Gallo, Stan Birchfi
eld; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR
), 2025, pp. 5249-5260

Tremendous progress has been made in deep stereo matching to excel on benchmark
datasets through per-domain fine-tuning. However, achieving strong zero-shot gen
eralization - a hallmark of foundation models in other computer vision tasks - r
emains challenging for stereo matching. We introduce FoundationStereo, a foundat
ion model for stereo depth estimation designed to achieve strong zero shot gener
alization. To this end, we first construct a large scale (1M stereo pairs) synth
etic training dataset featuring large diversity and high photorealism, followed
by an automatic self-curation pipeline to remove ambiguous samples. We then desi
gn a number of network architecture components to enhance scalability, including
 a side-tuning feature backbone that adapts rich monocular priors from vision fo
undation models to mitigate the sim-to-real gap, and long-range context reasonin
g for effective cost volume filtering. Together, these components lead to strong
 robustness and accuracy across domains, establishing a new standard in zero-sho
t stereo depth estimation. Project page: https://nvlabs.github.io/FoundationSter

Z-Magic: Zero-shot Multiple Attributes Guided Image Creator

Yingying Deng, Xiangyu He, Fan Tang, Weiming Dong; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 18390-18400
The customization of multiple attributes has gained increasing popularity with the rising demand for personalized content creation. Despite promising empirical results, the contextual coherence between different attributes has been largely overlooked. In this paper, we argue that subsequent attributes should follow the multivariable conditional distribution introduced by former attributes creation. In light of this, we reformulate multi-attribute creation from a conditional probability theory perspective and tackle the challenging zero-shot setting. By explicitly modeling the dependencies between attributes, we further enhance the coherence of generated images across diverse attribute combinations. Furthermore, we identify connections between multi-attribute customization and multi-task learning, effectively addressing the high computing cost encountered in multi-attribute synthesis. Extensive experiments demonstrate that Z-Magic outperforms existing models in zero-shot image generation, with broad implications for AI-driven design and creative applications.
****

UniNet: A Contrastive Learning-guided Unified Framework with Feature Selection for Anomaly Detection
Shun Wei, Jielin Jiang, Xiaolong Xu; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 9994-10003
Anomaly detection (AD) is a crucial visual task aimed at recognizing abnormal pattern within samples. However, most existing AD methods suffer from limited generalizability, as they are primarily designed for domain-specific applications, such as industrial scenarios, and often perform poorly when applied to other domains. This challenge largely stems from the inherent discrepancies in features across domains. To bridge this domain gap, we introduce UniNet, a generic unified framework that incorporates effective feature selection and contrastive learning-guided anomaly discrimination. UniNet comprises student-teacher models and a bottleneck, featuring several vital innovations: First, we propose domain-related feature selection, where the student is guided to select and focus on representative features from the teacher with domain-relevant priors, while restoring them effectively. Second, a similarity contrastive loss function is developed to strengthen the correlations among homogeneous features. Meanwhile, a margin loss function is proposed to enforce the separation between the similarities of abnormality and normality, effectively improving the model's ability to discriminate anomalies. Third, we propose a weighted decision mechanism for dynamically evaluating the anomaly score to achieve robust AD. Large-scale experiments on 12 datasets from various domains show that UniNet surpasses existing methods.

Chain of Semantics Programming in 3D Gaussian Splatting Representation for 3D Vision Grounding
Jiaxin Shi, Mingyue Xiang, Hao Sun, Yixuan Huang, Zhi Weng; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 24560-24569
3D Vision Grounding (3DVG) is a fundamental research area that enables agents to perceive and interact with the 3D world. The challenge of the 3DVG task lies in understanding fine-grained semantics and spatial relationships within both the utterance and 3D scene. To address this challenge, we propose a zero-shot neuro-symbolic framework that utilizes a large language model (LLM) as neuro-symbolic functions to ground the object within the 3D Gaussian Splatting (3DGS) representation. By utilizing 3DGS representation, we can dynamically render high-quality 2D images from various viewpoints to enrich the semantic information. Given the complexity of spatial relationships, we construct a relationship graph and chain of semantics that decouple spatial relationships and facilitate step-by-step reasoning within 3DGS representation. Additionally, we employ a grounded-aware self-check mechanism to enable the LLM to reflect on its responses and mitigate the effects of ambiguity in spatial reasoning. We evaluate our method using two publicly available datasets, Nr3D and Sr3D, achieving accuracies of 60.8% and 91.4%, respectively. Notably, our method surpasses current state-of-the-art zero-shot methods on the Nr3D dataset. In addition, it outperforms the recent supervised

models on the Sr3D dataset.
****
On the Zero-shot Adversarial Robustness of Vision-Language Models: A Truly Zero-shot and Training-free Approach
Baoshun Tong, Hanjiang Lai, Yan Pan, Jian Yin; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 19921-19930
Pre-trained Vision-Language Models (VLMs) like CLIP, have demonstrated strong zero-shot generalization capabilities. Despite their effectiveness on various downstream tasks, they remain vulnerable to adversarial samples. Existing methods fine-tune VLMs to improve their performance via performing adversarial training on a certain dataset. However, this can lead to model overfitting and is not a true zero-shot scenario. In this paper, we propose a truly zero-shot and training-free approach that can significantly improve the VLM's zero-shot adversarial robustness. Specifically, we first discover that simply adding Gaussian noise greatly enhances the VLM's zero-shot performance. Then, we treat the adversarial examples with added Gaussian noise as anchors and strive to find a path in the embedding space that leads from the adversarial examples to the cleaner samples. We improve the VLMs' generalization abilities in a truly zero-shot and training-free manner compared to previous methods. Extensive experiments on 16 datasets demonstrate that our method can achieve state-of-the-art zero-shot robust performance, improving the top-1 robust accuracy by an average of 9.77%. The code will be publicly available.

Towards General Visual-Linguistic Face Forgery Detection
Ke Sun, Shen Chen, Taiping Yao, Ziyin Zhou, Jiayi Ji, Xiaoshuai Sun, Chia-Wen Lin, Rongrong Ji; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 19576-19586
Face manipulation techniques have achieved significant advances, presenting serious challenges to security and social trust. Recent works demonstrate that leveraging multimodal models can enhance the generalization and interpretability of face forgery detection. However, existing annotation approaches, whether through human labeling or direct Multimodal Large Language Model (MLLM) generation, often suffer from hallucination issues, leading to inaccurate text descriptions, especially for high-quality forgeries. To address this, we propose Face Forgery Text Generator (FFTG), a novel annotation pipeline that generates accurate text descriptions by leveraging forgery masks for initial region and type identification, followed by a comprehensive prompting strategy to guide MLLMs in reducing hallucination. We validate our approach through fine-tuning both CLIP with a three-branch training framework combining unimodal and multimodal objectives, and MLLMs with our structured annotations. Experimental results demonstrate that our method not only achieves more accurate annotations with higher region identification accuracy, but also leads to improvements in model performance across various forgery detection benchmarks.
****
Movie Weaver: Tuning-Free Multi-Concept Video Personalization with Anchored Prompts
Feng Liang, Haoyu Ma, Zecheng He, Tingbo Hou, Ji Hou, Kunpeng Li, Xiaoliang Dai, Felix Juefei-Xu, Samaneh Azadi, Animesh Sinha, Peizhao Zhang, Peter Vajda, Diana Marculescu; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 13146-13156
Video personalization, which generates customized videos using reference images, has gained significant attention.However, prior methods typically focus on single-concept personalization, limiting broader applications that require multi-concept integration.Attempts to extend these models to multiple concepts often lead to identity blending, which results in composite characters with fused attributes from multiple sources.This challenge arises due to the lack of a mechanism to link each concept with its specific reference image.We address this with anchored prompts, which embed image anchors as unique tokens within text prompts, guiding accurate referencing during generation.Additionally, we introduce concept embeddings to encode the order of reference images.Our approach, Movie Weaver, sea

mlessly weaves multiple concepts--including face, body, and animal images--into one video, allowing flexible combinations in a single model.The evaluation shows that Movie Weaver outperforms existing methods for multi-concept video personalization in identity preservation and overall quality.

LongVALE: Vision-Audio-Language-Event Benchmark Towards Time-Aware Omni-Modal Perception of Long Videos
Tiantian Geng, Jinrui Zhang, Qingni Wang, Teng Wang, Jinming Duan, Feng Zheng; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 18959-18969
Despite impressive advancements in video understanding, most efforts remain limited to coarse-grained or visual-only video tasks. However, real-world videos encompass omni-modal information (vision, audio, and speech) with a series of events forming a cohesive storyline. The lack of multi-modal video data with fine-grained event annotations and the high cost of manual labeling are major obstacles to comprehensive omni-modality video perception. To address this gap, we propose an automatic pipeline consisting of high-quality multi-modal video filtering, semantically coherent omni-modal event boundary detection, and cross-modal correlation-aware event captioning. In this way, we present LongVALE, the first-ever Vision-Audio-Language Event understanding benchmark comprising 105K omni-modal events with precise temporal boundaries and detailed relation-aware captions within 8.4K high-quality long videos. Further, we build a baseline that leverages LongVALE to enable video large language models (LLMs) for omni-modality fine-grained temporal video understanding for the first time. Extensive experiments demonstrate the effectiveness and great potential of LongVALE in advancing comprehensive multi-modal video understanding.

MVPortrait: Text-Guided Motion and Emotion Control for Multi-view Vivid Portrait Animation
Yukang Lin, Hokit Fung, Jianjin Xu, Zeping Ren, Adela S.M. Lau, Guosheng Yin, Xiu Li; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 26242-26252
Recent portrait animation methods have made significant strides in generating realistic lip synchronization. However, they often lack explicit control over head movements and facial expressions, and cannot produce videos from multiple viewpoints, resulting in less controllable and expressive animations. Moreover, text-guided portrait animation remains underexplored, despite its user-friendly nature. In this paper, we present a novel two-stage text-guided framework, MVPortrait, to generate expressive multi-view portrait animations that faithfully capture the described motion and emotion. MVPortrait is the first to introduce FLAME as an intermediate representation, effectively embedding facial movements, expressions, and view transformations within its parameter space. In the first stage, we separately train the FLAME motion and emotion diffusion models based on text input. In the second stage, we train a multi-view video generation model conditioned on a reference portrait image and multi-view FLAME rendering sequences from the first stage. Experimental results exhibit that MVPortrait outperforms existing methods in terms of motion and emotion control, as well as view consistency. Furthermore, by leveraging FLAME as a bridge, MVPortrait becomes the first controllable portrait animation framework that is compatible with text, speech, and video as driving signals.

MoEdit: On Learning Quantity Perception for Multi-object Image Editing
Yanfeng Li, Kahou Chan, Yue Sun, Chantong Lam, Tong Tong, Zitong Yu, Keren Fu, Xiaohong Liu, Tao Tan; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 2683-2693
Multi-object images are widely present in the real world, spanning various areas of daily life. Efficient and accurate editing of these images is crucial for applications such as augmented reality, advertisement design, and medical imaging. Stable Diffusion (SD) has ushered in a new era of high-quality image generation and editing. However, existing methods struggle to analyze abstract relationshi

ps between multiple objects, often yielding suboptimal performance. To address t
his, we propose MoEdit, an auxiliary-free method for multi-object image editing.
 This method enables high-quality editing of attributes in multi-object images,
such as style, object features, and background, by maintaining quantity consiste
ncy between the input and output images. To preserve the concept of quantity, we
 introduce a Quantity Attention (QTTN) module to control the editing process. Ad
ditionally, we present a Feature Compensation (FeCom) module to enhance the robu
stness of object preservation. We also employ a null-text training strategy to r
etain the guiding capability of text prompts, making them plug-and-play modules.
 This method leverages the powerful image perception and generation capabilities
 of the SD model, enabling specific concepts to be preserved and altered between
 input and output images. Experimental results demonstrate that MoEdit achieves
the state-of-the-art performance in high-quality multi-object image editing. Dat
a and codes will be available at https://github.com/Tear-kitty/MoEdit.

Seeing More with Less: Human-like Representations in Vision Models
Andrey Gizdov, Shimon Ullman, Daniel Harari; Proceedings of the Computer Vision
and Pattern Recognition Conference (CVPR), 2025, pp. 4408-4417
Large multimodal models (LMMs) typically process visual inputs with uniform reso
lution across the entire field of view, leading to inefficiencies when non-criti
cal image regions are processed as precisely as key areas. Inspired by the human
 visual system's foveated approach, we apply a sampling method to leading archit
ectures such as MDETR, BLIP2, InstructBLIP, LLaVA, and ViLT, and evaluate their
performance with variable (foveated) resolution inputs. Results show that foveat
ed sampling boosts accuracy in visual tasks like question answering and object d
etection under tight pixel budgets, improving performance by up to 2.7% on the G
QA dataset, 2.1% on SEED-Bench, and 2.0% on VQAv2 compared to uniform sampling.
Furthermore, we show that indiscriminate resolution increases yield diminishing
returns, with models achieving up to 80% of their full capability using just 3%
of the pixels, even on complex tasks. Foveated sampling prompts more human-like
processing within models, such as neuronal selectivity and globally acting self-
attention in vision transformers. This paper provides a foundational analysis of
 foveated sampling's impact on existing models, suggesting that more efficient a
rchitectural adaptations, mimicking human visual processing, are a promising res
earch venue for the community. Potential applications of our findings center low
 power minimal bandwidth devices (such as UAVs and edge devices), where compact
and efficient vision is critical.

Modeling Thousands of Human Annotators for Generalizable Text-to-Image Person Re
-identification
Jiayu Jiang, Changxing Ding, Wentao Tan, Junhong Wang, Jin Tao, Xiangmin Xu; Pro
ceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025,
 pp. 9220-9230
Text-to-image person re-identification (ReID) aims to retrieve the images of an
interested person based on textual descriptions. One main challenge for this tas
k is the high cost in manually annotating large-scale databases, which affects t
he generalization ability of ReID models. Recent works handle this problem by le
veraging Multi-modal Large Language Models (MLLMs) to describe pedestrian images
 automatically. However, the captions produced by MLLMs lack diversity in descri
ption styles. To address this issue, we propose a Human Annotator Modeling (HAM)
 approach to enable MLLMs to mimic the description styles of thousands of human
annotators. Specifically, we first extract style features from human textual des
criptions and perform clustering on them. This allows us to group textual descri
ptions with similar styles into the same cluster. Then, we employ a prompt to re
present each of these clusters and apply prompt learning to mimic the descriptio
n styles of different human annotators. Furthermore, we define a style feature s
pace and perform uniform sampling in this space to obtain more diverse clusterin
g prototypes, which further enriches the diversity of the MLLM-generated caption
s. Finally, we adopt HAM to automatically annotate a massive-scale database for
text-to-image ReID. Extensive experiments on this database demonstrate that it s

ignificantly improves the generalization ability of ReID models.

Accelerating Multimodal Large Language Models by Searching Optimal Vision Token Reduction
Shiyu Zhao, Zhenting Wang, Felix Juefei-Xu, Xide Xia, Miao Liu, Xiaofang Wang, Mingfu Liang, Ning Zhang, Dimitris N. Metaxas, Licheng Yu; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 29869-29879
Prevailing Multimodal Large Language Models (MLLMs) encode the input image(s) as vision tokens and feed them into the language backbone, similar to how Large Language Models (LLMs) process the text tokens. However, the number of vision tokens increases quadratically as the image resolutions, leading to huge computational costs.In this paper, we consider improving MLLM's efficiency from two scenarios, (I) Reducing computational cost without degrading the performance. (II) Improving the performance with given budgets. We start with our main finding that the ranking of each vision token sorted by attention scores is similar in each layer except the first layer. Based on it, we assume that the number of essential top vision tokens does not increase along layers. Accordingly, for Scenario I, we propose a greedy search algorithm (G-Search) to find the least number of vision tokens to keep at each layer from the shallow to the deep. Interestingly, G-Search is able to reach the optimal reduction strategy based on our assumption. For Scenario II, based on the reduction strategy from G-Search, we design a parametric sigmoid function (P-Sigmoid) to guide the reduction at each layer of the MLLM, whose parameters are optimized by Bayesian Optimization. Extensive experiments demonstrate that our approach can significantly accelerate those popular MLLMs, e.g. LLaVA, and InternVL2 models, by more than 2 xwithout performance drops. Our approach also far outperforms other token reduction methods when budgets are limited, achieving a better trade-off between efficiency and effectiveness.

Matrix-Free Shared Intrinsics Bundle Adjustment
Daniel Safari; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 27017-27026
Research on accelerating bundle adjustment has focused on photo collections where each image is accompanied by its own set of camera parameters. However, real-world applications overwhelmingly call for shared intrinsics bundle adjustment (SI-BA) where camera parameters are shared across multiple images. Utilizing overlooked optimization opportunities specific to SI-BA, most notably matrix-free computation, we present a solver that is eight times faster than alternatives while consuming a tenth of the memory. Additionally, we examine factors contributing to BA instability under single-precision computation and propose mitigations.

AeroGen: Enhancing Remote Sensing Object Detection with Diffusion-Driven Data Generation
Datao Tang, Xiangyong Cao, Xuan Wu, Jialin Li, Jing Yao, Xueru Bai, Dongsheng Jiang, Yin Li, Deyu Meng; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 3614-3624
Remote sensing image object detection (RSIOD) aims to identify and locate specific objects within satellite or aerial imagery. However, there is a scarcity of labeled data in current RSIOD datasets, which significantly limits the performance of current detection algorithms. Although existing techniques, e.g., data augmentation and semi-supervised learning, can mitigate this scarcity issue to some extent, they are heavily dependent on high-quality labeled data and perform worse in rare object classes. To address this issue, this paper proposes a layout-controllable diffusion generative model (i.e. AeroGen) tailored for RSIOD. To our knowledge, AeroGen is the first model to simultaneously support horizontal and rotated bounding box condition generation, thus enabling the generation of high-quality synthetic images that meet specific layout and object category requirements. Additionally, we propose an end-to-end data augmentation framework that integrates a diversity-conditioned generator and a filtering mechanism to enhance both the diversity and quality of generated data. Experimental results demonstrate that the synthetic data produced by our method are of high quality and diversit

y. Furthermore, the synthetic RSIOD data can significantly improve the detection performance of existing RSIOD models, i.e., the mAP metrics on DIOR, DIOR-R, and HRSC datasets are improved by 3.7%, 4.3%, and 2.43%, respectively.
****

Tra-MoE: Learning Trajectory Prediction Model from Multiple Domains for Adaptive Policy Conditioning
Jiange Yang, Haoyi Zhu, Yating Wang, Gangshan Wu, Tong He, Limin Wang; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 6960-6970
Learning from multiple domains is a primary factor that influences the generalization of a single unified robot system. In this paper, we aim to learn the trajectory prediction model by using broad out-of-domain data to improve its performance and generalization ability. Trajectory model is designed to predict any-point trajectories in the current frame given an instruction and can provide detailed control guidance for robotic policy learning. To handle the diverse out-of-domain data distribution, we propose a sparsely-gated MoE (Top-1 gating strategy) architecture for trajectory model, coined as Tra-MoE. The sparse activation design enables good balance between parameter cooperation and specialization, effectively benefiting from large-scale out-of-domain data while maintaining constant FLOPs per token. In addition, we further introduce an adaptive policy conditioning technique by learning 2D mask representations for predicted trajectories, which is explicitly aligned with image observations to guide action prediction more flexibly. We perform extensive experiments on both simulation and real-world scenarios to verify the effectiveness of Tra-MoE and adaptive policy conditioning technique. We also conduct a comprehensive empirical study to train Tra-MoE, demonstrating that our Tra-MoE consistently exhibits superior performance compared to the dense baseline model, even when the latter is scaled to match Tra-MoE's parameter count.

Mitigating Hallucinations in Large Vision-Language Models via DPO: On-Policy Data Hold the Key
Zhihe Yang, Xufang Luo, Dongqi Han, Yunjian Xu, Dongsheng Li; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 10610-10620
Hallucination remains a major challenge for Large Vision-Language Models (LVLMs). Direct Preference Optimization (DPO) has gained increasing attention as a simple solution to hallucination issues. It directly learns from constructed preference pairs that reflect the severity of hallucinations in responses to the same prompt and image. Nonetheless, different data construction methods in existing works bring notable performance variations. We identify a crucial factor here: outcomes are largely contingent on whether the constructed data aligns on-policy w.r.t the initial (reference) policy of DPO. Theoretical analysis suggests that learning from off-policy data is impeded by the presence of KL-divergence between the updated policy and the reference policy. From the perspective of dataset distribution, we systematically summarize the inherent flaws in existing algorithms that employ DPO to address hallucination issues. To alleviate the problems, we propose On-Policy Alignment (OPA)-DPO framework, which uniquely leverages expert feedback to correct hallucinated responses and aligns both the original and expert-revised responses in an on-policy manner. Notably, with only 4.8k data, OPA-DPO achieves an additional reduction in the hallucination rate of LLaVA-1.5-7B: 13.26% on the AMBER benchmark and 5.39% on the Object-Hal benchmark, compared to the previous SOTA algorithm trained with 16k samples.

Style Quantization for Data-Efficient GAN Training
Jian Wang, Xin Lan, Jizhe Zhou, Yuxin Tian, Jiancheng Lv; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 7696-7706
Under limited data setting, GANs often struggle to navigate and effectively exploit the input latent space. Consequently, images generated from adjacent variables in a sparse input latent space may exhibit significant discrepancies in realism, leading to suboptimal consistency regularization (CR) outcomes. To address t

his, we propose SQ-GAN, a novel approach that enhances CR by introducing a style space quantization scheme. This method transforms the sparse, continuous input latent space into a compact, structured discrete proxy space, allowing each element to correspond to a specific data point, thereby improving CR performance. Instead of direct quantization, we first map the input latent variables into a less entangled "style" space and apply quantization using a learnable codebook. This enables each quantized code to control distinct factors of variation. Additionally, we optimize the optimal transport distance to align the codebook codes with features extracted from the training data by a foundation model, embedding external knowledge into the codebook and establishing a semantically rich vocabulary that properly describes the training dataset. Extensive experiments demonstrate significant improvements in both discriminator robustness and generation quality with our method.

Localizing Events in Videos with Multimodal Queries

Gengyuan Zhang, Mang Ling Ada Fok, Jialu Ma, Yan Xia, Daniel Cremers, Philip Torr, Volker Tresp, Jindong Gu; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 3339-3351

Localizing events in videos based on semantic queries is a pivotal task in video understanding research and user-oriented applications like video search. Yet, current research predominantly relies on natural language queries (NLQs), overlooking the potential of using multimodal queries (MQs) that incorporate images to flexibly represent semantic queries, particularly when it is difficult to express non-verbal or unfamiliar concepts in words. To bridge this gap, we introduce ICQ, a new benchmark designed for localizing events in videos with MQs, alongside an evaluation dataset ICQ-Highlight. To adapt and reevaluate existing video localization models for this new task, we propose 3 Multimodal Query Adaptation methods and a novel Surrogate Fine-tuning strategy, serving as strong baseline methods. ICQ systematically benchmarks 12 state-of-the-art backbone models, spanning from specialized video localization models to Video Large Language Models. Our extensive experiments highlight the high potential of using MQs in real-world applications. We believe this is a first step toward video event localization with MQs.

PhysVLM: Enabling Visual Language Models to Understand Robotic Physical Reachability

Weijie Zhou, Manli Tao, Chaoyang Zhao, Haiyun Guo, Honghui Dong, Ming Tang, Jinqiao Wang; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 6940-6949

Understanding the environment and a robot's physical reachability is crucial for task execution. While state-of-the-art vision-language models (VLMs) excel in environmental perception, they often generate inaccurate or impractical responses in embodied visual reasoning tasks due to a lack of understanding of robotic physical reachability. To address this issue, we propose a unified representation of physical reachability across diverse robots, i.e., Space-Physical Reachability Map (S-P Map), and PhysVLM, a vision-language model that integrates this reachability information into visual reasoning. Specifically, the S-P Map abstracts a robot's physical reachability into a generalized spatial representation, independent of specific robot configurations, allowing the model to focus on reachability features rather than robot-specific parameters. Subsequently, PhysVLM extends traditional VLM architectures by incorporating an additional feature encoder to process the S-P Map, enabling the model to reason about physical reachability without compromising its general vision-language capabilities. To train and evaluate PhysVLM, we constructed a large-scale multi-robot dataset, Phys100K, and a challenging benchmark, EQA-phys, which includes tasks for six different robots in both simulated and real-world environments. Experimental results demonstrate that PhysVLM outperforms existing models, achieving a 14% improvement over GPT-4o on EQA-phys and surpassing advanced embodied VLMs such as RoboMamba and SpatialVLM on the RoboVQA-val and OpenEQA benchmarks. Additionally, the S-P Map shows strong compatibility with various VLMs, and its integration into GPT-4o-mini yiel

ds a 7.1% performance improvement.
****
CleanDIFT: Diffusion Features without Noise
Nick Stracke, Stefan Andreas Baumann, Kolja Bauer, Frank Fundel, Björn Ommer; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 117-127
Internal features from large-scale pre-trained diffusion models have recently been established as powerful semantic descriptors for a wide range of downstream tasks. Works that use these features generally need to add noise to images before passing them through the model to obtain the semantic features, as the models do not offer the most useful features when given images with little to no noise. We show that this noise has a critical impact on the usefulness of these features that cannot be remedied by ensembling with different random noises. We address this issue by introducing a lightweight, unsupervised fine-tuning method that enables diffusion backbones to provide high-quality, noise-free semantic features. We show that these features readily outperform previous diffusion features by a wide margin in a wide variety of extraction setups and downstream tasks, offering better performance than even ensemble-based methods at a fraction of the cost.
****
Simpler Diffusion: 1.5 FID on ImageNet512 with Pixel-space Diffusion
Emiel Hoogeboom, Thomas Mensink, Jonathan Heek, Kay Lamerigts, Ruiqi Gao, Tim Salimans; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 18062-18071
Latent diffusion models have become the popular choice for scaling up diffusion models for high resolution image synthesis. Compared to pixel-space models that are trained end-to-end, latent models are perceived to be more efficient and to produce higher image quality at high resolution. Here we challenge these notions, and show that pixel-space models can be very competitive to latent models both in quality and efficiency, achieving 1.5 FID on ImageNet512 and new SOTA results on ImageNet128, ImageNet256 and Kinetics600. We present a simple recipe for scaling end-to-end pixel-space diffusion models to high resolutions. 1: Use the sigmoid loss-weighting (Kingma & Gao, 2023) with our prescribed hyper-parameters. 2: Use our simplified memory-efficient architecture with fewer skip-connections. 3: Scale the model to favor processing the image at a high resolution with fewer parameters, rather than using more parameters at a lower resolution. Combining these with guidance intervals, we obtain a family of pixel-space diffusion models we call Simpler Diffusion (SiD2).
****
Uncertainty-Instructed Structure Injection for Generalizable HD Map Construction
Xiaolu Liu, Ruizi Yang, Song Wang, Wentong Li, Junbo Chen, Jianke Zhu; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 22359-22368
Reliable high-definition (HD) map construction is crucial for the driving safety of autonomous vehicles. While recent studies demonstrate improved performance, their generalization capability across unfamiliar driving scenes remains unexplored. To tackle this issue, we propose UIGenMap, an uncertainty-instructed structure injection approach for generalizable HD map vectorization, which concerns the uncertainty resampling in statistical distribution and employs explicit instance features to reduce the excessive reliance on training data. Specifically, we introduce the perspective-view (PV) detection branch to obtain explicit structural features, in which the uncertainty-aware decoder is designed to dynamically sample probability distributions considering the difference in scenes. With probabilistic embedding and selection, UI2DPrompt is proposed to construct PV learnable prompts. These PV prompts are integrated into the map decoder by designed hybrid injection to compensate for neglected instance structures. To ensure real-time inference, a lightweight Mimic Query Distillation is designed to learn from PV prompts, which can serve as an efficient alternative to the flow of PV branches. Extensive experiments on challenging geographically disjoint (geo-based) data splits demonstrate that our UIGenMap achieves superior performance, with +5.7 m

AP improvement on nuScenes dataset. Source code is available at \href https://github.com/xiaolul2/UIGenMap https://github.com/xiaolul2/UIGenMap .

STING-BEE: Towards Vision-Language Model for Real-World X-ray Baggage Security Inspection
Divya Velayudhan, Abdelfatah Ahmed, Mohamad Alansari, Neha Gour, Abderaouf Behouch, Taimur Hassan, Syed Talal Wasim, Nabil Maalej, Muzammal Naseer, Juergen Gall, Mohammed Bennamoun, Ernesto Damiani, Naoufel Werghi; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 20767-20777
Advancements in Computer-Aided Screening (CAS) systems are essential for improving the detection of security threats in X-ray baggage scans. However, current datasets are limited in representing real-world, sophisticated threats and concealment tactics, and existing approaches are constrained by a closed-set paradigm with predefined labels. To address these challenges, we introduce STCray, the first multimodal X-ray baggage security dataset, comprising 46,642 image-caption paired scans across 21 threat categories, generated using an X-ray scanner for airport security. STCray is meticulously developed with our specialized protocol that ensures domain-aware, coherent captions, that lead to the multi-modal instruction following data in X-ray baggage security. This allows us to train a domain-aware visual AI assistant named STING-BEE that supports a range of vision-language tasks, including scene comprehension, referring threat localization, visual grounding, and visual question answering (VQA), establishing novel baselines for multi-modal learning in X-ray baggage security. Further, STING-BEE shows state-of-the-art generalization in cross-domain settings. Code, data, and models are available at https://divs1159.github.io/STING-BEE/.
****
Not All Parameters Matter: Masking Diffusion Models for Enhancing Generation Ability
Lei Wang, Senmao Li, Fei Yang, Jianye Wang, Ziheng Zhang, Yuhan Liu, Yaxing Wang, Jian Yang; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 12880-12890
The diffusion models, in early stages focus on constructing basic image structures, while the refined details, including local features and textures, are generated in later stages. Thus the same network layers are forced to learn both structural and textural information simultaneously, significantly differing from the traditional deep learning architectures (e.g., ResNet or GANs) which captures or generates the image semantic information at different layers. This difference inspires us to explore the time-wise diffusion models. We initially investigate the key contributions of the U-Net parameters to the denoising process and identify that properly zeroing out certain parameters (including large parameters) contributes to denoising, substantially improving the generation quality on the fly. Capitalizing on this discovery, we propose a simple yet effective method--termed "MaskUNet"-- that enhances generation quality with negligible parameter numbers. Our method fully leverages timestep- and sample-dependent effective U-Net parameters. To optimize MaskUNet, we offer two fine-tuning strategies: a training-based approach and a training-free approach, including tailored networks and optimization functions. In zero-shot inference on the COCO dataset, MaskUNet achieves the best FID score and further demonstrates its effectiveness in downstream task evaluations. Project page: https://gudaochangsheng.github.io/MaskUnet-Page/

MAD: Memory-Augmented Detection of 3D Objects
Ben Agro, Sergio Casas, Patrick Wang, Thomas Gilles, Raquel Urtasun; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 1449-1460
To perceive, humans use memory to fill in gaps caused by our limited visibility, whether due to occlusion or our narrow field of view. However, most 3D object detectors are limited to using sensor evidence from a short temporal window (0.1s-0.3s). In this work, we present a simple and effective add-on for enhancing any existing 3D object detector with long-term memory regardless of its sensor moda

lity (e.g., LiDAR, camera) and network architecture. We propose a model to effec tively align and fuse object proposals from a detector with object proposals fro m a memory bank of past predictions, exploiting trajectory forecasts to align pr oposals across time. We propose a novel schedule to train our model on temporal data that balances data diversity and the gap between training and inference. By applying our method to existing LiDAR and camera-based detectors on the Waymo O pen Dataset (WOD) and Argoverse 2 Sensor (AV2) dataset, we demonstrate significa nt improvements in detection performance (+2.5 to +7.6 AP points). Our method at tains the best performance on the WOD 3D detection leaderboard among online meth ods (excluding ensembles or test-time augmentation).

Doppelgangers and Adversarial Vulnerability
George Kamberov; Proceedings of the Computer Vision and Pattern Recognition Conf erence (CVPR), 2025, pp. 10244-10254
Many machine learning (ML) classifiers are claimed to outperform humans, but the y still make mistakes that humans do not. The most notorious examples of such mi stakes are adversarial visual metamers. This paper aims to define and investigat e the phenomenon of adversarial Doppelgangers (AD), which includes adversarial v isual metamers, and to compare the performance and robustness of ML classifiers to human performance.We find that AD are inputs that are close to each other wit h respect to a perceptual metric defined in this paper, and show that AD are qua litatively different from the usual adversarial examples. The vast majority of c lassifiers are vulnerable to AD and robustness-accuracy trade-offs may not impro ve them. Some classification problems may not admit any AD robust classifiers be cause the underlying classes are ambiguous. We provide criteria that can be use d to determine whether a classification problem is well defined or not; describe of an AD robust classifiers' structure and attributes; introduce and explore th e notions of conceptual entropy and regions of conceptual ambiguity for classifi ers that are vulnerable to AD attacks, along with methods to bound the AD foolin g rate of an attack. We define the notion of classifiers that exhibit hyper-sens itive behavior, that is, classifiers whose only mistakes are adversarial Doppelg angers. Improving the AD robustness of hyper-sensitive classifiers proving accur acy. We identify conditions guaranteeing that all classifiers with sufficiently high accuracy are hyper-sensitive.

Complexity Experts are Task-Discriminative Learners for Any Image Restoration
Eduard Zamfir, Zongwei Wu, Nancy Mehta, Yuedong Tan, Danda Pani Paudel, Yulun Zh ang, Radu Timofte; Proceedings of the Computer Vision and Pattern Recognition Co nference (CVPR), 2025, pp. 12753-12763
Recent advancements in all-in-one image restoration models have revolutionized t he ability to address diverse degradations through a unified framework. However, parameters tied to specific tasks often remain inactive for other tasks, making mixture-of-experts (MoE) architectures a natural extension. Despite this, MoEs often show inconsistent behavior, with some experts unexpectedly generalizing ac ross tasks while others struggle within their intended scope. This hinders lever aging MoEs' computational benefits by bypassing irrelevant experts during infere nce.We attribute this undesired behavior to the uniform and rigid architecture o f traditional MoEs. To address this, we introduce "complexity experts" -- flexib le expert blocks with varying computational complexity and receptive fields. A k ey challenge is assigning tasks to each expert, as degradation complexity is unk nown in advance. Thus, we execute tasks with a simple bias toward lower complexi ty.To our surprise, this preference effectively drives task-specific allocation, assigning tasks to experts with the appropriate complexity. Extensive experimen ts validate our approach, demonstrating the ability to bypass irrelevant experts during inference while maintaining superior performance. The proposed MoCE-IR m odel outperforms state-of-the-art methods, affirming its efficiency and practica l applicability. The source code and models are publicly available at \href http s://eduardzamfir.github.io/moceir/ \texttt eduardzamfir.github.io/MoCE-IR/

Generative Omnimatte: Learning to Decompose Video into Layers

Yao-Chih Lee, Erika Lu, Sarah Rumbley, Michal Geyer, Jia-Bin Huang, Tali Dekel, Forrester Cole; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 12522-12532

Given a video and a set of input object masks, an omnimatte method aims to decompose the video into semantically meaningful layers containing individual objects along with their associated effects, such as shadows and reflections.Existing omnimatte methods assume a static background or accurate pose and depth estimation and produce poor decompositions when these assumptions are violated. Furthermore, due to the lack of generative prior on natural videos, existing methods cannot complete dynamic occluded regions.We present a novel generative layered video decomposition framework to address the omnimatte problem. Our method does not assume a stationary scene or require camera pose or depth information and produces clean, complete layers, including convincing completions of occluded dynamic regions. Our core idea is to train a video diffusion model to identify and remove scene effects caused by a specific object. We show that this model can be finetuned from an existing video inpainting model with a small, carefully curated dataset, anddemonstrate high-quality decompositions and editing results for a wide range of casually captured videos containing soft shadows, glossy reflections, splashing water, and more.

5%>100%: Breaking Performance Shackles of Full Fine-Tuning on Visual Recognition Tasks

Dongshuo Yin, Leiyi Hu, Bin Li, Youqun Zhang, Xue Yang; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 20071-20081

Pre-training & fine-tuning can enhance the transferring efficiency and performance in visual tasks. Recent delta-tuning methods provide more options for visual classification tasks. Despite their success, existing visual delta-tuning art fails to exceed the upper limit of full fine-tuning on challenging tasks. To find a competitive alternative to full fine-tuning, we propose the Multi-cognitive Visual Adapter (Mona) tuning, a novel adapter-based tuning method. First, we introduce multiple vision-friendly filters into the adapter to enhance its ability for processing visual signals, while previous methods mainly rely on language-friendly linear filters. Second, we add the scaled layernorm in the adapter to regulate the distribution of input features for visual filters. To fully demonstrate the practicality and generality of Mona, we conduct experiments on representative visual tasks, including instance segmentation on COCO, semantic segmentation on ADE20K, object detection on Pascal VOC, oriented object detection on DOTA/STAR, and image classification on three common datasets. Exciting results illustrate that Mona surpasses full fine-tuning on all these tasks by tuning less than 5% params of the backbone, and is the only delta-tuning method outperforming full fine-tuning on all tasks. For example, Mona achieves 1% performance gain on the COCO compared to full fine-tuning. Comprehensive results suggest that Mona-tuning is more suitable for retaining and utilizing the capabilities of pre-trained models than full fine-tuning. The code is publicly available on https://github.com/Leiyi-Hu/mona.

Precise Event Spotting in Sports Videos: Solving Long-Range Dependency and Class Imbalance

Sanchayan Santra, Vishal Chudasama, Pankaj Wasnik, Vineeth N Balasubramanian; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 3163-3172

Precise Event Spotting (PES) aims to identify events and their class from long, untrimmed videos, particularly in sports. The main objective of PES is to detect the event at the exact moment it occurs. Existing methods mainly rely on features from a large pre-trained network, which may not be ideal for the task. Furthermore, these methods overlook the issue of imbalanced event class distribution present in the data, negatively impacting performance in challenging scenarios. This paper demonstrates that an appropriately designed network, trained end-to-end, can outperform state-of-the-art (SOTA) methods. Particularly, we propose a network with a convolutional spatial-temporal feature extractor enhanced with our

proposed Adaptive Spatio-Temporal Refinement Module (ASTRM) and a long-range tem
poral module. The ASTRM enhances the features with spatio-temporal information.
Meanwhile, the long-range temporal module helps extract global context from the
data by modeling long-range dependencies. To address the class imbalance issue,
we introduce the Soft Instance Contrastive (Soft-IC) loss that promotes feature
compactness and class separation. Extensive experiments show that the proposed m
ethod is efficient and outperforms the SOTA methods, specifically in more challe
nging settings.

Real-IAD D3: A Real-World 2D/Pseudo-3D/3D Dataset for Industrial Anomaly Detecti
on

Wenbing Zhu, Lidong Wang, Ziqing Zhou, Chengjie Wang, Yurui Pan, Ruoyi Zhang, Zh
uhao Chen, Linjie Cheng, Bin-Bin Gao, Jiangning Zhang, Zhenye Gan, Yuxie Wang, Y
ulong Chen, Shuguang Qian, Mingmin Chi, Bo Peng, Lizhuang Ma; Proceedings of the
 Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 15214-1522
3

The increasing complexity of industrial anomaly detection (IAD) has positioned m
ultimodal detection methods as a focal area of machine vision research. However,
 dedicated multimodal datasets specifically tailored for IAD remain limited. Pio
neering datasets like MVTec 3D have laid essential groundwork in multimodal IAD
by incorporating RGB+3D data, but still face challenges in bridging the gap with
 real industrial environments due to limitations in scale and resolution. To add
ress these challenges, we introduce Real-IAD D3, a high-precision multimodal dat
aset that uniquely incorporates an additional pseudo-3D modality generated throu
gh photometric stereo, alongside high-resolution RGB images and micrometer-level
 3D point clouds. Real-IAD D3 comprises industrial components with smaller dimen
sions and finer defects than existing datasets, offering diverse anomalies acros
s modalities and presenting a more challenging benchmark for multimodal IAD rese
arch. With 20 product categories, the dataset offers significantly greater scale
 and diversity compared to current alternatives. Additionally, we introduce an e
ffective approach that integrates RGB, point cloud, and pseudo-3D depth informat
ion to leverage the complementary strengths of each modality, enhancing detectio
n performance. Our experiments highlight the importance of these modalities in b
oosting detection robustness and overall IAD performance. The Real-IAD D3 datase
t will be publicly available to advance research and innovation in multimodal IA
D.The dataset and code are publicly accessible for research purposes at https://
realiad4ad.github.io/Real-IAD_D3.

Steady Progress Beats Stagnation: Mutual Aid of Foundation and Conventional Mode
ls in Mixed Domain Semi-Supervised Medical Image Segmentation

Qinghe Ma, Jian Zhang, Zekun Li, Lei Qi, Qian Yu, Yinghuan Shi; Proceedings of t
he Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 5175-518
5

Large pretrained visual foundation models exhibit impressive general capabilitie
s. However, the extensive prior knowledge inherent in these models can sometimes
 be a double-edged sword when adapting them to downstream tasks in specific doma
ins.In the context of semi-supervised medical image segmentation with domain shi
ft, foundation models like MedSAM tend to make overconfident predictions, some o
f which are incorrect. The error accumulation hinders the effective utilization
of unlabeled data and limits further improvements.In this paper, we introduce a
Synergistic training framework for Foundation and Conventional models (SynFoC) t
o address the issue. We observe that a conventional model trained from scratch h
as the ability to correct the high-confidence mispredictions of the foundation m
odel, while the foundation model can supervise it with high-quality pseudo-label
s in the early training stages. Furthermore, to enhance the collaborative traini
ng effectiveness of both models and promote reliable convergence towards optimiz
ation, the consensus-divergence consistency regularization is proposed. We demon
strate the superiority of our method across four public multi-domain datasets. I
n particular, our method improves the Dice score by 10.31% on the Prostate datas
et. Our code is available in the supplementary material.

ATP: Adaptive Threshold Pruning for Efficient Data Encoding in Quantum Neural Networks
Mohamed Afane, Gabrielle Ebbrecht, Ying Wang, Juntao Chen, Junaid Farooq; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 20427-20436
Quantum Neural Networks (QNNs) offer promising capabilities for complex data tasks, but are often constrained by limited qubit resources and high entanglement, which can hinder scalability and efficiency. In this paper, we introduce Adaptive Threshold Pruning (ATP), an encoding method that reduces entanglement and optimizes data complexity for efficient computations in QNNs. ATP dynamically prunes non-essential features in the data based on adaptive thresholds, effectively reducing quantum circuit requirements while preserving high performance. Extensive experiments across multiple datasets demonstrate that ATP reduces entanglement entropy and improves adversarial robustness when combined with adversarial training methods like FGSM. Our results highlight ATP's ability to balance computational efficiency and model resilience, achieving significant performance improvements with fewer resources, which will help make QNNs more feasible in practical, resource-constrained settings.

Color Alignment in Diffusion
Ka Chun Shum, Binh-Son Hua, Duc Thanh Nguyen, Sai-Kit Yeung; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 28446-28455
Diffusion models have shown great promise in synthesizing visually appealing images. However, it remains challenging to condition the synthesis at a fine-grained level, for instance, synthesizing image pixels following some generic color pattern. Existing image synthesis methods often produce contents that fall outside the desired pixel conditions. To address this, we introduce a novel color alignment algorithm that confines the generative process in diffusion models within a given color pattern. Specifically, we project diffusion terms, either imagery samples or latent representations, into a conditional color space to align with the input color distribution. This strategy simplifies the prediction in diffusion models within a color manifold while still allowing plausible structures in generated contents, thus enabling the generation of diverse contents that comply with the target color pattern. Experimental results demonstrate our state-of-the-art performance in conditioning and controlling of color pixels, while maintaining on-par generation quality and diversity in comparison with regular diffusion models.

LLAVIDAL: A Large LAnguage VIsion Model for Daily Activities of Living
Dominick Reilly, Rajatsubhra Chakraborty, Arkaprava Sinha, Manish Kumar Govind, Pu Wang, Francois Bremond, Le Xue, Srijan Das; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 24297-24308
Current Large Language Vision Models (LLVMs) trained on web videos perform well in general video understanding but struggle with fine-grained details, complex human-object interactions (HOI), and view-invariant representation learning essential for Activities of Daily Living (ADL). This limitation stems from a lack of specialized ADL video instruction-tuning datasets and insufficient modality integration to capture discriminative action representations. To address this, we propose a semi-automated framework for curating ADL datasets, creating ADL-X, a multi-view, multi-modal RGBS instruction-tuning dataset. Additionally, we introduce LLAVIDAL, an LLVM integrating videos, 3D skeletons, and HOIs to model ADL's complex spatiotemporal relationships. For training LLAVIDAL, a simple joint alignment of all modalities yields suboptimal results; thus, we propose a Multimodal Progressive (MMPro) training strategy, incorporating modalities in stages following a curriculum. We also establish ADL MCQ and video description benchmarks to assess LLVM performance in ADL tasks. Trained on ADL-X, LLAVIDAL achieves state-of-the-art performance across ADL benchmarks. Code and data will be made publicly available at https://adl-x.github.io/.

Language-Guided Salient Object Ranking
Fang Liu, Yuhao Liu, Ke Xu, Shuquan Ye, Gerhard Petrus Hancke, Rynson W. H. Lau; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 29803-29813
Salient Object Ranking (SOR) aims to study human attention shifts across different objects in the scene. It is a challenging task, as it requires comprehension of the relations among the salient objects in the scene. However, existing works often overlook such relations or model them implicitly. In this work, we observe that when Large Vision-Language Models (LVLMs) describe a scene, they usually focus on the most salient object first, and then discuss the relations as they move on to the next (less salient) one. Based on this observation, we propose a novel Language-Guided Salient Object Ranking approach (named LG-SOR), which utilizes the internal knowledge within the LVLM-generated language descriptions, i.e., semantic relation cues and the implicit entity order cues, to facilitate saliency ranking. Specifically, we first propose a novel Text-Guided Visual Modulation (TGVM) module to incorporate semantic information in the description for saliency ranking. TGVM controls the flow of linguistic information to the visual features, suppresses noisy background image features, and enables propagation of useful textual features. We then propose a novel Text-Aware Visual Reasoning (TAVR) module to enhance model reasoning in object ranking, by explicitly learning a multimodal graph based on the entity and relation cues derived from the description. Extensive experiments demonstrate superior performances of our model on two SOR benchmarks.

Decoupled Motion Expression Video Segmentation
Hao Fang, Runmin Cong, Xiankai Lu, Xiaofei Zhou, Sam Kwong, Wei Zhang; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 13821-13831
Motion expression video segmentation aims to segment objects based on input motion descriptions. Compared with traditional referring video object segmentation, it focuses on motion and multi-object expressions and is more challenging. Previous works achieved it by simply injecting text information into the video instance segmentation (VIS) model. However, this requires retraining the entire model and optimization is difficult. In this work, we propose DMVS, a simple framework constructed on the existing query-based VIS model, emphasizing decoupling the task into video instance segmentation and motion expression understanding. Firstly, we use a frozen video instance segmenter to extract object-specific contexts and convert them into frame-level and video-level queries. Secondly, we interact two levels of queries with static and motion cues, respectively, to further encode visually enhanced motion expressions. Furthermore, we propose a novel query initialization strategy that uses video queries guided by classification priors to initialize motion queries, greatly reducing the difficulty of optimization. Without bells and whistles, DMVS achieves state-of-the-art performance on the MeViS dataset at a lower training cost. Extensive experiments verify the effectiveness and efficiency of our framework.

K-LoRA: Unlocking Training-Free Fusion of Any Subject and Style LoRAs
Ziheng Ouyang, Zhen Li, Qibin Hou; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 13041-13050
Recent studies have explored combining different LoRAs to jointly generate learned style and content. However, existing methods either fail to effectively preserve both the original subject and style simultaneously or require additional training. In this paper, we argue that the intrinsic properties of LoRA can effectively guide diffusion models in merging learned subject and style. Building on this insight, we propose K-LoRA, a simple yet effective training-free LoRA fusion approach. In each attention layer, K-LoRA compares the Top-K elements in each LoRA to be fused, determining which LoRA to select for optimal fusion. This selection mechanism ensures that the most representative features of both subject and style are retained during the fusion process, effectively balancing their contributions. Experimental results demonstrate that the proposed method effectively i

ntegrates the subject and style information learned by the original LoRAs, outperforming state-of-the-art training-based approaches in both qualitative and quantitative results.

Towards More General Video-based Deepfake Detection through Facial Component Guided Adaptation for Foundation Model
Yue-Hua Han, Tai-Ming Huang, Kai-Lung Hua, Jun-Cheng Chen; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 22995-23005
The current deep generative models have enabled the creation of synthetic facial images with remarkable photorealism, raising significant societal concerns over their potential misuse. Despite rapid advancements in the field of deepfake detection, developing an efficient and effective approach for the generalized deepfake detection of unseen forgery samples remains challenging. To address this challenge, we leverage the rich semantic priors of foundation models and propose a novel side-network-based decoder that extracts spatial and temporal cues using the CLIP image encoder for generalized video-based Deepfake detection. Additionally, we introduce Facial Component Guidance (FCG) to enhance spatial learning generalizability by encouraging the model to focus on key facial regions. By leveraging the generic features of a vision-language foundation model, our approach demonstrates promising generalizability on challenging Deepfake datasets while also exhibiting superiority in training data efficiency, parameter efficiency, and model robustness. The source code is available at: https://github.com/aiiu-lab/DFD-FCG.

WF-VAE: Enhancing Video VAE by Wavelet-Driven Energy Flow for Latent Video Diffusion Model
Zongjian Li, Bin Lin, Yang Ye, Liuhan Chen, Xinhua Cheng, Shenghai Yuan, Li Yuan ; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 17778-17788
Video Variational Autoencoder (VAE) encodes videos into a low-dimensional latent space, becoming a key component of most Latent Video Diffusion Models (LVDMs) to reduce model training costs. However, as the resolution and duration of generated videos increase, the encoding cost of Video VAEs becomes a limiting bottleneck in training LVDMs. Moreover, the block-wise inference method adopted by most LVDMs can lead to discontinuities of latent space when processing long-duration videos. The key to addressing the computational bottleneck lies in decomposing videos into distinct components and efficiently encoding the critical information. Wavelet transform can decompose videos into multiple frequency-domain components and improve the efficiency significantly, we thus propose Wavelet Flow VAE (WF-VAE), an autoencoder that leverages multi-level wavelet transform to facilitate low-frequency energy flow into latent representation. Furthermore, we introduce a method called Causal Cache, which maintains the integrity of latent space during block-wise inference. Compared to state-of-the-art video VAEs, WF-VAE demonstrates superior performance in both PSNR and LPIPS metrics, achieving 2x higher throughput and 4x lower memory consumption while maintaining competitive reconstruction quality. Our code and models are available at https://github.com/PKU-YuanGroup/WF-VAE.

SP3D: Boosting Sparsely-Supervised 3D Object Detection via Accurate Cross-Modal Semantic Prompts
Shijia Zhao, Qiming Xia, Xusheng Guo, Pufan Zou, Maoji Zheng, Hai Wu, Chenglu Wen, Cheng Wang; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 29374-29384
Recently, sparsely-supervised 3D object detection has gained great attention, achieving performance close to fully-supervised 3D detectors while requiring only a few annotated instances. Nevertheless, these methods suffer challenges when accurate labels are extremely absent. In this paper, we propose a boosting strategy, termed SP3D, explicitly utilizing the cross-modal semantic prompts generated from Large Multimodal Models (LMMs) to boost the 3D detector with robust feature discrimination capability under sparse annotation settings. Specifically, we fi

rst develop a Confident Points Semantic Transfer (CPST) module that generates ac
curate cross-modal semantic prompts through boundary-constrained center cluster
selection. Based on these accurate semantic prompts, which we treat as seed poin
ts, we introduce a Dynamic Cluster Pseudo-label Generation (DCPG) module to yiel
d pseudo-supervision signals from the geometry shape of multi-scale neighbor poi
nts. Additionally, we design a Distribution Shape score (DS score) that chooses
high-quality supervision signals for the initial training of the 3D detector. Ex
periments on the KITTI dataset and Waymo Open Dataset (WOD) have validated that
SP3D can enhance the performance of sparsely supervised detectors by a large mar
gin under meager labeling conditions. Moreover, we verified SP3D in the zero-sho
t setting, where its performance exceeded that of the state-of-the-art methods.
The code is available at https://github.com/xmuqimingxia/SP3D.

VoCo-LLaMA: Towards Vision Compression with Large Language Models
Xubing Ye, Yukang Gan, Xiaoke Huang, Yixiao Ge, Yansong Tang; Proceedings of the
 Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 29836-2984
6
Vision-Language Models (VLMs) have achieved remarkable success in various multi-
modal tasks, but they are often bottlenecked by the limited context window and h
igh computational cost of processing high-resolution image inputs and videos. Vi
sion compression can alleviate this problem by reducing the vision token count.
Previous approaches compress vision tokens with external modules and force LLMs
to understand the compressed ones, leading to visual information loss. However,
the LLMs' understanding paradigm of vision tokens is not fully utilised in the c
ompression learning process. We propose VoCo-LLaMA, the first approach to compre
ss vision tokens using LLMs. By introducing Vision Compression tokens during the
 vision instruction tuning phase and leveraging attention distillation, our meth
od distill how LLMs comprehend vision tokens into their processing of VoCo token
s. VoCo-LLaMA facilitates effective vision compression and improves the computat
ional efficiency during the inference stage. Specifically, our method can achiev
e a 576x compression rate while maintaining 83.7% performance. Furthermore, thro
ugh continuous training using time-series compressed token sequences of video fr
ames, VoCo-LLaMA demonstrates the ability to understand temporal correlations, o
utperforming previous methods on popular video question-answering benchmarks. Ou
r approach presents a promising way to unlock the full potential of VLMs' contex
tual window, enabling more scalable multi-modal applications. The project page c
an be accessed via https://yxxxb.github.io/VoCo-LLaMA-page.

StreamingT2V: Consistent, Dynamic, and Extendable Long Video Generation from Tex
t
Roberto Henschel, Levon Khachatryan, Hayk Poghosyan, Daniil Hayrapetyan, Vahram
Tadevosyan, Zhangyang Wang, Shant Navasardyan, Humphrey Shi; Proceedings of the
Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 2568-2577

Text-to-video diffusion models enable the generation of high-quality videos that follow text instructions, simplifying the process of producing diverse and individual content. Current methods excel in generating short videos (up to 16s), but produce hard-cuts when naively extended to long video synthesis. To overcome these limitations, we present StreamingT2V, an autoregressive method that generates long videos of up to 2 minutes or longer with seamless transitions. The key components are: (i) a short-term memory block called conditional attention module (CAM), which conditions the current generation on the features extracted from the preceding chunk via an attentional mechanism, leading to consistent chunk transitions, (ii) a long-term memory block called appearance preservation module (APM), which extracts high-level scene and object features from the first video chunk to prevent the model from forgetting the initial scene, and (iii) a randomized blending approach that allows for the autoregressive application of a video enhancer on videos of indefinite length, ensuring consistency across chunks. Experiments show that StreamingT2V produces more motion, while competing methods suffer from video stagnation when applied naively in an autoregressive fashion. Thus, we propose with StreamingT2V a high-quality seamless text-to-long video generator, surpassing competitors in both consistency and motion.

Focal Split: Untethered Snapshot Depth from Differential Defocus
Junjie Luo, John Mamish, Alan Fu, Thomas Concannon, Josiah Hester, Emma Alexander, Qi Guo; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 26965-26974
We introduce Focal Split, a handheld, snapshot depth camera with fully onboard power and computing based on depth-from-differential-defocus (DfDD). Focal Split is passive, avoiding power consumption of light sources. Its achromatic optical system simultaneously forms two differentially defocused images of the scene, which can be independently captured using two photosensors in a snapshot. The data processing is based on the DfDD theory, which efficiently computes a depth and a confidence value for each pixel with only 500 floating point operations (FLOPs) per pixel from the camera measurements. We demonstrate a Focal Split prototype, which comprises a handheld custom camera system connected to a Raspberry Pi 5 for real-time data processing. The system consumes 4.9 W and is powered on a 5 V, 10,000 mAh battery. The prototype can measure objects with distances from 0.4 m to 1.2 m, outputting 480 x 360 sparse depth maps at 2.1 frames per second (FPS) using unoptimized Python scripts. Focal Split is DIY friendly. A comprehensive guide to building your own Focal Split depth camera, code, and additional data can be found at https://focal-split.qiguo.org.

AFL: A Single-Round Analytic Approach for Federated Learning with Pre-trained Models
Run He, Kai Tong, Di Fang, Han Sun, Ziqian Zeng, Haoran Li, Tianyi Chen, Huiping Zhuang; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 4988-4998
In this paper, we introduce analytic federated learning (AFL), a new training paradigm that brings analytical (i.e., closed-form) solutions to the federated learning (FL) with pre-trained models. Our AFL draws inspiration from analytic learning---a gradient-free technique that trains neural networks with analytical solutions in one epoch. In the local client training stage, the AFL facilitates a one-epoch training, eliminating the necessity for multi-epoch updates. In the aggregation stage, we derive an absolute aggregation (AA) law. This AA law allows a single-round aggregation, reducing heavy communication overhead and achieving fast convergence by removing the need for multiple aggregation rounds. More importantly, the AFL exhibits a property that invariance to data partitioning, meaning that regardless of how the full dataset is distributed among clients, the aggregated result remains identical. This could spawn various potentials, such as data heterogeneity invariance and client-number invariance. We conduct experiments across various FL settings including extremely non-IID ones, and scenarios with a large number of clients (e.g., \ge 1000). In all these settings, our AFL constantly performs competitively while existing FL techniques encounter various ob

stacles.

XLRS-Bench: Could Your Multimodal LLMs Understand Extremely Large Ultra-High-Resolution Remote Sensing Imagery?
Fengxiang Wang, Hongzhen Wang, Zonghao Guo, Di Wang, Yulin Wang, Mingshuo Chen, Qiang Ma, Long Lan, Wenjing Yang, Jing Zhang, Zhiyuan Liu, Maosong Sun; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 14325-14336
The astonishing breakthrough of multimodal large language models (MLLMs) has necessitated new benchmarks to quantitatively assess their capabilities, reveal their limitations, and indicate future research directions. However, this is challenging in the context of remote sensing (RS), since the imagery features ultra-high resolution that incorporates extremely complex semantic relationships. Existing benchmarks usually adopt notably smaller image sizes than real-world RS scenarios, suffer from limited annotation quality, and consider insufficient dimensions of evaluation. To address these issues, we present XLRS-Bench: a comprehensive benchmark for evaluating the perception and reasoning capabilities of MLLMs in ultra-high-resolution RS scenarios. XLRS-Bench boasts the largest average image size (8500x8500) observed thus far, with all evaluation samples meticulously annotated manually, assisted by a novel semi-automatic captioner on ultra-high-resolution RS images. On top of the XLRS-Bench, 16 sub-tasks are defined to evaluate MLLMs' 10 kinds of perceptual capabilities and 6 kinds of reasoning capabilities, with a primary emphasis on advanced cognitive processes that facilitate real-world decision-making and the capture of spatiotemporal changes. The results of both general and RS-focused MLLMs on XLRS-Bench indicate that further efforts are needed for real-world RS applications. We will open source XLRS-Bench to support further research of developing more powerful MLLMs for RS.
****
BOLT: Boost Large Vision-Language Model Without Training for Long-form Video Understanding
Shuming Liu, Chen Zhao, Tianqi Xu, Bernard Ghanem; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 3318-3327
Large video-language models (VLMs) have demonstrated promising progress in various video understanding tasks. However, their effectiveness in long-form video analysis is constrained by limited context windows. Traditional approaches, such as uniform frame sampling, often inevitably allocate resources to irrelevant content, diminishing their effectiveness in real-world scenarios. In this paper, we introduce BOLT, a method to boost large VLMs without additional training through a comprehensive study of frame selection strategies. First, to enable a more realistic evaluation of VLMs in long-form video understanding, we propose a multi-source retrieval evaluation setting. Our findings reveal that uniform sampling performs poorly in noisy contexts, underscoring the importance of selecting the right frames. Second, we explore several frame selection strategies based on query-frame similarity and analyze their effectiveness at inference time. Our results show that inverse transform sampling yields the most significant performance improvement, increasing accuracy on the Video-MME benchmark from 53.8% to 56.1% and MLVU benchmark from 58.9% to 63.4%.
****
Efficient Data Driven Mixture-of-Expert Extraction from Trained Networks
Uranik Berisha, Jens Mehnert, Alexandru Paul Condurache; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 20082-20091
Vision Transformers (ViTs) have emerged as the state-of-the-art models in various Computer Vision (CV) tasks, but their high computational and resource demands pose significant challenges. While Mixture of Experts (MoE) can make these models more efficient, they often require costly retraining or even training from scratch. Recent developments aim to reduce these computational costs by leveraging pretrained networks. These have been shown to produce sparse activation patterns in the Multi-Layer Perceptrons (MLPs) of the encoder blocks, allowing for conditional activation of only relevant subnetworks for each sample. Building on this idea, we propose a new method to construct MoE variants from pretrained models.

Our approach extracts expert subnetworks from the model's MLP layers post-training in two phases. First, we cluster output activations to identify distinct activation patterns. In the second phase, we use these clusters to extract the corresponding subnetworks responsible for producing them. On ImageNet-1k recognition tasks, we demonstrate that these extracted experts can perform surprisingly well out of the box and require only minimal fine-tuning to regain 98% of the original performance, all while reducing FLOPs and model size, by up to 36% and 32% respectively.

Reference-Based 3D-Aware Image Editing with Triplanes

Bahri Batuhan Bilecen, Yigit Yalin, Ning Yu, Aysegul Dundar; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 5904-5915

Generative Adversarial Networks (GANs) have emerged as powerful tools for high-quality image generation and real image editing by manipulating their latent spaces. Recent advancements in GANs include 3D-aware models such as EG3D, which feature efficient triplane-based architectures capable of reconstructing 3D geometry from single images. However, limited attention has been given to providing an integrated framework for 3D-aware, high-quality, reference-based image editing. This study addresses this gap by exploring and demonstrating the effectiveness of the triplane space for advanced reference-based edits. Our novel approach integrates encoding, automatic localization, spatial disentanglement of triplane features, and fusion learning to achieve the desired edits. We demonstrate how our approach excels across diverse domains, including human faces, 360-degree heads, animal faces, partially stylized edits like cartoon faces, full-body clothing edits, and edits on class-agnostic samples. Our method shows state-of-the-art performance over relevant latent direction, text, and image-guided 2D and 3D-aware diffusion and GAN methods, both qualitatively and quantitatively.

****

StyleSSP: Sampling StartPoint Enhancement for Training-free Diffusion-based Method for Style Transfer

Ruojun Xu, Weijie Xi, XiaoDi Wang, Yongbo Mao, Zach Cheng; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 18260-18269

Training-free diffusion-based methods have achieved remarkable success in style transfer, eliminating the need for extensive training or fine-tuning. However, due to the lack of targeted training for style information extraction and constraints on the content image layout, training-free methods often suffer from layout changes of original content and content leakage from style images. Through a series of experiments, we discovered that an effective startpoint in the sampling stage significantly enhances the style transfer process. Based on this discovery, we propose StyleSSP, which focuses on obtaining a better startpoint to address layout changes of original content and content leakage from style image. StyleSSP comprises two key components: (1) Frequency Manipulation: To improve content preservation, we reduce the low-frequency components of the DDIM latent, allowing the sampling stage to pay more attention to the layout of content images; and (2) Negative Guidance via Inversion: To mitigate the content leakage from style image, we employ negative guidance in the inversion stage to ensure that the startpoint of the sampling stage is distanced from the content of style image. Experiments show that StyleSSP surpasses previous training-free style transfer baselines, particularly in preserving original content and minimizing the content leakage from style image.

PURA: Parameter Update-Recovery Test-Time Adaption for RGB-T Tracking

Zekai Shao, Yufan Hu, Bin Fan, Hongmin Liu; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 22089-22098

Maintaining stable tracking of objects in domain shift scenarios is crucial for RGB-T tracking, prompting us to explore the use of unlabeled test sample information for effective online model adaptation. However, current Test-Time Adaptation (TTA) methods in RGB-T tracking dramatically change the model's internal parameters during long-term adaptation. At the same time, the gradient computations involved in the optimization process impose a significant computational burden. T

o address these challenges, we propose a Parameter Update-Recovery Adaptation (PURA) framework based on parameter decomposition. Firstly, our fast parameter update strategy adjusts model parameters using statistical information from test samples without requiring gradient calculations, ensuring consistency between the model and test data distribution. Secondly, our parameter decomposition recovery employs orthogonal decomposition to identify the principal update direction and recover parameters in this direction, aiding in the retention of critical knowledge. Finally, we leverage the information obtained from decomposition to provide feedback on the momentum during the update phase, ensuring a stable updating process. Experimental results demonstrate that PURA outperforms current state-of-the-art methods across multiple datasets, validating its effectiveness. The project page is at https://melantech.github.io/PURA.

One is Plenty: A Polymorphic Feature Interpreter for Immutable Heterogeneous Collaborative Perception

Yuchen Xia, Quan Yuan, Guiyang Luo, Xiaoyuan Fu, Yang Li, Xuanhan Zhu, Tianyou Luo, Siheng Chen, Jinglin Li; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 1592-1601

Collaborative perception in autonomous driving significantly enhances the perception capabilities of individual agents. Immutable heterogeneity in collaborative perception, where agents have different and fixed perception networks, presents a major challenge due to the semantic gap in their exchanged intermediate features without modifying the perception networks. Most existing methods bridge the semantic gap through interpreters. However, they either require training a new interpreter for each new agent type, limiting extensibility, or rely on a two-stage interpretation via an intermediate standardized semantic space, causing cumulative semantic loss. To achieve both extensibility in immutable heterogeneous scenarios and low-loss feature interpretation, we propose PolyInter, a polymorphic feature interpreter. It contains an extension point through which emerging new agents can seamlessly integrate by overriding only their specific prompts, which are learnable parameters intended to guide the interpretation, while reusing PolyInter's remaining parameters. By leveraging polymorphism, our design ensures that single interpreter is sufficient to accommodate diverse agents and interpret their features into the ego agent's semantic space. Experiments conducted on OPV2V dataset demonstrate that PolyInter improves collaborative perception precision by up to 11.1% compared to SOTA interpreters, while comparable results can be achieved by training only 1.4% of PolyInter's parameters when adapting to new agents.

Towards All-in-One Medical Image Re-Identification

Yuan Tian, Kaiyuan Ji, Rongzhao Zhang, Yankai Jiang, Chunyi Li, Xiaosong Wang, Guangtao Zhai; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 30774-30786

Medical image re-identification (MedReID) is under-explored so far, despite its critical applications in personalized healthcare and privacy protection.In this paper, we introduce a thorough benchmark and a unified model for this problem.First, to handle various medical modalities, we propose a novel Continuous Modality-based Parameter Adapter (ComPA). ComPA condenses medical content into a continuous modality representation and dynamically adjusts the modality-agnostic model with modality-specific parameters at runtime. This allows a single model to adaptively learn and process diverse modality data.Furthermore, we integrate medical priors into our model by aligning it with a bag of pre-trained medical foundation models, in terms of the differential features.Compared to single-image feature, modeling the inter-image difference better fits the re-identification problem, which involves discriminating multiple images.We evaluate the proposed model against 25 foundation models and 8 large multi-modal language models across 11 image datasets, demonstrating consistently superior performance.Additionally, we deploy the proposed MedReID technique to two real-world applications, i.e., history-augmented personalized diagnosis and medical privacy protection.

SegAgent: Exploring Pixel Understanding Capabilities in MLLMs by Imitating Human Annotator Trajectories
Muzhi Zhu, Yuzhuo Tian, Hao Chen, Chunluan Zhou, Qingpei Guo, Yang Liu, Ming Yang, Chunhua Shen; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 3686-3696
While MLLMs have demonstrated adequate image understanding capabilities, they still struggle with pixel-level comprehension, limiting their practical applications. Current evaluation tasks like VQA and visual grounding remain too coarse to assess fine-grained pixel comprehension accurately. Though segmentation is foundational for pixel-level understanding, existing methods often require MLLMs to generate implicit tokens, decoded through external pixel decoders. This approach disrupts the MLLM's text output space, potentially compromising language capabilities and reducing flexibility and extensibility, while failing to reflect the model's intrinsic pixel-level understanding.Thus, We introduce the Human-Like Mask Annotation Task (HLMAT), a new paradigm where MLLMs mimic human annotators using interactive segmentation tools. Modeling segmentation as a multi-step Markov Decision Process, HLMAT enables MLLMs to iteratively generate text-based click points, achieving high-quality masks without architectural changes or implicit tokens. Through this setup, we develop SegAgent, a model fine-tuned on human-like annotation trajectories, which achieves performance comparable to SOTA methods and supports additional tasks like mask refinement and annotation filtering.HLMAT provides a protocol for assessing fine-grained pixel understanding in MLLMs and introduces a vision-centric, multi-step decision-making task that facilitates exploration of MLLMs' visual reasoning abilities. Our adaptations of policy improvement method StaR and PRM guided tree search further enhance model robustness in complex segmentation tasks, laying a foundation for future advancements in fine-grained visual perception and multi-step decision-making for MLLMs.

Motions as Queries: One-Stage Multi-Person Holistic Human Motion Capture
Kenkun Liu, Yurong Fu, Weihao Yuan, Jing Lin, Peihao Li, Xiaodong Gu, Lingteng Qiu, Haoqian Wang, Zilong Dong, Xiaoguang Han; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 17529-17539
Existing methods for capturing multi-person holistic human motions from a monocular video usually involve integrating the detector, the tracker, and the human pose & shape estimator into a cascaded system. Differently, we develop a one-stage multi-person holistic human motion capture system, which 1) employs only one network, enabling significant benefits from the end-to-end training on a large-scale dataset; 2) enables performance improving of the tracking module during training, avoiding being limited by a pre-trained tracker; 3) captures the motions of all individuals within a single shot, rather than tracking and estimating each person sequentially. In this system, each query within a temporal cross-attention module is responsible for the long motion of a specific individual, implicitly aggregating individual-specific information throughout the entire video. To further boost the proposed system from end-to-end training, we also construct a synthetic human video dataset, with multi-person and whole-body annotations. Extensive experiments across different datasets demonstrate both the efficacy and the efficiency of both the proposed method and the dataset. The code of our method will be made publicly available.

SceneCrafter: Controllable Multi-View Driving Scene Editing
Zehao Zhu, Yuliang Zou, Chiyu Max Jiang, Bo Sun, Vincent Casser, Xiukun Huang, Jiahao Wang, Zhenpei Yang, Ruiqi Gao, Leonidas Guibas, Mingxing Tan, Dragomir Anguelov; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 6812-6822
Simulation is crucial for developing and evaluating autonomous vehicle (AV) systems. Recent literature builds on a new generation of generative models to synthesize highly realistic images for full-stack simulation. However, purely synthetically generated scenes are not grounded in reality and have difficulty in inspiring confidence in the relevance of its outcomes. Editing models, on the other hand, leverage source scenes from real driving logs, and enable the simulation of

different traffic layouts, behaviors, and operating conditions such as weather a
nd time of day. While image editing is an established topic in computer vision,
it presents fresh sets of challenges in driving simulation: (1) the need for cro
ss-camera 3D consistency, (2) learning "empty street" priors from driving data w
ith foreground occlusions, and (3) obtaining paired image tuples of varied editi
ng conditions while preserving consistent layout and geometry. To address these
challenges, we propose SceneCrafter, a versatile editor for realistic 3D-consist
ent manipulation of driving scenes captured from multiple cameras. We build on r
ecent advancements in multi-view diffusion models, using a fully controllable fr
amework that scales seamlessly to multi-modality conditions like weather, time o
f day, agent boxes and high-definition maps. To generate paired data for supervi
sing the editing model, we propose a novel framework on top of Prompt-to-Prompt
to generate geometrically consistent synthetic paired data with global edits. We
 also introduce an alpha-blending framework to synthesize data with local edits,
 leveraging a model trained on empty street priors through novel masked training
 and multi-view repaint paradigm. SceneCrafter demonstrates powerful editing cap
abilities and achieves state-of-the-art realism, controllability, 3D consistency
, and scene editing quality compared to existing baselines.

AMO Sampler: Enhancing Text Rendering with Overshooting
Xixi Hu, Keyang Xu, Bo Liu, Qiang Liu, Hongliang Fei; Proceedings of the Compute
r Vision and Pattern Recognition Conference (CVPR), 2025, pp. 13157-13166
Achieving precise alignment between textual instructions and generated images in
 text-to-image generation is a significant challenge, particularly in rendering
written text within images. Open-source models like Stable Diffusion 3 (SD3), Fl
ux, and AuraFlow often struggle with accurate text depiction, resulting in missp
elled or inconsistent text. We introduce a training-free method with minimal com
putational overhead that significantly enhances text rendering quality. Specific
ally, we introduce an overshooting sampler for a pretrained RF model, by alterna
ting between over-simulating the learned ordinary differential equation (ODE) an
d reintroducing noise. Compared to the Euler sampler, the overshooting sampler e
ffectively introduces an extra Langevin dynamics term that can help correct the
compounding error from successive Euler steps and therefore improve the text ren
dering. However, when the overshooting strength is high, we observe over-smoothi
ng artifacts on the generated images. To address this issue, we adaptively contr
ol the strength of the overshooting for each image patch according to their atte
ntion score with the text content. We name the proposed sampler Attention Modula
ted Overshooting sampler (AMO). AMO demonstrates a 32.3% and 35.9% improvement i
n text rendering accuracy on SD3 and Flux without compromising overall image qua
lity or increasing inference cost.

ImViD: Immersive Volumetric Videos for Enhanced VR Engagement
Zhengxian Yang, Shi Pan, Shengqi Wang, Haoxiang Wang, Li Lin, Guanjun Li, Zhengq
i Wen, Borong Lin, Jianhua Tao, Tao Yu; Proceedings of the Computer Vision and P
attern Recognition Conference (CVPR), 2025, pp. 16554-16564
User engagement is greatly enhanced by fully immersive multimodal experiences th
at combine visual and auditory stimuli. Consequently, the next frontier in VR/AR
 technologies lies in immersive volumetric videos with complete scene capture, l
arge 6-DoF interactive space, Multi-modal feedback, and high resolution & frame-
rate contents. To stimulate the reconstruction of immersive volumetric videos, w
e introduce ImViD, a multi-view, multi-modal dataset featuring complete space-or
iented data capture and various indoor/outdoor scenarios. Our capture rig suppor
ts multi-view video-audio capture while on the move, a capability absent in exis
ting datasets, which significantly enhances the completeness, flexibility, and e
fficiency of data capture. The captured multi-view videos (with synchronized aud
ios) are in 5K resolution at 60FPS, lasting from 1-5 minutes, and include rich f
oreground-background elements, and complex dynamics. We benchmark existing metho
ds using our dataset and establish a base pipeline for constructing immersive vo
lumetric videos from multi-view audiovisual inputs for 6-DoF multimodal immersiv
e VR experiences. The benchmark and the reconstruction and interaction results d

emonstrate the effectiveness of our dataset and baseline method, which we believ e will stimulate future research on immersive volumetric video production.

Integral Fast Fourier Color Constancy
Wenjun Wei, Yanlin Qian, Huaian Chen, Junkang Dai, Yi Jin; Proceedings of the Co mputer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 26420-26429
Traditional auto white balance (AWB) algorithms typically assume a single global illuminant source, which leads to color distortions in multi-illuminant scenes. While recent neural network-based methods have shown excellent accuracy in such scenarios, their high parameter count and computational demands limit their pra cticality for real-time video applications. The Fast Fourier Color Constancy (FF CC) algorithm was proposed for single-illuminant-source scenes, predicting a glo bal illuminant source with high efficiency. However, it cannot be directly appli ed to multi-illuminant scenarios unless specifically modified. To address this, we propose Integral Fast Fourier Color Constancy (IFFCC), an extension of FFCC t ailored for multi-illuminant scenes. IFFCC leverages the proposed integral UV hi stogram to accelerate histogram computations across all possible regions in Cart esian space and parallelizes Fourier-based convolution operations, resulting in a spatially-smooth illumination map. This approach enables high-accuracy, real-t ime AWB in multi-illuminant scenes. Extensive experiments show that IFFCC achiev es accuracy that is on par with or surpasses that of pixel-level neural networks , while reducing the parameter count by over 400x and processing speed by 20 - 1 00x faster than network-based approaches.

I2VGuard: Safeguarding Images against Misuse in Diffusion-based Image-to-Video M odels
Dongnan Gui, Xun Guo, Wengang Zhou, Yan Lu; Proceedings of the Computer Vision a nd Pattern Recognition Conference (CVPR), 2025, pp. 12595-12604
Recent advances in image-to-video generation have enabled animation of still ima ges and offered pixel-level controllability. While these models hold great poten tial to transform single images into vivid and dynamic videos, they also carry r isks of misuse that could impact privacy, security, and copyright protection. Th is paper proposes a novel approach that applies imperceptible perturbations on i mages to degrade the quality of the generated videos, thereby protecting images from misuse in white-box image-to-video diffusion models. Specifically, we funct ion our approach as an adversarial attack, incorporating spatial, temporal, and diffusion attack modules. The spatial attack shifts image features from their o riginal distribution to a lower-quality target distribution, reducing visual fid elity. The temporal attack disrupts coherent motion by interfering with temporal attention maps that guide motion generation. To enhance the robustness of our a pproach across different models, we further propose a diffusion attack module le veraging contrastive loss. Our approach can be easily integrated with mainstream diffusion-based I2V models. Extensive experiments on SVD, CogVideoX, and Contro lNeXt demonstrate that our method significantly impairs generation quality in te rms of visual clarity and motion consistency, while introducing only minimal art ifacts to the images. To the best of our knowledge, we are the first to explore adversarial attacks on image-to-video generation for security purposes.

Saliuitl: Ensemble Salience Guided Recovery of Adversarial Patches against CNNs
Mauricio Byrd Victorica, György Dán, Henrik Sandberg; Proceedings of the Compute r Vision and Pattern Recognition Conference (CVPR), 2025, pp. 20360-20369
Adversarial patches are capable of misleading computer vision systems based on c onvolutional neural networks. Existing recovery methods suffer of at least one o f three fundamental shortcomings: no information about the presence of patches i n the scene, inability to efficiently handle noncontiguous patch attacks, and a strong reliance on fixed saliency thresholds. We propose Saliuitl, a recovery m ethod independent of the number of patches and their shape, which unlike prior w orks, explicitly detects patch attacks before attempting recovery. In our approa ch, detection is based on the attributes of a binarized feature map ensemble, wh ich is generated by using an ensemble of saliency thresholds. If an attack is de

tected, Saliuitl recovers clean predictions locating patches guided by an ensemb le of binarized feature maps and inpainting them. We evaluate Saliuitl on widely used object detection and image classification benchmarks from the adversarial patch literature, and our results show that compared to recent state-of-the-art defenses, Saliuitl achieves a recovery rate up to 97.81 and 42.63 percentage po ints higher at the same rate of lost predictions for image classification and ob ject detection, respectively. By design, Saliuitl has low computational complexi ty and is robust to adaptive white-box attacks. Our code is available at https:/ /github.com/Saliuitl/Saliuitl/tree/main.

HeatFormer: A Neural Optimizer for Multiview Human Mesh Recovery
Yuto Matsubara, Ko Nishino; Proceedings of the Computer Vision and Pattern Recog nition Conference (CVPR), 2025, pp. 6415-6424
We introduce a novel method for human shape and pose recovery that can fully lev erage multiple static views. We target fixed-multiview people monitoring, includ ing elderly care and safety monitoring, in which cameras can be installed at the corners of a room or an open space but whose configuration may vary depending o n the environment. Our key idea is to formulate it as neural optimization. We ac hieve this with HeatFormer, a neural optimizer that iteratively refines the SMPL parameters given multiview images. HeatFormer realizes this SMPL parameter esti mation as heatmap generation and alignment with a novel transformer encoder and decoder. Our formulation makes HeatFormer fundamentally agnostic to the number o f cameras, their configuration, and calibration. We demonstrate the effectivenes s of HeatFormer including its accuracy, robustness to occlusion, and generalizab ility through an extensive set of experiments. We believe HeatFormer can serve a key role in passive human behavior modeling.

ResCLIP: Residual Attention for Training-free Dense Vision-language Inference
Yuhang Yang, Jinhong Deng, Wen Li, Lixin Duan; Proceedings of the Computer Visio n and Pattern Recognition Conference (CVPR), 2025, pp. 29968-29978
While vision-language models like CLIP have shown remarkable success in open-voc abulary tasks, their application is currently confined to image-level tasks, and they still struggle with dense predictions. Recent works often attribute such d eficiency in dense predictions to the self-attention layers in the final block, and have achieved commendable results by modifying the original query-key attent ion to self-correlation attention, (e.g., query-query and key-key attention). Ho wever, these methods overlook the cross-correlation attention (query-key) proper ties, which capture the rich spatial correspondence. In this paper, we reveal th at the cross-correlation of self-attention in non-final layers of CLIP also exhi bits localization properties. Therefore, we propose the Residual Cross-correlati on Self-attention (RCS) module, which leverages the cross-correlation self-atten tion from intermediate layers to remold the attention in the final block. The RC S module effectively reorganizes spatial information, unleashing the localizatio n potential within CLIP for dense vision-language inference. Furthermore, to enh ance the focus on regions of the same categories and local consistency, we propo se the Semantic Feedback Refinement (SFR) module, which utilizes semantic segmen tation maps to further adjust the attention scores. By integrating these two str ategies, our method, termed ResCLIP, can be easily incorporated into existing ap proaches as a plug-and-play module, significantly boosting their performance in dense vision-language inference. Extensive experiments across multiple standard benchmarks demonstrate that our method surpasses state-of-the-art training-free methods, validating the effectiveness of the proposed approach. Code is availabl e at https://github.com/yvhangyang/ResCLIP.

GPS as a Control Signal for Image Generation
Chao Feng, Ziyang Chen, Aleksander Holynski, Alexei A. Efros, Andrew Owens; Proc eedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 2766-2778
We show that the GPS tags contained in photo metadata provide a useful control s ignal for image generation. We train GPS-to-image models and use them for tasks

that require a fine-grained understanding of how images vary within a city. In particular, we train a diffusion model to generate images conditioned on both GPS and text. The learned model generates images that capture the distinctive appearance of different neighborhoods, parks, and landmarks. We also extract 3D models from 2D GPS-to-image models through score distillation sampling, using GPS conditioning to constrain the appearance of the reconstruction from each viewpoint. Our evaluations suggest that our GPS-conditioned models successfully learn to generate images that vary based on location, and that GPS conditioning improves estimated 3D structure.

CPath-Omni: A Unified Multimodal Foundation Model for Patch and Whole Slide Image Analysis in Computational Pathology

Yuxuan Sun, Yixuan Si, Chenglu Zhu, Xuan Gong, Kai Zhang, Pingyi Chen, Ye Zhang, Zhongyi Shui, Tao Lin, Lin Yang; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 10360-10371

The emergence of large multimodal models (LMMs) has brought significant advancements to pathology. Previous research has primarily focused on separately training patch-level and whole-slide image (WSI)-level models, limiting the integration of learned knowledge across patches and WSIs and resulting in redundant models. In this work, we introduce CPath-Omni, the first 15B parameter LMM that unifies patch and WSI analysis, consolidating a variety of tasks at both levels, including classification, visual question answering, captioning, and visual referring prompting. Extensive experiments demonstrate that CPath-Omni achieves state-of-the-art (SOTA) performance across seven diverse tasks on 39 out of 42 datasets, outperforming or matching task-specific models trained for individual tasks. Additionally, we develop a specialized pathology CLIP-based visual processor for CPath-Omni, CPath-CLIP, which, for the first time, integrates different vision models and incorporates a large language model as a text encoder to build a more powerful CLIP model, which achieves SOTA performance on nine zero-shot and four few-shot datasets. Our findings highlight CPath-Omni's ability to unify diverse pathology tasks, demonstrating its potential to streamline and advance the field of foundation model in pathology. The code and model are available at https://github.com/PathFoundation/CPath-Omni.

OPTICAL: Leveraging Optimal Transport for Contribution Allocation in Dataset Distillation

Xiao Cui, Yulei Qin, Wengang Zhou, Hongsheng Li, Houqiang Li; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 15245-15254

The demands for increasingly large-scale datasets pose substantial storage and computation challenges to building deep learning models. Dataset distillation methods, especially those via sample generation techniques, rise in response to condensing large original datasets into small synthetic ones while preserving critical information. Existing subset synthesis methods simply minimize the homogeneous distance where uniform contributions from all real instances are allocated to shaping each synthetic sample. We demonstrate that such equal allocation fails to consider the instance-level relationship between each real-synthetic pair and gives rise to insufficient modeling of geometric structural nuances between the distilled and original sets. In this paper, we propose a novel framework named OPTICAL to reformulate the homogeneous distance minimization into a bi-level optimization problem via matching-and-approximating. In the matching step, we leverage optimal transport matrix to dynamically allocate contributions from real instances. Subsequently, we polish the generated samples in accordance with the established allocation scheme for approximating the real ones. Such a strategy better measures intricate geometric characteristics and handles intra-class variations for high fidelity of data distillation. Extensive experiments across seven datasets and three model architectures demonstrate our method's versatility and effectiveness. Its plug-and-play characteristic makes it compatible with a wide range of distillation frameworks.
****

MAGiC-SLAM: Multi-Agent Gaussian Globally Consistent SLAM
Vladimir Yugay, Theo Gevers, Martin R. Oswald; Proceedings of the Computer Visio n and Pattern Recognition Conference (CVPR), 2025, pp. 6741-6750
Simultaneous localization and mapping (SLAM) systems with novel view synthesis c apabilities are widely used in computer vision, with applications in augmented r eality, robotics, and autonomous driving. However, existing approaches are limit ed to single-agent operation. Recent work has addressed this problem using a dis tributed neural scene representation. Unfortunately, existing methods are slow, cannot accurately render real-world data, are restricted to two agents, and have limited tracking accuracy. In contrast, we propose a rigidly deformable 3D Gaus sian-based scene representation that dramatically speeds up the system. However, improving tracking accuracy and reconstructing a globally consistent map from m ultiple agents remains challenging due to trajectory drift and discrepancies acr oss agents' observations. Therefore, we propose new tracking and map-merging mec hanisms and integrate loop closure in the Gaussian-based SLAM pipeline. We evalu ate \ours on synthetic and real-world datasets and find it more accurate and fas ter than the state of the art.

Dispider: Enabling Video LLMs with Active Real-Time Interaction via Disentangled Perception, Decision, and Reaction
Rui Qian, Shuangrui Ding, Xiaoyi Dong, Pan Zhang, Yuhang Zang, Yuhang Cao, Dahua Lin, Jiaqi Wang; Proceedings of the Computer Vision and Pattern Recognition Con ference (CVPR), 2025, pp. 24045-24055
Active Real-time interaction with video LLMs introduces a new paradigm for human -computer interaction, where the model not only understands user intent but also responds while continuously processing streaming video on the fly. Unlike offli ne video LLMs, which analyze the entire video before answering questions, active real-time interaction requires three capabilities: 1) Perception: real-time vid eo monitoring and interaction capturing. 2) Decision: raising proactive interact ion in proper situations, 3) Reaction: continuous interaction with users. Howeve r, inherent conflicts exist among the desired capabilities. The Decision and Rea ction require a contrary Perception scale and grain, and the autoregressive deco ding blocks the real-time Perception and Decision during the Reaction. To unify the conflicted capabilities within a harmonious system, we present Dispider, a s olution built on a Disentangled Perception, Decision, and Reaction framework. Di spider features a lightweight Proactive Streaming Video Processing module that t racks the video stream and identifies optimal moments for interaction. Once the interaction is triggered, an asynchronous Precise Interaction module provides de tailed responses, while the processing module continues to monitor the video in the meantime. Our disentangled and asynchronous design ensures timely, contextua lly accurate, and computationally efficient responses, making Dispider ideal for active real-time interaction for long-duration video streams. Experiments prove that Dispider outperforms existing methods not only in its superior understandi ng of video content in conventional video QA settings, but also in proactive res ponse capability and temporal awareness under the streaming setting.
****

NTClick: Achieving Precise Interactive Segmentation With Noise-tolerant Clicks
Chenyi Zhang, Ting Liu, Xiaochao Qu, Luoqi Liu, Yao Zhao, Yunchao Wei; Proceedin gs of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 8 921-8930
Interactive segmentation is a pivotal task in computer vision, focused on predic ting precise masks with minimal user input. Although the click has recently beco me the most prevalent form of interaction due to its flexibility and efficiency, its advantages diminish as the complexity and details of target objects increas e because it's time-consuming and user-unfriendly to precisely locate and click on narrow, fine regions. To tackle this problem, we propose NTClick, a powerful click-based interactive segmentation method capable of predicting accurate masks even with imprecise user clicks when dealing with intricate targets. We first i ntroduce a novel interaction form called Noist-tolerant Click, a type of click t hat does not require user's precise localization when selecting fine regions. Th

en, we design a two-stage workflow, consisting of an Explicit Coarse Perception network for initial estimation and a High Resolution Refinement network for final classification. Quantitative results across extensive datasets demonstrate that NTClick not only maintains an efficient and flexible interaction mode but also significantly outperforms existing methods in segmentation accuracy.
****

Show and Segment: Universal Medical Image Segmentation via In-Context Learning
Yunhe Gao, Di Liu, Zhuowei Li, Yunsheng Li, Dongdong Chen, Mu Zhou, Dimitris N. Metaxas; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 20830-20840
Medical image segmentation remains challenging due to the vast diversity of anatomical structures, imaging modalities, and segmentation tasks. While deep learning has made significant advances, current approaches struggle to generalize as they require task-specific training or fine-tuning on unseen classes. We present Iris, a novel In-context Reference Image guided Segmentation framework that enables flexible adaptation to novel tasks through the use of reference examples without fine-tuning. At its core, Iris features a lightweight context task encoding module that distills task-specific information from reference context image-label pairs. This rich context embedding information is used to guide the segmentation of target objects. Given a decoupled architecture on 3D data processing, Iris supports diverse inference strategies including one-shot inference, context example ensemble, object-level context example retrieval, and in-context tuning. Through comprehensive evaluation across twelve datasets, we demonstrate that Iris performs strongly compared to specialized supervised models on in-distribution tasks. On seven held-out dataset, Iris shows superior generalization to out-of-distribution data and unseen classes. Further, Iris's task encoding module can automatically discover anatomical relationships across datasets and modalities, offering insights into cross-modality medical objects without explicit anatomical supervision.

MVGenMaster: Scaling Multi-View Generation from Any Image via 3D Priors Enhanced Diffusion Model
Chenjie Cao, Chaohui Yu, Shang Liu, Fan Wang, Xiangyang Xue, Yanwei Fu; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 6045-6056
We introduce MVGenMaster, a multi-view diffusion model enhanced with 3D priors to address versatile Novel View Synthesis (NVS) tasks. MVGenMaster leverages 3D priors that are warped using metric depth and camera poses, significantly enhancing both generalization and 3D consistency in NVS. Our model features a simple yet effective pipeline that can generate up to 100 novel views conditioned on variable reference views and camera poses with a single forward process. Additionally, we have developed a comprehensive large-scale multi-view image dataset called MvD-1M, comprising up to 1.6 million scenes, equipped with well-aligned metric depth to train MVGenMaster. Moreover, we present several training and model modifications to strengthen the model with scaled-up datasets. Extensive evaluations across in- and out-of-domain benchmarks demonstrate the effectiveness of our proposed method and data formulation.

CADCrafter: Generating Computer-Aided Design Models from Unconstrained Images
Cheng Chen, Jiacheng Wei, Tianrun Chen, Chi Zhang, Xiaofeng Yang, Shangzhan Zhang, Bingchen Yang, Chuan-Sheng Foo, Guosheng Lin, Qixing Huang, Fayao Liu; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 11073-11082
Creating CAD digital twins from the physical world is crucial for manufacturing, design, and simulation. However, current methods typically rely on costly 3D scanning with labor-intensive post-processing. To provide a user-friendly design process, we explore the problem of reverse engineering from unconstrained real-world CAD images that can be easily captured by users of all experiences. However, the scarcity of real-world CAD data poses challenges in directly training such models. To tackle these challenges, we propose CADCrafter, an image-to-parametri

c CAD model generation framework that trains solely on synthetic textureless CAD data while testing on real-world images. To bridge the significant representation disparity between images and parametric CAD models, we introduce a geometry encoder to accurately capture diverse geometric features. Moreover, the texture-invariant properties of the geometric features can also facilitate the generalization to real-world scenarios. Since compiling CAD parameter sequences into explicit CAD models is a non-differentiable process, the network training inherently lacks explicit geometric supervision. To impose geometric validity constraints, we employ direct preference optimization (DPO) to fine-tune our model with the automatic code checker feedback on CAD sequence quality. Furthermore, we collected a real-world dataset, comprised of multi-view images and corresponding CAD command sequence pairs, to evaluate our method. Experimental results demonstrate that our approach can robustly handle real unconstrained CAD images, and even generalize to unseen general objects.

Bayesian Test-Time Adaptation for Vision-Language Models

Lihua Zhou, Mao Ye, Shuaifeng Li, Nianxin Li, Xiatian Zhu, Lei Deng, Hongbin Liu, Zhen Lei; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 29999-30009

Test-time adaptation with pre-trained vision-language models, such as CLIP, aims to adapt the model to new, potentially out-of-distribution test data. Existing methods calculate the similarity between visual embedding and learnable class embeddings, which are initialized by text embeddings, for zero-shot image classification. In this work, we first analyze this process based on Bayes theorem, and observe that the core factors influencing the final prediction are the likelihood and the prior. However, existing methods essentially focus on adapting class embeddings to adapt likelihood, but they often ignore the importance of prior. To address this gap, we propose a novel approach, Bayesian Class Adaptation (BCA), which in addition to continuously updating class embeddings to adapt likelihood, also uses the posterior of incoming samples to continuously update the prior for each class embedding. This dual updating mechanism allows the model to better adapt to distribution shifts and achieve higher prediction accuracy. Our method not only surpasses existing approaches in terms of performance metrics but also maintains superior inference rates and memory usage, making it highly efficient and practical for real-world applications.

Generative Multiview Relighting for 3D Reconstruction under Extreme Illumination Variation

Hadi Alzayer, Philipp Henzler, Jonathan T. Barron, Jia-Bin Huang, Pratul P. Srinivasan, Dor Verbin; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 10933-10942

Reconstructing the geometry and appearance of objects from photographs taken in different environments is difficult as the illumination and therefore the object appearance vary across captured images. This is particularly challenging for more specular objects whose appearance strongly depends on the viewing direction. Some prior approaches model appearance variation across images using a per-image embedding vector, while others use physically-based rendering to recover the materials and per-image illumination. Such approaches fail at faithfully recovering view-dependent appearance given significant variation in input illumination and tend to produce mostly diffuse results. We present an approach that reconstructs objects from images taken under different illuminations by first relighting the images under a single reference illumination with a multiview relighting diffusion model and then reconstructing the object's geometry and appearance with a radiance field architecture that is robust to the small remaining inconsistencies among the relit images. We validate our proposed approach on both simulated and real datasets and demonstrate that it greatly outperforms existing techniques at reconstructing high-fidelity appearance from images taken under extreme illumination variation. Moreover, our approach is particularly effective at recovering view-dependent "shiny" appearance which cannot be reconstructed by prior methods.

Causal Composition Diffusion Model for Closed-loop Traffic Generation
Haohong Lin, Xin Huang, Tung Phan, David Hayden, Huan Zhang, Ding Zhao, Siddhartha Srinivasa, Eric Wolff, Hongge Chen; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 27542-27552
Simulation is critical for safety evaluation in autonomous driving, particularly in capturing complex interactive behaviors. However, generating **realistic** and **controllable** traffic scenarios in long-tail situations remains a significant challenge. Existing generative models suffer from the conflicting objective between user-defined controllability and realism constraints, which is amplified in safety-critical contexts. In this work, we introduce the **C**ausal **C**ompositional **Diff**usion Model (***CCDiff***), a structure-guided diffusion framework to address these challenges. We first formulate the learning of controllable and realistic closed-loop simulation as a constrained optimization problem. Then, CCDiff maximizes controllability while adhering to realism by automatically identifying and injecting causal structures directly into the diffusion process, providing structured guidance to enhance both realism and controllability. Through rigorous evaluations on benchmark datasets and in a closed-loop simulator, CCDiff demonstrates substantial gains over state-of-the-art approaches in generating realistic and user-preferred trajectories. Our results show CCDiff's effectiveness in extracting and leveraging causal structures, showing improved closed-loop performance based on key metrics such as collision rate, off-road rate, FDE, and comfort. For more details, welcome to check our project website: https://sites.google.com/view/ccdiff/.

Change3D: Revisiting Change Detection and Captioning from A Video Modeling Perspective
Duowang Zhu, Xiaohu Huang, Haiyan Huang, Hao Zhou, Zhenfeng Shao; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 24011-24022
In this paper, we present Change3D, a framework that reconceptualizes the change detection and captioning tasks through video modeling. Recent methods have achieved remarkable success by regarding each pair of bi-temporal images as separate frames. They employ a shared-weight image encoder to extract spatial features and then use a change extractor to capture differences between the two images. However, image feature encoding, being a task-agnostic process, cannot attend to changed regions effectively. Furthermore, different change extractors designed for various change detection and captioning tasks make it difficult to have a unified framework. To tackle these challenges, Change3D regards the bi-temporal images as comprising two frames akin to a tiny video. By integrating learnable perception frames between the bi-temporal images, a video encoder enables the perception frames to interact with the images directly and perceive their differences. Therefore, we can get rid of the intricate change extractors, providing a unified framework for different change detection and captioning tasks. We verify Change3D on multiple tasks, encompassing change detection (including binary change detection, semantic change detection, and building damage assessment) and change captioning, across eight standard benchmarks. Without bells and whistles, this simple yet effective framework can achieve superior performance with an ultra-light video model comprising only ~6%-13% of the parameters and ~8%-34% of the FLOPs compared to state-of-the-art methods. We hope that Change3D could be an alternative to 2D-based models and facilitate future research.
****
DyMO: Training-Free Diffusion Model Alignment with Dynamic Multi-Objective Scheduling
Xin Xie, Dong Gong; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 13220-13230
Text-to-image diffusion model alignment is critical for improving the alignment between the generated images and human preferences. While training-based methods are constrained by high computational costs and dataset requirements, training-free alignment methods remain underexplored and are often limited by inaccurate

guidance. We propose a plug-and-play training-free alignment method, DyMO, for a ligning the generated images and human preferences during inference. Apart from text-aware human preference scores, we introduce a semantic alignment objective for enhancing the semantic alignment in the early stages of diffusion, relying o n the fact that the attention maps are effective reflections of the semantics in noisy images. We propose dynamic scheduling of multiple objectives and intermed iate recurrent steps to reflect the requirements at different steps. Experiments with diverse pre-trained diffusion models and metrics demonstrate the effective ness and robustness of the proposed method.

HiMoR: Monocular Deformable Gaussian Reconstruction with Hierarchical Motion Rep resentation
Yiming Liang, Tianhan Xu, Yuta Kikuchi; Proceedings of the Computer Vision and P attern Recognition Conference (CVPR), 2025, pp. 886-895
We present Hierarchical Motion Representation (HiMoR), a novel deformation repre sentation for 3D Gaussian primitives capable of achieving high-quality monocular dynamic 3D reconstruction. The insight behind HiMoR is that motions in everyday scenes can be decomposed into coarser motions that serve as the foundation for finer details. Using a tree structure, HiMoR's nodes represent different levels of motion detail, with shallower nodes modeling coarse motion for temporal smoot hness and deeper nodes capturing finer motion. Additionally, our model uses a fe w shared motion bases to represent motions of different sets of nodes, aligning with the assumption that motion tends to be smooth and simple. This motion repre sentation design provides Gaussians with a more structured deformation, maximizi ng the use of temporal relationships to tackle the challenging task of monocular dynamic 3D reconstruction. We also propose using a more reliable perceptual met ric as an alternative, given that pixel-level metrics for evaluating monocular d ynamic 3D reconstruction can sometimes fail to accurately reflect the true quali ty of reconstruction. Extensive experiments demonstrate our method's efficacy in achieving superior novel view synthesis from challenging monocular videos with complex motions.

GENIUS: A Generative Framework for Universal Multimodal Search
Sungyeon Kim, Xinliang Zhu, Xiaofan Lin, Muhammet Bastan, Douglas Gray, Suha Kwa k; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 19659-19669
Generative retrieval is an emerging approach in information retrieval that gener ates identifiers (IDs) of target data based on a query, providing an efficient a lternative to traditional embedding-based retrieval methods. However, existing m odels are task-specific and fall short of embedding-based retrieval in performan ce. This paper proposes GENIUS, a universal generative retrieval framework suppo rting diverse tasks across multiple modalities and domains. At its core, GENIUS introduces modality-decoupled semantic quantization, transforming multimodal dat a into discrete IDs encoding both modality and semantics. Moreover, to enhance g eneralization, we propose a query augmentation that interpolates between a query and its target, allowing GENIUS to adapt to varied query forms. Evaluated on th e M-BEIR benchmark, it surpasses prior generative methods by a clear margin. Unl ike embedding-based retrieval, GENIUS consistently maintains high retrieval spee d across database size, with competitive performance across multiple benchmarks. With additional re-ranking, GENIUS often achieves results close to those of emb edding-based methods while preserving efficiency.

Enhanced Visual-Semantic Interaction with Tailored Prompts for Pedestrian Attrib ute Recognition
Junyi Wu, Yan Huang, Min Gao, Yuzhen Niu, Yuzhong Chen, Qiang Wu; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 9570-9 579
Pedestrian attribute recognition (PAR) seeks to predict multiple semantic attrib utes associated with a specific pedestrian. There are two types of approaches fo r PAR: unimodal framework and bimodal framework. The former one is to seek a rob

ust visual feature. However, the lack of exploiting semantic feature of linguist ic modality is the main concern. The latter one utilizes prompt learning techniq ues to integrate linguistic data. However, static prompt templates and simple bi modal concatenation cannot to capture the extensive intra-class attribute variab ility and support active modalities collaboration. In this paper, we propose an Enhanced Visual-Semantic Interaction with Tailored Prompts (EVSITP) framework fo r PAR. We present an Image-Conditional Dual-Prompt Initialization Module (IDIM) to adaptively generate context-sensitive prompts from visual inputs. Subsequentl y, a Prompt Enhanced and Regularization Module (PERM) is proposed to strengthen linguistic information from IDIM. We further design a Bimodal Mutual Interaction Module (BMIM) to ensure bidirectional modalities communication. In addition, e xisting PAR datasets are collected over a short period in limited scenarios, whi ch do not align with real-world scenarios. Therefore, we annotate a long-term pe rson re-identification dataset to create a new PAR dataset, Celeb-PAR. Experimen ts on several challenging PAR datasets show that our method outperforms state-of -the-art approaches.

SF3D: Stable Fast 3D Mesh Reconstruction with UV-unwrapping and Illumination Dis entanglement

Mark Boss, Zixuan Huang, Aaryaman Vasishta, Varun Jampani; Proceedings of the Co mputer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 16240-16250

We present SF3D, a novel method for rapid and high-quality textured object mesh reconstruction from a single image in just 0.5 seconds. Unlike most existing app roaches, SF3D is explicitly trained for mesh generation, incorporating a fast UV unwrapping technique that enables swift texture generation rather than relying on vertex colors. The method also learns to predict material parameters and norm al maps to enhance the visual quality of the reconstructed 3D meshes. Furthermor e, SF3D integrates a delighting step to effectively remove low-frequency illumin ation effects, ensuring that the reconstructed meshes can be easily used in nove l illumination conditions. Experiments demonstrate the superior performance of S F3D over the existing techniques

HSI-GPT: A General-Purpose Large Scene-Motion-Language Model for Human Scene Int eraction

Yuan Wang, Yali Li, Xiang Li, Shengjin Wang; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 7147-7157

While flourishing developments have been witnessed in text-to-motion generation, synthesizing physically realistic, controllable, language-conditioned Human Sce ne Interactions (HSI) remains a relatively underexplored landscape. Current HSI methods naively rely on conditional Variational AutoEncoder (cVAE) and diffusion models. They are typically associated with limited modalities of control signal s and task-specific frameworks design, leading to inflexible adaptation across v arious interaction scenarios and descriptive-unfaithful motions in diverse 3D ph ysical environments. In this paper, we propose HSI-GPT, a General-Purpose Large Scene-Motion-Language Model that applies "next-token prediction" paradigm of Lar ge Language Models to the HSI domain. HSI-GPT not only exhibits remarkable flexi bility to accommodate diverse control signals (3D scenes, textual commands, key- frame poses, as well as scene affordances), but it seamlessly supports various H SI-related tasks (e.g., multi-modal controlled HSI generation, HSI understanding , and general motion completion in 3D scenes). First, HSI-GPT quantizes textual descriptions and human motions into discrete, LLM-interpretable tokens with mult i-modal tokenizers. Inspired by multi-modal learning, we develop a recipe for al igning mixed-modality tokens into the shared embedding space of LLMs. These inte raction tokens are then organized into unified instruction following prompts, al lowing HSI-GPT to fine-tune on question-and-answer tasks. Extensive experiments and visualizations validate that our general-purpose HSI-GPT model delivers exce ptional performance across multiple HSI-related tasks.

Towards Precise Embodied Dialogue Localization via Causality Guided Diffusion

Haoyu Wang, Le Wang, Sanping Zhou, Jingyi Tian, Zheng Qin, Yabing Wang, Gang Hua

, Wei Tang; Proceedings of the Computer Vision and Pattern Recognition Conferenc e (CVPR), 2025, pp. 13350-13360
Embodied localization based on vision and natural language dialogues presents a persistent challenge in embodied intelligence. Existing methods often approach t his task as an image translation problem, leveraging encoder-decoder architectur es to predict heatmaps. However, these methods frequently experience a deficienc y in accuracy, largely due to their heavy reliance on resolution. To address thi s issue, we introduce CGD, a novel framework that utilizes causality guided diff usion model to directly model coordinate distributions. Specifically, CGD employ s a denoising network to regress coordinates, while integrating causal learning modules, namely back-door adjustment (BDA) and front-door adjustment (FDA) to mi tigate confounders during the diffusion process. This approach reduces the depen dency on high resolution for improving accuracy, while effectively minimizing sp urious correlations, thereby promoting unbiased learning. By guiding the denoisi ng process with causal adjustments, CGD offers flexible control over intensity, ensuring seamless integration with diffusion models. Experimental results demons trate that CGD outperforms state-of-the-art methods across all metrics. Addition ally, we also evaluate CGD in a multi-shot setting, achieving consistently high accuracy.

Vid2Avatar-Pro: Authentic Avatar from Videos in the Wild via Universal Prior
Chen Guo, Junxuan Li, Yash Kant, Yaser Sheikh, Shunsuke Saito, Chen Cao; Proceed ings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 5559-5570
We present Vid2Avatar-Pro, a method to create photorealistic and animatable 3D h uman avatars from monocular in-the-wild videos. Building a high-quality avatar t hat supports animation with diverse poses from a monocular video is challenging because the observation of pose diversity and view points is inherently limited. The lack of pose variations typically leads to poor generalization to novel pos es, and avatars can easily overfit to limited input view points, producing artif acts and distortions from other views. In this work, we address these limitation s by leveraging a universal prior model (UPM) learned from a large corpus of mul ti-view clothed human performance capture data. We build our representation on t op of expressive 3D Gaussians with canonical front and back maps shared across i dentities. Once the UPM is learned to accurately reproduce the large-scale multi -view human images, we fine-tune the model with an in-the-wild video via inverse rendering to obtain a personalized photorealistic human avatar that can be fait hfully animated to novel human motions and rendered from novel views. The experi ments show that our approach based on the learned universal prior sets a new sta te-of-the-art in monocular avatar reconstruction by substantially outperforming existing approaches relying only on heuristic regularization or a shape prior of minimally clothed bodies (e.g., SMPL) on publicly available datasets.

RoomPainter: View-Integrated Diffusion for Consistent Indoor Scene Texturing
Zhipeng Huang, Wangbo Yu, Xinhua Cheng, Chengshu Zhao, Yunyang Ge, Mingyi Guo, L i Yuan, Yonghong Tian; Proceedings of the Computer Vision and Pattern Recognitio n Conference (CVPR), 2025, pp. 574-584
Indoor scene texture synthesis has garnered significant interest due to its impo rtant potential applications in virtual reality, digital media and creative arts . Existing diffusion-model-based researches either rely on per-view inpainting t echniques, which are plagued by severe cross-view inconsistencies and conspicuou s seams, or adopt optimization-based approaches that involve substantial computa tional overhead. In this work, we present **RoomPainter**, a framework that seam lessly integrates efficiency and consistency to achieve high-fidelity texturing of indoor scenes. The core of RoomPainter features a zero-shot technique that ef fectively adapts a 2D diffusion model for 3D-consistent texture synthesis, along with a two-stage generation strategy that ensures both global and local consist ency. Specifically, we introduce Attention-Guided Multi-View Integrated Sampling (**MVIS**) combined with a neighbor-integrated attention mechanism for zero-sho t texture map generation. Using the **MVIS**, we firstly generate texture map fo

r the entire room to ensure global consistency, then adopt its variant, namely A ttention-Guided Multi-View Integrated Repaint Sampling (**MVRS**) to repaint ind ividual instances within the room, thereby further enhancing local consistency a nd addressing the occlusion problem. Experiments demonstrate that RoomPainter ac hieves superior performance for indoor scene texture synthesis in visual quality , global consistency and generation efficiency.

Attribute-formed Class-specific Concept Space: Endowing Language Bottleneck Mode l with Better Interpretability and Scalability
Jianyang Zhang, Qianli Luo, Guowu Yang, Wenjing Yang, Weide Liu, Guosheng Lin, F engmao Lv; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 30291-30300
Language Bottleneck Models (LBMs) are proposed to achieve interpretable image re cognition by classifying images based on textual concept bottlenecks. However, c urrent LBMs simply list all concepts together as the bottleneck layer, leading t o the spurious cue inference problem and cannot generalized to unseen classes. T o address these limitations, we propose the Attribute-formed Language Bottleneck Model (ALBM). ALBM organizes concepts in the attribute-formed class-specific sp ace, where concepts are descriptions of specific attributes for specific classes . In this way, ALBM can avoid the spurious cue inference problem by classifying solely based on the essential concepts of each class. In addition, the cross-cla ss unified attribute set also ensures that the concept spaces of different class es have strong correlations, as a result, the learned concept classifier can be easily generalized to unseen classes. Moreover, to further improve interpretabil ity, we propose Visual Attribute Prompt Learning (VAPL) to extract visual featur es on fine-grained attributes. Furthermore, to avoid labor-intensive concept ann otation, we propose the Description, Summary, and Supplement (DSS) strategy to a utomatically generate high-quality concept sets with a complete and precise attr ibute. Extensive experiments on 9 widely used few-shot benchmarks demonstrate th e interpretability, transferability, and performance of our approach. The code a nd collected concept sets are available at https://github.com/tiggers23/ALBM.

Customized Condition Controllable Generation for Video Soundtrack
Fan Qi, Kunsheng Ma, Changsheng Xu; Proceedings of the Computer Vision and Patte rn Recognition Conference (CVPR), 2025, pp. 23914-23924
Recent advances in latent diffusion models (LDMs) have enabled data-driven parad igms for video soundtrack generation, improving multimodal alignment capabilitie s. However, current two-stage frameworks--which separately optimize audio-visual correspondence and conditional audio synthesis--fundamentally limit joint model ing of dynamic acoustic properties. In this paper, we propose a novel framework for generating video soundtracks that simultaneously produces music and sound ef fect tailored to the video content. Our method incorporates a Contrastive Visual -Sound-Music pretraining process that maps these modalities into a unified featu re space, enhancing the model's ability to capture intricate audio dynamics. We design Spectrum Divergence Masked Attention for Unet to differentiate between th e unique characteristics of sound effect and music. We utilize Score-guided Nois e Iterative Optimization to provide musicians with customizable control during t he generation process. Extensive evaluations on the FilmScoreDB and SymMV&HIMV d atasets demonstrate that our approach significantly outperforms state-of-the-art baselines in both subjective and objective assessments, highlighting its potent ial as a robust tool for video soundtrack generation.

ProjAttacker: A Configurable Physical Adversarial Attack for Face Recognition vi a Projector
Yuanwei Liu, Hui Wei, Chengyu Jia, Ruqi Xiao, Weijian Ruan, Xingxing Wei, Joey T ianyi Zhou, Zheng Wang; Proceedings of the Computer Vision and Pattern Recogniti on Conference (CVPR), 2025, pp. 21248-21257
Previous physical adversarial attacks have shown that carefully crafted perturba tions can deceive face recognition systems, revealing critical security vulnerab ilities. However, these attacks often struggle to impersonate multiple targets a

nd frequently fail to bypass liveness detection. For example, attacks using huma n-skin masks are challenging to fabricate, inconvenient to swap between users, a nd often fail liveness detection due to facial occlusions. A projector, however, can generate content-rich light without obstructing the face, making it ideal f or non-intrusive attacks. Thus, we propose a novel physical adversarial attack u sing a projector and explore the superposition of projected and natural light to create adversarial facial images. This approach eliminates the need for physica l artifacts on the face, effectively overcoming these limitations. Specifically, our proposed ProjAttacker generates adversarial 3D textures that are projected onto human faces. To ensure physical realizability, we introduce a light reflect ion function that models complex optical interactions between projected light an d human skin, accounting for reflection and diffraction effects. Furthermore, we incorporate camera Image Signal Processing (ISP) simulation to maintain the rob ustness of adversarial perturbations across real-world diverse imaging condition s. Comprehensive evaluations conducted in both digital and physical scenarios va lidate the effectiveness of our method.

EfficientViM: Efficient Vision Mamba with Hidden State Mixer based State Space D uality

Sanghyeok Lee, Joonmyung Choi, Hyunwoo J. Kim; Proceedings of the Computer Visio n and Pattern Recognition Conference (CVPR), 2025, pp. 14923-14933

For the deployment of neural networks in resource-constrained environments, prio r works have built lightweight architectures with convolution and attention for capturing local and global dependencies, respectively. Recently, the state space model (SSM) has emerged as an effective operation for global interaction with i ts favorable linear computational cost in the number of tokens. To harness the e fficacy of SSM, we introduce Efficient Vision Mamba (EfficientViM), a novel arch itecture built on hidden state mixer-based state space duality (HSM-SSD) that ef ficiently captures global dependencies with further reduced computational cost. With the observation that the runtime of the SSD layer is driven by the linear p rojections on the input sequences, we redesign the original SSD layer to perform the channel mixing operation within compressed hidden states in the HSM-SSD lay er. Additionally, we propose multi-stage hidden state fusion to reinforce the re presentation power of hidden states and provide the design to alleviate the bott leneck caused by the memory-bound operations. As a result, the EfficientViM fami ly achieves a new state-of-the-art speed-accuracy trade-off on ImageNet-1k, offe ring up to a 0.7% performance improvement over the second-best model SHViT with faster speed. Further, we observe significant improvements in throughput and acc uracy compared to prior works, when scaling images or employing distillation tra ining. Code is available at https://github.com/mlvlab/EfficientViM.

A4A: Adapter for Adapter Transfer via All-for-All Mapping for Cross-Architecture Models

Keyu Tu, Mengqi Huang, Zhuowei Chen, Zhendong Mao; Proceedings of the Computer V ision and Pattern Recognition Conference (CVPR), 2025, pp. 18476-18485

Large-scale text-to-image models evolve rapidly in size and architecture. The ex isting adapters struggle to keep pace with these models, requiring extensive ret raining. This paper proposes a novel adapter transfer framework, A4A (Adapter fo r Adapter), which uses an all-for-all mapping approach to seamlessly transfer at tention-based adapters across different model architectures (e.g., U-Net to tran sformer). The framework consists of Coupling Space Projection and Upgraded Space Mapping. During Coupling Space Projection, all attention features of the pretra ined adapter are aggregated to fully capture the coupling relationship before be ing projected into a unified space. The unified space maintains coupling feature s in a consistent dimension, effectively and efficiently addressing feature scal e discrepancies arising from the base model's architecture. In the Upgraded Spac e Mapping Module, randomly initialized learnable features are introduced to conn ect the unified and upgraded spaces by integrating reference features via the at tention mechanism. The learned features are adaptively injected into the upgrade model through the Alignment module, which bridges the discrepancies between the

models using the all-for-all mapping. Experimental results on personalized image generation tasks demonstrate that A4A outperforms previous methods in transferring adapters while being the first to achieve adapter transfer across model architectures.

ViCaS: A Dataset for Combining Holistic and Pixel-level Video Understanding using Captions with Grounded Segmentation

Ali Athar, Xueqing Deng, Liang-Chieh Chen; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 19023-19035

Recent advances in multimodal large language models (MLLMs) have expanded research in video understanding, primarily focusing on high-level tasks such as video captioning and question-answering. Meanwhile, a smaller body of work addresses dense, pixel-precise segmentation tasks, which typically involve category-guided or referral-based object segmentation. Although both research directions are essential for developing models with human-level video comprehension, they have largely evolved separately, with distinct benchmarks and architectures. This paper aims to unify these efforts by introducing ViCaS, a new dataset containing thousands of challenging videos, each annotated with detailed, human-written captions and temporally consistent, pixel-accurate masks for multiple objects with phrase grounding. Our benchmark evaluates models on both holistic/high-level understanding and language-guided, pixel-precise segmentation. We also present carefully validated evaluation measures and propose an effective model architecture that can tackle our benchmark. Project page: https://ali2500.github.io/vicas-project/

A Universal Scale-Adaptive Deformable Transformer for Image Restoration across Diverse Artifacts

Xuyi He, Yuhui Quan, Ruotao Xu, Hui Ji; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 12731-12741

Structured artifacts are semi-regular, repetitive patterns that closely intertwine with genuine image content, making their removal highly challenging. In this paper, we introduce the Scale-Adaptive Deformable Transformer, an network architecture specifically designed to eliminate such artifacts from images. The proposed network features two key components: a scale-enhanced deformable convolution module for modeling scale-varying patterns with abundant orientations and potential distortions, and a scale-adaptive deformable attention mechanism for capturing long-range relationships among repetitive patterns with different sizes and non-uniform spatial distributions. Extensive experiments show that our network consistently outperforms state-of-the-art methods in diverse artifact removal tasks, including image deraining, image demoireing, and image debanding.

****

WISE: A Framework for Gigapixel Whole-Slide-Image Lossless Compression

Yu Mao, Jun Wang, Nan Guan, Chun Jason Xue; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 29342-29351

Whole-Slide Images (WSIs) have revolutionized medical analysis by presenting high-resolution images of the whole tissue slide. Despite avoiding the physical storage of the slides, WSIs require considerable data volume, which makes the storage and maintenance of WSI records costly and unsustainable. To this end, this work presents the first investigation of lossless compression of WSI images. Interestingly, we find that most existing compression methods fail to compress the WSI images effectively. Furthermore, our analysis reveals that the failure of existing compressors is mainly due to information irregularity in WSI images. To resolve this issue, we develop a simple yet effective lossless compressor called WISE, specifically designed for WSI images. WISE employs a hierarchical encoding strategy to extract effective bits, reducing the entropy of the image and then adopting a dictionary-based method to handle the irregular frequency patterns. Through extensive experiments, we show that WISE can effectively compress the gigapixel WSI images to 36 times on average and up to 136 times.

Gromov-Wasserstein Problem with Cyclic Symmetry

Shoichiro Takeda, Yasunori Akagi; Proceedings of the Computer Vision and Pattern

Recognition Conference (CVPR), 2025, pp. 21011-21020
We propose novel fast algorithms for the Gromov--Wasserstein problem (GW) with cyclic symmetry of input data. This problem naturally appears as an object-matching task, which underlies various real-world computer vision applications, e.g., image registration, point cloud registration, stereo matching, and 3D reconstruction. Gradient-based algorithms have been widely used to solve GW, and our main idea is to utilize the following remarkable property that emerges in GW with cyclic symmetry: By setting the initial solution to have cyclic symmetry, all intermediate solutions and matrices that appear in the gradient-based algorithms have the same cyclic symmetry until convergence. Based on this property, our gradient-based algorithms restrict the solution space to have cyclic symmetry and update only one symmetric part of solutions and matrices at each iteration, resulting in faster computation. Moreover, our algorithms solve the optimal transport problem at each iteration, which also exhibits cyclic symmetry. This problem can be solved efficiently, and as a result, our algorithms perform significantly faster. Experiments showed the effectiveness of our algorithms in synthetic and real-world data with strict and approximate cyclic symmetry.

IRIS: Inverse Rendering of Indoor Scenes from Low Dynamic Range Images
Chih-Hao Lin, Jia-Bin Huang, Zhengqin Li, Zhao Dong, Christian Richardt, Tuotuo Li, Michael Zollhöfer, Johannes Kopf, Shenlong Wang, Changil Kim; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 465-474
Inverse rendering seeks to recover 3D geometry, surface material, and lighting from captured images, enabling advanced applications such as novel-view synthesis, relighting, and virtual object insertion. However, most existing techniques rely on high dynamic range (HDR) images as input, limiting accessibility for general users. In response, we introduce IRIS, an inverse rendering framework that recovers the physically based material, spatially-varying HDR lighting, and camera response functions from multi-view, low-dynamic-range (LDR) images. By eliminating the dependence on HDR input, we make inverse rendering technology more accessible. We evaluate our approach on real-world and synthetic scenes and compare it with state-of-the-art methods. Our results show that IRIS effectively recovers HDR lighting, accurate material, and plausible camera response functions, supporting photorealistic relighting and object insertion.

SimAvatar: Simulation-Ready Avatars with Layered Hair and Clothing
Xueting Li, Ye Yuan, Shalini De Mello, Gilles Daviet, Jonathan Leaf, Miles Macklin, Jan Kautz, Umar Iqbal; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 26320-26330
We introduce SimAvatar, a framework designed to generate simulation-ready clothed 3D human avatars from a text prompt. Current text-driven human avatar generation methods either model hair, clothing and human body using a unified geometry or produce hair and garments that are not easily adaptable for simulation within existing graphics pipelines. The primary challenge lies in representing the hair and garment geometry in a way that allows leveraging established prior knowledge from foundational image diffusion models (e.g., Stable Diffusion) while being simulation-ready using either physics or neural simulators. To address this task, we propose a two-stage framework that combines the flexibility of 3D Gaussians with simulation-ready hair strands and garment meshes. Specifically, we first leverage two text-conditioned diffusion models to generate garment mesh and hair strands from the given text prompt. To leverage prior knowledge from foundational diffusion models, we attach 3D Gaussians to the body mesh, garment mesh, as well as hair strands and learn the avatar appearance through optimization. To drive the avatar given a pose sequence, we first apply physics simulators onto the garment meshes and hair strands. We then transfer the motion onto 3D Gaussians through carefully designed mechanism for different body parts. As a result, our synthesized avatars have vivid texture and realistic dynamic motion. To the best of our knowledge, our method is the first to produce highly realistic, fully simulation-ready 3D avatars, surpassing the capabilities of current approaches.

Test-Time Backdoor Detection for Object Detection Models
Hangtao Zhang, Yichen Wang, Shihui Yan, Chenyu Zhu, Ziqi Zhou, Linshan Hou, Shengshan Hu, Minghui Li, Yanjun Zhang, Leo Yu Zhang; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 24377-24386
Object detection models are vulnerable to backdoor attacks, where attackers poison a small subset of training samples by embedding a predefined trigger to manipulate prediction. Detecting poisoned samples (i.e., those containing triggers) at test time can prevent backdoor activation. However, unlike image classification tasks, the unique characteristics of object detection---particularly its output of numerous objects---pose fresh challenges for backdoor detection. The complex attack effects (e.g., "ghost" object emergence or "vanishing" object) further render current defenses fundamentally inadequate. To this end, we design TRAnsformation Consistency Evaluation (TRACE), a brand-new method for detecting poisoned samples at test time in object detection. Our journey begins with two intriguing observations: (1) poisoned samples exhibit significantly more consistent detection results than clean ones across varied backgrounds. (2) clean samples show higher detection consistency when introduced to different focal information. Based on these phenomena, TRACE applies foreground and background transformations to each test sample, then assesses transformation consistency by calculating the variance in objects confidences. TRACE achieves black-box, universal backdoor detection, with extensive experiments showing a 30% improvement in AUROC over state-of-the-art defenses and resistance to adaptive attacks.

Towards Precise Scaling Laws for Video Diffusion Transformers
Yuanyang Yin, Yaqi Zhao, Mingwu Zheng, Ke Lin, Jiarong Ou, Rui Chen, Victor Shea-Jay Huang, Jiahao Wang, Xin Tao, Pengfei Wan, Di Zhang, Baoqun Yin, Wentao Zhang, Kun Gai; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 18155-18165
Achieving optimal performance of video diffusion transformers within given data and compute budget is crucial due to their high training costs. This necessitates precisely determining the optimal model size and training hyperparameters before large-scale training. While scaling laws are employed in language models to predict performance, their existence and accurate derivation in visual generation models remain underexplored. In this paper, we systematically analyze scaling laws for video diffusion transformers and confirm their presence. Moreover, we discover that, unlike language models, video diffusion models are more sensitive to learning rate and batch size--two hyperparameters often not precisely modeled. To address this, we propose a new scaling law that predicts optimal hyperparameters for any model size and compute budget. Under these optimal settings, we achieve comparable performance and reduce inference costs by 40.1% compared to conventional scaling methods, within a compute budget of 1e10 TFlops. Furthermore, we establish a more generalized and precise relationship among validation loss, any model size, and compute budget. This enables performance prediction for non-optimal model sizes, which may also be appealed under practical inference cost constraints, achieving a better trade-off.
****
RoGSplat: Learning Robust Generalizable Human Gaussian Splatting from Sparse Multi-View Images
Junjin Xiao, Qing Zhang, Yonewei Nie, Lei Zhu, Wei-Shi Zheng; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 5980-5990
This paper presents RoGSplat, a novel approach for synthesizing high-fidelity novel views of unseen human from sparse multi-view images, while requiring no cumbersome per-subject optimization. Unlike previous methods that typically struggle with sparse views with few overlappings and are less effective in reconstructing complex human geometry, the proposed method enables robust reconstruction in such challenging conditions. Our key idea is to lift SMPL vertices to dense and reliable 3D prior points representing accurate human body geometry, and then regress human Gaussian parameters based on the points. To account for possible misalignment between SMPL model and images, we propose to predict image-aligned 3D pr

ior points by leveraging both pixel-level features and voxel-level features, fro m which we regress the coarse Gaussians. To enhance the ability to capture high- frequency details, we further render depth maps from the coarse 3D Gaussians to help regress fine-grained pixel-wise Gaussians. Experiments on several benchmark datasets demonstrate that our method outperforms state-of-the-art methods in no vel view synthesis and cross-dataset generalization. Our code is available at ht tps://github.com/iSEE-Laboratory/RoGSplat.

SDBF: Steep-Decision-Boundary Fingerprinting for Hard-Label Tampering Detection of DNN Models

Xiaofan Bai, Shixin Li, Xiaojing Ma, Bin Benjamin Zhu, Dongmei Zhang, Linchen Yu ; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 29278-29287

Cloud-based AI systems offer significant benefits but also introduce vulnerabili ties, making deep neural network (DNN) models susceptible to malicious tampering . This tampering may involve harmful behavior injection or resource reduction, c ompromising model integrity and performance. To detect model tampering, hard-lab el fingerprinting techniques generate sensitive samples to probe and reveal tamp ering. Existing fingerprinting methods are mainly based on gradient-defined sens itivity decision boundary, with the latter showing a manifest superior detection performance. However, all existing fingerprinting methods either suffer from in sufficient sensitivity or incur high computational costs. In this paper, we theo retically analyze the black-box co-optimal tampering detection sensitivity of fi ngerprint samples in the context of decision boundary and gradient-defined sensi tivity. Based on this, we further propose Steep-Decision-Boundary Fingerprinting (SDBF), a novel lightweight approach for hard-label tampering detection that in herently and efficiently combines the strengths of existing fingerprinting techn iques. SDBF places fingerprint samples near the steep decision boundary, where t he outputs of samples are inherently highly sensitive to tampering. We also desi gn a Max Boundary Coverage Strategy (MBCS), which enhances samples' diversity o ver the decision boundary. Theoretical analysis and extensive experimental resul ts show that SDBF outperforms existing SOTA hard-label fingerprinting methods in both sensitivity and efficiency.

EnliveningGS: Active Locomotion of 3DGS

Siyuan Shen, Tianjia Shao, Kun Zhou, Chenfanfu Jiang, Yin Yang; Proceedings of t he Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 896-905

This paper presents a novel pipeline named EnliveningGS, which enables active lo comotion of 3D models represented with 3D Gaussian splatting (3DGS). We are insp ired by the fact that real-world lives pose their bodies in a natural and physic ally meaningful manner by compressing or elongating muscle fibers embedded in th e body. EnliveningGS aims to replicate the similar functionality of 3DGS models so that the object within a 3DGS scene acts like a living creature rather than a static shape --- they walk, jump, and twist in the scene under provided motion trajectories driven by muscle activations. While the concept is straightforward, many challenging technical difficulties need to be taken care of. Synthesizing realistic locomotion of a 3DGS model embodies an inverse physics problem of very high dimensions. The core challenge is how to efficiently and robustly model fr ictional contacts between an "enlivened model" and the environment, as it is the composition of contact/collision/friction forces triggered by muscle activation that generates the final movement of the object. We propose a hybrid numerical method mixing LCP and penalty method to tackle this NP-hard problem robustly. Ou r pipeline also addresses the limitation of existing 3DGS deformation algorithms and inpainting the missing information when models move around.

SPMTrack: Spatio-Temporal Parameter-Efficient Fine-Tuning with Mixture of Expert s for Scalable Visual Tracking

Wenrui Cai, Qingjie Liu, Yunhong Wang; Proceedings of the Computer Vision and Pa ttern Recognition Conference (CVPR), 2025, pp. 16871-16881

Most state-of-the-art trackers adopt one-stream paradigm, using a single Vision

Transformer for joint feature extraction and relation modeling of template and s
earch region images. However, relation modeling between different image patches
exhibits significant variations. For instance, background regions dominated by t
arget-irrelevant information require reduced attention allocation, while foregro
und, particularly boundary areas, need to be be emphasized. A single model may n
ot effectively handle all kinds of relation modeling simultaneously. In this pap
er, we propose a novel tracker called SPMTrack based on mixture-of-experts tailo
red for visual tracking task (TMoE), combining the capability of multiple expert
s to handle diverse relation modeling more flexibly. Benefiting from TMoE, we ex
tend relation modeling from image pairs to spatio-temporal context, further impr
oving tracking accuracy with minimal increase in model parameters. Moreover, we
employ TMoE as a parameter-efficient fine-tuning method, substantially reducing
trainable parameters, which enables us to train SPMTrack of varying scales effic
iently and preserve the generalization ability of pretrained models to achieve s
uperior performance. We conduct experiments on seven datasets, and experimental
results demonstrate that our method significantly outperforms current state-of-t
he-art trackers. The source code is available at https://github.com/WenRuiCai/SP
MTrack.

AnyCam: Learning to Recover Camera Poses and Intrinsics from Casual Videos
Felix Wimbauer, Weirong Chen, Dominik Muhle, Christian Rupprecht, Daniel Cremers
; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR),
2025, pp. 16717-16727
Estimating camera motion and intrinsics from casual videos is a core challenge i
n computer vision. Traditional bundle-adjustment based methods, such as SfM and
SLAM, struggle to perform reliably on arbitrary data. Although specialized SfM a
pproaches have been developed for handling dynamic scenes, they either require i
ntrinsics or computationally expensive test-time optimization and often fall sho
rt in performance. Recently, methods like Dust3r have reformulated the SfM probl
em in a more data-driven way. While such techniques show promising results, they
 are still 1) not robust towards dynamic objects and 2) require labeled data for
 supervised training. As an alternative, we propose AnyCam, a fast transformer m
odel that directly estimates camera poses and intrinsics from a dynamic video se
quence in feed-forward fashion. Our intuition is that such a network can learn s
trong priors over realistic camera poses. To scale up our training, we rely on a
n uncertainty-based loss formulation and pre-trained depth and flow networks ins
tead of motion or trajectory supervision. This allows us to use diverse, unlabel
led video datasets obtained mostly from YouTube. Additionally, we ensure that th
e predicted trajectory does not accumulate drift over time through a lightweight
 trajectory refinement step. We test AnyCam on established datasets, where it de
livers accurate camera poses and intrinsics both qualitatively and quantitativel
y. Furthermore, even with trajectory refinement, AnyCam is significantly faster
than existing works for SfM in dynamic settings. Finally, by combining camera in
formation, uncertainty, and depth, our model can produce high-quality 4D pointcl
ouds. For more details and code, please check out our project page: https://fwmb
.github.io/anycam

Knowledge-Aligned Counterfactual-Enhancement Diffusion Perception for Unsupervis
ed Cross-Domain Visual Emotion Recognition
Wen Yin, Yong Wang, Guiduo Duan, Dongyang Zhang, Xin Hu, Yuan-Fang Li, Tao He; P
roceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 202
5, pp. 3888-3898
Visual Emotion Recognition (VER) is a critical yet challenging task aimed at inf
erring emotional states of individuals based on visual cues. However, existing
works focus on single domains, e.g., realistic images or stickers, limiting VER
models' cross-domain generalizability. To fill this gap, we introduce an Unsupe
rvised Cross-Domain Visual Emotion Recognition (UCDVER) task, which aims to gene
ralize visual emotion recognition from the source domain (e.g., realistic images
) to the low-resource target domain (e.g., stickers) in an unsupervised manner.
Compared to the conventional unsupervised domain adaptation problems, UCDVER pre

sents two key challenges: a significant emotional expression variability and an affective distribution shift. To mitigate these issues, we propose the Knowledge-aligned Counterfactual-enhancement Diffusion Perception (KCDP) framework. Specifically, KCDP leverages a VLM to align emotional representations in a shared knowledge space and guides diffusion models for improved visual affective perception. Furthermore, a Counterfactual-Enhanced Language-image Emotional Alignment (CLIEA) method generates high-quality pseudo-labels for the target domain. Extensive experiments demonstrate that our model surpasses SOTA models in both perceptibility and generalization, e.g., gaining 12% improvements over SOTA VER model TGCA-PVT.

Distilling Multi-modal Large Language Models for Autonomous Driving

Deepti Hegde, Rajeev Yasarla, Hong Cai, Shizhong Han, Apratim Bhattacharyya, Shweta Mahajan, Litian Liu, Risheek Garrepalli, Vishal M. Patel, Fatih Porikli; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 27575-27585

Autonomous driving demands safe motion planning, especially in critical "long-tail" scenarios. Recent end-to-end autonomous driving systems leverage large language models (LLMs) as planners to improve generalizability to rare events. However, using LLMs at test time introduces high computational costs. To address this, we propose DiMA, an end-to-end autonomous driving system that maintains the efficiency of an LLM-free (or vision-based) planner while leveraging the world knowledge of an LLM. DiMA distills the information from a multi-modal LLM to a vision-based end-to-end planner through a set of specially designed surrogate tasks. Under a joint training strategy, a scene encoder common to both networks produces structured representations that are semantically grounded as well as aligned to the final planning objective. Notably, the LLM is optional at inference, enabling robust planning without compromising on efficiency. Training with DiMA results in a 37% reduction in the L2 trajectory error and an 80% reduction in the collision rate of the vision-based planner, as well as a 44% trajectory error reduction in long-tail scenarios. \ours also achieves state-of-the-art performance on the nuScenes planning benchmark.

Pixel-aligned RGB-NIR Stereo Imaging and Dataset for Robot Vision

Jinnyeong Kim, Seung-Hwan Baek; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 11482-11492

Integrating RGB and NIR imaging provides complementary spectral information, enhancing robotic vision in challenging lighting conditions. However, existing datasets and imaging systems lack pixel-level alignment between RGB and NIR images, posing challenges for downstream tasks.In this paper, we develop a robotic vision system equipped with two pixel-aligned RGB-NIR stereo cameras and a LiDAR sensor mounted on a mobile robot. The system simultaneously captures RGB stereo images, NIR stereo images, and temporally synchronized LiDAR point cloud. Utilizing the mobility of the robot, we present a dataset containing continuous video frames with pixel-aligned RGB and NIR stereo pairs under diverse lighting conditions.We introduce two methods that utilize our pixel-aligned RGB-NIR images: an RGB-NIR image fusion method and a feature fusion method. The first approach enables existing RGB-pretrained vision models to directly utilize RGB-NIR information without fine-tuning. The second approach fine-tunes existing vision models to more effectively utilize RGB-NIR information.Experimental results demonstrate the effectiveness of using pixel-aligned RGB-NIR images across diverse lighting conditions.

Can Machines Understand Composition? Dataset and Benchmark for Photographic Image Composition Embedding and Understanding

Zhaoran Zhao, Peng Lu, Anran Zhang, Peipei Li, Xia Li, Xuannan Liu, Yang Hu, Shiyi Chen, Liwei Wang, Wenhao Guo; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 14411-14421

With the rapid growth of social media and digital photography, visually appealing images have become essential for effective communication and emotional engagem

ent. Among the factors influencing aesthetic appeal, composition--the arrangemen t of visual elements within a frame--plays a crucial role. In recent years, spec ialized models for photographic composition have achieved impressive results acr oss various aesthetic tasks. Meanwhile, rapidly advancing multimodal large langu age models (MLLMs) have excelled in several visual perception tasks. However, th eir ability to embed and understand compositional information remains underexplo red, primarily due to the lack of suitable evaluation datasets. To address this gap, we introduce the Photographic Image Composition Dataset (PICD), a large-sca le dataset consisting of 36,857 images categorized into 24 composition categorie s across 355 diverse scenes. We demonstrate the advantages of PICD over existing datasets in terms of data scale, composition category, label quality, and scene diversity. Building on PICD, we establish benchmarks to evaluate the compositio n embedding capabilities of specialized models and the compositional understandi ng ability of MLLMs. To enable efficient and effective evaluation, we propose a novel Composition Discrimination Accuracy (CDA) metric. Our evaluation highlight s the limitations of current models and provides insights into directions for im proving their ability to embed and understand composition.

LPOSS: Label Propagation Over Patches and Pixels for Open-vocabulary Semantic Se gmentation

Vladan Stojni■, Yannis Kalantidis, Ji■í Matas, Giorgos Tolias; Proceedings of th e Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 9794-9803

We propose a training-free method for open-vocabulary semantic segmentation usin g Vision-and-Language Models (VLMs). Our approach enhances the initial per-patch predictions of VLMs through label propagation, which jointly optimizes predicti ons by incorporating patch-to-patch relationships. Since VLMs are primarily opti mized for cross-modal alignment and not for intra-modal similarity, we use a Vis ion Model (VM) that is observed to better capture these relationships. We addres s resolution limitations inherent to patch-based encoders by applying label prop agation at the pixel level as a refinement step, significantly improving segment ation accuracy near class boundaries. Our method, called LPOSS+, performs infere nce over the entire image, avoiding window-based processing and thereby capturin g contextual interactions across the full image. LPOSS+ achieves state-of-the-ar t performance among training-free methods, across a diverse set of datasets. Cod e: https://github.com/vladan-stojnic/LPOSS

Towards Efficient Foundation Model for Zero-shot Amodal Segmentation

Zhaochen Liu, Limeng Qiao, Xiangxiang Chu, Lin Ma, Tingting Jiang; Proceedings o f the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 20254 -20264

Aiming to predict the complete shape of partially occluded objects, amodal segme ntation is an important capacity towards visual intelligence. In order to promot e the practicability, zero-shot foundation model competent for the open world ga ins growing attention in this field. Nevertheless, prior models exhibit deficien cies in efficiency and stability. To address this problem, utilizing the implici t prior knowledge, we propose the first SAM-based amodal segmentation foundation model, SAMBA. Methodologically, a novel framework with multilevel facilitation is designed to better adapt the task characteristics and unleash the potential c apabilities of SAM. In the modality level, a separation-to-fusion structure is e mployed that jointly learns modal and amodal segmentation to enhance mutual coor dination. In the instance level, to ease the complexity of amodal feature extrac tion, we introduce a principal focusing mechanism to indicate objects of interes t. In the pixel level, mixture-of-experts is incorporated with a specialized dis tribution loss, by which distinct occlusion rates correspond to different expert s to improve the accuracy. Experiments are conducted on several eminent datasets , and the results show that the performance of SAMBA is superior to existing zer o-shot and even supervised approaches. Furthermore, our proposed model has notab le advantages in terms of speed and size.

PhysGen3D: Crafting a Miniature Interactive World from a Single Image

Boyuan Chen, Hanxiao Jiang, Shaowei Liu, Saurabh Gupta, Yunzhu Li, Hao Zhao, She
nlong Wang; Proceedings of the Computer Vision and Pattern Recognition Conferenc
e (CVPR), 2025, pp. 6178-6189

Envisioning physically plausible outcomes from a single image requires a deep un
derstanding of the world's dynamics. To address this, we introduce MiniTwin, a n
ovel framework that transforms a single image into an amodal, camera-centric, in
teractive 3D scene. By combining advanced image-based geometric and semantic und
erstanding with physics-based simulation, MiniTwin creates an interactive 3D wor
ld from a static image, enabling us to "imagine" and simulate future scenarios b
ased on user input. At its core, MiniTwin estimates 3D shapes, poses, physical a
nd lighting properties of objects, thereby capturing essential physical attribut
es that drive realistic object interactions. This framework allows users to spec
ify precise initial conditions, such as object speed or material properties, for
 enhanced control over generated video outcomes. We evaluate MiniTwin's performa
nce against closed-source state-of-the-art (SOTA) image-to-video models, includi
ng Pika, Kling, and Gen-3, showing MiniTwin's capacity to generate videos with r
ealistic physics while offering greater flexibility and fine-grained control. Ou
r results show that MiniTwin achieves a unique balance of photorealism, physical
 plausibility, and user-driven interactivity, opening new possibilities for gene
rating dynamic, physics-grounded video from an image.

Docopilot: Improving Multimodal Models for Document-Level Understanding

Yuchen Duan, Zhe Chen, Yusong Hu, Weiyun Wang, Shenglong Ye, Botian Shi, Lewei L
u, Qibin Hou, Tong Lu, Hongsheng Li, Jifeng Dai, Wenhai Wang; Proceedings of the
 Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 4026-4037

Despite significant progress in multimodal large language models (MLLMs), their
 performance on complex, multi-page document comprehension remains inadequate, la
rgely due to the lack of high-quality, document-level datasets. While current re
trieval-augmented generation (RAG) methods offer partial solutions, they suffer
 from issues, such as fragmented retrieval contexts, multi-stage error accumulati
on, and extra time costs of retrieval. In this work, we present a high-quality d
ocument-level dataset, Doc-750K, designed to support in-depth understanding of m
ultimodal documents. This dataset includes diverse document structures, extensiv
e cross-page dependencies, and real question-answer pairs derived from the origi
nal documents. Building on the dataset, we develop a native multimodal model--Do
copilot, which can accurately handle document-level dependencies without relying
 on RAG. Experiments demonstrate that Docopilot achieves superior coherence, acc
uracy, and efficiency in document understanding tasks and multi-turn interaction
s, setting a new baseline for document-level multimodal understanding. Data, cod
e, and models are released at https://github.com/OpenGVLab/Docopilot.

Scaling Properties of Diffusion Models For Perceptual Tasks

Rahul Ravishankar, Zeeshan Patel, Jathushan Rajasegaran, Jitendra Malik; Proceed
ings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp.
 12945-12954

In this paper, we argue that iterative computation with diffusion models offers
 a powerful paradigm for not only generation but also visual perception tasks. We
 unify tasks such as depth estimation, optical flow, and amodal segmentation und
er the framework of image-to-image translation, and show how diffusion models be
nefit from scaling training and test-time compute for these perceptual tasks. Th
rough a careful analysis of these scaling properties, we formulate compute-optim
al training and inference recipes to scale diffusion models for visual perceptio
n tasks. Our models achieve competitive performance to state-of-the-art methods
using significantly less data and compute.

HD-EPIC: A Highly-Detailed Egocentric Video Dataset

Toby Perrett, Ahmad Darkhalil, Saptarshi Sinha, Omar Emara, Sam Pollard, Kranti
Kumar Parida, Kaiting Liu, Prajwal Gatti, Siddhant Bansal, Kevin Flanagan, Jacob
 Chalk, Zhifan Zhu, Rhodri Guerrier, Fahd Abdelazim, Bin Zhu, Davide Moltisanti,
 Michael Wray, Hazel Doughty, Dima Damen; Proceedings of the Computer Vision and

Pattern Recognition Conference (CVPR), 2025, pp. 23901-23913
We present a validation dataset of newly-collected kitchen based egocentric videos, manually annotated with highly detailed and interconnected ground-truth labels covering: recipe steps, fine-grained actions, ingredients with nutritional values, moving objects, and audio annotations. Importantly, all annotations are grounded in 3D through digital twinning of the scene, fixtures, object locations, and primed with gaze. Footage is collected from unscripted recordings in diverse home environments, making HD-EPIC the first dataset collected in-the-wild but with detailed annotations matching those in controlled lab environments. We show the potential of our highly-detailed annotations through a challenging VQA benchmark of 26K questions assessing capability to recognise recipes, ingredients, nutrition, fine-grained actions, 3D perception, object motion, and gaze direction. The powerful long-context Gemini Pro only achieves 37.0% on this benchmark, showcasing its difficulty and highlighting shortcomings in current VLMs. We additionally assess action recognition, sound recognition, and long-term video-object segmentation on HD-EPIC. HD-EPIC is 41 hours of video in 9 kitchens with digital twins of 404 kitchen fixtures, capturing 69 recipes, 59K fine-grained actions, 51K audio events, 20K object movements and 37K object masks lifted to 3D. On average, we have 263 annotations per min of our unscripted videos.
****

Exact: Exploring Space-Time Perceptive Clues for Weakly Supervised Satellite Image Time Series Semantic Segmentation
Hao Zhu, Yan Zhu, Jiayu Xiao, Tianxiang Xiao, Yike Ma, Yucheng Zhang, Feng Dai; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 14036-14045
Automated crop mapping through Satellite Image Time Series (SITS) has emerged as a crucial avenue for agricultural monitoring and management. However, due to the low resolution and unclear parcel boundaries, annotating pixel-level masks is exceptionally complex and time-consuming in SITS. This paper embraces the weakly supervised paradigm (i.e., only image-level categories available) to liberate the crop mapping task from the exhaustive annotation burden. The unique characteristics of SITS give rise to several challenges in weakly supervised learning: (1) noise perturbation from spatially neighboring regions, and (2) erroneous semantic bias from anomalous temporal periods. To address the above difficulties, we propose a novel method, termed exploring space-time perceptive clues (Exact). First, we introduce a set of spatial clues to explicitly capture the representative patterns of different crops from the most class-relative regions. Besides, we leverage the temporal-to-class interaction of the model to emphasize the contributions of pivotal clips, thereby enhancing the model perception for crop regions. Build upon the space-time perceptive clues, we derive the clue-based CAMs to effectively supervise the SITS segmentation network. Our method demonstrates impressive performance on various SITS benchmarks. Remarkably, the segmentation network trained on Exact-generated masks achieves 95% of its fully supervised performance, showing the bright promise of weakly supervised paradigm in crop mapping scenario.

Advancing Myopia To Holism: Fully Contrastive Language-Image Pre-training
Haicheng Wang, Chen Ju, Weixiong Lin, Shuai Xiao, Mengting Chen, Yixuan Huang, Chang Liu, Mingshuai Yao, Jinsong Lan, Ying Chen, Qingwen Liu, Yanfeng Wang; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 29791-29802
In rapidly evolving field of vision-language models (VLMs), contrastive language-image pre-training (CLIP) has made significant strides, becoming foundation for various downstream tasks. However, relying on one-to-one (image, text) contrastive paradigm to learn alignment from large-scale messy web data, CLIP faces a serious myopic dilemma, resulting in biases towards monotonous short texts and shallow visual expressivity. To overcome these issues, this paper advances CLIP into one novel holistic paradigm, by updating both diverse data and alignment optimization. To obtain colorful data with low cost, we use image-to-text captioning to generate multi-texts for each image, from multiple perspectives, granularitie

s, and hierarchies. Two gadgets are proposed to encourage textual diversity. To match such (image, multi-texts) pairs, we modify the CLIP image encoder into multi-branch, and propose multi-to-multi contrastive optimization for image-text part-to-part matching. As a result, diverse visual embeddings are learned for each image, bringing good interpretability and generalization. Extensive experiments and ablations across over ten benchmarks indicate that our holistic CLIP significantly outperforms existing myopic CLIP, including image-text retrieval, open-vocabulary classification, and dense visual tasks. Project page is available to further promote the prosperity of VLMs: https://voide1220.github.io/Holism/.

PolarFree: Polarization-based Reflection-Free Imaging
Mingde Yao, Menglu Wang, King-Man Tam, Lingen Li, Tianfan Xue, Jinwei Gu; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 10890-10899
Reflection removal is challenging due to complex light interactions, where reflections obscure important details and hinder scene understanding. Polarization naturally provides a powerful cue to distinguish between reflected and transmitted light, enabling more accurate reflection removal. However, existing methods often rely on small-scale or synthetic datasets, which fail to capture the diversity and complexity of real-world scenarios. To this end, we construct a large-scale dataset, PolaRGB, for Polarization-based reflection removal of RGB images, which enables us to train models that generalize effectively across a wide range of real-world scenarios. The PolaRGB dataset contains 6,500 well-aligned mixed-transmission image pairs, 8xlarger than existing polarization datasets, and is the first to include both RGB and polarization images captured across diverse indoor and outdoor environments with varying lighting conditions. Besides, to fully exploit the potential of polarization cues for reflection removal, we introduce PolarFree, which leverages diffusion process to generate reflection-free cues for accurate reflection removal. Extensive experiments show that PolarFree significantly enhances image clarity in challenging reflective scenarios, setting a new benchmark for polarized imaging and reflection removal. Code and dataset are available at https://github.com/mdyao/PolarFree.

H-MoRe: Learning Human-centric Motion Representation for Action Analysis
Zhanbo Huang, Xiaoming Liu, Yu Kong; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 22702-22713
In this paper, we propose H-MoRe, a novel pipeline for learning precise human-centric motion representation. Our approach dynamically preserves relevant human motion while filtering out background movement. Notably, unlike previous methods relying on fully supervised learning from synthetic data, H-MoRe learns directly from real-world scenarios in a self-supervised manner, incorporating both human pose and body shape information. Inspired by kinematics, H-MoRe represents absolute and relative movements of each body point in a matrix format that captures nuanced motion details, termed world-local flows. H-MoRe offers refined insights into human motion, which can be integrated seamlessly into various action-related applications. Experimental results demonstrate that H-MoRe brings substantial improvements across various downstream tasks, including gait recognition(CL@R1: +16.01%), action recognition(Acc@1: +8.92%), and video generation(FVD: -67.07%). Additionally, H-MoRe exhibits high inference efficiency (34 fps), making it suitable for most real-time scenarios. Models and code will be released upon publication.
****

Hierarchical Compact Clustering Attention (COCA) for Unsupervised Object-Centric Learning
Can Kucuksozen, Yucel Yemez; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 25388-25398
We propose the Compact Clustering Attention (COCA) layer, an effective building block that introduces a hierarchical strategy for object-centric representation learning, while solving the unsupervised object discovery task on single images. COCA is an attention-based clustering module capable of extracting object-centr

ic representations from multi-object scenes, when cascaded into a bottom-up hier archical network architecture, referred to as COCA-Net. At its core, COCA utiliz es a novel clustering algorithm that leverages the physical concept of compactne ss, to highlight distinct object centroids in a scene, providing a spatial induc tive bias. Thanks to this strategy, COCA-Net generates high-quality segmentation masks on both the decoder side and, notably, the encoder side of its pipeline. Additionally, COCA-Net is not bound by a predetermined number of object masks th at it generates and handles the segmentation of background elements better than its competitors. We demonstrate COCA-Net's segmentation performance on six widel y adopted datasets, achieving superior or competitive results against the state-of-the-art models across nine different evaluation metrics.

****

Effortless Active Labeling for Long-Term Test-Time Adaptation

Guowei Wang, Changxing Ding; Proceedings of the Computer Vision and Pattern Reco gnition Conference (CVPR), 2025, pp. 25633-25642

Long-term test-time adaptation (TTA) is a challenging task due to error accumula tion. Recent approaches tackle this issue by actively labeling a small proportio n of samples in each batch, yet the annotation burden quickly grows as the batch number increases. In this paper, we investigate how to achieve effortless activ e labeling so that a maximum of one sample is selected for annotation in each ba tch. First, we annotate the most valuable sample in each batch based on the sing le-step optimization perspective in the TTA context. In this scenario, the sampl es that border between the source- and target-domain data distributions are cons idered the most feasible for the model to learn in one iteration. Then, we intro duce an efficient strategy to identify these samples using feature perturbation. Second, we discover that the gradient magnitudes produced by the annotated and unannotated samples have significant variations. Therefore, we propose balancing their impact on model optimization using two dynamic weights. Extensive experim ents on the popular ImageNet-C, -R, -K, -A and PACS databases demonstrate that o ur approach consistently outperforms state-of-the-art methods with significantly lower annotation costs. Code is available at: \href https://github.com/flash18 03/EATTA https://github.com/flash1803/EATTA .

Leveraging Temporal Cues for Semi-Supervised Multi-View 3D Object Detection

Jinhyung Park, Navyata Sanghvi, Hiroki Adachi, Yoshihisa Shibata, Shawn Hunt, Sh inya Tanaka, Hironobu Fujiyoshi, Kris Kitani; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 27401-27412

While recent advancements in camera-based 3D object detection demonstrate remark able performance, they require thousands or even millions of human-annotated fra mes. This requirement significantly inhibits their deployment in various locatio ns and sensor configurations. To address this gap, we propose a performant semi-supervised framework that leverages unlabeled RGB-only driving sequences - data easily collected with cost-effective RGB cameras - to significantly improve temp oral, camera-only 3D detectors. We observe that the standard semi-supervised pse udo-labeling paradigm underperforms in this temporal, camera-only setting due to poor 3D localization of pseudo-labels. To address this, we train a single 3D de tector to handle RGB sequences both forward and backward in time, then ensemble both its forwards and backwards pseudo-labels for semi-supervised learning. We f urther improve the pseudo-label quality by leveraging 3D object tracking to infi ll missing detections and by eschewing simple confidence thresholding in favor o f using the auxiliary 2D detection head to filter 3D predictions. Finally, to en able the backbone to learn directly from the unlabeled data itself, we introduce an object-query conditioned masked reconstruction objective. Our framework demo nstrates remarkable performance improvement on large-scale autonomous driving da tasets nuScenes and nuPlan.

Self-supervised ControlNet with Spatio-Temporal Mamba for Real-world Video Super -resolution

Shijun Shi, Jing Xu, Lijing Lu, Zhihang Li, Kai Hu; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 7385-7395

Existing diffusion-based video super-resolution (VSR) methods are susceptible to introducing complex degradations and noticeable artifacts into high-resolution videos due to their inherent randomness. In this paper, we propose a noise-robust real-world VSR framework by incorporating self-supervised learning and Mamba into pre-trained latent diffusion models. To ensure content consistency across adjacent frames, we enhance the diffusion model with a global spatio-temporal attention mechanism using the Video State-Space block with a 3D Selective Scan module, which reinforces coherence at an affordable computational cost. To further reduce artifacts in generated details, we introduce a self-supervised ControlNet that leverages HR features as guidance and employs contrastive learning to extract degradation-insensitive features from LR videos. Finally, a three-stage training strategy based on a mixture of HR-LR videos is proposed to stabilize VSR training. The proposed Self-supervised ControlNet with Spatio-Temporal Continuous Mamba based VSR algorithm achieves superior perceptual quality than state-of-the-arts on real-world VSR benchmark datasets, validating the effectiveness of the proposed model design and training strategies.

LATTE-MV: Learning to Anticipate Table Tennis Hits from Monocular Videos

Daniel Etaat, Dvij Kalaria, Nima Rahmanian, S. Shankar Sastry; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 7115-7124

Physical agility is a necessary skill in competitive table tennis, but by no means sufficient. Champions excel in this fast-paced and highly dynamic environment by anticipating their opponent's intent - buying themselves the necessary time to react. In this work, we take one step towards designing such an anticipatory agent. Previous works have developed systems capable of real-time table tennis gameplay, though they often do not leverage anticipation. Among the works that forecast opponent actions, their approaches are limited by dataset size and variety. Our paper contributes (1) a scalable system for reconstructing monocular video of table tennis matches in 3D and (2) an uncertainty-aware controller that anticipates opponent actions. We demonstrate in simulation that our policy improves the ball return rate against high-speed hits from 49.9% to 59.0% as compared to a baseline non-anticipatory policy.

Logits DeConfusion with CLIP for Few-Shot Learning

Shuo Li, Fang Liu, Zehua Hao, Xinyi Wang, Lingling Li, Xu Liu, Puhua Chen, Wenping Ma; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 25411-25421

With its powerful visual-language alignment capability, CLIP performs well in zero-shot and few-shot learning tasks. However, we found in experiments that CLIP's logits suffer from serious inter-class confusion problems in downstream tasks, and the ambiguity between categories seriously affects the accuracy. To address this challenge, we propose a novel method called Logits DeConfusion, which effectively learns and eliminates inter-class confusion in logits by combining our Multi-level Adapter Fusion (MAF) module with our Inter-Class Deconfusion (ICD) module. Our MAF extracts features from different levels and fuses them uniformly to enhance feature representation. Our ICD learnably eliminates inter-class confusion in logits with a residual structure. Experimental results show that our method can significantly improve the classification performance and alleviate the inter-class confusion problem. The code is available at https://github.com/LiShuo1001/LDC.

Distilling Spatially-Heterogeneous Distortion Perception for Blind Image Quality Assessment

Xudong Li, Wenjie Nie, Yan Zhang, Runze Hu, Ke Li, Xiawu Zheng, Liujuan Cao; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 2344-2354

In the Blind Image Quality Assessment (BIQA) field, accurately assessing the quality of authentically distorted images presents a substantial challenge due to the diverse distortion types in natural settings. Existing state-of-the-art IQA methods mix a sequence of distortions into entire images to establish global dist

ortion priors, but are inadequate for authentic images with spatially varied dis tortions. To address this, we introduce a novel IQA framework that employs knowl edge distillation tailored to perceive spatially heterogeneous distortions, enha ncing quality-distortion awareness. Specifically, we introduce a novel Block-wis e Degradation Modelling approach that applies distinct distortions to different spatial blocks of an image, thereby expanding local distortion priors. Following this, we present a Block-wise Aggregation and Filtering module that enables fin e-grained attention to the quality information within different distortion areas of the image. Furthermore, to effectively capture the complex relationships bet ween distortions across different regions while preserving overall quality perce ption, we introduce Contrastive Knowledge Distillation to enhance the model's ab ility to discriminate between different types of distortions and Affinity Knowle dge Distillation to model the correlation among distortions in different regions . Extensive experiments on standard BIQA datasets demonstrate the effectiveness and competitiveness of the proposed method.

****

Pay Attention to the Foreground in Object-Centric Learning

Pinzhuo Tian, Shengjie Yang, Hang Yu, Alex Kot; Proceedings of the Computer Visi on and Pattern Recognition Conference (CVPR), 2025, pp. 30281-30290

The slot attention-based method is widely used in unsupervised object-centric le arning, aiming to decompose scenes into interpretable objects and associate them with slots. However, complex backgrounds in the real images can disrupt the mod el's focus, leading it to excessively segment background stuff into different re gions based on low-level information such as color or texture variations. As a r esult, the detailed segmentation of foreground objects, which requires shape or geometric information, is often neglected. To address this issue, we introduce a contrastive learning-based indicator designed to differentiate between foregro und and background. Integrating this indicator into the existing slot attention- based method enables the model to focus more on segmenting foreground objects wh ile minimizing background distractions. During the testing phase, we utilize a s pectral clustering mechanism to refine the results based on the similarity betwe en the slots. Experimental results show that incorporating our method with vario us state-of-the-art models significantly improves their performance on both simu lated data and real-world datasets. Furthermore, multiple sets of ablation exper iments confirm the effectiveness of each proposed component.

2DMamba: Efficient State Space Model for Image Representation with Applications on Giga-Pixel Whole Slide Image Classification

Jingwei Zhang, Anh Tien Nguyen, Xi Han, Vincent Quoc-Huy Trinh, Hong Qin, Dimitr is Samaras, Mahdi S. Hosseini; Proceedings of the Computer Vision and Pattern Re cognition Conference (CVPR), 2025, pp. 3583-3592

Efficiently modeling large 2D contexts is essential for various fields including Giga-Pixel Whole Slide Imaging (WSI) and remote sensing. Transformer-based mode ls offer high parallelism but face challenges due to their quadratic complexity for handling long sequences. Recently, Mamba introduced a selective State Space Model (SSM) with linear complexity and high parallelism, enabling effective and efficient modeling of wide context in 1D sequences. However, extending Mamba to vision tasks, which inherently involve 2D structures, results in spatial discrep ancies due to the limitations of 1D sequence processing. On the other hand, curr ent 2D SSMs inherently model 2D structures but they suffer from prohibitively sl ow computation due to the lack of efficient parallel algorithms. In this work, w e propose 2DMamba, a novel 2D selective SSM framework that incorporates the 2D s patial structure of images into Mamba, with a highly optimized hardware-aware op erator, adopting both spatial continuity and computational efficiency. We valida te the versatility of our approach on both WSIs and natural images. Extensive ex periments on 10 public datasets for WSI classification and survival analysis sho w that 2DMamba improves up to 2.48% in AUC, 3.11% in F1 score, 2.47% in accuracy and 5.52% in C-index. Additionally, integrating our method with VMamba for natu ral imaging yields 0.5 to 0.7 improvements in mIoU on the ADE20k semantic segmen tation dataset, and 0.2% accuracy improvement on ImageNet-1K classification data

set. Our code is available at https://github.com/AtlasAnalyticsLab/2DMamba.

Unboxed: Geometrically and Temporally Consistent Video Outpainting
Zhongrui Yu, Martina Megaro-Boldini, Robert W. Sumner, Abdelaziz Djelouah; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 7309-7319
Extending the field of view of video content beyond its original version has many applications: immersive viewing experience with VR devices, reformatting 4:3 legacy content to today's viewing conditions with wide screens, or simply extending vertically captured phone videos. Many existing works focus on synthesizing the video using generative models only. Despite promising results, this strategy seems at the moment limited in terms of quality. In this work, we address this problem using two key ideas: 3D supported outpainting for the static regions of the images, and leveraging pre-trained video diffusion model to ensure realistic and temporally coherent results, particularly for the dynamic parts. In the first stage, we iterate between image outpainting and updating the 3D scene representation - we use 3D Gaussian Splatting. Then we consider dynamic objects independently per frame and inpaint missing pixels. Finally, we propose a denoising scheme that allows to maintain known reliable regions and update the dynamic parts to obtain temporally realistic results.We achieve state-of-the-art video outpainting. This is validated quantitatively and through a user study. We are also able to extend the field of view largely beyond the limits reached by existing methods.

K-Sort Arena: Efficient and Reliable Benchmarking for Generative Models via K-wise Human Preferences
Zhikai Li, Xuewen Liu, Dongrong Joe Fu, Jianquan Li, Qingyi Gu, Kurt Keutzer, Zhen Dong; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 9131-9141
The rapid advancement of visual generative models necessitates efficient and reliable evaluation methods. Arena platform, which gathers user votes on model comparisons, can rank models with human preferences. However, traditional Arena methods, while established, require an excessive number of comparisons for ranking to converge and are vulnerable to preference noise in voting, suggesting the need for better approaches tailored to contemporary evaluation challenges. In this paper, we introduce K-Sort Arena, an efficient and reliable platform based on a key insight: images and videos possess higher perceptual intuitiveness than texts, enabling rapid evaluation of multiple samples simultaneously. Consequently, K-Sort Arena employs K-wise comparisons, allowing K models to engage in free-for-all competitions, which yield much richer information than pairwise comparisons. To enhance the robustness of the system, we leverage probabilistic modeling and Bayesian updating techniques. We propose an exploration-exploitation-based matchmaking strategy to facilitate more informative comparisons. In our experiments, K-Sort Arena exhibits 16.3xfaster convergence compared to the widely used ELO algorithm. To further validate the superiority and obtain a comprehensive leaderboard, we collect human feedback via crowdsourced evaluations of numerous cutting-edge text-to-image and text-to-video models. Thanks to its high efficiency, K-Sort Arena can continuously incorporate emerging models and update the leaderboard with minimal votes. Our project has undergone several months of internal testing and is now available online.

Seeking Consistent Flat Minima for Better Domain Generalization via Refining Loss Landscapes
Aodi Li, Liansheng Zhuang, Xiao Long, Minghong Yao, Shafei Wang; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 15349-15359
Domain generalization aims to learn a model from multiple training domains and generalize it to unseen test domains. Recent theory has shown that seeking the deep models, whose parameters lie in the flat minima of the loss landscape, can significantly reduce the out-of-domain generalization error. However, existing met

hods often neglect the consistency of loss landscapes in different domains, resu
lting in models that are not simultaneously in the optimal flat minima in all do
mains, which limits their generalization ability. To address this issue, this pa
per proposes an iterative Self-Feedback Training (SFT) framework to seek consist
ent flat minima that are shared across different domains by progressively refini
ng loss landscapes during training. It alternatively generates a feedback signal
 by measuring the inconsistency of loss landscapes in different domains and refi
nes these loss landscapes for greater consistency using this feedback signal. Be
nefiting from the consistency of the flat minima within these refined loss lands
capes, our SFT helps achieve better out-of-domain generalization. Extensive expe
riments on DomainBed demonstrate superior performances of SFT when compared to s
tate-of-the-art sharpness-aware methods and other prevalent DG baselines. On ave
rage across five DG benchmarks, SFT surpasses the sharpness-aware minimization b
y 2.6% with ResNet-50 and 1.5% with ViT-B/16, respectively.

MultimodalStudio: A Heterogeneous Sensor Dataset and Framework for Neural Render
ing across Multiple Imaging Modalities
Federico Lincetto, Gianluca Agresti, Mattia Rossi, Pietro Zanuttigh; Proceedings
 of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 109
64-10973
Neural Radiance Fields (NeRF) have shown impressive performances in the renderin
g of 3D scenes from arbitrary viewpoints. While RGB images are widely preferred
for training volume rendering models, the interest in other radiance modalities
is also growing. However, the capability of the underlying implicit neural model
s to learn and transfer information across heterogeneous imaging modalities has
seldom been explored, mostly due to the limited training data availability. For
this purpose, we present MultimodalStudio (MMS): it encompasses MMS-DATA and MMS
-FW. MMS-DATA is a multimodal multi-view dataset containing 32 scenes acquired w
ith 5 different imaging modalities: RGB, monochrome, near-infrared, polarization
 and multispectral. MMS-FW is a novel modular multimodal NeRF framework designed
 to handle multimodal raw data and able to support an arbitrary number of multi-
channel devices. Through extensive experiments, we demonstrate that MMS-FW train
ed on MMS-DATA can transfer information between different imaging modalities and
 produce higher quality renderings than using single modalities alone. We public
ly release the dataset and the framework, to promote the research on multimodal
volume rendering and beyond.

Dense-SfM: Structure from Motion with Dense Consistent Matching
JongMin Lee, Sungjoo Yoo; Proceedings of the Computer Vision and Pattern Recogni
tion Conference (CVPR), 2025, pp. 6404-6414
We present Dense-SfM, a novel Structure from Motion (SfM) framework designed for
 dense and accurate 3D reconstruction from multi-view images. Sparse keypoint ma
tching, which traditional SfM methods often rely on, limits both accuracy and po
int density, especially in texture-less areas. Dense-SfM addresses this limitati
on by integrating dense matching with a Gaussian Splatting (GS) based track exte
nsion which gives more consistent, longer feature tracks. To further improve rec
onstruction accuracy, Dense-SfM is equipped with a multi-view kernelized matchin
g module leveraging transformer and Gaussian Process architectures, for robust t
rack refinement across multi-views. Evaluations on the ETH3D and Texture-Poor Sf
M datasets show that Dense-SfM offers significant improvements in accuracy and d
ensity over state-of-the-art methods. Project page: https://icetea-cv.github.io/
densesfm/.

FluidNexus: 3D Fluid Reconstruction and Prediction from a Single Video
Yue Gao, Hong-Xing Yu, Bo Zhu, Jiajun Wu; Proceedings of the Computer Vision and
 Pattern Recognition Conference (CVPR), 2025, pp. 26091-26101
We study reconstructing and predicting 3D fluid appearance and velocity from a s
ingle video. Current methods require multi-view videos for fluid reconstruction.
 We present FluidNexus, a novel framework that bridges video generation and phys
ics simulation to tackle this task. Our key insight is to synthesize multiple no

vel-view videos as references for reconstruction. FluidNexus consists of two key components: (1) a novel-view video synthesizer that combines frame-wise view synthesis with video diffusion refinement for generating realistic videos, and (2) a physics-integrated particle representation coupling differentiable simulation and rendering to simultaneously facilitate 3D fluid reconstruction and prediction. To evaluate our approach, we collect two new real-world fluid datasets featuring textured backgrounds and object interactions. Our method enables dynamic novel view synthesis, future prediction, and interaction simulation from a single fluid video. Project website: https://yuegao.me/FluidNexus.

MuTri: Multi-view Tri-alignment for OCT to OCTA 3D Image Translation
Zhuangzhuang Chen, Hualiang Wang, Chubin Ou, Xiaomeng Li; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 20885-20894
Optical coherence tomography angiography (OCTA) shows its great importance in imaging microvascular networks by providing accurate 3D imaging of blood vessels, but it relies upon specialized sensors and expensive devices. For this reason, previous works show the potential to translate the readily available 3D Optical Coherence Tomography (OCT) images into 3D OCTA images. However, existing OCTA translation methods directly learn the mapping from the OCT domain to the OCTA domain in continuous and infinite space with guidance from only a single view, i.e., the OCTA project map, resulting in suboptimal results. To this end, we propose the multi-view Tri-alignment framework for OCT to OCTA 3D image translation in discrete and finite space, named MuTri. In the first stage, we pre-train two vector-quantized variational auto-encoder (VQVAE) by reconstructing 3D OCT and 3D OCTA data, providing semantic prior for subsequent multi-view guidances. In the second stage, our multi-view tri-alignment facilitates another VQVAE model to learn the mapping from the OCT domain to the OCTA domain in discrete and finite space. Specifically, a contrastive-inspired semantic alignment is proposed to maximize the mutual information with the pre-trained models from OCT and OCTA views, to facilitate codebook learning. Meanwhile, a vessel structure alignment is proposed to minimize the structure discrepancy with the pre-trained models from the OCTA project map view, benefiting from learning the detailed vessel structure information. We also collect the first large-scale dataset, namely, OCTA2024, which contains a pair of OCT and OCTA volumes from 846 subjects. Our codes and datasets are available at: https://github.com/xmed-lab/MuTri.

Sketchy Bounding-box Supervision for 3D Instance Segmentation
Qian Deng, Le Hui, Jin Xie, Jian Yang; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 8879-8888
Bounding box supervision has gained considerable attention in weakly supervised 3D instance segmentation. While this approach alleviates the need for extensive point-level annotations, obtaining accurate bounding boxes in practical applications remains challenging. To this end, we explore the inaccurate bounding box, named sketchy bounding box, which is imitated through perturbing ground truth bounding box by adding scaling, translation, and rotation. In this paper, we propose Sketchy-3DIS, a novel weakly 3D instance segmentation framework, which jointly learns pseudo labeler and segmentator to improve the performance under the sketchy bounding-box supervisions. Specifically, we first propose an adaptive box-to-point pseudo labeler that adaptively learns to assign points located in the overlapped parts between two sketchy bounding boxes to the correct instance, resulting in compact and pure pseudo instance labels. Then, we present a coarse-to-fine instance segmentator that first predicts coarse instances from the entire point cloud and then learns fine instances based on the region of coarse instances. Finally, by using the pseudo instance labels to supervise the instance segmentator, we can gradually generate high-quality instances through joint training. Extensive experiments show that our method achieves state-of-the-art performance on both the ScanNetV2 and S3DIS benchmarks, and even outperforms several fully supervised methods using sketchy bounding boxes. Code is available at https://github.com/dengq7/Sketchy-3DIS.

Image Quality Assessment: Investigating Causal Perceptual Effects with Abductive Counterfactual Inference

Wenhao Shen, Mingliang Zhou, Yu Chen, Xuekai Wei, Yong Feng, Huayan Pu, Weijia Jia; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 17990-17999

Existing full-reference image quality assessment (FR-IQA) methods often fail to capture the complex causal mechanisms that underlie human perceptual responses to image distortions, limiting their ability to generalize across diverse scenarios. In this paper, we propose an FR-IQA method based on abductive counterfactual inference to investigate the causal relationships between deep network features and perceptual distortions. First, we explore the causal effects of deep features on perception and integrate causal reasoning with feature comparison, constructing a model that effectively handles complex distortion types across different IQA scenarios. Second, the analysis of the perceptual causal correlations of our proposed method is independent of the backbone architecture and thus can be applied to a variety of deep networks. Through abductive counterfactual experiments, we validate the proposed causal relationships, confirming the model's superior perceptual relevance and interpretability of quality scores. The experimental results demonstrate the robustness and effectiveness of the method, providing competitive quality predictions across multiple benchmarks. The source code is available at https://anonymous.4open.science/r/DeepCausalQuality-25BC.

Pos3R: 6D Pose Estimation for Unseen Objects Made Easy

Weijian Deng, Dylan Campbell, Chunyi Sun, Jiahao Zhang, Shubham Kanitkar, Matt E. Shaffer, Stephen Gould; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 16818-16828

Foundation models have significantly reduced the need for task-specific training, while also enhancing generalizability. However, state-of-the-art 6D pose estimators either require further training with pose supervision or neglect advances obtainable from 3D foundation models. The latter is a missed opportunity, since these models are better equipped to predict 3D-consistent features, which are of significant utility for the pose estimation task. To address this gap, we propose Pos3R, a method for estimating the 6D pose of any object from a single RGB image, making extensive use of a 3D reconstruction foundation model and requiring no additional training. We identify template selection as a particular bottleneck for existing methods that is significantly alleviated by the use of a 3D model, which can more easily distinguish between template poses than a 2D model. Despite its simplicity, Pos3R achieves competitive performance on the Benchmark for 6D Object Pose Estimation (BOP), matching or surpassing existing refinement-free methods. Additionally, Pos3R integrates seamlessly with render-and-compare refinement techniques, demonstrating adaptability for high-precision applications.

DeformCL: Learning Deformable Centerline Representation for Vessel Extraction in 3D Medical Image

Ziwei Zhao, Zhixing Zhang, Yuhang Liu, Zhao Zhang, Haojun Yu, Dong Wang, Liwei Wang; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 30896-30905

In the field of 3D medical imaging, accurately extracting and representing the blood vessels with curvilinear structures holds paramount importance for clinical diagnosis. Previous methods have commonly relied on discrete representation like mask, often resulting in local fractures or scattered fragments due to the inherent limitations of the per-pixel classification paradigm. In this work, we introduce DeformCL, a new continuous representation based on Deformable Centerlines, where centerline points act as nodes connected by edges that capture spatial relationships. Compared with previous representations, DeformCL offers three key advantages: natural connectivity, noise robustness, and interaction facility. We present a comprehensive training pipeline structured in a cascaded manner to fully exploit these favorable properties of DeformCL. Extensive experiments on four 3D vessel segmentation datasets demonstrate the effectiveness and superiority of our method. Furthermore, the visualization of curved planar reformation image

s validates the clinical significance of the proposed framework.

OCRT: Boosting Foundation Models in the Open World with Object-Concept-Relation Triad
Luyao Tang, Yuxuan Yuan, Chaoqi Chen, Zeyu Zhang, Yue Huang, Kun Zhang; Proceedi ngs of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 25422-25433
Although foundation models (FMs) claim to be powerful, their generalization abil ity significantly decreases when faced with distribution shifts, weak supervisio n, or malicious attacks in the open world. On the other hand, most domain genera lization or adversarial fine-tuning methods are task-related or model-specific, ignoring the universality in practical applications and the transferability betw een FMs. This paper delves into the problem of generalizing FMs to the out-of-do main data. We propose a novel framework, Object-Concept-Relation Triad (OCRT), t hat enables FMs to extract sparse, high-level concepts and intricate relational structures from raw visual inputs. The key idea is to bind objects in visual sce nes and a set of object-centric representations through unsupervised decoupling and iterative refinement. To be specific, we project the object-centric represen tations onto a semantic concept space that the model can readily interpret, and estimate their importance to filter out irrelevant elements. Then, a concept-bas ed graph, which has a flexible degree, is constructed to incorporate the set of concepts and their corresponding importance, enabling the extraction of high-ord er factors from informative concepts and facilitating relational reasoning among these concepts. Extensive experiments demonstrate that OCRT can substantially b oost the generalizability and robustness of SAM and CLIP across multiple downstr eam tasks.

SPARS3R: Semantic Prior Alignment and Regularization for Sparse 3D Reconstructio n
Yutao Tang, Yuxiang Guo, Deming Li, Cheng Peng; Proceedings of the Computer Visi on and Pattern Recognition Conference (CVPR), 2025, pp. 26810-26821
Recent efforts in Gaussian-Splat-based Novel View Synthesis can achieve photorea listic rendering; however, such capability is limited in sparse-view scenarios d ue to sparse initialization and over-fitting floaters. Recent progress in depth estimation and alignment can provide dense point cloud using few views; however, the resulting pose accuracy is suboptimal. In this work, we present SPARS3R, wh ich combines the advantages of accurate pose estimation from Structure-from-Moti on and dense point cloud from depth estimation. To this end, SPARS3R first perfo rms a Global Fusion Alignment process that maps a prior dense point cloud to a s parse point cloud from Structure-from-Motion based on triangulated correspondenc es. RANSAC is applied during this process to distinguish inliers and outliers. S

PARS3R then performs a second, Semantic Outlier Alignment step, which extracts s
emantically coherent regions around the outliers and performs local alignment in
 these regions. Along with several improvements in the evaluation process, we de
monstrate that SPARS3R can achieve photorealistic rendering with sparse images a
nd significantly outperforms existing approaches.

VidBot: Learning Generalizable 3D Actions from In-the-Wild 2D Human Videos for Z
ero-Shot Robotic Manipulation
Hanzhi Chen, Boyang Sun, Anran Zhang, Marc Pollefeys, Stefan Leutenegger; Procee
dings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp
. 27661-27672
Future robots are envisioned as versatile systems capable of performing a variet
y of household tasks. The big question remains, how can we bridge the embodiment
 gap while minimizing physical robot learning, which fundamentally does not scal
e well. We argue that learning from in-the-wild human videos offers a promising
solution for robotic manipulation tasks, as vast amounts of relevant data alread
y exist on the internet. In this work, we present VidBot, a framework enabling z
ero-shot robotic manipulation using learned 3D affordance from in-the-wild monoc
ular RGB-only human videos. VidBot leverages a pipeline to extract explicit repr
esentations from them, namely 3D hand trajectories from videos, combining a dept
h foundation model with structure-from-motion techniques to reconstruct temporal
ly consistent, metric-scale 3D affordance representations agnostic to embodiment
s. We introduce a coarse-to-fine affordance learning model that first identifies
 coarse actions from the pixel space and then generates fine-grained interaction
 trajectories with a diffusion model, conditioned on coarse actions and guided b
y test-time constraints for context-aware interaction planning, enabling substan
tial generalization to novel scenes and embodiments. Extensive experiments demon
strate the efficacy of VidBot, which significantly outperforms counterparts acro
ss 13 manipulation tasks in zero-shot settings and can be seamlessly deployed ac
ross robot systems in real-world environments. VidBot paves the way for leveragi
ng everyday human videos to make robot learning more scalable.

Learning Person-Specific Animatable Face Models from In-the-Wild Images via a Sh
ared Base Model
Yuxiang Mao, Zhenfeng Fan, ZhiJie Zhang, Zhiheng Zhang, Shihong Xia; Proceedings
 of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 560
2-5613
Training a generic 3D face reconstruction model in a self-supervised manner usin
g large-scale, in-the-wild 2D face image datasets enhances robustness to varying
 lighting conditions and occlusions while allowing the model to capture animatab
le wrinkle details across diverse facial expressions. However, a generic model o
ften fails to adequately represent the unique characteristics of specific indivi
duals. In this paper, we propose a method to train a generic base model and then
 transfer it to yield person-specific models by integrating lightweight adapters
 within the large-parameter ViT-MAE base model. These person-specific models exc
el at capturing individual facial shapes and detailed features while preserving
the robustness and prior knowledge of detail variations from the base model. Dur
ing training, we introduce a silhouette vertex re-projection loss to address bou
ndary "landmark marching" issues on the 3D face caused by pose variations. Addit
ionally, we employ an innovative teacher-student loss to leverage the inherent s
trengths of UNet in feature boundary localization for training our detail MAE. Q
uantitative and qualitative experiments demonstrate that our approach achieves s
tate-of-the-art performance in face alignment, detail accuracy, and richness. Th
e source code is available at https://github.com/danielmao2000/person-specific-a
nimatable-face.

TIMotion: Temporal and Interactive Framework for Efficient Human-Human Motion Ge
neration
Yabiao Wang, Shuo Wang, Jiangning Zhang, Ke Fan, Jiafu Wu, Zhucun Xue, Yong Liu;
 Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2

025, pp. 7169-7178
Human-human motion generation is essential for understanding humans as social beings. Current methods fall into two main categories: single-person-based methods and separate modeling-based methods. To delve into this field, we abstract the overall generation process into a general framework MetaMotion, which consists of two phases: temporal modeling and interaction mixing. For temporal modeling, the single-person-based methods concatenate two people into a single one directly, while the separate modeling-based methods skip the modeling of interaction sequences. The inadequate modeling described above resulted in sub-optimal performance and redundant model parameters. In this paper, we introduce TIMotion (Temporal and Interactive Modeling), an efficient and effective framework for human-human motion generation. Specifically, we first propose Causal Interactive Injection to model two separate sequences as a causal sequence leveraging the temporal and causal properties. Then we present Role-Evolving Scanning to adjust to the change in the active and passive roles throughout the interaction. Finally, to generate smoother and more rational motion, we design Localized Pattern Amplification to capture short-term motion patterns.Extensive experiments on InterHuman and InterX demonstrate that our method achieves superior performance.

Which Viewpoint Shows it Best? Language for Weakly Supervising View Selection in Multi-view Instructional Videos
Sagnik Majumder, Tushar Nagarajan, Ziad Al-Halah, Reina Pradhan, Kristen Grauman; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 29016-29028
Given a multi-view video, which viewpoint is most informative for a human observer? Existing methods rely on heuristics or expensive "best-view" supervision to answer this question, limiting their applicability. We propose a weakly supervised approach that leverages language accompanying an instructional multi-view video as a means to recover its most informative viewpoint(s). Our key hypothesis is that the more accurately an individual view can predict a view-agnostic text summary, the more informative it is. To put this into action, we propose LangView, a framework that uses the relative accuracy of view dependent caption predictions as a proxy for best view pseudo-labels. Then, those pseudo-labels are used to train a view selector, together with an auxiliary camera pose predictor that enhances view-sensitivity. During inference, our model takes as input only a multi-view video--no language or camera poses--and returns the best viewpoint to watch at each timestep. On two challenging datasets comprised of diverse multi-camera setups and how-to activities, our model consistently outperforms state-of-the-art baselines, both with quantitative metrics and human evaluation. Project: https://vision.cs.utexas.edu/projects/which-view-shows-it-best.

RaCFormer: Towards High-Quality 3D Object Detection via Query-based Radar-Camera Fusion
Xiaomeng Chu, Jiajun Deng, Guoliang You, Yifan Duan, Houqiang Li, Yanyong Zhang; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 17081-17091
We propose Radar-Camera fusion transformer (RaCFormer) to boost the accuracy of 3D object detection by the following insight. The Radar-Camera fusion in outdoor 3D scene perception is capped by the image-to-BEV transformation-if the depth of pixels is not accurately estimated, the naive combination of BEV features actually integrates unaligned visual content. To avoid this problem, we propose a query-based framework that enables adaptive sampling of instance-relevant features from both the bird's-eye view (BEV) and the original image view. Furthermore, we enhance system performance by two key designs: optimizing query initialization and strengthening the representational capacity of BEV. For the former, we introduce an adaptive circular distribution in polar coordinates to refine the initialization of object queries, allowing for a distance-based adjustment of query density. For the latter, we initially incorporate a radar-guided depth head to refine the transformation from image view to BEV. Subsequently, we focus on leveraging the Doppler effect of radar and introduce an implicit dynamic catcher to ca

pture the temporal elements within the BEV. Extensive experiments on nuScenes an
d View-of-Delft (VoD) datasets validate the merits of our design. Remarkably, ou
r method achieves superior results of 64.9% mAP and 70.2% NDS on nuScenes. RaCFo
rmer also secures the state-of-the-art performance on the VoD dataset. Code is a
vailable at https://github.com/cxmomo/RaCFormer.

Hybrid Reciprocal Transformer with Triplet Feature Alignment for Scene Graph Gen
eration
Jiawei Fu, Tiantian Zhang, Kai Chen, Qi Dou; Proceedings of the Computer Vision
and Pattern Recognition Conference (CVPR), 2025, pp. 8953-8963
Scene graph generation is a pivotal task in computer vision, focusing on compreh
ensive identification of visual relation tuples embedded within images. The adva
ncement of methods involving triplets has sought to enhance task performance by
integrating triplets as contextual features for more precise predicate identific
ation from component level. However, challenges remain due to interference from
multi-role objects in overlapping tuples within complex environments, which impa
irs the model's ability to distinguish and align specific triplet features for r
easoning diverse semantics of multi-role objects. To address these issues, we in
troduce a novel framework that incorporates a triplet alignment model into a hyb
rid reciprocal transformer architecture, starting from using triplet mask featur
es to guide the learning of component-level relation graphs. To effectively dist
inguish multi-role objects characterized by overlapping visual relation tuples,
we introduce a triplet alignment loss, which provides multi-role objects with al
igned features from triplet and helps customize them. Additionally, we explore t
he inherent connectivity between hybrid aligned triplet and component features t
hrough a bidirectional refinement module, which enhances feature interaction and
 reciprocal reinforcement. Experimental results demonstrate that our model achie
ves state-of-the-art performance on the Visual Genome and Action Genome datasets
, underscoring its effectiveness and adaptability. Project page: hq-sg.github.io

Understanding Multi-Task Activities from Single-Task Videos
Yuhan Shen, Ehsan Elhamifar; Proceedings of the Computer Vision and Pattern Reco
gnition Conference (CVPR), 2025, pp. 19120-19131
(MT-TAS), a novel paradigm that addresses the challenges of interleaved actions
when performing multiple tasks simultaneously. Traditional action segmentation m
odels, trained on single-task videos, struggle to handle task switches and compl
ex scenes inherent in multi-task scenarios. To overcome these challenges, our MT
-TAS approach synthesizes multi-task video data from single-task sources using o
ur Multi-task Sequence Blending and Segment Boundary Learning modules. Additiona
lly, we propose to dynamically isolate foreground and background elements within
 video frames, addressing the intricacies of object layouts in multi-task scenar
ios and enabling a new two-stage temporal action segmentation framework with For
eground-Aware Action Refinement. Also, we introduce the Multi-task Egocentric Ki
tchen Activities (MEKA) dataset, containing 12 hours of egocentric multi-task vi
deos, to rigorously benchmark MT-TAS models. Extensive experiments demonstrate t
hat our framework effectively bridges the gap between single-task training and m
ulti-task testing, advancing temporal action segmentation with state-of-the-art
performance in complex environments.

Co-Speech Gesture Video Generation with Implicit Motion-Audio Entanglement
Xinjie Li, Ziyi Chen, Xinlu Yu, Iek-Heng Chu, Peng Chang, Jing Xiao; Proceedings
 of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 113
84-11394
Co-speech gestures are essential to non-verbal communication, enhancing both the
 naturalness and effectiveness of human interaction. Although recent methods hav
e made progress in generating co-speech gesture videos, many rely on strong visu
al controls, such as pose images or TPS keypoint movements, which often lead to
artifacts like blurry hands and distorted fingers. In response to these challeng
es, we present the Implicit Motion-Audio Entanglement (IMAE) method for co-speec

h gesture video generation. IMAE strengthens audio control by entangling implici t motion parameters, including pose and expression, with audio inputs. Our metho d utilizes a two-branch framework that combines an audio-to-motion generation br anch with a video diffusion branch, enabling realistic gesture generation withou t requiring additional inputs during inference. To improve training efficiency, we propose a two-stage slow-fast training strategy that balances memory constrai nts while facilitating the learning of meaningful gestures from long frame seque nces.Extensive experimental results demonstrate that our method achieves state-o f-the-art performance across multiple metrics.

TransPixeler: Advancing Text-to-Video Generation with Transparency
Luozhou Wang, Yijun Li, Zhifei Chen, Jui-Hsien Wang, Zhifei Zhang, He Zhang, Zhe Lin, Ying-Cong Chen; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 18229-18239
Text-to-video generative models have made significant strides, enabling diverse applications in entertainment, advertising, and education. However, generating R GBA video, which includes alpha channels for transparency, remains a challenge d ue to limited datasets and the difficulty of adapting existing models. Alpha cha nnels are crucial for visual effects (VFX), allowing transparent elements like s moke and reflections to blend seamlessly into scenes.We introduce TransPixeler, a method to extend pretrained video models for RGBA generation while retaining t he original RGB capabilities. TransPixar leverages a diffusion transformer (DiT) architecture, incorporating alpha-specific tokens and using LoRA-based fine-tun ing to jointly generate RGB and alpha channels with high consistency. By optimiz ing attention mechanisms, TransPixeler preserves the strengths of the original R GB model and achieves strong alignment between RGB and alpha channels despite li mited training data.Our approach effectively generates diverse and consistent RG BA videos, advancing the possibilities for VFX and interactive content creation.

Adaptive Keyframe Sampling for Long Video Understanding
Xi Tang, Jihao Qiu, Lingxi Xie, Yunjie Tian, Jianbin Jiao, Qixiang Ye; Proceedin gs of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 2 9118-29128
Multimodal large language models (MLLMs) have enabled open-world visual understa nding by injecting visual input as extra tokens into large language models (LLMs) as contexts. However, when the visual input changes from a single image to a l ong video, the above paradigm encounters difficulty because the vast amount of v ideo tokens has significantly exceeded the maximal capacity of MLLMs. Therefore, existing video-based MLLMs are mostly established upon sampling a small portion of tokens from input data, which can cause key information to be lost and thus produce incorrect answers. This paper presents a simple yet effective algorithm named Adaptive Keyframe Sampling (AKS). It inserts a plug-and-play module known as keyframe selection, which aims to maximize the useful information with a fixe d number of video tokens. We formulate keyframe selection as an optimization inv olving (1) the relevance between the keyframes and the prompt, and (2) the cover age of the keyframes over the video, and present an adaptive algorithm to approx imate the best solution. Experiments on two long video understanding benchmarks validate that AKS improves video QA accuracy (beyond strong baselines) upon sele cting informative keyframes. Our study reveals the importance of information pre -filtering in video-based MLLMs. Our code are available at https://github.com/nc TimTang/AKS

What's in the Image? A Deep-Dive into the Vision of Vision Language Models
Omri Kaduri, Shai Bagon, Tali Dekel; Proceedings of the Computer Vision and Patt ern Recognition Conference (CVPR), 2025, pp. 14549-14558
Vision-Language Models (VLMs) have recently demonstrated remarkable capabilities in comprehending complex visual content. However, the mechanisms underlying how VLMs process visual information remain largely unexplored. In this paper, we c onduct a thorough empirical analysis, focusing on the attention modules across l ayers, by which we reveal several key insights about how these models process vi

sual data: (i) the internal representation of the query tokens (e.g., representations of "describe the image"), is utilized by the model to store global image information; we demonstrate that the model generates surprisingly descriptive responses solely from these tokens, without direct access to image tokens. (ii) Cross-modal information flow is predominantly influenced by the middle layers (approximately 25% of all layers), while early and late layers contribute only marginally. (iii) Fine-grained visual attributes and object details are directly extracted from image tokens in a spatially localized manner, i.e., the generated tokens associated with a specific object or attribute attend strongly to their corresponding regions in the image. We propose novel quantitative evaluation to validate our observations, leveraging real-world complex visual scenes. Finally, we demonstrate the potential of our findings in facilitating efficient visual processing in state-of-the-art VLMs.

****

Person De-reidentification: A Variation-guided Identity Shift Modeling

Yi-Xing Peng, Yu-Ming Tang, Kun-Yu Lin, Qize Yang, Jingke Meng, Xihan Wei, Wei-Shi Zheng; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 29331-29341

Person re-identification (ReID) is to associate images of individuals from different camera views against cross-view variations. Like other surveillance technologies, Re-ID faces serious privacy challenges, particularly the potential for unauthorized tracking. Although various tasks (e.g., face recognition) have developed machine unlearning techniques to address privacy concerns, such methods have not yet been explored within the Re-ID field. In this work, we pioneer the exploration of the person de-reidentification (De-ReID) problem and present its inherent challenges. In the context of ReID, De-ReID is to unlearn the knowledge about accurately matching specific persons so that these "unlearned persons" cannot be re-identified across cameras for privacy guarantee. The primary challenge is to achieve the unlearning without degrading the identity-discriminative feature embeddings to ensure the model's utility. To address this, we formulate a De-ReID framework that utilizes a labeled dataset of unlearned persons for unlearning and an unlabeled dataset of accessible persons for knowledge preservation. Instead of unlearning based on (pseudo) identity labels, we introduce a variation-guided identity shift mechanism that unlearns the specific persons by fitting the variations in their images while preserving ReID ability on other persons by overcoming the variations in images of accessible persons. As a result, the model shifts the unlearned persons to a feature space that is vulnerable to cross-view variations. Extensive experiments on benchmarks demonstrate the superiority of our method.

FreeSim: Toward Free-viewpoint Camera Simulation in Driving Scenes

Lue Fan, Hao Zhang, Qitai Wang, Hongsheng Li, Zhaoxiang Zhang; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 12004-12014

We propose FreeSim, a camera simulation method for driving scenes via 3D Gaussian Splatting and diffusion-based image generation. FreeSim emphasizes high-quality rendering from viewpoints beyond the recorded ego trajectories. In such viewpoints, previous methods have unacceptable degradation because the training data of these viewpoints is unavailable. To address such data scarcity, we first propose a generative enhancement model with a matched data construction strategy. The resulting model can generate high-quality images in a viewpoint slightly deviated from the recorded trajectories, conditioned on the degraded rendering of this viewpoint. We then propose a progressive reconstruction strategy, which progressively adds generated images in unrecorded views into the reconstruction process, starting from slightly off-trajectory viewpoints and moving progressively farther away. With this progressive generation-reconstruction pipeline, FreeSim supports high-quality off-trajectory view synthesis under large deviations of more than 3 meters.

Gradient Inversion Attacks on Parameter-Efficient Fine-Tuning

Hasin Us Sami, Swapneel Sen, Amit K. Roy-Chowdhury, Srikanth V. Krishnamurthy, Basak Guler; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 10224-10234

Federated learning (FL) allows multiple data-owners to collaboratively train machine learning models by exchanging local gradients, while keeping their private data on-device. To simultaneously enhance privacy and training efficiency, recently parameter-efficient fine-tuning (PEFT) of large-scale pretrained models has gained substantial attention in FL. While keeping a pretrained (backbone) model frozen, each user fine-tunes only a few lightweight modules to be used in conjunction, to fit specific downstream applications. Accordingly, only the gradients with respect to these lightweight modules are shared with the server. In this work, we investigate how the privacy of the fine-tuning data of the users can be compromised via a malicious design of the pretrained model and trainable adapter modules. We demonstrate gradient inversion attacks on a popular PEFT mechanism, the adapter, which allow an attacker to reconstruct local data samples of a target user, using only the accessible adapter gradients. Via extensive experiments, we demonstrate that a large batch of fine-tuning images can be retrieved with high fidelity. Our attack highlights the need for privacy-preserving mechanisms for PEFT, while opening up several future directions. Our code is available at https://github.com/info-ucr/PEFTLeak.

UPME: An Unsupervised Peer Review Framework for Multimodal Large Language Model Evaluation

Qihui Zhang, Munan Ning, Zheyuan Liu, Yue Huang, Shuo Yang, Yanbo Wang, Jiayi Ye, Xiao Chen, Yibing Song, Li Yuan; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 9165-9174

Multimodal Large Language Models (MLLMs) have emerged to tackle the challenges of Visual Question Answering (VQA), sparking a new research focus on conducting objective evaluations of these models. Existing evaluation mechanisms face limitations due to the significant human workload required to design Q&A pairs for visual images, which inherently restricts the scale and scope of evaluations. Although automated MLLM-as-judge approaches attempt to reduce the human workload through mutual model evaluations, they often introduce biases. To address these problems, we propose an unsupervised evaluation method -- an Unsupervised Peer review MLLM Evaluation framework. This framework utilizes only image data, allowing models to automatically generate questions and conduct peer review assessments of answers from other models, effectively alleviating the reliance on human workload. Additionally, we introduce the vision-language scoring system to mitigate the bias issues, which focuses on three aspects: (i) response correctness; (ii) the model capability of visual understanding and reasoning; (iii) relevance of text-image matching. Experimental results demonstrate that UPME achieves a Pearson correlation of 0.944 with human evaluations on the MMstar dataset and 0.814 on the ScienceQA dataset, indicating that our UPME framework closely aligns with human-designed QA benchmarks and inherent human preferences.

DiGIT: Multi-Dilated Gated Encoder and Central-Adjacent Region Integrated Decoder for Temporal Action Detection Transformer

Ho-Joong Kim, Yearang Lee, Jung-Ho Hong, Seong-Whan Lee; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 24286-24296

In this paper, we examine a key limitation in query-based detectors for temporal action detection (TAD), which arises from their direct adaptation of originally designed architectures for object detection. Despite the effectiveness of the existing models, they struggle to fully address the unique challenges of TAD, such as the redundancy in multi-scale features and the limited ability to capture sufficient temporal context. To address these issues, we propose a multi-dilated gated encoder and central-adjacent region integrated decoder for temporal action detection transformer (DiGIT). Our approach replaces the existing encoder that consists of multi-scale deformable attention and feedforward network with our multi-dilated gated encoder. Our proposed encoder reduces the redundant information caused by multi-level features while maintaining the ability to capture fine-g

rained and long-range temporal information. Furthermore, we introduce a central-adjacent region integrated decoder that leverages a more comprehensive sampling strategy for deformable cross-attention to capture the essential information. Extensive experiments demonstrate that DiGIT achieves state-of-the-art performance on THUMOS14, ActivityNet v1.3, and HACS-Segment.

MBQ: Modality-Balanced Quantization for Large Vision-Language Models
Shiyao Li, Yingchun Hu, Xuefei Ning, Xihui Liu, Ke Hong, Xiaotao Jia, Xiuhong Li, Yaqi Yan, Pei Ran, Guohao Dai, Shengen Yan, Huazhong Yang, Yu Wang; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 4167-4177
Vision-Language Models (VLMs) have already enabled a variety of real-world applications. The large parameter size of VLMs brings large memory and computation overhead which poses significant challenges for deployment. Post-Training Quantization (PTQ) is an effective technique to reduce the memory and computation overhead. Existing PTQ methods mainly focus on the language modality in large language models (LLMs), without considering the differences across other modalities. In this paper, we discover that there is a significant difference in sensitivity between language and vision tokens in large VLMs. Therefore, treating tokens from different modalities equally, as in existing PTQ methods, may over-emphasize the insensitive modalities, leading to significant accuracy loss. To deal with the above issue, we propose a simple yet effective method, Modality-Balanced Quantization (MBQ), for large VLMs. Specifically, MBQ incorporates the different sensitivities across modalities during the calibration process to minimize the reconstruction loss for better quantization parameters. Extensive experiments show that MBQ can significantly improve task accuracy by up to 4.4% and 11.6% under W3A16 and W4A8 quantization for 7B to 70B VLMs, compared to SOTA baselines. Additionally, we implement a W3A16 GPU kernel that fuses the dequantization and GEMV operators, achieving a 1.4x speedup on LLaVA-onevision-7B on the RTX 4090. We will release the code.

Florence-VL: Enhancing Vision-Language Models with Generative Vision Encoder and Depth-Breadth Fusion
Jiuhai Chen, Jianwei Yang, Haiping Wu, Dianqi Li, Jianfeng Gao, Tianyi Zhou, Bin Xiao; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 24928-24938
We present Florence-VL, a new family of multimodal large language models (MLLMs) with enriched visual representations produced by Florence-2, a generative vision foundation model. Unlike the widely used CLIP-style vision transformer trained by contrastive learning, Florence-2 can capture different levels and aspects of visual features, which are more versatile to be adapted to diverse downstream tasks. We propose a novel feature-fusion architecture and an innovative training recipe that effectively integrates Florence-2's visual features into pretrained LLMs, such as Phi 3.5 and LLama 3. In particular, we propose "depth-breath fusion (DBFusion)" to fuse the visual features extracted from different depths and under multiple prompts. Our model training is composed of end-to-end pretraining of the whole model followed by finetuning of the projection layer and the LLM, on a carefully designed recipe of diverse open-source datasets that include high-quality image captions and instruction-tuning pairs. Our quantitative analysis and visualization of Florence-VL's visual features show its advantages over popular vision encoders on vision-language alignment, where the enriched depth and breath play important roles. Florence-VL achieves significant improvements over existing state-of-the-art MLLMs across various multi-modal and vision-centric benchmarks covering general VQA, perception, hallucination, OCR, Chart, knowledge-intensive understanding, etc. To facilitate future research, our models and the complete training recipe are open-sourced.
****

VideoDPO: Omni-Preference Alignment for Video Diffusion Generation
Runtao Liu, Haoyu Wu, Ziqiang Zheng, Chen Wei, Yingqing He, Renjie Pi, Qifeng Chen; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR)

, 2025, pp. 8009-8019
Recent progress in generative diffusion models has greatly advanced text-to-video generation. While text-to-video models trained on large-scale, diverse datasets can produce varied outputs, these generations often deviate from user preferences, highlighting the need for preference alignment on pre-trained models. Although Direct Preference Optimization (DPO) has demonstrated significant improvements in language and image generation, we pioneer its adaptation to video diffusion models and propose a VideoDPO pipeline by making several key adjustments. Unlike previous image alignment methods that focus solely on either (i) visual quality or (ii) semantic alignment between text and videos, we comprehensively consider both dimensions and construct a preference score accordingly, which we term the OmniScore. We design a pipeline to automatically collect preference pair data based on the proposed OmniScore and discover that re-weighting these pairs based on the score significantly impacts overall preference alignment. Our experiments demonstrate substantial improvements in both visual quality and semantic alignment, ensuring that no preference aspect is neglected. Code and data will be shared at https://videodpo.github.io/.
****

Seq2Time: Sequential Knowledge Transfer for Video LLM Temporal Grounding
Andong Deng, Zhongpai Gao, Anwesa Choudhuri, Benjamin Planche, Meng Zheng, Bin Wang, Terrence Chen, Chen Chen, Ziyan Wu; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 13766-13775
Temporal awareness is essential for video large language models (LLMs) to understand and reason about events within long videos, enabling applications like dense video captioning and temporal video grounding in a unified system. However, the scarcity of long videos with detailed captions and precise temporal annotations limits their temporal awareness. In this paper, we propose Seq2Time, a data-oriented training paradigm that leverages sequences of images and short video clips to enhance temporal awareness in long videos. By converting sequence positions into temporal annotations, we transform large-scale image and clip captioning datasets into sequences that mimic the temporal structure of long videos, enabling self-supervised training with abundant time-sensitive data. To enable sequence-to-time knowledge transfer, we introduce a novel time representation that unifies positional information across image sequences, clip sequences, and long videos. Experiments demonstrate the effectiveness of our method, achieving a 27.6% improvement in F1 score and 44.8% in CIDEr on the YouCook2 benchmark and a 14.7% increase in recall on the Charades-STA benchmark compared to the baseline.
****

GPVK-VL: Geometry-Preserving Virtual Keyframes for Visual Localization under Large Viewpoint Changes
Yunxuan Li, Lei Fan, Xiaoying Xing, Jianxiong Zhou, Ying Wu; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 16728-16738
Visual localization, the task of determining the position and orientation of a camera, typically involves three core components: offline construction of a keyframe database, efficient online keyframes retrieval, and robust local feature matching. However, significant challenges arise when there are large viewpoint disparities between the query view and the database, such as attempting localization in a corridor previously build from an opposing direction. Intuitively, this issue can be addressed by synthesizing a set of virtual keyframes that cover all viewpoints. However, existing methods for synthesizing novel views to assist localization often fail to ensure geometric accuracy under large viewpoint changes. In this paper, we introduce a confidence-aware geometric prior into 2D Gaussian splatting to ensure the geometric accuracy of the scene. Then we can render novel views through the mesh with clear structures and accurate geometry, even under significant viewpoint changes, enabling the synthesis of a comprehensive set of virtual keyframes. Incorporating this geometry-preserving virtual keyframe database into the localization pipeline significantly enhances the robustness of visual localization.
****

Realistic Test-Time Adaptation of Vision-Language Models

Maxime Zanella, Clément Fuchs, Christophe De Vleeschouwer, Ismail Ben Ayed; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 25103-25112

The zero-shot capabilities of Vision-Language Models (VLMs) have been widely leveraged to improve predictive performance. However, previous works on transductive or test-time adaptation (TTA) often make strong assumptions about the data distribution, such as the presence of all classes. Our work challenges these favorable deployment scenarios and introduces a more realistic evaluation framework, including (i) a variable number of effective classes for adaptation within a single batch, and (ii) non-i.i.d. batches of test samples in online adaptation settings. We provide comprehensive evaluations, comparisons, and ablation studies that demonstrate how current transductive or TTA methods for VLMs systematically compromise the models' initial zero-shot robustness across various realistic scenarios, favoring performance gains under advantageous assumptions about the test sample distributions. Furthermore, we introduce StatA, a versatile method that can handle a wide range of deployment scenarios, including those with a variable number of effective classes at test time. Our approach incorporates a novel regularization term designed specifically for VLMs, which acts as a statistical anchor preserving the initial text-encoder knowledge, particularly in low-data regimes. Code available at https://github.com/MaxZanella/StatA.

****

SelfSplat: Pose-Free and 3D Prior-Free Generalizable 3D Gaussian Splatting

Gyeongjin Kang, Jisang Yoo, Jihyeon Park, Seungtae Nam, Hyeonsoo Im, Sangheon Shin, Sangpil Kim, Eunbyung Park; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 22012-22022

We propose SelfSplat, a novel 3D Gaussian Splatting model designed to perform pose-free and 3D prior-free generalizable 3D reconstruction from unposed multi-view images. These settings are inherently ill-posed due to the lack of ground-truth data, learned geometric information, and the need to achieve accurate 3D reconstruction without finetuning, making it difficult for conventional methods to achieve high-quality results. Our model addresses these challenges by effectively integrating explicit 3D representations with self-supervised depth and pose estimation techniques, resulting in reciprocal improvements in both pose accuracy and 3D reconstruction quality. Furthermore, we incorporate a matching-aware pose estimation network and a depth refinement module to enhance geometry consistency across views, ensuring more accurate and stable 3D reconstructions. To present the performance of our method, we evaluated it on large-scale real-world datasets, including RealEstate10K, ACID, and DL3DV. SelfSplat achieves superior results over previous state-of-the-art methods in both appearance and geometry quality, also demonstrates strong cross-dataset generalization capabilities. Extensive ablation studies and analysis also validate the effectiveness of our proposed methods.

Enhancing Virtual Try-On with Synthetic Pairs and Error-Aware Noise Scheduling

Nannan Li, Kevin J. Shih, Bryan A. Plummer; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 21238-21247

Given an isolated garment image in a canonical product view and a separate image of a person, the virtual try-on task aims to generate a new image of the person wearing the target garment.Prior virtual try-on works face two major challenges in achieving this goal: a) the paired (human, garment) training data has limited availability; b) generating textures on the human that perfectly match that of the prompted garment is difficult, often resulting in distorted text and faded textures. Our work explores ways to tackle these issues through both synthetic data as well as model refinement. We introduce a garment extraction model that generates (human, synthetic garment) pairs from a single image of a clothed individual. The synthetic pairs can then be used to augment the training of virtual try-on. We also propose an Error-Aware Refinement-based Schrodinger Bridge (EARSB) that surgically targets localized generation errors for correcting the output of a base virtual try-on model. To identify likely errors, we propose a weakly-supervised error classifier that localizes regions for refinement, subsequently au

gmenting the Schrodinger Bridge's noise schedule with its confidence heatmap. Experiments on VITON-HD and DressCode-Upper demonstrate that our synthetic data augmentation enhances the performance of prior work, while EARSB improves the overall image quality. In user studies, our model is preferred by the users in an average of 59% of cases.

Exploring Simple Open-Vocabulary Semantic Segmentation

Zihang Lai; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 30221-30230

Open-vocabulary semantic segmentation models aim to accurately assign a semantic label to each pixel in an image from a set of arbitrary open-vocabulary texts. In order to learn such pixel-level alignment, current approaches typically rely on a combination of (i) image-level VL model (e.g. CLIP), (ii) ground truth masks, (iii) custom grouping encoders, and (iv) the Segment Anything Model (SAM). In this paper, we introduce S-Seg, a simple model that can achieve surprisingly strong performance without depending on any of the above elements. S-Seg leverages pseudo-mask and language to train a MaskFormer, and can be easily trained from publicly available image-text datasets. Contrary to prior works, our model directly trains for pixel-level features and language alignment. Once trained, S-Seg generalizes well to multiple testing datasets without requiring fine-tuning. In addition, S-Seg has the extra benefits of scalability with data and consistently improving when augmented with self-training. We believe that our simple yet effective approach will serve as a solid baseline for future research. Our code and demo will be made publicly available soon.

MP-GUI: Modality Perception with MLLMs for GUI Understanding

Ziwei Wang, Weizhi Chen, Leyang Yang, Sheng Zhou, Shengchu Zhao, Hanbei Zhan, Jiongchao Jin, Liangcheng Li, Zirui Shao, Jiajun Bu; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 29711-29721

Graphical user interface (GUI) has become integral to modern society, making it crucial to be understood for human-centric systems. However, unlike natural images or documents, GUIs comprise artificially designed graphical elements arranged to convey specific semantic meanings. Current multi-modal large language models (MLLMs) already proficient in processing graphical and textual components suffer from hurdles in GUI understanding due to the lack of explicit spatial structure modeling. Moreover, obtaining high-quality spatial structure data is challenging due to privacy issues and noisy environments. To address these challenges, we present MP-GUI, a specially designed MLLM for GUI understanding. MP-GUI features three precisely specialized perceivers to extract graphical, textual, and spatial modalities from the screen as GUI-tailored visual clues, with spatial structure refinement strategy and adaptively combined via a fusion gate to meet the specific preferences of different GUI understanding tasks. To cope with the scarcity of training data, we also introduce a pipeline for automatically data collecting. Extensive experiments demonstrate that MP-GUI achieves impressive results on various GUI understanding tasks with limited data. Our codes and datasets are publicly available at https://github.com/BigTaige/MP-GUI.

Associative Transformer

Yuwei Sun, Hideya Ochiai, Zhirong Wu, Stephen Lin, Ryota Kanai; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 4518-4527

Emerging from the pairwise attention in conventional Transformers, there is a growing interest in sparse attention mechanisms that align more closely with localized, contextual learning in the biological brain. Existing studies such as the Coordination method employ iterative cross-attention mechanisms with a bottleneck to enable the sparse association of inputs. However, these methods are parameter inefficient and fail in more complex relational reasoning tasks. To this end, we propose Associative Transformer (AiT) to enhance the association among sparsely attended input tokens, improving parameter efficiency and performance in various vision tasks such as classification and relational reasoning. AiT leverages

a learnable explicit memory comprising specialized priors that guide bottleneck attentions to facilitate the extraction of diverse localized tokens. Moreover, AiT employs an associative memory-based token reconstruction using a Hopfield energy function. The extensive empirical experiments demonstrate that AiT requires significantly fewer parameters and attention layers outperforming a broad range of sparse Transformer models. Additionally, AiT outperforms the SOTA sparse Transformer models including the Coordination method on the Sort-of-CLEVR dataset.

Improving Adversarial Transferability on Vision Transformers via Forward Propagation Refinement

Yuchen Ren, Zhengyu Zhao, Chenhao Lin, Bo Yang, Lu Zhou, Zhe Liu, Chao Shen; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 25071-25080

Vision Transformers (ViTs) have been widely applied in various computer vision and vision-language tasks. To gain insights into their robustness in practical scenarios, transferable adversarial examples on ViTs have been extensively studied. A typical approach to improving adversarial transferability is by refining the surrogate model. However, existing work on ViTs has restricted their surrogate refinement to backward propagation. In this work, we instead focus on Forward Propagation Refinement (FPR) and specifically refine two key modules of ViTs: attention maps and token embeddings. For attention maps, we propose Attention Map Diversification (AMD), which diversifies certain attention maps and also implicitly imposes beneficial gradient vanishing during backward propagation. For token embeddings, we propose Momentum Token Embedding (MTE), which accumulates historical token embeddings to stabilize the forward updates in both the Attention and MLP blocks. We conduct extensive experiments with adversarial examples transferred from ViTs to various CNNs and ViTs, demonstrating that our FPR outperforms the current best (backward) surrogate refinement by up to 7.0% on average. We also validate its superiority against popular defenses and its compatibility with other transfer methods. Codes and appendix are available at https://github.com/RYC-98/FPR.

Seeing What Matters: Empowering CLIP with Patch Generation-to-Selection

Gensheng Pei, Tao Chen, Yujia Wang, Xinhao Cai, Xiangbo Shu, Tianfei Zhou, Yazhou Yao; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 24862-24872

The CLIP model has demonstrated significant advancements in aligning visual and language modalities through large-scale pre-training on image-text pairs, enabling strong zero-shot classification and retrieval capabilities on various domains. However, CLIP's training remains computationally intensive, with high demands on both data processing and memory. To address these challenges, recent masking strategies have emerged, focusing on the selective removal of image patches to improve training efficiency. Although effective, these methods often compromise key semantic information, resulting in suboptimal alignment between visual features and text descriptions.In this work, we present a concise yet effective approach called Patch Generation-to-Selection (CLIP-PGS) to enhance CLIP's training efficiency while preserving critical semantic content. Our method introduces a gradual masking process in which a small set of candidate patches is first pre-selected as potential mask regions. Then, we apply Sobel edge detection across the entire image to generate an edge mask that prioritizes the retention of the primary object areas. Finally, similarity scores between the candidate mask patches and their neighboring patches are computed, with optimal transport normalization refining the selection process to ensure a balanced similarity matrix.Our approach, CLIP-PGS, sets new state-of-the-art results in zero-shot classification and retrieval tasks, achieving superior performance in robustness evaluation and language compositionality benchmarks.

ChatGarment: Garment Estimation, Generation and Editing via Large Language Models

Siyuan Bian, Chenghao Xu, Yuliang Xiu, Artur Grigorev, Zhen Liu, Cewu Lu, Michae

l J. Black, Yao Feng; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 2924-2934

We introduce ChatGarment, a novel approach that leverages large vision-language models (VLMs) to automate the estimation, generation, and editing of 3D garment sewing patterns from images or text descriptions. Unlike previous methods that often lack robustness and interactive editing capabilities, ChatGarment finetunes a VLM to produce GarmentCode, a JSON-based, language-friendly format for 2D sewing patterns, enabling both estimating and editing from images and text instructions. To optimize performance, we refine GarmentCode by expanding its support for more diverse garment types and simplifying its structure, making it more efficient for VLM finetuning. Additionally, we develop an automated data construction pipeline to generate a large-scale dataset of image-to-sewing-pattern and text-to-sewing-pattern pairs, empowering ChatGarment with strong generalization across various garment types. Extensive evaluations demonstrate ChatGarment's ability to accurately reconstruct, generate, and edit garments from multimodal inputs, highlighting its potential to revolutionize workflows in fashion and gaming applications.

Enhancing Online Continual Learning with Plug-and-Play State Space Model and Class-Conditional Mixture of Discretization

Sihao Liu, Yibo Yang, Xiaojie Li, David A. Clifton, Bernard Ghanem; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 20502-20511

Online continual learning (OCL) seeks to learn new tasks from data streams that appear only once, while retaining knowledge of previously learned tasks. Most existing methods rely on replay, focusing on enhancing memory retention through regularization or distillation. However, they often overlook the adaptability of the model, limiting the ability to learn generalizable and discriminative features incrementally from online training data.To address this, we introduce a plug-and-play module, S6MOD, which can be integrated into most existing methods and directly improve adaptability. Specifically, S6MOD introduces an extra branch after the backbone, where a mixture of discretization selectively adjusts parameters in a selective state space model, enriching selective scan patterns such that the model can adaptively select the most sensitive discretization method for current dynamics.We further design a class-conditional routing algorithm for dynamic, uncertainty-based adjustment and implement a contrastive discretization loss to optimize it. Extensive experiments combining our module with various models demonstrate that S6MOD significantly enhances model adaptability, leading to substantial performance gains and achieving the state-of-the-art results. The code is available at https://github.com/MyToumaKazusa/S6MOD.

RDD: Robust Feature Detector and Descriptor using Deformable Transformer

Gonglin Chen, Tianwen Fu, Haiwei Chen, Wenbin Teng, Hanyuan Xiao, Yajie Zhao; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 6394-6403

As a core step in structure-from-motion and SLAM, robust feature detection and description under challenging scenarios such as significant viewpoint changes remain unresolved despite their ubiquity. While recent works have identified the importance of local features in modeling geometric transformations, these methods fail to learn the visual cues present in long-range relationships. We present Robust Deformable Detector (RDD), a novel and robust keypoint detector/descriptor leveraging the deformable transformer, which captures global context and geometric invariance through deformable self-attention mechanisms. Specifically, we observed that deformable attention focuses on key locations, effectively reducing the search space complexity and modeling the geometric invariance. Furthermore, we collected an Air-to-Ground dataset for training in addition to the standard MegaDepth dataset. Our proposed method outperforms all state-of-the-art keypoint detection/description methods in sparse matching tasks and is also capable of semi-dense matching. To ensure comprehensive evaluation, we introduce two challenging benchmarks: one emphasizing large viewpoint and scale variations, and the oth

er being an Air-to-Ground benchmark -- an evaluation setting that has recently g aining popularity for 3D reconstruction across different altitudes.

Building Vision Models upon Heat Conduction
Zhaozhi Wang, Yue Liu, Yunjie Tian, Yunfan Liu, Yaowei Wang, Qixiang Ye; Proceed ings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 9707-9717
Visual representation models leveraging attention mechanisms are challenged by s ignificant computational overhead, particularly when pursuing large receptive fi elds. In this study, we aim to mitigate this challenge by introducing the Heat C onduction Operator (HCO) built upon the physical heat conduction principle. HCO conceptualizes image patches as heat sources and models their correlations throu gh adaptive thermal energy diffusion, enabling robust visual representations. HC O enjoys a computational complexity of O(N^1.5), as it can be implemented using discrete cosine transformation (DCT) operations. HCO is plug-and-play, combining with deep learning backbones produces visual representation models (termed vHea t) with global receptive fields. Experiments across vision tasks demonstrate tha t, beyond the stronger performance, vHeat achieves up to a 3x throughput, 80% le ss GPU memory allocation, and 35% fewer computational FLOPs compared to the Swin -Transformer.

GRAPHGPT-O: Synergistic Multimodal Comprehension and Generation on Graphs
Yi Fang, Bowen Jin, Jiacheng Shen, Sirui Ding, Qiaoyu Tan, Jiawei Han; Proceedin gs of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 1 9467-19476
The rapid development of Multimodal Large Language Models (MLLMs) has enabled th e integration of multiple modalities, including texts and images, within the lar ge language model (LLM) framework.However, texts and images are usually intercon nected, forming a multimodal attributed graph (MMAG).It is underexplored how MLL Ms can incorporate the relational information (i.e., graph structure) and semant ic information (i.e., texts and images) on such graphs for multimodal comprehens ion and generation.In this paper, we propose GraphGPT-o, which supports omni-mul timodal understanding and creation on MMAGs.We first comprehensively study linea rization variants to transform semantic and structural information as input for MLLMs.Then, we propose a hierarchical aligner that enables deep graph encoding, bridging the gap between MMAGs and MLLMs.Finally, we explore the inference choic es, adapting MLLM to interleaved text and image generation in graph scenarios. E xtensive experiments on three datasets from different domains demonstrate the ef fectiveness of our proposed method.

Model Poisoning Attacks to Federated Learning via Multi-Round Consistency
Yueqi Xie, Minghong Fang, Neil Zhenqiang Gong; Proceedings of the Computer Visio n and Pattern Recognition Conference (CVPR), 2025, pp. 15454-15463
Model poisoning attacks are critical security threats to Federated Learning (FL) . Existing model poisoning attacks suffer from two key limitations: 1) they achi eve suboptimal effectiveness when defenses are deployed, and/or 2) they require knowledge of the model updates or local training data on genuine clients. In thi s work, we make a key observation that their suboptimal effectiveness arises fro m only leveraging model-update consistency among malicious clients within indivi dual training rounds, making the attack effect self-cancel across training round s. In light of this observation, we propose PoisonedFL, which enforces multi-rou nd consistency among the malicious clients' model updates while not requiring an y knowledge about the genuine clients. Our empirical evaluation on five benchmar k datasets shows that PoisonedFL breaks eight state-of-the-art defenses and outp erforms seven existing model poisoning attacks. Our study shows that FL systems are considerably less robust than previously thought, underlining the urgency fo r the development of new defense mechanisms. Our source code is available at htt ps://github.com/xyq7/PoisonedFL/.

TaoAvatar: Real-Time Lifelike Full-Body Talking Avatars for Augmented Reality vi

a 3D Gaussian Splatting
Jianchuan Chen, Jingchuan Hu, Gaige Wang, Zhonghua Jiang, Tiansong Zhou, Zhiwen Chen, Chengfei Lv; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 10723-10734
Realistic 3D full-body talking avatars hold great potential in AR, with applications ranging from e-commerce live streaming to holographic communication. Despite advances in 3D Gaussian Splatting (3DGS) for lifelike avatar creation, existing methods struggle with fine-grained control of facial expressions and body movements in full-body talking tasks. Additionally, they often lack sufficient details and cannot run in real-time on mobile devices. We present TaoAvatar, a high-fidelity, lightweight, 3DGS-based full-body talking avatar driven by various signals. Our approach starts by creating a personalized clothed human parametric template that binds Gaussians to represent appearances. We then pre-train a StyleUnet-based network to handle complex pose-dependent non-rigid deformation, which can capture high-frequency appearance details but is too resource-intensive for mobile devices. To overcome this, we "bake" the non-rigid deformations into a lightweight MLP-based network using a distillation technique and develop blend shapes to compensate for details. Extensive experiments show that TaoAvatar achieves state-of-the-art rendering quality while running in real-time across various devices, maintaining 90 FPS on high-definition stereo devices such as the Apple Vision Pro.

Erasing Undesirable Influence in Diffusion Models
Jing Wu, Trung Le, Munawar Hayat, Mehrtash Harandi; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 28263-28273
Diffusion models are highly effective at generating high-quality images but pose risks, such as the unintentional generation of NSFW (not safe for work) content.Although various techniques have been proposed to mitigate unwanted influences in diffusion models while preserving overall performance, achieving a balance between these goals remains challenging.In this work, we introduce EraseDiff, an algorithm designed to preserve the utility of the diffusion model on retained data while removing the unwanted information associated with the data to be forgotten.Our approach formulates this task as a constrained optimization problem using the value function, resulting in a natural first-order algorithm for solving the optimization problem.By altering the generative process to deviate away from the ground-truth denoising trajectory, we update parameters for preservation while controlling constraint reduction to ensure effective erasure, striking an optimal trade-off.Extensive experiments and thorough comparisons with state-of-the-art algorithms demonstrate that EraseDiff effectively preserves the model's utility, efficacy, and efficiency.
****
LT3SD: Latent Trees for 3D Scene Diffusion
Quan Meng, Lei Li, Matthias Nießner, Angela Dai; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 650-660
We present LT3SD, a novel latent diffusion model for large-scale 3D scene generation. Recent advances in diffusion models have shown impressive results in 3D object generation, but are limited in spatial extent and quality when extended to 3D scenes. To generate complex and diverse 3D scene structures, we introduce a latent tree representation to effectively encode both lower-frequency geometry and higher-frequency detail in a coarse-to-fine hierarchy. We can then learn a generative diffusion process in this latent 3D scene space, modeling the latent components of a scene at each resolution level. To synthesize large-scale scenes with varying sizes, we train our diffusion model on scene patches and synthesize arbitrary-sized output 3D scenes through shared diffusion generation across multiple scene patches. Through extensive experiments, we demonstrate the efficacy and benefits of LT3SD for large-scale, high-quality unconditional 3D scene generation and for probabilistic completion for partial scene observations.

Stacking Brick by Brick: Aligned Feature Isolation for Incremental Face Forgery Detection

Jikang Cheng, Zhiyuan Yan, Ying Zhang, Li Hao, Jiaxin Ai, Qin Zou, Chen Li, Zhon gyuan Wang; Proceedings of the Computer Vision and Pattern Recognition Conferenc e (CVPR), 2025, pp. 13927-13936

The rapid advancement of face forgery techniques has introduced a growing variet y of forgeries.Incremental Face Forgery Detection (IFFD), involvinggradually add ing new forgery data to fine-tune the previously trained model, has been introdu ced as a promising strategy to deal with evolving forgery methods.However, a nai vely trained IFFD model is prone to catastrophic forgetting when new forgeries a re integrated, as treating all forgeries as a single "Fake" class in the Real/Fa ke classification can cause different forgery types overriding one another, ther eby resulting in the forgetting of unique characteristics from earlier tasks and limiting the model's effectiveness in learning forgery specificity and generali ty.In this paper, we propose to stack the latent feature distributions of previo us and new tasks brick by brick, i.e., achieving aligned feature isolation. In this manner, we aim to preserve learned forgery information and accumulate new k nowledge by minimizing distribution overriding, thereby mitigating catastrophic forgetting.To achieve this, we first introduce Sparse Uniform Replay (SUR) to ob tain the representative subsets that could be treated as the uniformly sparse ve rsions of the previous global distributions.We then propose a Latent-space Incre mental Detector (LID) that leverages SUR data to isolate and align distributions . For evaluation, we construct a more advanced and comprehensive benchmark tailo red for IFFD. The leading experimental results validate the superiority of our m ethod.

CO-SPY: Combining Semantic and Pixel Features to Detect Synthetic Images by AI

Siyuan Cheng, Lingjuan Lyu, Zhenting Wang, Xiangyu Zhang, Vikash Sehwag; Proceed ings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 13455-13465

With the rapid advancement of generative AI, it is now possible to synthesize hi gh-quality images in a few seconds. Despite the power of these technologies, the y raise significant concerns regarding misuse. Current efforts to distinguish be tween real and AI-generated images may lack generalization, being effective for only certain types of generative models and susceptible to post-processing techn iques like JPEG compression. To overcome these limitations, we propose a novel f ramework, CO-SPY, that first enhances existing semantic features (e.g., the numb er of fingers in a hand) and artifact features (e.g., pixel value differences), and then adaptively integrates them to achieve more general and robust synthetic image detection. Additionally, we create CO-SPYBench, a comprehensive dataset c omprising 5 real image datasets and 22 state-of-the-art generative models, inclu ding the latest models like FLUX. We also collect 50k synthetic images in the wi ld from the Internet to enable evaluation in a more practical setting. Our exten sive evaluations demonstrate that our detector outperforms existing methods unde r identical training conditions, achieving an average accuracy improvement of ap proximately 11% to 34%.

Closest Neighbors are Harmful for Lightweight Masked Auto-encoders

Jian Meng, Ahmed Hasssan, Li Yang, Deliang Fan, Jinwoo Shin, Jae-sun Seo; Procee dings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp . 25230-25239

Learning the visual representation via masked auto-encoder (MAE) training has be en proven to be a powerful technique. Transferring the pre-trained vision transf ormer (ViT) to downstream tasks leads to superior performance compared to conven tional task-by-task supervised learning. Recent research works on MAE focus on large-sized vision transformers (>50 million parameters) with outstanding perfor mance. However, improving the generality of the under-parametrized lightweight m odel has been widely ignored. In practice, downstream applications are commonly intended for resource-constrained platforms, where large-scale ViT cannot easil y meet the resource budget. Current lightweight MAE training heavily relies on k nowledge distillation with a pre-trained teacher, whereas the root cause behind the poor performance remains under-explored. Motivated by that, this paper firs

t introduces the concept of "closest neighbor patch" to characterize the local s emantics among the input tokens. Our discovery shows that the lightweight model failed to distinguish different local information, leading to aliased understand ing and poor accuracy. Motivated by this finding, we propose NoR-MAE, a novel MA E training algorithm for lightweight vision transformers. NoR-MAE elegantly repe ls the semantic aliasing between patches and their closest neighboring patch (se mantic centroid) with negligible training cost overhead. With the ViT-Tiny model , NoR-MAE achieves up to 7.22%/3.64% accuracy improvements on ImageNet-100/Image Net-1K datasets, as well as up to 5.13% accuracy improvements in tested downstre am tasks. https://github.com/SeoLabCornell/NoR-MAE

CraftsMan3D: High-fidelity Mesh Generation with 3D Native Diffusion and Interact ive Geometry Refiner
Weiyu Li, Jiarui Liu, Hongyu Yan, Rui Chen, Yixun Liang, Xuelin Chen, Ping Tan, Xiaoxiao Long; Proceedings of the Computer Vision and Pattern Recognition Confer ence (CVPR), 2025, pp. 5307-5317
We present a novel generative 3D modeling system, coined CraftsMan, which can ge nerate high-fidelity 3D geometries with highly varied shapes, regular mesh topol ogies, and detailed surfaces, and, notably, allows for refining the geometry in an interactive manner. Despite the significant advancements in 3D generation, ex isting methods still struggle with lengthy optimization processes, self-occlusio n, irregular mesh topologies, and difficulties in accommodating user edits, cons equently impeding their widespread adoption and implementation in 3D modeling so ftwares. Our work is inspired by the craftsman, who usually roughs out the holis tic figure of the work first and elaborates the surface details subsequently. Sp ecifically, we first introduce a robust data preprocessing pipeline that utilize s visibility check and winding mumber to maximize the use of existing 3D data. L everaging this data, we employ a 3D-native DiT model that directly models the di stribution of 3D data in latent space, generating coarse geometries with regular mesh topology in seconds. Subsequently, a normal-based geometry refiner enhance s local surface details, which can be applied automatically or interactively wit h user input. Extensive experiments demonstrate that our method achieves high ef ficacy in producing superior quality 3D assets compared to existing methods.

Decouple-Then-Merge: Finetune Diffusion Models as Multi-Task Learning
Qianli Ma, Xuefei Ning, Dongrui Liu, Li Niu, Linfeng Zhang; Proceedings of the C omputer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 23281-23291
Diffusion models are trained by learning a sequence of models that reverse each step of noise corruption. Typically, the model parameters are fully shared acros s multiple timesteps to enhance training efficiency. However, since the denoisin g tasks differ at each timestep, the gradients computed at different timesteps m ay conflict, potentially degrading the overall performance of image generation. To solve this issue, this work proposes a Decouple-then-Merge (DeMe) framework, which begins with a pretrained model and finetunes separate models tailored to s pecific timesteps. We introduce several improved techniques during the finetunin g stage to promote effective knowledge sharing while minimizing training interfe rence across timesteps. Finally, after finetuning, these separate models can be merged into a single model in the parameter space, ensuring efficient and practi cal inference. Experimental results show significant generation quality improvem ents upon 6 benchmarks including Stable Diffusion on COCO30K, ImageNet1K, PartiP rompts, and DDPM on LSUN Church, LSUN Bedroom, and CIFAR10. Code is included in the supplementary material and will be released on Github.

GIF: Generative Inspiration for Face Recognition at Scale
Saeed Ebrahimi, Sahar Rahimi, Ali Dabouei, Srinjoy Das, Jeremy M. Dawson, Nasser M. Nasrabadi; Proceedings of the Computer Vision and Pattern Recognition Confer ence (CVPR), 2025, pp. 3528-3539
Aiming to reduce the computational cost of Softmax in massive label space of Fac e Recognition (FR) benchmarks, recent studies estimate the output using a subset of identities. Although promising, the association between the computation cost

and the number of identities in the dataset remains linear only with a reduced ratio. A shared characteristic among available FR methods is the employment of atomic scalar labels during training. Consequently, the input to label matching is through a dot product between the feature vector of the input and the Softmax centroids. Inspired by generative modeling, we present a simple yet effective method that substitutes scalar labels with structured identity code, i.e., a sequence of integers. Specifically, we propose a tokenization scheme that transforms atomic scalar labels into structured identity codes. Then, we train an FR backbone to predict the code for each input instead of its scalar label. As a result, the associated computational cost becomes logarithmic \wrt number of identities. We demonstrate the benefits of the proposed method by conducting experiments. In particular, our method outperforms its competitors by 1.52%, and 0.6% at TAR@FAR=1e-4 on IJB-B and IJB-C, respectively, while transforming the association between computational cost and the number of identities from linear to logarithmic. \href https://github.com/msed-Ebrahimi/GIF Code

HELVIPAD: A Real-World Dataset for Omnidirectional Stereo Depth Estimation

Mehdi Zayene, Jannik Endres, Albias Havolli, Charles Corbière, Salim Cherkaoui, Alexandre Kontouli, Alexandre Alahi; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 26975-26984

Despite progress in stereo depth estimation, omnidirectional imaging remains underexplored, mainly due to the lack of appropriate data. We introduce Helvipad, a real-world dataset for omnidirectional stereo depth estimation, featuring 40K video frames from video sequences across diverse environments, including crowded indoor and outdoor scenes with various lighting conditions. Collected using two 360deg cameras in a top-bottom setup and a LiDAR sensor, the dataset includes accurate depth and disparity labels by projecting 3D point clouds onto equirectangular images. Additionally, we provide an augmented training set with an increased label density by using depth completion. We benchmark leading stereo depth estimation models for both standard and omnidirectional images. The results show that while recent stereo methods perform decently, a challenge persists in accurately estimating depth in omnidirectional imaging. To address this, we introduce necessary adaptations to stereo models, leading to improved performance.

GENMANIP: LLM-driven Simulation for Generalizable Instruction-Following Manipulation

Ning Gao, Yilun Chen, Shuai Yang, Xinyi Chen, Yang Tian, Hao Li, Haifeng Huang, Hanqing Wang, Tai Wang, Jiangmiao Pang; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 12187-12198

Robotic manipulation in real-world settings remains challenging, especially regarding robust generalization. Existing simulation platforms lack sufficient support for exploring how policies adapt to varied instructions and scenarios. Thus, they lag behind the growing interest in instruction-following foundation models like LLMs, whose adaptability is crucial yet remains underexplored in fair comparisons. To bridge this gap, we introduce GenManip, a realistic tabletop simulation platform tailored for policy generalization studies. It features an automatic pipeline via LLM-driven task-oriented scene graph to synthesize large-scale, diverse tasks using 10K annotated 3D object assets. To systematically assess generalization, we present GenManip-Bench, a benchmark of 200 scenarios refined via human-in-the-loop corrections. We evaluate two policy types: (1) modular manipulation systems integrating foundation models for perception, reasoning, and planning, and (2) end-to-end policies trained through scalable data collection. Results show that while data scaling benefits end-to-end methods, modular systems enhanced with foundation models generalize more effectively across diverse scenarios. We anticipate this platform to facilitate critical insights for advancing policy generalization in realistic conditions. All code will be made publicly available.

SKDream: Controllable Multi-view and 3D Generation with Arbitrary Skeletons

Yuanyou Xu, Zongxin Yang, Yi Yang; Proceedings of the Computer Vision and Patter

n Recognition Conference (CVPR), 2025, pp. 314-325
Controllable generation has achieved substantial progress in both 2D and 3D doma ins, yet current conditional generation methods still face limitations in descri bing detailed shape structures. Skeletons can effectively represent and describe object anatomy and pose. Unfortunately, past studies are often limited to human skeletons. In this work, we generalize skeletal conditioned generation to arbit rary structures. First, we design a reliable mesh skeletonization pipeline to ge nerate a large-scale mesh-skeleton paired dataset.Based on the dataset, a multi- view and 3D generation pipeline is built. We propose to represent 3D skeletons b y Coordinate Color Encoding as 2D conditional images. A Skeletal Correlation Mod ule is designed to extract global skeletal features for condition injection. Aft er multi-view images are generated, 3D assets can be obtained by incorporating a large reconstruction model, followed by a UV texture refinement stage. As a res ult, our method achieves instant generation of multi-view and 3D contents that a re aligned with given skeletons. The proposed techniques largely improve the obj ect-skeleton alignment and generation quality.

Towards Enhanced Image Inpainting: Mitigating Unwanted Object Insertion and Pres erving Color Consistency
Yikai Wang, Chenjie Cao, Junqiu Yu, Ke Fan, Xiangyang Xue, Yanwei Fu; Proceeding s of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 23 237-23248
Recent advances in image inpainting increasingly use generative models to handle large irregular masks. However, these models can create unrealistic inpainted i mages due to two main issues: (1) Unwanted object insertion: Even with unmasked areas as context, generative models may still generate arbitrary objects in the masked region that don't align with the rest of the image. (2) Color inconsisten cy: Inpainted regions often have color shifts that causes a smeared appearance, reducing image quality. Retraining the generative model could help solve these i ssues, but it's costly since state-of-the-art latent-based diffusion and rectifi ed flow models require a three-stage training process: training a VAE, training a generative U-Net or transformer, and fine-tuning for inpainting. Instead, this paper proposes a post-processing approach, dubbed as ASUKA (Aligned Stable inpa inting with UnKnown Areas prior), to improve inpainting models. To address unwan ted object insertion, we leverage a Masked Auto-Encoder (MAE) for reconstruction -based priors. This mitigates object hallucination while maintaining the model's generation capabilities. To address color inconsistency, we propose a specializ ed VAE decoder that treats latent-to-image decoding as a local harmonization tas k, significantly reducing color shifts for color-consistent inpainting. We valid ate ASUKA on SD 1.5 and FLUX inpainting variants with Places2 and MISATO, our pr oposed diverse collection of datasets. Results show that ASUKA mitigates object hallucination and improves color consistency over standard diffusion and rectifi ed flow models and other inpainting methods.

Optimus-2: Multimodal Minecraft Agent with Goal-Observation-Action Conditioned P olicy
Zaijing Li, Yuquan Xie, Rui Shao, Gongwei Chen, Dongmei Jiang, Liqiang Nie; Proc eedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 9039-9049
Building an agent that can mimic human behavior patterns to accomplish various o pen-world tasks is a long-term goal. To enable agents to effectively learn beha vioral patterns across diverse tasks, a key challenge lies in modeling the intri cate relationships among observations, actions, and language. To this end, we pr opose Optimus-2, a novel Minecraft agent that incorporates a Multimodal Large La nguage Model (MLLM) for high-level planning, alongside a Goal-Observation-Action Conditioned Policy (GOAP) for low-level control. GOAP contains (1) an Action-gu ided Behavior Encoder that models causal relationships between observations and actions at each timestep, then dynamically interacts with the historical observa tion-action sequence, consolidating it into fixed-length behavior tokens, and (2) an MLLM that aligns behavior tokens with open-ended language instructions to p

redict actions auto-regressively. Moreover, we introduce a high-quality Minecraft Goal-Observation-Action (MGOA) dataset, which contains 25,000 videos across 8 atomic tasks, providing about 30M goal-observation-action pairs. The automated construction method, along with the MGOA dataset, can contribute to the community's efforts in training Minecraft agents. Extensive experimental results demonstrate that Optimus-2 exhibits superior performance across atomic tasks, long-horizon tasks, and open-ended instruction tasks in Minecraft.

Classic Video Denoising in a Machine Learning World: Robust, Fast, and Controllable

Xin Jin, Simon Niklaus, Zhoutong Zhang, Zhihao Xia, Chunle Guo, Yuting Yang, Jiawen Chen, Chongyi Li; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 2084-2093

Denoising is a crucial step in many video processing pipelines such as in interactive editing, where high quality, speed, and user control are essential. While recent approaches achieve significant improvements in denoising quality by leveraging deep learning, they are prone to unexpected failures due to discrepancies between training data distributions and the wide variety of noise patterns found in real-world videos. These methods also tend to be slow and lack user control. In contrast, traditional denoising methods perform reliably on in-the-wild videos and run relatively quickly on modern hardware. However, they require manually tuning parameters for each input video, which is not only tedious but also requires skill. We bridge the gap between these two paradigms by proposing a differentiable denoising pipeline based on traditional methods. A neural network is then trained to predict the optimal denoising parameters for each specific input, resulting in a robust and efficient approach that also supports user control.
****

Practical Solutions to the Relative Pose of Three Calibrated Cameras

Charalambos Tzamos, Viktor Kocur, Yaqing Ding, Daniel Barath, Zuzana Berger Haladova, Torsten Sattler, Zuzana Kukelova; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 21913-21923

We study the challenging problem of estimating the relative pose of three calibrated cameras from four point correspondences. We propose novel efficient solutions to this problem that are based on the simple idea of using four correspondences to estimate an approximate geometry of the first two views. We model this geometry either as an affine or a fully perspective geometry estimated using one additional approximate correspondence. We generate such an approximate correspondence using a very simple and efficient strategy, where the new point is the mean point of three corresponding input points. The new solvers are efficient and easy to implement, since they are based on existing efficient minimal solvers, i.e., the 4-point affine fundamental matrix, the well-known 5-point relative pose solver, and the \texttt P3P solver. Extensive experiments on real data show that the proposed solvers, when properly coupled with local optimization, achieve state-of-the-art results, with the novel solver based on approximate mean-point correspondences being more robust and accurate than the affine-based solver.
****

Localized Concept Erasure for Text-to-Image Diffusion Models Using Training-Free Gated Low-Rank Adaptation

Byung Hyun Lee, Sungjin Lim, Se Young Chun; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 18596-18606

Fine-tuning based concept erasing has demonstrated promising results in preventing generation of harmful contents from text-to-image diffusion models by removing target concepts while preserving remaining concepts. To maintain the generation capability of diffusion models after concept erasure, it is necessary to remove only the image region containing the target concept when it locally appears in an image, leaving other regions intact. However, prior arts often compromise fidelity of the other image regions in order to erase the localized target concept appearing in a specific area, thereby reducing the overall performance of image generation. To address these limitations, we first introduce a framework called localized concept erasure, which allows for the deletion of only the specific a

rea containing the target concept in the image while preserving the other region s. As a solution for the localized concept erasure, we propose a training-free a pproach, dubbed Gated Low-rank adaptation for Concept Erasure (GLoCE), that inje cts a lightweight module into the diffusion model. GLoCE consists of low-rank ma trices and a simple gate, determined only by several generation steps for concep ts without training. By directly applying GLoCE to image embeddings and designin g the gate to activate only for target concepts, GLoCE can selectively remove on ly the region of the target concepts, even when target and remaining concepts co exist within an image. Extensive experiments demonstrated GLoCE not only improve s the image fidelity to text prompts after erasing the localized target concepts , but also outperforms prior arts in efficacy, specificity, and robustness by la rge margin and can be extended to mass concept erasure.

PARC: A Quantitative Framework Uncovering the Symmetries within Vision Language Models

Jenny Schmalfuss, Nadine Chang, Vibashan VS, Maying Shen, Andres Bruhn, Jose M. Alvarez; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 25081-25091

Vision language models (VLMs) respond to user-crafted text prompts and visual in puts, and are applied to numerous real-world problems. VLMs integrate visual mod alities with large language models (LLMs), which are well known to be prompt-sen sitive. Hence, it is crucial to determine whether VLMs inherit this instability to varying prompts. We therefore investigate which prompt variations VLMs are mo st sensitive to and which VLMs are most agnostic to prompt variations. To this e nd, we introduce PARC (Prompt Analysis via Reliability and Calibration), a VLM p rompt sensitivity analysis framework built on three pillars: (1) plausible promp t variations in both the language and vision domain, (2) a novel model reliabili ty score with built-in guarantees, and (3) a calibration step that enables datas et- and prompt-spanning prompt variation analysis. Regarding prompt variations, PARC's evaluation shows that VLMs mirror LLM language prompt sensitivity in the vision domain, and most destructive variations change the expected answer. Regar ding models, outstandingly robust VLMs among 22 evaluated models come from the I nternVL2 family. We further find indications that prompt sensitivity is linked t o training data. https://github.com/NVlabs/PARC

RoboTwin: Dual-Arm Robot Benchmark with Generative Digital Twins

Yao Mu, Tianxing Chen, Zanxin Chen, Shijia Peng, Zhiqian Lan, Zeyu Gao, Zhixuan Liang, Qiaojun Yu, Yude Zou, Mingkun Xu, Lunkai Lin, Zhiqiang Xie, Mingyu Ding, Ping Luo; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 27649-27660

In the rapidly advancing field of robotics, dual-arm coordination and complex ob ject manipulation are essential capabilities for developing advanced autonomous systems. However, the scarcity of diverse, high-quality demonstration data and r eal-world-aligned evaluation benchmarks severely limits such development. To add ress this, we introduce RoboTwin, a generative digital twin framework that uses 3D generative foundation models and large language models to produce diverse exp ert datasets and provide a real-world-aligned evaluation platform for dual-arm r obotic tasks. Specifically, RoboTwin creates varied digital twins of objects fro m single 2D images, generating realistic and interactive scenarios. It also intr oduces a spatial relation-aware code generation framework that combines object a nnotations with large language models to break down tasks, determine spatial con straints, and generate precise robotic movement code. Our framework offers a com prehensive benchmark with both simulated and real-world data, enabling standardi zed evaluation and better alignment between simulated training and real-world pe rformance. We validated our approach using the open-source COBOT Magic Robot pla tform. Policies pre-trained on RoboTwin-generated data and fine-tuned with limit ed real-world samples demonstrate significant potential for enhancing dual-arm r obotic manipulation systems by improving success rates by over 70% for single-ar m tasks and over 40% for dual-arm tasks compared to models trained solely on rea l-world data.

Population Normalization for Federated Learning
Zhuoyao Wang, Fan Yi, Peizhu Gong, Caitou He, Cheng Jin, Weizhong Zhang; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 10214-10223
Batch normalization (BN) is widely recognized as an essential method in training deep neural networks, facilitating convergence and enhancing model stability. However, in Federated Learning (FL) contexts, where training data are typically heterogeneous and clients often face resource constraints, the effectiveness of BN is considerably limited for two primary reasons. First, the population statistics, specifically the mean and variance of these heterogeneous datasets, vary substantially, resulting in inconsistent BN layers across client models, which ultimately drives these models to diverge further. Second, estimating statistics from a mini-batch is often imprecise since the batch size has to be small in resource-limited clients. This paper introduces Population Normalization, a novel technique for FL, in which the statistics are learned as trainable parameters rather than calculated from mini-batches as in BN. Thus, our normalization layers are homogeneous among the clients and the adverse impact of small batch size is eliminated as the model can be well-trained even when the batch size equals to one. To enhance the flexibility of our method in practical applications, we investigate the role of stochastic uncertainty in BN's statistical estimation. When larger batch sizes are available, we demonstrate that injecting simple artificial noise can effectively mimic this stochastic uncertainty and improve the model's generalization capability. Experimental results validate the efficacy of our approach across various FL tasks.

AnimateAnything: Consistent and Controllable Animation for Video Generation
Guojun Lei, Chi Wang, Rong Zhang, Yikai Wang, Hong Li, Weiwei Xu; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 27946-27956
We propose a unified approach for video-controlled generation, enabling text-based guidance and manual annotations to control the generation of videos, similar to camera direction guidance. Specifically, we designed a two-stage algorithm. In the first stage, we convert all control information into frame-by-frame motion flows. In the second stage, we use these motion flows as guidance to control the final video generation. Additionally, to reduce instability in the generated videos caused by large motion variations (such as those from camera movement, object motion, or manual inputs), which can result in flickering or the intermittent disappearance of objects, we transform the temporal feature computation in the video model into frequency-domain feature computation. This is because frequency-domain signals better capture the essential characteristics of an image, and by ensuring consistency in the video's frequency-domain features, we can enhance temporal coherence and reduce flickering in the final generated video.

PRaDA: Projective Radial Distortion Averaging
Daniil Sinitsyn, Linus Härenstam-Nielsen, Daniel Cremers; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 21902-21912
We tackle the problem of automatic calibration of radially distorted cameras in challenging conditions. Accurately determining distortion parameters typically requires either 1) solving the full Structure from Motion (SfM) problem involving camera poses, 3D points, and the distortion parameters, which is only possible if many images with sufficient overlap are provided, or 2) relying heavily on learning-based methods that are comparatively less accurate. In this work, we demonstrate that distortion calibration can be decoupled from 3D reconstruction, maintaining the accuracy of SfM-based methods while avoiding many of the associated complexities. This is achieved by working in Projective Space, where the geometry is unique up to a homography, which encapsulates all camera parameters except for distortion. Our proposed method, Projective Radial Distortion Averaging, averages multiple distortion estimates in a fully projective framework without creating 3d points and full bundle adjustment. By relying on pairwise projective re

lations, our methods support any feature-matching approaches without constructin g point tracks across multiple images.

GenAssets: Generating in-the-wild 3D Assets in Latent Space
Ze Yang, Jingkang Wang, Haowei Zhang, Sivabalan Manivasagam, Yun Chen, Raquel Ur tasun; Proceedings of the Computer Vision and Pattern Recognition Conference (CV PR), 2025, pp. 22392-22403
High-quality 3D assets for traffic participants are critical for multi-sensor si mulation, which is essential for the safe end-to-end development of autonomy. Bu ilding assets from in-the-wild data is key for diversity and realism, but existi ng neural-rendering based reconstruction methods are slow and generate assets th at render well only from viewpoints close to the original observations, limiting their usefulness in simulation. Recent diffusion-based generative models build complete and diverse assets, but perform poorly on in-the-wild driving scenes, w here observed actors are captured under sparse and limited fields of view, and a re partially occluded. In this work, we propose a 3D latent diffusion model that learns on in-the-wild LiDAR and camera data captured by a sensor platform and g enerates high-quality 3D assets with complete geometry and appearance. Key to ou r method is a "reconstruct-then-generate" approach that first leverages occlusio n-aware neural rendering trained over multiple scenes to build a high-quality la tent space for objects, and then trains a diffusion model that operates on the l atent space. We show our method outperforms existing reconstruction and generati on based methods, unlocking diverse and scalable content creation for simulation . Please visit https://waabi.ai/genassets for more details.

RipVIS: Rip Currents Video Instance Segmentation Benchmark for Beach Monitoring and Safety
Andrei Dumitriu, Florin Tatui, Florin Miron, Aakash Ralhan, Radu Tudor Ionescu, Radu Timofte; Proceedings of the Computer Vision and Pattern Recognition Confere nce (CVPR), 2025, pp. 3427-3437
Rip currents are strong, localized and narrow currents of water that flow outwar ds into the sea, causing numerous beach-related injuries and fatalities worldwid e. Accurate identification of rip currents remains challenging due to their amor phous nature and the lack of annotated data, which often requires expert knowled ge. To address these issues, we present RipVIS, a large-scale video instance seg mentation benchmark explicitly designed for rip current segmentation. RipVIS is an order of magnitude larger than previous datasets, featuring 184 videos (212,3 28 frames), of which 150 videos (163,528 frames) are with rip currents, collecte d from various sources, including drones, mobile phones, and fixed beach cameras . Our dataset encompasses diverse visual contexts, such as wave-breaking pattern s, sediment flows, and water color variations, across multiple global locations, including USA, Mexico, Costa Rica, Portugal, Italy, Greece, Romania, Sri Lanka, Australia and New Zealand. Most videos are annotated at 5 FPS to ensure accurac y in dynamic scenarios, supplemented by an additional 34 videos (48,800 frames) without rip currents. We conduct comprehensive experiments with Mask R-CNN, Casc ade Mask R-CNN, SparseInst and YOLO11, fine-tuning these models for the task of rip current segmentation. Results are reported in terms of multiple metrics, wit h a particular focus on the F2 score to prioritize recall and reduce false negat ives. To enhance segmentation performance, we introduce a novel post-processing step based on Temporal Confidence Aggregation (TCA). RipVIS aims to set a new st andard for rip current segmentation, contributing towards safer beach environmen ts. We offer a benchmark website to share data, models, and results with the res earch community, encouraging ongoing collaboration and future contributions, at https://ripvis.ai.

Low-Rank Adaptation in Multilinear Operator Networks for Security-Preserving Inc remental Learning
Huu Binh Ta, Duc Nguyen, Quyen Tran, Toan Tran, Tung Pham; Proceedings of the Co mputer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 24341-24350
In security-sensitive fields, data should be encrypted to protect against unauth

orized access and maintain confidentiality throughout processing. However, traditional networks like ViTs and CNNs return different results when processing original data versus its encrypted form, meaning that they require data to be decrypted, posing a security risk by exposing sensitive information. One solution for this issue is using polynomial networks, including state-of-the-art Multilinear Operator Networks, which return the same outputs given the real data and their encrypted forms under Leveled Fully Homomorphic Encryption. Nevertheless, these models are susceptible to catastrophic forgetting in incremental learning settings. Thus, this paper will present a new low-rank adaptation method combined with the Gradient Projection Memory mechanism to minimize the issue. Our proposal is compatible with Leveled Fully Homomorphic Encryption while achieving a sharp improvement in performance compared to existing models.

Camera Resection from Known Line Pencils and a Radially Distorted Scanline
Juan C. Dibene, Enrique Dunn; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 15843-15851
We present a marker-based geometric estimation framework for the absolute pose of a camera by analyzing the 1D observations in a single radially distorted pixel scanline.We leverage a pair of known co-planar pencils of lines, along with lens distortion parameters, to propose an ensemble of solvers exploring the space of estimation strategies applicable to our setup.First, we present a minimal algebraic solver requiring only six measurements and yielding eight solutions, which relies on the intersection of two conics defined by one of the pencils of lines.Then, we present a unique closed-form geometric solver from seven measurements. Finally, we present an homography-based formulation amenable to linear least-squares from eight or more measurements.Our geometric framework constitutes a theoretical analysis on the minimum geometric context necessary to solve in closed form for the absolute pose of a single camera from a single radially distorted scanline.

ESCAPE: Equivariant Shape Completion via Anchor Point Encoding
Burak Bekci, Nassir Navab, Federico Tombari, Mahdi Saleh; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 6480-6489
Shape completion, a crucial task in 3D computer vision, involves predicting and filling the missing regions of scanned or partially observed objects. Current methods expect known pose or canonical coordinates and do not perform well under varying rotations, limiting their real-world applicability. We introduce ESCAPE (Equivariant Shape Completion via Anchor Point Encoding), a novel framework designed to achieve rotation-equivariant shape completion. Our approach employs a distinctive encoding strategy by selecting anchor points from a shape and representing all points as a distance to all anchor points. This enables the model to capture a consistent, rotation-equivariant understanding of the object's geometry. ESCAPE leverages a transformer architecture to encode and decode the distance transformations, ensuring that generated shape completions remain accurate and equivariant under rotational transformations. Subsequently, we perform optimization to calculate the predicted shapes from the encodings. Experimental evaluations demonstrate that ESCAPE achieves robust, high-quality reconstructions across arbitrary rotations and translations, showcasing its effectiveness in real-world applications without additional pose estimation modules.

SPC-GS: Gaussian Splatting with Semantic-Prompt Consistency for Indoor Open-World Free-view Synthesis from Sparse Inputs
Guibiao Liao, Qing Li, Zhenyu Bao, Guoping Qiu, Kanglin Liu; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 11264-11274
3D Gaussian Splatting-based indoor open-world free-view synthesis approaches have shown significant performance with dense input images. However, they exhibit poor performance when confronted with sparse inputs, primarily due to the sparse distribution of Gaussian points and insufficient view supervision. To relieve these challenges, we propose SPC-GS, leveraging Scene-layout-based Gaussian Initialization (SGI) and Semantic-Prompt Consistency (SPC) Regularization for open-wor

ld free view synthesis with sparse inputs. Specifically, SGI provides a dense, s
cene-layout-based Gaussian distribution by utilizing view-changed images generat
ed from the video generation model and view-constraint Gaussian points densifica
tion. Additionally, SPC mitigates limited view supervision by employing semantic
-prompt-based consistency constraints developed by SAM2. This approach leverages
 available semantics from training views, serving as instructive prompts, to opt
imize visually overlapping regions in novel views with 2D and 3D consistency con
straints. Extensive experiments demonstrate the superior performance of SPC-GS a
cross Replica and ScanNet benchmarks. Notably, our SPC-GS achieves a 3.06 dB gai
n in PSNR for reconstruction quality and a 7.3% improvement in mIoU for open-wor
ld semantic segmentation.

M3amba: Memory Mamba is All You Need for Whole Slide Image Classification
Tingting Zheng, Kui Jiang, Yi Xiao, Sicheng Zhao, Hongxun Yao; Proceedings of th
e Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 15601-156
10
Multi-instance learning (MIL) has demonstrated impressive performance in whole s
lide image (WSI) analysis. However, existing approaches struggle with undesirabl
e results and unbearable computational overhead due to the quadratic complexity
 of Transformers. Recently, Mamba has offered a feasible solution for modeling lo
ng-range dependencies with linear complexity. However, vanilla Mamba inherently
 suffers from contextual forgetting issues, making it ill-suited for capturing gl
obal dependencies across instances in large-scale WSIs. To address this, we prop
ose a memory-driven Mamba network, dubbed M3amba, to fully explore the global la
tent relations among instances. Specifically, M3amba retains and iteratively upd
ates historical information with a dynamic memory bank (DMB), thus overcoming th
e catastrophic forgetting defects of Mamba for long-term context representation.
 For better feature representation, M3amba involves an intra-group bidirectional
 Mamba (BiMamba) block to refine local interactions within groups. Meanwhile, we
 additionally perform cross-attention fusion to incorporate relevant historical
information across groups, facilitating richer inter-group connections. The join
t learning of inter- and intra-group representations with memory merits enables
M3amba with a more powerful capability for achieving accurate and comprehensive
WSI representation. Extensive experiments on four datasets demonstrate that M3am
ba outperforms the state-of-the-art by 6.2% and 7.0% in accuracy on the TCGA BRA
C and TCGA Lung datasets while maintaining low computational costs.

Satellite to GroundScape - Large-scale Consistent Ground View Generation from Sa
tellite Views
Ningli Xu, Rongjun Qin; Proceedings of the Computer Vision and Pattern Recogniti
on Conference (CVPR), 2025, pp. 6068-6077
Generating consistent ground-view images from satellite imagery is challenging,
primarily due to the large discrepancies in viewing angles and resolution betwee
n satellite and ground-level domains. Previous efforts mainly concentrated on si
ngle-view generation, often resulting in inconsistencies across neighboring grou
nd views. In this work, we propose a novel cross-view synthesis approach designe
d to overcome these challenges by ensuring consistency across ground-view images
 generated from satellite views. Our method, based on a fixed latent diffusion m
odel, introduces two conditioning modules: satellite-guided denoising, which ext
racts high-level scene layout to guide the denoising process, and satellite-temp
oral denoising, which captures camera motion to maintain consistency across mult
iple generated views. We further contribute a large-scale satellite-ground datas
et containing over 100,000 perspective pairs to facilitate extensive ground scen
e or video generation. Experimental results demonstrate that our approach outper
forms existing methods on perceptual and temporal metrics, achieving high photor
ealism and consistency in multi-view outputs. The project page is at https://gda
osu.github.io/sat2groundscape

Variance-Based Membership Inference Attacks Against Large-Scale Image Captioning
 Models

Daniel Samira, Edan Habler, Yuval Elovici, Asaf Shabtai; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 9210-9219
The proliferation of multi-modal generative models has introduced new privacy and security challenges, especially due to the risks of memorization and unintentional disclosure of sensitive information. This paper focuses on the vulnerability of multi-modal image captioning models to membership inference attacks (MIAs). These models, which synthesize textual descriptions from visual content, could inadvertently reveal personal or proprietary data embedded in their training datasets. We explore the feasibility of MIAs in the context of such models. Specifically, our approach leverages a variance-based strategy tailored for image captioning models, utilizing only image data without knowing the corresponding caption. We introduce the means-of-variance threshold attack (MVTA) and confidence-based weakly supervised attack (C-WSA) based on the metric, means-of-variance (MV), to assess variability among vector embeddings. Our experiments demonstrate that these models are susceptible to MIAs, indicating substantial privacy risks. The effectiveness of our methods is validated through rigorous evaluations on these real-world models, confirming the practical implications of our findings.

Redefining <Creative> in Dictionary: Towards an Enhanced Semantic Understanding of Creative Generation
Fu Feng, Yucheng Xie, Xu Yang, Jing Wang, Xin Geng; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 18444-18454
Creative remains an inherently abstract concept for both humans and diffusion models. While text-to-image (T2I) diffusion models can easily generate out-of-distribution concepts like "a blue banana", they struggle with generating combinatorial objects such as "a creative mixture that resembles a lettuce and a mantis", due to difficulties in understanding the semantic depth of "creative". Current methods rely heavily on synthesizing reference prompts or images to achieve a creative effect, typically requiring retraining for each unique creative output-a process that is computationally intensive and limits practical applications. To address this, we introduce CreTok, which brings meta-creativity to diffusion models by redefining "creative" as a new token, <CreTok>, thus enhancing models' semantic understanding for combinatorial creativity. CreTok achieves such redefinition by iteratively sampling diverse text pairs from our proposed CangJie dataset to form adaptive prompts and restrictive prompts, and then optimizing the similarity between their respective text embeddings. Extensive experiments demonstrate that <CreTok> enables the universal and direct generation of combinatorial creativity across diverse concepts without additional training, achieving state-of-the-art performance with improved text-image alignment and higher human preference ratings. Code will be made available at https://github.com/fu-feng/CreTok.

FiRe: Fixed-points of Restoration Priors for Solving Inverse Problems
Matthieu Terris, Ulugbek S. Kamilov, Thomas Moreau; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 23185-23194
Selecting an appropriate prior to compensate for information loss due to the measurement operator is a fundamental challenge in imaging inverse problems. Implicit priors based on denoising neural networks have become central to widely-used frameworks such as Plug-and-Play (PnP) algorithms. In this work, we introduce Fixed-points of Restoration (FiRe) priors as a new framework for expanding the notion of priors in PnP to general restoration models beyond traditional denoising models. The key insight behind FiRe is that smooth images emerge as fixed points of the composition of a degradation operator with the corresponding restoration model. This enables us to derive an explicit formula for our implicit prior by quantifying invariance of images under this composite operation. Adopting this fixed-point perspective, we show how various restoration networks can effectively serve as priors for solving inverse problems. The FiRe framework further enables ensemble-like combinations of multiple restoration models as well as acquisition-informed restoration networks, all within a unified optimization approach. Experimental results validate the effectiveness of FiRe across various inverse problems, establishing a new paradigm for incorporating pretrained restoration mode

ls into PnP-like algorithms. Code available at https://github.com/matthieutrs/fire.

Learning Dynamic Collaborative Network for Semi-supervised 3D Vessel Segmentation

Jiao Xu, Xin Chen, Lihe Zhang; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 10445-10454

In this paper, we present a new dynamic collaborative network for semi-supervised 3D vessel segmentation, termed DiCo. Conventional mean teacher (MT) methods typically employ a static approach, where the roles of the teacher and student models are fixed. However, due to the complexity of 3D vessel data, the teacher model may not always outperform the student model, leading to cognitive biases that can limit performance. To address this issue, we propose a dynamic collaborative network that allows the two models to dynamically switch their teacher-student roles. Additionally, we introduce a multi-view integration module to capture various perspectives of the inputs, mirroring the way doctors conduct medical analysis. We also incorporate adversarial supervision to constrain the shape of the segmented vessels in unlabeled data. In this process, the 3D volume is projected into 2D views to mitigate the impact of label inconsistencies. Experiments demonstrate that our DiCo method sets new state-of-the-art performance on three 3D vessel segmentation benchmarks. The code repository address is https://github.com/xujiaommcome/DiCo.

Temporal Alignment-Free Video Matching for Few-shot Action Recognition

SuBeen Lee, WonJun Moon, Hyun Seok Seong, Jae-Pil Heo; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 5412-5421

Few-Shot Action Recognition (FSAR) aims to train a model with only a few labeled video instances. A key challenge in FSAR is handling divergent narrative trajectories for precise video matching. While the frame- and tuple-level alignment approaches have been promising, their methods heavily rely on pre-defined and length-dependent alignment units (e.g., frames or tuples), which limits flexibility for actions of varying lengths and speeds. In this work, we introduce a novel TEmporal Alignment-free Matching (TEAM) approach, which eliminates the need for temporal units in action representation and brute-force alignment during matching. Specifically, TEAM represents each video with a fixed set of pattern tokens that capture globally discriminative clues within the video instance regardless of action length or speed, ensuring its flexibility. Furthermore, TEAM is inherently efficient, using token-wise comparisons to measure similarity between videos, unlike existing methods that rely on pairwise comparisons for temporal alignment. Additionally, we propose an adaptation process that identifies and removes common information across classes, establishing clear boundaries even between novel categories. Extensive experiments demonstrate the effectiveness of TEAM. Codes are available at github.com/leesb7426/TEAM.

OSLoPrompt: Bridging Low-Supervision Challenges and Open-Set Domain Generalization in CLIP

Mohamad Hassan N C, Divyam Gupta, Mainak Singha, Sai Bhargav Rongali, Ankit Jha, Muhammad Haris Khan, Biplab Banerjee; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 10110-10120

We introduce Low-Shot Open-Set Domain Generalization (LSOSDG), a novel paradigm unifying low-shot learning with open-set domain generalization (ODG). While prompt-based methods using models like CLIP have advanced DG, they falter in low-data regimes (e.g., 1-shot) and lack precision in detecting open-set samples with fine-grained semantics related to training classes. To address these challenges, we propose OSLoPrompt, an advanced prompt-learning framework for CLIP with two core innovations. First, to manage limited supervision across source domains and improve DG, we introduce a domain-agnostic prompt-learning mechanism that integrates adaptable domain-specific cues and visually guided semantic attributes through a novel cross-attention module, besides being supported by learnable domain- and class-generic visual prompts to enhance cross-modal adaptability. Second, t

o improve outlier rejection during inference, we classify unfamiliar samples as "unknown" and train specialized prompts with systematically synthesized pseudo-open samples that maintain fine-grained relationships to known classes, generated through a targeted query strategy with off-the-shelf foundation models. This strategy enhances feature learning, enabling our model to detect open samples with varied granularity more effectively. Extensive evaluations across five benchmarks demonstrate that OSLoPrompt establishes a new state-of-the-art in LSOSDG, significantly outperforming existing methods.
****
Dinomaly: The Less Is More Philosophy in Multi-Class Unsupervised Anomaly Detection
Jia Guo, Shuai Lu, Weihang Zhang, Fang Chen, Huiqi Li, Hongen Liao; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 20405-20415
Recent studies highlighted a practical setting of unsupervised anomaly detection (UAD) that builds a unified model for multi-class images. Despite various advancements addressing this challenging task, the detection performance under the multi-class setting still lags far behind state-of-the-art class-separated models. Our research aims to bridge this substantial performance gap. In this paper, we present Dinomaly, a minimalist reconstruction-based anomaly detection framework that harnesses pure Transformer architectures without relying on complex designs, additional modules, or specialized tricks. Given this powerful framework consisting of only Attentions and MLPs, we found four simple components that are essential to multi-class anomaly detection: (1) Scalable foundation Transformers that extracts universal and discriminative features, (2) Noisy Bottleneck where pre-existing Dropouts do all the noise injection tricks, (3) Linear Attention that naturally cannot focus, and (4) Loose Reconstruction that does not force layer-to-layer and point-by-point reconstruction. Extensive experiments are conducted across popular anomaly detection benchmarks including MVTec-AD, VisA, and Real-IAD. Our proposed Dinomaly achieves impressive image-level AUROC of 99.6%, 98.7%, and 89.3% on the three datasets respectively, which is not only superior to state-of-the-art multi-class UAD methods, but also achieves the most advanced class-separated UAD records.
****
VLog: Video-Language Models by Generative Retrieval of Narration Vocabulary
Kevin Qinghong Lin, Mike Zheng Shou; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 3218-3228
Human daily activities can be concisely narrated as sequences of routine events (e.g., turning off an alarm) in video streams, forming an event vocabulary. Motivated by this, we introduce **VLog**, a novel video understanding framework that defines video narrations as a vocabulary, going beyond the typical subword vocabularies in existing generative video-language models. Built on the lightweight language model GPT-2, **VLog** features three key innovations:1. **A Generative Retrieval Model** Marrying the language model's complex reasoning capabilities with contrastive retrieval's efficient similarity search.2. **A Hierarchical Vocabulary** Derived from large-scale video narrations using our narration pair encoding algorithm, enabling efficient indexing of specific events (e.g., cutting a tomato) by identifying broader scenarios (e.g., kitchen) with expressive postfixes (e.g., by the left hand).3. **A Vocabulary Update Strategy** Leveraging generative models to extend the vocabulary for novel events encountered during inference.To validate our approach, we introduce **VidCab-Eval**, a development set requiring concise narrations with reasoning relationships (e.g., before and after). Experiments on **EgoSchema**, **COIN**, and **HiREST** further demonstrate the effectiveness of **VLog**, highlighting its ability to generate concise, contextually accurate, and efficient narrations. This offers a novel perspective on video understanding.

CoMBO: Conflict Mitigation via Branched Optimization for Class Incremental Segmentation
Kai Fang, Anqi Zhang, Guangyu Gao, Jianbo Jiao, Chi Harold Liu, Yunchao Wei; Pro

ceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 25667-25676
Effective Class Incremental Segmentation (CIS) requires simultaneously mitigating catastrophic forgetting and ensuring sufficient plasticity to integrate new classes. The inherent conflict above often leads to a back-and-forth, which turns the objective into finding the balance between the performance of previous (old) and incremental (new) classes. To address this conflict, we introduce a novel approach, Conflict Mitigation via Branched Optimization (CoMBO). Within this approach, we present the Query Conflict Reduction module, designed to explicitly refine queries for new classes through lightweight, class-specific adapters. This module provides an additional branch for the acquisition of new classes while preserving the original queries for distillation. Moreover, we develop two strategies to further mitigate the conflict following the branched structure, i.e., the Half-Learning Half-Distillation (HDHL) over classification probabilities, and the Importance-Based Knowledge Distillation (IKD) over query features. HDHL selectively engages in learning for classification probabilities of queries that match the ground truth of new classes, while aligning unmatched ones to the corresponding old probabilities, thus ensuring retention of old knowledge while absorbing new classes via learning negative samples. Meanwhile, IKD assesses the importance of queries based on their matching degree to old classes, prioritizing the distillation of important features and allowing less critical features to evolve. Extensive experiments in Class Incremental Panoptic and Semantic Segmentation settings have demonstrated the superior performance of CoMBO. Project page: https://guangyu-ryan.github.io/CoMBO.

Forensics-Bench: A Comprehensive Forgery Detection Benchmark Suite for Large Vision Language Models
Jin Wang, Chenghui Lv, Xian Li, Shichao Dong, Huadong Li, Kelu Yao, Chao Li, Wenqi Shao, Ping Luo; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 4233-4245
Recently, the rapid development of AIGC has significantly boosted the diversities of fake media spread in the Internet, posing unprecedented threats to social security, politics, law, and etc.To detect the ever-increasingly **diverse** malicious fake media in the new era of AIGC, recent studies have proposed to exploit Large Vision Language Models (LVLMs) to design **robust** forgery detectors due to their impressive performance on a **wide** range of multimodal tasks.However, it still lacks a comprehensive benchmark designed to comprehensively assess LVLMs' discerning capabilities on forgery media.To fill this gap, we present Forensics-Bench, a new forgery detection evaluation benchmark suite to assess LVLMs across massive forgery detection tasks, requiring comprehensive recognition, location and reasoning capabilities on diverse forgeries.Forensics-Bench comprises 63,292 meticulously curated multi-choicevisual questions, covering 112 unique forgery detection types from 5 perspectives: forgery semantics, forgery modalities, forgery tasks, forgery types and forgery models.We conduct thorough evaluations on 22 open-sourced LVLMs and 3 proprietary models GPT-4o, Gemini 1.5 Pro, and Claude 3.5 Sonnet, highlighting the significant challenges of comprehensive forgery detection posed by Forensics-Bench.We anticipate that Forensics-Bench will motivate the community to advance the frontier of LVLMs, striving for all-around forgery detectors in the era of AIGC.

Detect-and-Guide: Self-regulation of Diffusion Models for Safe Text-to-Image Generation via Guideline Token Optimization
Feifei Li, Mi Zhang, Yiming Sun, Min Yang; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 13252-13262
Text-to-image diffusion models have achieved state-of-the-art results in synthesis tasks; however, there is a growing concern about their potential misuse in creating harmful content. To mitigate these risks, post-hoc model intervention techniques, such as concept unlearning and safety guidance, have been developed. However, fine-tuning model weights or adapting the hidden states of the diffusion model operates in an uninterpretable way, making it unclear which part of the in

termediate variables is responsible for unsafe generation. These interventions s everely affect the sampling trajectory when erasing harmful concepts from comple x, multi-concept prompts, thus hindering their practical use in real-world setti ngs. In this work, we propose the safe generation framework Detect-and-Guide (DA G), leveraging the internal knowledge of diffusion models to perform self-diagno sis and fine-grained self-regulation during the sampling process. DAG first dete cts harmful concepts from noisy latents using refined cross-attention maps of op timized tokens, then applies safety guidance with adaptive strength and editing regions to negate unsafe generation. The optimization only requires a small anno tated dataset and can provide precise detection maps with generalizability and c oncept specificity. Moreover, DAG does not require fine-tuning of diffusion mode ls, and therefore introduces no loss to their generation diversity. Experiments on erasing sexual content show that DAG achieves state-of-the-art safe generatio n performance, balancing harmfulness mitigation and text-following performance o n multi-concept real-world prompts.

MirrorVerse: Pushing Diffusion Models to Realistically Reflect the World

Ankit Dhiman, Manan Shah, R Venkatesh Babu; Proceedings of the Computer Vision a nd Pattern Recognition Conference (CVPR), 2025, pp. 11239-11249

Diffusion models have become central to various image editing tasks, yet they of ten fail to fully adhere to physical laws, particularly with effects like shadow s, reflections, and occlusions. In this work, we address the challenge of genera ting photorealistic mirror reflections using diffusion-based generative models. Despite extensive training data, existing diffusion models frequently overlook t he nuanced details crucial to authentic mirror reflections. Recent approaches ha ve attempted to resolve this by creating synthetic datasets and framing reflecti on generation as an inpainting task; however, they struggle to generalize across different object orientations and positions relative to the mirror. Our method overcomes these limitations by introducing key augmentations into the synthetic data pipeline: (1) random object positioning, (2) randomized rotations, and (3) grounding of objects, significantly enhancing generalization across poses and pl acements. To further address spatial relationships and occlusions in scenes with multiple objects, we implement a strategy to pair objects during dataset genera tion, resulting in a dataset robust enough to handle these complex scenarios. Ac hieving generalization to real-world scenes remains a challenge, so we introduce a three-stage training curriculum to develop the MirrorFusion 2.0 model, aimed at improving real-world performance. We provide extensive qualitative and quanti tative evaluations to support our approach. The project page is available at: ht tps://mirror-verse.github.io/.

EAP-GS: Efficient Augmentation of Pointcloud for 3D Gaussian Splatting in Few-sh ot Scene Reconstruction

Dongrui Dai, Yuxiang Xing; Proceedings of the Computer Vision and Pattern Recogn ition Conference (CVPR), 2025, pp. 16498-16507

3D Gaussian splatting (3DGS) has shown impressive performance in 3D scene recons truction. However, it suffers from severe degradation when the number of trainin g views is limited, resulting in blur and floaters. Many works have been devoted to standardize the optimization process of 3DGS through regularization techniqu es. However, we identify that inadequate initialization is a critical issue over looked by current studies. To address this, we propose EAP-GS, a method to enhan ce initialization for fast, accurate, and stable few-shot scene reconstruction. Specifically, we introduce an Attentional Pointcloud Augmentation (APA) techniqu e, which retains two-view tracks as an option for pointcloud generation. Additio nally, the scene complexity is used to determine the required density distributi on, thereby constructing a better pointcloud. We implemented APA by extending St ructure-From-Motion (SFM) to focus on pointcloud generation in regions with comp lex structure but sparse pointcloud distribution, which significantly increases the number of valuable points and effectively harmonizes the density distributio n. A better pointcloud leads to more accurate scene geometry and mitigates local overfitting during reconstruction stage. Furthermore, our APA can be framed as

a modular augmentation to existing methods with minimal overhead. Experimental r
esults from various indoor and outdoor scenes demonstrate that the proposed EAP-
GS achieves outstanding scene reconstruction performance and surpasses state-of-
the-art methods. Project page: https://osierddr.github.io/eapgs/

Empowering Large Language Models with 3D Situation Awareness
Zhihao Yuan, Yibo Peng, Jinke Ren, Yinghong Liao, Yatong Han, Chun-Mei Feng, Hen
gshuang Zhao, Guanbin Li, Shuguang Cui, Zhen Li; Proceedings of the Computer Vis
ion and Pattern Recognition Conference (CVPR), 2025, pp. 19435-19445
Driven by the great success of Large Language Models (LLMs) in the 2D image doma
in, their applications in 3D scene understanding has emerged as a new trend. A k
ey difference between 3D and 2D is that the situation of an egocentric observer
in 3D scenes can change, resulting in different descriptions (e.g., "left" or "r
ight"). However, current LLM-based methods overlook the egocentric perspective a
nd simply use datasets from a global viewpoint. To address this issue, we propos
e a novel approach to automatically generate a situation-aware dataset by levera
ging the scanning trajectory during data collection and utilizing Vision-Languag
e Models (VLMs) to produce high-quality captions and question-answer pairs. Furt
hermore, we introduce a situation grounding module to explicitly predict the pos
ition and orientation of observer's viewpoint, thereby enabling LLMs to ground s
ituation description in 3D scenes. We evaluate our approach on several benchmark
s, demonstrating that our method effectively enhances the 3D situational awarene
ss of LLMs while significantly expanding existing datasets and reducing manual e
ffort.

Forensic Self-Descriptions Are All You Need for Zero-Shot Detection, Open-Set So
urce Attribution, and Clustering of AI-generated Images
Tai D. Nguyen, Aref Azizpour, Matthew C. Stamm; Proceedings of the Computer Visi
on and Pattern Recognition Conference (CVPR), 2025, pp. 3040-3050
The emergence of advanced AI-based tools to generate realistic images poses sign
ificant challenges for forensic detection and source attribution, especially as
new generative techniques appear rapidly. Traditional methods often fail to gene
ralize to unseen generators due to reliance on features specific to known source
s during training. To address this problem, we propose a novel approach that exp
licitly models forensic microstructures--subtle, pixel-level patterns unique to
the image creation process. Using only real images in a self-supervised manner,
we learn a set of diverse predictive filters to extract residuals that capture d
ifferent aspects of these microstructures. By jointly modeling these residuals a
cross multiple scales, we obtain a compact model whose parameters constitute a u
nique forensic self-description for each image. This self-description enables us
 to perform zero-shot detection of synthetic images, open-set source attribution
 of images, and clustering based on source without prior knowledge. Extensive ex
periments demonstrate that our method achieves superior accuracy and adaptabilit
y compared to competing techniques, advancing the state of the art in synthetic
media forensics.

EchoTraffic: Enhancing Traffic Anomaly Understanding with Audio-Visual Insights
Zhenghao Xing, Hao Chen, Binzhu Xie, Jiaqi Xu, Ziyu Guo, Xuemiao Xu, Jianye Hao,
 Chi-Wing Fu, Xiaowei Hu, Pheng-Ann Heng; Proceedings of the Computer Vision and
 Pattern Recognition Conference (CVPR), 2025, pp. 19098-19108
Traffic Anomaly Understanding (TAU) is essential for improving public safety and
 transportation efficiency by enabling timely detection and response to incident
s. Beyond existing methods, which rely largely on visual data, we propose to con
sider audio cues, a valuable source that offers strong hints to anomaly scenario
s such as crashes and honking. Our contributions are twofold. First, we compile
AV-TAU, the first large-scale audio-visual dataset for TAU, providing 29,865 tra
ffic anomaly videos and 149,325 Q&A pairs, while supporting five essential TAU t
asks. Second, we develop EchoTraffic, a multimodal LLM that integrates audio and
 visual data for TAU, through our audio-insight frame selector and dynamic conne
ctor to effectively extract crucial audio cues for anomaly understanding with a

two-phase training framework. Experimental results on AV-TAU manifest that EchoTraffic sets a new SOTA performance in TAU, outperforming the existing multimodal LLMs. Our contributions, including AV-TAU and EchoTraffic, pave a new direction for multimodal TAU.

FlexDrive: Toward Trajectory Flexibility in Driving Scene Gaussian Splatting Reconstruction and Rendering
Jingqiu Zhou, Lue Fan, Linjiang Huang, Xiaoyu Shi, Si Liu, Zhaoxiang Zhang, Hongsheng Li; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 1549-1558
Driving scene reconstruction and rendering have advanced significantly using the 3D Gaussian Splatting.However, most prior research has focused on the rendering quality along a pre-recorded vehicle path and struggles to generalize to out-of-path viewpoints, which is caused by the lack of high-quality supervision in those out-of-path views. To address this issue, we introduce an Inverse View Warping technique to create compact and high-quality images as supervision for the reconstruction of the out-of-path views, enabling high-quality rendering results for those views.For accurate and robust inverse view warping, a depth bootstrap strategy is proposed to obtain on-the-fly dense depth maps during the optimization process, overcoming the sparsity and incompleteness of LiDAR depth data.Our method achieves superior in-path and out-of-path reconstruction and rendering performance on the widely used Waymo Open dataset.In addition, a simulator-based benchmark is proposed to obtain the out-of-path ground truth and quantitatively evaluate the performance of out-of-path rendering, where our method outperforms previous methods by a significant margin.

Taming Video Diffusion Prior with Scene-Grounding Guidance for 3D Gaussian Splatting from Sparse Inputs
Yingji Zhong, Zhihao Li, Dave Zhenyu Chen, Lanqing Hong, Dan Xu; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 6133-6143
Despite recent successes in novel view synthesis using 3D Gaussian Splatting (3DGS), modeling scenes with sparse inputs remains a challenge. In this work, we address two critical yet overlooked issues in real-world sparse-input modeling: extrapolation and occlusion. To tackle these issues, we propose to use a reconstruction by generation pipeline that leverages learned priors from video diffusion models to provide plausible interpretations for regions outside the field of view or occluded. However, the generated sequences exhibit inconsistencies that do not fully benefit subsequent 3DGS modeling. To address the challenge of inconsistency, we introduce a novel scene-grounding guidance based on rendered sequences from an optimized 3DGS, which tames the diffusion model to generate consistent sequences. This guidance is training-free and does not require any fine-tuning of the diffusion model. To facilitate holistic scene modeling, we also propose a trajectory initialization method. It effectively identifies regions that are outside the field of view and occluded. We further design a scheme tailored for 3DGS optimization with generated sequences. Experiments demonstrate that our method significantly improves upon the baseline and achieves state-of-the-art performance on challenging benchmarks.

Interactive Medical Image Segmentation: A Benchmark Dataset and Baseline
Junlong Cheng, Bin Fu, Jin Ye, Guoan Wang, Tianbin Li, Haoyu Wang, Ruoyu Li, He Yao, Junren Cheng, Jingwen Li, Yanzhou Su, Min Zhu, Junjun He; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 20841-20851
Interactive Medical Image Segmentation (IMIS) has long been constrained by the limited availability of large-scale, diverse, and densely annotated datasets, which hinders model generalization and consistent evaluation across different models. In this paper, we introduce the IMed-361M benchmark dataset, a significant advancement in general IMIS research. First, we collect and standardize over 6.4 million medical images and their corresponding ground truth masks from multiple d

ata sources. Then, leveraging the strong object recognition capabilities of a vi sion foundational model, we automatically generated dense interactive masks for each image and ensured their quality through rigorous quality control and granul arity management. Unlike previous datasets, which are limited by specific modali ties or sparse annotations, IMed-361M spans 14 modalities and 204 segmentation t argets, totaling 361 million masks--an average of 56 masks per image. Finally, w e developed an IMIS baseline network on this dataset that supports high-quality mask generation through interactive inputs, including clicks, bounding boxes, te xt prompts, and their combinations. We evaluate its performance on medical image segmentation tasks from multiple perspectives, demonstrating superior accuracy and scalability compared to existing interactive segmentation models. To facilit ate research on foundational models in medical computer vision, we release the I Med-361M and model at https://github.com/uni-medical/IMIS-Bench.

AutoSSVH: Exploring Automated Frame Sampling for Efficient Self-Supervised Video Hashing

Niu Lian, Jun Li, Jinpeng Wang, Ruisheng Luo, Yaowei Wang, Shu-Tao Xia, Bin Chen ; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 18881-18890

Self-Supervised Video Hashing (SSVH) compresses videos into hash codes for effic ient indexing and retrieval using unlabeled training videos. Existing approaches rely on random frame sampling to learn video features and treat all frames equa lly. This results in suboptimal hash codes, as it ignores frame-specific informa tion density and reconstruction difficulty. To address this limitation, we propo se a new framework, termed AutoSSVH, that employs adversarial frame sampling wit h hash-based contrastive learning. Our adversarial sampling strategy automatical ly identifies and selects challenging frames with richer information for reconst ruction, enhancing encoding capability. Additionally, we introduce a hash compon ent voting strategy and a point-to-set (P2Set) hash-based contrastive objective, which help capture complex inter-video semantic relationships in the Hamming sp ace and improve the discriminability of learned hash codes. Extensive experiment s demonstrate that AutoSSVH achieves superior retrieval efficacy and efficiency compared to state-of-the-art approaches. Code is available at https://github.com /EliSpectre/CVPR25-AutoSSVH.

Augmenting Multimodal LLMs with Self-Reflective Tokens for Knowledge-based Visua l Question Answering

Federico Cocchi, Nicholas Moratelli, Marcella Cornia, Lorenzo Baraldi, Rita Cucc hiara; Proceedings of the Computer Vision and Pattern Recognition Conference (CV PR), 2025, pp. 9199-9209

Multimodal LLMs (MLLMs) are the natural extension of large language models to ha ndle multimodal inputs, combining text and image data. They have recently garner ed attention due to their capability to address complex tasks involving both mod alities. However, their effectiveness is limited to the knowledge acquired durin

g training, which restricts their practical utility. In this work, we introduce a novel method to enhance the adaptability of MLLMs by integrating external knowledge sources. Our proposed model, Reflective LLaVA (ReflectiVA), utilizes reflective tokens to dynamically determine the need for external knowledge and predict the relevance of information retrieved from an external database. Tokens are trained following a two-stage two-model training recipe. This ultimately enables the MLLM to manage external knowledge while preserving fluency and performance on tasks where external knowledge is not needed. Through our experiments, we demonstrate the efficacy of ReflectiVA for knowledge-based visual question answering, highlighting its superior performance compared to existing methods. Source code and trained models are publicly available at https://aimagelab.github.io/ReflectiVA.

DifIISR: A Diffusion Model with Gradient Guidance for Infrared Image Super-Resolution

Xingyuan Li, Zirui Wang, Yang Zou, Zhixin Chen, Jun Ma, Zhiying Jiang, Long Ma, Jinyuan Liu; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 7534-7544

Infrared imaging is essential for autonomous driving and robotic operations as a supportive modality due to its reliable performance in challenging environments. Despite its popularity, the limitations of infrared cameras, such as low spatial resolution and complex degradations, consistently challenge imaging quality and subsequent visual tasks. Hence, infrared image super-resolution (IISR) has been developed to address this challenge. While recent developments in diffusion models have greatly advanced this field, current methods to solve it either ignore the unique modal characteristics of infrared imaging or overlook the machine perception requirements. To bridge these gaps, we propose DifIISR, an infrared image super-resolution diffusion model optimized for visual quality and perceptual performance. Our approach achieves task-based guidance for diffusion by injecting gradients derived from visual and perceptual priors into the noise during the reverse process. Specifically, we introduce an infrared thermal spectrum distribution regulation to preserve visual fidelity, ensuring that the reconstructed infrared images closely align with high-resolution images by matching their frequency components. Subsequently, we incorporate various visual foundational models as the perceptual guidance for downstream visual tasks, infusing generalizable perceptual features beneficial for detection and segmentation. As a result, our approach gains superior visual results while attaining State-Of-The-Art downstream task performance.

Recurrent Feature Mining and Keypoint Mixup Padding for Category-Agnostic Pose Estimation

Junjie Chen, Weilong Chen, Yifan Zuo, Yuming Fang; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 22035-22044

Category-agnostic pose estimation aims to locate keypoints on query images according to a few annotated support images for arbitrary novel classes. Existing methods generally extract support features via heatmap pooling, and obtain interacted features from support and query via cross-attention. Hence, these works neglect to mine fine-grained and structure-aware (FGSA) features from both support and query images, which are crucial for pixel-level keypoint localization. To this end, we propose a novel yet concise framework, which recurrently mines FGSA features from both support and query images. Specifically, we design a FGSA mining module based on deformable attention mechanism. On the one hand, we mine fine-grained features by applying deformable attention head over multi-scale feature maps. On the other hand, we mine structure-aware features by offsetting the reference points of keypoints to their linked keypoints. By means of above module, we recurrently mine FGSA features from support and query images, and thus obtain better support features and query estimations. In addition, we propose to use mixup keypoints to pad various classes to a unified keypoint number, which could provide richer supervision than the zero padding used in existing works. We conduct extensive experiments and in-depth studies on large-scale MP-100 dataset, and o

utperform SOTA method dramatically (+3.2% PCK\@0.05).

FrugalNeRF: Fast Convergence for Extreme Few-shot Novel View Synthesis without L
earned Priors
Chin-Yang Lin, Chung-Ho Wu, Chang-Han Yeh, Shih-Han Yen, Cheng Sun, Yu-Lun Liu;
Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 20
25, pp. 11227-11238
Neural Radiance Fields (NeRF) face significant challenges in extreme few-shot sc
enarios, primarily due to overfitting and long training times. Existing methods,
 such as FreeNeRF and SparseNeRF, use frequency regularization or pre-trained pr
iors but struggle with complex scheduling and bias. We introduce FrugalNeRF, a n
ovel few-shot NeRF framework that leverages weight-sharing voxels across multipl
e scales to efficiently represent scene details. Our key contribution is a cross
-scale geometric adaptation scheme that selects pseudo ground truth depth based
on reprojection errors across scales. This guides training without relying on ex
ternally learned priors, enabling full utilization of the training data. It can
also integrate pre-trained priors, enhancing quality without slowing convergence
. Experiments on LLFF, DTU, and RealEstate-10K show that FrugalNeRF outperforms
 other few-shot NeRF methods while significantly reducing training time, making
it a practical solution for efficient and accurate 3D scene reconstruction.
****
3D-GSW: 3D Gaussian Splatting for Robust Watermarking
Youngdong Jang, Hyunje Park, Feng Yang, Heeju Ko, Euijin Choo, Sangpil Kim; Proc
eedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025,
pp. 5938-5948
As 3D Gaussian Splatting (3D-GS) gains significant attention and its commercial
usage increases, the need for watermarking technologies to prevent unauthorized
use of the 3D-GS models and rendered images has become increasingly important. I
n this paper, we introduce a robust watermarking method for 3D-GS that secures c
opyright of both the model and its rendered images. Our proposed method remains
robust against distortions in rendered images and model attacks while maintainin
g high rendering quality. To achieve these objectives, we present Frequency-Guid
ed Densification (FGD), which removes 3D Gaussians based on their contribution t
o rendering quality, enhancing real-time rendering and the robustness of the mes
sage. FGD utilizes Discrete Fourier Transform to split 3D Gaussians in high-freq
uency areas, improving rendering quality. Furthermore, we employ a gradient mask
 for 3D Gaussians and design a wavelet-subband loss to enhance rendering quality
. Our experiments show that our method embeds the message in the rendered images
 invisibly and robustly against various attacks, including model distortion. Our
 method achieves superior performance in both rendering quality and watermark ro
bustness while improving real-time rendering efficiency. Project page: https://k
uai-lab.github.io/cvpr20253dgsw/

Pioneering 4-Bit FP Quantization for Diffusion Models: Mixup-Sign Quantization a
nd Timestep-Aware Fine-Tuning
Maosen Zhao, Pengtao Chen, Chong Yu, Yan Wen, Xudong Tan, Tao Chen; Proceedings
of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 1813
4-18143
Model quantization reduces the bit-width of weights and activations, improving m
emory efficiency and inference speed in diffusion models. However, achieving 4-b
it quantization remains challenging. Existing methods, primarily based on intege
r quantization and post-training quantization fine-tuning, struggle with inconsi
stent performance. Inspired by the success of floating-point (FP) quantization i
n large language models, we explore low-bit FP quantization for diffusion models
 and identify key challenges: the failure of signed FP quantization to handle as
ymmetric activation distributions, the insufficient consideration of temporal co
mplexity in the denoising process during fine-tuning, and the misalignment betwe
en fine-tuning loss and quantization error. To address these challenges, we prop
ose the mixup-sign floating-point quantization (MSFP) framework, first introduci
ng unsigned FP quantization in model quantization, along with timestep-aware LoR

A (TALoRA) and denoising-factor loss alignment (DFA), which ensure precise and s
table fine-tuning. Extensive experiments show that we are the first to achieve s
uperior performance in 4-bit FP quantization for diffusion models, outperforming
 existing PTQ fine-tuning methods in 4-bit INT quantization.

OpenING: A Comprehensive Benchmark for Judging Open-ended Interleaved Image-Text
 Generation
Pengfei Zhou, Xiaopeng Peng, Jiajun Song, Chuanhao Li, Zhaopan Xu, Yue Yang, Ziy
ao Guo, Hao Zhang, Yuqi Lin, Yefei He, Lirui Zhao, Shuo Liu, Tianhua Li, Yuxuan
Xie, Xiaojun Chang, Yu Qiao, Wenqi Shao, Kaipeng Zhang; Proceedings of the Compu
ter Vision and Pattern Recognition Conference (CVPR), 2025, pp. 56-66
Multimodal Large Language Models (MLLMs) have made significant strides in visual
 understanding and generation tasks. However, generating interleaved image-text
content remains a challenge, which requires integrated multimodal understanding
and generation abilities. While the progress in unified models offers new soluti
ons, existing benchmarks are insufficient for evaluating these methods due to da
ta size and diversity limitations. To bridge this gap, we introduce OpenING, a c
omprehensive benchmark comprising 5,400 high-quality human-annotated instances a
cross 56 real-world tasks. OpenING covers diverse daily scenarios such as travel
 guide, design, and brainstorming, offering a robust platform for challenging in
terleaved generation methods. In addition, we present IntJudge, a judge model fo
r evaluating open-ended multimodal generation methods. Trained with a novel data
 pipeline, our IntJudge achieves an agreement rate of 82.42% with human judgment
s, outperforming GPT-based evaluators by 11.34%. Extensive experiments on OpenIN
G reveal that current interleaved generation methods still have substantial room
 for improvement. Key findings on interleaved image-text generation are further
presented to guide the development of next-generation models.

Dual Exposure Stereo for Extended Dynamic Range 3D Imaging
Juhyung Choi, Jinnyeong Kim, Seokjun Choi, Jinwoo Lee, Samuel Brucker, Mario Bij
elic, Felix Heide, Seung-Hwan Baek; Proceedings of the Computer Vision and Patte
rn Recognition Conference (CVPR), 2025, pp. 6283-6293
Achieving robust stereo 3D imaging under diverse illumination conditions is an i
mportant however challenging task, largely due to the limited dynamic ranges (DR
s) of cameras, which are significantly smaller than real world DR. As a result,
the accuracy of existing stereo depth estimation methods is often compromised by
 under- or over-exposed images.In this work, we introduce dual-exposure stereo f
or extended dynamic range 3D imaging. We develop automatic dual-exposure control
 method that adjusts the dual exposures, diverging them when the scene DR exceed
s the camera DR, thereby providing information about broader DR. From the captur
ed dual-exposure stereo images, we estimate depth by developing a motion-aware d
ual-exposure stereo depth network.To validate our proposed method, we develop a
robot-vision system, collect real-world stereo video datasets, and generate a sy
nthetic dataset. Our approach outperforms traditional exposure control and depth
 estimation methods.

Unbiasing through Textual Descriptions: Mitigating Representation Bias in Video
Benchmarks
Nina Shvetsova, Arsha Nagrani, Bernt Schiele, Hilde Kuehne, Christian Rupprecht;
 Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2
025, pp. 29050-29059
We propose a new "Unbiased through Textual Description (UTD)" video benchmark ba
sed on unbiased subsets of existing video classification and retrieval datasets
to enable a more robust assessment of video understanding capabilities. Namely,
we tackle the problem that current video benchmarks may suffer from different re
presentation biases, e.g., object bias or single-frame bias, where mere recognit
ion of objects or utilization of only a single frame is sufficient for correct p
rediction. We leverage VLMs and LLMs to analyze and debias benchmarks from such
representation biases. Specifically, we generate frame-wise textual descriptions
 of videos, filter them for specific information (e.g. only objects) and leverag

e them to examine representation biases across three dimensions: 1) concept bias -- determining if a specific concept (e.g., objects) alone suffice for prediction; 2) temporal bias -- assessing if temporal information contributes to prediction; and 3) common sense vs. dataset bias -- evaluating whether zero-shot reasoning or dataset correlations contribute to prediction. We conduct a systematic analysis of 12 popular video classification and retrieval datasets and create new object-debiased test splits for these datasets. Moreover, we benchmark 30 state-of-the-art video models on original and debiased splits and analyze biases in the models. To facilitate the future development of more robust video understanding benchmarks and models, we release: "UTD-descriptions", a dataset with our rich structured descriptions for each dataset, and "UTD-splits", a dataset of object-debiased test splits.

Embodied Scene Understanding for Vision Language Models via MetaVQA

Weizhen Wang, Chenda Duan, Zhenghao Peng, Yuxin Liu, Bolei Zhou; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 22453-22464

Vision Language Models (VLMs) demonstrate significant potential as embodied AI agents for various mobility applications. However, a standardized, closed-loop benchmark for evaluating their spatial reasoning and sequential decision-making capabilities is lacking. To address this, we present MetaVQA: a comprehensive benchmark designed to assess and enhance VLMs' understanding of spatial relationships and scene dynamics through Visual Question Answering (VQA) and closed-loop simulations. MetaVQA leverages Set-of-Mark prompting and top-down view ground-truth annotations from nuScenes and Waymo datasets to automatically generate extensive question-answer pairs based on diverse real-world traffic scenarios, ensuring object-centric and context-rich instructions. Our experiments show that fine-tuning VLMs with the MetaVQA Dataset significantly improves their embodied scene understanding, which is evident not only in improved VQA accuracy but also in emerging safety-aware driving maneuvers. In addition, the learning exhibits strong transferability from simulation to real-world observation. The project webpage is at https://metadriverse.github.io/metavqa.

CompGS: Unleashing 2D Compositionality for Compositional Text-to-3D via Dynamically Optimizing 3D Gaussians

Chongjian Ge, Chenfeng Xu, Yuanfeng Ji, Chensheng Peng, Masayoshi Tomizuka, Ping Luo, Mingyu Ding, Varun Jampani, Wei Zhan; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 18509-18520

Recent breakthroughs in text-guided image generation have significantly advanced the field of 3D generation. While generating a single high-quality 3D object is now feasible, generating multiple objects with reasonable interactions within a 3D space, a.k.a. compositional 3D generation, presents substantial challenges. This paper introduces CompGS, a novel generative framework that employs 3D Gaussian Splatting (GS) for efficient, compositional text-to-3D content generation. To achieve this goal, two core designs are proposed: (1) 3D Gaussians Initialization with 2D compositionality: We transfer the well-established 2D compositionality to initialize the Gaussian parameters on an entity-by-entity basis, ensuring both consistent 3D priors for each entity and reasonable interactions among multiple entities; (2) Dynamic Optimization: We propose a dynamic strategy to optimize 3D Gaussians using Score Distillation Sampling (SDS) loss. CompGS first automatically decomposes 3D Gaussians into distinct entity parts, enabling optimization at both the entity and composition levels. Additionally, CompGS optimizes across objects of varying scales by dynamically adjusting the spatial parameters of each entity, enhancing the generation of fine-grained details, particularly in smaller entities. Qualitative comparisons and quantitative evaluations on T3Bench demonstrate the effectiveness of CompGS in generating compositional 3D objects with superior image quality and semantic alignment over existing methods. CompGS can also be easily extended to progressively adding 3D objects, facilitating complex scene generation. We hope CompGS will provide new insights to the compositional 3D generation.

Learning Temporally Consistent Video Depth from Video Diffusion Priors
Jiahao Shao, Yuanbo Yang, Hongyu Zhou, Youmin Zhang, Yujun Shen, Vitor Guizilini, Yue Wang, Matteo Poggi, Yiyi Liao; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 22841-22852
This work addresses the challenge of streamed video depth estimation, which expects not only per-frame accuracy but, more importantly, cross-frame consistency. We argue that sharing contextual information between frames or clips is pivotal in fostering temporal consistency. Therefore, we reformulate depth prediction into a conditional generation problem to provide contextual information within a clip and across clips. Specifically, we propose a consistent context-aware training and inference strategy for arbitrarily long videos to provide cross-clip context. We sample independent noise levels for each frame within a clip during training while using a sliding window strategy and initializing overlapping frames with previously predicted frames without adding noise. Moreover, we design an effective training strategy to provide context within a clip. Extensive experimental results validate our design choices and demonstrate the superiority of our approach, dubbed ChronoDepth. Project page: https://xdimlab.github.io/ChronoDepth/.

FIRE: Robust Detection of Diffusion-Generated Images via Frequency-Guided Reconstruction Error
Beilin Chu, Xuan Xu, Xin Wang, Yufei Zhang, Weike You, Linna Zhou; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 12830-12839
The rapid advancement of diffusion models has significantly improved high-quality image generation, making generated content increasingly challenging to distinguish from real images and raising concerns about potential misuse. In this paper, we observe that diffusion models struggle to accurately reconstruct mid-band frequency information in real images, suggesting the limitation could serve as a cue for detecting diffusion model generated images. Motivated by this observation, we propose a novel method called Frequency-guIded Reconstruction Error (FIRE), which, to the best of our knowledge, is the first to investigate the influence of frequency decomposition on reconstruction error. FIRE assesses the variation in reconstruction error before and after the frequency decomposition, offering a robust method for identifying diffusion model generated images. Extensive experiments show that FIRE generalizes effectively to unseen diffusion models and maintains robustness against diverse perturbations.

Assessing and Learning Alignment of Unimodal Vision and Language Models
Le Zhang, Qian Yang, Aishwarya Agrawal; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 14604-14614
How well are unimodal vision and language models aligned? While prior work has explored this question, their assessment methods do not directly translate to practical vision-language tasks. In this paper, we propose a direct assessment method, inspired by linear probing, to evaluate vision-language alignment. We identify that the degree of alignment of SSL vision models depends on their SSL training objective and find that clustering quality of SSL representations impacts alignment performance more than their linear separability. We then introduce Swift Alignment of Image and Language (SAIL), an efficient transfer learning framework that aligns pretrained unimodal vision and language models for downstream tasks. SAIL requires significantly less paired image-text data (6%) compared to models like CLIP, which are trained from scratch. It trains with a single A100 GPU in 5 hours and supports a batch size of up to 32,768. SAIL achieves 73.4% zero-shot accuracy on ImageNet (compared to CLIP's 72.7%) and excels in zero-shot retrieval, complex reasoning, and semantic segmentation. SAIL also enhances the language-compatibility of vision encoders, improving the performance of multimodal large language models. The full codebase and model weights are open-source: https://lezhang7.github.io/sail.github.io/

Samba: A Unified Mamba-based Framework for General Salient Object Detection

Jiahao He, Keren Fu, Xiaohong Liu, Qijun Zhao; Proceedings of the Computer Visio n and Pattern Recognition Conference (CVPR), 2025, pp. 25314-25324
Existing salient object detection (SOD) models primarily resort to convolutional neural networks (CNNs) and Transformers. However, the limited receptive fields of CNNs and quadratic computational complexity of transformers both constrain th e performance of current models on discovering attention-grabbing objects. The e merging state space model, namely Mamba, has demonstrated its potential to balan ce global receptive fields and computational complexity. Therefore, we propose a novel unified framework based on the pure Mamba architecture, dubbed saliency M amba (Samba), to flexibly handle general SOD tasks, including RGB/RGB-D/RGB-T SO D, video SOD (VSOD), and RGB-D VSOD. Specifically, we rethink Mamba's scanning s trategy from the perspective of SOD, and identify the importance of maintaining spatial continuity of salient patches within scanning sequences. Based on this, we propose a saliency-guided Mamba block (SGMB), incorporating a spatial neighbo ring scanning (SNS) algorithm to preserve spatial continuity of salient patches. Additionally, we propose a context-aware upsampling (CAU) method to promote hie rarchical feature alignment and aggregations by modeling contextual dependencies . Experimental results show that our Samba outperforms existing methods across f ive SOD tasks on 21 datasets with lower computational cost, confirming the super iority of introducing Mamba to the SOD areas. Our code is available at https:// github.com/Jia-hao999/Samba.

Action Detail Matters: Refining Video Recognition with Local Action Queries
Mengmeng Wang, Zeyi Huang, Xiangjie Kong, Guojiang Shen, Guang Dai, Jingdong Wan g, Yong Liu; Proceedings of the Computer Vision and Pattern Recognition Conferen ce (CVPR), 2025, pp. 19132-19142
Video action recognition involves interpreting both global context and specific details to accurately identify actions. While previous models are effective at c apturing spatiotemporal features, they often lack a focused representation of ke y action details. To address this, we introduce \nameo, a framework designed for refining video action recognition through integrated global and local feature l earning. Inspired by human visual cognition theory, our approach balances the fo cus on both broad contextual changes and action-specific details, minimizing the influence of irrelevant background noise. We first employ learnable action quer ies to selectively emphasize action-relevant regions without requiring region-sp ecific labels. Next, these queries are learned by a local action streaming branc h that enables progressive query propagation. Moreover, we introduce a parameter -free feature interaction mechanism for effective multi-scale interaction betwee n global and local features with minimal additional overhead. Extensive experime nts demonstrate that \name achieves state-of-the-art performance across multiple action recognition datasets, validating its effectiveness and robustness in han dling action-relevant details.

PAVE: Patching and Adapting Video Large Language Models
Zhuoming Liu, Yiquan Li, Khoi Duc Nguyen, Yiwu Zhong, Yin Li; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 3306-3317
We present PAVE, a framework for adapting pre-trained video large language model s (Video-LLMs) to downstream tasks that incorporate side-channel signals, such a s audio, camera pose, or high frame rate videos. PAVE introduces a lightweight a daptation strategy called "patching", which adds a small number of parameters an d operations to the base model without modifying its architecture or pre-trained weights. We demonstrate that PAVE effectively enhances pre-trained Video-LLMs w ith the cost of adding <1% additional FLOPs and parameters for diverse tasks, in cluding audio-visual understanding, 3D reasoning, and multi-view video understan ding, surpassing state-of-the-art task-specific models. Moreover, when applied t o high frame rate videos, PAVE further improves video understanding, enhancing t he performance of strong base models. Finally, our experiments show that our fra mework generalizes well across different Video-LLMs.

LesionLocator: Zero-Shot Universal Tumor Segmentation and Tracking in 3D Whole-B

ody Imaging
Maximilian Rokuss, Yannick Kirchhoff, Seval Akbal, Balint Kovacs, Saikat Roy, Co nstantin Ulrich, Tassilo Wald, Lukas T. Rotkopf, Heinz-Peter Schlemmer, Klaus Ma ier-Hein; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 30872-30885
In this work, we present LesionLocator, a framework for zero-shot longitudinal l esion tracking and segmentation in 3D medical imaging, establishing the first en d-to-end model capable of 4D tracking with dense spatial prompts. Our model leve rages an extensive dataset of 23,262 annotated medical scans, as well as synthes ized longitudinal data across diverse lesion types. The diversity and scale of o ur dataset significantly enhances model generalizability to real-world medical i maging challenges and addresses key limitations in longitudinal data availabilit y. LesionLocator outperforms all existing promptable models in lesion segmentati on by nearly 10 dice points, reaching human-level performance, and achieves stat e-of-the-art results in lesion tracking, with superior lesion retrieval and segm entation accuracy. LesionLocator not only sets a new benchmark in universal prom ptable lesion segmentation and automated longitudinal lesion tracking but also p rovides the first open-access solution of its kind, releasing our synthetic 4D d ataset and model to the community, empowering future advancements in medical ima ging. Code is available at: www.github.com/MIC-DKFZ/LesionLocator

Generative Map Priors for Collaborative BEV Semantic Segmentation
Jiahui Fu, Yue Gong, Luting Wang, Shifeng Zhang, Xu Zhou, Si Liu; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 11919-11928
Collaborative perception aims to address the constraint of single-agent percepti on by exchanging information among multiple agents. Previous works primarily foc us on collaborative object detection, exploring compressed transmission and fusi on prediction tailored to sparse object features. However, these strategies are not well-suited for dense features in collaborative BEV semantic segmentation. T herefore, we propose CoGMP, a novel Collaborative framework that leverages Gener ative Map Priors to achieve efficient compression and robust fusion. CoGMP intro duces two key innovations: Element Format Feature Compression (EFFC) and Structu re Guided Feature Fusion (SGFF). Specifically, EFFC leverages map element priors from codebook to encode BEV features as discrete element indices for transmitte d information compression. Meanwhile, SGFF utilizes a diffusion model with struc tural priors to coherently integrate multi-agent features, thereby achieving con sistent fusion predictions. Evaluations on the OPV2V dataset show that CoGMP ach ieves a 6.89/7.64 Road/Lane IoU improvement and a 32-fold reduction in communica tion volume.

Coherent 3D Portrait Video Reconstruction via Triplane Fusion
Shengze Wang, Xueting Li, Chao Liu, Matthew Chan, Michael Stengel, Henry Fuchs, Shalini De Mello, Koki Nagano; Proceedings of the Computer Vision and Pattern Re cognition Conference (CVPR), 2025, pp. 10712-10722
Recent breakthroughs in single-image 3D portrait reconstruction have enabled tel epresence systems to stream 3D portrait videos from a single camera in real-time , democratizing telepresence. However, per-frame 3D reconstruction exhibits temp oral inconsistency and forgets the user's appearance. On the other hand, self-re enactment methods can render coherent 3D portraits by driving a 3D avatar built from a single reference image but fail to faithfully preserve the user's per-fra me appearance (e.g., instantaneous facial expressions and lighting). As a result , neither of these two frameworks is an ideal solution for democratized 3D telep resence. In this work, we address this dilemma and propose a novel solution that maintains both coherent identity and dynamic per-frame appearance to enable the best possible realism. To this end, we propose a new fusion-based method that t akes the best of both worlds by fusing a canonical 3D prior from a reference vie w with dynamic appearance from per-frame input views, producing temporally stabl e 3D videos with faithful reconstruction of the user's per-frame appearance. Tra ined only using synthetic data produced by an expression-conditioned 3D GAN, our

encoder-based method achieves both state-of-the-art 3D reconstruction and temporal consistency on in-studio and in-the-wild datasets.

Generative Image Layer Decomposition with Visual Effects
Jinrui Yang, Qing Liu, Yijun Li, Soo Ye Kim, Daniil Pakhomov, Mengwei Ren, Jianming Zhang, Zhe Lin, Cihang Xie, Yuyin Zhou; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 7643-7653
Recent advancements in large generative models, particularly diffusion-based methods, have significantly enhanced the capabilities of image editing. However, achieving precise control over image composition tasks remains a challenge. Layered representations, which allow for independent editing of image components, are essential for user-driven content creation, yet existing approaches often struggle to decompose image into plausible layers with accurately retained transparent visual effects such as shadows and reflections. We propose LayerDecomp, a generative framework for image layer decomposition which outputs photorealistic clean backgrounds and high-quality transparent foregrounds with faithfully preserved visual effects. To enable effective training, we first introduce a dataset preparation pipeline that automatically scales up simulated multi-layer data with synthesized visual effects. To further enhance real-world applicability, we supplement this simulated dataset with camera-captured images containing natural visual effects. Additionally, we propose a consistency loss which enforces the model to learn accurate representations for the transparent foreground layer when ground-truth annotations are not available. Our method achieves superior quality in layer decomposition, outperforming existing approaches in object removal and spatial editing tasks across several benchmarks and multiple user studies, unlocking various creative possibilities for layer-wise image editing.

AR-Diffusion: Asynchronous Video Generation with Auto-Regressive Diffusion
Mingzhen Sun, Weining Wang, Gen Li, Jiawei Liu, Jiahui Sun, Wanquan Feng, Shanshan Lao, Siyu Zhou, Qian He, Jing Liu; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 7364-7373
The task of video generation requires synthesizing visually realistic and temporally coherent video frames. Existing methods primarily use asynchronous auto-regressive models or synchronous diffusion models to address this challenge. However, asynchronous auto-regressive models often suffer from inconsistencies between training and inference, leading to issues such as error accumulation, while synchronous diffusion models are limited by their reliance on rigid sequence length. To address these issues, we introduce Auto-Regressive Diffusion (AR-Diffusion), a novel model that combines the strengths of auto-regressive and diffusion models for flexible, asynchronous video generation. Specifically, our approach leverages diffusion to gradually corrupt video frames in both training and inference, reducing the discrepancy between these phases. Inspired by auto-regressive generation, we incorporate a non-decreasing constraint on the corruption timesteps of individual frames, ensuring that earlier frames remain clearer than subsequent ones. This setup, together with temporal causal attention, enables flexible generation of videos with varying lengths while preserving temporal coherence. In addition, we design two specialized timestep schedulers: the FoPP scheduler for balanced timestep sampling during training, and the AD scheduler for flexible timestep differences during inference, supporting both synchronous and asynchronous generation. Extensive experiments demonstrate the superiority of our proposed method, by achieving competitive and state-of-the-art results across four challenging benchmarks.

ManiVideo: Generating Hand-Object Manipulation Video with Dexterous and Generalizable Grasping
Youxin Pang, Ruizhi Shao, Jiajun Zhang, Hanzhang Tu, Yun Liu, Boyao Zhou, Hongwen Zhang, Yebin Liu; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 12209-12219
In this paper, we introduce ManiVideo, a novel method for generating consistent and temporally coherent bimanual hand-object manipulation videos from given moti

on sequences of hands and objects. The core idea of ManiVideo is the constructio n of a multi-layer occlusion (MLO) representation that learns 3D occlusion relat ionships from occlusion-free normal maps and occlusion confidence maps. By embed ding the MLO structure into the UNet in two forms, the model enhances the 3D con sistency of dexterous hand-object manipulation. To further achieve the generaliz able grasping of objects, we integrate Objaverse, a large-scale 3D object datase t, to address the scarcity of video data, thereby facilitating the learning of e xtensive object consistency. Additionally, we propose an innovative training str ategy that effectively integrates multiple datasets, supporting downstream tasks such as human-centric hand-object manipulation video generation. Through extens ive experiments, we demonstrate that our approach not only achieves video genera tion with plausible hand-object interaction and generalizable objects, but also outperforms existing SOTA methods.

DOF-GS: Adjustable Depth-of-Field 3D Gaussian Splatting for Post-Capture Refocus ing, Defocus Rendering and Blur Removal

Yujie Wang, Praneeth Chakravarthula, Baoquan Chen; Proceedings of the Computer V ision and Pattern Recognition Conference (CVPR), 2025, pp. 21297-21306

3D Gaussian Splatting (3DGS) techniques have recently enabled high-quality 3D sc ene reconstruction and real-time novel view synthesis. These approaches, however , are limited by the pinhole camera model and lack effective modeling of defocus effects. Departing from this, we introduce DOF-- a new 3DGS-based framework wit h a finite-aperture camera model and explicit, differentiable defocus rendering, enabling it to function as a post-capture control tool. By training with multi- view images with moderate defocus blur, DOF-GS learns inherent camera characteri stics and reconstructs sharp details of the underlying scene, particularly, enab ling rendering of varying DOF effects through on-demand aperture and focal dista nce control, post-capture and optimization. Additionally, our framework extracts circle-of-confusion cues during optimization to identify in-focus regions in in put views, enhancing the reconstructed 3D scene details. Experimental results de monstrate that DOF-GS supports post-capture refocusing, adjustable defocus and h igh-quality all-in-focus rendering, from multi-view images with uncalibrated def ocus blur.

The Photographer's Eye: Teaching Multimodal Large Language Models to See, and Cr itique Like Photographers

Daiqing Qi, Handong Zhao, Jing Shi, Simon Jenni, Yifei Fan, Franck Dernoncourt, Scott Cohen, Sheng Li; Proceedings of the Computer Vision and Pattern Recognitio n Conference (CVPR), 2025, pp. 24807-24816

Photographer, curator, and former director of photography at the Museum of Moder n Art (MoMA), John Szarkowski remarked in *William Eggleston's Guide*, "While ed iting directly from life, photographers have found it too difficult to see simul taneously both the blue and the sky." Szarkowski insightfully revealed a notable gap between general and aesthetic visual understanding: while the former emphas izes identifying factual elements in an image (the sky), the latter transcends m ere object identification, viewing it instead as an aesthetic component--a pure expanse of blue, valued purely as a color block in visual aesthetics. Such disti nctions between general visual understanding (detection, localization, etc.) and aesthetic perception (color, lighting, composition, etc.) pose a significant ch allenge for existing Multimodal Large Language Models (MLLMs) in comprehending i mage aesthetics, which is increasingly needed in real-world applications, from i mage recommendation and enhancement to generation. To fundamentally advance the aesthetic understanding of MLLMs, we introduce a novel dataset, PhotoCritique, d erived from extensive discussions among professional photographers and enthusias ts, distinguished by its large scale, expertise, and diversity. Additionally, we propose a new model, PhotoEye, an MLLM featuring a language-guided multi-view v ision fusion mechanism for understanding image aesthetics from multiple perspect ives. Finally, we introduce PhotoBench, a comprehensive and professional benchma rk for aesthetic visual understanding. Our model demonstrates significant advant ages over both open-source and commercial models on existing benchmarks and Phot

oBench.

Revisiting Audio-Visual Segmentation with Vision-Centric Transformer
Shaofei Huang, Rui Ling, Tianrui Hui, Hongyu Li, Xu Zhou, Shifeng Zhang, Si Liu, Richang Hong, Meng Wang; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 8352-8361
Audio-Visual Segmentation (AVS) aims to segment sound-producing objects in video frames based on the associated audio signal. Prevailing AVS methods typically adopt an audio-centric Transformer architecture, where object queries are derived from audio features. However, audio-centric Transformers suffer from two limitations: perception ambiguity caused by the mixed nature of audio, and weakened dense prediction ability due to visual detail loss. To address these limitations, we propose a new Vision-Centric Transformer (VCT) framework that leverages vision-derived queries to iteratively fetch corresponding audio and visual information, enabling queries to better distinguish between different sounding objects from mixed audio and accurately delineate their contours. Additionally, we also introduce a Prototype Prompted Query Generation (PPQG) module within our VCT framework to generate vision-derived queries that are both semantically aware and visually rich through audio prototype prompting and pixel context grouping, facilitating audio-visual information aggregation. Extensive experiments demonstrate that our VCT framework achieves new state-of-the-art performances on three subsets of the AVSBench dataset.
****
Synergizing Motion and Appearance: Multi-Scale Compensatory Codebooks for Talking Head Video Generation
Shuling Zhao, Fa-Ting Hong, Xiaoshui Huang, Dan Xu; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 26232-26241
Talking head video generation aims to generate a realistic talking head video that preserves the person's identity from a source image and the motion from a driving video. Despite the promising progress made in the field, it remains a challenging and critical problem to generate videos with accurate poses and fine-grained facial details simultaneously. Essentially, facial motion is often highly complex to model precisely, and the one-shot source face image cannot provide sufficient appearance guidance during generation due to dynamic pose changes. To tackle the problem, we propose to jointly learn motion and appearance codebooks and perform multi-scale codebook compensation to effectively refine both the facial motion conditions and appearance features for talking face image decoding. Specifically, the designed multi-scale motion and appearance codebooks are learned simultaneously in a unified framework to store representative global facial motion flow and appearance patterns. Then, we present a novel multi-scale motion and appearance compensation module, which utilizes a transformer-based codebook retrieval strategy to query complementary information from the two codebooks for joint motion and appearance compensation. The entire process produces motion flows of greater flexibility and appearance features with fewer distortions across different scales, resulting in a high-quality talking head video generation framework. Extensive experiments on various benchmarks validate the effectiveness of our approach and demonstrate superior generation results from both qualitative and quantitative perspectives when compared to state-of-the-art competitors. The project page is available at https://shaelynz.github.io/synergize-motion-appearance/.

HOIGPT: Learning Long-Sequence Hand-Object Interaction with Language Models
Mingzhen Huang, Fu-Jen Chu, Bugra Tekin, Kevin J. Liang, Haoyu Ma, Weiyao Wang, Xingyu Chen, Pierre Gleize, Hongfei Xue, Siwei Lyu, Kris Kitani, Matt Feiszli, Hao Tang; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 7136-7146
We introduce HOIGPT, a token-based generative method that unifies 3D hand-object interactions (HOI) perception and generation, offering the first comprehensive solution for captioning and generating high-quality 3D HOI sequences from a diverse range of conditional signals (e.g. text, objects, partial sequences). At its

core, HOIGPT utilizes a large language model to predict the bidirectional transformation between HOI sequences and natural language descriptions. Given text inputs, HOIGPT generates a sequence of hand and object meshes; given (partial) HOI sequences, HOIGPT generates text descriptions and completes the sequences. To facilitate HOI understanding with a large language model, this paper introduces two key innovations: (1) a novel physically grounded HOI tokenizer, the hand-object decomposed VQ-VAE, for discretizing HOI sequences, and (2) a motion-aware language model trained to process and generate both text and HOI tokens. Extensive experiments demonstrate that HOIGPT sets new state-of-the-art performance on both text generation (+2.01% R Precision) and HOI generation (-2.56 FID) across multiple tasks and benchmarks.

GraphI2P: Image-to-Point Cloud Registration with Exploring Pattern of Correspondence via Graph Learning

Lin Bie, Shouan Pan, Siqi Li, Yining Zhao, Yue Gao; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 22161-22171

Although the fusion of images and LiDAR point clouds is crucial to many applications in computer vision, the relative poses of cameras and LiDAR scanners are often unknown. The general registration pipeline first establishes correspondences and then performs pose estimation based on the generated matches. However, 2D-3D correspondences are inherently challenging to establish due to the large gap between images and LiDAR point clouds. To this end, we build a bridge to alleviate the 2D-3D gap and propose a practical framework to align LiDAR point clouds to the virtual points generated by images. In this way, the modality gap is converted to the domain gap of point clouds. Moreover, we propose a virtual-spherical representation and adaptive distribution sample module to narrow the domain gap between virtual and LiDAR point clouds. Then, we explore the reliable correspondence pattern consistency through a graph-based selection process. We improve the correspondence representation through a graph neural network. Experimental results demonstrate that our method outperforms the state-of-the-art methods by more than 10.77% and 12.53% performance on the KITTI Odometry and nuScenes datasets, respectively. The results demonstrate that our method can effectively solve non-synchronized random frame registration.

SoftVQ-VAE: Efficient 1-Dimensional Continuous Tokenizer

Hao Chen, Ze Wang, Xiang Li, Ximeng Sun, Fangyi Chen, Jiang Liu, Jindong Wang, Bhiksha Raj, Zicheng Liu, Emad Barsoum; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 28358-28370

Efficient image tokenization with high compression ratios remains a critical challenge for training generative models.We present SoftVQ-VAE, a continuous image tokenizer that leverages soft categorical posteriors to aggregate multiple codewords into each latent token, substantially increasing the representation capacity of the latent space. When applied to Transformer-based architectures, our approach compresses 256x256 and 512x512 images using only 32 or 64 1-dimensional tokens.Not only does SoftVQ-VAE show consistent and high-quality reconstruction, more importantly, it also achieves state-of-the-art and significantly faster image generation results across different denoising-based generative models. Remarkably, SoftVQ-VAE improves inference throughput by up to 18x for generating 256x256 images and 55x for 512x512 images while achieving competitive FID scores of 1.78 and 2.21 for SiT-XL.It also improves the training efficiency of the generative models by reducing the number of training iterations by 2.3x while maintaining comparable performance. With its fully-differentiable design and semantic-rich latent space, our experiment demonstrates that SoftVQ-VQE achieves efficient tokenization without compromising generation quality, paving the way for more efficient generative models.Code and model will be released.

FedCS: Coreset Selection for Federated Learning

Chenhe Hao, Weiying Xie, Daixun Li, Haonan Qin, Hangyu Ye, Leyuan Fang, Yunsong Li; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 15434-15443

Federated Learning (FL) is an emerging direction in distributed machine learning that enables jointly training a model without sharing the data. However, as the size of datasets grows exponentially, computational costs of FL increase. In this paper, we propose the first Coreset Selection criterion for Federated Learning (FedCS) by exploring the Distance Contrast (DC) in feature space. Our FedCS is inspired by the discovery that DC can indicate the intrinsic properties inherent to samples regardless of the networks. Based on the observation, we develop a method that is mathematically formulated to prune samples with high DC. The principle behind our pruning is that high DC samples either contain less information or represent rare extreme cases, thus removal of them can enhance the aggregation performance. Besides, we experimentally show that samples with low DC usually contain substantial information and reflect the common features of samples within their classes, such that they are suitable for constructing coreset. With only two time of linear-logarithmic complexity operation, FedCS leads to significant improvements over the methods using whole dataset in terms of computational costs, with similar accuracies. For example, on the CIFAR-10 dataset with Dirichlet coefficient \alpha=0.1, FedCS achieves 58.88% accuracy using only 44% of the entire dataset, whereas other methods require twice the data volume as FedCS for same performance.

DPC: Dual-Prompt Collaboration for Tuning Vision-Language Models

Haoyang Li, Liang Wang, Chao Wang, Jing Jiang, Yan Peng, Guodong Long; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 25623-25632

The Base-New Trade-off (BNT) problem universally exists during the optimization of CLIP-based prompt tuning, where continuous fine-tuning on base (target) classes leads to a simultaneous decrease of generalization ability on new (unseen) classes. Existing approaches attempt to regulate the prompt tuning process to balance BNT by appending constraints. However, imposed on the same target prompt, these constraints fail to fully avert the mutual exclusivity between the optimization directions for base and new. As a novel solution to this challenge, we propose the plug-and-play Dual-Prompt Collaboration (DPC) framework, the first that decoupling the optimization processes of base and new tasks at the prompt level. Specifically, we clone a learnable parallel prompt based on the backbone prompt, and introduce a variable Weighting-Decoupling framework to independently control the optimization directions of dual prompts specific to base or new tasks, thus avoiding the conflict in generalization. Meanwhile, we propose a Dynamic Hard Negative Optimizer, utilizing dual prompts to construct a more challenging optimization task on base classes for enhancement. For interpretability, we prove the feature channel invariance of the prompt vector during the optimization process, providing theoretical support for the Weighting-Decoupling of DPC. Extensive experiments on multiple backbones demonstrate that DPC can significantly improve base performance without introducing any external knowledge beyond the base classes, while maintaining generalization to new classes. Code is available at: https://github.com/JREion/DPC.

Dual-Granularity Semantic Guided Sparse Routing Diffusion Model for General Pansharpening

Yinghui Xing, Litao Qu, Shizhou Zhang, Di Xu, Yingkun Yang, Yanning Zhang; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 12658-12668

Pansharpening aims at integrating complementary information from panchromatic and multispectral images. Available deep-learning based pansharpening methods typically perform exceptionally with particular satellite datasets. At the same time, it has been observed that these models also exhibit scene dependence, for example, if the majority of the training samples come from the urban scenes, the model's performance may decline in the river scene. To address the domain gap produced by varying satellite sensors and distinct scenes, we propose a dual-granularity semantic guided sparse routing diffusion model for general pansharpening. By utilizing the large Vision-Language Models (VLMs) in the field of geoscience, e

.g, GeoChat, we introduce the dual granularity semantics to generate dynamic spa rse routing scores for adaptation of different satellite sensors and scenes. Thi s scene-level and region-level dual-granularity semantic information serves as g uidance for dynamically activating specialized experts within the diffusion mode l. Extensive experiments on WorldView-3, QuickBird, and GaoFen-2 datasets show t he effectiveness of our proposed method. Notably, the proposed method outperform s the comparison approaches in adapting to new satellite sensors and scenes. The codes are available at https://github.com/codgodtao/SGDiff.

AIM-Fair: Advancing Algorithmic Fairness via Selectively Fine-Tuning Biased Mode ls with Contextual Synthetic Data

Zengqun Zhao, Ziquan Liu, Yu Cao, Shaogang Gong, Ioannis Patras; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 28748-2 8758

Recent advances in generative models have sparked research on improving model fa irness with AI-generated data. However, existing methods often face limitations in the diversity and quality of synthetic data, leading to compromised fairness and overall model accuracy. Moreover, many approaches rely on the availability o f demographic group labels, which are often costly to annotate. This paper propo ses AIM-Fair, aiming to overcome these limitations and harness the potential of cutting-edge generative models in promoting algorithmic fairness. We investigate a fine-tuning paradigm starting from a biased model initially trained on real-w orld data without demographic annotations. This model is then fine-tuned using u nbiased synthetic data generated by a state-of-the-art diffusion model to improv e its fairness. Two key challenges are identified in this fine-tuning paradigm, 1) the low quality of synthetic data, which can still happen even with advanced generative models, and 2) the domain and bias gap between real and synthetic dat a. To address the limitation of synthetic data quality, we propose Contextual Sy nthetic Data Generation (CSDG) to generate data using a text-to-image diffusion model (T2I) with prompts generated by a context-aware LLM, ensuring both data di versity and control of bias in synthetic data. To resolve domain and bias shifts , we introduce a novel selective fine-tuning scheme in which only model parameter s more sensitive to bias and less sensitive to domain shift are updated. Experi ments on CelebA and UTKFace datasets show that our AIM-Fair improves model fairn ess while maintaining utility, outperforming both fully and partially fine-tuned approaches to model fairness.

Robust Multi-Object 4D Generation for In-the-wild Videos

Wen-Hsuan Chu, Lei Ke, Jianmeng Liu, Mingxiao Huo, Pavel Tokmakov, Katerina Frag kiadaki; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 22067-22077

We address the challenge of generating dynamic 4D scenes from monocular multi-ob ject videos with heavy occlusions and introduce Robust4DGen, a novel approach th at integrates rendering-based deformable 3D Gaussian optimization with generativ e priors for view synthesis. While existing view-synthesis models excel at novel view generation for isolated objects, they struggle with full scenes due to the ir complexity and data demands. To overcome this, Robust4DGen decomposes scenes into individual objects, optimizing a differentiable set of deformable Gaussians per object while capturing 2D occlusions from a 3D perspective through joint Ga ussian splatting. Joint splatting ensures occlusion-aware rendering losses in ob served frames while explicit object decomposition allows the usage of object-cen tric diffusion models for object completion in unobserved viewpoints. To reconci le the differences between object-centric priors and the global frame-centric co ordinate system of the video, Robust4DGen employs differentiable transformations to unify the rendering and generative constraints within a single framework. Th e result is a model capable of generating 4D objects across space and time while producing 2D and 3D point tracks from monocular videos. To rigorously evaluate the quality of scene generation and the accuracy of the motion under multi-objec t occlusions, we introduce MOSE-PTS, a subset of the challenging MOSE benchmark, which we annotated with high-quality 2D point tracks. Quantitative evaluations

and perceptual human studies confirm that Robust4DGen generates more realistic n
ovel views of scenes and produces more accurate point tracks compared to existin
g approaches.

OmniMMI: A Comprehensive Multi-modal Interaction Benchmark in Streaming Video Co
ntexts

Yuxuan Wang, Yueqian Wang, Bo Chen, Tong Wu, Dongyan Zhao, Zilong Zheng; Proceed
ings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp.
 18925-18935

The rapid advancement of multi-modal language models (MLLMs) like GPT-4o has pro
pelled the development of Omni language models, designed to process and proactiv
ely respond to continuous streams of multi-modal data. Despite their potential,
evaluating their real-world interactive capabilities in streaming video contexts
 remains a formidable challenge. In this work, we introduce OmniMMI, a comprehen
sive multi-modal interaction benchmark tailored for OmniLLMs in streaming video
contexts. OmniMMI encompasses over 1,121 videos and 2,290 questions, addressing
two critical yet underexplored challenges in existing video benchmarks: streamin
g video understanding and proactive reasoning, across six distinct subtasks. Mo
reover, we propose a novel framework, Multi-modal Multiplexing Modeling (M4), de
signed to enable an inference-efficient streaming model that can see, listen whi
le generating.

SOAP: Vision-Centric 3D Semantic Scene Completion with Scene-Adaptive Decoder an
d Occluded Region-Aware View Projection

Hyo-Jun Lee, Yeong Jun Koh, Hanul Kim, Hyunseop Kim, Yonguk Lee, Jinu Lee; Proce
edings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, p
p. 17145-17154

Existing view transformations in vision-centric 3D Semantic Scene Completion (SS
C) inevitably experience erroneous feature duplication in the reconstructed voxe
l space due to occlusions, leading to a dilution of informative contexts. Furthe
rmore, semantic classes exhibit high variability in their appearance in real-wor
ld driving scenarios. To address these issues, we introduce a novel 3D SSC metho
d, called SOAP, including two key components: an occluded region-aware view proj
ection and a scene-adaptive decoder. The occluded region-aware view projection e
ffectively converts 2D image features into voxel space, refining the duplicated
features of occluded regions using information gathered from previous observatio
ns. The scene-adaptive decoder guides query embeddings to learn diverse driving
environments based on a comprehensive semantic repository. Extensive experiments
 validate that the proposed SOAP significantly outperforms existing methods for
the vision-centric 3D SSC on automated driving datasets, SemanticKITTI and SSCBe
nch. Code is available at https://github.com/gywns6287/SOAP.

Taxonomy-Aware Evaluation of Vision-Language Models

Vésteinn Snæbjarnarson, Kevin Du, Niklas Stoehr, Serge Belongie, Ryan Cotterell,
 Nico Lang, Stella Frank; Proceedings of the Computer Vision and Pattern Recogni
tion Conference (CVPR), 2025, pp. 9109-9120

When a vision-language model (VLM) is prompted to identify an entity depicted in
 an image, it may answer "I see a conifer," rather than the specific label "Norw
ay spruce". This raises two issues for evaluation: Firstly, the unconstrained ge
nerated text needs to be mapped to the evaluation label space (i.e., "conifer").
 Secondly, a useful classification measure should give partial credit to less sp
ecific, but not incorrect, answers ("Norway spruce" being a type of "conifer").
To meet these requirements, we propose a framework for evaluating unconstrained
text predictions such as those generated from a vision-language model against a
taxonomy. Specifically, we propose the use of hierarchical precision and recall
measures to assess the level of correctness and specificity of predictions with
regard to a taxonomy. Experimentally, we first show that existing text similarit
y measures do not capture taxonomic similarity well. We then develop and compare
 different methods to map textual VLM predictions onto a taxonomy. This allows u
s to compute hierarchical similarity measures between the generated text and the

ground truth labels. Finally, we analyze modern VLMs on fine-grained visual classification tasks based on our proposed taxonomic evaluation scheme.

Active Event-based Stereo Vision
Jianing Li, Yunjian Zhang, Haiqian Han, Xiangyang Ji; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 971-981
Conventional frame-based imaging for active stereo systems has encountered major challenges in fast-motion scenarios. However, how to design a novel paradigm for high-speed depth sensing still remains an open issue. In this paper, we propose a novel problem setting, namely active event-based stereo vision, which provides the first insight of integrating binocular event cameras and an infrared projector for high-speed depth sensing. Technically, we first build a stereo camera prototype system and present a real-world dataset with over 21.5k spatiotemporal synchronized labels at 15 Hz, while also creating a realistic synthetic dataset with stereo event streams and 23.8k synchronized labels at 20 Hz. Then, we propose ActiveEventNet, a lightweight yet effective active event-based stereo matching neural network that learns to generate high-quality dense disparity maps from stereo event streams with low latency. Experiments demonstrate that our ActiveEventNet outperforms state-of-the-art methods meanwhile significantly reducing computational complexity. Our solution offers superior depth sensing compared to conventional stereo cameras in high-speed scenes, while also achieving the inference speed of up to 150 FPS with our prototype. We believe that this novel paradigm will provide new insights into future depth sensing systems. Our project can be available at https://github.com/jianing-li/active_event_based_stereo.

Mono-InternVL: Pushing the Boundaries of Monolithic Multimodal Large Language Models with Endogenous Visual Pre-training
Gen Luo, Xue Yang, Wenhan Dou, Zhaokai Wang, Jiawen Liu, Jifeng Dai, Yu Qiao, Xizhou Zhu; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 24960-24971
In this paper, we focus on monolithic Multimodal Large Language Models (MLLMs) that integrate visual encoding and language decoding into a single LLM. In particular, we identify that existing pre-training strategies for monolithic MLLMs often suffer from unstable optimization or catastrophic forgetting. To address this issue, our core idea is to embed a new visual parameter space into a pre-trained LLM, thereby stably learning visual knowledge from noisy data while freezing the LLM. Based on this principle, we present Mono-InternVL, a novel monolithic MLLM that seamlessly integrates a set of visual experts via a multimodal mixture-of-experts structure. Moreover, we propose an innovative pre-training strategy to maximize the visual capability of Mono-InternVL, namely Endogenous Visual Pre-training (EViP). In particular, EViP is designed as a progressive learning process for visual experts, which aims to fully exploit the visual knowledge from noisy data to high-quality data. To validate our approach, we conduct extensive experiments on 16 benchmarks. Experimental results confirm the superior performance of Mono-InternVL over existing monolithic MLLMs on 13 of 16 multimodal benchmarks, e.g., +80 points over Emu3 on OCRBench. Compared to the modular baseline, i.e., InternVL-1.5, Mono-InternVL still retains comparable multimodal performance while reducing up to 67% first token latency. Our project is available at https://internvl.github.io/blog/2024-10-10-Mono-InternVL/.

SimVS: Simulating World Inconsistencies for Robust View Synthesis
Alex Trevithick, Roni Paiss, Philipp Henzler, Dor Verbin, Rundi Wu, Hadi Alzayer, Ruiqi Gao, Ben Poole, Jonathan T. Barron, Aleksander Holynski, Ravi Ramamoorthi, Pratul P. Srinivasan; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 16464-16474
Novel-view synthesis techniques achieve impressive results for static scenes but struggle when faced with the inconsistencies inherent to casual capture settings: varying illumination, scene motion, and other unintended effects that are difficult to model explicitly. We present an approach for leveraging generative video models to simulate the inconsistencies in the world that can occur during cap

ture. We use this process, along with existing multi-view datasets, to create synthetic data for training a multi-view harmonization network that is able to reconcile inconsistent observations into a consistent 3D scene. We demonstrate that our world-simulation strategy significantly outperforms traditional augmentation methods in handling real-world scene variations, thereby enabling highly accurate static 3D reconstructions in the presence of a variety of challenging inconsistencies.
****

FLAVC: Learned Video Compression with Feature Level Attention
Chun Zhang, Heming Sun, Jiro Katto; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 28019-28028
Learned Video Compression (LVC) aims to reduce redundancy in sequential data through deep learning approaches. Recent advances have significantly boosted LVC performance by shifting compression operations to feature domain, often combining Motion Estimation and Motion Compensation module(MEMC) with CNN-based context extraction. However, reliance on motions and convolution-driven context models limits its generalizability and global perception. To address these issues, we propose a Feature-level Attention (FLA) module within a Transformer-based framework that perceives full-frame explicitly, thus bypassing confined motion signatures. FLA accomplishes global perception by converting high-level local patch embeddings to one-dimensional batch-wise vectors and replacing traditional attention weights to a global context matrix. Amongst this, a dense overlapping patcher (DP) is introduced to retain local features before embedding projection. Furthermore, a Transformer-CNN mixed encoder is applied to alleviate the spatial feature bottleneck without expanding latent size. Experiments demonstrate excellent generalizability with universally efficient redundancy reduction in different scenarios. Extensive tests on four video compression datasets show that our method achieves state-of-the-art Rate-Distortion performance compared to existing LVC methods and traditional codecs. A down-scaled version of our model reduced computation overhead by a great margin while maintained great performance.

An End-to-End Robust Point Cloud Semantic Segmentation Network with Single-Step Conditional Diffusion Models
Wentao Qu, Jing Wang, YongShun Gong, Xiaoshui Huang, Liang Xiao; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 27325-27335
Existing conditional Denoising Diffusion Probabilistic Models (DDPMs) with a Noise-Conditional Framework (NCF) remain challenging for 3D scene understanding tasks, as the complex geometric details in scenes increase the difficulty of fitting the gradients of the data distribution (the scores) from semantic labels. This also results in longer training and inference time for DDPMs compared to non-DDPMs. From a different perspective, we delve deeply into the model paradigm dominated by the Conditional Network. In this paper, we propose an end-to-end robust semantic Segmentation Network based on a Conditional-Noise Framework (CNF) of DDPMs, named CDSegNet. Specifically, CDSegNet models the Noise Network (NN) as a learnable noise-feature generator. This enables the Conditional Network (CN) to understand 3D scene semantics under multi-level feature perturbations, enhancing the generalization in unseen scenes. Meanwhile, benefiting from the noise system of DDPMs, CDSegNet exhibits strong robustness for data noise and sparsity in experiments. Moreover, thanks to CNF, CDSegNet can generate the semantic labels in a single-step inference like non-DDPMs, due to avoiding directly fitting the scores from semantic labels in the dominant network of CDSegNet. On public indoor and outdoor benchmarks, CDSegNet significantly outperforms existing methods, achieving state-of-the-art performance.

From Zero to Detail: Deconstructing Ultra-High-Definition Image Restoration from Progressive Spectral Perspective
Chen Zhao, Zhizhou Chen, Yunzhe Xu, Enxuan Gu, Jian Li, Zili Yi, Qian Wang, Jian Yang, Ying Tai; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 17935-17946

Ultra-high-definition (UHD) image restoration faces significant challenges due t
o its high resolution, complex content, and intricate details. To cope with thes
e challenges, we analyze the restoration process in depth through a progressive
spectral perspective, and deconstruct the complex UHD restoration problem into t
hree progressive stages: zero-frequency enhancement, low-frequency restoration,
and high-frequency refinement. Building on this insight, we propose a novel fram
ework, ERR, which comprises three collaborative sub-networks: the zero-frequenc
y enhancer (ZFE), the low-frequency restorer (LFR), and the high-frequency refin
er (HFR). Specifically, the ZFE integrates global priors to learn global mapping
, while the LFR restores low-frequency information, emphasizing reconstruction o
f coarse-grained content. Finally, the HFR employs our designed frequency-windo
wed Kolmogorov-Arnold Networks (FW-KAN) to refine textures and details, producin
g high-quality image restoration. Our approach significantly outperforms previou
s UHD methods across various tasks, with extensive ablation studies validating t
he effectiveness of each component.

SMILE: Infusing Spatial and Motion Semantics in Masked Video Learning
Fida Mohammad Thoker, Letian Jiang, Chen Zhao, Bernard Ghanem; Proceedings of th
e Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 8438-8449
Masked video modeling, such as VideoMAE, is an effective paradigm for video self
-supervised learning (SSL). However, they are primarily based on reconstructing
pixel level details on natural videos which have substantial temporal redundancy
, limiting their capability for semantic representation and sufficient encoding
of motion dynamics. To address these issues, this paper introduces a novel SSL a
pproach for video representation learning, dubbed as SMILE, by infusing both spa
tial and motion semantics. In SMILE, we leverage image-language pretrained model
s, such as CLIP, to guide the learning process with their high-level spatial sem
antics. We enhance the representation of motion by introducing synthetic motion
patterns in the training data, allowing the model to capture more complex and dy
namic content. Furthermore, using SMILE, we establish a new self-supervised vide
o learning paradigm capable of learning strong video representations without req
uiring any natural video data. We have carried out extensive experiments on 7 da
tasets with various downstream scenarios. SMILE surpasses current state-of-the-a
rt SSL methods, showcasing its effectiveness in learning more discriminative and
generalizable video representations.

Video Language Model Pretraining with Spatio-temporal Masking
Yue Wu, Zhaobo Qi, Junshu Sun, Yaowei Wang, Qingming Huang, Shuhui Wang; Proceed
ings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp.
8557-8567
The development of self-supervised video-language models based on mask learning
has significantly advanced downstream video tasks. These models leverage masked
reconstruction to facilitate joint learning of visual and linguistic information
. However, recent study reveals that reconstructing image features yields superi
or downstream performance compared to video feature reconstruction. We hypothesi
ze that this performance gap stems from the way how masking strategies influence
the model's attention to temporal dynamics. To validate this hypothesis, we per
formed two sets of experiments that demonstrate that alignment between the maske
d target and the reconstruction target is crucial for self-supervised video-lang
uage learning. Based on these findings, we propose a spatio-temporal masking str
ategy (STM) for video-language model pretraining that operates across adjacent f
rames, and a decoder leverages semantic information to enhance the spatio-tempor
al representations of masked tokens. Thanks to the combination of masking strate
gy and reconstruction decoder, STM enforces the model to learn spatio-temporal f
eature representation comprehensively. Experiments in three video understanding
downstream tasks validate the superiority of our method.

COSMOS: Cross-Modality Self-Distillation for Vision Language Pre-training
Sanghwan Kim, Rui Xiao, Mariana-Iuliana Georgescu, Stephan Alaniz, Zeynep Akata;
Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2

025, pp. 14690-14700
Vision-Language Models (VLMs) trained with contrastive loss have achieved signif icant advancements in various vision and language tasks. However, the global nat ure of the contrastive loss makes VLMs focus predominantly on foreground objects , neglecting other crucial information in the image, which limits their effectiv eness in downstream tasks. To address these challenges, we propose COSMOS: CrOSs -MOdality Self-distillation for vision-language pre-training that integrates a n ovel text-cropping strategy and cross-attention module into a self-supervised le arning framework. We create global and local views of images and texts (i.e., mu lti-modal augmentations), which are essential for self-distillation in VLMs. We further introduce a cross-attention module, enabling COSMOS to learn comprehensi ve cross-modal representations optimized via a cross-modality self-distillation loss. COSMOS consistently outperforms previous strong baselines on various zero- shot downstream tasks, including retrieval, classification, and semantic segment ation. Additionally, it surpasses CLIP-based models trained on larger datasets i n visual perception and contextual understanding tasks. Code is available at htt ps://github.com/ExplainableML/cosmos.

Lifting Motion to the 3D World via 2D Diffusion
Jiaman Li, C. Karen Liu, Jiajun Wu; Proceedings of the Computer Vision and Patte rn Recognition Conference (CVPR), 2025, pp. 17518-17528
Estimating 3D motion from 2D observations is a long-standing research challenge. Prior work typically requires training on datasets containing ground truth 3D m otions, limiting their applicability to activities well-represented in existing motion capture data. This dependency particularly hinders generalization to out- of-distribution scenarios or subjects where collecting 3D ground truth is challe nging, such as complex athletic movements or animal motion. We introduce MVLift, a novel approach to predict global 3D motion---including both joint rotations a nd root trajectories in the world coordinate system---using only 2D pose sequenc es for training. Our multi-stage framework leverages 2D motion diffusion models to progressively generate consistent 2D pose sequences across multiple views, a key step in recovering accurate global 3D motion. MVLift generalizes across vari ous domains, including human poses, human-object interactions, and animal poses. Despite not requiring 3D supervision, it outperforms prior work on five dataset s, including those methods that require 3D supervision.

TAPT: Test-Time Adversarial Prompt Tuning for Robust Inference in Vision-Languag e Models
Xin Wang, Kai Chen, Jiaming Zhang, Jingjing Chen, Xingjun Ma; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 19910-1992 0
Large pre-trained Vision-Language Models (VLMs) such as CLIP have demonstrated e xcellent zero-shot generalizability across various downstream tasks. However, re cent studies have shown that the inference performance of CLIP can be greatly de graded by small adversarial perturbations, especially its visual modality, posin g significant safety threats. To mitigate this vulnerability, in this paper, we propose a novel defense method called Test-Time Adversarial Prompt Tuning (TAPT) to enhance the inference robustness of CLIP against visual adversarial attacks. TAPT is a test-time defense method that learns defensive bimodal (textual and v isual) prompts to robustify the inference process of CLIP. Specifically, it is a n unsupervised method that optimizes the defensive prompts for each test sample by minimizing a multi-view entropy and aligning adversarial-clean distributions. We evaluate the effectiveness of TAPT on 11 benchmark datasets, including Image Net and 10 other zero-shot datasets, demonstrating that it enhances the zero-sho t adversarial robustness of the original CLIP by at least 48.9% against AutoAtta ck (AA), while largely maintaining performance on clean examples. Moreover, TAPT outperforms existing adversarial prompt tuning methods across various backbones , achieving an average robustness improvement of at least 36.6%. Code is availab le at https://github.com/xinwong/TAPT.

Active Data Curation Effectively Distills Large-Scale Multimodal Models
Vishaal Udandarao, Nikhil Parthasarathy, Muhammad Ferjad Naeem, Talfan Evans, Samuel Albanie, Federico Tombari, Yongqin Xian, Alessio Tonioni, Olivier J. Henaff ; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 14422-14437
Knowledge distillation (KD) is the de facto standard for compressing large-scale models into smaller ones. Prior works have explored ever more complex KD strategies involving different objective functions, teacher-ensembles, and weight inheritance. In this work we explore an alternative, yet simple approach---active data curation as effective distillation for contrastive multimodal pretraining. Our simple online batch selection method, ACID, outperforms strong KD baselines across various model-, data- and compute-configurations. Further, we find such an active data curation strategy to in fact be complementary to standard KD, and can be effectively combined to train highly performant inference-efficient models. Our simple and scalable pretraining framework, ACED, achieves state-of-the-art results across 27 zero-shot classification and retrieval tasks with upto 11% less inference FLOPs. We further demonstrate that our ACED models yield strong vision-encoders for training generative multimodal models in the LiT-Decoder setting, outperforming larger vision encoders for image-captioning and visual question-answering tasks.

PCDreamer: Point Cloud Completion Through Multi-view Diffusion Priors
Guangshun Wei, Yuan Feng, Long Ma, Chen Wang, Yuanfeng Zhou, Changjian Li; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 27243-27253
This paper presents PCDreamer, a novel method for point cloud completion. Traditional methods typically extract features from partial point clouds to predict missing regions, but the large solution space often leads to unsatisfactory results. More recent approaches have started to use images as extra guidance, effectively improving performance, but obtaining paired data of images and partial point clouds is challenging in practice. To overcome these limitations, we harness the relatively view-consistent multi-view diffusion priors within large models, to generate novel views of the desired shape. The resulting image set encodes both global and local shape cues, which are especially beneficial for shape completion. To fully exploit the priors, we have designed a shape fusion module for producing an initial complete shape from multi-modality input (i.e., images and point clouds), and a follow-up shape consolidation module to obtain the final complete shape by discarding unreliable points introduced by the inconsistency from diffusion priors. Extensive experimental results demonstrate our superior performance, especially in recovering fine details.

Your ViT is Secretly an Image Segmentation Model
Tommie Kerssies, Niccolò Cavagnero, Alexander Hermans, Narges Norouzi, Giuseppe Averta, Bastian Leibe, Gijs Dubbelman, Daan de Geus; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 25303-25313
Vision Transformers (ViTs) have shown remarkable performance and scalability across various computer vision tasks. To apply single-scale ViTs to image segmentation, existing methods adopt a convolutional adapter to generate multi-scale features, a pixel decoder to fuse these features, and a Transformer decoder that uses the fused features to make predictions. In this paper, we show that the inductive biases introduced by these task-specific components can instead be learned by the ViT itself, given sufficiently large models and extensive pre-training. Based on these findings, we introduce the Encoder-only Mask Transformer (EoMT), which repurposes the plain ViT architecture to conduct image segmentation. With large-scale models and pre-training, EoMT obtains a segmentation accuracy similar to state-of-the-art models that use task-specific components. At the same time, EoMT is significantly faster than these methods due to its architectural simplicity, e.g., up to 4x faster with ViT-L. Across a range of model sizes, EoMT demonstrates an optimal balance between segmentation accuracy and prediction speed, suggesting that compute resources are better spent on scaling the ViT itself rath

er than adding architectural complexity. Code: https://www.tue-mps.org/eomt/.

Cross-Rejective Open-Set SAR Image Registration
Shasha Mao, Shiming Lu, Zhaolong Du, Licheng Jiao, Shuiping Gou, Luntian Mou, Xu equan Lu, Lin Xiong, Yimeng Zhang; Proceedings of the Computer Vision and Patter n Recognition Conference (CVPR), 2025, pp. 23027-23036
Synthetic Aperture Radar (SAR) image registration is an essential upstream task in geoscience applications, in which pre-detected keypoints from two images are employed as observed objects to seek matched-point pairs. In general, the regist ration is regarded as a typical closed-set classification, which forces each key point to be classified into the given classes, but ignoring an essential issue t hat numerous redundant keypoints are beyond the given classes, which unavoidably results in capturing incorrect matched-point pairs. Based on this, we propose a Cross-Rejective Open-set SAR Image Registration (CroR-OSIR) method. In this wor k, these redundant keypoints are regarded as out-of-distribution (OOD) samples, and we formulate the registration as a special open-set task with two modules: s upervised contrastive feature-tuning and cross-rejective open-set recognition (C roR-OSR). Unlike traditional open-set recognition, all samples, including OOD sa mples, are available in the CroR-OSR module. CroR-OSR conducts the closed-set cl assifications in individual open-set domains from two images, meanwhile employin g the cross-domain rejection during training, to exclude these OOD samples based on confidence and consistency. Moreover, a new supervised contrastive tuning st rategy is incorporated for feature-tuning. Especially, the cross-domain estimati on labels obtained by CroR-OSR are fed back to the feature-tuning module for fea ture-tuning, to enhance feature discriminability. The experimental results illus trate that the proposed method achieves more precise registration than the state -of-the-art methods. The code is released at https://github.com/XDyaoshi/CroR-OS IR-main.

Synthetic Data is an Elegant GIFT for Continual Vision-Language Models
Bin Wu, Wuxuan Shi, Jinqiao Wang, Mang Ye; Proceedings of the Computer Vision an d Pattern Recognition Conference (CVPR), 2025, pp. 2813-2823
Pre-trained Vision-Language Models (VLMs) require Continual Learning (CL) to eff iciently update their knowledge and adapt to various downstream tasks without re training from scratch. However, for VLMs, in addition to the loss of knowledge p reviously learned from downstream tasks, pre-training knowledge is also corrupte d during continual fine-tuning. This issue is exacerbated by the unavailability of original pre-training data, leaving VLM's generalization ability degrading. I n this paper, we propose GIFT, a novel continual fine-tuning approach that utili zes synthetic data to overcome catastrophic forgetting in VLMs. Taking advantage of recent advances in text-to-image synthesis, we employ a pre-trained diffusio n model to recreate both pre-training and learned downstream task data. In this way, the VLM can revisit previous knowledge through distillation on matching dif fusion-generated images and corresponding text prompts. Leveraging the broad dis tribution and high alignment between synthetic image-text pairs in VLM's feature space, we propose a contrastive distillation loss along with an image-text alig nment constraint. To further combat in-distribution overfitting and enhance dist illation performance with limited amount of generated data, we incorporate adapt ive weight consolidation, utilizing Fisher information from these synthetic imag e-text pairs and achieving a better stability-plasticity balance. Extensive expe riments demonstrate that our method consistently outperforms previous state-of-t he-art approaches across various settings.

SplineGS: Robust Motion-Adaptive Spline for Real-Time Dynamic 3D Gaussians from Monocular Video
Jongmin Park, Minh-Quan Viet Bui, Juan Luis Gonzalez Bello, Jaeho Moon, Jihyong Oh, Munchurl Kim; Proceedings of the Computer Vision and Pattern Recognition Con ference (CVPR), 2025, pp. 26866-26875
Synthesizing novel views from in-the-wild monocular videos is challenging due to scene dynamics and the lack of multi-view cues. To address this, we propose Spl

ineGS, a COLMAP-free dynamic 3D Gaussian Splatting (3DGS) framework for high-qua lity reconstruction and fast rendering from monocular videos. At its core is a n ovel Motion-Adaptive Spline (MAS) method, which represents continuous dynamic 3D Gaussian trajectories using cubic Hermite splines with a small number of contro l points. For MAS, we introduce a Motion-Adaptive Control points Pruning (MACP) method to model the deformation of each dynamic 3D Gaussian across varying motio ns, progressively pruning control points while maintaining dynamic modeling inte grity. Additionally, we present a joint optimization strategy for camera paramet er estimation and 3D Gaussian attributes, leveraging photometric and geometric c onsistency. This eliminates the need for Structure-from-Motion preprocessing and enhances SplineGS's robustness in real-world conditions. Experiments show that SplineGS significantly outperforms state-of-the-art methods in novel view synthe sis quality for dynamic scenes from monocular videos, achieving thousands times faster rendering speed.

SCSA: A Plug-and-Play Semantic Continuous-Sparse Attention for Arbitrary Semanti c Style Transfer

Chunnan Shang, Zhizhong Wang, Hongwei Wang, Xiangming Meng; Proceedings of the C omputer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 13051-13060

Attention-based arbitrary style transfer methods, including CNN-based, Transform er-based, and Diffusion-based, have flourished and produced high-quality stylize d images. However, they perform poorly on the content and style images with the same semantics, i.e., the style of the corresponding semantic region of the gene rated stylized image is inconsistent with that of the style image. We argue that the root cause lies in their failure to consider the relationship between local regions and semantic regions. To address this issue, we propose a plug-and-play semantic continuous-sparse attention, dubbed SCSA, for arbitrary semantic style transfer---each query point considers certain key points in the corresponding s emantic region. Specifically, semantic continuous attention ensures each query p oint fully attends to all the continuous key points in the same semantic region that reflect the overall style characteristics of that region; Semantic sparse a ttention allows each query point to focus on the most similar sparse key point i n the same semantic region that exhibits the specific stylistic texture of that region. By combining the two modules, the resulting SCSA aligns the overall styl e of the corresponding semantic regions while transferring the vivid textures of these regions. Qualitative and quantitative results demonstrate that SCSA enabl es attention-based arbitrary style transfer methods to produce high-quality sema ntic stylized images.

Timestep Embedding Tells: It's Time to Cache for Video Diffusion Model

Feng Liu, Shiwei Zhang, Xiaofeng Wang, Yujie Wei, Haonan Qiu, Yuzhong Zhao, Ying ya Zhang, Qixiang Ye, Fang Wan; Proceedings of the Computer Vision and Pattern R ecognition Conference (CVPR), 2025, pp. 7353-7363

As a fundamental backbone for video generation, diffusion models are challenged by low inference speed due to the sequential nature of denoising.Previous method s speed up the models by caching and reusing model outputs at uniformly selected timesteps.However, such a strategy neglects the fact that differences among mod el outputs are not uniform across timesteps, which hinders selecting the appropr iate model outputs to cache, leading to a poor balance between inference efficie ncy and visual quality.In this study, we introduce Timestep Embedding Aware Cach e (TeaCache), a training-free caching approach that estimates and leverages the fluctuating differences among model outputs across timesteps.Rather than directl y using the time-consuming model outputs, TeaCache focuses on model inputs, whic h have a strong correlation with the modeloutputs while incurring negligible com putational cost.TeaCache first modulates the noisy inputs using the timestep emb eddings to ensure their differences better approximating those of model outputs. TeaCache then introduces a rescaling strategy to refine the estimated differenc es and utilizes them to indicate output caching.Experiments show that TeaCache a chieves up to 4.41xacceleration over Open-Sora-Plan with negligible (-0.07% Vben ch score) degradation of visual quality.

Can't Slow Me Down: Learning Robust and Hardware-Adaptive Object Detectors against Latency Attacks for Edge Devices
Tianyi Wang, Zichen Wang, Cong Wang, Yuanchao Shu, Ruilong Deng, Peng Cheng, Jiming Chen; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 19230-19240
Object detection is a fundamental enabler for many real-time downstream applications such as autonomous driving, augmented reality and supply chain management. However, the algorithmic backbone of neural networks is brittle to imperceptible perturbations in the system inputs, which were generally known as misclassifying attacks. By targeting the real-time processing capability, a new class of latency attacks has been reported recently. They exploit new attack surfaces in object detectors by creating a computational bottleneck in the post-processing module, which leads to cascading failure and puts the real-time downstream tasks at risk. In this work, we take an initial attempt to defend against this attack via background-attentive adversarial training that is also cognizant of the underlying hardware capabilities. We first draw system-level connections between latency attacks and hardware capacity across heterogeneous GPU devices. Based on the particular adversarial behaviors, we utilize objectness loss as a proxy and build background attention into the adversarial training pipeline, and achieve a favorable balance between clean and robust accuracy. The extensive experiments demonstrate the effectiveness of the defense in restoring real-time processing capability from 13 FPS to 43 FPS on Jetson Orin NX, with a better trade-off between the clean and robust accuracy. The source code is available at: https://github.com/Hill-Wu-1998/underload.

Multi-modal Knowledge Distillation-based Human Trajectory Forecasting
Jaewoo Jeong, Seohee Lee, Daehee Park, Giwon Lee, Kuk-Jin Yoon; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 24222-24233
Pedestrian trajectory forecasting is crucial in various applications such as autonomous driving and mobile robot navigation. In such applications, camera-based perception enables the extraction of additional modalities (human pose, text) to enhance prediction accuracy. Indeed, we find that textual descriptions play a crucial role in integrating additional modalities into a unified understanding. However, online extraction of text requires the use of VLM, which may not be feasible for resource-constrained systems. To address this challenge, we propose a multi-modal knowledge distillation framework: a student model with limited modality is distilled from a teacher model trained with full range of modalities. The comprehensive knowledge of a teacher model trained with trajectory, human pose, and text is distilled into a student model using only trajectory or human pose as a sole supplement. In doing so, we separately distill the core locomotion insights from intra-agent multi-modality and inter-agent interaction. Our generalizable framework is validated with two state-of-the-art models across three datasets on both ego-view (JRDB, SIT) and BEV-view (ETH/UCY) setups, utilizing both annotated and VLM-generated text captions. Distilled student models show consistent improvement in all prediction metrics for both full and instantaneous observations, improving up to 13%. The code is available at github.com/Jaewoo97/KDTF.

SAM2Object: Consolidating View Consistency via SAM2 for Zero-Shot 3D Instance Segmentation
Jihuai Zhao, Junbao Zhuo, Jiansheng Chen, Huimin Ma; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 19325-19334
In the field of zero-shot 3D instance segmentation, existing 2D-to-3D lifting methods typically obtain 2D segmentation across multiple RGB frames using vision foundation models, which are then projected and merged into 3D space. However, since the inference of vision foundation models on a single frame is not integrated with adjacent frames, the masks of the same object may vary across different frames, leading to a lack of view consistency in the 2D segmentation. Furthermore, current lifting methods average the 2D segmentation from multiple views during

the projection into 3D space, causing low-quality masks and high-quality masks to share the same weight. These factors can lead to fragmented 3D segmentation. In this paper, we present SAM2Object, a novel zero-shot 3D instance segmentation method that effectively utilizes the Segment Anything Model 2 to segment and track objects, consolidating view consistency across frames. Our approach combines these consistent 2D masks with 3D geometric priors, improving the robustness of 3D segmentation. Additionally, we introduce mask consolidation module to filter out low-quality masks across frames, which enables more precise 2D-to-3D matching. Comprehensive evaluations on ScanNetV2, ScanNet++ and ScanNet200 demonstrate the robustness and effectiveness of SAM2Object, showcasing its ability to outperform previous methods. Our project page is at https://jihuaizhaohd.github.io/SAM2Object.

CDI: Copyrighted Data Identification in Diffusion Models

Jan Dubi■ski, Antoni Kowalczuk, Franziska Boenisch, Adam Dziedzic; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 18674-18684

Diffusion Models (DMs) benefit from large and diverse datasets for their training. Since this data is often scraped from the Internet without permission from the data owners, this raises concerns about copyright and intellectual property protections. While (illicit) use of data is easily detected for training samples perfectly re-created by a DM at inference time, it is much harder for data owners to verify if their data was used for training when the outputs from the suspect DM are not close replicas. Conceptually, membership inference attacks (MIAs), which detect if a given data point was used during training, present themselves as a suitable tool to address this challenge. However, we demonstrate that existing MIAs are not strong enough to reliably determine the membership of individual images in large, state-of-the-art DMs. To overcome this limitation, we propose Copyrighted Data Identification (CDI), a framework for data owners to identify whether their dataset was used to train a given DM. CDI relies on dataset inference techniques, i.e., instead of using the membership signal from a single data point, CDI leverages the fact that most data owners, such as providers of stock photography, visual media companies, or even individual artists, own datasets with multiple publicly exposed data points which might all be included in the training of a given DM. By selectively aggregating signals from existing MIAs and using new handcrafted methods to extract features from these datasets, feeding them to a scoring model, and applying rigorous statistical testing, CDI allows data owners with as little as 70 data points to identify with a confidence of more than 99% whether their data was used to train a given DM. Thereby, CDI represents a valuable tool for data owners to claim illegitimate use of their copyrighted data.

Hypergraph Vision Transformers: Images are More than Nodes, More than Edges

Joshua Fixelle; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 9751-9761

Recent advancements in computer vision have highlighted the scalability of Vision Transformers (ViTs) across various tasks, yet challenges remain in balancing adaptability, computational efficiency, and the ability to model higher-order relationships. Vision Graph Neural Networks (ViGs) offer an alternative by leveraging graph-based methodologies but are hindered by the computational bottlenecks of clustering algorithms used for edge generation. To address these issues, we propose the Hypergraph Vision Transformer (HgVT), which incorporates a hierarchical bipartite hypergraph structure into the vision transformer framework to capture higher-order semantic relationships while maintaining computational efficiency. HgVT leverages population and diversity regularization for dynamic hypergraph construction without clustering, and expert edge pooling to enhance semantic extraction and facilitate graph-based image retrieval. Empirical results demonstrate that HgVT achieves strong performance on image classification and retrieval, positioning it as an efficient framework for semantic-based vision tasks.

Binarized Neural Network for Multi-spectral Image Fusion
Junming Hou, Xiaoyu Chen, Ran Ran, Xiaofeng Cong, Xinyang Liu, Jian Wei You, Liang-Jian Deng; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 2236-2245
Pan-sharpening technology refers to generating a high-resolution (HR) multi-spectral (MS) image with broad applications by fusing a low-resolution (LR) MS image and HR panchromatic (PAN) image. While deep learning approaches have shown impressive performance in pan-sharpening, they generally require extensive hardware with high memory and computational power, limiting their deployment on resource-constrained satellites. In this study, we investigate the use of binary neural networks (BNNs) for pan-sharpening and observe that binarization leads to distinct information degradation across different frequency components of an image. Building on this insight, we propose a novel binary pan-sharpening network, termed BNNPan, structured around the Prior-Integrated Binary Frequency (PIBF) module that features three key ingredients: Binary Wavelet Transform Convolution, Latent Diffusion Prior Compensation, and Channel-wise Distribution Calibration. Specifically, the first decomposes input features into distinct frequency components using Wavelet Transform, then applies a "divide-and-conquer" strategy to optimize binary feature learning for each component, informed by the corresponding full-precision residual statistics. The second integrates a latent diffusion prior to compensate for compromised information during binarization, while the third performs channel-wise calibration to further refine feature representation. Our BNNPan, developed with the proposed techniques, achieves promising pan-sharpening performance on multiple remote sensing datasets, surpassing state-of-the-art binarization algorithms.

CRISP: Object Pose and Shape Estimation with Test-Time Adaptation
Jingnan Shi, Rajat Talak, Harry Zhang, David Jin, Luca Carlone; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 11644-11653
We consider the problem of estimating object pose and shape from an RGB-D image. Our first contribution is to introduce CRISP, a category-agnostic object pose and shape estimation pipeline. The pipeline implements an encoder-decoder model for shape estimation. It uses FiLM-conditioning for implicit shape reconstruction and a DPT-based network for estimating pose-normalized points for pose estimation. As a second contribution, we propose an optimization-based pose and shape corrector that can correct estimation errors caused by a domain gap. Observing that the shape decoder is well behaved in the convex hull of known shapes, we approximate the shape decoder with an active shape model, and show that this reduces the shape correction problem to a constrained linear least squares problem, which can be solved efficiently by an interior point algorithm. Third, we introduce a self-training pipeline to perform self-supervised domain adaptation of CRISP. The self-training is based on a correct-and-certify approach, which leverages the corrector to generate pseudo-labels at test time, and uses them to self-train CRISP. We demonstrate CRISP (and the self-training) on YCBV, SPE3R, and NOCS datasets. CRISP shows high performance on all the datasets. Moreover, our self-training is capable of bridging a large domain gap. Finally, CRISP also shows an ability to generalize to unseen objects. Code, pre-trained models and videos of sample results are available on the project webpage https://web.mit.edu/sparklab/research/crisp_object_pose_shape/.

ShiftwiseConv: Small Convolutional Kernel with Large Kernel Effect
Dachong Li, Li Li, Zhuangzhuang Chen, Jianqiang Li; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 25281-25291
Large kernels make standard convolutional neural networks (CNNs) great again over transformer architectures in various vision tasks. Nonetheless, recent studies meticulously designed around increasing kernel size have shown diminishing returns or stagnation in performance. Thus, the hidden factors of large kernel convolution that affect model performance remain unexplored. In this paper, we reveal that the key hidden factors of large kernels can be summarized as two separate

components: extracting features at a certain granularity and fusing features by multiple pathways. To this end, we leverage the multi-path long-distance sparse dependency relationship to enhance feature utilization via the proposed Shiftwise (SW) convolution operator with a pure CNN architecture. In a wide range of vision tasks such as classification, segmentation, and detection, SW surpasses state-of-the-art transformers and CNN architectures, including SLaK and UniRepLKNet. More importantly, our experiments demonstrate that 3 x3 convolutions can replace large convolutions in existing large kernel CNNs to achieve comparable effects, which may inspire follow-up works. Code and all the models at https://github.com/lidc54/shift-wiseConv.

GaussianIP: Identity-Preserving Realistic 3D Human Generation via Human-Centric Diffusion Prior

Zichen Tang, Yuan Yao, Miaomiao Cui, Liefeng Bo, Hongyu Yang; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 348-358

Text-guided 3D human generation has advanced with the development of efficient 3D representations and 2D-lifting methods like score distillation sampling (SDS). However, current methods suffer from prolonged training times and often produce results that lack fine facial and garment details. In this paper, we propose GaussianIP, an effective two-stage framework for generating identity-preserving realistic 3D humans from text and image prompts. Our core insight is to leverage human-centric knowledge to facilitate the generation process. In stage 1, we propose a novel Adaptive Human Distillation Sampling (AHDS) method to rapidly generate a 3D human that maintains high identity consistency with the image prompt and achieves a realistic appearance. Compared to traditional SDS methods, AHDS better aligns with the human-centric generation process, enhancing visual quality with notably fewer training steps. To further improve the visual quality of the face and clothes regions, we design a View-Consistent Refinement (VCR) strategy in stage 2. Specifically, it produces detail-enhanced results of the multi-view images from stage 1 iteratively, ensuring the 3D texture consistency across views via mutual attention and distance-guided attention fusion. Then a polished version of the 3D human can be achieved by directly perform reconstruction with the refined images. Extensive experiments demonstrate that GaussianIP outperforms existing methods in both visual quality and training efficiency, particularly in generating identity-preserving results.

Creating Your Editable 3D Photorealistic Avatar with Tetrahedron-constrained Gaussian Splatting

Hanxi Liu, Yifang Men, Zhouhui Lian; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 15976-15986

Personalized 3D avatar editing holds significant promise due to its user-friendliness and availability to applications such as AR/VR and virtual try-ons. Previous studies have explored the feasibility of 3D editing, but often struggle to generate visually pleasing results, possibly due to the unstable representation learning under mixed optimization of geometry and texture in complicated reconstructed scenarios. In this paper, we aim to provide an accessible solution for ordinary users to create their editable 3D avatars with precise region localization, geometric adaptability, and photorealistic renderings. To tackle this challenge, we introduce a meticulously designed framework that decouples the editing process into local spatial adaptation and realistic appearance learning, utilizing a hybrid Tetrahedron-constrained Gaussian Splatting (TetGS) as the underlying representation. TetGS combines the controllable explicit structure of tetrahedral grids with the high-precision rendering capabilities of 3D Gaussian Splatting and is optimized in a progressive manner comprising three stages: 3D avatar instantiation from real-world monocular videos to provide accurate priors for TetGS initialization; localized spatial adaptation with explicitly partitioned tetrahedrons to guide the redistribution of Gaussian kernels; and geometry-based appearance generation with a coarse-to-fine activation strategy. Both qualitative and quantitative experiments demonstrate the effectiveness and superiority of our approach in generating photorealistic 3D editable avatars.

FineVQ: Fine-Grained User Generated Content Video Quality Assessment
Huiyu Duan, Qiang Hu, Jiarui Wang, Liu Yang, Zitong Xu, Lu Liu, Xiongkuo Min, Chunlei Cai, Tianxiao Ye, Xiaoyun Zhang, Guangtao Zhai; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 3206-3217
The rapid growth of user-generated content (UGC) videos has produced an urgent need for effective video quality assessment (VQA) algorithms to monitor video quality and guide optimization and recommendation procedures. However, current VQA models generally only give an overall rating for a UGC video, which lacks fine-grained labels for serving video processing and recommendation applications. To address the challenges and promote the development of UGC videos, we establish the first large-scale Fine-grained Video quality assessment Database, termed FineVD, which comprises 6104 UGC videos with fine-grained quality scores and descriptions across multiple dimensions. Based on this database, we propose a Fine-grained Video Quality assessment (FineVQ) model to learn the fine-grained quality of UGC videos, with the capabilities of quality rating, quality scoring, and quality attribution. Extensive experimental results demonstrate that our proposed FineVQ can produce fine-grained video-quality results and achieve state-of-the-art performance on FineVD and other commonly used UGC-VQA datasets. Both FineVD and FineVQ are publicly available at: https://github.com/IntMeGroup/FineVQ.

Unveiling the Ignorance of MLLMs: Seeing Clearly, Answering Incorrectly
Yexin Liu, Zhengyang Liang, Yueze Wang, Xianfeng Wu, Feilong Tang, Muyang He, Jian Li, Zheng Liu, Harry Yang, Sernam Lim, Bo Zhao; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 9087-9097
Multimodal **L**arge **L**anguage **M**odels (MLLMs) have displayed remarkable performance in multimodal tasks, particularly in visual comprehension. However, we reveal that MLLMs often generate incorrect answers even when they understand the visual content. To this end, we manually construct a benchmark with 12 categories and design evaluation metrics that assess the degree of error in MLLM responses even when the visual content is seemingly understood. Based on this benchmark, we test 15 leading MLLMs and analyze the distribution of attention maps and logits of some MLLMs. Our investigation identifies two primary issues: 1) most instruction tuning datasets predominantly feature questions that "directly" relate to the visual content, leading to a bias in MLLMs' responses to other indirect questions, and 2) MLLMs' attention to visual tokens is notably lower than to system and question tokens. We further observe that attention scores between questions and visual tokens as well as the model's confidence in the answers are lower in response to misleading questions than to straightforward ones. To address the first challenge, we introduce a paired positive and negative data construction pipeline to diversify the dataset. For the second challenge, we propose to enhance the model's focus on visual content during decoding by refining the text and visual prompt. For the text prompt, we propose a content-guided refinement strategy that performs preliminary visual content analysis to generate structured information before answering the question. Additionally, we employ a visual attention refinement strategy that highlights question-relevant visual tokens to increase the model's attention to visual content that aligns with the question. Extensive experiments demonstrate that these challenges can be significantly mitigated with our proposed dataset and techniques. The benchmark, training set, and code will be available.

Object-Shot Enhanced Grounding Network for Egocentric Video
Yisen Feng, Haoyu Zhang, Meng Liu, Weili Guan, Liqiang Nie; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 24190-24200
Egocentric video grounding is a crucial task for embodied intelligence applications, distinct from exocentric video moment localization. Existing methods primarily focus on the distributional differences between egocentric and exocentric videos but often neglect key characteristics of egocentric videos and the fine-grained information emphasized by question-type queries. To address these limitations, we propose OSGNet, an Object-Shot enhanced Grounding Network for egocentric

video. Specifically, we extract object information from videos to enrich video r
epresentation, particularly for objects highlighted in the textual query but not
 directly captured in the video features. Additionally, we analyze the frequent
shot movements inherent to egocentric videos, leveraging these features to extra
ct the wearer's attention information, which enhances the model's ability to per
form modality alignment. Experiments conducted on three datasets demonstrate tha
t OSGNet achieves state-of-the-art performance, validating the effectiveness of
our approach. Our code can be found at https://github.com/Yisen-Feng/OSGNet.

MANTA: Diffusion Mamba for Efficient and Effective Stochastic Long-Term Dense Ac
tion Anticipation

Olga Zatsarynna, Emad Bahrami, Yazan Abu Farha, Gianpiero Francesca, Juergen Gal
l; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR),
 2025, pp. 3438-3448

Long-term dense action anticipation is very challenging since it requires predic
ting actions and their durations several minutes into the future based on provid
ed video observations. To model the uncertainty of future outcomes, stochastic m
odels predict several potential future action sequences for the same observation
. Recent work has further proposed to incorporate uncertainty modelling for obse
rved frames by simultaneously predicting per-frame past and future actions in a
unified manner. While such joint modelling of actions is beneficial, it requires
 long-range temporal capabilities to connect events across distant past and futu
re time points. However, the previous work struggles to achieve such a long-rang
e understanding due to its limited and/or sparse receptive field. To alleviate t
his issue, we propose a novel MANTA (MAmba for ANTicipation) network. Our model
enables effective long-term temporal modelling even for very long sequences whil
e maintaining linear complexity in sequence length. We demonstrate that our appr
oach achieves state-of-the-art results on three datasets - Breakfast, 50Salads,
and Assembly101 - while also significantly improving computational and memory ef
ficiency. Our code is available at https://github.com/olga-zats/DIFF_MANTA.

METASCENES: Towards Automated Replica Creation for Real-world 3D Scans

Huangyue Yu, Baoxiong Jia, Yixin Chen, Yandan Yang, Puhao Li, Rongpeng Su, Jiaxi
n Li, Qing Li, Wei Liang, Song-Chun Zhu, Tengyu Liu, Siyuan Huang; Proceedings o
f the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 1667-
1679

Embodied AI (EAI) research requires high-quality, diverse 3D scenes to effective
ly support skill acquisition, sim-to-real transfer, and generalization. Achievin
g these quality standards, however, necessitates the precise replication of real
-world object diversity. Existing datasets demonstrate that this process heavily
 relies on artist-driven designs, which demand substantial human effort and pres
ent significant scalability challenges. To scalably produce realistic and intera
ctive 3D scenes, we first present MetaScenes, a large-scale simulatable 3D scene
 dataset constructed from real-world scans, which includes 15366 objects spannin
g 831 fine-grained categories. Then, we introduce Scan2Sim, a robust multi-modal
 alignment model, which enables the automated, high-quality replacement of asset
s, thereby eliminating the reliance on artist-driven designs for scaling 3D scen
es. We further propose two benchmarks to evaluate MetaScenes: a detailed scene s
ynthesis task focused on small item layouts for robotic manipulation and a domai
n transfer task in vision-and-language navigation (VLN) to validate cross-domain
 transfer. Results confirm MetaScenes's potential to enhance EAI by supporting m
ore generalizable agent learning and sim-to-real applications, introducing new p
ossibilities for EAI research.

Robust Multimodal Survival Prediction with Conditional Latent Differentiation Va
riational AutoEncoder

Junjie Zhou, Jiao Tang, Yingli Zuo, Peng Wan, Daoqiang Zhang, Wei Shao; Proceedi
ngs of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp.
10384-10393

The integrative analysis of histopathological images and genomic data has receiv

ed increasing attention for survival prediction of human cancers. However, the existing studies always hold the assumption that full modalities are available. As a matter of fact, the cost for collecting genomic data is high, which sometimes makes genomic data unavailable in testing samples. A common way of tackling such incompleteness is to generate the genomic representations from the pathology images. Nevertheless, such strategy still faces the following two challenges: (1) The gigapixel whole slide images (WSIs) are huge and thus hard for representation. (2) It is difficult to generate the genomic embeddings with diverse function categories in a unified generative framework. To address the above challenges, we propose a Conditional Latent Differentiation Variational AutoEncoder (LD-CVAE) for robust multimodal survival prediction, even with missing genomic data. Specifically, a Variational Information Bottleneck Transformer (VIB-Trans) module is proposed to learn compressed pathological representations from the gigapixel WSIs. To generate different functional genomic features, we develop a novel Latent Differentiation Variational AutoEncoder (LD-VAE) to learn the genomic and function-specific posteriors for the genomic embeddings with diverse functions. Finally, we use the product-of-experts technique to integrate the genomic posterior and image posterior for the joint latent distribution estimation in LD-CVAE. We test the effectiveness of our method on five different cancer datasets, and the experimental results demonstrate its superiority in both complete and missing modality scenarios.

Sim-to-Real Causal Transfer: A Metric Learning Approach to Causally-Aware Interaction Representations

Ahmad Rahimi, Po-Chien Luan, Yuejiang Liu, Frano Raji■, Alexandre Alahi; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 17271-17281

Modeling spatial-temporal interactions among neighboring agents is at the heart of multi-agent problems such as motion forecasting and crowd navigation. Despite notable progress, it remains unclear to which extent modern representations can capture the causal relationships behind agent interactions. In this work, we take an in-depth look at the causal awareness of these representations, from computational formalism to real-world practice. First, we revisit the notion of non-causal robustness studied in the recent CausalAgents benchmark. We show that existing representations are already partially resilient to perturbations of non-causal agents, and yet modeling indirect causal effects involving mediator agents remains challenging. To address this challenge, we introduce a metric learning approach that regularizes latent representations with causal annotations. Our controlled experiments show that this approach not only leads to higher degrees of causal awareness but also yields stronger out-of-distribution robustness. To further operationalize it in practice, we propose a sim-to-real causal transfer method via cross-domain multi-task learning. Experiments on trajectory prediction datasets show that our method can significantly boost generalization, even in the absence of real-world causal annotations, where we acquire higher prediction accuracy by only using 25% of real-world data. We hope our work provides a new perspective on the challenges and potential pathways toward causally-aware representations of multi-agent interactions. Our code is available in supplementary materials. Our code is available at https://github.com/vita-epfl/CausalSim2Real.

Ev-3DOD: Pushing the Temporal Boundaries of 3D Object Detection with Event Cameras

Hoonhee Cho, Jae-Young Kang, Youngho Kim, Kuk-Jin Yoon; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 27197-27210

Detecting 3D objects in point clouds plays a crucial role in autonomous driving systems. Recently, advanced multi-modal methods incorporating camera information have achieved notable performance. For a safe and effective autonomous driving system, algorithms that excel not only in accuracy but also in speed and low latency are essential. However, existing algorithms fail to meet these requirements due to the latency and bandwidth limitations of fixed frame rate sensors, e.g., LiDAR and camera. To address this limitation, we introduce asynchronous event c

ameras into 3D object detection for the first time. We leverage their high tempo ral resolution and low bandwidth to enable high-speed 3D object detection. Our m ethod enables detection even during inter-frame intervals when synchronized data is unavailable, by retrieving previous 3D information through the event camera. Furthermore, we introduce the first event-based 3D object detection datasets, E v-Waymo and DSEC-3DOD, both of which include ground truth 3D bounding boxes at 1 00 FPS, establishing the first benchmarks for event-based 3D detectors. The code and dataset are available at https://github.com/mickeykang16/Ev3DOD.

Nearly Zero-Cost Protection Against Mimicry by Personalized Diffusion Models
Namhyuk Ahn, KiYoon Yoo, Wonhyuk Ahn, Daesik Kim, Seung-Hun Nam; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 28801-2 8810
Recent advancements in diffusion models revolutionize image generation but pose risks of misuse, such as replicating artworks or generating deepfakes. Existing image protection methods, though effective, struggle to balance protection effic acy, invisibility, and latency, thus limiting practical use. We introduce pertur bation pre-training to reduce latency and propose a mixture-of-perturbations app roach that dynamically adapts to input images to minimize performance degradatio n. Our novel training strategy computes protection loss across multiple VAE feat ure spaces, while adaptive targeted protection at inference enhances robustness and invisibility. Experiments show comparable protection performance with improv ed invisibility and drastically reduced inference time.
****

Tripartite Weight-Space Ensemble for Few-Shot Class-Incremental Learning
Juntae Lee, Munawar Hayat, Sungrack Yun; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 15329-15338
Few-shot class incremental learning (FSCIL) enables the continual learning of ne w concepts with only a few training examples. In FSCIL, the model undergoes subs tantial updates, making it prone to forgetting previous concepts and overfitting to the limited new examples. Most recent trend is typically to disentangle the learning of the representation from the classification head of the model. A well -generalized feature extractor on the base classes (many examples and many class es) is learned, and then fixed during incremental learning. Arguing that the fix ed feature extractor restricts the model's adaptability to new classes, we intro duce a novel FSCIL method to effectively address catastrophic forgetting and ove rfitting issues. Our method enables to seamlessly update the entire model with a few examples. We mainly propose a tripartite weight-space ensemble (Tri-WE). Tr i-WE interpolates the base, immediately previous, and current models in weight-s pace, especially for the classification heads of the models. Then, it collaborat ively maintains knowledge from the base and previous models. In addition, we rec ognize the challenges of distilling generalized representations from the previou s model from scarce data. Hence, we suggest a regularization loss term using amp lified data knowledge distillation. Simply intermixing the few-shot data, we can produce richer data enabling the distillation of critical knowledge from the pr evious model. Consequently, we attain state-of-the-art results on the miniImageN

et, CUB200, and CIFAR100 datasets.
****
The Devil is in Temporal Token: High Quality Video Reasoning Segmentation
Sitong Gong, Yunzhi Zhuge, Lu Zhang, Zongxin Yang, Pingping Zhang, Huchuan Lu; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 29183-29192
Existing methods for Video Reasoning Segmentation rely heavily on a single special token to represent the object in the keyframe or the entire video, inadequately capturing spatial complexity and inter-frame motion. To overcome these challenges, we propose VRS-HQ, an end-to-end video reasoning segmentation approach that leverages Multimodal Large Language Models (MLLMs) to inject rich spatiotemporal features into hierarchical tokens. Our key innovations include a Temporal Dynamic Aggregation (TDA) and a Token-driven Keyframe Selection (TKS). Specifically, we design frame-level <SEG> and temporal-level <TAK> tokens that utilize MLLM's autoregressive learning to effectively capture both local and global information. Subsequently, we apply a similarity-based weighted fusion and frame selection strategy, then utilize SAM2 to perform keyframe segmentation and propagation. To enhance keyframe localization accuracy, the TKS filters keyframes based on SAM2's occlusion scores during inference. VRS-HQ achieves state-of-the-art performance on ReVOS, surpassing VISA by 5.9%/12.5%/9.1% in J&F scores across the three subsets. These results highlight the strong temporal reasoning and segmentation capabilities of our method.

PerLA: Perceptive 3D Language Assistant
Guofeng Mei, Wei Lin, Luigi Riz, Yujiao Wu, Fabio Poiesi, Yiming Wang; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 14369-14379
Enabling Large Language Models (LLMs) to understand the 3D physical world is an emerging yet challenging research direction. Current strategies for processing point clouds typically downsample the scene or divide it into smaller parts for separate analysis. However, both approaches risk losing key local details or global contextual information. In this paper, we introduce PerLA, a 3D language assistant designed to be more perceptive to both details and context, making visual representations more informative for the LLM. PerLA captures high-resolution (local) details in parallel from different point cloud areas and integrates them with (global) context obtained from a lower-resolution whole point cloud. We present a novel algorithm that preserves point cloud locality through the Hilbert curve and effectively aggregates local-to-global information via cross-attention and a graph neural network. Lastly, we introduce a novel loss for local representation consensus to promote training stability. PerLA outperforms state-of-the-art 3D language assistants, with gains of up to +1.34 CiDEr on ScanQA for question answering, and +4.22 on ScanRefer and +3.88 on Nr3D for dense captioning.

LITA-GS: Illumination-Agnostic Novel View Synthesis via Reference-Free 3D Gaussian Splatting and Physical Priors
Han Zhou, Wei Dong, Jun Chen; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 21580-21589
Directly employing 3D Gaussian Splatting (3DGS) on images with adverse illumination conditions exhibits considerable difficulty in achieving high-quality normally-exposed representation due to: (1) The limited Structure from Motion (SfM) points estimated in adverse illumination scenarios fail to capture sufficient scene details; (2) Without ground-truth references, the intensive information loss, huge noise, and color distortion poses substantial challenges for 3DGS to produce high-quality results; (3) Combining existing exposure correction methods with 3DGS can not achieve satisfactory performance due to their individual enhancement process, which leads to the illumination inconsistency between enhanced images from different viewpoints. To address these issues, we propose LITA-GS, a novel illumination-agnostic novel view synthesis method via reference-free 3DGS and physical priors. Firstly, we introduce an illumination-invariant physical prior extraction pipeline. Secondly, based on the extracted robust spatial structure pr

ior, we develop the lighting-agnostic structure rendering strategy, which facili tates the optimization of the scene structure and object appearance. Moreover, a progressive denoising module is introduced to effectively surpass the noise wit hin the light-invariant representation. We adopt the unsupervised strategy for t he training of LITA-GS and extensive experiments demonstrate that LITA-GS surpas s the state-of-the-art (SOTA) NeRF-based method by 1.7 dB in PSNR and 0.09 in SS IM while enjoying faster inference speed and costing reduced training time. The code will be released upon acceptance.

PhyT2V: LLM-Guided Iterative Self-Refinement for Physics-Grounded Text-to-Video Generation

Qiyao Xue, Xiangyu Yin, Boyuan Yang, Wei Gao; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 18826-18836

Text-to-video (T2V) generation has been recently enabled by transformer-based di ffusion models, but current T2V models lack capabilities in adhering to the real -world common knowledge and physical rules, due to their limited understanding o f physical realism and deficiency in temporal modeling. Existing solutions are e ither data-driven or require extra model inputs, but cannot be generalizable to out-of-distribution domains. In this paper, we present PhyT2V, a new data-indepe ndent T2V technique that expands the current T2V model's capability of video gen eration to out-of-distribution domains, by enabling chain-of-thought and step-ba ck reasoning in T2V prompting. Our experiments show that PhyT2V improves existin g T2V models' adherence to real-world physical rules by 2.3x, and achieves 35% i mprovement compared to T2V prompt enhancers.

Track4Gen: Teaching Video Diffusion Models to Track Points Improves Video Genera tion

Hyeonho Jeong, Chun-Hao P. Huang, Jong Chul Ye, Niloy J. Mitra, Duygu Ceylan; Pr oceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025 , pp. 7276-7287

While recent foundational video generators produce visually rich output, they st ill struggle with appearance drift, where objects gradually degrade or change in consistently across frames, breaking visual coherence. We hypothesize that this is because there is no explicit supervision in terms of spatial tracking at the feature level. We propose Track4Gen, a spatially aware video generator that comb ines video diffusion loss with point tracking across frames, providing enhanced spatial supervision on the diffusion features. Track4Gen merges the video genera tion and point tracking tasks into a single network by making minimal changes to existing video generation architectures. Using Stable Video Diffusion as a back bone, Track4Gen demonstrates that it is possible to unify video generation and p oint tracking, which are typically handled as separate tasks. Our extensive eval uations show that Track4Gen effectively reduces appearance drift, resulting in t emporally stable and visually coherent video generation. Mask^2DiT: Dual Mask-based Diffusion Transformer for Multi-Scene Long Video Gene ration

Tianhao Qi, Jianlong Yuan, Wanquan Feng, Shancheng Fang, Jiawei Liu, SiYu Zhou, Qian He, Hongtao Xie, Yongdong Zhang; Proceedings of the Computer Vision and Pat tern Recognition Conference (CVPR), 2025, pp. 18837-18846

Sora has unveiled the immense potential of the Diffusion Transformer (DiT) archi tecture in single-scene video generation. However, the more challenging task of multi-scene video generation, which offers broader applications, remains relativ ely underexplored. To bridge this gap, we propose Mask^2DiT, a novel approach th at establishes fine-grained, one-to-one alignment between video segments and the ir corresponding text annotations. Specifically, we introduce a symmetric binary mask at each attention layer within the DiT architecture, ensuring that each te xt annotation applies exclusively to its respective video segment while preservi ng temporal coherence across visual tokens. This attention mechanism enables pre cise segment-level textual-to-visual alignment, allowing the DiT architecture to

effectively handle video generation tasks with a fixed number of scenes. To further equip the DiT architecture with the ability to generate additional scenes based on existing ones, we incorporate a segment-level conditional mask, which conditions each newly generated segment on the preceding video segments, thereby enabling auto-regressive scene extension. Both qualitative and quantitative experiments confirm that Mask^2DiT excels in maintaining visual consistency across segments while ensuring semantic alignment between each segment and its corresponding text description. Our project page is \href https://tianhao-qi.github.io/Mask2DiTProject/ https://tianhao-qi.github.io/Mask2DiTProject/ .

JamMa: Ultra-lightweight Local Feature Matching with Joint Mamba
Xiaoyong Lu, Songlin Du; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 14934-14943
Existing state-of-the-art feature matchers capture long-range dependencies with Transformers but are hindered by high spatial complexity,leading to demanding training and high-latency inference.Striking a better balance between performance and efficiency remains a critical challenge in feature matching.Inspired by the linear complexity \mathcal O (N) of Mamba, we propose an ultra-lightweight Mamba-based matcher, named JamMa, which converges on a single GPU and achieves an impressive performance-efficiency balance in inference.To unlock the potential of Mamba for feature matching,we propose Joint Mamba with a scan-merge strategy named JEGO, which enables:(1) Joint scan of two images to achieve high-frequency mutual interaction, (2) Efficient scan with skip steps to reduce sequence length, (3) Global receptive field, and (4) Omnidirectional feature representation.With the above properties, the JEGO strategy significantly outperforms the scan-merge strategies proposed in VMamba and EVMamba in the feature matching task.Compared to attention-based sparse and semi-dense matchers, JamMa demonstrates a notably superior balance between performance and efficiency,delivering better performance with less than 50% of the parameters and FLOPs.
****

DyCoke: Dynamic Compression of Tokens for Fast Video Large Language Models
Keda Tao, Can Qin, Haoxuan You, Yang Sui, Huan Wang; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 18992-19001
Video large language models (VLLMs) have significantly advanced recently in processing complex video content. Yet, their inference efficiency remains constrained because of the high computational cost stemming from the thousands of visual tokens generated from the video inputs. We empirically observe that, unlike single image inputs, VLLMs typically attend visual tokens from different frames at different decoding iterations. This makes a one-shot pruning strategy prone to removing important tokens by mistake. Motivated by this, we present DyCoke, a training-free token compression method to optimize token representation and accelerate VLLMs. DyCoke incorporates a plug-and-play temporal compression module to minimize temporal redundancy by merging redundant tokens across frames and applying dynamic KV cache reduction to prune spatially redundant tokens selectively. It ensures high-quality inference by dynamically retaining the critical tokens at each decoding step. Extensive experimental results demonstrate that DyCoke can outperform the prior SoTA counterparts, achieving 1.5x inference speedup, and 1.4x memory reduction against the baseline VLLM, while still improving the performance, with no training.

T-FAKE: Synthesizing Thermal Images for Facial Landmarking
Philipp Flotho, Moritz Piening, Anna Kukleva, Gabriele Steidl; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 26356-26366
Facial analysis is a key component in a wide range of applications such as security, autonomous driving, entertainment, and healthcare. Despite the availability of various facial RGB datasets, the thermal modality, which plays a crucial role in life sciences, medicine, and biometrics, has been largely overlooked. To address this gap, we introduce the T-FAKE dataset, a new large-scale synthetic thermal dataset with sparse and dense landmarks. To facilitate the creation of the

dataset, we propose a novel RGB2Thermal loss function, which enables the domain-adaptive transfer of thermal style to RGB faces. By utilizing the Wasserstein distance between thermal and RGB patches and the statistical analysis of clinical temperature distributions on faces, we ensure that the generated thermal images closely resemble real samples. Using RGB2Thermal style transfer based on our RGB2Thermal loss function, we create the large-scale synthetic thermal T-FAKE dataset. Leveraging our novel T-FAKE dataset, probabilistic landmark prediction, and label adaptation networks, we demonstrate significant improvements in landmark detection methods on thermal images across different landmark conventions. Our models show excellent performance with both sparse 70-point landmarks and dense 478-point landmark annotations

Multi-Resolution Pathology-Language Pre-training Model with Text-Guided Visual Representation

Shahad Albastaki, Anabia Sohail, Iyyakutti Iyappan Ganapathi, Basit Alawode, Asim Khan, Sajid Javed, Naoufel Werghi, Mohammed Bennamoun, Arif Mahmood; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 25907-25919

In Computational Pathology (CPath), the introduction of Vision-Language Models (VLMs) has opened new avenues for research, focusing primarily on aligning image-text pairs at a single magnification level. However, this approach might not be sufficient for tasks like cancer subtype classification, tissue phenotyping, and survival analysis due to the limited level of detail that a single-resolution image can provide. Addressing this, we propose a novel multi-resolution paradigm leveraging Whole Slide Images (WSIs) to extract histology patches at multiple resolutions and generate corresponding textual descriptions through advanced CPath VLM. We introduce visual-textual alignment at multiple resolutions as well as cross-resolution alignment to establish more effective text-guided visual representations. Cross-resolution alignment using a multi-modal encoder enhances the model's ability to capture context from multiple resolutions in histology images. Our model aims to capture a broader range of information, supported by novel loss functions, enriches feature representation, improves discriminative ability, and enhances generalization across different resolutions. Pre-trained on a comprehensive TCGA dataset with 34 million image-language pairs at various resolutions, our fine-tuned model outperforms State-Of-The-Art (SOTA) counterparts across multiple datasets and tasks, demonstrating its effectiveness in CPath. The code is available on GitHub at: https://github.com/BasitAlawode/MR-PLIP.

InteractAnything: Zero-shot Human Object Interaction Synthesis via LLM Feedback and Object Affordance Parsing

Jinlu Zhang, Yixin Chen, Zan Wang, Jie Yang, Yizhou Wang, Siyuan Huang; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 7015-7025

Recent advances in 3D human-aware generation have made significant progress. However, existing methods still struggle with generating novel Human Object Interaction (HOI) from text, particularly for open-set objects. We identify three main challenges of this task: precise human-object relation reasoning, affordance parsing for any object, and detailed human interaction pose synthesis aligning description and object geometry. In this work, we propose a novel zero-shot 3D HOI generation framework without training on specific datasets, leveraging the knowledge from large-scale pre-trained models. Specifically, the human-object relations are inferred from large language models (LLMs) to initialize object properties and guide the optimization process. Then we utilize a pre-trained 2D image diffusion model to parse unseen objects and extract contact points, avoiding the limitations imposed by existing 3D asset knowledge. The initial human pose is generated by sampling multiple hypotheses through multi-view SDS based on the input text and object geometry. Finally, we introduce a detailed optimization to generate fine-grained, precise, and natural interaction, enforcing realistic 3D contact between the 3D object and the involved body parts, including hands in grasping. This is achieved by distilling human-level feedback from LLMs to capture detai

led human-object relations from the text instruction. Extensive experiments validate the effectiveness of our approach compared to prior works, particularly in terms of the fine-grained nature of interactions and the ability to handle open-set 3D objects. Project page: jinluzhang.site/projects/interactanything.

MammAlps: A Multi-view Video Behavior Monitoring Dataset of Wild Mammals in the Swiss Alps
Valentin Gabeff, Haozhe Qi, Brendan Flaherty, Gencer Sumbul, Alexander Mathis, Devis Tuia; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 13854-13864
Monitoring wildlife is essential for ecology and ethology, especially in light of the increasing human impact on ecosystems. Camera traps have emerged as habitat-centric sensors enabling the study of wildlife populations at scale with minimal disturbance. However, the lack of annotated video datasets limits the development of powerful video understanding models needed to process the vast amount of fieldwork data collected. To advance research in wild animal behavior monitoring we present MammAlps, a multimodal and multi-view dataset of wildlife behavior monitoring from 9 camera-traps in the Swiss National Park. MammAlps contains over 14 hours of video with audio, 2D segmentation maps and 8.5 hours of individual tracks densely labeled for species and behavior. Based on 6135 single animal clips, we propose the first hierarchical and multimodal animal behavior recognition benchmark using audio, video and reference scene segmentation maps as inputs. Furthermore, we also propose a second ecology-oriented benchmark aiming at identifying activities, species, number of individuals and meteorological conditions from 397 multi-view and long-term ecological events, including false positive triggers. We advocate that both tasks are complementary and contribute to bridging the gap between machine learning and ecology. Code and data are available at: https://github.com/eceo-epfl/MammAlps

Diffusion-based Realistic Listening Head Generation via Hybrid Motion Modeling
Yinuo Wang, Yanbo Fan, Xuan Wang, Guo Yu, Fei Wang; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 15885-15895
Listening head generation aims to synthesize non-verbal responsive listening head videos that naturally react to a certain speaker, for which, both realistic head movements, expressive facial expressions, and high visual qualities are expected. Previous approaches typically follow a two-stage pipeline that first generates intermediate 3D motion signals such as 3DMM coefficients, and then synthesizes the videos by deterministic rendering, suffering from limited motion expressiveness and low visual quality (eg, 256 x256). In this work, we propose a novel listening head generation method that harnesses the generative capabilities of the diffusion model for both motion generation and high-quality rendering. Crucially, we propose an effective hybrid motion modeling module that addresses training difficulties caused by the scarcity of listening head data while preserving the intricate details that may be lost in explicit motion representations. We further develop a tailored control guidance for head pose and facial expression, by integrating their intrinsic motion characteristics. Our method enables high-fidelity video generation with 512x512 resolution and delivers vivid listener motion feedback. We conduct comprehensive experiments and obtain superior performance in terms of both visual quality and motion expressiveness compared with existing methods.
****

SAT-HMR: Real-Time Multi-Person 3D Mesh Estimation via Scale-Adaptive Tokens
Chi Su, Xiaoxuan Ma, Jiajun Su, Yizhou Wang; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 16796-16806
We propose a one-stage framework for real-time multi-person 3D human mesh estimation from a single RGB image. While current one-stage methods, which follow a DETR-style pipeline, achieve state-of-the-art (SOTA) performance with high-resolution inputs, we observe that this particularly benefits the estimation of individuals in smaller scales of the image (e.g., those far from the camera), but at the cost of significantly increased computation overhead. To address this, we intr

oduce scale-adaptive tokens that are dynamically adjusted based on the relative scale of each individual in the image within the DETR framework. Specifically, individuals in smaller scales are processed at higher resolutions, larger ones at lower resolutions, and background regions are further distilled. These scale-adaptive tokens more efficiently encode the image features, facilitating subsequent decoding to regress the human mesh, while allowing the model to allocate computational resources more effectively and focus on more challenging cases. Experiments show that our method preserves the accuracy benefits of high-resolution processing while substantially reducing computational cost, achieving real-time inference with performance comparable to SOTA methods. Code and models are available at https://ChiSu001.github.io/SAT-HMR/.

PICD: Versatile Perceptual Image Compression with Diffusion Rendering

Tongda Xu, Jiahao Li, Bin Li, Yan Wang, Ya-Qin Zhang, Yan Lu; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 28436-28445

Recently, perceptual image compression has achieved significant advancements, delivering high visual quality at low bitrates for natural images. However, for screen content, existing methods often produce noticeable artifacts when compressing text. To tackle this challenge, we propose versatile perceptual screen image compression with diffusion rendering (PICD), a codec that works well for both screen and natural images. More specifically, we propose a compression framework that encodes the text and image separately, and renders them into one image using diffusion model. For this diffusion rendering, we integrate conditional information into diffusion models at three distinct levels: 1). Domain level: We fine-tune the base diffusion model using text content prompts with screen content. 2). Adaptor level: We develop an efficient adaptor to control the diffusion model using compressed image and text as input. 3). Instance level: We apply instance-wise guidance to further enhance the decoding process. Empirically, our PICD surpasses existing perceptual codecs in terms of both text accuracy and perceptual quality. Additionally, without text conditions, our approach serves effectively as a perceptual codec for natural images.

UniScene: Unified Occupancy-centric Driving Scene Generation

Bohan Li, Jiazhe Guo, Hongsi Liu, Yingshuang Zou, Yikang Ding, Xiwu Chen, Hu Zhu, Feiyang Tan, Chi Zhang, Tiancai Wang, Shuchang Zhou, Li Zhang, Xiaojuan Qi, Hao Zhao, Mu Yang, Wenjun Zeng, Xin Jin; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 11971-11981

Generating high-fidelity, controllable, and annotated training data is critical for autonomous driving. Existing methods typically generate a single data form directly from a coarse scene layout, which not only fails to output rich data forms required for diverse downstream tasks but also struggles to model the direct layout-to-data distribution. In this paper, we introduce UniScene, the first unified framework for generating three key data forms - semantic occupancy, video, and LiDAR - in driving scenes. UniScene employs a progressive generation process that decomposes the complex task of scene generation into two hierarchical steps: (a) first generating semantic occupancy from a customized scene layout as a meta scene representation rich in both semantic and geometric information, and then (b) conditioned on occupancy, generating video and LiDAR data, respectively, with two novel transfer strategies of Gaussian-based Joint Rendering and Prior-guided Sparse Modeling. This occupancy-centric approach reduces the generation burden, especially for intricate scenes, while providing detailed intermediate representations for the subsequent generation stages. Extensive experiments demonstrate that UniScene outperforms previous SOTAs in the occupancy, video, and LiDAR generation, which also indeed benefits downstream driving tasks. The Project is available at https://arlo0o.github.io/uniscene/.

Wonderland: Navigating 3D Scenes from a Single Image

Hanwen Liang, Junli Cao, Vidit Goel, Guocheng Qian, Sergei Korolev, Demetri Terzopoulos, Konstantinos N. Plataniotis, Sergey Tulyakov, Jian Ren; Proceedings of

the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 798-810
This paper addresses a challenging question: how can we efficiently create high-quality, wide-scope 3D scenes from a single arbitrary image?Existing methods face several constraints, such as requiring multi-view data, time-consuming per-scene optimization, low visual quality, and distorted reconstructions for unseen areas. We propose a novel pipeline to overcome these limitations.Specifically, we introduce a large-scale reconstruction model that uses latents from a video diffusion model to predict 3D Gaussian Splatting, even from a single-condition image, in a feed-forward manner. The video diffusion model is designed to precisely follow a specified camera trajectory, allowing it to generate compressed latents that contain multi-view information while maintaining 3D consistency.We further train the 3D reconstruction model to operate on the video latent space with a progressive training strategy, enabling the generation of high-quality, wide-scope, and generic 3D scenes.Extensive evaluations on various datasets show that our model significantly outperforms existing methods for single-view 3D rendering, particularly with out-of-domain images. For the first time, we demonstrate that a 3D reconstruction model can be effectively built upon the latent space of a diffusion model to realize efficient 3D scene generation.

Learning from Streaming Video with Orthogonal Gradients
Tengda Han, Dilara Gokay, Joseph Heyward, Chuhan Zhang, Daniel Zoran, Viorica Patraucean, Joao Carreira, Dima Damen, Andrew Zisserman; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 13651-13660
We address the challenge of representation learning from a continuous stream of video as input, in a self-supervised manner. This differs from the standard approaches to video learning where videos are chopped and shuffled during training in order to create a non-redundant batch that satisfies the independently and identically distributed (IID) sample assumption expected by conventional training paradigms. When videos are only available as a continuous stream of input, the IID assumption is evidently broken, leading to poor performance. We demonstrate the drop in performance when moving from shuffled to sequential learning on three tasks: the one-video representation learning method DoRA, standard VideoMAE on multi-video datasets, and the task of future video prediction. To address this drop, we propose a geometric modification to standard optimizers, to decorrelate batches by utilising orthogonal gradients during training. The proposed modification can be applied to any optimizer -- we demonstrate it with Stochastic Gradient Descent (SGD) and AdamW. Our proposed orthogonal optimizer allows models trained from streaming videos to alleviate the drop in representation learning performance, as evaluated on downstream tasks. On three scenarios (DoRA, VideoMAE, future prediction), we show our orthogonal optimizer outperforms the strong AdamW in all three scenarios.

Towards Satellite Image Road Graph Extraction: A Global-Scale Dataset and A Novel Method
Pan Yin, Kaiyu Li, Xiangyong Cao, Jing Yao, Lei Liu, Xueru Bai, Feng Zhou, Deyu Meng; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 1527-1537
Recently, road graph extraction has garnered increasing attention due to its crucial role in autonomous driving, navigation, etc. However, accurately and efficiently extracting road graphs remains a persistent challenge, primarily due to the severe scarcity of labeled data. To address this limitation, we collect a global-scale satellite road graph extraction dataset, i.e. Global-Scale dataset. Specifically, the Global-Scale dataset is 20x larger than the largest existing public road extraction dataset and spans over 13,800 km^2 globally. Additionally, we develop a novel road graph extraction model, i.e. SAM-Road++, which adopts a node-guided resampling method to alleviate the mismatch issue between training and inference in SAM-Road, a pioneering state-of-the-art road graph extraction model. Furthermore, we propose a simple yet effective "extended-line" strategy in SAM-Road++ to mitigate the occlusion issue on the road. Extensive experiments demonstrate the validity of the collected Global-Scale dataset and the proposed SAM

-Road++ method, particularly highlighting its superior predictive power in unsee
n regions.

SuperLightNet: Lightweight Parameter Aggregation Network for Multimodal Brain Tu
mor Segmentation

Feng Yu, Jiacheng Cao, Li Liu, Minghua Jiang; Proceedings of the Computer Vision
 and Pattern Recognition Conference (CVPR), 2025, pp. 5197-5206

Multimodal 3D segmentation involves a significant number of 3D convolution opera
tions, which requires substantial computational resources and high-performance c
omputing devices in MRI multimodal brain tumor segmentation. The key challenge i
n multimodal 3D segmentation is how to minimize network computational load while
 maintaining high accuracy. To address the issue, a novel lightweight parameter
aggregation network (SuperLightNet) is proposed to realize the efficient encoder
 and decoder for the high accurate and low computation. A random multiview drop
encoder is designed to learn the spatial structure of multimodal images through
a random multi-view approach for solving the high computational time complexity
that has arisen in recent years with methods relying on transformers and Mamba.
A learnable residual skip decoder is designed to incorporate learnable residual
and group skip weights for addressing the reduced computational efficiency cause
d by the use of overly heavy convolution and deconvolution decoders. Experimenta
l results demonstrate that the proposed method achieves a leading reduction in p
arameter count by 95.59%, the 96.78% improvement in computational efficiency, th
e 96.86% enhancement in memory access performance, and the average performance g
ain of 0.21% on the BraTS2019 and BraTS2021 datasets in comparison with the stat
e-of-the-art methods. Code is available at https://github.com/WTU1020-Medical-Se
gmentation/SuperLightNet.

VideoSPatS: Video SPatiotemporal Splines for Disentangled Occlusion, Appearance
 and Motion Modeling and Editing

Juan Luis Gonzalez, Xu Yao, Alex Whelan, Kyle Olszewski, Hyeongwoo Kim, Pablo Ga
rrido; Proceedings of the Computer Vision and Pattern Recognition Conference (CV
PR), 2025, pp. 22901-22910

We present an implicit video representation for occlusions, appearance, and moti
on disentanglement from monocular videos, which we refer to as Video Spatiotempo
ral Splines (VideoSPatS).Unlike previous methods that map time and coordinates t
o deformation and canonical colors, our VideoSPatS maps input coordinates into S
patial and Color Spline deformation fields Ds and Dc, which disentangle motion a
nd appearance in videos. With spline-based parametrization, our method naturally
 generates temporally consistent flow and guarantees long-term temporal consiste
ncy, which is crucial for convincing video editing.Aided by additional predictio
n blocks, our VideoSPatS also performs layer separation between the latent video
 and the selected occluder. By disentangling occlusions, appearance, and motion,
 our method allows for better spatiotemporal modeling and editing of diverse vid
eos, including in-the-wild talking head videos with challenging occlusions, shad
ows, and specularities while maintaining a reasonable canonical space for editin
g.We also present general video modeling results on the DAVIS, and CoDeF dataset
s, as well as our own talking head video dataset collected from open-source web
videos. Extensive ablations show the combination of Ds and Dc under neural spli
nes can overcome motion and appearance ambiguities, paving the way to more advan
ced video editing models.

Classifier-to-Bias: Toward Unsupervised Automatic Bias Detection for Visual Clas
sifiers

Quentin Guimard, Moreno D'Incà, Massimiliano Mancini, Elisa Ricci; Proceedings o
f the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 15151
-15161

A person downloading a pre-trained model from the web should be aware of its bia
ses. Existing approaches for bias identification rely on datasets containing lab
els for the task of interest, something that a non-expert may not have access to
, or may not have the necessary resources to collect: this greatly limits the nu

mber of tasks where model biases can be identified. In this work, we present Cla ssifier-to-Bias (C2B), the first bias discovery framework that works without acc ess to any labeled data: it only relies on a textual description of the classifi cation task to identify biases in the target classification model. This descript ion is fed to a large language model to generate bias proposals and correspondin g captions depicting biases together with task-specific target labels. A retriev al model collects images for those captions, which are then used to assess the a ccuracy of the model w.r.t. the given biases. C2B is training-free, does not req uire any annotations, has no constraints on the list of biases, and can be appli ed to any pre-trained model on any classification task. Experiments on two publi cly available datasets show that C2B discovers biases beyond those of the origin al datasets and outperforms a recent state-of-the-art bias detection baseline th at relies on task-specific annotations, being a promising first step toward addr essing task-agnostic unsupervised bias detection.

Self-Supervised Spatial Correspondence Across Modalities

Ayush Shrivastava, Andrew Owens; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 6383-6393

We present a method for finding cross-modal space-time correspondences. Given t wo images from different visual modalities, such as an RGB image and a depth map , our model identifies which pairs of pixels correspond to the same physical poi nts in the scene. To solve this problem, we extend the contrastive random walk f ramework to simultaneously learn cycle-consistent feature representations for bo th cross-modal and intra-modal matching. The resulting model is simple and has n o explicit photo-consistency assumptions. It can be trained entirely using unlab eled data, without the need for any spatially aligned multimodal image pairs. We evaluate our method on both geometric and semantic correspondence tasks. For ge ometric matching, we consider challenging tasks such as RGB-to-depth and RGB-to- thermal matching (and vice versa); for semantic matching, we evaluate on photo-s ketch and cross-style image alignment. Our method achieves strong performance ac ross all benchmarks.

****

MOS-Attack: A Scalable Multi-objective Adversarial Attack Framework

Ping Guo, Cheng Gong, Xi Lin, Fei Liu, Zhichao Lu, Qingfu Zhang, Zhenkun Wang; P roceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 202 5, pp. 5041-5051

Crafting adversarial examples is crucial for evaluating and enhancing the robust ness of Deep Neural Networks (DNNs), presenting a challenge equivalent to maximi zing a non-differentiable 0-1 loss function. However, existing single objecti ve methods, namely adversarial attacks focus on a surrogate loss function, do no t fully harness the benefits of engaging multiple loss functions, as a result of insufficient understanding of their synergistic and conflicting nature. To o vercome these limitations, we propose the Multi-Objective Set-based Attack (MOS Attack), a novel adversarial attack framework leveraging multiple loss functions and automatically uncovering their interrelations. The MOS Attack adopts a s et-based multi-objective optimization strategy, enabling the incorporation of nu merous loss functions without additional parameters. It also automatically mi nes synergistic patterns among various losses, facilitating the generation of po tent adversarial attacks with fewer objectives. Extensive experiments have sh own that our MOS Attack outperforms single-objective attacks. Furthermore, by ha rnessing the identified synergistic patterns, MOS Attack continues to show super ior results with a reduced number of loss functions.

Six-CD: Benchmarking Concept Removals for Text-to-image Diffusion Models

Jie Ren, Kangrui Chen, Yingqian Cui, Shenglai Zeng, Hui Liu, Yue Xing, Jiliang T ang, Lingjuan Lyu; Proceedings of the Computer Vision and Pattern Recognition Co nference (CVPR), 2025, pp. 28769-28778

Text-to-image (T2I) diffusion models have shown exceptional capabilities in gene rating images that closely correspond to textual prompts. However, the advanceme nt of T2I diffusion models presents significant risks, as the models could be ex

ploited for malicious purposes, such as generating images with violence or nudity, or creating unauthorized portraits of public figures in inappropriate contexts. To mitigate these risks, concept removal methods have been proposed. These methods aim to modify diffusion models to prevent the generation of malicious and unwanted concepts. Despite these efforts, existing research faces several challenges: (1) a lack of consistent comparisons on a comprehensive dataset, (2) ineffective prompts in harmful and nudity concepts, (3) overlooked evaluation of the ability to generate the benign part within prompts containing malicious concepts. To address these gaps, we propose to benchmark the concept removal methods by introducing a new dataset, Six-CD, along with a novel evaluation metric. In this benchmark, we conduct a thorough evaluation of concept removals, with the experimental observations and discussions offering valuable insights in the field.

Motion Modes: What Could Happen Next?

Karran Pandey, Yannick Hold-Geoffroy, Matheus Gadelha, Niloy J. Mitra, Karan Singh, Paul Guerrero; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 2030-2039

Predicting diverse object motions from a single static image remains challenging, as current video generation models often entangle object movement with camera motion and other scene changes. While recent methods can predict specific motions from motion arrow input, they rely on synthetic data and predefined motions, limiting their application to complex scenes. We introduce Motion Modes, a training-free approach that explores a pre-trained image-to-video generator's latent distribution to discover various distinct and plausible motions focused on selected objects in static images. We achieve this by employing a flow generator guided by energy functions designed to disentangle object and camera motion. Additionally, we use an energy inspired by particle guidance to diversify the generated motions, without requiring explicit training data. Experimental results demonstrate that Motion Modes generates realistic and varied object animations, surpassing previous methods and even human predictions regarding plausibility and diversity.

Finer-CAM: Spotting the Difference Reveals Finer Details for Visual Explanation

Ziheng Zhang, Jianyang Gu, Arpita Chowdhury, Zheda Mai, David Carlyn, Tanya Berger-Wolf, Yu Su, Wei-Lun Chao; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 9611-9620

Class activation map (CAM) has been widely used to highlight image regions that contribute to class predictions. Despite its simplicity and computational efficiency, CAM often struggles to identify discriminative regions that distinguish visually similar fine-grained classes. Prior efforts address this limitation by introducing more sophisticated explanation processes, but at the cost of extra complexity. In this paper, we propose Finer-CAM, a method that retains CAM's efficiency while achieving precise localization of discriminative regions. Our key insight is that the deficiency of CAM lies not in "how" it explains, but in "what" it explains. Specifically, previous methods attempt to identify all cues contributing to the target class's logit value, which inadvertently also activates regions predictive of visually similar classes. By explicitly comparing the target class with similar classes and spotting their differences, Finer-CAM suppresses features shared with other classes and emphasizes the unique, discriminative details of the target class. Finer-CAM is easy to implement, compatible with various CAM methods, and can be extended to multi-modal models for accurate localization of specific concepts. Additionally, Finer-CAM allows adjustable comparison strength, enabling users to selectively highlight coarse object contours or fine discriminative details. Quantitatively, we show that masking out the top 5% of activated pixels by Finer-CAM results in a larger relative confidence drop compared to baselines. The source code and demo are available at https://github.com/Imageomics/Finer-CAM.

The Change You Want To Detect: Semantic Change Detection In Earth Observation With Hybrid Data Generationf

Yanis Benidir, Nicolas Gonthier, Clement Mallet; Proceedings of the Computer Vis
ion and Pattern Recognition Conference (CVPR), 2025, pp. 2204-2214
Bi-temporal change detection at scale based on Very High Resolution (VHR) images
 is crucial for Earth monitoring. Such task remains poorly addressed even in the
 deep learning era: it either requires large volumes of annotated data - in the
semantic case - or is limited to restricted datasets for binary set-ups. Most ap
proaches do not exhibit the versatility required for temporal and spatial adapta
tion: simplicity in architecture design and pretraining on realistic and compreh
ensive datasets. Synthetic datasets is the key solution but still fails handling
 complex and diverse scenes. In this paper, we present HySCDG a generative pipel
ine for creating a large hybrid semantic change detection dataset that contains
both real VHR images and inpainted ones, along with land cover semantic map at b
oth dates and the change map. Being semantically and spatially guided, HySCDG ge
nerates realistic images, leading to a comprehensive and hybrid transfer-proof d
ataset FSC-180k. We evaluate FSC-180k on five change detection cases (binary and
 semantic), from zero-shot to mixed and sequential training, and also under low
data regime training. Experiments demonstrate that pretraining on our hybrid dat
aset leads to a significant performance boost, outperforming SyntheWorld, a full
y synthetic dataset, in every configuration. All codes, models, and data will be
 made available.

Black-Box Forgery Attacks on Semantic Watermarks for Diffusion Models
Andreas Müller, Denis Lukovnikov, Jonas Thietke, Asja Fischer, Erwin Quiring; Pr
oceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025
, pp. 20937-20946
Integrating watermarking into the generation process of latent diffusion models
(LDMs) simplifies detection and attribution of generated content. Semantic water
marks, such as Tree-Rings and Gaussian Shading, represent a novel class of water
marking techniques that are easy to implement and highly robust against various
perturbations. However, our work demonstrates a fundamental security vulnerabili
ty of semantic watermarks. We show that attackers can leverage unrelated models,
 even with different latent spaces and architectures (UNet vs DiT), to perform p
owerful and realistic forgery attacks. Specifically, we design two watermark for
gery attacks. The first \imprints a targeted watermark into real images by manip
ulating the latent representation of an arbitrary image in an unrelated LDM to g
et closer to the latent representation of a watermarked image. We also show that
 this technique can be used for watermark removal. The second attack generates n
ew images with the target watermark by inverting a watermarked image and re-gene
rating it with an arbitrary prompt. Both attacks just need a single reference im
age with the target watermark. Overall, our findings question the applicability
of semantic watermarks by revealing that attackers can easily forge or remove th
ese watermarks under realistic conditions.

An Image-like Diffusion Method for Human-Object Interaction Detection
Xiaofei Hui, Haoxuan Qu, Hossein Rahmani, Jun Liu; Proceedings of the Computer V
ision and Pattern Recognition Conference (CVPR), 2025, pp. 14002-14012
Human-object interaction (HOI) detection often faces high levels of ambiguity an
d indeterminacy, as the same interaction can appear vastly different across diff
erent human-object pairs. Additionally, the indeterminacy can be further exacerb
ated by issues such as occlusions and cluttered backgrounds. To handle such a ch
allenging task, in this work, we begin with a key observation: the output of HOI
 detection for each human-object pair can be recast as an image. Thus, inspired
by the strong image generation capabilities of image diffusion models, we propos
e a new framework, HOI-IDiff. In HOI-IDiff, we tackle HOI detection from a novel
 perspective, using an Image-like Diffusion process to generate HOI detection ou
tputs as images. Furthermore, recognizing that our recast images differ in certa
in properties from natural images, we enhance our framework with a customized HO
I diffusion process and a slice patchification model architecture, which are spe
cifically tailored to generate our recast "HOI images". Extensive experiments de
monstrate the efficacy of our framework.

VidSeg: Training-free Video Semantic Segmentation based on Diffusion Models
Qian Wang, Abdelrahman Eldesokey, Mohit Mendiratta, Fangneng Zhan, Adam Kortylewski, Christian Theobalt, Peter Wonka; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 22985-22994
We introduce the first training-free approach for Video Semantic Segmentation (VSS) based on pre-trained diffusion models. A growing research direction attempts to employ diffusion models to perform downstream vision tasks by exploiting their deep understanding of image semantics. Yet, the majority of these approaches have focused on image-related tasks like semantic segmentation, with less emphasis on video tasks such as VSS. Ideally, diffusion-based image semantic segmentation approaches can be applied to videos in a frame-by-frame manner. However, we find their performance on videos to be subpar due to the absence of any modeling of temporal information inherent in the video data. To this end, we tackle this problem and introduce a framework tailored for VSS based on pre-trained image and video diffusion models. We propose building a scene context model based on the diffusion features, where the model is autoregressively updated to adapt to scene changes. This context model predicts per-frame coarse segmentation maps that are temporally consistent. To refine these maps further, we propose a correspondence-based refinement strategy that aggregates predictions temporally, resulting in more confident predictions. Finally, we introduce a masked modulation approach to upsample the coarse maps to a high-quality full resolution. Experiments show that our proposed approach significantly outperforms existing training-free image semantic segmentation approaches on various VSS benchmarks without any training or fine-tuning. Moreover, it rivals supervised VSS approaches on the VSPW dataset despite not being explicitly trained for VSS.
****
COB-GS: Clear Object Boundaries in 3DGS Segmentation Based on Boundary-Adaptive Gaussian Splitting
Jiaxin Zhang, Junjun Jiang, Youyu Chen, Kui Jiang, Xianming Liu; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 19335-19344
Accurate object segmentation is crucial for high-quality scene understanding in the 3D vision domain. However, 3D segmentation based on 3D Gaussian Splatting (3DGS) struggles with accurately delineating object boundaries, as Gaussian primitives often span across object edges due to their inherent volume and the lack of semantic guidance during training. In order to tackle these challenges, we introduce Clear Object Boundaries for 3DGS Segmentation (COB-GS), which aims to improve segmentation accuracy by clearly delineating blurry boundaries of interwoven Gaussian primitives within the scene. Unlike existing approaches that remove ambiguous Gaussians and sacrifice visual quality, COB-GS, as a 3DGS refinement method, jointly optimizes semantic and visual information, allowing the two different levels to cooperate with each other effectively. Specifically, for the semantic guidance, we introduce a boundary-adaptive Gaussian splitting technique that leverages semantic gradient statistics to identify and split ambiguous Gaussians, aligning them closely with object boundaries. For the visual optimization, we rectify the degraded suboptimal texture of the 3DGS scene, particularly along the refined boundary structures. Experimental results show that COB-GS substantially improves segmentation accuracy and robustness against inaccurate masks from pre-trained model, yielding clear boundaries while preserving high visual quality. Code is available at https://github.com/ZestfulJX/COB-GS.

Weakly Supervised Semantic Segmentation via Progressive Confidence Region Expansion
Xiangfeng Xu, Pinyi Zhang, Wenxuan Huang, Yunhang Shen, Haosheng Chen, Jingzhong Lin, Wei Li, Gaoqi He, Jiao Xie, Shaohui Lin; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 9829-9838
Weakly supervised semantic segmentation (WSSS) has garnered considerable attention due to its effective reduction of annotation costs. Most approaches utilize Class Activation Maps (CAM) to produce pseudo-labels, thereby localizing target r

egions using only image-level annotations. However, the prevalent methods relyin g on vision transformers (ViT) encounter an "over-expansion" issue, i.e., CAM in correctly expands high activation value from the target object to the background regions, as it is difficult to learn pixel-level local intrinsic inductive bias in ViT from weak supervisions. To solve this problem, we propose a Progressive Confidence Region Expansion (PCRE) framework for WSSS, it gradually learns a fai thful mask over the target region and utilizes this mask to correct the confusio n in CAM. PCRE has two key components: Confidence Region Mask Expansion (CRME) a nd Class-Prototype Enhancement (CPE). CRME progressively expands the mask in the small region with the highest confidence, eventually encompassing the entire ta rget, thereby avoiding unintended CPE aims to enhance mask generation in CRME by leveraging the similarity between the learned, dataset-level class prototypes a nd patch features as supervision to optimize the mask output from CRME. Extensiv e experiments demonstrate that our method outperforms the existing single-stage and multi-stage approaches on the PASCAL VOC and MS COCO benchmark datasets. Our code is available at https://github.com/xxf011/WSSS-PCRE .

RELOCATE: A Simple Training-Free Baseline for Visual Query Localization Using Re gion-Based Representations

Savya Khosla, Sethuraman T V, Alexander Schwing, Derek Hoiem; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 3697-3706

We present RELOCATE, a simple training-free baseline designed to perform the cha llenging task of visual query localization in long videos. To eliminate the need for task-specific training and efficiently handle long videos, RELOCATE leverag es a region-based representation derived from pretrained vision models. At a hig h level, it follows the classic object localization approach: (1) identify all o bjects in each video frame, (2) compare the objects with the given query and sel ect the most similar ones, and (3) perform bidirectional tracking to get a spati o-temporal response. However, we propose some key enhancements to handle small o bjects, cluttered scenes, partial visibility, and varying appearances. Notably, we refine the selected objects for accurate localization and generate additional visual queries to capture visual variations. We evaluate RELOCATE on the challe nging Ego4D Visual Query 2D Localization dataset, establishing a new baseline th at outperforms prior task-specific methods by 49% (relative improvement) in spat io-temporal average precision.

****

PEER Pressure: Model-to-Model Regularization for Single Source Domain Generaliza tion

Dong Kyu Cho, Inwoo Hwang, Sanghack Lee; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 15360-15370

Data augmentation is a popular tool for single source domain generalization, whi ch expands the source domain by generating simulated ones, improving generalizat ion on unseen target domains. In this work, we show that the performance of such augmentation-based methods in the target domains universally fluctuates during training, posing challenges in model selection under realistic scenarios. We arg ue that the fluctuation stems from the inability of the model to accumulate the knowledge learned from diverse augmentations, exacerbating feature distortion du ring training. Based on this observation, we propose a novel generalization meth od, coined Parameter-Space Ensemble with Entropy Regularization (PEER), that use s a proxy model to learn the augmented data on behalf of the main model. The mai n model is updated by averaging its parameters with the proxy model, progressive ly accumulating knowledge over the training steps. Maximizing the mutual informa tion between the output representations of the two models guides the learning pr ocess of the proxy model, mitigating feature distortion during training. Experim ental results demonstrate the effectiveness of PEER in reducing the OOD performa nce fluctuation and enhancing generalization across various datasets, including PACS, Digits, Office-Home, and VLCS. Notably, our method with simple random augm entation achieves state-of-the-art performance, surpassing prior approaches on s DG that utilize complex data augmentation strategies.

HOTFormerLoc: Hierarchical Octree Transformer for Versatile Lidar Place Recognition Across Ground and Aerial Views

Ethan Griffiths, Maryam Haghighat, Simon Denman, Clinton Fookes, Milad Ramezani; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 6648-6658

We present HOTFormerLoc, a novel and versatile Hierarchical Octree-based TransFormer, for large-scale 3D place recognition in both ground-to-ground and ground-to-aerial scenarios across urban and forest environments. We propose an octree-based multi-scale attention mechanism that captures spatial and semantic features across granularities. To address the variable density of point distributions from spinning lidar, we present cylindrical octree attention windows to reflect the underlying distribution during attention.We introduce relay tokens to enable efficient global-local interactions and multi-scale representation learning at reduced computational cost. Our pyramid attentional pooling then synthesises a robust global descriptor for end-to-end place recognition in challenging environments. In addition, we introduce CS-Wild-Places, a novel 3D cross-source dataset featuring point cloud data from aerial and ground lidar scans captured in dense forests. Point clouds in CS-Wild-Places contain representational gaps and distinctive attributes such as varying point densities and noise patterns, making it a challenging benchmark for cross-view localisation in the wild. HOTFormerLoc achieves a top-1 average recall improvement of 5.5% - 11.5% on the CS-Wild-Places benchmark. Furthermore, it consistently outperforms SOTA 3D place recognition methods, with an average performance gain of 4.9% on well-established urban and forest datasets. The code and CS-Wild-Places benchmark is available at https://csiro-robotics.github.io/HOTFormerLoc.

Revisiting Fairness in Multitask Learning: A Performance-Driven Approach for Variance Reduction

Xiaohan Qin, Xiaoxing Wang, Junchi Yan; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 20492-20501

Multi-task learning (MTL) can leverage shared knowledge across tasks to improve data efficiency and generalization performance, and has been applied in various scenarios. However, task imbalance remains a major challenge for existing MTL methods. While the prior works have attempted to mitigate inter-task unfairness through loss-based and gradient-based strategies, they still exhibit imbalanced performance across tasks on common benchmarks.This key observation motivates us to consider performance-level information as an explicit fairness indicator, which can precisely reflect the current optimization status of each task, and accordingly help to adjust the gradient aggregation process.Specifically, we utilize the performance variance among tasks as the fairness indicator and introduce a dynamic weighting strategy to gradually reduce the performance variance. Based on this, we propose PIVRG, a novel performance-informed variance reduction gradient aggregation approach.Extensive experiments show that PIVRG achieves SOTA performance across various benchmarks, spanning both supervised learning and reinforcement learning tasks with task numbers ranging from 2 to 40. Results from the ablation study also show that our approach can be integrated into existing methods, significantly enhancing their performance while reducing the performance variance among tasks, thus achieving fairer optimization.

UniK3D: Universal Camera Monocular 3D Estimation

Luigi Piccinelli, Christos Sakaridis, Mattia Segu, Yung-Hsu Yang, Siyuan Li, Wim Abbeloos, Luc Van Gool; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 1028-1039

Monocular 3D estimation is crucial for visual perception. However, current methods fall short by relying on oversimplified assumptions, such as pinhole camera models or rectified images. These limitations severely restrict their general applicability, causing poor performance in real-world scenarios with fisheye or panoramic images and resulting in substantial context loss. To address this, we present UniK3D, the first generalizable method for monocular 3D estimation able to model any camera. Our method introduces a spherical 3D representation which allo

ws for better disentanglement of camera and scene geometry and enables accurate metric 3D reconstruction for unconstrained camera models. Our camera component features a novel, model-independent representation of the pencil of rays, achieved through a learned superposition of spherical harmonics. We also introduce an angular loss, which, together with the camera module design, prevents the contraction of the 3D outputs for wide-view cameras. A comprehensive zero-shot evaluation on 13 diverse datasets demonstrates the state-of-the-art performance of UniK3D across 3D, depth, and camera metrics, with substantial gains in challenging large-field-of-view and panoramic settings, while maintaining top accuracy in conventional pinhole small-field-of-view domains. Code and models are available at github.com/lpiccinelli-eth/unik3d

****

ConMo: Controllable Motion Disentanglement and Recomposition for Zero-Shot Motion Transfer

Jiayi Gao, Zijin Yin, Changcheng Hua, Yuxin Peng, Kongming Liang, Zhanyu Ma, Jun Guo, Yang Liu; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 7191-7200

The development of Text-to-Video (T2V) generation has made motion transfer possible, enabling the control of video motion based on existing footage. However, current methods have two limitations: 1) struggle to handle multi-subjects videos, failing to transfer specific subject motion; 2) struggle to preserve the diversity and accuracy of motion as transferring to subjects with varying shapes. To overcome these, we introduce ConMo, a zero-shot framework that disentangle and recompose the motions of subjects and camera movements. ConMo isolates individual subject and background motion cues from complex trajectories in source videos using only subject masks, and reassembles them for target video generation. This approach enables more accurate motion control across diverse subjects and improves performance in multi-subject scenarios. Additionally, we propose soft guidance in the recomposition stage which controls the retention of original motion to adjust shape constraints, aiding subject shape adaptation and semantic transformation. Unlike previous methods, ConMo unlocks a wide range of applications, including subject size and position editing, subject removal, semantic modifications, and camera motion simulation. Extensive experiments demonstrate that ConMo significantly outperforms state-of-the-art methods in motion fidelity and semantic consistency. The code is available at https://github.com/Andyplus1/ConMo.

****

VideoMage: Multi-Subject and Motion Customization of Text-to-Video Diffusion Models

Chi-Pin Huang, Yen-Siang Wu, Hung-Kai Chung, Kai-Po Chang, Fu-En Yang, Yu-Chiang Frank Wang; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 17603-17612

Customized text-to-video generation aims to produce high-quality videos that incorporate user-specified subject identities or motion patterns. However, existing methods mainly focus on personalizing a single concept, either subject identity or motion pattern, limiting their effectiveness for multiple subjects with the desired motion patterns. To tackle this challenge, we propose a unified framework VideoMage for video customization over both multiple subjects and their interactive motions. VideoMage employs subject and motion LoRAs to capture personalized content from user-provided images and videos, along with an appearance-agnostic motion learning approach to disentangle motion patterns from visual appearance. Furthermore, we develop a spatial-temporal composition scheme to guide interactions among subjects within the desired motion patterns. Extensive experiments demonstrate that VideoMage outperforms existing methods, generating coherent, user-controlled videos with consistent subject identities and interactions.

****

AG-VPReID: A Challenging Large-Scale Benchmark for Aerial-Ground Video-based Person Re-Identification

Huy Nguyen, Kien Nguyen, Akila Pemasiri, Feng Liu, Sridha Sridharan, Clinton Fookes; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 1241-1251

We introduce AG-VPReID, a new large-scale dataset for aerial-ground video-based person re-identification (ReID) that comprises 6,632 subjects, 32,321 tracklets and over 9.6 million frames captured by drones (altitudes ranging from 15-120m), CCTV, and wearable cameras. This dataset offers a real-world benchmark for evaluating the robustness to significant viewpoint changes, scale variations, and resolution differences in cross-platform aerial-ground settings. In addition, to address these challenges, we propose AG-VPReID-Net, an end-to-end framework composed of three complementary streams: (1) an Adapted Temporal-Spatial Stream addressing motion pattern inconsistencies and facilitating temporal feature learning, (2) a Normalized Appearance Stream leveraging physics-informed techniques to tackle resolution and appearance changes, and (3) a Multi-Scale Attention Stream handling scale variations across drone altitudes. We integrate visual-semantic cues from all streams to form a robust, viewpoint-invariant whole-body representation. Extensive experiments demonstrate that AG-VPReID-Net outperforms state-of-the-art approaches on both our new dataset and existing video-based ReID benchmarks, showcasing its effectiveness and generalizability. Nevertheless, the performance gap observed on AG-VPReID across all methods underscores the dataset's challenging nature. The dataset, code and trained models are available at https://github.com/agvpreid25/AG-VPReID-Net.

EBS-EKF: Accurate and High Frequency Event-based Star Tracking

Albert W. Reed, Connor Hashemi, Dennis Melamed, Nitesh Menon, Keigo Hirakawa, Scott McCloskey; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 6510-6519

Event-based sensors (EBS) are a promising new technology for star tracking due to their low latency and power efficiency, but prior work has thus far been evaluated exclusively in simulation with simplified signal models. We propose a novel algorithm for event-based star tracking, grounded in an analysis of the EBS circuit and an extended Kalman filter (EKF). We quantitatively evaluate our method using real night sky data, comparing its results with those from a space-ready active-pixel sensor (APS) star tracker. We demonstrate that our method is an order-of-magnitude more accurate than existing methods due to improved signal modeling and state estimation, while providing more frequent updates and greater motion tolerance than conventional APS trackers. We provide all code and the first dataset of events synchronized with APS solutions.

PersonaBooth: Personalized Text-to-Motion Generation

Boeun Kim, Hea In Jeong, JungHoon Sung, Yihua Cheng, Jeongmin Lee, Ju Yong Chang, Sang-Il Choi, Younggeun Choi, Saim Shin, Jungho Kim, Hyung Jin Chang; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 22756-22765

This paper introduces Motion Personalization, a new task that generates personalized motions aligned with text descriptions using several basic motions containing Persona. To support this novel task, we introduce a new large-scale motion dataset called PerMo (PersonaMotion), which captures the unique personas of multiple actors. We also propose a multi-modal finetuning method of a pretrained motion diffusion model called PersonaBooth. PersonaBooth addresses two main challenges: i) A significant distribution gap between the persona-focused PerMo dataset and the pretraining datasets, which lack persona-specific data, and ii) the difficulty of capturing a consistent persona from the motions vary in content (action type). To tackle the dataset distribution gap, we introduce a persona token to accept new persona features and perform multi-modal adaptation for both text and visuals during finetuning. To capture a consistent persona, we incorporate a contrastive learning technique to enhance intra-cohesion among samples with the same persona. Furthermore, we introduce a context-aware fusion mechanism to maximize the integration of persona cues from multiple input motions. PersonaBooth outperforms state-of-the-art motion style transfer methods, establishing a new benchmark for motion personalization.

Benchmarking Object Detectors under Real-World Distribution Shifts in Satellite

Imagery
Sara A. Al-Emadi, Yin Yang, Ferda Ofli; Proceedings of the Computer Vision and P attern Recognition Conference (CVPR), 2025, pp. 8299-8309
Object detectors have achieved remarkable performance in many applications; howe ver, these deep learning models are typically designed under the i.i.d. assumpti on, meaning they are trained and evaluated on data sampled from the same (source) distribution. In real-world deployment, however, target distributions often di ffer from source data, leading to substantial performance degradation. Domain Ge neralisation (DG) seeks to bridge this gap by enabling models to generalise to O ut-Of-Distribution (OOD) data without access to target distributions during trai ning, enhancing robustness to unseen conditions. In this work, we examine the ge neralisability and robustness of state-of-the-art object detectors under real-wo rld distribution shifts, focusing particularly on spatial domain shifts. Despite the need, a standardised benchmark dataset specifically designed for assessing object detection under realistic DG scenarios is currently lacking. To address t his, we introduce Real-World Distribution Shifts (RWDS), a suite of three novel DG benchmarking datasets that focus on humanitarian and climate change applicati ons. These datasets enable the investigation of domain shifts across (i) climate zones and (ii) various disasters and geographic regions. To our knowledge, thes e are the first DG benchmarking datasets tailored for object detection in real-w orld, high-impact contexts. We aim for these datasets to serve as valuable resou rces for evaluating the robustness and generalisation of future object detection models. Our datasets and code are available at https://github.com/RWGAI/RWDS.

SAIST: Segment Any Infrared Small Target Model Guided by Contrastive Language-Im age Pretraining
Mingjin Zhang, Xiaolong Li, Fei Gao, Jie Guo, Xinbo Gao, Jing Zhang; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 954 9-9558
Infrared Small Target Detection (IRSTD) aims to identify low signal-to-noise rat io small targets in infrared images with complex backgrounds, which is crucial f or various applications. However, existing IRSTD methods typically rely solely o n image modalities for processing, which fail to fully capture contextual inform ation, leading to limited detection accuracy and adaptability in complex environ ments. Inspired by vision-language models, this paper proposes a novel framework , SAIST, which integrates textual information with image modalities to enhance I RSTD performance. The framework consists of two main components: Scene Recogniti on Contrastive Language-Image Pretraining (SR-CLIP) and CLIP-guided Segment Anyt hing Model (CG-SAM). SR-CLIP generates a set of visual descriptions through obj ect-object similarity and object-scene relevance, embedding them into learnable prompts to refine the textual description set. This reduces the domain gap betwe en vision and language, generating precise textual and visual prompts. CG-SAM ut ilizes the prompts generated by SR-CLIP to accurately guide the Mask Decoder in learning prior knowledge of background features, while incorporating infrared im aging equations to improve small target recognition in complex backgrounds and s ignificantly reduce the false alarm rate. Additionally, this paper introduces th e first multimodal IRSTD dataset, MIRSTD, which contains abundant image-text pai rs. Experimental results demonstrate that the proposed SAIST method outperforms existing state-of-the-art approaches.

Closed-Loop Supervised Fine-Tuning of Tokenized Traffic Models
Zhejun Zhang, Peter Karkus, Maximilian Igl, Wenhao Ding, Yuxiao Chen, Boris Ivan ovic, Marco Pavone; Proceedings of the Computer Vision and Pattern Recognition C onference (CVPR), 2025, pp. 5422-5432
Traffic simulation aims to learn a policy for traffic agents that, when unrolled in closed-loop, faithfully recovers the joint distribution of trajectories obse rved in the real world. Inspired by large language models, tokenized multi-agent policies have recently become the state-of-the-art in traffic simulation. Howev er, they are typically trained through open-loop behavior cloning, and thus suff er from covariate shift when executed in closed-loop during simulation. In this work, we present Closest Among Top-K (CAT-K) rollouts, a simple yet effective cl osed-loop fine-tuning strategy to mitigate covariate shift. CAT-K fine-tuning on ly requires existing trajectory data, without reinforcement learning or generati ve adversarial imitation. Concretely, CAT-K fine-tuning enables a small 7M-param eter tokenized traffic simulation policy to outperform a 102M-parameter model fr om the same model family, achieving the top spot on the Waymo Sim Agent Challeng e leaderboard at the time of submission. The code is available at https://github .com/NVlabs/catk.

DIFIX3D+: Improving 3D Reconstructions with Single-Step Diffusion Models
Jay Zhangjie Wu, Yuxuan Zhang, Haithem Turki, Xuanchi Ren, Jun Gao, Mike Zheng S hou, Sanja Fidler, Zan Gojcic, Huan Ling; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 26024-26035
Neural Radiance Fields and 3D Gaussian Splatting have revolutionized 3D reconstr uction and novel-view synthesis task. However, achieving photorealistic renderin g from extreme novel viewpoints remains challenging, as artifacts persist across representations. In this work, we introduce Difix3D+, a novel pipeline designed to enhance 3D reconstruction and novel-view synthesis through single-step diffu sion models. At the core of our approach is Difix, a single-step image diffusion model trained to enhance and remove artifacts in rendered novel views caused by underconstrained regions of the 3D representation.Difix serves two critical rol es in our pipeline. First, it is used during the reconstruction phase to clean u p pseudo-training views that are rendered from the reconstruction and then disti lled back into 3D. This greatly enhances underconstrained regions and improves t he overall 3D representation quality. More importantly, Difix also acts as a neu ral enhancer during inference, effectively removing residual artifacts arising f rom imperfect 3D supervision and the limited capacity of current reconstruction models. Difix3D+ is a general solution, a single model compatible with both NeRF and 3DGS representations, and it achieves an average 2x improvement in FID scor e over baselines while maintaining 3D consistency.

Time of the Flight of the Gaussians: Optimizing Depth Indirectly in Dynamic Radi ance Fields
Runfeng Li, Mikhail Okunev, Zixuan Guo, Anh Ha Duong, Christian Richardt, Matthe w O'Toole, James Tompkin; Proceedings of the Computer Vision and Pattern Recogni tion Conference (CVPR), 2025, pp. 21021-21030
We present a method to reconstruct dynamic scenes from monocular continuous-wave time-of-flight (C-ToF) cameras using raw sensor samples that achieves similar o r better accuracy than neural volumetric approaches and is 100xfaster. Quickly a chieving high-fidelity dynamic 3D reconstruction from a single viewpoint is a si gnificant challenge in computer vision. In C-ToF radiance field reconstruction, the property of interest---depth---is not directly measured, causing an addition al challenge. This problem has a large and underappreciated impact upon the opti mization when using a fast primitive-based scene representation like 3D Gaussian

splatting, which is commonly used with multi-view data to produce satisfactory results and is brittle in its optimization otherwise. We incorporate two heuristics into the optimization to improve the accuracy of scene geometry represented by Gaussians. Experimental results show that our approach produces accurate reconstructions under constrained C-ToF sensing conditions, including for fast motions like swinging baseball bats.

Align3R: Aligned Monocular Depth Estimation for Dynamic Videos

Jiahao Lu, Tianyu Huang, Peng Li, Zhiyang Dou, Cheng Lin, Zhiming Cui, Zhen Dong, Sai-Kit Yeung, Wenping Wang, Yuan Liu; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 22820-22830

Recent developments in monocular depth estimation methods enable high-quality depth estimation of single-view images but fail to estimate consistent video depth across different frames. Recent works address this problem by applying a video diffusion model to generate video depth conditioned on the input video, which is training-expensive and can only produce scale-invariant depth values without camera poses. In this paper, we propose a novel video-depth estimation method called Align3R to estimate temporal consistent depth maps for a dynamic video. Our key idea is to utilize the recent DUSt3R model to align estimated monocular depth maps of different timesteps. First, we fine-tune the DUSt3R model with additional estimated monocular depth as inputs for the dynamic scenes. Then, we apply optimization to reconstruct both depth maps and camera poses. Extensive experiments demonstrate that Align3R estimates consistent video depth and camera poses for a monocular video with superior performance than baseline methods.

Compositional Caching for Training-free Open-vocabulary Attribute Detection

Marco Garosi, Alessandro Conti, Gaowen Liu, Elisa Ricci, Massimiliano Mancini; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 15098-15107

Attribute detection is crucial for many computer vision tasks, as it enables systems to describe properties such as color, texture, and material. Current approaches often rely on labor-intensive annotation processes which are inherently limited: objects can be described at an arbitrary level of detail (e.g., color vs. color shades), leading to ambiguities when the annotators are not instructed carefully. Furthermore, they operate within a predefined set of attributes, reducing scalability and adaptability to unforeseen downstream applications. We present Compositional Caching (ComCa), a training-free method for open-vocabulary attribute detection that overcomes these constraints. ComCa requires only the list of target attributes and objects as input, using them to populate an auxiliary cache of images by leveraging web-scale databases and Large Language Models to determine attribute-object compatibility. To account for the compositional nature of attributes, cache images receive soft attribute labels. Those are aggregated at inference time based on the similarity between the input and cache images, refining the predictions of underlying Vision-Language Models (VLMs). Importantly, our approach is model-agnostic, compatible with various VLMs. Experiments on public datasets demonstrate that ComCa significantly outperforms zero-shot and cache-based baselines, competing with recent training-based methods, proving that a carefully designed training-free approach can successfully address open-vocabulary attribute detection.

Seek Common Ground While Reserving Differences: Semi-Supervised Image-Text Sentiment Recognition

Wuyou Xia, Guoli Jia, Sicheng Zhao, Jufeng Yang; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 29601-29611

Multimodal sentiment analysis has attracted extensive research attention as increasing users share images and texts to express their emotions and opinions on social media. Collecting large amounts of labeled sentiment data is an expensive and challenging task due to the high cost of labeling and unavoidable label ambiguity. Semi-supervised learning (SSL) is explored to utilize the extensive unlabeled data to alleviate the demand for annotation. However, different from typical

multimodal tasks, the inconsistent sentiment between image and text leads to th
e sub-optimal performance of SSL algorithms. To address this issue, we propose S
CDR, the first semi-supervised image-text sentiment recognition framework. To be
tter utilize the discriminative features of each modality, we decouple features
into common and private parts and then use the private features to train unimoda
l classifiers for enhanced modality-specific sentiment representation. Consideri
ng the complex relation between modalities, we devise a modal selection-based at
tention module that adaptively assesses the dominant sentiment modality at the s
ample level to guide the fusion of multimodal representations. Furthermore, to p
revent the model predictions from overly relying on common features under the gu
idance of multimodal labels, we design a pseudo-label filtering strategy based o
n the matching degree of prediction and dominant modality. Extensive experiments
and comparisons on five publicly available datasets demonstrate that SCDR outpe
rforms state-of-the-art methods. The code is provided in the supplementary mater
ial and will be released to the public.

CoLLM: A Large Language Model for Composed Image Retrieval
Chuong Huynh, Jinyu Yang, Ashish Tawari, Mubarak Shah, Son Tran, Raffay Hamid, T
rishul Chilimbi, Abhinav Shrivastava; Proceedings of the Computer Vision and Pat
tern Recognition Conference (CVPR), 2025, pp. 3994-4004
Composed Image Retrieval (CIR) is a complex task that aims to retrieve images ba
sed on a multimodal query. Typical training data consists of triplets containing
a reference image, a textual description of desired modifications, and the targ
et image, which are expensive and time-consuming to acquire. The scarcity of CIR
datasets has led to zero-shot approaches utilizing synthetic triplets or levera
ging vision-language models (VLMs) with ubiquitous web-crawled image-caption pai
rs. However, these methods have significant limitations: synthetic triplets suff
er from limited scale, lack of diversity, and unnatural modification text, while
image-caption pairs hinder joint embedding learning of the multimodal query due
to the absence of triplet data. Moreover, existing approaches struggle with com
plex and nuanced modification texts that demand sophisticated fusion and underst
anding of vision and language modalities. We present CoLLM, a one-stop framework
that effectively addresses these limitations. Our approach generates triplets o
n-the-fly from image-caption pairs, enabling supervised training without manual
annotation. We leverage Large Language Models (LLMs) to generate joint embedding
s of reference images and modification texts, facilitating deeper multimodal fus
ion. Additionally, we introduce Multi-Text CIR (MTCIR), a large-scale dataset co
mprising 3.4M samples, and refine existing CIR benchmarks (CIRR and Fashion-IQ)
to enhance evaluation reliability. Experimental results demonstrate that CoLLM a
chieves state-of-the-art performance across multiple CIR benchmarks and settings
. MTCIR yields competitive results, with up to 15% performance improvement. Our
refined benchmarks provide more reliable evaluation metrics for CIR models, cont
ributing to the advancement of this important field. Project page is at collm-cv
pr25.github.io

Anomize: Better Open Vocabulary Video Anomaly Detection
Fei Li, Wenxuan Liu, Jingjing Chen, Ruixu Zhang, Yuran Wang, Xian Zhong, Zheng W
ang; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR
), 2025, pp. 29203-29212
Open Vocabulary Video Anomaly Detection (OVVAD) seeks to detect and classify bot
h base and novel anomalies. However, existing methods face two specific challeng
es related to novel anomalies. The first challenge is detection ambiguity, where
the model struggles to assign accurate anomaly scores to unfamiliar anomalies.
The second challenge is categorization confusion, where novel anomalies are ofte
n misclassified as visually similar base instances. To address these challenges,
we explore supplementary information from multiple sources to mitigate detectio
n ambiguity by leveraging multiple levels of visual data alongside matching text
ual information. Furthermore, we propose incorporating label relations to guide
the encoding of new labels, thereby improving alignment between novel videos and
their corresponding labels, which helps reduce categorization confusion. The re

sulting Anomize framework effectively tackles these issues, achieving superior performance on UCF-Crime and XD-Violence datasets, demonstrating its effectiveness in OVVAD.

Efficient Diffusion as Low Light Enhancer
Guanzhou Lan, Qianli Ma, Yuqi Yang, Zhigang Wang, Dong Wang, Xuelong Li, Bin Zhao; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 21277-21286
The computational burden of the iterative sampling process remains a major challenge in diffusion-based Low-Light Image Enhancement (LLIE). Current acceleration methods, whether training-based or training-free, often lead to significant performance degradation, highlighting the trade-off between performance and efficiency.In this paper, we identify two primary factors contributing to performance degradation: fitting errors and the inference gap. Our key insight is that fitting errors can be mitigated by linearly extrapolating the incorrect score functions, while the inference gap can be reduced by shifting the Gaussian flow to a reflectance-aware residual space.Based on the above insights, we design Reflectance-Aware Trajectory Refinement (RATR) module, a simple yet effective module to refine the teacher trajectory using the reflectance component of images. Following this, we introduce Reflectance-aware Diffusion with Distilled Trajectory ReDDiT, an efficient and flexible distillation framework tailored for LLIE. Our framework achieves comparable performance to previous diffusion-based methods with redundant steps in just 2 steps while establishing new state-of-the-art (SOTA) results with 8 or 4 steps. Comprehensive experimental evaluations on 10 benchmark datasets validate the effectiveness of our method, consistently outperforming existing SOTA methods.

GraphMimic: Graph-to-Graphs Generative Modeling from Videos for Policy Learning
Guangyan Chen, Te Cui, Meiling Wang, Chengcai Yang, Mengxiao Hu, Haoyang Lu, Yao Mu, Zicai Peng, Tianxing Zhou, Xinran Jiang, Yi Yang, Yufeng Yue; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 1756-1768
Learning from demonstration is a powerful method for robotic skill acquisition. However, the significant expense of collecting such action-labeled robot data presents a major bottleneck. Video data, a rich data source encompassing diverse behavioral and physical knowledge, emerges as a promising alternative. In this paper, we present GraphMimic, a novel paradigm that leverages video data via graph-to-graphs generative modeling, which pre-trains models to generate future graphs conditioned on the graph within a video frame. Specifically, GraphMimic abstracts video frames into object and visual action vertices, and constructs graphs for state representations. The graph generative modeling network then effectively models internal structures and spatial relationships within the constructed graphs, aiming to generate future graphs. The generated graphs serve as conditions for the control policy, mapping to robot actions. Our concise approach captures important spatial relations and enhances future graph generation accuracy, enabling the acquisition of robust policies from limited action-labeled data. Furthermore, the transferable graph representations facilitate the effective learning of manipulation skills from cross-embodiment videos. Our experiments exhibit that GraphMimic achieves superior performance using merely 20% action-labeled data. Moreover, our method outperforms the state-of-the-art method by over 17% and 23% in simulation and real-world experiments, and delivers improvements of over 33% in cross-embodiment transfer experiments.

VI^3NR: Variance Informed Initialization for Implicit Neural Representations
Chamin Hewa Koneputugodage, Yizhak Ben-Shabat, Sameera Ramasinghe, Stephen Gould; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 13477-13486
Implicit Neural Representations (INRs) are a versatile and powerful tool for encoding various forms of data, including images, videos, sound, and 3D shapes. A critical factor in the success of INRs is the initialization of the network, whic

h can significantly impact the convergence and accuracy of the learned model. Unfortunately, commonly used neural network initializations are not widely applicable for many activation functions, especially those used by INRs. In this paper, we improve upon previous initialization methods by deriving an initialization that has stable variance across layers, and applies to any activation function. We show that this generalizes many previous initialization methods, and has even better stability for well studied activations. We also show that our initialization leads to improved results with INR activation functions in multiple signal modalities. Our approach is particularly effective for Gaussian INRs, where we demonstrate that the theory of our initialization matches with task performance in multiple experiments, allowing us to achieve improvements in image, audio, and 3D surface reconstruction.

MMVU: Measuring Expert-Level Multi-Discipline Video Understanding

Yilun Zhao, Haowei Zhang, Lujing Xie, Tongyan Hu, Guo Gan, Yitao Long, Zhiyuan Hu, Weiyuan Chen, Chuhan Li, Zhijian Xu, Chengye Wang, Ziyao Shangguan, Zhenwen Liang, Yixin Liu, Chen Zhao, Arman Cohan; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 8475-8489

We introduce MMVU, a comprehensive expert-level, multi-discipline benchmark for evaluating foundation models in video understanding. MMVU includes 3,000 expert-annotated questions spanning 27 subjects across four core disciplines: Science, Healthcare, Humanities & Social Sciences, and Engineering. Compared to prior benchmarks, MMVU features three key advancements. First, it challenges models to apply domain-specific knowledge and perform expert-level reasoning to analyze specialized-domain videos, moving beyond the basic visual perception typically assessed in current video benchmarks. Second, each example is annotated by human experts from scratch. We implement strict data quality controls to ensure the high quality of the dataset. Finally, each example is enriched with expert-annotated reasoning rationals and relevant domain knowledge, facilitating in-depth analysis. We conduct an extensive evaluation of 36 frontier multimodal foundation models on MMVU. The latest System-2-capable models, o1 and Gemini 2.0 Flash Thinking, achieve the highest performance among the tested models. However, they still fall short of matching human expertise. Through in-depth error analyses and case studies, we offer actionable insights for future advancements in expert-level, knowledge-intensive video understanding for specialized domains.

M-LLM Based Video Frame Selection for Efficient Video Understanding

Kai Hu, Feng Gao, Xiaohan Nie, Peng Zhou, Son Tran, Tal Neiman, Lingyun Wang, Mubarak Shah, Raffay Hamid, Bing Yin, Trishul Chilimbi; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 13702-13712

Recent advances in Multi-Modal Large Language Models (M-LLMs) show promising results in video reasoning. Popular Multi-Modal Large Language Model (M-LLM) frameworks usually apply naive uniform sampling to reduce the number of video frames that are fed into an M-LLM, particularly for long context videos. However, it could lose crucial context in certain periods of a video, so that the downstream M-LLM may not have sufficient visual information to answer a question. To attack this pain point, we propose a light-weight M-LLM -based frame selection method that adaptively select frames that are more relevant to users' queries. In order to train the proposed frame selector, we introduce two supervision signals (i) Spatial signal, where single frame importance score by prompting an M-LLM; (ii) Temporal signal, in which multiple frames selection by prompting Large Language Model (LLM) using the captions of all frame candidates. The selected frames are then digested by a frozen downstream video M-LLM for visual reasoning and question answering. Empirical results show that the proposed M-LLM video frame selector improves the performances various downstream video Large Language Model (video-LLM) across medium (ActivityNet, NExT-QA) and long (EgoSchema, LongVideoBench) context video question answering benchmarks.

Search and Detect: Training-Free Long Tail Object Detection via Web-Image Retrieval

Mankeerat Sidhu, Hetarth Chopra, Ansel Blume, Jeonghwan Kim, Revanth Gangi Reddy, Heng Ji; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 15129-15138
In this paper, we introduce SearchDet, a training-free long-tail object detection framework that significantly enhances open-vocabulary object detection performance. SearchDet retrieves a set of positive and negative images of an object to ground, embeds these images, and computes an input image--weighted query which is used to detect the desired concept in the image. Our proposed method is simple and training-free, yet achieves over 16.81% mAP improvement on ODinW and 59.85% mAP improvement on LVIS compared to state-of-the-art models such as GroundingDINO. We further show that our approach of basing object detection on a set of Web-retrieved exemplars is stable with respect to variations in the exemplars, suggesting a path towards eliminating costly data annotation and training procedures.
****
EgoLM: Multi-Modal Language Model of Egocentric Motions
Fangzhou Hong, Vladimir Guzov, Hyo Jin Kim, Yuting Ye, Richard Newcombe, Ziwei Liu, Lingni Ma; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 5344-5354
As wearable devices become more prevalent, understanding the user's motion is crucial for improving contextual AI systems. We introduce EgoLM, a versatile framework designed for egocentric motion understanding using multi-modal data. EgoLM integrates the rich contextual information from egocentric videos and motion sensors afforded by wearable devices. It also combines dense supervision signals from motion and language, leveraging the vast knowledge encoded in pre-trained large language models (LLMs). EgoLM models the joint distribution of egocentric motions and natural language using LLMs, conditioned on observations from egocentric videos and motion sensors. It unifies a range of motion understanding tasks, including motion narration from video or motion data, as well as motion generation from text or sparse sensor data. Unique to wearable devices, it also enables a novel task to generate text descriptions from sparse sensors. Through extensive experiments, we validate the effectiveness of EgoLM in addressing the challenges of under-constrained egocentric motion learning, and demonstrate its capability as a generalist model through a variety of applications.
****
Unleashing the Potential of Multi-modal Foundation Models and Video Diffusion for 4D Dynamic Physical Scene Simulation
Zhuoman Liu, Weicai Ye, Yan Luximon, Pengfei Wan, Di Zhang; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 11016-11025
Realistic simulation of dynamic scenes requires accurately capturing diverse material properties and modeling complex object interactions grounded in physical principles. However, existing methods are constrained to basic material types with limited predictable parameters, making them insufficient to represent the complexity of real-world materials. We introduce PhysFlow, a novel approach that leverages multi-modal foundation models and video diffusion to achieve enhanced 4D dynamic scene simulation. Our method utilizes multi-modal models to identify material types and initialize material parameters through image queries, while simultaneously inferring 3D Gaussian splats for detailed scene representation. We further refine these material parameters using video diffusion with a differentiable Material Point Method (MPM) and optical flow guidance rather than render loss or Score Distillation Sampling (SDS) loss. This integrated framework enables accurate prediction and realistic simulation of dynamic interactions in real-world scenarios, advancing both accuracy and flexibility in physics-based simulations.
****
Diffusion Model is Effectively Its Own Teacher
Xinyin Ma, Runpeng Yu, Songhua Liu, Gongfan Fang, Xinchao Wang; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 12901-12911
In this paper, we introduce a novel self-distillation paradigm for improving the

performance of diffusion models. Previous studies have shown that introducing a teacher to distill the diffusion model can enhance its sampling efficiency. We raise an intriguing question: can the diffusion model itself serve as its teacher to further improve the performance of itself? To this end, we propose a new paradigm called Self Step-Distillation (SSD). The core idea of SSD is to integrate the predictions or the intermediate activations of the diffusion model at each timestep with its preceding timestep through a fusion mechanism. We propose two forms, explicit SSD and implicit SSD (iSSD), to perform N-step to N-step distillation from the diffusion model itself to achieve improved image quality. We further elucidate the relationship between SSD and high-order solver, highlighting their underlying relationship. The effectiveness of SSD is validated through extensive experiments on diffusion transformers of various sizes and across different sampling steps. Our results show that this novel self-distillation paradigm can significantly enhance performance. Additionally, our method is compatible with the distillation method designed for few-step inference. Notably, with iSSD trained less than one epoch, we obtain a 32-step DiT-XL/2 achieving an FID of 1.99, outperforming the original 250-step DiT-XL/2 with an FID of 2.26. We further validate the effectiveness of our method on text-to-image diffusion models, such as Stable Diffusion, and also observe notable improvement in image quality.

Long Video Diffusion Generation with Segmented Cross-Attention and Content-Rich Video Data Curation

Xin Yan, Yuxuan Cai, Qiuyue Wang, Yuan Zhou, Wenhao Huang, Huan Yang; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 3184-3194

We introduce Presto, a novel video diffusion model designed to generate 15-second videos with long-range coherence and rich content. Extending video generation to maintain scenario diversity over long durations presents significant challenges. To address this, we propose a Segmented Cross-Attention (SCA) strategy, which splits hidden states into segments along the temporal dimension, allowing each segment to cross-attend to a corresponding sub-caption. SCA requires no additional parameters, enabling seamless incorporation into current DiT-based architectures. To facilitate high-quality long video generation, we build the LongTake-HD dataset, consisting of 261k content-rich videos with scenario coherence, annotated with an overall video caption and five progressive sub-captions. Experiments show that our Presto achieves 78.5% on the VBench Semantic Score and 100% on the Dynamic Degree, outperforming existing state-of-the-art video generation methods. This demonstrates that our proposed Presto significantly enhances the content richness, maintains long-range coherence, and captures intricate textual details. All code and model weights will be made publicly available.

Learning Heterogeneous Tissues with Mixture of Experts for Gigapixel Whole Slide Images

Junxian Wu, Minheng Chen, Xinyi Ke, Tianwang Xun, Xiaoming Jiang, Hongyu Zhou, Lizhi Shao, Youyong Kong; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 5144-5153

Analyzing gigapixel Whole Slide Images (WSIs) is challenging due to the complex pathological tissue environment and the absence of target-driven domain knowledge. Previous methods incorporated pathological priors to mitigate this issue but relied on additional inference steps and specialized workflows, restricting scalability and the model's capacity to identify novel outcome-related factors. To address these challenges, we propose a plug-and-play Pathology-Aware Mixture-of-Experts (PAMoE) module, which based on mixture of experts to learn pathology-related knowledge and extract useful information. We train the experts to become 'specialists' in specific intratumoral tissues by learning to route each tissue to its mapped expert. In addition, to reduce the impact of irrelevant content on the model, we introduce a new routing rule that discards patches in which none of the experts express interest, which helps the model better capture the relationships between relevant patches. Through a comprehensive evaluation of PAMoE on survival task, we demonstrate that 1) Our module enhances the performance of basel

ine models in most cases, and 2) The sparse expert processing across different t issues enhances the learning of patch representations by addressing tissue heter ogeneity.

HyperNVD: Accelerating Neural Video Decomposition via Hypernetworks
Maria Pilligua, Danna Xue, Javier Vazquez-Corral; Proceedings of the Computer Vi sion and Pattern Recognition Conference (CVPR), 2025, pp. 22933-22942
Decomposing a video into a layer-based representation is crucial for easy video editing for the creative industries, as it enables independent editing of specif ic layers. Existing video-layer decomposition models rely on implicit neural rep resentations (INRs) trained independently for each video, making the process tim e-consuming when applied to new videos. Noticing this limitation, we propose a m eta-learning strategy to learn a generic video decomposition model to speed up t he training on new videos. Our model is based on a hypernetwork architecture whi ch, given a video-encoder embedding, generates the parameters for a compact INR- based neural video decomposition model. Our strategy mitigates the problem of si ngle-video overfitting and, importantly, shortens the convergence of video decom position on new, unseen videos. Our code is available at: https://hypernvd.githu b.io/

Disentangled Pose and Appearance Guidance for Multi-Pose Generation
Tengfei Xiao, Yue Wu, Yuelong Li, Can Qin, Maoguo Gong, Qiguang Miao, Wenping Ma ; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 5646-5655
Human pose generation is a complex task due to the non-rigid and highly variable nature of human body structures and appearances. However, existing methods ofte n overlook the fundamental differences between spatial transformations of poses and texture generation for appearance, which makes them prone to overfitting. To address this issue, we propose a multi-pose generation framework driven by dise ntangled pose and appearance guidance. Our approach includes a Global-aware Pose Generation module that iteratively generates pose embeddings, enabling effectiv e control over non-rigid body deformations. Additionally, we introduce the Globa l-aware Transformer Decoder, which leverages similarity queries and attention me chanisms to achieve spatial transformations and enhance pose consistency through a Global-aware block. In the appearance generation phase, we condition a diffus ion model on pose embeddings produced in the initial stage and introduce an Appe arance Adapter that extracts high-level contextual semantic information from mul ti-scale features, enabling further refinement of pose appearance textures and p roviding appearance guidance. Extensive experiments on the UBC Fashion and TikTo k datasets demonstrate that our framework achieves state-of-the-art results in b oth quality and fidelity, establishing it as a powerful approach for complex pos e generation tasks.

Mind the Gap: Confidence Discrepancy Can Guide Federated Semi-Supervised Learning Across Pseudo-Mismatch
Yijie Liu, Xinyi Shang, Yiqun Zhang, Yang Lu, Chen Gong, Jing-Hao Xue, Hanzi Wang; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 10173-10182
Federated Semi-Supervised Learning (FSSL) aims to leverage unlabeled data across clients with limited labeled data to train a global model with strong generalization ability. Most FSSL methods rely on consistency regularization with pseudo-labels, converting predictions from local or global models into hard pseudo-labels as supervisory signals. However, we discover that the quality of pseudo-label is largely deteriorated by data heterogeneity, an intrinsic facet of federated learning. In this paper, we study the problem of FSSL in-depth and show that (1) heterogeneity exacerbates pseudo-label mismatches, further degrading model performance and convergence, and (2) local and global models' predictive tendencies diverge as heterogeneity increases. Motivated by these findings, we propose a simple and effective method called Semi-supervised Aggregation for Globally-Enhanced Ensemble (SAGE), that can flexibly correct pseudo-labels based on confidence discrepancies. This strategy effectively mitigates performance degradation caused by incorrect pseudo-labels and enhances consensus between local and global models. Experimental results demonstrate that SAGE outperforms existing FSSL methods in both performance and convergence. Our code is available at \href https://github.com/Jay-Codeman/SAGE https://github.com/Jay-Codeman/SAGE .

Instant Adversarial Purification with Adversarial Consistency Distillation
Chun Tong Lei, Hon Ming Yam, Zhongliang Guo, Yifei Qian, Chun Pong Lau; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 24331-24340
Neural networks have revolutionized numerous fields with their exceptional performance, yet they remain susceptible to adversarial attacks through subtle perturbations. While diffusion-based purification methods like DiffPure offer promising defense mechanisms, their computational overhead presents a significant practical limitation. In this paper, we introduce One Step Control Purification (OSCP), a novel defense framework that achieves robust adversarial purification in a single Neural Function Evaluation (NFE) within diffusion models. We propose Gaussian Adversarial Noise Distillation (GAND) as the distillation objective and Controlled Adversarial Purification (CAP) as the inference pipeline, which makes OSCP demonstrate remarkable efficiency while maintaining defense efficacy. Our proposed GAND addresses a fundamental tension between consistency distillation and adversarial perturbation, bridging the gap between natural and adversarial manifolds in the latent space, while remaining computationally efficient through Parameter-Efficient Fine-Tuning (PEFT) methods such as LoRA, eliminating the high computational budget request from full parameter fine-tuning. The CAP guides the purification process through the unlearnable edge detection operator calculated by the input image as an extra prompt, effectively preventing the purified images from deviating from their original appearance when using large purification steps. Our experimental results on ImageNet showcase OSCP's superior performance, achieving a 74.19% defense success rate with merely 0.1s per purification --- a 100-fold speedup compared to conventional approaches.

Learning Textual Prompts for Open-World Semi-Supervised Learning
Yuxin Fan, Junbiao Cui, Jiye Liang; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 14756-14765
Traditional semi-supervised learning achieves significant success in closed-world scenarios. To better align with the openness of the real world, researchers propose open-world semi-supervised learning (OWSSL), which enables models to effectively recognize known and unknown classes even without labels for unknown classes. Recently, researchers have attempted to enhance the model performance in recognizing visually similar classes by integrating textual information. However, these attempts do not effectively align images with text, resulting in limited improvements in model performance. In response to this challenge, we propose a nov

el OWSSL method. By adopting a global-and-local textual prompt learning strategy to enhance image-text alignment effectiveness, and implementing a forward-and-backward strategy to reduce noise in image-text matching for unlabeled samples, we ultimately enhance the model's ability to extract and recognize discriminative features across different classes. Experimental results on multiple fine-grained datasets demonstrate that our method achieves significant performance improvements compared to state-of-the-art methods.

Electromyography-Informed Facial Expression Reconstruction for Physiological-Based Synthesis and Analysis
Tim Büchner, Christoph Anders, Orlando Guntinas-Lichius, Joachim Denzler; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 215-227
The relationship between muscle activity and resulting facial expressions is crucial for various fields, including psychology, medicine, and entertainment. The synchronous recording of facial mimicry and muscular activity via surface electromyography (sEMG) provides a unique window into these complex dynamics. Unfortunately, existing methods for facial analysis cannot handle electrode occlusion, rendering them ineffective. Even with occlusion-free reference images of the same person, variations in expression intensity and execution are unmatchable. Our electromyography-informed facial expression reconstruction (EIFER) approach is a novel method to restore faces under sEMG occlusion faithfully in an adversarial manner. We decouple facial geometry and visual appearance (e.g., skin texture, lighting, electrodes) by combining a 3D Morphable Model (3DMM) with neural unpaired image-to-image translation via reference recordings. Then, EIFER learns a bidirectional mapping between 3DMM expression parameters and muscle activity, establishing correspondence between the two domains. We validate the effectiveness of our approach through experiments on a dataset of synchronized sEMG recordings and facial mimicry, demonstrating faithful geometry and appearance reconstruction. Further, we synthesize expressions based on muscle activity and how observed expressions can predict dynamic muscle activity. Consequently, EIFER introduces a new paradigm for facial electromyography, which could be extended to other forms of multi-modal face recordings.

LongDiff: Training-Free Long Video Generation in One Go
Zhuoling Li, Hossein Rahmani, Qiuhong Ke, Jun Liu; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 17789-17798
Video diffusion models have recently achieved remarkable results in video generation. Despite their encouraging performance, most of these models are mainly designed and trained for short video generation, leading to challenges in maintaining temporal consistency and visual details in long video generation. In this paper, through theoretical analysis of the mechanisms behind video generation, we identify two key challenges that hinder short-to-long generalization, namely, temporal position ambiguity and information dilution. To address these challenges, we propose LongDiff, a novel training-free method that unlocks the potential of the off-the-shelf video diffusion models to achieve high-quality long video generation in one go. Extensive experiments demonstrate the efficacy of our method.

Feature Selection for Latent Factor Models
Rittwika Kansabanik, Adrian Barbu; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 30742-30751
Feature selection is crucial for pinpointing relevant features in high-dimensional datasets, mitigating the 'curse of dimensionality,' and enhancing machine learning performance. Traditional feature selection methods for classification use data from all classes to select features for each class.This paper explores feature selection methods that select features for each class separately, using class models based on low-rank generative methods and introducing a signal-to-noise ratio (SNR) feature selection criterion. This novel approach theoretically guarantees true feature recovery under certain assumptions and is shown to outperform

some existing feature selection methods on standard classification datasets.

Preserve or Modify? Context-Aware Evaluation for Balancing Preservation and Modification in Text-Guided Image Editing

Yoonjeon Kim, Soohyun Ryu, Yeonsung Jung, Hyunkoo Lee, Joowon Kim, June Yong Yang, Jaeryong Hwang, Eunho Yang; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 23474-23483

The development of vision-language and generative models has significantly advanced text-guided image editing, which seeks the preservation of core elements in the source image while implementing modifications based on the target text. However, existing metrics have a context-blindness problem, indiscriminately applying the same evaluation criteria on completely different pairs of source image and target text, biasing towards either modification or preservation. Directional CLIP similarity, the only metric that considers both source image and target text, is also biased towards modification aspects and attends to irrelevant editing regions of the image. We propose AugCLIP, a context-aware metric that adaptively coordinates preservation and modification aspects, depending on the specific context of a given source image and target text. This is done by deriving the CLIP representation of an ideally edited image, that preserves the source image with necessary modifications to align with target text. More specifically, using a multi-modal large language model, AugCLIP augments the textual descriptions of the source and target, then calculates a modification vector through a hyperplane that separates source and target attributes in CLIP space. Extensive experiments on five benchmark datasets, encompassing a diverse range of editing scenarios, show that AugCLIP aligns remarkably well with human evaluation standards, outperforming existing metrics. The code is available at https://github.com/augclip/augclip_eval.

Mask-Adapter: The Devil is in the Masks for Open-Vocabulary Segmentation

Yongkang Li, Tianheng Cheng, Bin Feng, Wenyu Liu, Xinggang Wang; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 14998-15008

Recent open-vocabulary segmentation methods adopt mask generators to predict segmentation masks and leverage pre-trained vision-language models, *e.g.*, CLIP, to classify these masks via mask pooling.Although these approaches show promising results, it is counterintuitive that accurate masks often fail to yield accurate classification results through pooling CLIP image embeddings within the mask regions.In this paper, we reveal the performance limitations of mask pooling and introduce **Mask-Adapter**, a simple yet effective method to address these challenges in open-vocabulary segmentation.Compared to directly using proposal masks, our proposed Mask-Adapter extracts *semantic activation maps* from proposal masks, providing richer contextual information and ensuring alignment between masks and CLIP.Additionally, we propose a *mask consistency loss* that encourages proposal masks with similar IoUs to obtain similar CLIP embeddings to enhance models' robustness to varying predicted masks.Mask-Adapter integrates seamlessly into open-vocabulary segmentation methods based on mask pooling in a plug-and-play manner, delivering more accurate classification results. Extensive experiments across several zero-shot benchmarks demonstrate significant performance gains for the proposed Mask-Adapter on several well-established methods.Notably, Mask-Adapter also extends effectively to SAM and achieves impressive results on several open-vocabulary segmentation datasets. Code and models are available at https://github.com/hustvl/MaskAdapter.

MPDrive: Improving Spatial Understanding with Marker-Based Prompt Learning for Autonomous Driving

Zhiyuan Zhang, Xiaofan Li, Zhihao Xu, Wenjie Peng, Zijian Zhou, Miaojing Shi, Shuangping Huang; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 12089-12099

Autonomous driving visual question answering (AD-VQA) aims to answer questions related to perception, prediction, and planning based on given driving scene imag

es, heavily relying on the model's spatial understanding capabilities. Prior wor ks typically express spatial information through textual representations of coor dinates, resulting in semantic gaps between visual coordinate representations an d textual descriptions. This oversight hinders the accurate transmission of spat ial information and increases the expressive burden. To address this, we propose a novel Marker-based Prompt learning framework (MPDrive), which represents spat ial coordinates by concise visual markers, ensuring linguistic expressive consis tency and enhancing the accuracy of both visual perception and spatial expressio n in AD-VQA. Specifically, we create marker images by employing a detection expe rt to overlay object regions with numerical labels, converting complex textual c oordinate generation into straightforward text-based visual marker predictions. Moreover, we fuse original and marker images as scene-level features and integra te them with detection priors to derive instance-level features. By combining th ese features, we construct dual-granularity visual prompts that stimulate the LL M's spatial perception capabilities. Extensive experiments on the DriveLM and CO DA-LM datasets show that MPDrive achieves state-of-the-art performance, particul arly in cases requiring sophisticated spatial understanding.

Improving the Transferability of Adversarial Attacks on Face Recognition with Di verse Parameters Augmentation

Fengfan Zhou, Bangjie Yin, Hefei Ling, Qianyu Zhou, Wenxuan Wang; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 3516-3 527

Face Recognition (FR) models are vulnerable to adversarial examples that subtly manipulate benign face images, underscoring the urgent need to improve the trans ferability of adversarial attacks in order to expose the blind spots of these sy stems. Existing adversarial attack methods often overlook the potential benefits of augmenting the surrogate model with diverse initializations, which limits th e transferability of the generated adversarial examples. To address this gap, we propose a novel method called Diverse Parameters Augmentation (DPA) attack meth od, which enhances surrogate models by incorporating diverse parameter initializ ations, resulting in a broader and more diverse set of surrogate models. Specifi cally, DPA consists of two key stages: Diverse Parameters Optimization (DPO) and Hard Model Aggregation (HMA). In the DPO stage, we initialize the parameters of the surrogate model using both pre-trained and random parameters. Subsequently, we save the models in the intermediate training process to obtain a diverse set of surrogate models. During the HMA stage, we enhance the feature maps of the d iversified surrogate models by incorporating beneficial perturbations, thereby f urther improving the transferability. Experimental results demonstrate that our proposed attack method can effectively enhance the transferability of the crafte d adversarial face examples.

Adapting to Observation Length of Trajectory Prediction via Contrastive Learning

Ruiqi Qiu, Jun Gong, Xinyu Zhang, Siqi Luo, Bowen Zhang, Yi Cen; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 1645-16 54

The ability to adapt to varying observation lengths is crucial for human traject ory prediction tasks, particularly in scenarios with limited observation lengths or missing data. Existing approaches mainly focus on introducing novel architec tures or additional structural components, which substantially increase model co mplexity and present challenges for integration into existing models. We argue t hat current network architectures are sufficiently sophisticated to handle the O bservation Length Shift problem, with the key challenge lying in improving featu re representation for trajectories with limited lengths. To tackle this issue, w e introduce a general and effective contrastive learning approach, called Contra stive Learning for Length Shift (CLLS). By incorporating contrastive learning du ring the training phase, our method encourages the model to extract length-invar iant features, thus mitigating the impact of observation length variations. Furt hermore, to better accommodate length adaptation tasks, we introduce a lightweig ht RNN network that, combined with CLLS, achieves state-of-the-art performance i

n both general prediction and observation length shift tasks. Experimental resul
ts demonstrate that our approach outperforms existing methods across multiple wi
dely-used trajectory prediction datasets.

Fine-Grained Image-Text Correspondence with Cost Aggregation for Open-Vocabulary
 Part Segmentation

Jiho Choi, Seonho Lee, Minhyun Lee, Seungho Lee, Hyunjung Shim; Proceedings of t
he Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 9782-979
3

Open-Vocabulary Part Segmentation (OVPS) is an emerging field for recognizing fi
ne-grained parts in unseen categories. We identify two primary challenges in OVP
S: (1) the difficulty in aligning part-level image-text correspondence, and (2)
the lack of structural understanding in segmenting object parts. To address thes
e issues, we propose PartCATSeg, a novel framework that integrates object-aware
part-level cost aggregation, compositional loss, and structural guidance from DI
NO. Our approach employs a disentangled cost aggregation strategy that handles o
bject and part-level costs separately, enhancing the precision of part-level seg
mentation. We also introduce a compositional loss to better capture part-object
relationships, compensating for the limited part annotations. Additionally, stru
ctural guidance from DINO features improves boundary delineation and inter-part
understanding. Extensive experiments on Pascal-Part-116, ADE20K-Part-234, and Pa
rtImageNet datasets demonstrate that our method significantly outperforms state-
of-the-art approaches, setting a new baseline for robust generalization to unsee
n part categories.

NitroFusion: High-Fidelity Single-Step Diffusion through Dynamic Adversarial Tra
ining

Dar-Yen Chen, Hmrishav Bandyopadhyay, Kai Zou, Yi-Zhe Song; Proceedings of the C
omputer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 7654-7663

We introduce NitroFusion, a fundamentally different approach to single-step diff
usion that achieves high-quality generation through a dynamic adversarial framew
ork. While one-step methods offer dramatic speed advantages, they typically suff
er from quality degradation compared to their multi-step counterparts. Just as a
 panel of art critics provides comprehensive feedback by specializing in differe
nt aspects like composition, color, and technique, our approach maintains a larg
e pool of specialized discriminator heads that collectively guide the generation
 process. Each discriminator group develops expertise in specific quality aspect
s at different noise levels, providing diverse feedback that enables high-fideli
ty one-step generation. Our framework combines: (i) a dynamic discriminator pool
 with specialized discriminator groups to improve generation quality, (ii) strat
egic refresh mechanisms to prevent discriminator overfitting, and (iii) global-l
ocal discriminator heads for multi-scale quality assessment, and unconditional/c
onditional training for balanced generation. Additionally, our framework uniquel
y supports flexible deployment through bottom-up refinement, allowing users to d
ynamically choose between 1-4 denoising steps with the same model for direct qua
lity-speed trade-offs. Through comprehensive experiments, we demonstrate that Ni
troFusion significantly outperforms existing single-step methods across multiple
 evaluation metrics, particularly excelling in preserving fine details and globa
l consistency.

ByTheWay: Boost Your Text-to-Video Generation Model to Higher Quality in a Train
ing-free Way

Jiazi Bu, Pengyang Ling, Pan Zhang, Tong Wu, Xiaoyi Dong, Yuhang Zang, Yuhang Ca
o, Dahua Lin, Jiaqi Wang; Proceedings of the Computer Vision and Pattern Recogni
tion Conference (CVPR), 2025, pp. 12999-13008

The text-to-video (T2V) generation models, offering convenient visual creation,
have recently garnered increasing attention. Despite their substantial potential
, the generated videos may present artifacts, including structural implausibilit
y, temporal inconsistency, and a lack of motion, often resulting in near-static
video. In this work, we have identified a correlation between the disparity of t

emporal attention maps across different blocks and the occurrence of temporal in consistencies. Additionally, we have observed that the energy contained within t he temporal attention maps is directly related to the magnitude of motion amplit ude in the generated videos. Based on these observations, we present ByTheWay, a training-free method to improve the quality of text-to-video generation without introducing additional parameters, augmenting memory or sampling time. Specific ally, ByTheWay is composed of two principal components: 1) Temporal Self-Guidanc e improves the structural plausibility and temporal consistency of generated vid eos by reducing the disparity between the temporal attention maps across various decoder blocks. 2) Fourier-based Motion Enhancement enhances the magnitude and richness of motion by amplifying the energy of the map. Extensive experiments de monstrate that ByTheWay significantly improves the quality of text-to-video gene ration with negligible additional cost.

CMMLoc: Advancing Text-to-PointCloud Localization with Cauchy-Mixture-Model Base d Framework

Yanlong Xu, Haoxuan Qu, Jun Liu, Wenxiao Zhang, Xun Yang; Proceedings of the Com puter Vision and Pattern Recognition Conference (CVPR), 2025, pp. 6637-6647

The goal of point cloud localization based on linguistic description is to ident ify a 3D position using textual description in large urban environments, which h as potential applications in various fields, such as determining the location fo r vehicle pickup or goods delivery. Ideally, for a textual description and its c orresponding 3D location, the objects around the 3D location should be fully des cribed in the text description. However, in practical scenarios, e.g., vehicle p ickup, passengers usually describe only the part of the most significant and nea rby surroundings instead of the entire environment. In response to this partiall y relevant challenge, we propose CMMLoc, an uncertainty-aware Cauchy-Mixture-Mod el (CMM) based framework for text-to-point-cloud Localization. To model the unce rtain semantic relations between text and point cloud, we integrate CMM constrai nts as a prior during the interaction between the two modalities. We further des ign a spatial consolidation scheme to enable adaptive aggregation of different 3 D objects with varying receptive fields. To achieve precise localization, we pro pose a cardinal direction integration module alongside a modality pre-alignment strategy, helping capture the spatial relationships among objects and bringing t he 3D objects closer to the text modality. Comprehensive experiments validate th at CMMLoc outperforms existing methods, achieving state-of-the-art results on th e KITTI360Pose dataset. Codes are available in this anonymous GitHub repository https://github.com/anonymous0819/CMMLoc.

Decoupling Training-Free Guided Diffusion by ADMM

Youyuan Zhang, Zehua Liu, Zenan Li, Zhaoyu Li, James J. Clark, Xujie Si; Proceed ings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 23292-23302

In this paper, we consider the conditional generation problem by guiding off-the-shelf unconditional diffusion models with differentiable loss functions in a plug-and-play fashion. While previous research has primarily focused on balancing the unconditional diffusion model and the guided loss through a tuned weight hyperparameter, we propose a novel framework that distinctly decouples these two components. Specifically, we introduce two variables x and z, to represent the generated samples governed by the unconditional generation model and the guidance function, respectively. This decoupling reformulates conditional generation into two manageable subproblems, unified by the constraint $x = z$. Leveraging this setup, we develop a new algorithm based on the Alternating Direction Method of Multipliers (ADMM) to adaptively balance these components. Additionally, we establish the equivalence between the diffusion reverse step and the proximal operator of ADMM and provide a detailed convergence analysis of our algorithm under certain mild assumptions. Our experiments demonstrate that our proposed method \OurMethod consistently generates high-quality samples while ensuring strong adherence to the conditioning criteria. It outperforms existing methods across a range of conditional generation tasks, including image generation with various guidance and controllable motion synthesis.

On the Generalization of Handwritten Text Recognition Models
Carlos Garrido-Munoz, Jorge Calvo-Zaragoza; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 15275-15286
Recent advances in Handwritten Text Recognition (HTR) have led to significant reductions in transcription errors on standard benchmarks under the i.i.d. assumption, thus focusing on minimizing in-distribution (ID) errors.However, this assumption does not hold in real-world applications, which has motivated HTR research to explore Transfer Learning and Domain Adaptation techniques. In this work, we investigate the unaddressed limitations of HTR models in generalizing to out-of-distribution (OOD) data. We adopt the challenging setting of Domain Generalization, where models are expected to generalize to OOD data without any prior access. To this end, we analyze 336 OOD cases from eight state-of-the-art HTR models across seven widely used datasets, spanning five languages. Additionally, we study how HTR models leverage synthetic data to generalize. We reveal that the most significant factor for generalization lies in the textual divergence between domains, followed by visual divergence. We demonstrate that the error of HTR models in OOD scenarios can be reliably estimated, with discrepancies falling below 10 points in 70% of cases. We identify the underlying limitations of HTR models, laying the foundation for future research to address this challenge.
****

SwiftEdit: Lightning Fast Text-Guided Image Editing via One-Step Diffusion
Trong-Tung Nguyen, Quang Nguyen, Khoi Nguyen, Anh Tran, Cuong Pham; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 21492-21501
Recent advances in text-guided image editing enable users to perform image edits through simple text inputs, leveraging the extensive priors of multi-step diffusion-based text-to-image models. However, these methods often fall short of the speed demands required for real-world and on-device applications due to the costly multi-step inversion and sampling process involved. In response to this, we introduce SwiftEdit, a simple yet highly efficient editing tool that achieve instant text-guided image editing in 0.23s. The advancement of SwiftEdit lies in its two novel contributions: a one-step inversion framework that enables one-step image reconstruction via inversion and a mask-guided editing technique with our proposed attention rescaling mechanism to perform localized image editing. Extensive experiments are provided to demonstrate the effectiveness and efficiency of SwiftEdit. In particular, SwiftEdit enables instant text-guided image editing, which is extremely faster than previous multi-step methods (at least 50 times faster) while maintain a competitive performance in editing results. Our project is at https://swift-edit.github.io/.

Learning from Synchronization: Self-Supervised Uncalibrated Multi-View Person As

sociation in Challenging Scenes
Keqi Chen, Vinkle Srivastav, Didier Mutter, Nicolas Padoy; Proceedings of the Co mputer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 24419-24428
Multi-view person association is a fundamental step towards multi-view analysis of human activities. Although the person re-identification features have been pr oven effective, they become unreliable in challenging scenes where persons share similar appearances. Therefore, cross-view geometric constraints are required f or a more robust association. However, most existing approaches are either fully -supervised using ground-truth identity labels or require calibrated camera para meters that are hard to obtain. In this work, we investigate the potential of le arning from synchronization, and propose a self-supervised uncalibrated multi-vi ew person association approach, Self-MVA, without using any annotations. Specifi cally, we propose a self-supervised learning framework, consisting of an encoder -decoder model and a self-supervised pretext task, cross-view image synchronizat ion, which aims to distinguish whether two images from different views are captu red at the same time. The model encodes each person's unified geometric and appe arance features, and we train it by utilizing synchronization labels for supervi sion after applying Hungarian matching to bridge the gap between instance-wise a nd image-wise distances. To further reduce the solution space, we propose two t ypes of self-supervised linear constraints: multi-view re-projection and pairwis e edge association. Extensive experiments on three challenging public benchmark datasets (WILDTRACK, MVOR, and SOLDIERS) show that our approach achieves state-o f-the-art results, surpassing existing unsupervised and fully-supervised approac hes. Code is available at https://github.com/CAMMA-public/Self-MVA.

RC-AutoCalib: An End-to-End Radar-Camera Automatic Calibration Network
Van-Tin Luu, Yon-Lin Cai, Vu-Hoang Tran, Wei-Chen Chiu, Yi-Ting Chen, Ching-Chun Huang; Proceedings of the Computer Vision and Pattern Recognition Conference (C VPR), 2025, pp. 6700-6709
This paper presents a groundbreaking approach - the first online automatic geome tric calibration method for radar and camera systems. Given the significant data sparsity and measurement uncertainty in radar height data, achieving automatic calibration during system operation has long been a challenge. To address the sp arsity issue, we propose a Dual-Perspective representation that gathers features from both frontal and bird's-eye views. The frontal view contains rich but sens itive height information, whereas the bird's-eye view provides robust features a gainst height uncertainty. We thereby propose a novel Selective Fusion Mechanism to identify and fuse reliable features from both perspectives, reducing the eff ect of height uncertainty. Moreover, for each view, we incorporate a Multi-Modal Cross-Attention Mechanism to explicitly find location correspondences through c ross-modal matching. During the training phase, we also design a Noise-Resistant Matcher to provide better supervision and enhance the robustness of the matchin g mechanism against sparsity and height uncertainty. Our experimental results, t ested on the nuScenes dataset, demonstrate that our method significantly outperf orms previous radar-camera auto-calibration methods, as well as existing state-o f-the-art LiDAR-camera calibration techniques, establishing a new benchmark for future research.

Argus: A Compact and Versatile Foundation Model for Vision
Weiming Zhuang, Chen Chen, Zhizhong Li, Sina Sajadmanesh, Jingtao Li, Jiabo Huan g, Vikash Sehwag, Vivek Sharma, Hirotaka Shinozaki, Felan Carlo Garcia, Yihao Zh an, Naohiro Adachi, Ryoji Eki, Michael Spranger, Peter Stone, Lingjuan Lyu; Proc eedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 4418-4429
While existing vision and multi-modal foundation models can handle multiple comp uter vision tasks, they often suffer from significant limitations, including hug e demand for data and computational resources during training and inconsistent p erformance across vision tasks at deployment time. To address these challenges, we introduce Argus (The name comes from Argus Panoptes -- a hundred-eyed giant w ith "all-seeing" capability in Greek mythology), a compact and versatile vision

foundation model designed to support a wide range of vision tasks through a unified multitask architecture. Argus employs a two-stage training strategy: (i) multitask pretraining over core vision tasks with a shared backbone that includes a lightweight adapter to inject task-specific inductive biases, and (ii) scalable and efficient adaptation to new tasks by fine-tuning only the task-specific decoders. Extensive evaluations demonstrate that Argus, despite its relatively compact and training-efficient design of merely 100M backbone parameters (only 13.6% of which are trained using 1.6M images), competes with and even surpasses much larger models. Compared to state-of-the-art foundation models, Argus not only covers a broader set of vision tasks but also matches or outperforms the models with similar sizes on 12 tasks. We expect that Argus will accelerate the real-world adoption of vision foundation models in resource-constrained scenarios.

CLIP-driven Coarse-to-fine Semantic Guidance for Fine-grained Open-set Semi-supervised Learning
Xiaokun Li, Yaping Huang, Qingji Guan; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 30312-30321
Fine-grained open-set semi-supervised learning (OSSL) investigates a practical scenario where unlabeled data may contain fine-grained out-of-distribution (OOD) samples. Due to the subtle visual differences among in-distribution (ID) samples, as well as between ID and OOD samples, it is extremely challenging to separate the ID and OOD samples. Due to the subtle visual differences among in-distribution (ID) and OOD samples. Recent Vision-Language Models, such as CLIP, have shown excellent generalization capabilities. However, it tends to focus on general attributes, and thus is insufficient to distinguish the fine-grained details. To tackle the issues, in this paper, we propose a novel CLIP-driven coarse-to-fine semantic-guided framework, named CFSG-CLIP, to progressively focus on the distinctive fine-grained clues. Specifically, CFSG-CLIP comprises a coarse-guidance branch and a fine-guidance branch derived from the pre-trained CLIP model. In the coarse-guidance branch, we design a semantic filtering module to initially filter and highlight local visual features guided by cross-modality features. Then, in the fine-guidance branch, we further design a visual-semantic injection strategy, which embeds category-related visual cues into the visual encoder to further refine the local visual features. By the designed dual-guidance framework, local subtle cues are progressively discovered to distinct the subtle difference between ID and OOD samples. Extensive experiments demonstrate that CFSG-CLIP achieves competitive performance on multiple fine-grained datasets. The source code is available at https://github.com/LxxxxK/CFSG-CLIP.
****

InsTaG: Learning Personalized 3D Talking Head from Few-Second Video
Jiahe Li, Jiawei Zhang, Xiao Bai, Jin Zheng, Jun Zhou, Lin Gu; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 10690-10700
Despite exhibiting impressive performance in synthesizing lifelike personalized 3D talking heads, prevailing methods based on radiance fields suffer from high demands for training data and time for each new identity. This paper introduces InsTaG, a 3D talking head synthesis framework that allows a fast learning of realistic personalized 3D talking head from few training data. Built upon a lightweight 3DGS person-specific synthesizer with universal motion priors, InsTaG achieves high-quality and fast adaptation while preserving high-level personalization and efficiency. As preparation, we first propose an Identity-Free Pre-training strategy that enables the pre-training of the person-specific model and encourages the collection of universal motion priors from long-video data corpus. To fully exploit the universal motion priors to learn an unseen new identity, we then present a Motion-Aligned Adaptation strategy to adaptively align the target head to the pre-trained field, and constrain a robust dynamic head structure under few training data. Experiments demonstrate our outstanding performance and efficiency under various data scenarios to render high-quality personalized talking heads. Project page: https://fictionarry.github.io/InsTaG/.

Sampling Innovation-Based Adaptive Compressive Sensing
Zhifu Tian, Tao Hu, Chaoyang Niu, Di Wu, Shu Wang; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 2387-2397
Scene-aware Adaptive Compressive Sensing (ACS) has attracted significant interest due to its promising capability for efficient and high-fidelity acquisition of scene images. ACS typically prescribes adaptive sampling allocation (ASA) based on previous samples in the absence of ground truth. However, when confronting unknown scenes, existing ACS methods often lack accurate judgment and robust feedback mechanisms for ASA, thus limiting the high-fidelity sensing of the scene. In this paper, we introduce a Sampling Innovation-Based ACS (SIB-ACS) method that can effectively identify and allocate sampling to challenging image reconstruction areas, culminating in high-fidelity image reconstruction. An innovation criterion is proposed to judge ASA by predicting the decrease in image reconstruction error attributable to sampling increments, thereby directing more samples towards regions where the reconstruction error diminishes significantly. A sampling innovation-guided multi-stage adaptive sampling (AS) framework is proposed, which iteratively refines the ASA through a multi-stage feedback process. For image reconstruction, we propose a Principal Component Compressed Domain Network (PCCD-Net), which efficiently and faithfully reconstructs images under AS scenarios. Extensive experiments demonstrate that the proposed SIB-ACS method significantly outperforms the state-of-the-art methods in terms of image reconstruction fidelity and visual effects. Codes are available at https://github.com/giant-pandada/SIB-ACS_CVPR2025.

A Simple Data Augmentation for Feature Distribution Skewed Federated Learning
Yunlu Yan, Huazhu Fu, Yuexiang Li, Jinheng Xie, Jun Ma, Guang Yang, Lei Zhu; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 25749-25758
Federated Learning (FL) facilitates collaborative learning among multiple clients in a distributed manner and ensures the security of privacy. However, its performance inevitably degrades with non-Independent and Identically Distributed (non-IID) data. In this paper, we focus on the feature distribution skewed FL scenario, a common non-IID situation in real-world applications where data from different clients exhibit varying underlying distributions. This variation leads to feature shift, which is a key issue of this scenario. While previous works have made notable progress, few pay attention to the data itself, i.e., the root of this issue. The primary goal of this paper is to mitigate feature shift from the perspective of data. To this end, we propose a simple yet remarkably effective input-level data augmentation method, namely FedRDN, which randomly injects the statistical information of the local distribution from the entire federation into the client's data. This is beneficial to improve the generalization of local feature representations, thereby mitigating feature shift. Moreover, our FedRDN is a plug-and-play component, which can be seamlessly integrated into the data augmentation flow with only a few lines of code. Extensive experiments on several datasets show that the performance of various representative FL methods can be further improved by integrating our FedRDN, demonstrating its effectiveness, strong compatibility and generalizability. Code is available at https://github.com/IAMJackYan/FedRDN.

MotionBench: Benchmarking and Improving Fine-grained Video Motion Understanding for Vision Language Models
Wenyi Hong, Yean Cheng, Zhuoyi Yang, Weihan Wang, Lefan Wang, Xiaotao Gu, Shiyu Huang, Yuxiao Dong, Jie Tang; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 8450-8460
In the quest for artificial general intelligence, Multi-modal Large Language Models (MLLMs) have emerged as a focal point in recent advancements. However, the predominant focus remains on developing their capabilities in static image understanding. The potential of MLLMs in processing sequential visual data is still insufficiently explored, highlighting the absence of a comprehensive, high-quality assessment of their performance. In this paper, we introduce Video-MME, the fir

st-ever full-spectrum, Multi-Modal Evaluation benchmark of MLLMs in Video analysis. Our work distinguishes from existing benchmarks through four key features: 1) Diversity in video types, spanning 6 primary visual domains with 30 subfields to ensure broad scenario generalizability; 2) Duration in temporal dimension, encompassing both short-, medium-, and long-term videos, ranging from 11 seconds to 1 hour, for robust contextual dynamics; 3) Breadth in data modalities, integrating multi-modal inputs besides video frames, including sub- titles and audios, to unveil the all-round capabilities of MLLMs; 4) Quality in annotations, utilizing rigorous manual labeling by expert annotators to facilitate precise and reliable model assessment. 900 videos with a total of 254 hours are manually selected and annotated by repeatedly viewing all the video content, resulting in 2,700 question-answer pairs. With Video-MME, we extensively evaluate various state-of-the-art MLLMs, including GPT-4 series and Gemini 1.5 Pro, as well as open-source image models like InternVL-Chat-V1.5 and video models like LLaVA-NeXT-Video. Our experiments reveal that Gemini 1.5 Pro is the best-performing commercial model, significantly outperforming the open-source models with an average accuracy of 75%, compared to 71.9% for GPT-4o. The results also demonstrate that Video-MME is a universal benchmark, which applies to both image and video MLLMs. Further analysis indicates that subtitle and audio information could significantly enhance video understanding. Besides, a decline in MLLM performance is observed as video duration increases for all models. Our dataset along with these findings underscores the need for further improvements in handling longer sequences and multi-modal data, shedding light on future MLLM development. Benchmarking Large Vision-Language Models via Directed Scene Graph for Comprehensive Image Captioning

Fan Lu, Wei Wu, Kecheng Zheng, Shuailei Ma, Biao Gong, Jiawei Liu, Wei Zhai, Yang Cao, Yujun Shen, Zheng-Jun Zha; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 19618-19627

Generating detailed captions comprehending text-rich visual content in images has received growing attention for Large Vision-Language Models (LVLMs). However, few studies have developed benchmarks specifically tailored for detailed captions to measure their accuracy and comprehensiveness. In this paper, we introduce a detailed caption benchmark, termed as CompreCap, to evaluate the visual context from a directed scene graph view. Concretely, we first manually segment the image into semantically meaningful regions (i.e., semantic segmentation mask) according to common-object vocabulary, while also distinguishing attributes of objects within all those regions. Then directional relation labels of these objects are annotated to compose a directed scene graph that can well encode rich compositional information of the image. Based on our directed scene graph, we develop a pipeline to assess the generated detailed captions from LVLMs on multiple levels, including the object-level coverage, the accuracy of attribute descriptions, the score of key relationships, etc. Experimental results on the CompreCap dataset confirm that our evaluation method aligns closely with human evaluation scores across LVLMs. We will release the code and the dataset to support the community.

ART: Anonymous Region Transformer for Variable Multi-Layer Transparent Image Generation

Yifan Pu, Yiming Zhao, Zhicong Tang, Ruihong Yin, Haoxing Ye, Yuhui Yuan, Dong Chen, Jianmin Bao, Sirui Zhang, Yanbin Wang, Lin Liang, Lijuan Wang, Ji Li, Xiu Li, Zhouhui Lian, Gao Huang, Baining Guo; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 7952-7962

Multi-layer image generation is a fundamental task that enables users to isolate, select, and edit specific image layers, thereby revolutionizing interactions with generative models. In this paper, we introduce the Anonymous Region Transformer (ART), which facilitates the direct generation of variable multi-layer transparent images based on a global text prompt and an anonymous region layout. Inspired by Schema theory, this anonymous region layout allows the generative model

to autonomously determine which set of visual tokens should align with which tex
t tokens, which is in contrast to the previously dominant semantic layout for th
e image generation task. In addition, the layer-wise region crop mechanism, whic
h only selects the visual tokens belonging to each anonymous region, significant
ly reduces attention computation costs and enables the efficient generation of i
mages with numerous distinct layers (e.g., 50+). When compared to the full atten
tion approach, our method is over 12 times faster and exhibits fewer layer confl
icts. Furthermore, we propose a high-quality multi-layer transparent image autoe
ncoder that supports the direct encoding and decoding of the transparency of var
iable multi-layer images in a joint manner. By enabling precise control and scal
able layer generation, ART establishes a new paradigm for interactive content cr
eation.

Rotation-Equivariant Self-Supervised Method in Image Denoising
Hanze Liu, Jiahong Fu, Qi Xie, Deyu Meng; Proceedings of the Computer Vision and
 Pattern Recognition Conference (CVPR), 2025, pp. 12720-12730
Self-supervised image denoising methods have garnered significant research atten
tion in recent years, for this kind of method reduces the requirement of large t
raining datasets.Compared to supervised methods, self-supervised methods rely mo
re on the prior embedded in deep networks themselves. As a result, most of the s
elf-supervised methods are designed with Convolution Neural Networks(CNNs) archi
tectures, which well capture one of the most important image prior, translation
equivariant prior. Inspired by the great success achieved by the introduction of
 translational equivariance, in this paper, we explore the way to further incorp
orate another important image prior. Specifically, we first apply high-accuracy
rotation equivariant convolution to self-supervised image denoising. Through rig
orous theoretical analysis, we have proved that simply replacing all the convolu
tion layers with rotation equivariant convolution layers would modify the networ
k into its rotation equivariant version.To the best of our knowledge, this is th
e first time that rotation equivariant image prior is introduced to self-supervi
sed image denoising at the network architecture level with a comprehensive theor
etical analysis of equivariance errors, whichoffers a new perspective to the fie
ld of self-supervised image denoising.Moreover, to further improve the performan
ce, we design a new mask mechanism to fusion the output of rotation equivariant
network and vanilla CNN-based network, and construct an adaptive rotation equiva
riant framework. Through extensive experiments on three typical methods, we have
 demonstrated the effectiveness of the proposed method.

ArcPro: Architectural Programs for Structured 3D Abstraction of Sparse Points
Qirui Huang, Runze Zhang, Kangjun Liu, Minglun Gong, Hao Zhang, Hui Huang; Proce
edings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, p
p. 6563-6572
We introduce ArcPro, a novel learning framework built on architectural programs
to recover structured 3D abstractions from highly sparse and low-quality point c
louds. Specifically, we design a domain-specific language (DSL) to hierarchicall
y represent building structures as a program, which can be efficiently converted
 into a mesh. We bridge feedforward and inverse procedural modeling by using a f
eedforward process for training data synthesis, allowing the network to make rev
erse predictions. We train an encoder-decoder on the points-program pairs to est
ablish a mapping from unstructured point clouds to architectural programs, where
 a 3D convolutional encoder extracts point cloud features and a transformer deco
der autoregressively predicts the programs in a tokenized form. Inference by our
 method is highly efficient and produces plausible and faithful 3D abstractions.
 Comprehensive experiments demonstrate that ArcPro outperforms both traditional
architectural proxy reconstruction and learning-based abstraction methods. We fu
rther explore its potential when working with multi-view image and natural langu
age inputs.

GLane3D: Detecting Lanes with Graph of 3D Keypoints
Halil ■brahim Öztürk, Muhammet Esat Kalfao■lu, Ozsel Kilinc; Proceedings of the

Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 27508-27518
Accurate and efficient lane detection in 3D space is essential for autonomous driving systems, where robust generalization is the foremost requirement for 3D lane detection algorithms. Considering the extensive variation in lane structures worldwide, achieving high generalization capacity is particularly challenging, as algorithms must accurately identify a wide variety of lane patterns worldwide. Traditional top-down approaches rely heavily on learning lane characteristics from training datasets, often struggling with lanes exhibiting previously unseen attributes. To address this generalization limitation, we propose a method that detects keypoints of lanes and subsequently predicts sequential connections between them to construct complete 3D lanes. Each key point is essential for maintaining lane continuity, and we predict multiple proposals per keypoint by allowing adjacent grids to predict the same keypoint using an offset mechanism. PointNMS is employed to eliminate overlapping proposal keypoints, reducing redundancy in the estimated BEV graph and minimizing computational overhead from connection estimations. Our model surpasses previous state-of-the-art methods on both the Apollo and OpenLane datasets, demonstrating superior F1 scores and a strong generalization capacity when models trained on OpenLane are evaluated on the Apollo dataset, compared to prior approaches.
****

Minimal Interaction Seperated Tuning: A New Paradigm for Visual Adaptation
Ningyuan Tang, Minghao Fu, Jianxin Wu; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 25208-25217
The rapid scaling of large vision pretrained models makes fine-tuning tasks more and more difficult on devices with low computational resources. We explore a new visual adaptation paradigm called separated tuning, which treats large pretrained models as standalone feature extractors that run on powerful cloud servers. The fine-tuning carries out on devices which possess only low computational resources (slow CPU, no GPU, small memory, etc.) Existing methods that are potentially suitable for our separated tuning paradigm are discussed. But, three major drawbacks hinder their application in separated tuning: low adaptation capability, large adapter network, and in particular, high information transfer overhead. To address these issues, we propose Minimal Interaction Separated Tuning, or MIST, which reveals that the sum of intermediate features from pretrained models not only has minimal information transfer but also has high adaptation capability. With a lightweight attention-based adaptor network, MIST achieves information transfer efficiency, parameter efficiency, computational and memory efficiency, and at the same time demonstrates competitive results on various visual adaptation benchmarks.
****

Hardware-Rasterized Ray-Based Gaussian Splatting
Samuel Rota Bulò, Nemanja Bartolovic, Lorenzo Porzi, Peter Kontschieder; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 485-494
We present a novel, hardware-rasterized rendering approach for ray-based 3D Gaussian Splatting (RayGS), obtaining both fast and high-quality results for novel view synthesis. Our work contains a mathematically rigorous and geometrically intuitive derivation about how to efficiently estimate all relevant quantities for rendering RayGS models, structured with respect to standard hardware rasterization shaders. Our solution is the first enabling rendering RayGS models at sufficiently high frame rates to support quality-sensitive applications like Virtual and Mixed Reality. Our second contribution enables alias-free rendering for RayGS, by addressing MIP-related issues arising when rendering diverging scales during training and testing. We demonstrate significant performance gains, across different benchmark scenes, while retaining state-of-the-art appearance quality of RayGS.
****

FlashSloth : Lightning Multimodal Large Language Models via Embedded Visual Compression
Bo Tong, Bokai Lai, Yiyi Zhou, Gen Luo, Yunhang Shen, Ke Li, Xiaoshuai Sun, Rong

rong Ji; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 14570-14581
Despite a big leap forward in capability, multimodal large language models (MLLM s) tend to behave like a sloth in practical use, i.e., slow response and large l atency. Recent efforts are devoted to building tiny MLLMs for better efficiency, but the plethora of visual tokens still used limit their actual speedup. In thi s paper, we propose a powerful and fast tiny MLLM called FlashSloth. Different f rom previous efforts, FlashSloth focuses on improving the descriptive power of v isual tokens in the process of compressing their redundant semantics. In particu lar, FlashSloth introduces embedded visual compression designs to capture both v isually salient and instruction-related image information, so as to achieving su perior multimodal performance with fewer visual tokens. Extensive experiments ar e conducted to validate the proposed FlashSloth, and a bunch of tiny but strong MLLMs are also comprehensively compared, e.g., InternVL-2, MiniCPM-V2 and Qwen2- VL. The experimental results show that compared with these advanced tiny MLLMs, our FlashSloth can greatly reduce the number of visual tokens, training memory a nd computation complexity while retaining high performance on various VL tasks. Our code is released at: https://github.com/codefanw/FlashSloth.

FreqDebias: Towards Generalizable Deepfake Detection via Consistency-Driven Freq uency Debiasing
Hossein Kashiani, Niloufar Alipour Talemi, Fatemeh Afghah; Proceedings of the Co mputer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 8775-8785
Deepfake detectors often struggle to generalize to novel forgery types due to bi ases learned from limited training data. In this paper, we identify a new type o f model bias in the frequency domain, termed spectral bias, where detectors over ly rely on specific frequency bands, restricting their ability to generalize acr oss unseen forgeries. To address this, we propose FreqDebias, a frequency debias ing framework that mitigates spectral bias through two complementary strategies. First, we introduce a novel Forgery Mixup (Fo-Mixup) augmentation, which dynami cally diversifies frequency characteristics of training samples. Second, we inco rporate a dual consistency regularization (CR), which enforces both local consis tency using class activation maps (CAMs) and global consistency through a von Mi ses-Fisher (vMF) distribution on a hyperspherical embedding space. This dual CR mitigates over-reliance on certain frequency components by promoting consistent representation learning under both local and global supervision. Extensive exper iments show that FreqDebias significantly enhances cross-domain generalization a nd outperforms state-of-the-art methods in both cross-domain and in-domain setti ngs.

Multi-subject Open-set Personalization in Video Generation
Tsai-Shien Chen, Aliaksandr Siarohin, Willi Menapace, Yuwei Fang, Kwot Sin Lee, Ivan Skorokhodov, Kfir Aberman, Jun-Yan Zhu, Ming-Hsuan Yang, Sergey Tulyakov; P roceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 202 5, pp. 6099-6110
Video personalization methods allow us to synthesize videos with specific concep ts such as people, pets, and places. However, existing methods often focus on li mited domains, require time-consuming optimization per subject, or support only a single subject. We present Video Alchemist--a video model with built-in multi- subject, open-set personalization capabilities for both foreground objects and b ackground, eliminating the need for time-consuming test-time optimization. Our m odel is built on a new Diffusion Transformer module that fuses each conditional reference image and its corresponding subject-level text prompt with cross-atten tion layers. Developing such a large model presents two main challenges: dataset and evaluation. First, as paired datasets of reference images and videos are ex tremely hard to collect, we sample selected video frames as reference images and synthesize a clip of the target video. However, while models can easily denoise training videos given reference frames, they fail to generalize to new contexts . To mitigate this issue, we design a new automatic data construction pipeline w ith extensive image augmentations. Second, evaluating open-set video personaliza

tion is a challenge in itself. To address this, we introduce a personalization b enchmark that focuses on accurate subject fidelity and supports diverse personal ization scenarios. Finally, our extensive experiments show that our method signi ficantly outperforms existing personalization methods in both quantitative and q ualitative evaluations.

Wav2Sem: Plug-and-Play Audio Semantic Decoupling for 3D Speech-Driven Facial Ani mation
Hao Li, Ju Dai, Xin Zhao, Feng Zhou, Junjun Pan, Lei Li; Proceedings of the Comp uter Vision and Pattern Recognition Conference (CVPR), 2025, pp. 183-192
In 3D speech-driven facial animation generation, existing methods commonly emplo y pre-trained self-supervised audio models as encoders. However, due to the prev alence of phonetically similar syllables with distinct lip shapes in language, t hese near-homophone syllables tend to exhibit significant coupling in self-super vised audio feature spaces, leading to the averaging effect in subsequent lip mo tion generation. To address this issue, this paper proposes a plug-and-play sema ntic decorrelation module--Wav2Sem. This module extracts semantic features corre sponding to the entire audio sequence, leveraging the added semantic information to decorrelate audio encodings within the feature space, thereby achieving more expressive audio features. Extensive experiments across multiple Speech-driven models indicate that the Wav2Sem module effectively decouples audio features, si gnificantly alleviating the averaging effect of phonetically similar syllables i n lip shape generation, thereby enhancing the precision and naturalness of facia l animations. Our source code is available at https://github.com/wslh852/Wav2Sem .git.

Attraction Diminishing and Distributing for Few-Shot Class-Incremental Learning
Li-Jun Zhao, Zhen-Duo Chen, Yongxin Wang, Xin Luo, Xin-Shun Xu; Proceedings of t he Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 25657-25 666
Few-Shot Class-Incremental Learning (FSCIL) aims to continuously learn novel cla sses with limited samples after pre-training on a set of base classes. To avoid catastrophic forgetting and overfitting, most FSCIL methods first train the mode l on the base classes and then freeze the feature extractor in the incremental s essions. However, the reliance on nearest neighbor classification makes FSCIL pr one to the hubness phenomenon, which negatively impacts performance in this dyna mic and open scenario. While recent methods attempt to adapt to the dynamic and open nature of FSCIL, they are often limited to biased optimizations to the feat ure space. In this paper, we pioneer the theoretical analysis of the inherent hu bness in FSCIL. To mitigate the negative effects of hubness, we propose a novel Attraction Diminishing and Distributing (D2A) method from the essential perspect ives of distance metric and feature space. Extensive experimental results demons trate that our method can broadly and significantly improve the performance of e xisting methods.

4DTAM: Non-Rigid Tracking and Mapping via Dynamic Surface Gaussians
Hidenobu Matsuki, Gwangbin Bae, Andrew J. Davison; Proceedings of the Computer V ision and Pattern Recognition Conference (CVPR), 2025, pp. 26921-26932
We propose the first 4D tracking and mapping method that jointly performs camera localization and non-rigid surface reconstruction via differentiable rendering. Our approach captures 4D scenes from an online stream of color images with dept h measurements or predictions by simultaneously optimizing scene geometry, appea rance, dynamics, and camera ego-motion. Although natural environments exhibit co mplex non-rigid motions, 4D-SLAM remains relatively underexplored due to its inh erent challenges; even with 2.5D signals, the problem is ill-posed because of th e high dimensionality of the optimization space. To overcome these challenges, w e first introduce a SLAM method based on Gaussian surface primitives that levera ges depth signals more effectively than 3D Gaussians, thereby achieving accurate surface reconstruction. To further model non-rigid deformations, we employ a wa rp-field represented by a multi-layer perceptron (MLP) and introduce a novel cam

era pose estimation technique along with surface regularization terms that facil itate spatio-temporal reconstruction. In addition to these algorithmic challenge s, a significant hurdle in 4D-SLAM research is the lack of publicly available da tasets with reliable ground truth and evaluation protocols. To address this, we present a novel synthetic dataset of everyday objects with diverse motions, leve raging large-scale object models and animation modeling. In summary, we open up the modern 4D-SLAM research by introducing a novel method and evaluation protoco ls grounded in modern vision and rendering techniques.

T2SG: Traffic Topology Scene Graph for Topology Reasoning in Autonomous Driving
Changsheng Lv, Mengshi Qi, Liang Liu, Huadong Ma; Proceedings of the Computer Vi sion and Pattern Recognition Conference (CVPR), 2025, pp. 17197-17206
Understanding the traffic scenes and then generating high-definition (HD) maps p resent significant challenges in autonomous driving. In this paper, we defined a novel \underline T raffic \underline T opology \underline S cene \underline G raph (\text T ^2\text SG), a unified scene graph explicitly modeling the lane, controlled and guided by different road signals (e.g. , right turn), and topol ogy relationships among them, which is always ignored by previous high-definitio n (HD) mapping methods. For the generation of \text T ^2\text SG , we propose To poFormer, a novel one-stage \underline Topo logy Scene Graph Trans\underline Fo rmer with two newly-designed layers. Specifically, TopoFormer incorporates a L ane Aggregation Layer (LAL) that leverages the geometric distance among the cent erline of lanes to guide the aggregation of global information. Furthermore, we proposed a Counterfactual Intervention Layer (CIL) to model the reasonable road structure (e.g. , intersection, straight) among lanes under counterfactual inte rvention. Then the generated \text T ^2\text SG can provide a more accurate and explainable description of the topological structure in traffic scenes. Experim ental results demonstrate that TopoFormer outperforms existing methods on the \t ext T ^2\text SG generation task, and the generated \text T ^2\text SG signifi cantly enhances traffic topology reasoning in downstream tasks, achieving a stat e-of-the-art performance of 46.3 OLS on the OpenLane-V2 benchmark. Our source co de is available at https://github.com/MICLAB-BUPT/T2SG.

Unseen Visual Anomaly Generation
Han Sun, Yunkang Cao, Hao Dong, Olga Fink; Proceedings of the Computer Vision an d Pattern Recognition Conference (CVPR), 2025, pp. 25508-25517
Visual anomaly detection (AD) presents significant challenges due to the scarcit y of anomalous data samples. While numerous works have been proposed to synthesi ze anomalous samples, these synthetic anomalies often lack authenticity or requi re extensive training data, limiting their applicability in real-world scenarios . In this work, we propose Anomaly Anything (AnomalyAny), a novel framework that leverages Stable Diffusion (SD)'s image generation capabilities to generate div erse and realistic unseen anomalies. By conditioning on a single normal sample d uring test time, AnomalyAny is able to generate unseen anomalies for arbitrary o bject types with text descriptions. Within AnomalyAny, we propose attention-guid ed anomaly optimization to direct SD's attention on generating hard anomaly conc epts. Additionally, we introduce prompt-guided anomaly refinement, incorporating detailed descriptions to further improve the generation quality. Extensive expe riments on MVTec AD and VisA datasets demonstrate AnomalyAny's ability in genera ting high-quality unseen anomalies and its effectiveness in enhancing downstream AD performance. Our demo and code are available at https://hansunhayden.github. io/CUT.github.io.

T2ICount: Enhancing Cross-modal Understanding for Zero-Shot Counting
Yifei Qian, Zhongliang Guo, Bowen Deng, Chun Tong Lei, Shuai Zhao, Chun Pong Lau , Xiaopeng Hong, Michael P. Pound; Proceedings of the Computer Vision and Patter n Recognition Conference (CVPR), 2025, pp. 25336-25345
Zero-shot object counting aims to count instances of arbitrary object categories specified by text descriptions. Existing methods typically rely on vision-langu age models like CLIP, but often exhibit limited sensitivity to text prompts. We

present T2ICount, a diffusion-based framework that leverages rich prior knowledge and fine-grained visual understanding from pretrained diffusion models. While one-step denoising ensures efficiency, it leads to weakened text sensitivity. To address this challenge, we propose a Hierarchical Semantic Correction Module that progressively refines text-image feature alignment, and a Representational Regional Coherence Loss that provides reliable supervision signals by leveraging the cross-attention maps extracted from the denoising U-Net. Furthermore, we observe that current benchmarks mainly focus on majority objects in images, potentially masking models' text sensitivity. To address this, we contribute a challenging re-annotated subset of FSC147 for better evaluation of text-guided counting ability. Extensive experiments demonstrate that our method achieves superior performance across different benchmarks. Code is available at https://github.com/cha15yq/T2ICount

RealEdit: Reddit Edits As a Large-scale Empirical Dataset for Image Transformations

Peter Sushko, Ayana Bharadwaj, Zhi Yang Lim, Vasily Ilin, Ben Caffee, Dongping Chen, Mohammadreza Salehi, Cheng-Yu Hsieh, Ranjay Krishna; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 13403-13413

Existing image editing models struggle to meet realworld demands; despite excelling in academic benchmarks, we are yet to see them adopted to solve real user needs. The datasets that power these models use artificial edits, lacking the scale and ecological validity necessary to address the true diversity of user requests. In response, we introduce REALEDIT, a large-scale image editing dataset with authentic user requests and human-made edits sourced from Reddit. REALEDIT contains a test set of 9.3K examples the community can use to evaluate models on real user requests. Our results show that existing models fall short on these tasks, implying a need for realistic training data. So, we introduce 48K training examples, with which we train our REALEDIT model. Our model achieves substantial gains--outperforming competitors by up to 165 Elo points in human judgment and 92% relative improvement on the automated VIEScore metric on our test set. We deploy our model back on Reddit, testing it on new requests, and receive positive feedback. Beyond image editing, we explore REALEDIT 's potential in detecting edited images by partnering with a deepfake detection non-profit. Finetuning their model on REALEDIT data improves its F1-score by 14 percentage points, underscoring the dataset's value for broad, impactful applications.

VideoScene: Distilling Video Diffusion Model to Generate 3D Scenes in One Step

Hanyang Wang, Fangfu Liu, Jiawei Chi, Yueqi Duan; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 16475-16485

Recovering 3D scenes from sparse views is a challenging task due to its inherent ill-posed problem. Conventional methods have developed specialized solutions (e.g., geometry regularization or feed-forward deterministic model) to mitigate the issue. However, they still suffer from performance degradation by minimal overlap across input views with insufficient visual information. Fortunately, recent video generative models show promise in addressing this challenge as they are capable of generating video clips with plausible 3D structures. Powered by large pretrained video diffusion models, some pioneering research start to explore the potential of video generative prior and create 3D scenes from sparse views. Despite impressive improvements, they are limited by slow inference time and the lack of 3D constraint, leading to inefficiencies and reconstruction artifacts that do not align with real-world geometry structure. In this paper, we propose VideoScene to distill the video diffusion model to generate 3D scenes in one step, aiming to build an efficient and effective tool to bridge the gap from video to 3D. Specifically, we design a 3D-aware leap flow distillation strategy to leap over time-consuming redundant information and train a dynamic denoising policy network to adaptively determine the optimal leap timestep during inference. Extensive experiments demonstrate that our VideoScene achieves faster and superior 3D scene generation results than previous video diffusion models, highlighting its potential as an efficient tool for future video to 3D applications.

3D-HGS: 3D Half-Gaussian Splatting
Haolin Li, Jinyang Liu, Mario Sznaier, Octavia Camps; Proceedings of the Compute r Vision and Pattern Recognition Conference (CVPR), 2025, pp. 10996-11005
Photo-realistic image rendering from 3D scene reconstruction has advanced signif icantly with neural rendering techniques. Among these, 3D Gaussian Splatting (3D -GS) outperforms Neural Radiance Fields (NeRFs) in quality and speed but struggl es with shape and color discontinuities. We propose 3D Half-Gaussian (3D-HGS) ke rnels as a plug-and-play solution to address these limitations. Our experiments show that 3D-HGS enhances existing 3D-GS methods, achieving state-of-the-art ren dering quality without compromising speed. More demos and code are available at https://lihaolin88.github.io/CVPR-2025-3DHGS
****
FG^2: Fine-Grained Cross-View Localization by Fine-Grained Feature Matching
Zimin Xia, Alexandre Alahi; Proceedings of the Computer Vision and Pattern Recog nition Conference (CVPR), 2025, pp. 6362-6372
We propose a novel fine-grained cross-view localization method that estimates th e 3 Degrees of Freedom pose of a ground-level image in an aerial image of the su rroundings by matching fine-grained features between the two images. The pose is estimated by aligning a point plane generated from the ground image with a poin t plane sampled from the aerial image. To generate the ground points, we first m ap ground image features to a 3D point cloud. Our method then learns to select f eatures along the height dimension to pool the 3D points to a Bird's-Eye-View (B EV) plane. This selection enables us to trace which feature in the ground image contributes to the BEV representation. Next, we sample a set of sparse matches f rom computed point correspondences between the two point planes and compute thei r relative pose using Procrustes alignment. Compared to the previous state-of-th e-art, our method reduces the mean localization error by 28% on the VIGOR cross- area test set. Qualitative results show that our method learns semantically cons istent matches across ground and aerial views through weakly supervised learning from the camera pose.

ReNeg: Learning Negative Embedding with Reward Guidance
Xiaomin Li, Yixuan Liu, Takashi Isobe, Xu Jia, Qinpeng Cui, Dong Zhou, Dong Li, You He, Huchuan Lu, Zhongdao Wang, Emad Barsoum; Proceedings of the Computer Vis ion and Pattern Recognition Conference (CVPR), 2025, pp. 23636-23645
In text-to-image (T2I) generation applications, negative embeddings have proven to be a simple yet effective approach for enhancing generation quality. Typicall y, these negative embeddings are derived from user-defined negative prompts, whi ch, while being functional, are not necessarily optimal. In this paper, we intro duce ReNeg, an end-to-end method designed to learn improved Negative embeddings guided by a Reward model. We employ a reward feedback learning framework and int egrate classifier-free guidance (CFG) into the training process, which was previ ously utilized only during inference, thus enabling the effective learning of ne gative embeddings. We also propose two strategies for learning both global and p er-sample negative embeddings. Extensive experiments show that the learned negat ive embedding significantly outperforms null-text and handcrafted counterparts, achieving substantial improvements in human preference alignment. Additionally, the negative embedding learned within the same text embedding space exhibits str ong generalization capabilities. For example, using the same CLIP text encoder, the negative embedding learned on SD1.5 can be seamlessly transferred to text-to -image or even text-to-video models such as ControlNet, ZeroScope, and VideCraft er2, resulting in consistent performance improvements across the board. Code is available at https://github.com/AMD-AIG-AIMA/ReNeg.

Scale Efficient Training for Large Datasets
Qing Zhou, Junyu Gao, Qi Wang; Proceedings of the Computer Vision and Pattern Re cognition Conference (CVPR), 2025, pp. 20458-20467
The rapid growth of dataset scales has been a key driver in advancing deep learn ing research. However, as dataset scale increases, the training process becomes

increasingly inefficient due to the presence of low-value samples, including exc
essive redundant samples, overly challenging samples, and inefficient easy sampl
es that contribute little to model improvement. To address this challenge, we pr
opose Scale Efficient Training (SeTa) for large datasets, a dynamic sample pruni
ng approach that losslessly reduces training time. To remove low-value samples,
SeTa first performs random pruning to eliminate redundant samples, then clusters
 the remaining samples according to their learning difficulty measured by loss.
Building upon this clustering, a sliding window strategy is employed to progress
ively remove both overly challenging and inefficient easy clusters following an
easy-to-hard curriculum. We conduct extensive experiments on large-scale synthet
ic datasets, including ToCa, SS1M, and ST+MJ, each containing over 3 million sam
ples. SeTa reduces training costs by up to 50% while maintaining or improving pe
rformance, with minimal degradation even at 70% cost reduction. Furthermore, exp
eriments on various scale real datasets across various backbones (including CNNs
, Transformers, and Mambas) and diverse tasks (instruction tuning, multi-view st
ereo, geo-localization, composed image retrieval, referring image segmentation)
demonstrate the powerful effectiveness and universality of our approach. Code is
 available at https://github.com/mrazhou/SeTa.

Distilled Prompt Learning for Incomplete Multimodal Survival Prediction
Yingxue Xu, Fengtao Zhou, Chenyu Zhao, Yihui Wang, Can Yang, Hao Chen; Proceedin
gs of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 5
102-5111
The integration of multimodal data including pathology images and gene profiles
is widely applied in precise survival prediction. Despite recent advances in mul
timodal survival models, collecting complete modalities for multimodal fusion st
ill poses a significant challenge, hindering their application in clinical setti
ngs. Current approaches tackling incomplete modalities often fall short, as they
 typically compensate for only a limited part of the knowledge of missing modali
ties. To address this issue, we propose a Distilled Prompt Learning framework (D
isPro) to utilize the strong robustness of Large Language Models (LLMs) to missi
ng modalities, which employs two-stage prompting for compensation of comprehensi
ve information for missing modalities. In the first stage, Unimodal Prompting (U
niPro) distills the knowledge distribution of each modality, preparing for suppl
ementing modality-specific knowledge of the missing modality in the subsequent s
tage. In the second stage, Multimodal Prompting (MultiPro) leverages available m
odalities as prompts for LLMs to infer the missing modality, which provides moda
lity-common information. Simultaneously, the unimodal knowledge acquired in the
first stage is injected into multimodal inference to compensate for the modality
-specific knowledge of the missing modality. Extensive experiments covering vari
ous missing scenarios demonstrated the superiority of the proposed method. The c
ode is available at https://github.com/Innse/DisPro.

Decoder Gradient Shield: Provable and High-Fidelity Prevention of Gradient-Based
 Box-Free Watermark Removal
Haonan An, Guang Hua, Zhengru Fang, Guowen Xu, Susanto Rahardja, Yuguang Fang; P
roceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 202
5, pp. 13424-13433
The intellectual property of deep image-to-image models can be protected by the
so-called box-free watermarking. It uses an encoder and a decoder, respectively,
 to embed into and extract from the model's output images invisible copyright ma
rks. Prior works have improved watermark robustness, focusing on the design of b
etter watermark encoders. In this paper, we reveal an overlooked vulnerability o
f the unprotected watermark decoder which is jointly trained with the encoder an
d can be exploited to train a watermark removal network. To defend against such
an attack, we propose the decoder gradient shield (DGS) as a protection layer in
 the decoder API to prevent gradient-based watermark removal with a closed-form
solution. The fundamental idea is inspired by the classical adversarial attack,
but is utilized for the first time as a defensive mechanism in the box-free mode
l watermarking. We then demonstrate that DGS can reorient and rescale the gradie

nt directions of watermarked queries and stop the watermark remover's training l
oss from converging to the level without DGS, while retaining decoder output ima
ge quality. Experimental results verify the effectiveness of the proposed method
. Code of paper is available at https://github.com/haonanAN309/CVPR-2025-Officia
l-Implementation-Decoder-Gradient-Shield.

MotionPro: A Precise Motion Controller for Image-to-Video Generation
Zhongwei Zhang, Fuchen Long, Zhaofan Qiu, Yingwei Pan, Wu Liu, Ting Yao, Tao Mei
; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR),
2025, pp. 27957-27967
Animating images with interactive motion control has garnered popularity for ima
ge-to-video (I2V) generation. Modern approaches typically rely on large Gaussian
 kernels to extend motion trajectories as condition without explicitly defining
movement region, leading to coarse motion control and failing to disentangle obj
ect and camera moving. To alleviate these, we present MotionPro, a precise motio
n controller that novelly leverages region-wise trajectory and motion mask to re
gulate fine-grained motion synthesis and identify target motion category (i.e.,
object or camera moving), respectively. Technically, MotionPro first estimates t
he flow maps on each training video via a tracking model, and then samples the r
egion-wise trajectories to simulate inference scenario. Instead of extending flo
w through large Gaussian kernels, our region-wise trajectory approach enables mo
re precise control by directly utilizing trajectories within local regions, ther
eby effectively characterizing fine-grained movements. A motion mask is simultan
eously derived from the predicted flow maps to capture the holistic motion dynam
ics of the movement regions. To pursue natural motion control, MotionPro further
 strengthens video denoising by incorporating both region-wise trajectories and
motion mask through feature modulation. More remarkably, we meticulously constru
ct a benchmark, i.e., MC-Bench, with 1.1K user-annotated image-trajectory pairs,
 for the evaluation of both fine-grained and object-level I2V motion control. Ex
tensive experiments conducted on WebVid-10M and MC-Bench demonstrate the effecti
veness of MotionPro. Please refer to our project page for more results: https://
zhw-zhang.github.io/MotionPro-page/.

Goku: Flow Based Video Generative Foundation Models
Shoufa Chen, Chongjian Ge, Yuqi Zhang, Yida Zhang, Fengda Zhu, Hao Yang, Hongxia
ng Hao, Hui Wu, Zhichao Lai, Yifei Hu, Ting-Che Lin, Shilong Zhang, Fu Li, Chuan
 Li, Xing Wang, Yanghua Peng, Peize Sun, Ping Luo, Yi Jiang, Zehuan Yuan, Bingyu
e Peng, Xiaobing Liu; Proceedings of the Computer Vision and Pattern Recognition
 Conference (CVPR), 2025, pp. 23516-23527
This paper introduces Goku, a state-of-the-art family of joint image-and-video g
eneration models leveraging rectified flow Transformers to achieve industry-lead
ing performance. We detail the foundational elements enabling high-quality visua
l generation, including the data curation pipeline, model architecture design, f
low formulation, and advanced infrastructure for efficient and robust large-scal
e training. The Goku models demonstrate superior performance in both qualitative
 and quantitative evaluations, setting new benchmarks across major tasks. Specif
ically, Goku achieves 0.76 on GenEval and 83.65 on DPG-Bench for text-to-image g
eneration, and 84.85 on VBench for text-to-video tasks. We believe that this wor
k provides valuable insights and practical advancements for the research communi
ty in developing joint image-and-video generation models.

Learning Conditional Space-Time Prompt Distributions for Video Class-Incremental
 Learning
Xiaohan Zou, Wenchao Ma, Shu Zhao; Proceedings of the Computer Vision and Patter
n Recognition Conference (CVPR), 2025, pp. 4862-4873
Recent advancements in prompt-based learning have significantly advanced image a
nd video class-incremental learning. However, the prompts learned by these metho
ds often fail to capture the diverse and informative characteristics of videos,
and struggle to generalize effectively to future tasks and classes. To address t
hese challenges, this paper proposes modeling the distribution of space-time pro

mpts conditioned on the input video using a diffusion model. This generative app
roach allows the proposed model to naturally handle the diverse characteristics
of videos, leading to more robust prompt learning and enhanced generalization ca
pabilities. Additionally, we develop a simple yet effective mechanism to transfe
r the token relationship modeling capabilities of pre-trained image transformers
 to spatio-temporal modeling in videos. Our approach has been thoroughly evaluat
ed across four established benchmarks, showing remarkable improvements over exis
ting state-of-the-art methods in video class-incremental learning.
****

Convex Combination Star Shape Prior for Data-driven Image Semantic Segmentation
Xinyu Zhao, Jun Xie, Shengzhe Chen, Jun Liu; Proceedings of the Computer Vision
and Pattern Recognition Conference (CVPR), 2025, pp. 14068-14077
Multi-center star shape is a prevalent object shape feature, which has proven ef
fective in model-based image segmentation methods. However, the shape field func
tion induced by the multi-center star shape is non-smooth, and directly applying
 it to the data-driven image segmentation network architecture design may lead t
o instability in backpropagation. This paper proposes a convex combination star
(CCS) shape, possessing multi-center star shape properties, and has the advantag
e of effectively controlling the shape of the region through a smooth field func
tion. The sufficient condition of the proposed CCS shape can be combined into th
e image segmentation neural network structure design through the bridge between
the variational segmentation model and the activation function of the data-drive
n method. Taking Segment Anything Model (SAM) and its improved version as backbo
ne networks, we have shown that the segmentation network architecture with CCS s
hape properties can greatly improve the accuracy of segmentation results.

Hyperbolic Safety-Aware Vision-Language Models
Tobia Poppi, Tejaswi Kasarla, Pascal Mettes, Lorenzo Baraldi, Rita Cucchiara; Pr
oceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025
, pp. 4222-4232
Addressing the retrieval of unsafe content from vision-language models such as C
LIP is an important step towards real-world integration. Current efforts have re
lied on unlearning techniques that try to erase the model's knowledge of unsafe
concepts. While effective in reducing unwanted outputs, unlearning limits the mo
del's capacity to discern between safe and unsafe content. In this work, we intr
oduce a novel approach that shifts from unlearning to an awareness paradigm by l
everaging the inherent hierarchical properties of the hyperbolic space. We propo
se to encode safe and unsafe content as an entailment hierarchy, where both are
placed in different regions of hyperbolic space. Our HySAC, Hyperbolic Safety-Aw
are CLIP, employs entailment loss functions to model the hierarchical and asymme
trical relations between safe and unsafe image-text pairs. This modelling - inef
fective in standard vision-language models due to their reliance on Euclidean em
beddings - endows the model with awareness of unsafe content, enabling it to ser
ve as both a multimodal unsafe classifier and a flexible content retriever, with
 the option to dynamically redirect unsafe queries toward safer alternatives or
retain the original output. Extensive experiments show that our approach not onl
y enhances safety recognition, but also establishes a more adaptable and interpr
etable framework for content moderation in vision-language models. Our source co
de is available at: https://github.com/aimagelab/HySAC

WISH: Weakly Supervised Instance Segmentation using Heterogeneous Labels
Hyeokjun Kweon, Kuk-Jin Yoon; Proceedings of the Computer Vision and Pattern Rec
ognition Conference (CVPR), 2025, pp. 25377-25387
Instance segmentation traditionally relies on dense pixel-level annotations, mak
ing it costly and labor-intensive. To alleviate this burden, weakly supervised i
nstance segmentation utilizes cost-effective weak labels, such as image-level ta
gs, points, and bounding boxes. However, existing approaches typically focus on
a single type of weak label, overlooking the cost-efficiency potential of combin
ing multiple types. In this paper, we introduce WISH, a novel heterogeneous fram
ework for weakly supervised instance segmentation that integrates diverse weak l

abel types within a single model. WISH unifies heterogeneous labels by leveragin g SAM's prompt latent space through a multi-stage matching strategy, effectively compensating for the lack of spatial information in class tags. Extensive exper iments on Pascal VOC and COCO demonstrate that our framework not only surpasses existing homogeneous weak supervision methods but also achieves superior results in heterogeneous settings with equivalent annotation costs.

SinGS: Animatable Single-Image Human Gaussian Splats with Kinematic Priors
Yufan Wu, Xuanhong Chen, Wen Li, Shunran Jia, Hualiang Wei, Kairui Feng, Jialian g Chen, Yuhan Li, Ang He, Weimin Zhang, Bingbing Ni, Wenjun Zhang; Proceedings o f the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 5571-5580
Despite significant advances in accurately estimating geometry in contemporary s ingle-image 3D human reconstruction, creating a high-quality, efficient, and ani matable 3D avatar remains an open challenge. Two key obstacles persist: incompl ete observation and inconsistent 3D priors. To address these challenges, we prop ose SinGS, aiming to achieve high-quality and efficient animatable 3D avatar rec onstruction. At the heart of SinGS are two key components: Kinematic Human Diffu sion and Geometry-Preserving 3D Gaussain Splatting. The former is a foundational human model that samples within pose space to generate a highly 3D-consistent a nd high-quality sequence of human images, inferring unseen viewpoints and provid ing kinematic priors. The latter is a system that reconstructs a compact, high-quality 3D avatar even under imperfect priors, achieved through a novel semantic Laplacian regularization and a geometry-preserving density control strategy tha t enable precise and compact assembly of 3D primitives. Extensive experiments de monstrate that SinGS enables lifelike, animatable human reconstructions, maintai ning both high quality and inference efficiency (up to 70FPS).

Parameter-efficient Fine-tuning in Hyperspherical Space for Open-vocabulary Sema ntic Segmentation
Zelin Peng, Zhengqin Xu, Zhilin Zeng, Yu Huang, Yaoming Wang, Wei Shen; Proceedi ngs of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 15009-15020
Open-vocabulary semantic segmentation seeks to label each pixel in an image with arbitrary text descriptions. Vision-language foundation models, especially CLIP , have recently emerged as powerful tools for acquiring open-vocabulary capabili ties. However, fine-tuning CLIP to equip it with pixel-level prediction ability often suffers three issues: 1) high computational cost, 2) misalignment between the two inherent modalities of CLIP, and 3) degraded generalization ability on u nseen categories. To address these issues, we propose \alg, a symmetrical parame ter-efficient fine-tuning (PEFT) strategy conducted in hyperspherical space for both of the two CLIP modalities. Specifically, the PEFT strategy is achieved by a series of efficient block-diagonal learnable transformation matrices and a dua l cross-relation communication module among all learnable matrices. Since the PE FT strategy is conducted symmetrically to the two CLIP modalities, the misalignm ent between them is mitigated. Furthermore, we apply an additional constraint to PEFT on the CLIP text encoder according to the hyperspherical energy principle, i.e., minimizing hyperspherical energy during fine-tuning preserves the intrins ic structure of the original parameter space, to prevent the destruction of the generalization ability offered by the CLIP text encoder. Extensive evaluations a cross various benchmarks show that H-CLIP achieves new SOTA open-vocabulary sema ntic segmentation results while only requiring updating approximately 4% of the total parameters of CLIP.

Relative Pose Estimation through Affine Corrections of Monocular Depth Priors
Yifan Yu, Shaohui Liu, Rémi Pautrat, Marc Pollefeys, Viktor Larsson; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 167 06-16716
Monocular depth estimation (MDE) models have undergone significant advancements over recent years. Many MDE models aim to predict affine-invariant relative dept

h from monocular images, while recent developments in large-scale training and v
ision foundation models enable reasonable estimation of metric (absolute) depth.
 However, effectively leveraging these predictions for geometric vision tasks, i
n particular relative pose estimation, remains relatively under explored. While
depths provide rich constraints for cross-view image alignment, the intrinsic no
ise and ambiguity from the monocular depth priors present practical challenges t
o improving upon classic keypoint-based solutions. In this paper, we develop thr
ee solvers for relative pose estimation that explicitly account for independent
affine (scale and shift) ambiguities, covering both calibrated and uncalibrated
conditions. We further propose a hybrid estimation pipeline that combines our pr
oposed solvers with classic point-based solvers and epipolar constraints. We fin
d that the affine correction modeling is beneficial to not only the relative dep
th priors but also, surprisingly, the "metric" ones. Results across multiple dat
asets demonstrate large improvements of our approach over classic keypoint-based
 baselines and PnP-based solutions, under both calibrated and uncalibrated setup
s. We also show that our method improves consistently with different feature mat
chers and MDE models, and can further benefit from very recent advances on both
modules.

Zero-1-to-A: Zero-Shot One Image to Animatable Head Avatars Using Video Diffusio
n

Zhenglin Zhou, Fan Ma, Hehe Fan, Tat-Seng Chua; Proceedings of the Computer Visi
on and Pattern Recognition Conference (CVPR), 2025, pp. 15941-15952

Animatable head avatar generation typically requires extensive data for training
. To reduce the data requirements, a natural solution is to leverage existing da
ta-free static avatar generation methods, such as pre-trained diffusion models w
ith score distillation sampling (SDS), which align avatars with pseudo ground-tr
uth outputs from the diffusion model. However, directly distilling 4D avatars fr
om video diffusion often leads to over-smooth results due to spatial and tempora
l inconsistencies in the generated video. To address this issue, we propose Zero
-1-to-A, a robust method that synthesizes a spatial and temporal consistency dat
aset for 4D avatar reconstruction using the video diffusion model. Specifically,
 Zero-1-to-A iteratively constructs video datasets and optimizes animatable avat
ars in a progressive manner, ensuring that avatar quality increases smoothly and
 consistently throughout the learning process. This progressive learning involve
s two stages: (1) Spatial Consistency Learning fixes expressions and learns from
 front-to-side views, and (2) Temporal Consistency Learning fixes views and lear
ns from relaxed to exaggerated expressions, generating 4D avatars in a simple-to
-complex manner. Extensive experiments demonstrate that Zero-1-to-A improves fid
elity, animation quality, and rendering speed compared to existing diffusion-bas
ed methods, providing a solution for lifelike avatar creation. Code is publicly
available at: https://github.com/ZhenglinZhou/Zero-1-to-A.

Occlusion-aware Text-Image-Point Cloud Pretraining for Open-World 3D Object Reco
gnition

Khanh Nguyen, Ghulam Mubashar Hassan, Ajmal Mian; Proceedings of the Computer Vi
sion and Pattern Recognition Conference (CVPR), 2025, pp. 16965-16975

Recent open-world representation learning approaches have leveraged CLIP to enab
le zero-shot 3D object recognition. However, performance on real point clouds wi
th occlusions still falls short due to unrealistic pretraining settings. Additio
nally, these methods incur high inference costs because they rely on Transformer
's attention modules. In this paper, we make two contributions to address these
limitations. First, we propose occlusion-aware text-image-point cloud pretrainin
g to reduce the training-testing domain gap. From 52K synthetic 3D objects, our
framework generates nearly 630K partial point clouds for pretraining, consistent
ly improving real-world recognition performances of existing popular 3D networks
. Second, to reduce computational requirements, we introduce DuoMamba, a two-str
eam linear state space model tailored for point clouds. By integrating two space
-filling curves with 1D convolutions, DuoMamba effectively models spatial depend
encies between point tokens, offering a powerful alternative to Transformer. Whe

n pretrained with our framework, DuoMamba surpasses current state-of-the-art met
hods while reducing latency and FLOPs, highlighting the potential of our approac
h for real-world applications. Our code and data are available at ndkhanh360.git
hub.io/project_occtip.

Conical Visual Concentration for Efficient Large Vision-Language Models
Long Xing, Qidong Huang, Xiaoyi Dong, Jiajie Lu, Pan Zhang, Yuhang Zang, Yuhang
Cao, Conghui He, Jiaqi Wang, Feng Wu, Dahua Lin; Proceedings of the Computer Vis
ion and Pattern Recognition Conference (CVPR), 2025, pp. 14593-14603
In large vision-language models (LVLMs), images serve as inputs that carry a wea
lth of information. As the idiom "A picture is worth a thousand words" implies,
representing a single image in current LVLMs can require hundreds or even thousa
nds of tokens. This results in significant computational costs, which grow quadr
atically as input image resolution increases, thereby severely impacting the eff
iciency. Previous approaches have attempted to reduce the number of image tokens
 either before or within the early layers of LVLMs. However, these strategies in
evitably result in the loss of crucial image information. To address this challe
nge, we conduct an empirical study revealing that all visual tokens are necessar
y for LVLMs in the shallow layers, and token redundancy progressively increases
in the deeper layers.To this end, we propose ViCo, a conical-style visual concen
tration strategy for LVLMs to boost their efficiency in both training and infere
nce with neglectable performance loss. Specifically, we partition the LVLM into
several stages and drop part of the image tokens at the end of each stage with a
 pre-defined ratio. The dropping is based on a lightweight similarity calculatio
n with a negligible time overhead. Extensive experiments demonstrate that ViCo c
an achieve over 40% training time reduction and 55% inference FLOPs acceleration
 on leading LVLMs like LLaVA-NeXT, maintaining comparable multi-modal performanc
e. Besides, ViCo can also serve as a plug-and-play strategy to accelerate infere
nce in a free way, with better performance and lower inference cost than counter
parts.
****

Good, Cheap, and Fast: Overfitted Image Compression with Wasserstein Distortion
Jona Ballé, Luca Versari, Emilien Dupont, Hyunjik Kim, Matthias Bauer; Proceedin
gs of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 2
3259-23268
Inspired by the success of generative image models, recent work on learned image
 compression increasingly focuses on better probabilistic models of the natural
image distribution, leading to excellent image quality. This, however, comes at
the expense of a computational complexity that is several orders of magnitude hi
gher than today's commercial codecs, and thus prohibitive for most practical app
lications. With this paper, we demonstrate that by focusing on modeling visual p
erception rather than the data distribution, we can achieve a very good trade-of
f between visual quality and bit rate similar to "generative" compression models
 such as HiFiC, while requiring less than 1% of the multiply-accumulate operatio
ns (MACs) for decompression. We do this by optimizing C3, an overfitted image co
dec, for Wasserstein Distortion (WD), and evaluating the image reconstructions w
ith a human rater study, showing that WD clearly outperforms LPIPS as an optimiz
ation objective. The study also reveals that WD outperforms other perceptual met
rics such as LPIPS, DISTS, and MS-SSIM as a predictor of human ratings, remarkab
ly achieving over 94% Pearson correlation with Elo scores.

Period-LLM: Extending the Periodic Capability of Multimodal Large Language Model
Yuting Zhang, Hao Lu, Qingyong Hu, Yin Wang, Kaishen Yuan, Xin Liu, Kaishun Wu;
Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 20
25, pp. 29237-29247
Periodic or quasi-periodic phenomena reveal intrinsic characteristics in various
 natural processes, such as weather patterns, movement behaviors, traffic flows,
 and biological signals. Given that these phenomena span multiple modalities, th
e capabilities of Multimodal Large Language Models (MLLMs) offer promising poten
tial to effectively capture and understand their complex nature. However, curren

t MLLMs struggle with periodic tasks due to limitations in: 1) lack of temporal modelling and 2) conflict between short and long periods. This paper introduces Period-LLM, a multimodal large language model designed to enhance the performance of periodic tasks across various modalities, and constructs a benchmark of various difficulty for evaluating the cross-modal periodic capabilities of large models. Specially, We adopt an "Easy to Hard Generalization" paradigm, starting with relatively simple text-based tasks and progressing to more complex visual and multimodal tasks, ensuring that the model gradually builds robust periodic reasoning capabilities. Additionally, we propose a "Resisting Logical Oblivion" optimization strategy to maintain periodic reasoning abilities during semantic alignment. Extensive experiments demonstrate the superiority of the proposed Period-LLM over existing MLLMs in periodic tasks. The code is available at https://github.com/keke-nice/Period-LLM.

V2X-R: Cooperative LiDAR-4D Radar Fusion with Denoising Diffusion for 3D Object Detection

Xun Huang, Jinlong Wang, Qiming Xia, Siheng Chen, Bisheng Yang, Xin Li, Cheng Wang, Chenglu Wen; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 27390-27400

Current Vehicle-to-Everything (V2X) systems have significantly enhanced 3D object detection using LiDAR and camera data. However, they face performance degradation in adverse weather. Weather-robust 4D radar, with Doppler velocity and additional geometric information, offers a promising solution to this challenge. To this end, we present V2X-R, the first simulated V2X dataset incorporating LiDAR, camera, and 4D radar modalities. V2X-R contains 12,079 scenarios with 37,727 frames of LiDAR and 4D radar point clouds, 150,908 images, and 170,859 annotated 3D vehicle bounding boxes. Subsequently, we propose a novel cooperative LiDAR-4D radar fusion pipeline for 3D object detection and implement it with multiple fusion strategies. To achieve weather-robust detection, we additionally propose a Multi-modal Denoising Diffusion (MDD) module in our fusion pipeline. MDD utilizes weather-robust 4D radar feature as a condition to guide the diffusion model in denoising noisy LiDAR features.Experiments show that our LiDAR-4D radar fusion pipeline demonstrates superior performance in the V2X-R dataset. Over and above this, our MDD module further improved the foggy/snowy performance of the basic fusion model by up to 5.73%/6.70% and barely disrupting normal performance. The dataset and code will be publicly available.

Multi-Modal Synergistic Implicit Image Enhancement for Efficient Optical Flow Estimation

Weichen Dai, Hexing Wu, Xiaoyang Weng, Yuxin Zheng, Yuhang Ming, Wanzeng Kong; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 2173-2182

As a fundamental visual task, optical flow estimation has widespread applications in computer vision. However, it faces significant challenges under adverse lighting conditions, where low texture and noise make accurate optical flow estimation particularly difficult.In this paper, we propose an optical flow method that employs implicit image enhancement through multi-modal synergistic training. To supplement the scene information missing in the original low-quality image, we utilize a high-low frequency feature enhancement network. The enhancement network is implicitly guided by multi-modal data and the specific subsequent tasks, enabling the model to learn multi-modal knowledge that enhances feature information suitable for optical flow estimation during inference. By using RGBD multi-modal data, the proposed method avoids the reliance on the images captured from the same view, a common limitation in traditional image enhancement methods.During training, the encoded features extracted from the enhanced images are synergistically supervised by features from the RGBD fusion as well as by the optical flow task.Experiments conducted on both synthetic and real datasets demonstrate that the proposed method significantly improves performance on public datasets.

TAROT: Towards Essentially Domain-Invariant Robustness with Theoretical Justific

ation
Dongyoon Yang, Jihu Lee, Yongdai Kim; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 25780-25789
Robust domain adaptation against adversarial attacks is a critical research area that aims to develop models capable of maintaining consistent performance across diverse and challenging domains. In this paper, we derive a new generalization bound for robust risk on the target domain using a novel divergence measure specifically designed for robust domain adaptation. Building upon this, we propose a new algorithm named TAROT, which is designed to enhance both domain adaptability and robustness. Through extensive experiments, TAROT not only surpasses state-of-the-art methods in accuracy and robustness but also significantly enhances domain generalization and scalability by effectively learning domain-invariant features. In particular, TAROT achieves superior performance on the challenging DomainNet dataset, demonstrating its ability to learn domain-invariant representations that generalize well across different domains, including unseen ones. These results highlight the broader applicability of our approach in real-world domain adaptation scenarios.

Foundations of the Theory of Performance-Based Ranking
Sébastien Piérard, Anaïs Halin, Anthony Cioppa, Adrien Deliege, Marc Van Droogenbroeck; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 14293-14302
Ranking entities such as algorithms, devices, methods, or models based on their performances, while accounting for application-specific preferences, is a challenge. To address this challenge, we establish the foundations of a universal theory for performance-based ranking. First, we introduce a rigorous framework built on top of both the probability and order theories. Our new framework encompasses the elements necessary to (1) manipulate performances as mathematical objects, (2) express which performances are worse than or equivalent to others, (3) model tasks through a variable called satisfaction, (4) consider properties of the evaluation, (5) define scores, and (6) specify application-specific preferences through a variable called importance. On top of this framework, we propose the first axiomatic definition of performance orderings and performance-based rankings. Then, we introduce a universal parametric family of scores, called ranking scores, that can be used to establish rankings satisfying our axioms, while considering application-specific preferences. Finally, we show, in the case of two-class classification, that the family of ranking scores encompasses well-known performance scores, including the accuracy, the true positive rate (recall, sensitivity), the true negative rate (specificity), the positive predictive value (precision), and F1. However, we also show that some other scores commonly used to compare classifiers are unsuitable to derive performance orderings satisfying the axioms.

Unveiling the Mist over 3D Vision-Language Understanding: Object-centric Evaluation with Chain-of-Analysis
Jiangyong Huang, Baoxiong Jia, Yan Wang, Ziyu Zhu, Xiongkun Linghu, Qing Li, Song-Chun Zhu, Siyuan Huang; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 24570-24581
Existing 3D vision-language (3D-VL) benchmarks fall short in evaluating 3D-VL models, creating a "mist" that obscures rigorous insights into model capabilities and 3D-VL tasks. This mist persists due to three key limitations. First, flawed test data, like ambiguous referential text in the grounding task, can yield incorrect and unreliable test results. Second, oversimplified metrics such as simply averaging accuracy per question answering (QA) pair, cannot reveal true model capability due to their vulnerability to language variations. Third, existing benchmarks isolate the grounding and QA tasks, disregarding the underlying coherence that QA should be based on solid grounding capabilities. To unveil the "mist", we propose Beacon3D, a benchmark for 3D-VL grounding and QA tasks, delivering a perspective shift in the evaluation of 3D-VL understanding. Beacon3D features (i) high-quality test data with precise and natural language, (ii) object-centric

evaluation with multiple tests per object to ensure robustness, and (iii) a novel chain-of-analysis paradigm to address language robustness and model performance coherence across grounding and QA. Our evaluation of state-of-the-art 3D-VL models on Beacon3D reveals that (i) object-centric evaluation elicits true model performance and particularly weak generalization in QA; (ii) grounding-QA coherence remains fragile in current 3D-VL models, and (iii) incorporating large language models (LLMs) to 3D-VL models, though as a prevalent practice, hinders grounding capabilities and has yet to elevate QA capabilities. We hope Beacon3D and our comprehensive analysis could benefit the 3D-VL community towards faithful developments.

Generating Multimodal Driving Scenes via Next-Scene Prediction

Yanhao Wu, Haoyang Zhang, Tianwei Lin, Lichao Huang, Shujie Luo, Rui Wu, Congpei Qiu, Wei Ke, Tong Zhang; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 6844-6853

Generative models in Autonomous Driving (AD) enable diverse scenario creation, yet existing methods fall short by only capturing a limited range of modalities, restricting the capability of generating controllable scenes for comprehensive evaluation of AD systems. In this paper, we introduce a multimodal generation framework that incorporates four major data modalities, including a novel addition of the map modality. With tokenized modalities, our scene sequence generation framework autoregressively predicts each scene while managing computational demands through a two-stage approach. The Temporal AutoRegressive (TAR) component captures inter-frame dynamics for each modality, while the Ordered AutoRegressive (OAR) component aligns modalities within each scene by sequentially predicting tokens in a fixed order. To maintain coherence between map and ego-action modalities, we introduce the Action-aware Map Alignment (AMA) module, which applies a transformation based on the ego-action to maintain coherence between these two modalities. Our framework effectively generates complex, realistic driving scenes over extended sequences, ensuring multimodal consistency and offering fine-grained control over scene elements. Project page: https://yanhaowu.github.io/UMGen/

BIGS: Bimanual Category-agnostic Interaction Reconstruction from Monocular Videos via 3D Gaussian Splatting

Jeongwan On, Kyeonghwan Gwak, Gunyoung Kang, Junuk Cha, Soohyun Hwang, Hyein Hwang, Seungryul Baek; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 17437-17447

Reconstructing 3Ds of hand-object interaction (HOI) is a fundamental problem that can find numerous applications. Despite recent advances, there is no comprehensive pipeline yet for bimanual class-agnostic interaction reconstruction from a monocular RGB video, where two hands and an unknown object are interacting with each other. Previous works tackled the limited hand-object interaction case, where object templates are pre-known or only one hand is involved in the interaction. The bimanual interaction reconstruction exhibits severe occlusions introduced by complex interactions between two hands and an object. To solve this, we first introduce BIGS (Bimanual Interaction 3D Gaussian Splatting), a method that reconstructs 3D Gaussians of hands and an unknown object from a monocular video. To robustly obtain object Gaussians avoiding severe occlusions, we leverage prior knowledge of pre-trained diffusion model with score distillation sampling (SDS) loss, to reconstruct unseen object parts. For hand Gaussians, we exploit the 3D priors of hand model (i.e., MANO) and share a single Gaussian for two hands to effectively accumulate hand 3D information, given limited views. To further consider the 3D alignment between hands and objects, we include the interacting-subjects optimization step during Gaussian optimization. Our method achieves the state-of-the-art accuracy on two challenging datasets, in terms of 3D hand pose estimation (MPJPE), 3D object reconstruction (CDh, CDo, F10), and rendering quality (PSNR, SSIM, LPIPS), respectively.

APT: Adaptive Personalized Training for Diffusion Models with Limited Data

JungWoo Chae, Jiyoon Kim, JaeWoong Choi, Kyungyul Kim, Sangheum Hwang; Proceedin

gs of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 28619-28628
Personalizing diffusion models using limited data presents significant challenges, including overfitting, loss of prior knowledge, and degradation of text alignment. Overfitting leads to shifts in the noise prediction distribution, disrupting the denoising trajectory and causing the model to lose semantic coherence. In this paper, we propose Adaptive Personalized Training, a novel framework that mitigates overfitting by employing adaptive training strategies and regularizing the model's internal representations during fine-tuning. APT consists of three key components: (1) Adaptive Training Adjustment, which introduces an overfitting indicator to detect the degree of overfitting at each time step bin and applies adaptive data augmentation and adaptive loss weighting based on this indicator; (2)Representation Stabilization, which regularizes the mean and variance of intermediate feature maps to prevent excessive shifts in noise prediction; and (3) Attention Alignment for Prior Knowledge Preservation, which aligns the cross-attention maps of the fine-tuned model with those of the pretrained model to maintain prior knowledge and semantic coherence. Through extensive experiments, we demonstrate that APT effectively mitigates overfitting, preserves prior knowledge, and outperforms existing methods in generating high-quality, diverse images with limited reference data.

Symmetry Strikes Back: From Single-Image Symmetry Detection to 3D Generation
Xiang Li, Zixuan Huang, Anh Thai, James M. Rehg; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 743-752
Symmetry is a ubiquitous and fundamental property in the visual world, serving as a critical cue for perception and structure interpretation. This paper investigates the detection of 3D reflection symmetry from a single RGB image, and reveals its significant benefit on single-image 3D generation. We introduce Reflect3D, a scalable, zero-shot symmetry detector capable of robust generalization to diverse and real-world scenarios. Inspired by the success of foundation models, our method scales up symmetry detection with a transformer-based architecture. We also leverage generative priors from multi-view diffusion models to address the inherent ambiguity in single-view symmetry detection. Extensive evaluations on various data sources demonstrate that Reflect3D establishes a new state-of-the-art in single-image symmetry detection. Furthermore, we show the practical benefit of incorporating detected symmetry into single-image 3D generation pipelines through a symmetry-aware optimization process. The integration of symmetry significantly enhances the structural accuracy, cohesiveness, and visual fidelity of the reconstructed 3D geometry and textures, advancing the capabilities of 3D content creation.

Frequency-Biased Synergistic Design for Image Compression and Compensation
Jiaming Liu, Qi Zheng, Zihao Liu, Yilian Zhong, Peiye Liu, Tao Liu, Shusong Xu, Yanheng Lu, Sicheng Li, Dimin Niu, Yibo Fan; Proceedings of the Computer Vision and Pattern Recognition Conference (CVPR), 2025, pp. 12820-12829
Compression artifacts removal (CAR), an effective post-processing method to reduce compression distortion in edge-side codecs, demonstrates remarkable results by utilizing convolutional neural networks (CNNs) on high computational power cloud side. Traditional image compression reduces redundancy in the frequency domain, and we observed that CNNs also exhibit a bias in frequency domain when handling compression distortions. However, no prior research leverages this frequency bias to design compression methods tailored to CAR CNNs, or vice versa. In this paper, we present a synergistic design that bridges the gap between image compression and learnable compensation for CAR. Our investigation reveals that different compensation networks have varying effects on low and high-frequencies. Building upon these insights, we propose a pioneering redesign of the quantization process, a fundamental component in lossy image compression, to more effectively compress low-frequency information. Additionally, we devise a novel compensation framework that applies different neural networks for reconstructing different frequencies, incorporating a basis attention block to prioritize intentionally dro

pped low-frequency information, thereby enhancing the overall compensation. We i
nstantiate two compensation networks based on this synergistic design and conduc
t extensive experiments on three image compression standards, demonstrating that
 our approach significantly reduces bitrate consumption while delivering high pe
rceptual quality.
