In this work, we propose a cross-architecture merging framework based on optimal transport (OT) that aligns activations to infer cross-neuron correspondences between heterogeneous models.
The resulting transport plans are then used to guide direct weight-space fusion, enabling effective high-resource to low-resource transfer using only a small set of inputs.
Extensive experiments across low-resource languages and specialized domains demonstrate consistent improvements over target models.

NAVIGATE: Evaluating Visual-Guided Search Decision-Making on the Open Web
YaoQi Fan, Zhe Chen, Zhu Wei, Kangxin Yin, Yangzhou Liu, Yue Cao, Zhi Zhu, Tong Lu
Vision–Language Models (VLMs) are increasingly deployed with web search tools, yet we still lack benchmarks that isolate a critical capability for real-world use: deciding when to search and how to steer search from ambiguous visual evidence, especially when multiple images provide overlapping or conflicting cues. We introduce NAVIGATE, a novel benchmark centered on images as primary evidence for open-web search planning and multi-step reasoning. It contains 500 questions across 20 domains and spans three difficulty tiers, from single-image, self-contained problems to multi-image joint search and multi-domain composition. Unlike prior benchmarks that specify explicit search targets, NAVIGATE evaluates search decision-making: models must infer whether external search is necessary and iteratively refine search directions based on holistic reasoning over visual cues. Across a broad set of VLMs and search-enabled systems, performance remains low, Gemini-3-Pro-Preview-Search reaches only 36.4% accuracy, highlighting persistent failures in cross-image grounding, search triggering, and search strategy coordination. We will release NAVIGATE publicly.
****

VisualScore: Learning Holistic Visual Quality Scores via Multi-Task Reasoning
Yiting Lu, Fengbin Guan, Yixin Gao, Yan Zhong, Xinge Peng, Jiakang Yuan, Yihao Liu, Bo Zhang, Xin Li, Zhibo Chen, Weisi Lin

Image quality assessment (IQA) is inherently multi-dimensional, yet existing reward models are typically limited to a single task and become unstable when extended to multi-task settings. In particular, heterogeneous reward scales and variances across tasks can lead to conflicting optimization signals during reinforcement learning.
We propose VisualScore, a unified visual evaluation framework that formulates multi-task IQA as structured, task-aware reasoning followed by continuous reward optimization. VisualScore produces interpretable rationales together with scalar quality scores under explicit evaluation principles.
We construct a reasoning-enhanced reward modeling dataset via rejection sampling and initialize the model through supervised fine-tuning. VisualScore is then optimized with Group Relative Policy Optimization (GRPO) using a Gaussian-based continuous reward. To address multi-task reward conflicts and stabilize training, we introduce standard deviation filtering and entropy gating to normalize task-wise reward signals and suppress noisy updates.
Experiments on technical quality, aesthetic quality, and text–image alignment show that VisualScore improves robustness, generalization, and interpretability, and can effectively guide text-to-image generation at test time without retraining.

Evolution of Benchmark: Black-Box Optimization Benchmark Design through Large Language Model
Chen Wang, Sijie Ma, Zeyuan Ma, Yue-Jiao Gong
Benchmark Design in Black-Box Optimization (BBO) is a fundamental yet open-ended topic. Early BBO benchmarks are predominantly human-crafted, introducing expert bias and constraining diversity. Automating this design process can relieve the human-in-the-loop burden while enhancing diversity and objectivity. We propose Evolution of Benchmark (EoB), an automated BBO benchmark designer empowered by the large language model (LLM) and its program evolution capability. Specifically, we formulate benchmark design as a bi-objective optimization problem towards maximizing (i) landscape similarity to target tasks and (ii) algorithm-differentiation ability across a portfolio of BBO solvers. Under this paradigm, EoB iteratively prompts LLM to evolve a population of benchmark programs and employs a reflection-based scheme to co-evolve the landscape and its corresponding program. Comprehensive experiments validate our EoB is a competitive candidate in multi-dimensional usages: 1) Benchmarking BBO algorithms; 2) Training and testing learning-assisted BBO algorithms; 3) Extending proxy for expensive real-world problems.

EcoVLA: Environment-Aware Adaptive Pruning with Interleaved Inference Orchestration for Vision-Language-Action Models
Yuting Huang, Leilei Ding, Zhipeng Tang, Zenghuan Zhu, Jiajun Deng, Xinrui Lin, Shuo Liu, Haojie Ren, Jianmin Ji, Yanyong Zhang
While Vision-Language-Action (VLA) models hold promise in embodied intelligence, their large parameter counts lead to substantial inference latency that hinders real-time manipulation, motivating parameter sparsification. However, as the environment evolves during VLA execution, the optimal sparsity patterns change accordingly. Static pruning lacks the adaptability required for environment dynamics, whereas fixed-interval dynamic layer pruning suffers from coarse granularity and high retraining overheads. To bridge this gap, we propose **EcoVLA**, a training-free, plug-and-play adaptive pruning framework that supports orthogonal combination with existing VLA acceleration methods. EcoVLA comprises two components: **E**nvironment-aware **A**daptive **P**runing (**EAP**) and **I**nterleaved **I**nference **O**rchestration (**I^2O**). EAP is a lightweight adaptive channel pruning method that incorporates the temporal consistency of the physical environment to update sparsity patterns. I^2O leverages the FLOPs bubbles inherent in VLA inference to schedule the pruning method in parallel, ensuring negligible impact on latency. Evaluated on diverse VLA models and benchmarks, EcoVLA delivers state-of-the-art performance, achieving up to 1.60$\times$ speedup with only a 0.4% drop in success rate, and further reaches 2.18$\times$ speedup with on

ly a 0.5% degradation when combined with token pruning. We further validate the effectiveness of EcoVLA on real-world robots. Our code is available [here](https://github.com/Echo-hyt/Ecovla).
****

Causal-EPIG: Causally Aligned Active CATE Estimation
Erdun Gao, Jake Fawkes, Dino Sejdinovic
Estimating the Conditional Average Treatment Effect (CATE) is constrained by the high cost of obtaining outcome measurements, making active learning valuable. However, conventional strategies suffer from a fundamental objective mismatch: they reduce uncertainty in model parameters or observable outcomes rather than the unobservable causal quantities of interest. We address this via the principle of causal objective alignment, positing that acquisition functions should target potential outcomes or CATE directly. We operationalize this through Causal-EPIG, a framework adapting Expected Predictive Information Gain to quantify uncertainty reduction in causal quantities. We derive two distinct strategies: a comprehensive approach that targets the joint potential-outcome structure, and a focused approach that directly targets the CATE estimand for sample efficiency. We provide theoretical justification for our framework, establishing a formal link between CATE estimation error and posterior uncertainty in causal quantities. Extensive experiments demonstrate that our strategies improve sample efficiency over standard baselines, and crucially, reveal that the preferred strategy is context-dependent, contingent on the base estimator and treatment-effect structure. Our framework thus provides a principled guide for sample-efficient CATE estimation in practice.

Robust Causal Discovery in Real-World Time Series with Power-Laws
Matteo Tusoni, Giuseppe Masi, Andrea Coletta, Aldo Glielmo, Viviana Arrigoni, Novella Bartolini
Exploring causal relationships in stochastic time series is a challenging yet crucial task with a vast range of applications, including finance, economics, neuroscience, and climate science. Many algorithms for Causal Discovery (CD) have been proposed; however, they often exhibit a high sensitivity to noise, resulting in spurious causal inferences on real data. In this paper, we observe that the frequency spectra of many real-world time series follow a power-law distribution, notably due to an inherent self-organizing behavior. Leveraging this insight, we build a robust CD method based on the extraction of power■law spectral features that amplify genuine causal signals. Our method consistently outperforms state-of-the-art alternatives on both synthetic benchmarks and real-world datasets with known causal structures, demonstrating its robustness and practical relevance.
****

Beyond Scalars: Evaluating and Understanding LLM Reasoning via Geometric Progress and Stability
Xinyan Jiang, Ninghao Liu, Di Wang, Lijie Hu
Evaluating LLM reliability via scalar probabilities often fails to capture the structural dynamics of reasoning. We introduce TRACED, a framework that assesses reasoning quality through theoretically grounded geometric kinematics. By decomposing reasoning traces into Progress (displacement) and Stability (curvature), we reveal a distinct topological divergence: correct reasoning manifests as high-progress, stable trajectories, whereas hallucinations are characterized by low-progress, unstable patterns (stalled displacement with high curvature fluctuations). Leveraging these signatures, our probabilistic framework achieves competitive performance and superior robustness across diverse benchmarks. Crucially, TRACED bridges geometry and cognition by mapping high curvature to "Hesitation Loops'' and displacement to ''Certainty Accumulation'', offering a physical lens to decode the internal dynamics of machine thought.

On the Sample Efficiency of Inverse Dynamics Models for Semi-Supervised Imitation Learning
Sacha Morin, Moonsub Byeon, Alexia Jolicoeur-Martineau, Sebastien Lachapelle

Semi-supervised imitation learning (SSIL) consists in learning a policy from a small dataset of action-labeled trajectories and a much larger dataset of action-free trajectories. Some SSIL methods learn an inverse dynamics model (IDM) to predict the action from the current state and the next state. An IDM can act as a policy when paired with a video model (VM-IDM) or as a label generator to perform behavior cloning on action-free data (IDM labeling). In this work, we first show that VM-IDM and IDM labeling learn the same policy in a limit case, which we call the IDM-based policy. We then argue that the previously observed advantage of IDM-based policies over behavior cloning is due to the superior sample efficiency of IDM learning, which we attribute to two causes: (i) the ground-truth IDM tends to be contained in a lower complexity hypothesis class relative to the expert policy, and (ii) the ground-truth IDM is often less stochastic than the expert policy. We argue these claims based on insights from statistical learning theory and novel experiments, including a study of IDM-based policies using recent architectures for unified video-action prediction (UVA). Motivated by these insights, we finally propose an improved version of the existing LAPO algorithm for latent action policy learning. We experiment on the Procgen, Push-T and LIBERO benchmarks.

When Do Hallucinations Arise? A Graph Perspective on the Evolution of Path Reuse and Path Compression

Xinnan Dai, Kai Yang, Cheng Luo, Shenglai Zeng, Kai Guo, Jiliang Tang

Reasoning hallucinations in large language models (LLMs) often appear as fluent yet unsupported conclusions that violate either the given context or underlying factual knowledge. Although such failures are widely observed, the mechanisms by which decoder-only Transformers produce them remain poorly understood. We model next-token prediction as a graph search process over an underlying graph, where entities correspond to nodes and learned transitions form edges. From this perspective, contextual reasoning is a constrained search over a sampled subgraph (intrinsic reasoning), while context-free queries rely on memorized structures in the underlying graph (extrinsic reasoning). We show that reasoning hallucinations arise from two fundamental mechanisms: path reuse, where memorized knowledge overrides contextual constraints during early training, and path compression, where frequently traversed multi-step paths collapse into shortcut edges in later training. Together, these mechanisms provide a unified explanation for reasoning hallucinations in LLMs and connected to well-known behaviors observed in downstream applications.

Discretely-Refined Multi-view Clustering via Aligned Anchor Learning

Yuemeng Huang, Huibing Wang, Jinjia Peng, Lu Jiang, Qian Liu, Zetian Mi, Jiqing Zhang

Anchor-based multi-view clustering has garnered wide attention for its ability to reduce the computational complexity of large-scale spectral clustering. However, existing methods mostly adopt a unidirectional optimization paradigm confined to sample-anchor bipartite graphs, treating the construction of the consensus graph and discrete clustering assignments as separate sub-problems to be solved independently. This weakens the information exchange between continuous representation and discrete structure, confining the optimization process to iterative updates within local modules.To address these limitations, we propose a Discretely-Refined Multi-view Clustering(DRMC) via Aligned Anchor Learning. Unlike approaches that directly perform fusion in the anchor space, our method starts from the anchor graph, elevates sample-anchor associations to sample-level similarity graph representations, and thereby enhances both within-cluster similarity and between-cluster separation. Furthermore, we design a discrete feedback module that jointly conducts spectral embedding learning and discrete label assignment by orthogonally aligning the continuous embedding matrix with the discrete indicator matrix. The resulting discrete partition is then fed back into the consensus graph construction, continuously refining the graph structure. Experiments on multiple benchmark datasets demonstrate that the proposed method exhibits significant advantages over existing state-of-the-art approaches.

****
DiffStyle3D: Consistent 3D Gaussian Stylization via Attention Optimization
Yitong Yang, Yinglin Wang, Xuexin Liu, Jing Wang, Hao Dou, Changshuo Wang, Shuti
ng He
3D style transfer enables the creation of visually expressive 3D content, enrich
ing the visual appearance of 3D scenes and objects. However, existing VGG- and C
LIP-based methods struggle to model multi-view consistency within the model itse
lf, while diffusion-based approaches can capture such consistency but rely on de
noising directions, leading to unstable training. To address these limitations,
we propose DiffStyle3D, a novel diffusion-based paradigm for 3DGS style transfer
 that directly optimizes in the latent space. Specifically, we introduce an Atte
ntion-Aware Loss that performs style transfer by aligning style features in the
self-attention space, while preserving original content through content feature
alignment. Inspired by the geometric invariance of 3D stylization, we propose a
Geometry-Guided Multi-View Consistency method that integrates geometric informat
ion into self-attention to enable cross-view correspondence modeling. Based on g
eometric information, we additionally construct a geometry-aware mask to prevent
 redundant optimization in overlapping regions across views, which further impro
ves multi-view consistency. Extensive experiments show that DiffStyle3D outperfo
rms state-of-the-art methods, achieving higher stylization quality and visual re
alism. The code is available at \url{https://github.com/yangyt46/DiffStyle3D}.

Turning Bias into Bugs: Bandit-Guided Style Manipulation Attacks on LLM Judges
XIANGLIN YANG, Bryan Hooi, Gelei Deng, Tianwei Zhang, Jin Song Dong
The known **stylistic biases** in LLM judges, such as a preference for verbosity
 or specific sentence structures, present an underexplored *security vulnerabili
ty*. In this work, we introduce BITE (**BI**as explora**T**ion and **E**xploitat
ion), a black-box adversarial framework that learns semantics-preserving edits t
o mislead an LLM judge and *artificially* inflate the scores it assigns. We cast
 the selection of stylistic edits as a contextual bandit problem and use a LinUC
B policy to adaptively choose edits that maximize the judge's score without acce
ss to model parameters or gradients. Empirically, we test BITE across a diverse
range of LLM judges and tasks, including both pointwise and pairwise comparisons
 on chatbot leaderboards and AI-reviewer benchmarks. BITE achieves an attack suc
cess rate exceeding 65% and raises scores by 1–2 points on a 9-point scale, all
while preserving semantic equivalence. We further assess the attack's stealthine
ss, showing that BITE evades standard style-control methods and several detectio
n baselines. Our findings expose a fundamental weakness in the LLM-as-a-judge pa
radigm and motivate robust, attack-aware evaluation. Our code is available at ht
tps://github.com/xianglinyang/llm-as-a-judge-attack.

Calibrated Multimodal Representation Learning with Missing Modalities
Xiaohao Liu, Xiaobo Xia, Jiaheng Wei, Shuo Yang, Xiu Su, See-Kiong Ng, Tat-Seng
Chua
Multimodal representation learning harmonizes distinct modalities by aligning th
em into a unified latent space. Recent research generalizes traditional cross-mo
dal alignment to produce enhanced multimodal synergy but requires all modalities
 to be present for a common instance, making it challenging to utilize prevalent
 datasets with missing modalities. We provide theoretical insights into this iss
ue from an \textit{anchor shift} perspective. Observed modalities are aligned wi
th a local anchor that deviates from the optimal one when all modalities are pre
sent, resulting in an inevitable shift.

    To address this, we propose CalMRL to calibrate incomplete alignments caused
 by missing modalities. CalMRL leverages the priors and the inherent connections
 among modalities to model the imputation for the missing ones at the representa
tion level. To resolve the optimization dilemma, we employ a bi-step learning me
thod with the closed-form solution of the posterior distribution of shared laten
ts. We validate its mitigation of anchor shift and convergence with theoretical
guidance. By equipping the calibrated alignment with the existing advanced metho
d, we offer new flexibility to absorb data with missing modalities, which is ori

ginally unattainable. Extensive experiments demonstrate the superiority of CalMRL. The code is released at https://github.com/Xiaohao-Liu/CalMRL.

IVQA-LD: Inclusive Multimodal Understanding for Population with Limb Deficiency
Yan Ke, Xin Shen, Jiaying Ying, Xin Li, Xin Yu
People with limb differences often face significant challenges in accessing inclusive AI services, largely due to the lack of structured, high-quality resources centered on disability contexts.
In this work, we introduce a limb-deficiency aware body-centric learning and evaluation paradigm that
involves (i) a large-scale limb-aware vision–language dataset and evaluation benchmark for multimodal reasoning, and (ii) a model adaptation strategy for Vision-Language Models (VLM) in limb-difference contexts.
Specifically, we first collect limb-difference data covering all eight limb-deficiency types across diverse real-world scenarios. The data are systematically organized into 96 limb-affected human action categories and 68 medical-functional classes defined by the World Health Organization (WHO).
Then, we curate an expert-annotated vision–language dataset for limb-aware multimodal understanding, named Inclusive VQA for Limb Deficiency (**IVQA-LD**). IVQA-LD comprises 80K VQA pairs spanning eight core tasks including visual grounding, quantitative reasoning, functional semantic classification, and instructional text generation.
We benchmark state-of-the-art VLMs on IVQA-LD and find that they consistently struggle across all tasks, exposing substantial deficiencies in limb-aware perception and reasoning.
To address this, we further propose a Body-centric Structure-aware Initialization (BSI) strategy that aligns model representations with limb-specific semantics. With BSI, VLMs fine-tuned on IVQA-LD achieve significant performance improvements across all the tasks.
We will publicly release the dataset to support future research.
****
Token-Efficient Change Detection in LLM APIs
Timothee Chauvin, Clément Lalanne, Erwan Le Merrer, Jean-Michel Loubes, Francois Taiani, Gilles Tredan
Remote change detection in LLMs is a difficult problem.
Existing methods are either too expensive for deployment at scale, or require initial white-box access to model weights or grey-box access to log probabilities. We aim to achieve both low cost and strict black-box operation, observing only output tokens.

Our approach hinges on specific inputs we call Border Inputs, for which there exists more than one output top token.
From a statistical perspective, optimal change detection depends on the model's Jacobian and the Fisher information of the output distribution, whose analysis at low temperature regimes shows that border inputs enable powerful change detection tests.

Building on this insight, we propose the Black-Box Border Input Tracking (B3IT) scheme. Extensive in-vivo and in-vitro experiments show that border inputs are easily found for non-reasoning tested endpoints, and present on-par performance with the best available grey-box approaches. B3IT reduces costs by $30\times$ compared to existing methods, while operating in a strict black-box setting.
****
Can Large Language Models Generalize Procedures Across Representations?
Fangru Lin, Valentin Hofmann, Xingchen Wan, Weixing Wang, Zifeng Ding, Anthony G Cohn, Janet B. Pierrehumbert
Large language models (LLMs) are trained and tested extensively on symbolic representations such as code and graphs, yet real-world user tasks are often specified in natural language. To what extent can LLMs generalize across these representations? Here, we approach this question by studying isomorphic tasks involving

procedures represented in code, graphs, and natural language (e.g., scheduling steps in planning). We find that training LLMs with popular post-training methods on graphs or code data alone does not reliably generalize to corresponding natural language tasks, while training solely on natural language can lead to inefficient performance gains. To address this gap, we propose a two-stage reinforcement learning curriculum that first trains on symbolic, then natural language data. The curriculum substantially improves model performance across model families and tasks. Remarkably, a 1.5B Qwen model trained by our method can closely match zero-shot GPT-4o in naturalistic planning. Finally, our analysis suggests that successful cross-representation generalization can be interpreted as a form of generative analogy, which our curriculum effectively encourages. The dataset and code used in this paper can be found \href{https://github.com/fangru-lin/procedure_generalization_llm}{here}.
****

When Does Sparsity Mitigate the Curse of Depth in LLMs
Dilxat Muhtar, Xinyuan Song, Sebastian Pokutta, Max Zimmer, Nico Pelleriti, Thomas Hofmann, Shiwei Liu
Recent work has demonstrated the curse of depth in large language models (LLMs), where later layers contribute less to learning and representation than earlier layers. Such under-utilization is linked to the accumulated growth of variance in Pre-Layer Normalization, which can push deep blocks toward near-identity behavior. In this paper, we provide evidence that sparsity-like mechanisms can dampen variance propagation and are associated with improved depth utilization Our investigation covers two sources of sparsity: (i) implicit sparsity, which emerges from training and data conditions, including weight sparsity induced by weight decay and attention sparsity induced by long-context inputs; and (ii) explicit sparsity, which is enforced by architectural design, including key/value-sharing in Grouped-Query Attention and expert-activation sparsity in Mixture-of-Experts. Our claim is thoroughly supported by controlled depth-scaling experiments and targeted layer effectiveness interventions. Across settings, we observe a consistent relationship: mechanisms with reduced effective interaction density tend to exhibit lower output variance and better layer differentiation. We eventually distill our findings into a practical rule-of-thumb recipe for training depth-effective LLMs, yielding a notable 4.6 accuracy improvement on downstream
tasks. Our results suggest that sparsity-like design choices are an important and previously underemphasized factor in effective depth scaling for LLMs. Code is available at https://github. com/pUmpKin-Co/SparsityAndCoD.

Mixtures of geodesic factor analyzers on Riemannian homogeneous spaces
Hengchao Chen, Yuanyao Tan, Chao Huang, Hongtu Zhu, Qiang Sun
This paper introduces Mixtures of Geodesic Factor Analyzers (MGFA) on Riemannian homogeneous spaces. MGFA uses a geodesic factor model within each mixture component, providing greater expressiveness than mixtures of Riemannian radial distributions and enabling clustering of manifold-valued data with anisotropic subpopulations. We establish root-n consistency for the MGFA maximum likelihood estimator (MLE), thereby filling a theoretical gap for mixtures of Riemannian radial distributions as a special case. We also propose an iterative estimation algorithm and implement it on spheres, shape spaces, and hyperbolic spaces. Numerical experiments show that MGFA substantially outperforms competing methods in well-specified regimes while remaining robust under model misspecification. Finally, case studies on corpus callosum and left hippocampus shape datasets demonstrate MGFA’s effectiveness for both 2D contour and 3D shape analysis.
****

PADA-Coder: Improving Plan-Following Code Generation via Perturbation-Verified Attention Distillation and Dynamic Alignment
Yihong Huang, Ke Qin, Rongzheng Wang, Muquan Li, Jiakai Li, Xiurui Xie, Shuang Liang
The Plan-then-Code paradigm effectively enhances Large Language Models (LLMs) in complex code generation by decomposing reasoning into explicit, interpretable steps. However, introducing the plan and verification report substantially enlarg

es the context, which in turn misdirects the model’s attention toward irrelevant tokens and the most recently generated code. This effect leads the model to overlook critical constraints and to generate incorrect code, especially for small-scale LLMs (less than 8B). To address this issue, we propose \textbf{P}erturbation-Verified \textbf{A}ttention \textbf{D}istillation and Dynamic \textbf{A}lignment (PADA). PADA identifies the key tokens most critical to the student model and constructs the optimal attention target matrix, dynamically aligning the student’s focus with key tokens for each plan step. We evaluate PADA with two teacher models and three student models across seven benchmarks, and the results show that PADA improves Pass@1 by up to 16.7\% and outperforms SOTA methods in overall average performance.

TetraJet-v2: Accurate NVFP4 Training for Large Language Models with Oscillation Suppression and Outlier Control

Yuxiang Chen, Yifan Liu, Xiaoming Xu, Pengle Zhang, Michael Beyer, Martin Rapp, Jun Zhu, Jianfei Chen

Large Language Models (LLMs) training is prohibitively expensive, driving interest in low-precision fully-quantized training (FQT).
While novel 4-bit formats like NVFP4 offer substantial efficiency gains, achieving near-lossless training at such low precision remains challenging.
We introduce **TetraJet-v2**, an end-to-end 4-bit FQT method that leverages NVFP4 for activations, weights and gradients in all linear layers.
We identify two critical issues hindering low-precision LLM training: weight oscillation and outliers.
To address these, we propose: 1) an unbiased double-block quantization method for NVFP4 linear layers, 2) **OsciReset**, an algorithm to suppress weight oscillation, and 3) **OutControl**, an algorithm to retain outlier accuracy. **TetraJet-v2** outperforms prior methods on FP4 pre-training for LLMs across models up to 370M parameters trained up to 212B tokens, reducing the performance gap to BF16 by an average of 51.3% while enabling an $1.67\times$ end-to-end speedup over FP8.

****

From Statics to Dynamics: Physics-Aware Image Editing with Latent Transition Priors

Liangbing Zhao, Le Zhuo, Sayak Paul, Hongsheng Li, Mohamed Elhoseiny

Instruction-based image editing has achieved remarkable success in semantic alignment, yet state-of-the-art models frequently fail to render physically plausible results when editing involves complex causal dynamics, such as refraction or material deformation.

We attribute this limitation to the dominant paradigm that treats editing as a discrete mapping between image pairs, which provides only boundary conditions and leaves transition dynamics underspecified.

To address this, we reformulate physics-aware editing as predictive physical state transitions and introduce PhysicTran38K, a large-scale video-based dataset comprising 38K transition trajectories across five physical domains, constructed via a two-stage filtering and constraint-aware annotation pipeline.

Building on this supervision, we propose PhysicEdit, an end-to-end framework equipped with a textual-visual dual-thinking mechanism. It combines a frozen Qwen2.5-VL for physically grounded reasoning with learnable transition queries that provide timestep-adaptive visual guidance to a diffusion backbone.

Experiments show that PhysicEdit improves over Qwen-Image-Edit by 5.9\% in physical realism and 10.1\% in knowledge-grounded editing, setting a new state-of-the-art for open-source methods, while remaining competitive with leading proprietary models.

Anytime-Valid Inference for Online Ranking of Large Language Models

Runzhe Gu, Wenguang Sun, Bowen Gang, Xintao Xia

Online evaluation of large language models increasingly relies on sequentially collected pairwise preferences, enabling human-aligned assessment and continuous data collection until closely performing models can be reliably distinguished. H

owever, adaptive sampling and continuous monitoring invalidate classical fixed-sample inference, rendering existing ranking procedures largely heuristic. We propose SERPANT (Sequential E-value Ranking and Pruning via Adaptive Null Testing), a principled framework for online LLM ranking with anytime-valid guarantees. SERPANT formulates model comparison as a collection of pairwise hypothesis tests and constructs e-processes to ensure family-wise error rate control at any monitoring time. Anytime validity provides a theoretical justification for early stopping, enabling substantial cost savings from expensive human annotation. To improve efficiency, we introduce a novel tournament-based sampling strategy that adaptively selects comparisons based on past outcomes. The proposed framework is also extended to top-k model identification.

****

De4D-SLAM: Gradient-Isolated Static-Dynamic Decoupling for Monocular SLAM in Dynamic Environments

Zhicheng Fan, Zitong Wu, Zhaoxing Fan, Xiao Zhang, Biao Hou, Bo REN

Conventional dynamic SLAM approaches typically treat dynamic objects as outliers based on pre-defined categories, creating perceptual blind spots that limit the comprehensive environmental perception required for embodied agents. Although integrating Gaussian Splatting into SLAM enables holistic scene representation, it introduces an optimization paradox: without categorical priors, flexible dynamic primitives rapidly overfit static residuals. This phenomenon undermines the self-supervised error signals necessary for distinguishing motion. In response, we present De4D-SLAM, a novel framework designed for decoupled 4D reconstruction from monocular video. Our approach features a Gradient-Isolated Decoupling strategy, which leverages static reconstruction residuals to supervise a Spatially-Aware Kolmogorov-Arnold Network (SA-KAN), ensuring robust, category-agnostic motion segmentation. Additionally, we propose a Flow-Induced Initialization prior to stabilize the non-convex optimization of 4D Gaussian primitives using dense optical flow. Extensive evaluations on the TUM and Bonn benchmarks demonstrate that De4D-SLAM achieves competitive performance in both tracking and dynamic reconstruction, successfully reconciling the tension between robust localization and high-fidelity 4D mapping.

Federated Bilevel Performative Prediction

Liangxin Qian, Chang Liu, Xuanyu Cao, Jun Zhao, Kwok-Yan Lam

Federated bilevel optimization is widely used for nested learning problems across distributed clients, such as federated hyperparameter tuning and meta-learning under privacy and communication constraints. Most existing formulations assume fixed client data distributions, which can be violated by performativity, where deployed decisions reshape client behavior and data collection, inducing client-specific, decision-dependent distribution shift. We study federated bilevel performative prediction, where both upper-level (UL) and lower-level (LL) objectives are evaluated under client-dependent, decision-dependent distributions. We formalize the federated bilevel performatively stable (FBPS) point under a decoupled-risk perspective and provide sufficient conditions for its existence and uniqueness. We then develop two federated methods to compute the FBPS solution: FBi-RRM, which converges linearly under a contraction condition, and FBi-SGD, a communication-efficient stochastic method based on federated hypergradient estimation with convergence guarantees under diminishing step sizes when sensitivities are sufficiently small. Experiments on strategic regression and meta strategic classification validate the predicted stability thresholds and demonstrate improved meta-generalization over non-performative baselines, and CNN-based classification further demonstrates the practical effectiveness of the proposed methods in non-convex neural network settings.

A Queueing-Theoretic Framework for Stability Analysis of LLM Inference with KV Cache Memory Constraints

Chengyi Nie, Nian Si, Zijie Zhou

The rapid adoption of large language models (LLMs) has created significant challenges for efficient inference at scale. Unlike traditional workloads, LLM infere

nce is constrained by both computation and the memory overhead of key–value (KV) caching, which accelerates decoding but quickly exhausts GPU memory. In this paper, we introduce the first queueing-theoretic framework that explicitly incorporates both computation and GPU memory constraints into the analysis of LLM inference. Based on this framework, we derive rigorous stability and instability conditions that determine whether an LLM inference service can sustain incoming demand without unbounded queue growth. This result offers a powerful tool for system deployment, potentially addressing the core challenge of GPU provisioning. By combining an estimated request arrival rate with our derived stable service rate, operators can calculate the necessary cluster size to avoid both costly over-purchasing and performance-violating under-provisioning. We further validate our theoretical predictions through extensive experiments in real GPU production environments. Our results show that the predicted stability conditions are highly accurate, with deviations typically within 10%.

TimeSAE: Causal Sparse Decoding for Faithful Explanations of Black-Box Time Series Models

Khalid Oublal, Quentin Bouniot, Qi Gan, Stephan Clémençon, Zeynep Akata

As black box models and pretrained models gain traction in time series applications, understanding and explaining their predictions becomes increasingly vital, especially in high-stakes domains where interpretability and trust are essential. However, most of the existing methods involve only in-distribution explanation, and do not generalize outside the training support, which requires the learning capability of generalization. In this work, we aim to provide a framework to explain black-box models for time series data through the dual lenses of Sparse Autoencoders (SAEs) and causality. We show that many current explanation methods are sensitive to distributional shifts, limiting their effectiveness in real-world scenarios. Building on the concept of Sparse Autoencoder, we introduce TimeSAE, a framework for black-box model explanation. We conduct extensive evaluations of TimeSAE on both synthetic and real-world time series datasets, comparing it to leading baselines. The results, supported by both quantitative metrics and qualitative insights, show that TimeSAE provides more faithful and robust explanations. Our code is available in an easy-to-use library TimeSAE-Lib: https://oublalkhalid.github.io/TimeSAE/

Continual GUI Agents

Ziwei Liu, Borui Kang, Hangjie Yuan, Zixiang Zhao, Wei Li, Yifan Zhu, Tao Feng

As digital environments (data distribution) are in flux, with new GUI data arriving over time-introducing new domains or resolutions-agents trained on static environments deteriorate in performance. In this work, we introduce Continual GUI Agents, a new task that requires GUI agents to perform continual learning under shifted domains and resolutions. We find existing methods fail to maintain stable grounding as GUI distributions shift over time, due to the diversity of UI interaction points and regions in fluxing scenarios. To address this, we introduce GUI-Anchoring in Flux (GUI-AiF), a new reinforcement fine-tuning framework that stabilizes continual learning through two novel rewards: Anchoring Point Reward in Flux (APR-iF) and Anchoring Region Reward in Flux (ARR-iF). These rewards guide the agents to align with shifting interaction points and regions, mitigating the tendency of existing reward strategies to over-adapt to static grounding cues (e.g., fixed coordinates or element scales). Extensive experiments show GUI-AiF surpasses state-of-the-art baselines. Our work establishes the first continual learning framework for GUI agents, revealing the untapped potential of reinforcement fine-tuning for continual GUI Agents.

UniMedVL: Unifying Medical Multimodal Understanding and Generation through Observation-Knowledge-Analysis

Junzhi Ning, Wei Li, Cheng Tang, Jiashi Lin, Chenglong Ma, Chaoyang Zhang, Jiyao Liu, Ying Chen, Shujian Gao, Yuandong Pu, Huihui Xu, Chenhui Gou, Ziyan Huang, Yi Xin, Qi Qin, Diping Song, Bin Fu, Guang Yang, Yuanfeng Ji, Tianbin Li, Yanzhou Su, Jin Ye, SHIXIANG TANG, Zhongying Deng, Lihao Liu, Ming Hu, Junjun He

Medical workflows routinely combine reading images with producing visual and tex
tual outputs, making both image understanding and generation central to medical
AI. Most existing systems, however, address these abilities in isolated models,
losing the shared knowledge that a unified architecture could exploit. To bridge
 this gap, we present UniMedVL, the first unified medical model that seamlessly
integrates multimodal understanding and generation capabilities within a single
model without switching weights. We achieve this via a tailored progressive trai
ning pipeline where understanding and generation mutually reinforce each other.
To effectively train UniMedVL, we curate UniMedVL-5M, the first large-scale medi
cal dataset comprising over 5.6M instances across 8 medical imaging modalities,
tailored for multimodal input-output tasks in unified medical understanding and
generation. Experimental results demonstrate that UniMedVL achieves competitive
performance on five medical understanding benchmarks. Crucially, UniMedVL native
ly supports diverse interleaved generation tasks, e.g., virtual staining, super-
resolution, cross-modal synthesis, essential for complex medical workflows. Our
code and dataset are publicly available.

Conditional Equivalence of DPO and RLHF: Assumptions, Failure Modes, and Provabl
e Alignment

Zhiqin Yang, Yonggang Zhang, Wei Xue, Dong Fang, Bo Han, Yike Guo

Direct Preference Optimization (DPO) has emerged as a popular alternative to Rei
nforcement Learning from Human Feedback (RLHF), offering theoretical equivalence
 with a simpler implementation. We prove this equivalence is _conditional_ rathe
r than universal, depending on an implicit assumption frequently violated in pra
ctice: the RLHF-optimal policy must prefer human-preferred responses. When this
assumption fails, DPO optimizes _relative advantage_ over the reference policy r
ather than _absolute alignment_ with human preferences, leading to pathological
convergence where policies decrease DPO loss while preferring dispreferred respo
nses. We characterize when this assumption is violated, show the existence of an
 undesirable solution space, and prove that DPO and RLHF optimize fundamentally
different objectives in such cases. To address this, we introduce Constrained Pr
eference Optimization (CPO), augmenting RLHF with constraints for provable align
ment. We further provide a geometric interpretation through soft margin ranking,
 revealing that DPO implements margin ranking with potentially negative targets.
 Our theoretical analysis establishes when DPOs' guarantees hold and provides so
lutions preserving simplicity with provable alignment. Comprehensive experiments
 on standard benchmarks demonstrate that CPO achieves state-of-the-art performan
ce. Code is available at: _https://github.com/visitworld123/CPO_.

$\mathbb{R}^{2k}$ is Theoretically Large Enough for Embedding-based Top-k Retr
ieval

Zihao Wang, Hang Yin, Lihui Liu, Hanghang Tong, Yangqiu Song, Ginny Wong, Simon
See

This paper studies the Minimal Embeddable Dimension (MED): the least dimension i
n which there exists a configuration of m object vectors so that every subset
of size at most k is exactly retrieved by score comparison. Our result shows M
ED is $\Theta(k)$, independent of m, for inner product, Euclidean distance, an
d cosine similarity. We then consider Robust MED (RMED), where all vectors are u
nit normed and an ϵ gap of scores is required. We derive the m-depend
ent feasibility ceiling $\epsilon_\star(m,k)=m/\sqrt{k(m-1)(m-k)}$, which approa
ches $1/\sqrt{k}$ when $m\gg k$, and a Gaussian centroid construction gives a ro
bust witness upper bound in the feasible margin regime. Numerical simulation on
synthetic top-2 retrieval with cyclic polytope and centroid query optimization
 confirmed our theoretical claims. Experiments on LIMIT and LIMIT-small datasets
 also show that simple embedding-based retrieval baselines can overfit and outpe
rform the reported single-vector LLM embedding baseline. Both theoretical and em
pirical findings rule out the lack of exact geometric capacity as the obstructio
n.

Harnessing Non-Adversarial Robustness in Large Language Models

Qinghua Zhou, Ellina Aleshina, Andrey Lovyagin, Oleg Somov, Mikhail Seleznyov, A
lexander Panchenko, Ivan Oseledets, Elena Tutubalina, Ivan Y Tyukin
The work presents an approach for addressing the challenge of robustness in Larg
e Language Models (LLMs) to alterations and potential errors caused by semantica
lly similar but textually different prompts. Recent works have shown that these
kinds of prompt variations can significantly impact the performance of LLMs on t
asks. The central question is: can LLMs' robustness to semantically-neutral prom
pt alterations be acquired without expensive retraining of the entire model? We
address this question both theoretically and through experiments. Our theoretica
l analysis reveals a crucial factor impacting model robustness -- a systematic e
xpected shift or perturbation-induced bias in neural network module outputs. Mot
ivated by this analysis, we show that robustness can be achieved via a simple fi
ne-tuning process: debiasing for robustness. We identify conditions when debiasi
ng helps and when it does not, and demonstrate, through both theory and extensiv
e experiments, that debiasing for robustness may indeed be a quick and efficient
 tool to enhance robustness and provide certification against random prompt pert
urbations.

V-ABS: Action-Observer Driven Beam Search for Dynamic Visual Reasoning
Zhiwei Ning, Xuanang Gao, Jiaxi Cao, Gengming Zhang, Shengnan Ma, Wenwen Tong, H
anming Deng, JIE YANG, Wei Liu
Multimodal large language models (MLLMs) have achieved remarkable success in gen
eral perception, yet complex multi-step visual reasoning remains a persistent ch
allenge. Although recent agentic approaches incorporate tool use, they often neg
lect critical execution feedback. Consequently, they suffer from the imagination
-action-observer (IAO) bias, a misalignment between prior imagination and observ
er feedback that undermines reasoning stability and optimality. To bridge this g
ap, we introduce V-ABS, an action-observer driven beam search framework that ena
bles deliberate reasoning through thinker-actor-observer iterations. We also pro
pose an entropy-based adaptive weighting algorithm to mitigate the IAO bias by d
ynamically balancing the confidence scores between the policy priors and the obs
ervational feedback. Moreover, we construct a large-scale supervised fine-tuning
 (SFT) dataset comprising over 80k samples to guide the model to assign higher p
rior confidence to correct action paths. Extensive experiments across eight dive
rse benchmarks show that V-ABS achieves state-of-the-art performance, delivering
 an average improvement of 19.7\% on the Qwen3-VL-8B baseline and consistent gai
ns across both open-source and proprietary models.
****

α-PFN: Fast Entropy Search via In-Context Learning
Herilalaina Rakotoarison, Steven Adriaensen, Tom Julian Viering, Carl Hvarfner,
Samuel Müller, Frank Hutter, Eytan Bakshy
Information-theoretic acquisition functions such as Entropy Search (ES) offer a
principled exploration–exploitation framework for Bayesian optimization (BO). Ho
wever, their practical implementation relies on complicated and slow approximati
ons, i.e., a Monte Carlo estimation of the information gain. This complexity can
 introduce numerical errors and requires specialized, hand-crafted implementatio
ns. We propose a two-stage amortization strategy that learns to approximate entr
opy search-based acquisition functions using Prior-data Fitted Networks (PFNs) i
n a single forward pass. A first PFN is trained to be conditioned on information
 about the optima; second, the α-PFN is trained to predict the expected informat
ion gain by training on information gains measured with the first PFN. The α-PFN
 offers a flexible
learned approximation, which replaces the complex heuristic approximations with
a single forward pass per candidate, enabling rapid and extensible acquisition e
valuation. Empirically, our approach is competitive with state-of-the-art entrop
y search implementations on synthetic and real-world benchmarks, while accelerat
ing the different entropy search variants across all our experiments, with speed
 ups over 50x.
****

Temper-Then-Tilt: Principled Unlearning for Generative Models through Tempering

and Classifier Guidance
Jacob L. Block, Mehryar Mohri, Aryan Mokhtari, Sanjay Shakkottai
We study machine unlearning in large generative models by framing the task as de
nsity ratio estimation to a target distribution rather than supervised fine-tuni
ng. While classifier guidance is a standard approach for approximating this rati
o and can succeed in general, we show it can fail to faithfully unlearn with fin
ite samples when the forget set represents a sharp, concentrated data distributi
on. To address this, we introduce **Temper-Then-Tilt Unlearning (T3-Unlearning)*
*, which freezes the base model and applies a two-step inference procedure: (i)
tempering the base distribution to flatten high-confidence spikes, and (ii) *t
ilting* the tempered distribution using a lightweight classifier trained to dist
inguish retain from forget samples. Our theoretical analysis provides finite-sam
ple guarantees linking the surrogate classifier's risk to unlearning quality, pr
oving that tempering is necessary to successfully unlearn for concentrated distr
ibutions. Empirical evaluations on the TOFU benchmark demonstrate that T3-Unlear
ning improves forget quality and generative utility over existing baselines, whi
le training only a fraction of the parameters with a minimal runtime.
****
Safety Game: Inference-Time Alignment of Black-Box LLMs via Constrained Optimiza
tion
Tuan Nguyen, Long Tran-Thanh
Ensuring that large language models (LLMs) comply with safety requirements is a
central challenge in AI deployment. Existing alignment approaches operate primar
ily during training, such as through fine-tuning or reinforcement learning from
human feedback, but these methods are costly and inflexible, requiring retrainin
g whenever new requirements arise. Recent efforts toward inference-time alignmen
t mitigate some of these limitations but still assume access to model internals,
 which is impractical, and not suitable for third party stakeholders who do not
have access to the models. In this work, we propose a model-independent, black-b
ox framework for safety alignment that does not require retraining or access to
the underlying LLM architecture. As a proof of concept, we address the problem o
f trading off between generating safe but uninformative answers versus helpful y
et potentially risky ones. We formulate this dilemma as a two-player zero-sum ga
me whose minimax equilibrium captures the optimal balance between safety and hel
pfulness. LLM agents operationalize this framework by leveraging a linear progra
mming solver at inference time to compute equilibrium strategies. Our results de
monstrate the feasibility of black-box safety alignment, offering a scalable and
 accessible pathway for stakeholders, including smaller organizations and entiti
es in resource-constrained settings, to enforce safety across rapidly evolving L
LM ecosystems.

Agent JIT Compilation for Latency-Optimizing Web Agent Planning and Scheduling
Caleb Winston, Ron Yifeng Wang, Azalia Mirhoseini, Christos Kozyrakis
Computer-use agents (CUAs) automate tasks specified with natural language such a
s
  "order the cheapest item from Taco Bell"
  by generating sequences of calls to tools such as click, type, and scroll on a
 browser.
  Current implementations follow a sequential fetch-screenshot-execute loop wher
e each iteration requires an LLM call,
  resulting in high latency and frequent errors from incorrect tool use.
  We present agent just-in-time (JIT) compilation, a system that compiles
  task descriptions directly into executable code that may include LLM calls, to
ol calls, and parallelization.
  Our approach comprises three components: (1) JIT-Planner,
  which generates multiple code plans, validates each against tool
  specifications, and selects the minimum-cost candidate; (2) JIT-Scheduler,
  which explores parallelization strategies via Monte Carlo cost estimation from
 learned latency
  distributions; and (3) an invariant-enforcing tool protocol specifying

precondition and postcondition requirements to reduce the rate of incorrect to
ol use.
Across five applications, JIT-Planner achieves $10.4\times$ speedup and 28% hi
gher
accuracy over Browser-Use, while JIT-Scheduler achieves $2.4\times$ speedup an
d
9% higher accuracy over OpenAI CUA.

Controlled SDEs for Long-Horizon Motion Generation under Latent Decision Uncerta
inty
Han Zhang, Nenggan Zheng
Long-horizon motion prediction under external commands is challenged by latent d
ecision uncertainty, where the internal states governing future behavior are uno
bservable and evolve stochastically over time. This issue is particularly pronou
nced in biological agents, whose motion trajectories reflect decision-making pro
cesses rooted in underlying cognitive states. To address these challenges, we pr
opose CogSDE, a formulation of a controlled stochastic differential equation (SD
E) for modeling instruction-driven latent decision dynamics. The drift term in t
he SDE incorporates a dual-channel control modulation mechanism, enabling extern
al commands to modulate the evolution of latent states. The diffusion term emplo
ys a state-dependent operator to model intrinsic uncertainty in latent decision
dynamics. Furthermore, we establish dissipativity-based mean-square boundedness
for the latent decision dynamics. Experiments demonstrate that CogSDE consistent
ly improves predictive accuracy in long-horizon motion generation. Importantly,
predicted trajectories remain well aligned with control commands over extended h
orizons, a property widely recognized as challenging in long-horizon motion pred
iction.
****
A Direct Approach for Handling Contextual Bandits with Latent State Dynamics
Zhen LI, Gilles Stoltz
We consider a linear contextual bandit model where contexts and rewards are gove
rned by a finite hidden Markov chain. We first revisit the simplified model by N
elson et al. (2022), in which rewards are linear functions of the posterior prob
abilities over the hidden states given the observed contexts (called beliefs), r
ather than functions of the hidden states themselves. This simplified model may
be handled through a direct reduction to standard linear contextual bandits. We
extend the theoretical analysis of this reduction to take into account the estim
ation of the parameters of the hidden Markov model [HMM] in the regret bound and
to provide high-probability bounds not depending anymore on the reward function
s and only depending on the model through the estimation of the HMM parameters.
Second, and most importantly, we instead study the more natural and more complex
model incorporating direct dependencies in the hidden states (on top of depende
ncies on the observed contexts, as is natural for contextual bandits). Under a c
lassic HMM forgetting condition, the main algorithmic tool introduced to cope wi
th the various statistical dependencies that the reward structure introduces is
to only periodically update reward-model parameters.
****
Uncertainty-Aware Clarification in LLM Agents with Information Gain
Mengyi DENG, Zhiwei Li, Xin Li, Tingyu ZHU, Ying Zhao, Zhijiang Guo, Wei Wang
Large Language Model (LLM) agents often operate under underspecified user instru
ctions, where latent uncertainty over user intent leads to erroneous tool action
s. To address this challenge, we propose a goal-oriented clarification framework
that aligns clarification behavior with ambiguity resolution. Central to our ap
proach is the Information Gain Reward, a metric that quantifies the utility of c
larification questions by measuring the Bayesian belief update towards the groun
d-truth goal induced by the clarification exchange. We train the clarifier (LLM)
using this reward to optimize for high information gain, ensuring that clarific
ations effectively reduce uncertainty and improve task completion within the age
nt-tool-user environment. We validate our framework within a clarification-enhan
ced τ-Bench environment, conducting cross-agent evaluations across five het

erogeneous backbones. Empirical results demonstrate that our method consistently improves the success rate by 3.7\% over the no-clarification baseline, while adding only 0.3 total interaction steps on average.
****
SCALE: Self-uncertainty Conditioned Adaptive Looking and Execution for Vision-Language-Action Models
Hyeonbeom Choi, Daechul Ahn, Youhan Lee, Taewook Kang, Seongwon Cho, Jonghyun Choi
Vision-Language-Action (VLA) models have emerged as a promising paradigm for general-purpose robotic control, with test-time scaling (TTS) gaining attention to enhance robustness beyond training. However, existing TTS methods for VLAs require additional training, verifiers, and multiple forward passes, making them impractical for deployment. Moreover, they intervene only at action decoding while keeping visual representations fixed—insufficient under perceptual ambiguity, where reconsidering how to perceive is as important as deciding what to do. To address these limitations, we propose SCALE, a simple inference strategy that jointly modulates visual perception and action based on 'self-uncertainty', inspired by uncertainty-driven exploration in Active Inference theory—requiring no additional training, no verifier, and only a single forward pass. SCALE broadens exploration in both perception and action under high uncertainty, while focusing on exploitation when confident—enabling adaptive execution across varying conditions. Experiments on simulated and real-world benchmarks demonstrate that SCALE improves state-of-the-art VLAs and outperforms existing TTS methods while maintaining single-pass efficiency. Our code is publicly available at https://github.com/sumprlab/scale.
****
Collaborative Threshold Watermarking
Tameem Bakr, Anish Ambreth, Nils Lukas
In federated learning (FL), K clients jointly train a model without sharing raw data. Because each participant invests data and compute, clients need mechanisms to later prove the provenance of a jointly trained model. Model watermarking embeds a hidden signal in the weights, but naive approaches either do not scale with many clients as per-client watermarks dilute as K grows, or give any individual client the ability to verify and potentially remove the watermark. We introduce (t,K)-threshold watermarking: clients collaboratively embed a shared watermark during training, while only coalitions of at least t clients can reconstruct the watermark key and verify a suspect model. We secret-share the watermark key τ so that coalitions of fewer than t clients cannot reconstruct it, and verification can be performed without revealing τ in the clear. We instantiate our protocol in the white-box setting and evaluate it on image classification tasks on both IID and non-IID partitions, as well as language models fine-tuning
setting. Our watermark remains detectable at scale ($K=128$) with minimal accuracy loss and stays above the detection threshold ($z\ge 4$) under attacks including adaptive fine-tuning using up to 20% of the training data. Code is available at \url{https://github.com/tameemalaa/collaborative-threshold-watermark}.

Any2Any: Unified Arbitrary Modality Translation for Remote Sensing
Haoyang Chen, Jing Zhang, Di Wang, Hebaixu Wang, Shiqin Wang, Pohsun Huang, Jiayuan Li, Haonan Guo, Zheng Wang, Bo Du
Multi-modal remote sensing imagery provides complementary observations of the same geographic scene, yet such observations are frequently incomplete in practice. Existing cross-modal translation methods treat each modality pair as an independent task, resulting in quadratic complexity and limited generalization to unseen modality combinations. We formulate Any-to-Any translation as inference over a shared latent representation of the scene, where different modalities correspond to partial observations of the same underlying semantics. Based on this formulation, we propose Any2Any, a unified latent diffusion framework that projects heterogeneous inputs into a geometrically aligned latent space. Such structure performs anchored latent regression with a shared backbone, decoupling modality-sp

ecific representation learning from semantic mapping. Moreover, lightweight targ
et-specific residual adapters are used to correct systematic latent mismatches w
ithout increasing inference complexity. To support learning under sparse but con
nected supervision, we introduce RST-1M, the first million-scale remote sensing
dataset with paired observations across five sensing modalities, providing super
vision anchors for any-to-any translation. Experiments across 14 translation tas
ks show that Any2Any consistently outperforms pairwise translation methods and e
xhibits strong zero-shot generalization to unseen modality pairs. Code and model
s are available at https://github.com/MiliLab/Any2Any.

POLIA: Policy Optimization with Visual-Object-Level Intrinsic Advantage for Mult
imodal Reasoning

Yiran Zeng, Da Chen, Hangyu Mao, Yuanxing Zhang, Pengfei Wan, Mengchen Zhao

Recent advances in group-based reinforcement learning (RL) greatly improve LLMs'
ability in text reasoning. Yet, these methods lack sufficient modeling of multi
modal information, leading to significant reasoning hallucination. In this work,
we propose POLIA, a novel group-based RL method with visual-object-level intrin
sic advantage for multimodal reasoning. POLIA introduces two advantage computati
on stages over candidate answers and visual objects, respectively. The answer-le
vel extrinsic advantages are computed based on the extrinsic rewards of a group
of candidate answers. Moreover, we compute an intrinsic advantage for each visua
l object based on its confidence score and reference relations with final answer
s. Intuitively, the intrinsic advantage of an object reflects its potential cont
ribution to the correct answer. This two-stage advantage computation ensures an
accurate credit assignment mechanism over multimodal reasoning sequences with mu
ltiple visual objects. Experimental results on diverse multimodal reasoning benc
hmarks show that POLIA significantly outperforms open MLLMs and strong baselines
. Code is available at https://github.com/dudu115/POLIAcode.

ASIR: Steganography for Diffusion Models via Antipodal Sampling and Iterative Re
covery

Yaofei Wang, Yufeng Zheng, Han Fang, Wenzhao Cao, Donghui Hu

Messages embedded in diffusion generation noise suffer from severe attenuation d
ue to denoising and VAE decoding, creating a persistent capacity–robustness trad
e-off. Identifying that extraction accuracy strictly correlates with the distanc
e between candidate hypothesis images, we propose ASIR, a training-free and prov
ably secure steganography framework for both pixel and latent diffusion models.
ASIR introduces two key innovations: (i) Antipodal Sampling, which maximizes sig
nal separation in probability space to enhance distinguishability, and (ii) Iter
ative Recovery, a paradigm shift that treats extraction as a gradient-based opti
mization problem to reverse non-linear distortions. Extensive experiments demons
trate that ASIR achieves state-of-the-art performance, embedding up to 65,536 bi
ts (pixel-space) and 16,384 bits (latent-space) with 99\% accuracy, while remain
ing statistically undetectable to deep steganalyzers.
****

Transitivity Meets Cyclicity: Explicit Preference Decomposition for Dynamic Larg
e Language Model Alignment

Yucong Huang, Xiucheng Li, Kaiqi Zhao, Jing Li

Standard RLHF relies on transitive scalar rewards, failing to capture the cyclic
nature of human preferences. While some approaches like the General Preference
Model (GPM) address this, we identify a theoretical limitation: their implicit f
ormulation entangles hierarchy with cyclicity, failing to guarantee dominant sol
utions. To address this, we propose the Hybrid Reward-Cyclic (HRC) model, which
utilizes game-theoretic decomposition to explicitly disentangle preferences into
orthogonal transitive (scalar) and cyclic (vector) components. Complementing th
is, we introduce Dynamic Self-Play Preference Optimization (DSPPO), which treats
alignment as a time-varying game to progressively guide the policy toward the N
ash equilibrium. Synthetic data experiments further validate HRC's structural su
periority in mixed transitive--cyclic settings, where HRC converges faster and a
chieves higher accuracy than GPM. Experiments on RewardBench 2 demonstrate that

HRC consistently improves over both BT and GPM baselines (e.g., +1.23\% on Gemma -2B-it). In particular, its superior performance in the Ties domain empirically validates the model's robustness in handling complex, non-strict preferences. Ex tensive downstream evaluations on AlpacaEval 2.0, Arena-Hard-v0.1, and MT-Bench confirm the efficacy of our framework. Notably, when using Gemma-2B-it as the ba se preference model, HRC+DSPPO achieves a peak length-controlled win-rate of 44. 75\% on AlpacaEval 2.0 and 46.8\% on Arena-Hard-v0.1, significantly outperformin g SPPO baselines trained with BT or GPM. Our code is publicly available at https ://github.com/lab-klc/Hybrid-Reward-Cyclic.

ExPLAIND: Unifying Model, Data, and Training Attribution to Study Model Behavior

Florian Eichin, Yupei Du, Philipp Mondorf, Maria Matveev, Barbara Plank, Michael A. Hedderich

Post-hoc interpretability methods typically attribute a model’s behavior to its components, data, or training trajectory in isolation, and are often tied to a p articular level of granularity along the local-to-global spectrum. This leads to explanations that lack a unified view and may miss key interactions. We present ExPLAIND, a theoretically grounded, unified framework that integrates model com ponents, data, and training trajectory while supporting explanations across gran ularities. We generalize recent work on gradient path kernels, reformulating mod els trained by AdamW as kernel machines. From the resulting kernel feature maps, we derive novel parameter-wise and step-wise influence scores. We empirically v alidate the resulting decomposition of model behavior in several settings and ap ply ExPLAIND to two case studies. Our findings on a Transformer exhibiting Grokk ing support previously proposed learning phases, while refining the final phase as one in which outer layers align around a representation pipeline learned afte r memorization. For EuroLLM pretraining, ExPLAIND reveals a two-phase dynamic, w ith the first characterized by outer-layer MLP learning and the second by increa sed relative influence of intermediate attention layers. These results establish ExPLAIND as a unified framework for interpreting model behavior and training dy namics.

Informed Asymmetric Actor-Critic: Leveraging Privileged Signals Beyond Full-Stat e Access

Daniel Ebi, Damien Ernst, Klemens Böhm, Gaspard Lambrechts

Asymmetric reinforcement learning leverages privileged information available dur ing training to improve learning under partial observability. Existing asymmetri c actor-critic methods typically assume access to the full environment state to condition the critic during training, which is often unrealistic in practice. We introduce the informed asymmetric actor-critic framework that allows the critic

to be conditioned on arbitrary state-dependent privileged signals, and show tha t any such signal yields unbiased policy gradient estimates. This substantially expands the set of admissible privileged information and raises the problem of s electing the most informative signals for learning. To this end, we propose two novel informativeness criteria: a dependence-based test that can be applied prio r to training, and a test based on improvements in value prediction that can be applied post hoc. Experiments on partially observable benchmarks and synthetic e nvironments demonstrate that carefully selected privileged signals can match or outperform full-state asymmetric baselines while relying on strictly less state information.

****

Breaking the Echo Chamber: A Dynamic Ensemble Pruning Perspective on MoE

Xinlai Kang, Dunyao Xue, Zhengbo Wang, Chengshuo Du, Xinghao Chen, Hang Zhou, Ha nting Chen, Cheng Meng

We introduce Mahalanobis-Pruned Mixture-of-Experts (MP-MoE), a novel routing fra mework that approaches expert selection from the perspective of ensemble pruning . Existing Mixture-of-Experts (MoE) routing strategies often suffer from represe ntation collapse due to greedy top-k selection mechanisms or rely on complex aux iliary regularization terms that may compromise model performance. To address th ese issues, we formulate routing as a diversity-aware subset selection problem a nd optimize a Mahalanobis-distance-based objective that explicitly enhances expe rt diversity. Specifically, we demonstrate that the expert co-occurrence matrix effectively captures inter-expert correlations, allowing us to efficiently model the covariance structure required for distance computation without accessing ex pert parameters. Furthermore, we devise a greedy strategy for the routing mechan ism, backed by theoretical approximation guarantees, rendering it a plug-and-pla y module with negligible overhead.

MP-MoE increases wall-clock training time by approximately 3\%, while incurring no additional latency at inference time.

Extensive experiments demonstrate that during the pre-training of the large lang uage model, our method consistently outperforms the baseline by 1-3 percentage p oints across a broad range of benchmarks.

Optimal Anytime Algorithms for Online Convex Optimization with Adversarial Const raints

Dhruv Sarkar, Abhishek Sinha

We propose an anytime online algorithm for learning a sequence of convex cost fu nctions while approximately satisfying a sequence of convex constraints, without prior knowledge of the time horizon. Both the cost and constraint functions may be chosen adversarially over time. While this problem has recently been resolve d in the setting where the time horizon is known, extending these guarantees to the anytime setting, without resorting to inefficient doubling tricks, has remai ned technically challenging. Our main contribution is the introduction of a time -varying yet horizon-oblivious Lyapunov function to track constraint violations. The use of such a time-varying Lyapunov function introduces new technical diffi culties, as a key monotonicity property underlying prior analyses no longer hold s. By developing a novel analytical technique, we show that our algorithm achiev es $O(\sqrt{t})$ regret and $\tilde{O}(\sqrt{t})$ cumulative constraint violatio n (CCV) for all $t \geq 1$. We further extend our framework to the dynamic regre t setting, obtaining bounds that adapt to the unknown path length of the compara tor sequence. Finally, we present an adaptive algorithm for the optimistic setti ng, whose performance scales gracefully with the cumulative prediction error. We validate the practical effectiveness of our approach through numerical experime nts on the online shortest path problem.

iLoRA: Bayesian Low-Rank Adaptation with Latent Interaction Graphs for Microbiom e Diagnosis

Yang Song, Yixuan Zhang, Lingfa Meng, Tongyuan Hu, Haizhou Shi, Hao Wang, Samir Bhatt, Hengguan Huang

Parameter-efficient adaptation has made LLMs practical for domain prediction, bu

t standard LoRA still relies on a static low-rank update and does not expose the latent interactions that often drive scientific labels. We introduce iLoRA. To our knowledge, it is the first Bayesian graph-conditioned LoRA framework. It infers a latent interaction graph from the input and uses it to generate input-conditioned LoRA updates. As a result, iLoRA learns prediction and latent interaction structure jointly, rather than training a predictor and applying interaction analysis only post hoc. We instantiate this idea for microbiome diagnosis, where disease state can depend on both species-level abundance and microbe–microbe cross-talk, and evaluate it in two complementary settings: interactive QA with human-annotated graphs, which tests latent structure recovery, and multi-cohort IBD diagnosis, which tests biomedical utility. Across both settings, iLoRA improves over strong LoRA and Bayesian adaptation baselines, recovers graphs aligned with human annotations and cohort-level microbiome associations, and provides calibrated uncertainty with moderate graph-branch overhead.
****
Query Circuits: Explaining How Language Models Answer User Prompts
Tung-Yu Wu, Fazl Barez
Explaining why a language model produces a particular output requires local, input-level explanations. Existing methods uncover global capability circuits (e.g., indirect object identification), but not why the model answers a specific input query in a particular way. We introduce query circuits, which directly trace the information flow inside a model that maps a specific input to the output. Unlike surrogate-based approaches (e.g., sparse autoencoders), query circuits are identified within the model itself, resulting in more faithful and computationally accessible explanations. To make query circuits practical, we address two challenges. First, we introduce Normalized Deviation Faithfulness (NDF), a robust metric to evaluate how well a discovered circuit recovers the model's decision for a specific input, and is broadly applicable to circuit discovery beyond our setting. Second, we develop sampling-based methods to efficiently identify circuits that are sparse yet faithfully describe the model’s behavior. Across benchmarks (IOI, arithmetic, MMLU, and ARC), we find that there exist sparse query circuits within the model that recover much of its performance on single queries. For example, on average, a circuit covering only 1.3\% of model connections can recover about 60\% of performance on an MMLU question. Overall, query circuits provide a step towards faithful, scalable explanations of how language models process individual inputs.
****
Towards Context-Invariant Safety Alignment for Large Language Models
Yixu Wang, Yang Yao, Xin Wang, Yifeng Gao, Yan Teng, Xingjun Ma, Yingchun Wang
Preference-based post-training aligns LLMs with human intent, yet safety behavior often remains brittle.
A model may refuse a harmful request in a standard prompt but comply when the same intent is wrapped in adversarial wording.
We suggest that robust safety requires context-invariant alignment, where behavior depends on the underlying intent rather than surface form.
Enforcing invariance is difficult in alignment because not all training signals are equally trustworthy; for some prompt variants we can obtain verifiable feedback (e.g., multiple-choice), while for open-ended variants we typically rely on noisy, gameable reward proxies (e.g., learned judges).
As a result, standard symmetric invariance regularizers can reduce cross-context discrepancies by lowering performance on reliable variants instead of improving open-ended robustness.
To address this, we introduce Anchor Invariance Regularization (AIR), which treats verifiable prompts as anchors and uses a stop-gradient target to regularize only the open-ended variants toward the anchor performance.
AIR is implemented as a plug-in auxiliary loss and combined with group-based preference optimization (e.g., GRPO) via heterogeneous prompt grouping. Across Safety, Moral Reasoning, and Math, AIR improves context invariance, boosting in-distribution group accuracy by 12.71% and out-of-distribution consistency by 33.49%, making safety constraints robust to adversarial framings.

What Really Improves Mathematical Reasoning: Structured Reasoning Signals Beyond Pure Code
Yuze Zhao, Junpeng Fang, Lu Yu, Zhenya Huang, Kai Zhang, Qing Cui, Qi Liu, JUN ZHOU, Enhong Chen
Incorporating code into training corpora has become a widely acknowledged practice in the development of modern foundation language models (LMs). Compared with a general Internet corpus, code offers high-quality, well-structured signals that substantially augment the coding proficiency of models. Beyond programming skills, prior research has suggested that code data may also contribute to non-coding capabilities. Nevertheless, through a series of rigorous controlled experiments, we demonstrate that the influence of code on other domains, particularly reasoning, remains limited.
Our principal findings are as follows: (1) Code corpus yields substantial gains in programming-related abilities but only competed with knowledge-intensive tasks. (2) We identify a core subset that functions as cognitive scaffolding for mathematical reasoning, especially for complex problem-solving scenarios. (3) Formal reasoning provides more pronounced improvements in challenging mathematical reasoning tasks, while natural language–based reasoning proves more effective for simpler reasoning problems.
Finally, by probing the internal mechanisms of LMs, we reveal how training data modulates routing patterns, thereby shaping emergent model behavior. As a central driver of model capability, our findings disentangle domain-specific data into finer-grained, cross-domain ability dimensions and underscore promising directions for future data optimization.

Integrated Episodic and Semantic Memory via Modulating Transformer FeedForward Layers
Yiqun Yao, Xiang Li, Xin Jiang, Xuezhi Fang, Naitong Yu, Siwei Dong, Wenjia Ma, Jing Li, Aixin Sun, Yequan Wang
It is widely recognized that, after generative pre-training, Transformer FeedForward layers implicitly function as semantic memory, encoding linguistic and factual knowledge, while the contexts in key–value (KV) cache contain raw events, serving as the source of models' episodic memory. In this work, we show that a same group of Transformer FeedForward-layer parameters can both be semantic and episodic memory, which is retrievable without explicitly attending to the related KV cache. To realize this idea, we introduce Hypermem, a hypernetwork that recurrently maps contexts into targeted updates of FeedForward parameters. We post-train the hypernetwork using continuation and random-access associative memory objectives, eliminating the need for test-time training. Extensive experiments demonstrate that our approach outperforms related methods, including MemoryLLM and generative adapter, on memory retrieval, long-context question answering, and personalization benchmarks, establishing a new state of the art for hypernetwork-based memory mechanisms. Our results suggest that directly bridging data and parameters provides a viable direction for exploring next-generation foundation models with more flexible and persistent memory capabilities.

SpikeNet: Sparse Spike-Driven Mask Vector Transformer for Energy-Efficient and Stable Spiking Point Cloud Processing
Zhiming Zhou, Yong He, Chaoxu Mu, Qiaoyun Wu, Ajmal Saeed Mian
The unordered nature of point cloud data poses significant challenges to conventional architectures primarily designed for structured data.
Spiking neural networks (SNN), by virtue of their inherent sparsity and dynamics, are particularly well-suited for processing point clouds to effectively extract meaningful features. We propose SpikeNet, a novel spiking neural network architecture for energy-efficient and robust point cloud analysis. We introduce spiking-driven sparse attention mechanism coined the Spiking Vector Mask Transformer (SVMT).
By dynamically aligning the sparsity of point cloud data through binary spiking masks, SVMT eliminates the need for softmax and multiplication operations, signi

ficantly improving computational efficiency. We also propose a Dynamic Sparse Sp iking Residual (DSSR) structure and integrate it with SVMT to form the Spiking N eural Network (SpikeNet) for point cloud classification and segmentation. SpikeN et overcomes the trade-off between accuracy and efficiency in previous SNN metho ds, achieving collaborative optimization of performance and energy-efficiency. E xperiments on benchmark datasets show that SpikeNet achieves state-of-the-art pe rformance in shape classification and segmentation tasks, comparable to artifici al neural network (ANN) based methods. Our source code is in supplementary mater ial and will be made publicly available.

Dissecting Quantization Error: A Concentration-Alignment Perspective
Marco Federici, Boris van Breugel, Paul N. Whatmough, Markus Nagel
Quantization can drastically increase the efficiency of large language and visio n models, but typically incurs an accuracy drop. Recently, function-preserving t ransforms (e.g. rotations, Hadamard transform, channel-wise scaling) have been s uccessfully applied to reduce post-training quantization error, yet a principled explanation remains elusive.

We analyze linear-layer quantization via the signal-to-quantization-noise rati o (SQNR), showing that for uniform integer quantization at a fixed bit width, SQ NR decomposes into (i) the concentration of weights and activations (capturing s pread and outliers), and (ii) the alignment of their dominant variation directio ns. This provides an actionable insight: enhancing alignment between weight and activation variation directions can reduce quantization error, complementing con centration-focused approaches. Motivated by this, we introduce Concentration–Ali gnment Transforms (CAT), a lightweight linear transformation that uses a covaria nce estimate from a small calibration set to jointly improve concentration and a lignment, approximately maximizing SQNR. Experiments across several LLMs show th at CAT consistently matches or outperforms prior transform-based quantization me thods at 4-bit precision.

Discriminative Visual Process Rewards for Scaling Thinking at Test-Time with Ima ges
Bo-Wen Yin, Qize Yang, Boyuan Sun, Xihan Wei, Qibin Hou
The “thinking with images” paradigm has led multimodal large language models to generate intermediate visual steps—such as cropping, annotation, spatial localiz ation, and sketches—to enhance high-resolution perception and complex reasoning. However, existing multimodal Process Reward Models (PRMs) evaluate only textual reasoning and cannot judge the correctness of these visual steps, creating a ke y gap when visual reasoning is essential for solving tasks. We propose Discrimin ative Visual Process Reward Model (DiscPRM), a multimodal PRM that jointly evalu ates textual and visual intermediate steps by modeling visual reasoning trajecto ries, image operations, and text-image consistency. To support this, we build VT Reward-100K, a dataset of step-by-step visual reasoning sequences with supervisi on. Experiments show that using DiscPRM for Best-of-N process supervision substa ntially improves multimodal reasoning performance on tasks requiring visual inte rmediate steps, achieving over 5% gains across benchmarks. We further introduce VABench, the first benchmark for evaluating PRMs on visual reasoning error detec tion. We hope this work can provide foundational support for advancing the emerg ing direction of visual–textual process reward.
****

RedDebate: Safer Responses Through Multi-Agent Red Teaming Debates
Ali Asad, Stephen Obadinma, Radin Shayanfar, Xiaodan Zhu
We introduce RedDebate, a novel multi-agent debate framework that provides the f oundation for Large Language Models (LLMs) to identify and mitigate their own un safe behaviors. Existing AI safety approaches often rely on costly human evaluat ion or isolated single-model assessment, both constrained by scalability and pro ne to oversight failures. RedDebate employs collaborative argumentation among mu ltiple LLMs across diverse debate scenarios, enabling them to critically evaluat e one another’s reasoning and systematically uncover unsafe failure modes throug h fully automated red-teaming. We further integrate distinct long-term memory mo

dules that preserve safety-relevant insights from debate interactions and levera ge them during subsequent inference, facilitating continuous refinement of model behavior. Empirical evaluation on safety benchmarks across a diverse set of mod els demonstrates that RedDebate substantially reduces unsafe outputs. While deba te alone allows LLMs to refine their behavior, the addition of memory modules yi elds further significant reductions. To the best of our knowledge, RedDebate is the first fully automated framework to unify multi-agent debate and red-teaming to progressively enhance LLM safety without human intervention.

It's TIME: Towards the Next Generation of Time Series Forecasting Benchmarks
Zhongzheng Qiao, Sheng Pan, Anni Wang, Viktoriya Zhukova, Yong Liu, Xudong Jiang , Qingsong Wen, Mingsheng Long, Ming Jin, Chenghao Liu
Time series foundation models (TSFMs) are revolutionizing the forecasting landsc ape from specific dataset modeling to generalizable task evaluation. However, we contend that existing benchmarks exhibit common limitations in four dimensions: constrained data composition dominated by reused legacy sources, compromised da ta integrity lacking rigorous quality assurance, misaligned task formulations de tached from real-world contexts, and rigid analysis perspectives that obscure ge neralizable insights. To bridge these gaps, we introduce **TIME**, a next-genera tion task-centric benchmark comprising 50 fresh datasets and 98 forecasting task s, tailored for strict zero-shot TSFM evaluation free from data leakage. Integra ting large language models and human expertise, we establish a human-in-the-loop benchmark construction pipeline to ensure high data integrity and redefine task formulation by aligning forecasting configurations with real-world operational requirements and variate predictability. Furthermore, we propose a novel pattern -level evaluation perspective that moves beyond traditional dataset-level evalua tions based on static meta labels. By leveraging structural time series features to characterize intrinsic temporal properties, this approach offers generalizab le insights into model capabilities across diverse patterns. We evaluate 12 TSFM s and establish a multi-granular leaderboard to facilitate in-depth analysis and visualized inspection. The leaderboard is available at https://huggingface.co/s paces/Real-TSF/TIME-leaderboard.

Are Common Substructures Transferable? Riemannian Graph Foundation Model with Ne ural Vector Bundles
Li Sun, Zhenhao Huang, Yiding Wang, Qin Chen, Pietro Lio, Philip S. Yu
Foundation models have sparked a revolution via a pretraining-adaptation paradig m, with recent efforts extending this success to graphs. Unlike other modalitie s, graphs contain rich structural patterns, yet their structural transferability remains poorly understood. Prior studies consider common substructures in the d iscrete realm, and we are motivated by a fundamental question: Are common substr uctures transferable? The underlying theory is largely underexplored. In this wo rk, we shift toward learning transferable structures through the lens of functio nal behavior. Theoretically, we connect transferable substructures to intrinsic geometry of the representation space. However, characterizing such intrinsic geo metry has rarely been touched. Grounded in Riemannian geometry, we develop a gra ph intrinsic geometry learning framework—\textbf{Neural Vector Bundle}, which en ables parsing intrinsic geometry with local coordinates. Building on this, we de sign \textbf{\textsc{Gauge}}, a pretrainable neural architecture that constructs the vector bundle, flattening geometrically compatible local coordinates, and a new Dirichlet loss, which also measures the transfer effort. We empirically val idate its superior expressiveness in challenging tasks including zero-shot link prediction and graph isomorphism.

Learn from A Rationalist: Distilling Intermediate Interpretable Rationales
Jiayi Dai, Randy Goebel
Because of the pervasive use of deep neural networks (DNNs), especially in high- stakes domains, the interpretability of DNNs has received increased attention. T he general idea of rationale extraction (RE) is to provide an interpretable-by-d esign framework for DNNs via a select-predict architecture where two neural netw

orks learn jointly to perform feature selection and prediction, respectively. Gi
ven only the remote supervision from the final task prediction, the process of l
earning to select subsets of features (or *rationales*) requires searching in th
e space of all possible feature combinations, which is computationally challengi
ng and even harder when the base neural networks are not sufficiently capable. T
o improve the predictive performance of RE models that are based on less capable
 or smaller neural networks (i.e., the students), we propose **REKD** (**R**atio
nale **E**xtraction with **K**nowledge **D**istillation) where a student RE mode
l learns from the rationales and predictions of a teacher (i.e., a *rationalist*
) in addition to the student's own RE optimization. This structural adjustment t
o RE aligns well with how humans could learn effectively from interpretable and
verifiable knowledge. Because of the neural-model agnostic nature of the method,
 any black-box neural network could be integrated as a backbone model. To demons
trate the viability of REKD, we conduct experiments with multiple variants of BE
RT and vision transformer (ViT) models. Our experiments across language and visi
on classification datasets (i.e., IMDB movie reviews, CIFAR 10 and CIFAR 100) sh
ow that REKD significantly improves the predictive performance of the student RE
 models. The code is publicly available: https://github.com/JiayiDai/REKD.

A Diagnostic Study of Multi-Agent LLMs for Real-World Debates

Priya Pitre, Gaurav Srivastava, Lu Zhang, Le Wang, Naren Ramakrishnan, Xuan Wang

Multi-agent LLM debates are increasingly used in domains such as policy, politic
s, and city planning, where ground truth is often unavailable. Yet existing eval
uations rely heavily on outcome-based proxies such as consensus, majority vote,
or LLM-as-judge scores, which can miss failures like sycophancy, domination, and
 premature convergence. We introduce a diagnostic framework that evaluates both
debate outcomes and the deliberative process using interpretable metrics for eng
agement, responsiveness, influence asymmetry, balance, stability, and agent util
ity. Across real-world debate settings and validation benchmarks, our process-le
vel diagnostics align more closely with human judgments and reveal interaction f
ailures that standard outcome-only measures overlook. These results show that re
liable evaluation of multi-agent debates requires measuring not only what answer
 agents reach, but how they reach it.

One Step Forward and K Steps Back: Better Reasoning with Denoising Recursion Mod
els

Chris Cameron, Wangzheng Wang, Nikita Ivanov, Ashmita Bhattacharyya, Didier Chét
elat, Yingxue Zhang

Looped transformers scale computational depth without increasing parameter count
 by repeatedly applying a shared transformer block and can be used for iterative
 refinement, where each loop rewrites a full fixed-size prediction in parallel.
On difficult problems, such as those that require search-like computation, reach
ing a highly structured solution starting from noise can require long refinement
 trajectories. Learning such trajectories is challenging when training specifies
 only the target solution and provides no supervision over the intermediate refi
nement path. Diffusion models tackle this issue by corrupting data with varying
magnitudes of noise and training the model to reverse it in a *single step*. How
ever, this process misaligns training and testing behaviour. We introduce Denois
ing Recursion Models, a method that similarly corrupts data with noise but train
s the model to reverse the corruption over *multiple* recursive steps. This stra
tegy provides a tractable curriculum of intermediate states, while better aligni
ng training with testing and incentivizing non-greedy, forward-looking generatio
n. Through extensive experiments, we show this approach outperforms the Tiny Rec
ursion Model (TRM) on ARC-AGI, where it recently achieved breakthrough performan
ce.

From Imagined Futures to Executable Actions: Mixture of Latent Actions for Robot
 Manipulation

Yajie Li, Bozhou Zhang, Chun Gu, Zipei Ma, Jiahui Zhang, Jiankang Deng, Xiatian
Zhu, Li Zhang

Video generation models offer a promising imagination mechanism for robot manipulation by predicting long-horizon future observations, but effectively exploiting these imagined futures for action execution remains challenging. Existing approaches either condition policies on predicted frames or directly decode generated videos into actions, both suffering from a mismatch between visual realism and control relevance. As a result, predicted observations emphasize perceptual fidelity rather than action-centric causes of state transitions, leading to indirect and unstable control.

To address this gap, we propose MoLA (Mixture of Latent Actions), a control-oriented interface that transforms imagined future videos into executable representations. Instead of passing predicted frames directly to the policy, MoLA leverages multiple pretrained inverse dynamics models to infer a mixture of latent actions implied by generated visual transitions. These modality-aware inverse dynamics models capture complementary semantic, depth, and flow cues, providing a structured and physically grounded action representation that bridges video imagination and policy execution.

We evaluate our approach on simulated benchmarks (LIBERO, CALVIN, and LIBERO-Plus) and real-world robot manipulation tasks, achieving consistent gains in task success, temporal consistency, and generalization.

FutureOmni: Evaluating Future Forecasting from Omni-Modal Context for Multimodal LLMs

Qian Chen, Jinlan Fu, Changsong Li, Min Zhang, See-Kiong Ng, Xipeng Qiu

Although Multimodal Large Language Models (MLLMs) demonstrate strong omni-modal perception, their ability to forecast future events from audio-visual cues remains largely unexplored, as existing benchmarks focus mainly on retrospective understanding. To bridge this gap, we introduce FutureOmni, the first benchmark designed to evaluate omni-modal future forecasting from audio-visual environments. The evaluated models are required to perform cross-modal causal and temporal reasoning, as well as effectively leverage internal knowledge to predict future events. FutureOmni is constructed via a scalable LLM-assisted, human-in-the-loop pipeline and contains 919 videos and 1,034 multiple-choice QA pairs across 8 primary domains. Evaluations on 13 omni-modal and 7 video-only models show that current systems struggle with audio-visual future prediction, particularly in speech-heavy scenarios, with the best accuracy of 64.8% achieved by Gemini 3 Flash. To mitigate this limitation, we curate a 7K-sample instruction-tuning dataset and propose an Omni-Modal Future Forecasting (OFF) training strategy. Evaluations on FutureOmni along with standard audio-visual and video-only benchmarks show that OFF improves future forecasting performance and generalization. Code and data are available at https://github.com/OpenMOSS/FutureOmni.

Inference-Time Conformal Reasoning with Valid Factuality Control for Large Language Models

Ting Wang, Yuanjie Shi, Yan Yan, Huan Zhang

Large language models (LLMs) increasingly perform multi-step reasoning, where intermediate claims form implicit directed acyclic graphs whose node correctness is structurally conditioned on their ancestors. This makes factuality uncertainty structural, rather than a trivial accumulation of node-wise errors, and necessitates inference-time uncertainty quantification over the reasoning structure. While conformal prediction (CP) offers flexible user-specified factuality control, existing work remains post-hoc and cannot intervene during generation. To fill the gap between CP's flexibility and its post-hoc limitation, we propose an *Inference-Time Conformal Reasoning (ITCR)* framework that integrates CP directly into reasoning graph generation. ITCR learns a structure-level factuality uncertainty function that aggregates claim-level factuality signals over reasoning graphs without complex modeling assumptions. We then design the non-conformity score based on graph-level factuality uncertainty and calibrate the conformal threshold to decide when to stop generation. We theoretically show such generation is nested, yielding valid coverage guarantees for factuality control. Experiments over multiple datasets and coverage objectives demonstrate empirically valid covera

ge. In downstream reasoning tasks, inference-time calibrated graphs yield more accurate generation than post-hoc pruned graphs.

Simultaneous Speech-to-Speech Translation Without Aligned Data
Tom Labiausse, Romain Fabre, Yannick Estève, Alexandre Défossez, Neil Zeghidour
Simultaneous speech translation requires translating source speech into a target language in real-time while handling non-monotonic word dependencies. Traditional approaches rely on supervised training with word-level aligned data, which is difficult to collect at scale and thus depends on synthetic alignments using language-specific heuristics that are suboptimal. We propose Hibiki-Zero, which eliminates the need for word-level alignments entirely. This fundamentally simplifies the training pipeline and enables seamless scaling to diverse languages with varying grammatical structures, removing the bottleneck of designing language-specific alignment heuristics. We first train on sentence-level aligned data to learn speech translation at high latency, then apply a novel reinforcement learning strategy using GRPO to optimize latency while preserving translation quality. Hibiki-Zero achieves state-of-the-art performance in translation accuracy, latency, voice transfer, and naturalness across four X-to-English tasks. Moreover, we demonstrate that our model can be adapted to support a new input language with less than 1000h of speech. We provide [examples](https://huggingface.co/spaces/kyutai/hibiki-zero-samples), [model weights](https://huggingface.co/kyutai/hibiki-zero-3b-pytorch-bf16), [inference code](https://github.com/kyutai-labs/hibiki-zero) and we release a [benchmark](https://huggingface.co/datasets/kyutai/Audio-NTREX-4L) containing 45h of multilingual data for speech translation evaluation.

Evaluating Parameter Efficient Methods for RLVR
Qingyu Yin, Yulun Wu, Zhennan Shen, Sunbowen Lee, Zhilin Wang, Yanshu Li, Chak Tou Leong, Jiale Kang, Jinjin Gu
We systematically evaluate Parameter-Efficient Fine-Tuning (PEFT) methods under the paradigm
of Reinforcement Learning with Verifiable Rewards (RLVR). RLVR incentivizes language models to
enhance their reasoning capabilities through verifiable feedback; however, while methods like LoRA are
commonly used, the optimal PEFT architecture for RLVR remains unidentified. In this work, we conduct
the first comprehensive evaluation of over 12 PEFT methodologies across the DeepSeek-R1-Distill
families on mathematical reasoning benchmarks. Our empirical results challenge the default adoption
of standard LoRA with three main findings. First, we demonstrate that structural variants, such as
DoRA, AdaLoRA, and MiSS, consistently outperform LoRA. Second, we uncover a spectral collapse
phenomenon in SVD-informed initialization strategies (e.g., PiSSA, MiLoRA), attributing their failure to
a fundamental misalignment between principal-component updates and RL optimization. Furthermore,
our ablations reveal that extreme parameter reduction (e.g., VeRA, Rank-1) severely bottlenecks
reasoning capacity. We further conduct ablation studies and scaling experiments to validate our findings.
This work provides a definitive guide for advocating for more exploration for parameter-efficient RL
methods.
****
Autoregressive Boltzmann Generators
Danyal Rehman, Charlie B. Tan, Yoshua Bengio, Joey Bose, Alexander Tong
Efficient sampling of molecular systems at thermodynamic equilibrium is a hallma

rk challenge in statistical physics. This challenge has driven the development o
f Boltzmann Generators (BGs), which allow rapid generation of uncorrelated equil
ibrium samples by combining a generative model with exact likelihoods and an imp
ortance sampling correction. However, modern BGs predominantly rely on Normalizi
ng Flows (NFs), which either suffer from limited expressivity due to strict inve
rtibility constraints (discrete time) or computationally expensive likelihoods (
continuous time). In this paper, we propose Autoregressive Boltzmann Generators
(ArBG), a novel autoregressive modelling framework that overcomes these limitati
ons by departing from the flow-based BG paradigm. ArBG circumvents the topologic
al constraints of flows and enables sequential inference-time interventions, whi
le offering enhanced scalability by leveraging architectures effective in Large
Language Models. We empirically demonstrate that ArBG leads to significant impro
vements over flow-based models across all benchmarks, but particularly in larger
 peptide systems such as the 10-residue Chignolin. Furthermore, we introduce Rob
in, a 132M parameter transferable model trained with the ArBG framework which im
proves over the previous state-of-the-art, reducing the zero-shot energy error,
$\mathcal{E}$-$\mathcal{W}_2$, on 8-residue systems by ~ 60\%.

Theoretical Analysis of Sparse Optimization with Reparameterization, Weight Deca
y, and Adaptive Learning Rate
Huangyu Xu, Jingqin Yang, Qianqian Xu, Jiaye Teng
Sparse optimization is a fundamental challenge in various practical applications
.
A popular approach to sparse optimization is Lp regularization.
However, it may encounter optimization instability due to the unbounded gradient
s when 0<p<1.
In this paper, we introduce a novel approach to sparse optimization termed ReWA,
 based on Reparameterization, Weight decay, and Adaptive learning rate. ReWA is
closely connected to lp-regularization, yet it unveils a distinct optimization l
andscape that helps mitigate instability issues.
Experiments on CIFAR-10 and ImageNet with ResNets demonstrate that ReWA leads to
 significant sparsity improvements over the L1-regularization approach while pre
serving test accuracy.

Algorithmic Recourse of In-Context Learning for Tabular Data
Wenshuo Dong, Jiaming Zhang, Shaopeng Fu, Hongbin Lin, Di Wang, Lijie Hu
As predictive models are increasingly deployed in high-stakes settings such as c
redit approval, there is a growing need for post-hoc methods that provide recour
se to affected individuals. Many such models operate on tabular data, where feat
ures correspond to real-world attributes. Recently, in-context learning (ICL) ha
s enabled large language models to perform tabular prediction by conditioning on
 labeled examples at inference time, without explicit training. However, algorit
hmic recourse for tabular decision-making under ICL remains largely unexplored.
In this work, we present the first study of algorithmic recourse for tabular dat
a under ICL. We carry out a theoretical analysis, showing that recourse remains
well-defined and bounded, and we characterize how recourse converges toward clas
sical solutions as the context size increases. In practice, we propose a novel z
eroth-order recourse framework, Adaptive Subspace Recourse for In-Context Learni
ng (ASR-ICL), that efficiently generates actionable and sparse recourse for blac
k-box ICL models. The proposed framework naturally extends to multi-class tabula
r tasks. Experiments across multiple real-world datasets and models demonstrate
that ASR-ICL achieves recourse quality comparable to existing methods with fewer
 queries and empirically confirm the predicted convergence behavior, supporting
our theoretical analysis.

On the Identifiability of Poisson Branching Structural Causal Model Under Latent
 Confounding
Jie Qiao, Zihuai Zeng, Ruichu Cai, Zhengming Chen, Zhifeng Hao
Causal discovery from observational count data poses unique challenges, particul
arly when the data exhibit inherent branching structures, such as an upstream ad

impression event triggering a downstream purchase event with certain probabilit
y. Such branching dynamics are naturally modeled by thinning operators (for bran
ching) and an independent Poisson distribution (for exogenous noise), constituti
ng a Poisson Branching Structural Causal Model (PB-SCM). However, existing appro
aches based on PB-SCM rely on the restrictive assumption of causal sufficiency,
failing to account for ubiquitous latent confounders. In this work, we propose a
Latent Confounding Poisson Branching Structural Causal Model (LC-PB-SCM) to bri
dge this gap. We leverage Probability Generating Function (PGF) to characterize
the complex dependencies introduced by latent confounding. Then, we establish a
Trie representation theorem that maps the branching structure to algebraic prope
rties of PGF monomials. Based on local PGF, we establish a complete identifiabil
ity condition for local 3-variables covering all causal patterns distinguishable
up to monomial equivalence. Finally, we propose a practical algorithm to learn
causal structures under latent confounding and demonstrate its effectiveness thr
ough experiments on both synthetic and real-world datasets.

FedUSD: Unbiased Synthetic Data for Federated Learning
Weiying Xie, Chenhe Hao, Haozhi Shi, Jitao Ma, Daixun Li, Jiazhe Li, Hengyi Wang
, Leyuan Fang, Yunsong Li
Aggregation-Free Federated Learning enables joint training by sharing synthetic
data, aiming to eliminate data heterogeneity across clients. However, existing m
ethods fail to explicitly separate the principal and residual components of data
set, leading to biased synthetic data. In this paper, we propose a novel Unbiase
d Synthetic Data optimization method FedUSD for Aggregation-Free Federated Learn
ing, which is achieved by exploring the High-energy Orthogonal Base (HOB) and va
riance of dataset in feature space. Our FedUSD is inspired by the discovery that
principal component concentrates in HOB while residual component independently
reflects in variance, regardless of networks. Based on the observation, we devel
op a method that mathematically optimizes synthetic data by matching both HOB an
d variance with those of real data. Besides, we experimentally show the superior
effectiveness of leveraging HOB and variance to separately extract the principa
l and residual components over existing methods. We also theoretically prove tha
t FedUSD achieves unbiased synthetic data and thus convergence. Without introduc
ing any constraints, FedUSD thereby yields significant improvements over the sta
te-of-the-arts in terms of global model performance, under equivalent communicat
ional costs. For example, on the SVHN dataset, FedUSD improves 6.74\% to 30.82\%
which is higher than others with Dirichlet coefficient $\alpha=0.01$.
****
Decentralized Bandits without Global Clock for Dynamic Matching Market
Mengtong Gao, Zhenhe Zhang, Jichen Li, Wentao Zhou, Xuanzhi Xia, Jing Chen
Two-sided matching markets are pervasive in numerous real-world applications, ra
nging from labor markets to online advertising. A rich line of research has stud
ied the matching bandit problem, where participants learn their preferences thro
ugh iterative interactions. However, existing works assume a static environment
with fixed participants and require synchronized learning, in which all particip
ants start simultaneously and have access to a global clock. In reality, matchin
g markets are inherently dynamic: participants may enter and leave at arbitrary
time steps without any global signal, creating coordination challenges.

To study the dynamic setting, we first investigate one-sided learning under unco
ordinated player arrivals, where only the players need to learn their preference
s. We propose the Way-SE algorithm, which achieves a regret of $O(\frac{K^2 \log
T}{\Delta_{\min}^2})$, where K is the number of arms, T is the time horizon
, and Δ_{min} is the minimum utility gap. This is done through a distribu
ted exploration mechanism that coordinates exploration implicitly via just local
clocks. More importantly, we extend our work to fully decentralized dynamic two
-sided learning, where both sides need to learn their preferences, and players a
rrive or depart arbitrarily. We introduce Way-SE-2S, the first algorithm to achi
eve sublinear regret $O\left(\frac{K T^{1-1/K}(\log T)^{2/K}}{\Delta_{\min}^2}\r
ight)$ in this challenging environment, without requiring global signals, restri

ctive preference structures, or observability of the results of competing agents. Our work provides the first theoretical guarantee for stable matching in fully decentralized and uncoordinated bandit markets.
****
Untied Ulysses: Memory-Efficient Context Parallelism via Headwise Chunking
Ravi Ghadia, Maksim Abraham, Sergei Vorobyov, Max Ryabinin
Efficiently processing long sequences with Transformer models usually requires splitting the computations across accelerators via context parallelism.
The dominant approaches in this family of methods, such as Ring Attention or DeepSpeed Ulysses, enable scaling over the context dimension but do not focus on memory efficiency, which limits the sequence lengths they can support.
More advanced techniques, such as Fully Pipelined Distributed Transformer or activation offloading, can further extend the possible context length at the cost of training throughput.
In this paper, we present UPipe, a simple yet effective context parallelism technique that performs fine-grained chunking at the attention head level.
This technique significantly reduces the activation memory usage of self-attention, breaking the activation memory barrier and unlocking much longer context lengths.
Our approach lowers the peak activation memory usage by as much as **82.5%** for 70B Transformers, while matching previous context parallelism techniques in terms of training speed.
UPipe can support maximum context lengths of up to 5M tokens for training 8B models on a single 8xH100 node, improving upon prior methods by **25%**.
****
Demystifying the Optimal Fair Classifier in Multi-Class Classification
Li Zhang, Yuyuan Li, XiaoHua Feng, Jiaming Zhang, Fengyuan Yu, Chaochao Chen
Ensuring fair and equitable treatment across diverse groups, particularly in multi-class classification tasks, poses a significant challenge due to the persistent biases inherent in machine learning models.
Most existing bias mitigation techniques are tailored to binary settings, and the presence of multi-dimensional outputs and complex fairness mechanisms makes their extension to multi-class scenarios neither straightforward nor effective.
In this paper, we investigate two fundamental, unresolved challenges in fair classification: (i) *characterizing the optimal accuracy-fairness frontier in multi-class settings*, and (ii) *designing practical algorithms that attain this optimum across different training phases*.
To tackle these challenges, we first specify an analytically tractable probabilistic formulation of the optimal classifier under fairness constraints.
Building upon this, we propose two attribute-blind algorithms to enforce fairness requirements in practice: an in-processing approach for fairness intervention during training via the reduction approach, and a post-processing approach for fine-tuning output probabilities with plug-in estimation.
Theoretical analysis reveals that both methods converge to the optimal accuracy-fairness Pareto frontier.
Experiments conducted on multiple datasets demonstrate the superior performance of our methods in balancing accuracy and fairness.
****
LIVEditor-14B: Lightning Unified Video Editing via In-Context Sparse Attention
Shitong Shao, zikai zhou, Haopeng Li, Yingwei Song, Wenliang Zhong, Lichen Bai, Zeke Xie
Video editing has evolved toward In-Context Learning (ICL) paradigms, yet the resulting quadratic attention costs create a critical computational bottleneck. In this work, we propose **I**n-context **S**parse **A**ttention (**ISA**), the first experimentally lossless sparse framework tailored for ICL video editing. Our design is grounded in two key insights: __**first**__, context tokens exhibit significantly lower saliency than source tokens; __**second**__, we theoretically prove and empirically validate that Query sharpness correlates with approximation error. Motivated by these findings, ISA implements an efficient pre-selection strategy to prune redundant context, followed by a dynamic query grouping mecha

nism that routes high-error queries to full attention and low-error ones to a co mputationally efficient 0-th order Taylor sparse attention. Furthermore, we cons truct a scalable pipeline to curate a 1M-sample dataset and train __**LIVEditor-14B**__, a novel lightning video editing model via ISA. Extensive experiments de monstrate that LIVEditor-14B achieves a ~60% reduction in latency while surpassi ng state-of-the-art methods across EditVerseBench, IVE-Bench, and VIE-Bench, del ivering experimentally lossless acceleration without compromising visual fidelit y.

OCNR: Stabilizing Self-Play by Mitigating Iteration-Collapse With One-Class Nove lty Rewards

Seungyoo Lee, Giung Nam, Hyungi Lee, Juho Lee

Training large language models via self-play often suffers from a persistent ite ration-collapse, where performance initially improves but subsequently regresses as training iterations increase. We analyze this phenomenon as arising from cro ss-iteration degeneration, where the task-generation distribution becomes increa singly confined to a narrow subset of familiar (seen) problems, weakening the ef fective learning signal and destabilizing training. To address this issue, we pr opose a plug-in approach that augments existing self-play pipelines with a one-c lass novelty reward. A Seen Detector trained on a historical buffer of previousl y used training problems identifies in-support instances and discourages redunda nt generation by the questioner, thereby steering exploration toward under-explo red yet learnable regions. Experimental results show that the proposed method mi tigates iteration-collapse during iterative training and yields consistent impro vements.

Attention with Routed-Memory for Learnable Sparse Control

QIUHAO Zeng, Jerry Huang, Peng Lu, Ruiyi Fang, Gezheng Xu, Zihao Jing, Yufei Cui , Charles Ling, Gang Niu, Boyu Wang

Despite advances in long-context inference, large language models (LLMs) remain fundamentally limited by the key-value (KV) caching mechanisms that are necessar y for stable computation. Techniques such as selective token eviction and prunin g have vastly mitigated these issues, but often discard core information to mana ge the growing cache.

In this paper, we propose _**A**ttention with **R**outed **M**emory_ (_**ARM**_) a novel KV caching structure that introduces a fully differentiable, fixed-size memory system organized as a hierarchical router. Via a Gumbel-Softmax, _**ARM** *_ learns to select memory slots and perform sigmoid-gated updates that softly c ombine new and stored information, avoiding hard eviction and reducing informati on loss. By further training a policy to dynamically select varying amounts of m emory at inference, _**ARM**_ adapts its accesses for both simple contexts and i nputs that require deeper reasoning, enabling more scalable and effective retrie val on both short- and long-contexts. Experimental results on standard commonsen se and long-context reasoning benchmarks demonstrate that _**ARM**_ achieves sup erior performance and efficiency compared to fixed KV-caching approaches, while remaining efficient and scalable in terms of both memory and generation latency.

VALUEFLOW: Toward Pluralistic and Steerable Value-based Alignment in Large Langu age Models

Woojin Kim, Sieun Hyeon, Jusang Oh, Jaeyoung Do

Aligning Large Language Models (LLMs) with the diverse spectrum of human values remains a central challenge: preference-based methods often fail to capture deep er motivational principles. Value-based approaches offer a more principled path, yet three gaps persist: extraction often ignores hierarchical structure, evalua tion detects presence but not calibrated intensity, and steerability of LLMs at controlled intensities remains insufficiently understood. To address these limit ations, we introduce VALUEFLOW, a unified framework that spans extraction, evalu ation, and steering with calibrated intensity control. The framework integrates three components: (i) HiVES, a hierarchical value embedding space that captures intra- and cross-theory value structure; (ii) the Value Intensity DataBase (VIDB

), a large-scale resource of value-labeled texts with intensity estimates derive d from ranking-based aggregation; and (iii) an anchor-based evaluator that produ ces consistent intensity scores for model outputs by ranking them against VIDB p anels. Using VALUEFLOW, we conduct a comprehensive large-scale study across ten models and four value theories, identifying asymmetries in steerability and comp osition laws for multi-value control. This paper establishes a scalable infrastr ucture for evaluating and controlling value intensity, advancing pluralistic ali gnment of LLMs.

Robust Human-AI Complementarity under Uncertainty
Yewon Byun, Bryan Wilder
Machine learning models are often intended to augment rather than replace human decision-makers, by providing information that is complementary to human judgeme nt.

Yet, in practice, human decision makers routinely fail to realize such complem entary gains, even when models provide useful signal.

In this work, we study how asymmetric information about the quality of informa tion available to a human decision maker vs. an AI impacts the ability of a deci sion maker to extract complementary value from AI predictions.

We show that a key factor is the error correlation structure between human and AI predictions. In particular, when the AI's prediction errors are \textit{nega tively correlated} with those of the human, the decision-maker can construct rob ust strategies which guarantee improvements in expected utility. We empirically investigate whether these conditions for complementarity arise in practice, usin g real-world forecasting benchmarks.
****

PGS: Effective LLM Code Refinement via Property-Oriented and Structurally Minima l Feedback
Lehan He, Zeren Chen, Zhe Zhang, Xiang Gao, Lu Sheng
Large Language Models (LLMs) excel at code generation, yet ensuring the function al correctness of their outputs remains a persistent challenge. Recent studies h ave applied Test-Driven Development (TDD) to refine code, leveraging execution f eedback to guide the model toward correct solutions. However, such feedback is o ften noisy and uninformative, stemming from the scarcity of high-quality test ca ses and the abundance of noisy, auto-generated ones. In this work, we shift the focus from test-case generation to feedback quality.
We introduce the Property-Generated Solver (PGS), a novel feedback-centric frame work designed to generate highly effective feedback via two principles: it must provide semantic guidance beyond simple I/O mismatches through property validati on, and be structurally minimal, to reduce cognitive load and isolate root cause s. PGS operates by checking high-level program properties (e.g., a sorting funct ion must produce a non-decreasing sequence) then providing the simplest failing counterexample to the LLM. This property-driven, minimal feedback steers LLMs to ward correct and generalizable solutions. Across diverse benchmarks, PGS demonst rates superior performance, achieving a bug fix rate 1.4x-1.6x higher than the s trongest debugging-based approaches and establishing a new state-of-the-art in a utomated code refinement.

Diagnosing the Reliability of LLM-as-a-Judge via Item Response Theory
Junhyuk Choi, Sohhyung Park, Chanhee Cho, Hyeonchu Park, Bugeun Kim
While LLM-as-a-Judge is widely used in automated evaluation, existing validation practices primarily operate at the level of observed outputs, offering limited insight into whether LLM judges themselves function as stable and reliable measu rement instruments. To address this limitation, we introduce a two-phase diagnos tic framework for assessing reliability of LLM-as-a-Judge, grounded in Item Resp onse Theory (IRT). The framework adopts Graded Response Model (GRM) of IRT and f ormalizes reliability along two complementary dimensions: (1) intrinsic consiste ncy, defined as the stability of measurement behavior under prompt variations, a nd (2) human alignment, capturing correspondence with human quality assessments. We empirically examine seven LLM judges with this framework, and show that leve

raging IRT-GRM yields interpretable signals for diagnosing judgments systematica
lly. These signals provide practical guidance for verifying reliability of LLM-a
s-a-Judge and identifying potential causes of unreliability.

Graph is a Substrate Across Data Modalities
Ziming Li, Xiao-Ming Wu, Zehong Wang, Jiazheng Li, Yijun Tian, Jinhe Bi, Yunpu M
a, Yanfang Ye, Chuxu Zhang
Graphs provide a natural representation of relational structure that arises
  across diverse domains. Despite this ubiquity, graph structure is typically
  learned in a modality- and task-isolated manner, where graph representations
  are constructed within individual task contexts and discarded thereafter. As a
   result, structural regularities across modalities and tasks are repeatedly
  reconstructed rather than accumulated at the level of intermediate graph
  representations. This motivates a representation-learning question: *how
  should graph structure be organized so that it can persist and accumulate
  across heterogeneous modalities and tasks?* We adopt a representation-centric
  perspective in which graph structure is treated as a structural substrate that
   persists across learning contexts. To instantiate this perspective, we
  propose **G-Substrate**, a **g**raph **substrate** framework that organizes
  learning around shared graph structures. G-Substrate comprises two
  complementary mechanisms: a unified structural schema that ensures
  compatibility among graph representations across heterogeneous modalities and
  tasks, and an interleaved role-based training strategy that exposes the same
  graph structure to multiple functional roles during learning. Experiments
  across multiple domains, modalities, and tasks show that G-Substrate
  outperforms task-isolated and naive multi-task learning methods. The codebase,
   model, and datasets are available at <https://github.com/zmli6/G-Substrate>.

Reward Learning through Ranking Mean Squared Error
Chaitanya Kharyal, Calarina Muslimani, Matthew E. Taylor
Reward design remains a significant bottleneck in applying reinforcement learnin
g (RL) to real-world problems.
A popular alternative is reward learning, where reward functions are inferred fr
om human feedback rather than manually specified.
Recent work has proposed learning reward functions from human ratings rather tha
n traditional binary preferences, enabling richer and potentially less cognitive
ly demanding supervision.
Building on this paradigm, we introduce a new rating-based RL method, Ranked Re
turn Regression for RL (R4).
At its core, R4 uses a novel ranking mean squared error loss that learns from a
dataset of trajectory–rating pairs, treating the human-provided discrete ratings
 (e.g., "bad," "neutral," "good") as ordinal targets.
Unlike prior rating-based approaches, R4 offers formal guarantees: its solution
set is provably minimal and complete under mild assumptions. Empirically, using
both human-provided and simulated ratings, we demonstrate that R4 consistently m
atches or outperforms existing rating and preference-based RL methods on robotic
 benchmarks from OpenAI Gym and the DeepMind Control Suite.

Identifiable Token Correspondence for World Models
Youngin Kim, Ray Sun, Inho Kim, Bumsoo Park, Hyun Oh Song
Token-based transformer world models have shown strong performance in visual rei
nforcement learning, but often suffer from temporal inconsistency in long-horizo
n rollouts, including object duplication, disappearance, and transmutation.
A key reason is that most existing approaches treat next-frame prediction purely
 as a token generation problem, without considering the persistence of tokens ac
ross time.
We introduce Identifiable Token Correspondence (ITC), a decoding step for token-
based transformer world models that formulates next-frame prediction as a struct
ured assignment problem with latent token correspondence variables: each next-fr
ame token is explained either by copying a token from the previous frame or by g

enerating a new one. ITC leaves the transformer architecture and training proced
ure unchanged and can be added on top of existing backbones.
Our experiments show state-of-the-art performance on 4 challenging benchmarks.
The proposed method achieves a return of 72.5% and a score of 35.6% on the Craft
ax-classic benchmark, significantly surpassing the previous best of 67.4% and 27
.9%.
We release our source code at https://github.com/snu-mllab/Identifiable-Token-Co
rrespondence.

Uncovering the Latent Potential of Deep Intermediate Representations
Arnesh Batra, Arush Gumber, Aniket Khandelwal, Jashn Khemani, Anubha Gupta
Foundational models pretrained on huge amounts of data learn representations tha
t evolve across depth, forming a hierarchy of embeddings with distinct semantic
content and geometric structure. Contrary to the widespread practice of using on
ly the final layer or shallow mixtures, we show that task-relevant information i
s distributed non-monotonically across layers and cannot be recovered by na\"ive
 aggregation. Through a geometric and empirical study across multiple modalities
, we show that effective transfer depends on identifying which layers encode tas
k-discriminative structure and how their embeddings are geometrically organized.
 We introduce Layer-wise Optimal Embedding Selection (LOES), a constructive spec
tral method that identifies task-discriminative subspaces by minimizing residual
 error under orthogonality and isotropy constraints. To align fine-tuning with t
his selection principle, we further propose Geometric Regularization (GeoReg), w
hich enforces a simplicial structure on class manifolds and stabilizes represent
ation geometry during fine-tuning. Across a wide range of architectures, depths,
 modalities, and data regimes, LOES consistently outperforms standard baselines,
 with gains that grow as model depth increases. Beyond accuracy, our method reve
als how semantic factors are distributed across layers, thereby enabling cross-l
ingual and cross-modal interpretability analyses. Together, our results provide
strong evidence that layerwise embedding geometry is not incidental but central
to how deep models represent and transfer knowledge.

Query Lens: Interpreting Sparse Key-Value Features with Indirect Effects
Hwiyeong Lee, Ingyu Bang, Uiji Hwang, Hyelim Lim, Taeuk Kim
While sparse autoencoders provide features more interpretable than individual ne
urons, reliably characterizing them remains challenging.
We propose Query Lens, which extends Logit Lens to enable more comprehensive and
 faithful interpretations of sparse features.
By jointly considering encoder-side key features and decoder-side value features
, we identify both the inputs that activate a feature and the outputs it promote
s.
We also account for indirect, module-mediated effects that arise when the featur
e is processed by downstream modules, going beyond the direct effect captured by
 Logit Lens.
In experiments, we find that Query Lens yields coherent token signatures for fea
tures that remain uninterpretable under Logit Lens.
Finally, we propose the Subspace Channel Hypothesis, suggesting that downstream
modules read features through layer-specific subspaces.

Quantum Robust Inner Minimization for Reinforcement Learning with Quadratic Spee
d-Up in Query Complexity
Hyun Kyu Lee, Joongheon Kim, Sung Whan Yoon
Robust reinforcement learning (RRL) aims to tackle unexpected environmental chan
ges by optimizing policies against the worst case.
However, RRL remains impractical due to the cost of the Max-Min optimization, wh
ere it suffers from the exhaustive query complexity for finding the worst-case (
dubbed 'Min') within the environmental uncertainty set $\mathcal{U}$, i.e., $\ma
thcal{O}(|\mathcal{U}|)$.
By viewing this via a lens of quantum perspective, we raise a pivotal question:
*If we can query from the environment with quantum superpositions, is it possibl

e to accelerate the Max-Min optimization of RRL?* Our answer is 'Yes'.
Our method, called quantum robust inner minimization (QRIM), encodes the uncerta
inty set with quantum superposition and amplifies low-return cases, thus enablin
g RL for solving the robust (i.e., worst-case) Bellman equation.
Importantly, QRIM achieves a quadratic speed-up in query complexity without alte
ring the outer RL pipeline, i.e., $\mathcal{O}(\sqrt{|\mathcal{U}|})$.
Validated through classical simulations to real quantum hardware execution, QRIM
 learns more robust policies with quadratically reduced queries than classical R
L.

More Sail than Ballast: Addressing Harmful Knowledge Leakage in the Expansive Re
asoning Space of LRMs
Qibing Ren, Xinhao Song, Ke Fan, Lijun Li, Zhanpeng Zhou, Gongshen Liu, Junchi Y
an, Lizhuang Ma, Jing Shao
The capabilities of large language models (LLMs), particularly large reasoning m
odels (LRMs), are rapidly advancing. This raises concerns about whether LRMs can
 maintain their safety awareness throughout long-form reasoning. Frustratingly,
we identify a prevalent safety issue across LLMs and LRMs, where LRMs can reveal
 dangerous thoughts, leading to harmful knowledge elicitation when confronting s
ensitive yet benign topics. For example, when explaining the chemical context of
 Lewisite, a biological weapon, LRMs analyze its synthesis in their reasoning wi
thout recognizing the associated risks. We refer to this issue as the *unintende
d elicitation* issue. Experiments on our benchmark show that it is a common issu
e across current LRMs due to their strong multi-step reasoning capabilities. To
address this issue, we propose placing LLMs in our synthesized open-ended enviro
nments, allowing them to self-search for a safety reasoning pattern to respond r
esponsibly and helpfully. We first design a scalable data synthesis pipeline to
generate data that triggers the *unintended elicitation* issue. We further propo
se a safety-first reward model design, which prioritizes safety while also evalu
ating the helpfulness of responses and the faithfulness of reasoning. Experiment
s show that our method improves safety, reduces over-refusal, and maintains stro
ng helpfulness, paving the way for safer deployment in high-stakes domains. Code
 is available at https://github.com/XinhaoS0101/Safety-CoT.

dnaHNet: A Scalable and Hierarchical Foundation Model for Genomic Sequence Learn
ing
Arnav Shah, Junzhe Li, Parsa Idehpour, Adibvafa Fallahpour, Brandon Wang, Sukjun
 Hwang, BO WANG, Patrick D Hsu, Hani Goodarzi, Albert Gu
Genomic foundation models have the potential to decode DNA syntax, yet face a fu
ndamental tradeoff. Standard subword tokenizers fragment biologically meaningful
 motifs such as codons and regulatory elements, while nucleotide-level models pr
eserve biological coherence but incur prohibitive computational costs for long c
ontexts. We introduce dnaHNet, a state-of-the-art tokenizer-free autoregressive
model that segments and models genomic sequences end to end. Using a differentia
ble dynamic chunking mechanism, dnaHNet compresses raw nucleotides into latent t
okens adaptively, balancing compression with predictive accuracy. Pretrained on
prokaryotic genomes, dnaHNet outperforms leading architectures including Striped
Hyena2 in scaling and efficiency. This recursive chunking yields quadratic FLOP
reductions, enabling $>3 \times$ inference speedup over Transformers. On zero-sh
ot tasks, dnaHNet achieves superior performance in predicting protein variant fi
tness and gene essentiality, while automatically discovering hierarchical biolog
ical structures without supervision. These results establish dnaHNet as a scalab
le, interpretable framework for next-generation genomic modeling.

Surgery: Mitigating Harmful Fine-Tuning for Large Language Models via Attention
 Sink
Guozhi Liu, Weiwei Lin, Tiansheng Huang, Ruichao Mo, Qi Mu, Xiumin Wang, Li Shen
Harmful fine-tuning can invalidate safety alignment of large language models, ex
posing significant safety risks. In this paper, we utilize the attention sink me
chanism to mitigate harmful fine-tuning. Specifically, we first measure a statis

tic named sink divergence for each attention head and observe that different att
ention heads exhibit two different signs of sink divergence. To understand its s
afety implications, we conduct experiments and find that the number of attention
 heads of positive sink divergence increases along with the increase of the mode
l's harmfulness when undergoing harmful fine-tuning. Based on this finding, we p
ropose a separable sink divergence hypothesis -- attention heads associating wit
h learning harmful patterns during fine-tuning are separable by their sign of si
nk divergence. Based on the hypothesis, we propose a fine-tuning-stage defense,
dubbed Surgery. Surgery utilizes a regularizer for sink divergence suppression,
which steers attention heads toward the negative sink divergence group, thereby
reducing the model’s tendency to learn and amplify harmful patterns. Extensive e
xperiments demonstrate that Surgery improves defense performance by 5.90\%, 11.2
5\%, and 9.55\% on the BeaverTails, HarmBench, and SorryBench benchmarks, respec
tively. Source code is available on https://github.com/Lslland/Surgery.

RulePlanner: All-in-One Reinforcement Learner for Unifying Design Rules in 3D Fl
oorplanning

Ruizhe Zhong, Xingbo Du, Junchi Yan

Floorplanning determines the coordinate and shape of each module in Integrated C
ircuit. With the advancement of technology node, in floorplanning stage especial
ly 3D scenarios with multiple stacked layers, it has become increasingly challen
ging to adhere to complex hardware design rules. Current methods are only capabl
e of handling specific and limited design rules, while violations of other rules
 require manual and meticulous adjustment. This leads to labor-intensive and tim
e-consuming post-processing for expert engineers. In this paper, we propose an a
ll-in-one deep reinforcement learning-based approach to tackle these challenges,
 and design novel representations for real-world IC design rules that have not b
een addressed by previous approaches. Specifically, the processing of various ha
rdware design rules is unified into a single framework with three key components
: 1) novel matrix representations to model the design rules, 2) constraints on t
he action space to filter out invalid actions that cause rule violations, and 3)
 quantitative analysis of constraint satisfaction as reward signals. Experiments
 on public benchmarks demonstrate the effectiveness and validity of our approach
. Furthermore, transferability are well shown on unseen circuits. Our framework
is extensible to accommodate new design rules, thus providing flexibility to add
ress emerging challenges in future chip design.

OpenSage: Self-programming Agent Generation Engine

Hongwei Li, Zhun Wang, Qinrun Dai, Yuzhou Nie, Jinjun Peng, Ruitong Liu, Jingyan
g Zhang, Kaijie Zhu, Jingxuan He, Lun Wang, Yangruibo Ding, Yueqi Chen, Wenbo Gu
o, Dawn Song

Agent development kits (ADKs) provide effective platforms and tooling for constr
ucting agents, and their designs are critical to the constructed agents' perform
ance, especially the functionality for agent topology, tools, and memory.
However, current ADKs either lack sufficient functional support or rely on human
s to manually design these components, limiting agents' generalizability and ove
rall performance.
We propose OpenSage, the first ADK that enables LLMs to automatically create age
nts with self-generated topology and toolsets while providing comprehensive and
structured memory support.
OpenSage offers effective functionality for agents to create and manage their ow
n sub-agents and toolkits.
It also features a hierarchical, graph-based memory system for efficient managem
ent and a specialized toolkit tailored to software engineering tasks.
Extensive experiments across three state-of-the-art benchmarks with various back
bone models demonstrate the advantages of OpenSage over existing ADKs.
We also conduct rigorous ablation studies to demonstrate the effectiveness of ou
r design for each component.
We believe OpenSage can pave the way for the next generation of agent developmen
t, shifting the focus from human-centered to AI-centered paradigms.

Our code is available at https://github.com/opensage-agent/opensage-adk.
****
GAE: Unleashing Physical Potential of VLM with Generalizable Action Expert
Mingyu Liu, Zheng Huang, Xiaoyi Lin, Muzhi Zhu, Canyu Zhao, Yating Wang, Haoyi Zhu, Hao Chen, Chunhua Shen
Vision-language models demonstrate strong reasoning and planning abilities, yet grounding these predictions into precise robot actions remains a central challenge. Existing Vision-Language-Action methods typically entangle reasoning and action generation, leading to limited generalization and costly adaptation. We propose to learn a \textbf{G}eneralizable \textbf{A}ction \textbf{E}xpert (\textbf{GAE}), a task-agnostic model that converts sparse geometric plans into dense robot actions. Our approach introduces a sparse geometric interface: the VLM predicts sparse 3D waypoints representing high-level intention, while GAE maps these waypoints together with real-time point cloud observations to continuous action trajectories. GAE is pretrained on a large-scale pointcloud–trajectory dataset comprising \textbf{150k} trajectories from both simulation and real-world robots. To further improve efficiency and generalization, we introduce an \textbf{Action Pre-training, Pointcloud Fine-tuning (APPF)} scheme that decouples learning action dynamics from geometry grounding. After pretraining, GAE is frozen and reused across downstream tasks, requiring only lightweight fine-tuning of the VLM to produce the sparse interface. Extensive experiments show that our method achieves strong performance and generalization across diverse visual domains, camera viewpoints, and natural language instructions.

MuCO: Generative Peptide Cyclization Empowered by Multi-stage Conformation Optimization
Yitian Wang, Fanmeng Wang, Angxiao Yue, Wentao Guo, Yaning Cui, Hongteng Xu
Modeling peptide cyclization is critical for the virtual screening of candidate peptides with desirable physical and pharmaceutical properties.

This task is challenging because a cyclic peptide often exhibits diverse, ring-shaped conformations, which cannot be well captured by deterministic prediction models derived from linear peptide folding.

In this study, we propose MuCO (Multi-stage Conformation Optimization), a generative peptide cyclization method that models the distribution of cyclic peptide conformations conditioned on the corresponding linear peptide.

In principle, MuCO decouples the peptide cyclization task into three stages: topology-aware backbone design, generative side-chain packing, and physics-aware all-atom optimization, thereby generating and optimizing conformations of cyclic peptides in a coarse-to-fine manner.

This multi-stage framework enables an efficient parallel sampling strategy for conformation generation and allows for rapid exploration of diverse, low-energy conformations.

Experiments on the large-scale CPSea dataset demonstrate that MuCO significantly and consistently outperforms state-of-the-art methods in physical stability, structural diversity, secondary structure recovery, and computational efficiency, making it a promising computational tool for exploring and designing cyclic peptides.

The demo of the proposed method can be found at https://github.com/mianqiu00/MuCO.
****
A Unified Framework for Diffusion Model Unlearning with f-Divergence
Nicola Novello, Federico Fontana, Luigi Cinque, Deniz Gunduz, Andrea M Tonello
Most existing methods for concept unlearning in text-to-image diffusion models minimize a mean squared error (MSE) loss between the denoiser outputs conditioned on a target and an anchor concept, which is implicitly the KL divergence between two Gaussians. We generalize this objective to any f-divergence, recovering MSE as the KL instance, and identify a family of α-divergences whose Gaussian closed-form yields cheap, MSE-like training objectives. For the remaining f-divergences, we provide a min-max objective based on the variational formulation of the f-divergence. We theoretically analyze and numerically validate how

different f-divergences impact the gradient magnitude and the convergence properties of the algorithm, affecting the quality of unlearning. For instance, we observe that the Hellinger closed-form instance consistently dominates MSE across multiple scenarios. More generally, the proposed unified framework offers a flexible paradigm for selecting the optimal divergence based on the application and user goal, allowing for finer control over the trade-off between unlearning efficacy and generative fidelity.

Fast and Expressive Multi-Byte Prediction with Probabilistic Circuits

Andreas Grivas, Lorenzo Loconte, Emile van Krieken, Piotr Nawrot, Yu Zhao, Euan Wielewski, Pasquale Minervini, Edoardo Ponti, Antonio Vergari

Multi-token prediction (MTP) is a prominent strategy to significantly speed up generation in large language models (LLMs), especially in byte-level LLMs, which are tokeniser-free but prohibitively slow. However, many existing MTP methods either assume independence between future tokens, sacrificing expressiveness, or generate tokens one at a time within the window, increasing latency. In this work, we investigate the trade-off between expressiveness and latency in MTP within the framework of probabilistic circuits (PCs). Our framework, MTPC, allows one to explore different ways to encode the joint distributions over future tokens by selecting circuit architectures, generalising classical models such as (hierarchical) mixture models, hidden Markov models, and tensor networks. We show the efficacy of MTPC by retrofitting existing byte-level LLMs, such as EvaByte, and byte-fied subword models, such as Llama3.2 3B. Our experiments show that, when combined with speculative decoding, MTPC substantially speeds up generation compared to MTP with independence assumptions, while guaranteeing to retain the performance of the original verifier LLM. We also rigorously study the optimal trade-off between expressiveness and latency when exploring the possible parameterisations of MTPC, such as PC architectures and partial layer sharing between the verifier and draft LLMs.

Robust Strategic Classification under Decision-Dependent Cost Uncertainty

Sura Alhanouti, Guzin Bayraksan, Parinaz Naghizadeh

Humans facing algorithmic decision systems have been found to ``game'' them by altering their input data (at a cost to them) in order to favorably change the algorithmic outcomes they receive (at a cost to the algorithm). The growing literature on strategic classification seeks to develop robust machine learning algorithms that account for, and reduce, unwanted strategic behavior. A limitation of these existing works is that they assume the cost of strategic behavior to be fixed and independent of the classifier's decision. In practice, however, manipulation costs evolve and depend on past algorithmic decisions: today's decisions influence tomorrow's costs. This paper proposes and analyzes a two-stage robust optimization framework with a decision-dependent uncertainty set to capture such dependencies. We highlight that awareness of policy-dependent costs not only reduces uncertainty, but also better curtails gaming of the algorithmic system over time.

Auditing Sybil: Explaining Deep Lung Cancer Risk Prediction Through Generative Interventional Attributions

Bartlomiej Sobieski, Jakub Grzywaczewski, Karol Dobiczek, Mateusz Wójcik, Tomasz Bartczak, Szatkowski Patryk, Przemys■aw Bombi■ski, Matthew Tivnan, Przemyslaw Biecek

Lung cancer remains the leading cause of cancer mortality, driving the development of automated screening tools to alleviate radiologist workload. Standing at the frontier of this effort is Sybil, a deep learning model capable of predicting future risk solely from computed tomography (CT) with high precision. However, despite extensive clinical validation, current assessments rely purely on observational metrics. This correlation-based approach overlooks the model's actual reasoning mechanism, necessitating a shift to causal verification to ensure robust decision-making before clinical deployment. We propose S(H)NAP, a model-agnostic auditing framework that constructs generative interventional attributions vali

dated by expert radiologists. By leveraging realistic 3D diffusion bridge modeli
ng to systematically modify anatomical features, our approach isolates object-sp
ecific causal contributions to the risk score. Providing the first interventiona
l audit of Sybil, we demonstrate that while the model often exhibits behavior ak
in to an expert radiologist, differentiating malignant pulmonary nodules from be
nign ones, it suffers from critical failure modes, including dangerous sensitivi
ty to clinically unjustified artifacts and a distinct radial bias.

Learning-augmented Rent-or-Buy with a Sample
Davidson Zhu, Sreenivas Gollapudi, Debmalya Panigrahi
In this paper, we study the rent-or-buy problem (also called the Bahncard proble
m) in the learning-augmented setting. In this problem, a traveler must complete
a sequence of trips that are revealed online over time, each of which has an ass
ociated cost with it. The traveler has the option of buying a discount card at a
 fixed cost that gives a discount on trip costs for a fixed time after buying th
e card. The goal is to minimize the overall cost of all the trips, including the
 money spent on buying discount cards. For this problem, it is well-known that t
he best deterministic algorithm has a competitive ratio of 2. In this paper, we
ask whether we can do better if the traveler has a *sample* of trips available o
ffline, e.g., obtained from an ML model based on historical data. We show that e
ven a sparse sample of the input can significantly improve the competitive ratio
 of the algorithm from 2 to 3/2, and further to close to 1 under some additional
 conditions. We also verify our theoretical bounds via numerical simulations, wh
ich reveal that our proposed algorithm obtains nearly optimal solutions for a va
riety of natural input classes.
****
Conflicting Biases at the Edge of Stability: Norm versus Sharpness Regularizatio
n
Maria Matveev, Vit Fojtik, Hung-Hsu Chou, Gitta Kutyniok, Johannes Maly
The remarkable generalization properties of overparameterized networks are often
 attributed to implicit biases, such as norm minimization at small learning rate
s and low sharpness in the Edge-of-Stability regime. In this work, we argue that
 a comprehensive understanding of the generalization performance of gradient des
cent requires analyzing the interaction between these various forms of implicit
regularization. We empirically demonstrate that the learning rate interpolates b
etween low parameter norm and low sharpness of the trained model. We furthermore
 prove that neither implicit bias alone minimizes the generalization error for d
iagonal linear networks trained on a simple regression task. These findings demo
nstrate that focusing on a single implicit bias is insufficient to explain good
generalization, and they motivate a broader view of implicit regularization that
 captures the dynamic trade-off between norm and sharpness induced by non-neglig
ible learning rates.
****
OvisOCR: End-to-End Document Parsing via Aligning Specialized Perception with Ge
neral Reasoning
Jun-Peng Jiang, Shiyin Lu, An-Yang Ji, Yinglun Li, Qing-Guo Chen, Zhao Xu, Weihu
a Luo, Kaifu Zhang, De-Chuan Zhan, Han-Jia Ye
This paper presents OvisOCR, a lightweight and strictly end-to-end Multimodal La
rge Language Model (MLLM) tailored for document parsing. Unlike current methods
that rely on complex "Crop-OCR-Merge'" cascades to handle high-resolution inputs
, OvisOCR directly maps full-page visual signals to structured Markdown without
localized slicing or layout detection dependencies. Through extensive evaluation
s on the OmniDocBench, OvisOCR achieves top-tier performance among all compared
methods in all aspects, demonstrating that a compact E2E model can effectively `
`digest'' the capabilities of intricate pipelines and surpass specialized and ge
neral methods.
  Technically, OvisOCR unifies fine-grained recognition and semantic correction
in a single model by leveraging supervision bootstrapped from strong OCR engines
 and refined via general-model-based data cleaning. To balance the performance a
cross diverse document constituents, we design category-specific reward mechanis

ms for distinct element types, such as dense text, complex tables, and formulas, and ensure the model enhances its formatting strengths for each modality concurrently. This approach effectively resolves the optimization conflict, guaranteeing that improvements in structural layout parsing do not come at the expense of omitting fine-grained textual details. Empirical results confirm that OvisOCR eliminates the error propagation inherent in split-and-merge architectures, offering a streamlined path for future document intelligence. Our model can be available at \url{https://huggingface.co/AIDC-AI/OvisOCR}.

Approximating f -Divergences with Rank Statistics
Viktor Stein, José Manuel de Frutos
We introduce a rank-statistic approximation of f-divergences that avoids explicit density-ratio estimation by working directly with the distribution of ranks. For a resolution parameter K, we map the mismatch between two univariate distributions μ and ν to a rank histogram on $\{ 0, \ldots, K\}$ and measure its deviation from uniformity via a discrete f-divergence, yielding a rank-statistic divergence estimator.
We prove that the resulting estimator of the divergence is monotone in K, is always a lower bound of the true f-divergence, and we establish quantitative convergence rates for $K\to\infty$ under mild regularity of the quantile-domain density ratio.
To handle high-dimensional data, we define the sliced rank-statistic f-divergence by averaging the univariate construction over random projections, and we provide convergence results for the sliced limit as well.
We also derive finite-sample deviation bounds along with asymptotic normality results for the estimator.
Finally, we empirically validate the approach by benchmarking against neural baselines and illustrating its use as a learning objective in generative modeling experiments.

GenDA: Generative Data Assimilation on Complex Urban Areas via Classifier-Free Diffusion Guidance
Francisco Giral, Álvaro Manzano Sevillano, Ignacio Gomez Perez, Ricardo Vinuesa, Soledad Le Clainche
Urban wind flow reconstruction is essential for assessing air quality, heat dispersion, and pedestrian comfort, yet remains challenging when only sparse sensor data are available. We propose GenDA, a generative data assimilation framework that reconstructs high-resolution wind fields on unstructured meshes from limited observations. The model employs a multiscale graph-based diffusion architecture trained on computational fluid dynamics (CFD) simulations and interprets classifier-free guidance as a learned posterior reconstruction mechanism: the unconditional branch learns a geometry-aware flow prior, while the sensor-conditioned branch injects observational constraints during sampling. This formulation enables obstacle-aware reconstruction and generalization to held-out mesh geometries, wind directions, and sensor configurations within the studied urban-flow setting, without retraining. We consider both sparse fixed sensors and trajectory-based observations using the same reconstruction procedure. When evaluated against supervised graph neural network (GNN) baselines and classical reduced-order data assimilation methods, GenDA reduces the relative root-mean-square error (RRMSE) by 25-57% and increases the structural similarity index (SSIM) by 23-33% across the tested meshes. Experiments are conducted on Reynolds-averaged Navier-Stokes (RANS) simulations of a real urban neighborhood in Bristol, United Kingdom, at a characteristic Reynolds number of $\mathrm{Re}\approx2\times10^{7}$, featuring complex building geometry and irregular terrain. The proposed framework provides a scalable path toward generative, geometry-aware data assimilation for environmental monitoring in complex domains.

Learning to Extrapolate to New Tasks: A Relational Approach to Task Extrapolation
Adam Ousherovitch, Yixin Wang

Modern learning systems excel at interpolation but struggle to generalize to unseen tasks outside the training distribution's support. This failure occurs even in simple settings, such as handling task parameters beyond the training range, and persists despite advances in foundation models. To this end, we develop the Relational Task Extrapolator (RTE), an algorithm designed to enable systematic extrapolation to novel tasks. The key observation is that extrapolation is inherently relational: extrapolating to unseen tasks requires learning how tasks transform into one another. If a model learns the transformation between tasks A and B during training, it can apply that same transformation to relate known tasks to unseen ones at test time. RTE operationalizes this idea by decomposing each target task into a known anchor task and a transformation linking the anchor and target. It then learns a relational operator, mapping an anchor–transformation pair to predictions for the target task. We instantiate RTE across multiple task extrapolation regimes in function prediction, e.g. where target tasks use out-of-range parameters (parameter extrapolation), has greater compositional depth (length extrapolation), and/or recombine function primitives in unseen ways (compositional extrapolation). We further extend RTE to sequence prediction, integrating it into fine-tuning algorithms for foundation models. Across empirical studies, we find that RTE substantially outperforms existing approaches on extrapolation to novel, unseen tasks.
****

Trust Functions: Near Lossless Weak-to-Strong Generalization by Learning to Trust the Weak Teacher
Arda Uzunoglu, Alvin Zhang, Daniel Khashabi
Weak-to-strong generalization studies how to improve a strong student using supervision from a weaker teacher when reliable labels are scarce. We view this primarily as a data selection problem, where the key challenge is to identify which weak labels are reliable enough to serve as a training signal. To address this, we introduce trust functions that assign each weak label a scalar trust score and use these scores to filter weak supervision. Across several domains, including world knowledge, quantitative reasoning, decision making, trust filtering yields students that match and sometimes surpass ground-truth supervision, achieving near-lossless weak-to-strong generalization. Moreover, trust functions enable an iterative weak-to-strong chain that compounds gains by training a student and reusing it as the next teacher, producing the strongest final model. Our analyses suggest that neural trust functions improve learning through more than label error reduction. They induce an implicit easy-first curriculum, recover near-optimal alternatives where ground truth labels are incomplete, and produce more coherent gradient updates, offering a mechanistic account of the stability and efficiency of trust-filtered weak-to-strong generalization.

Physics-informed coarsening for multigrid graph neural networks surrogates
Amir Bazzi, Ramy Nemer, Alves José, Elie Hachem
Learning-based surrogates for partial differential equations have recently matched the accuracy of classical solvers while achieving orders-of-magnitude speedups, predominantly in fluid settings and structured geometries. In contrast, robust surrogates for deformable solids remain underexplored, despite the presence of nonlinear elasticity, plasticity, and transient behavior that challenge standard architectures. We introduce a multigrid graph neural network for solid mechanics that couples an *encoder-processor-decoder* backbone with a physics-informed coarsening strategy. Instead of downsampling via geometric heuristics, our method scores nodes using a residual-based measure of local physical activity and preferentially retains regions of high strain or stress concentration, allocating multiscale capacity where it is most needed. This preserves long-range interactions through hierarchical message passing while improving stability over long rollouts. We evaluate on multiple datasets covering linear, nonlinear, and transient regimes, and observe consistent gains in accuracy and rollout stability compared to standard sampling baselines. Our results highlight the importance of physics-informed coarsening for scalable surrogate modeling in solid mechanics.

Reward Auditor: Inference on Reward Modeling Suitability in Real-World Perturbed Scenarios

Jianxiang Zang, Yongda Wei, Ruxue Bai, Shiyu Jiang, Nijia Mo, Binhong Li, Qiang Sun, Hui Liu

Reliable reward models (RMs) are critical for ensuring the safe alignment of large language models (LLMs). However, current RM evaluation methods focus solely on preference perception accuracies in given specific scenarios, obscuring the critical vulnerabilities of RMs in real-world scenarios. We identify the true challenge lies in assessing a novel dimension: Suitability, defined as conditional reliability under specific real-world perturbations. To this end, we introduce Reward Auditor, a hypothesis-testing framework specifically designed for RM suitability inference. Rather than answering “How accurate is the RM's preference perception for given samples?”, it employs scientific auditing to answer: “Can we infer RMs exhibit systematic vulnerabilities in specific real-world scenarios?". Under real-world perturbed scenarios, Reward Auditor quantifies statistical significance and effect size by auditing distribution degradation of RM preference perception confidence. This enables inference of both the certainty and severity of RM vulnerabilities across diverse real-world scenarios, thereby laying a solid foundation for building next-generation LLM alignment systems that are verifiably safe, more robust, and trustworthy.

Fix the Mind, Not the Move: Interpretable AI Assistance via Knowledge-Gap Localization

Ayano Hiranaka, Ya-Chuan Hsu, Stefanos Nikolaidis, Erdem Biyik, Daniel Seita

AI assistants in human-AI collaboration often correct suboptimal human actions through behavioral feedback (e.g., alerts or steering-wheel nudges in assistive driving). Such interventions can mitigate immediate errors, but long-term improvement requires addressing the underlying misconceptions that cause repeated mistakes. We introduce SENSEI, a framework that infers user misconceptions from interaction behavior and provides targeted, minimal yet sufficient suggestions to correct them. Our approach departs from action- or trajectory-level interventions by operating over a structured knowledge representation to localize and correct the sources of erroneous behavior. Across three long-horizon tasks with diverse misconceptions and corresponding behaviors, SENSEI demonstrates zero-shot compositional generalization, disentangling multiple overlapping misconceptions despite training only on single-misconception cases.

A user study further shows that our method identifies real human misconceptions and provides effective guidance that improves long-horizon task performance, successfully correcting 90% of student misconceptions.

Regulating Anatomy-Aware Rewards via Trajectory-Integral Feedback for Volumetric Computed Tomography Analysis

Tianwei Lin, Zhongwei Qiu, Jie Cao, Jiang Liu, Wenjie Yan, Zhang Bo, Yu Zhong, Wenqiao Zhang, Yingda Xia, Ling Zhang

Medical vision-language models (VLMs) have rapidly advanced as general-purpose multimodal assistants, yet their deployment in 3D Computed Tomography (CT) analysis remains constrained by a persistent mismatch between optimization objectives and clinical rigor. Current Reinforcement Learning (RL) paradigms still rely on lexical proxy signals that induce Evaluation Hallucinations, where models optimize linguistic fluency rather than factual clinical correctness, leading to diagnostically critical errors. To bridge this gap, we introduce the Clinical Abnormality Benchmarking Substrate (CABS), a structured system that decomposes radiology reports into verifiable clinical semantic units. Using CABS, we identify a Mechanistic Divergence in standard RL, where surface-similarity rewards drive policy gradients to bypass medical facts. We therefore propose Trajectory-Integral Feedback GRPO (TIF-GRPO), a novel framework integrating control-theoretic principles into policy optimization. By formulating clinical reasoning as a pseudo-temporal trajectory for anomaly discovery, TIF-GRPO regulates anatomy-aware rewards via an integral feedback loop that penalizes persistent omissions as cumulative state errors and suppresses hallucinations as excessive control effort. Experimen

ts on 3D CT benchmarks demonstrate that our approach significantly enhances abnormality detection and clinical faithfulness, establishing a new paradigm for fine-grained regulation in medical VLMs. Our project is available at https://github.com/ZJU4HealthCare/TIF-GRPO.

INDEXGUARD: Index-only Backdoor Vetting for Secure Federated PEFT of Large Language Models

Javad Dogani, Devri■ ■■ler, Nikolaos Laoutaris

Federated parameter-efficient fine-tuning (PEFT) enables customizing large language models on private data, yet it is vulnerable to backdoor poisoning—especially when privacy constraints prevent inspection of per-client real-valued updates. We exploit the intuition that poisoning leaves a similar backdoor imprint in which adapter coordinates become salient, so overlap in salient-index supports remains informative even without values. We introduce IndexGuard, an unsupervised index-only vetting primitive in which clients send only Top-K salient update indices and the server operates on the induced overlap geometry, clustering clients and filtering cohesion-outlier groups before aggregation. We analyze support stability under bounded rescaling and separability under shared-trigger poisoning under non-IID drift. Across attacks, backbones, and PEFT variants, IndexGuard provides end-to-end mitigation, preserving clean accuracy while achieving performance comparable to centralized methods.

Training Prompt Matters: State-Adaptive Optimization for Robust Fine-Tuning

Wenhang Shi, Yiren Chen, Shuqing Bian, Zhe Zhao, Jinhao Dong, Pengfei Hu, WEI LU, Xiaoyong Du

While prompt engineering is instrumental in maximizing the capabilities of Large Language Models (LLMs) during inference, the role of prompts during training remains critically underexplored. Prevailing fine-tuning paradigms typically treat training prompts as mere surface forms, assuming that semantically equivalent instructions yield identical learning outcomes. However, we reveal that this equivalence is deceptive: while paraphrased prompts often lead to comparable in-task performance, they induce drastically different cross-task impacts regarding catastrophic forgetting and generalization. Crucially, these impacts are positively correlated across tasks, indicating the existence of superior prompts that consistently yield better performance. Furthermore, we discover that these superior prompts can be robustly identified by task loss prior to learning. Leveraging these insights, we introduce State-Adaptive Prompt Optimization (SAPO), a lightweight yet effective training strategy that shifts task formulation from a static input to a dynamic, state-adaptive variable. Comprehensive experiments on diverse benchmarks confirm its effectiveness, which significantly mitigates forgetting while improving generalization, achieving substantial performance gains over state-of-the-art methods. These results provide insights into how training prompts shape learning dynamics and offer a practical recipe for robust fine-tuning. Our code is available at https://github.com/Eric8932/SAPO.

Variance-Reduced $(\varepsilon, \delta)-$Unlearning using Forget Set Gradients

Martin Van Waerebeke, Giovanni Neglia, Kevin Scaman, Marco Lorenzi, El-Mahdi El-Mhamdi

In machine unlearning, $(\varepsilon,\delta)-$unlearning is a popular framework that provides formal guarantees on the effectiveness of the removal of a subset of training data, the \emph{forget set}, from a trained model.

For strongly convex objectives, existing first-order methods achieve $(\varepsilon,\delta)-$unlearning, but they only use the forget set to calibrate injected noise, never as a direct optimization signal.

In contrast, efficient empirical heuristics often exploit the forget samples (e.g., via gradient ascent) but come with no formal unlearning guarantees.

We bridge this gap by presenting the Variance-Reduced Unlearning (*VRU*) algorithm. To the best of our knowledge, *VRU* is the first first-order algorithm that directly includes forget set gradients in its update rule, while provably satisfying $(\varepsilon,\delta)-$unlearning.

We establish the convergence of *VRU* and show that incorporating the forget se
t yields strictly improved rates, *i.e.*, a better dependence on the achieved er
ror
compared to existing first-order $(\varepsilon,\delta)-$unlearning methods. More
over, we prove that, in a low-error regime *VRU*
asymptotically outperforms
any first-order methods that ignores the forget set.
Experiments corroborate our theory, showing consistent gains over both state-of-
the-art certified unlearning methods and over empirical
baselines that explicitly leverage the forget set.

Transformers Learn the Optimal DDPM Denoiser for Multi-Token GMMs
Hongkang Li, Hancheng Min, Rene Vidal
Transformer-based diffusion models have demonstrated remarkable performance at g
enerating high-quality samples. However, our theoretical understanding of the re
asons for this success remains limited. For instance, existing models are typica
lly trained by minimizing a denoising objective, which is equivalent to fitting
the score function of the training data. However, we do not know why transformer
-based models can match the score function for denoising, or why gradient-based
methods converge to the optimal denoising model despite the non-convex loss land
scape. To the best of our knowledge, this paper provides the first convergence a
nalysis for training transformer-based diffusion models. More specifically, we c
onsider the population Denoising Diffusion Probabilistic Model (DDPM) objective
for denoising data that follow a \textit{multi-token Gaussian mixture} distribut
ion. We theoretically quantify the required number of tokens per data point and
training iterations for the global convergence towards the Bayes optimal risk of
 the denoising objective, thereby achieving a desired score matching error. A de
eper investigation reveals that the self-attention module of the trained transfo
rmer implements a \emph{mean denoising} mechanism that enables the trained model
 to approximate the oracle Minimum Mean Squared Error (MMSE) estimator of the in
jected noise in the diffusion steps. Numerical experiments validate these findin
gs.

Efficient Diffusion Models under Nonconvex Equality and Inequality constraints v
ia Landing
Kijung Jeon, Michael Muehlebach, Molei Tao
Generative modeling within constrained sets is essential for scientific and engi
neering applications involving physical, geometric, or safety requirements (e.g.
, molecular generation, robotics). We present a unified framework for constraine
d diffusion models on generic nonconvex feasible sets Σ that simultaneous
ly enforces equality and inequality constraints throughout the diffusion process
. Our framework incorporates both overdamped and underdamped dynamics for forwar
d and backward sampling. A key algorithmic innovation is a computationally effic
ient landing mechanism that replaces costly and often ill-defined projections on
to Σ, ensuring feasibility without iterative Newton solves or projection
failures. By leveraging underdamped dynamics, we accelerate mixing toward the pr
ior distribution, effectively alleviating the high simulation costs typically as
sociated with constrained diffusion. Empirically, this approach reduces function
 evaluations and memory usage during both training and inference while preservin
g sample quality. On benchmarks featuring equality and mixed constraints, our me
thod achieves comparable sample quality to state-of-the-art baselines while sign
ificantly reducing computational cost, providing a practical and scalable soluti
on for diffusion on nonconvex feasible sets.

Do Vision and Text Cues Exhibit Evidential Coupling? UFO: A Benchmark for Compos
itional Multimodal Reasoning in Unified Models
Zhongyu Yang, Dannong Xu, Yonghan Zhang, Kefan Chen, Xinyi Wang, Yang Xu, Wei Pa
ng, Yingfang Yuan
Unified Foundation Models (UFMs), which support interleaved multimodal generatio
n and understanding, have been proposed as a promising paradigm for reasoning ab

out dynamic world states, yet it remains unclear whether the visual content they generate functions as grounded evidence for subsequent reasoning or merely as auxiliary output. Existing benchmarks largely evaluate generation and understanding as separate capabilities and do not test their functional dependence during reasoning. We introduce UFO, a benchmark designed to evaluate whether UFMs generate and use image and text cues as evidence for compositional multimodal reasoning. UFO spans three state-transition regimes, state determination, state reconstruction, and state augmentation, which correspond to progressively smaller transformations of the underlying world state. Our analysis reveals a significant modality gap, as models often achieve high prediction accuracy even when the generated visual cues exert limited influence on their decisions, indicating weakened evidential coupling and a reliance on textual shortcuts rather than robust cross-modal grounding.

Controllable and Explainable Personality Sliders for LLMs at Inference Time

Florian Hoppe, David Khachaturov, Robert D. Mullins, Mark Huasong Meng

Aligning Large Language Models (LLMs) with specific personas typically relies on Supervised Fine-Tuning (SFT) or Reinforcement Learning from Human Feedback (RLHF); however, these methods are resource-intensive, requiring expensive data collection and distinct model training for each target personality. In this work, we propose a parameter-efficient framework for continuous, multi-dimensional personality control via inference-time activation steering. Our approach addresses the challenge of combining multiple interventions by iteratively retraining probes on the residual stream modified by prior traits, ensuring compatibility. Once established, these steering vectors function as modular, reusable primitives; users can instantly synthesize novel, complex personality profiles by simply adjusting steering coefficients (α) without any additional training. To support this, we introduce an automated pipeline that identifies optimal intervention layers via activation separation analysis and calibrates coefficients via hyperparameter optimization to maximize alignment while constraining perplexity. Empirical evaluations validate individual trait shifts using an LLM-as-a-judge framework and demonstrate, via the Big Five inventory, that our method effectively modulates the model's holistic personality profile without updating base model parameters.

Learning Global Representation from Queries for Vectorized HD Map Construction

Shoumeng Qiu, Xinrun Li, Yang Long, Xiangyang Xue, Varun Ojha, Jian Pu

The online construction of vectorized high-definition (HD) maps is a cornerstone of modern autonomous driving systems. State-of-the-art approaches, particularly those based on the DETR framework, formulate this as an instance detection problem. However, their reliance on independent, learnable object queries results in a predominantly local query perspective, neglecting the inherent global representation within HD maps. In this work, we propose \textbf{MapGR} (\textbf{G}lobal \textbf{R}epresentation learning for HD \textbf{Map} construction), an architecture designed to learn and utilize global representations from queries. Our method introduces two synergistic modules: a Global Representation Learning (GRL) module, which encourages the distribution of all queries to better align with the global map through a carefully designed holistic segmentation task, and a Global Representation Guidance (GRG) module, which endows each individual query with explicit, global-level contextual information to facilitate its optimization. Evaluations on the nuScenes and Argoverse2 datasets validate the efficacy of our approach, demonstrating substantial improvements in mean Average Precision (mAP) compared to leading baselines. Code is available at \href{https://github.com/skyshoumeng/MapGR}{\texttt{github.com/skyshoumeng/MapGR}}.

PsumQuant: In-line Post-training Partial Sum Quantizer for Energy Efficient NPU Inference

Sangwoo Hwang, Yeeun Hong, Jaeha Kung

The rapid growth of deep neural networks (DNNs) has intensified the demand for efficient hardware acceleration under quantization.

While prior research has successfully reduced weight and activation precision, partial sums generated during accumulation often retain high precision, resulting in significant energy overhead.
In this work, we analyze psum distributions in tiled architectures and reveal that within-tile outliers are input-dependent.
We propose PsumQuant, a post-training, input-aware quantization that predicts psum scales on-the-fly.
By leveraging the crest factor of input activations, our learnable scale predictor effectively bounds the psum bit-width while handling the extreme outliers in DNNs.
Experimental results on a 128×128 systolic array demonstrate that PsumQuant compresses psum precision down to 8-bit within only a 1\% accuracy drop on ResNet-18 and a marginal 0.04 perplexity increase on Llama-3.1.
Furthermore, bit-width reduction with PsumQuant results in a 45\% reduction in total energy with minimal accuracy loss, demonstrating that PsumQuant provides a highly efficient solution for actual NPU architectures.
****
OmniMoE: An Efficient MoE by Orchestrating Atomic Experts at Scale
Jingze Shi, Zhangyang Peng, Yizhang Zhu, Yifan Wu, Guang Liu, Yuyu Luo
Mixture-of-Experts (MoE) architectures are evolving towards finer granularity to improve parameter efficiency. However, existing MoE designs face an inherent trade-off between the granularity of expert specialization and hardware execution efficiency. In this paper, we propose OmniMoE, a system-algorithm co-designed MoE framework that pushes granularity to the extreme with vector-level Atomic Experts, orchestrating their routing and execution at scale within a single MoE layer, while retaining a shared dense MLP for general-purpose processing. While this atomic design maximizes capacity, it poses severe challenges for routing complexity and memory access. To address these, OmniMoE adopts a system-algorithm co-design: (i) a Cartesian Product Router that decomposes the massive index space to reduce routing complexity from $O(N)$ to $O(\sqrt{N})$; and (ii) Expert-Centric Scheduling that inverts the execution order to turn scattered, memory-bound lookups into efficient dense matrix operations. Validated on seven benchmarks, OmniMoE (with 1.7B active parameters) achieves 50.9\% zero-shot accuracy across seven benchmarks, outperforming coarse-grained (e.g., DeepSeekMoE) and fine-grained (e.g., PEER) baselines. Crucially, OmniMoE reduces inference latency from 73ms to 6.7ms (a 10.9$\times$ speedup) compared to PEER, demonstrating that massive-scale fine-grained MoE can be fast and accurate.

The Personality Illusion: Revealing Dissociation Between Self-Reports & Behavior in LLMs
Pengrui Han, Rafal Kocielnik, Peiyang Song, Ramit Debnath, Dean Mobbs, Anima Anandkumar, R. Michael Alvarez
Personality traits have long been studied as predictors of human behavior. Recent advances in Large Language Models (LLMs) suggest similar patterns may emerge in artificial systems, with advanced LLMs displaying consistent behavioral tendencies resembling human traits like agreeableness and self-regulation. Understanding these patterns is crucial, yet prior work primarily relied on simplified self-reports and heuristic prompting, with little behavioral validation. In this study, we systematically characterize LLM personality across three dimensions: (1) the dynamic emergence and evolution of trait profiles throughout training stages; (2) the predictive validity of self-reported traits in behavioral tasks; and (3) the impact of targeted interventions, such as persona injection, on both self-reports and behavior. Our findings reveal that instructional alignment (e.g., RLHF, instruction tuning) significantly stabilizes trait expression and strengthens trait correlations in ways that mirror human data. However, these self-reported traits do not reliably predict behavior, and observed associations often diverge from human patterns. While persona injection successfully steers self-reports in the intended direction, it exerts little or inconsistent effect on actual behavior. By distinguishing surface-level trait expression from behavioral consistency, our findings challenge assumptions about LLM personality and underscore t

he need for deeper evaluation in alignment and interpretability.
****
StretchTime: Adaptive Time Series Forecasting via Symplectic Attention
Yubin Kim, Viresh Pati, Jevon Twitty, Vinh Pham, Shihao Yang, Jiecheng Lu
Transformer architectures have established strong baselines in time series forec asting, yet they typically rely on positional encodings that assume uniform, ind ex-based temporal progression. However, real-world systems, from shifting financ ial cycles to elastic biological rhythms, frequently exhibit ``time-warped'' dyn amics where the effective flow of time decouples from the sampling index. In thi s work, we first formalize this misalignment and prove that rotary position embe dding (RoPE) is mathematically incapable of representing non-affine temporal war ping. To address this, we propose Symplectic Positional Embeddings (SyPE), a lea rnable encoding framework derived from Hamiltonian mechanics. SyPE strictly gene ralizes RoPE by extending the rotation group $\mathrm{SO}(2)$ to the symplectic group $\mathrm{Sp}(2,\mathbb{R})$, modulated by a novel input-dependent adaptive warp module. By allowing the attention mechanism to adaptively dilate or contra ct temporal coordinates end-to-end, our approach captures locally varying period icities without requiring pre-defined warping functions. We implement this mecha nism in StretchTime, a multivariate forecasting architecture that achieves state -of-the-art performance on standard benchmarks, demonstrating superior robustnes s on datasets exhibiting non-stationary temporal dynamics.

Video-in-the-Loop: Span-Grounded Long Video QA with Interleaved Reasoning
Chendong Wang, Donglin Bai, Yifan Yang, Xiao Jin, Anlan Zhang, Rui Wang, Shiqi J iang, Yuqing Yang, Hao Wu, Qi Dai, Chong Luo, Ting Cao, Lili Qiu, Suman Banerjee
We present $\textit{Video-in-the-Loop}$ (ViTL), a two-stage long-video QA framew ork that preserves a fixed token budget by first $\textit{localizing}$ question- relevant interval(s) with a low-fps skim and then $\textit{answering}$ via span- aware reallocation of visual tokens at higher effective frame rate, emitting an interleaved output with both spans and the final option for direct attribution. We also introduce $\textit{VGrounding-QA}$, which converts description based eve nt graphs into $\textit{span-grounded}$ multiple-choice QA by pairing each quest ion with $\textit{ground-truth}$ time span(s) and related reasoning. ViTL is tra ined end-to-end with an interleaved group-relative objective that couples tempor al IoU for localization with answer correctness, allowing credit to flow from an swers back to spans without increasing compute. Under fixed token budgets, ViTL attains up to 8.6\% with 50\% less frame input on long-video QA and temporal gro unding (e.g., Charades-STA, ActivityNet-Captions) and ablations show that span-a ware token reallocation consistently surpasses uniform sampling. Together, $\tex tit{VGrounding-QA}$ and ViTL provide an interpretable, compute-efficient recipe for scalable long-video QA.

When AI Agents Compete for Jobs: Strategic Capabilities and Economic Dynamics of AI Labour Markets
Christopher Chiu, Simpson Zhang, Mihaela van der Schaar
Emerging agentic marketplaces provide the economic infrastructure for matching a nd coordinating the large amounts of AI agents used in agentic swarms. Unlike hu man workers, AI agents can operate on multiple jobs simultaneously, acquire skil ls rapidly, and labor without wage floors. These differences introduce a new seg ment of AI labor markets, where AI agents interact with each other at a much hig her frequency than human markets. Yet we lack frameworks to understand how such markets behave in light of economic forces that shape labor markets, such as adv erse selection and reputation dynamics.
To explore this, we introduce AI-Work, a tractable, simulated gig economy where Large Language Model (LLM) agents compete for jobs, develop skills, and adapt th eir strategies under uncertainty and competitive pressure. Our experiments exami ne three domains of capabilities that successful agents possess: metacognition (accurate self-assessment of skills), competitive awareness (modeling rivals and market dynamics), and long-horizon strategic planning. Agents with these capabil ities consistently achieve higher profits, reputations, and market share than co

mpeting agents.
Through AI-Work, we hope to provide a foundation to explore the microeconomic pr
operties of AI-only labour markets, and a conceptual framework to study the stra
tegic reasoning capabilities of participating AI agents.

Laplacian Representations for Decision-Time Planning
Dikshant Shehmar, Matthew Kyle Schlegel, Matthew E. Taylor, Marlos C. Machado
Planning with a learned model remains a key challenge in model-based reinforceme
nt learning (RL). In decision-time planning, state representations are critical
as they must support local cost computation while preserving long-horizon struct
ure. In this paper, we show that the Laplacian representation provides an effect
ive latent space for planning by capturing state-space distances at multiple tim
e scales. This representation preserves meaningful distances and naturally decom
poses long-horizon problems into subgoals, also mitigating the compounding error
s that arise over long prediction horizons. Building on these properties, we int
roduce ALPS, a hierarchical planning algorithm, and demonstrate that it outperfo
rms commonly used baselines on a selection of offline goal-conditioned RL tasks
from OGBench, a benchmark previously dominated by model-free methods.
****
CacheEdit: Efficient Multi-round Image Editing via Adaptive Token-wise Reuse.
Jinxin Yu, Xueqing Chen, Yudong Pan, Lian Liu, shengwen Liang, Huawei Li, Xiaowe
i Li, Ying Wang
Instruction-based image editing (IIE) is a vital tool for iterative content crea
tion, enabling multi-round interactions that refine visual details while preserv
ing cross-round consistency. However, this workflow is constrained by the comput
e-bound nature of Diffusion Transformers (DiTs): because DiTs process tokens uni
formly, they waste substantial computation on regions untouched by the instructi
on. We investigate the Round--Step--Layer hierarchy of DiT-based editing and ide
ntify a phenomenon we term Delayed Latent Emergence (DLE). Although pronounced l
atent changes emerge only in the late denoising stages, deep-layer activations w
ithin transformer blocks at the very first sampling step already diverge markedl
y in edited regions. Building on this insight, we propose CacheEdit, a training-
free framework centered on an Adaptive Activation Cache (Acache) that exploits e
arly-step sensitivity to detect invariant tokens and reuse their cached activati
ons across subsequent sampling steps, thereby bypassing redundant computation. E
xperiments on FLUX.1 Kontext and Qwen-Image-Edit show that CacheEdit achieves up
 to $2.5\times$ end-to-end acceleration. Moreover, by isolating and reusing stat
ic features, CacheEdit mitigates stochastic drift and improves instruction-follo
wing and structural consistency over full-recomputation baselines.
****
BioFormer: Rethinking Cross-Subject Generalization via Spectral Structural Align
ment in Biomedical Time-Series
Guikang Du, Haoran Li, Xinyu Liu, Zhibo Zhang, Xiaoli Gong, Jin Zhang
Cross-subject generalization in biomedical time-series aims to learn representat
ions that generalize to unseen subjects while suppressing subject-specific varia
bility.
Most existing methods implicitly suppress the variability through model building
 or subject adversarial learning, but rarely model it explicitly.
We introduce \textbf{spectral drift} as a new perspective to characterize subjec
t specific variability.
Specifically, BTS signals under the same label often share consistent oscillator
y structure, yet exhibit subject-dependent magnitude or phase shifts in specific
 frequency components, which we interpret as subject-specific variability.
Building on this insight, we propose \textit{BioFormer}.
At its core is a Frequency-Band Alignment Module (FBAM) that generates band-wise
 modulation factors from the spectral distribution and adaptively adjusts amplit
ude and phase to align spectral structure, thereby mitigating variability.
We further pair FBAM with Sample Conditional Layer Normalization, which infers n
ormalization parameters from intrinsic signal statistics rather than subject ide
ntity, stabilizing cross-subject representations.

Extensive experiments on six datasets demonstrate that BioFormer outperforms 12 baselines, yielding absolute F1-score improvements of 6\%.
****

What Makes Synthetic Data Effective in Image Segmentation
Jinjin Zhang, Xiefan Guo, Yizhou jin, Nan Zhou, Di Huang
Driven by rapid advances in large-scale generative models, synthetic data has emerged as a promising solution for visual understanding. While modern diffusion models achieve remarkable photorealistic image synthesis, their potential in complex visual segmentation tasks remains underexplored. In this work, we conduct a systematic analysis of synthetic images from state-of-the-art diffusion models to uncover the factors governing their utility. In particular, synthetic images characterized by dense scene composition and fine instance fidelity demonstrate distinctive benefits, yielding significantly more discriminative spatial representations. Building on these insights, we propose SENSE, a unified framework that leverages flexible and scalable synthetic data to substantially enhance segmentation performance. Notably, SENSE is model-agnostic, compatible with diverse architectures (e.g., DPT and Mask2Former), and scales effectively across models with varying parameter capacities. Extensive experiments on Cityscapes, COCO, and ADE20K validate the effectiveness and generalization capability of our approach. Code is available at https://github.com/zhang0jhon/SENSE.

Unveiling Multi-regime Patterns in SciML: Distinct Failure Modes and Regime-specific Optimization
Yuxin Wang, Yuanzhe Hu, Xiaokun Zhong, Xiaopeng Wang, Haiquan Lu, Tianyu Pang, Michael W. Mahoney, Yujun Yan, Pu Ren, Yaoqing Yang
Neural networks trained under different hyperparameter settings can fall into distinct training "regimes," with consistent behavior within regimes and qualitative differences across regimes. In this paper, we study such multi-regime behavior in scientific machine learning (SciML) models through a *regime-aware diagnostic framework* that jointly analyzes performance, training dynamics, and loss-landscape geometry. We identify three key findings: (i) a consistent three-regime structure emerges across many standard SciML models, different constraint enforcements, and various optimizer designs; (ii) optimization effectiveness is regime-specific, with no single method performing well across all regimes; and (iii) SciML models can exhibit fine-grained failure modes that can challenge conventional interpretations of standard loss-landscape metrics. Our results provide an approach to establish a unified, task-oblivious perspective on failure modes in SciML and to inform regime-aware guidance for improving robustness. We validate these findings across widely-used SciML models, including physics-informed neural networks, neural operators, and neural ordinary differential equations, on benchmarks spanning representative ordinary and partial differential equations.

Distributionally Robust Reinforcement Learning from Human Feedback
Debmalya Mandal, Paulius Sasnauskas, Goran Radanovic
Reinforcement learning from human feedback (RLHF) has evolved to be one of the main methods for fine-tuning large language models (LLMs). However, existing RLHF methods are non-robust, and their performance deteriorates if the downstream task differs significantly from the preference dataset used in fine-tuning. In order to mitigate this problem, we introduce a distributionally robust RLHF for fine-tuning LLMs. In particular, our goal is to ensure that a fine-tuned model retains its performance even when the distribution of prompts significantly differs from the distribution encountered during fine-tuning. We formulate distributionally robust optimization (DRO) version of two popular fine-tuning methods -- (1) reward-based RLHF and (2) reward-free DPO (direct preference optimization). We propose a minibatch gradient descent based algorithms for both of them, and theoretically prove convergence guarantees for the algorithms. Subsequently, we evaluate our algorithms on an out-of-distribution (OOD) task by first training the model on the Unified-Feedback dataset and evaluating its performance on two different datasets. The experimental results show that our robust training improves the accuracy of the learned reward models on average, and markedly on some tasks,

such as reasoning. Furthermore, we show that the robust versions of policy optim
ization methods, similarly improve performance on OOD tasks.

OcclusionFormer: Arranging Z-Order for Layout-Grounded Image Generation
Ziye Li, Henghui Ding
Recent layout-to-image models have achieved remarkable progress in spatial contr
ollability. However, they still struggle with inter-object occlusion. When bound
ing boxes overlap, most existing methods lack explicit occlusion information, wh
ich makes the generation in intersection regions inherently ambiguous and hinder
s the determination of complex occlusion relationships. As a result, they often
produce entangled textures or physically inconsistent layering in the overlapped
 areas. To address this issue, we first construct ***SA-Z***, a large-scale data
set enriched with explicit occlusion ordering and pixel-level annotations. Build
ing upon our proposed dataset, we introduce ***OcclusionFormer***, a novel occlu
sion-aware Diffusion Transformer framework that explicitly models Z-order priori
ty by decoupling instances and compositing them via volume rendering. Furthermor
e, to ensure fine-grained spatial precision, we introduce a queried alignment lo
ss that explicitly supervises individual instances and enhances semantic consist
ency. The proposed method effectively reduces ambiguity in overlapping regions,
enforces correct occlusion dependencies, and preserves structural integrity, lea
ding to substantial accuracy gains across diverse scenes.

Tailoring the Training: Difficulty-Aware Learning Strategy Allocation for Large
Language Models
Xiaoling Zhou, Shuaiyu Zhou, Zhemg Lee, Tao Chen, Xirui Li, Peng Chen, Jie Jiang
, Wei Ye, Shikun Zhang
Although reinforcement learning (RL) enhances the reasoning capabilities of larg
e language models (LLMs), it is primarily learned from the model's self-generate
d distribution, limiting its ability to acquire reasoning skills beyond its init
ial knowledge. To overcome this, we propose a Difficulty-Aware Learning Strategy
 Allocation (DALSA) framework, which adaptively assigns appropriate learning str
ategies to samples based on their difficulty signals. DALSA is built on the key
insight that samples beyond models' knowledge scope are better addressed through
 supervised fine-tuning (SFT), while those within the boundary but insufficientl
y mastered benefit more from RL, and well-learned samples are discarded to avoid
 redundant updates. To realize this principle, we extract a series of difficulty
-aware training characteristics and employ a learnable strategy allocator to dyn
amically determine the optimal learning strategy for each sample based on its tr
aining dynamics. The allocator and the LLM are alternately optimized, enabling a
daptive strategy allocation. Furthermore, two regularization techniques, anti-cu
rriculum weighting and adversarial label smoothing, are integrated to alleviate
the inherent limitations of RL and SFT, backed by comprehensive theoretical anal
yses. Extensive experiments on ten LLMs ranging from 1.5B to 70B across various
tasks indicate that DALSA consistently outperforms baselines under both full and
 parameter-efficient fine-tuning settings.

Variable-Length Tokenization via Learnable Global Merging for Diffusion Transfor
mers
Dong Hoon Lee, Seunghoon Hong
Latent Diffusion Models (LDMs) have become dominant in visual synthesis, but the
ir quality–compute trade-off is largely constrained by the tokenizer’s fixed com
pression ratio.
Variable-length tokenizers (VLTs) promise adaptive compression by varying token
counts, allowing diffusion models to flexibly balance quality and compute.
However, conventional VLTs modulate length by truncating ordered token sequences
, which makes token semantics depend on token position and breaks representation
al alignment across lengths.
This leads to a cross-length shift in the latent distribution that hinders a sin
gle variable-length diffusion model from operating effectively.
To address this, we propose a novel variable-length tokenizer that modulates len

gth by merging tokens.
We show that encouraging similar tokens to merge enables direct cross-length rep
resentation alignment when the diffusion transformer operates according to the m
erging pattern.
Since conventional merging methods are data-dependent, making the merging patter
n inaccessible during generation, we introduce learnable global merging, which i
s data-independent, to ensure compatibility with diffusion transformers.
On ImageNet 256$\times$256 generation, our merging-based variable-length tokeniz
er integrated with a diffusion transformer achieves a superior gFID–compute trad
e-off compared to prior VLT methods.

1-Bit Wonder: Improving QAT Performance in the Low-Bit Regime through K-Means Qu
antization
Sohir Maskey, Constantin Eichenberg, Johannes Messner, Douglas Orr
Quantization-aware training (QAT) is an effective method to drastically reduce t
he memory footprint of LLMs while keeping performance degradation at an acceptab
le level. However, the optimal choice of quantization format and bit-width prese
nts a challenge in practice. The full design space of quantization is not fully
explored in the context of QAT, and the precise trade-off between quantization a
nd downstream performance is poorly understood, as comparisons often rely solely
 on perplexity-based evaluations. In this work, we address these shortcomings wi
th an empirical study of QAT in the low-bit regime. We show that k-means based w
eight quantization outperforms integer formats and can be implemented efficientl
y on standard hardware. Furthermore, we find that, under a fixed inference memor
y budget, the best performance on generative downstream tasks is achieved with $
1$-bit quantized weights.

Reward-Preserving Counterfactual State Editing for Offline Reinforcement Learnin
g
Siyu Wang, Xiaocong Chen, Mingming Gong, Yong Li, Quan Z. Sheng, Lina Yao
Transformer sequence models such as Decision Transformer can learn strong offlin
e policies from logged trajectories, but they often suffer from causal confusion
: reliance on spurious correlations that predict reward in the data but do not r
eflect the true causal mechanisms of the environment. We propose CSET (Counterfa
ctual State Editing Transformer), which improves robustness in strictly offline
reinforcement learning without learning environment transition dynamics. On the
data side, CSET fits a causal reward model as a conditional variational autoenco
der and uses a counterfactual state generator to propose minimally edited observ
ations whose predicted reward matches the factual reward, under a normalized mov
e-band constraint and an acceptance gate that enforce plausibility and reward co
nsistency; augmentation replaces only the observation token to avoid synthetic s
uccessor transitions. On the model side, CSET uses a causally structured hybrid
transformer: modality-specific convolutional encoders process return-to-go, stat
e, and action streams, and a final attention block is softly supervised so actio
n prediction focuses on its direct causal parents. Experiments on D4RL locomotio
n, AntMaze, and offline recommendation benchmarks show consistent gains within t
he DT family, and CSET remains substantially more robust than strong value-based
 and DT baselines under injected spurious distractors.

OMAC: A Holistic Optimization Framework for LLM-Based Multi-Agent Collaboration
Shijun Li, Hilaf Hasson, Joydeep Ghosh
Agents powered by advanced large language models (LLMs) have demonstrated impres
sive capabilities across diverse complex applications. Recently, Multi-Agent Sy
stems (MAS), wherein multiple agents collaborate and communicate with each other
, have exhibited enhanced capabilities in complex tasks, such as high-quality co
de generation and arithmetic reasoning. However, the development of such systems
 often relies on handcrafted methods, and the literature on systematic design an
d optimization of LLM-based MAS remains limited.
In this work, we introduce OMAC, a general framework designed for holistic optim
ization of LLM-based MAS. Specifically, we identify five key optimization dimens

ions for MAS, encompassing both agent functionality and collaboration structure. Building upon these dimensions, we first propose a general algorithm, utilizing two actors termed the Semantic Initializer and the Contrastive Comparator, to optimize any single dimension. Then, we present an algorithm for joint optimization across multiple dimensions. Extensive experiments demonstrate the superior performance of OMAC on diverse tasks against recent approaches. Codes are available at: https://github.com/xiwenchao/OMAC.

Reasoning as an Attack Surface: Adaptive Evolutionary CoT Jailbreaks for LLMs

Jianan Li, Simeng Qin, Xiaojun Jia, Lionel Z. WANG, Tianhang Zheng, Xiaoshuang Jia, Yang Liu, Xiaochun Cao

Large Reasoning Models (LRMs) have demonstrated remarkable capabilities in reasoning and generation tasks and are increasingly deployed in real-world applications. However, their explicit chain-of-thought (CoT) mechanism introduces new security risks, making them particularly vulnerable to jailbreak attacks. Existing approaches often rely on static CoT templates to elicit harmful outputs, but such fixed designs suffer from limited diversity, adaptability, and effectiveness. To overcome these limitations, we propose an adaptive evolutionary CoT jailbreak framework, called AE-CoT. Specifically, the method first rewrites harmful goals into mild prompts with teacher role-play and decomposes them into semantically coherent reasoning fragments to construct a pool of CoT jailbreak candidates. Then, within a structured representation space, we perform multi-generation evolutionary search, where candidate diversity is expanded through fragment-level crossover and a mutation strategy with an adaptive mutation-rate control mechanism. An independent scoring model provides graded harmfulness evaluations, and high-scoring candidates are further enhanced with a harmful CoT template to induce more destructive generations. Extensive experiments across multiple models and datasets demonstrate the effectiveness of the proposed AE-CoT, consistently outperforming state-of-the-art jailbreak methods.

EPiC: Efficient Video Camera Control Learning with Precise Anchor-Video Guidance

Zun Wang, Jaemin Cho, Jialu Li, Han Lin, Jaehong Yoon, Yue Zhang, Mohit Bansal

Recent approaches for video generation with camera control often create anchor videos
(i.e., rendered videos that approximate desired camera motions)
to guide diffusion models as a structured prior,
by rendering from estimated point clouds following camera trajectories.
However, errors in point cloud and camera trajectory estimation often lead to inaccurate anchor videos with
higher training cost and low efficiency, as the model is forced to compensate for rendering misalignments.
To address these limitations, we introduce EPiC, an efficient and precise camera control learning framework
that constructs well-aligned training anchor videos
without the need for camera pose or point cloud estimation.
Concretely, we create highly precise anchor videos by masking source videos based on first-frame visibility, which ensures strong alignment, eliminates the need for camera/point cloud estimation, and thus can be readily applied to any in-the-wild video.
Furthermore, we introduce Anchor-ControlNet, a lightweight module that integrates anchor video guidance in visible regions to pretrained video diffusion models,
with less than 1\% of additional parameters.
EPiC achieves efficient training with substantially fewer parameters, training steps, and less data, and
generalizes robustly to anchor videos made with point clouds at test time, enabling precise 3D-informed camera control.
EPiC achieves SoTA performance on RealEstate10K and MiraData for I2V camera control task.
Notably, EPiC also exhibits strong zero-shot generalization to video-to-video (V2V) scenarios.

Bregman meets Lévy: Stochastic Mirror Descent with Heavy-Tailed Noise in Continuous and Discrete Time
Pierre-Louis Cauvin, Panayotis Mertikopoulos
We study the robustness of stochastic mirror descent (SMD) under heavy-tailed noise, focusing on whether the method retains its convergence guarantees when run with infinite-variance stochastic gradient input. To address this question in a principled manner, we begin by introducing a continuous-time model of SMD as a stochastic differential equation (SDE) driven by a centered Lévy noise process with finite p-th order moments, $1 < p \leq 2$. This scheme—which we call the Lévy mirror flow (LMF)—arises naturally as the scaling limit of SMD in the presence of heavy-tailed noise. In particular, when $p < 2$—the heavy noise regime—the trajectories of LMF generically exhibit jump discontinuities of arbitrary magnitude which, if frequent enough, lead to infinite variance. Nonetheless, despite this highly singular behavior, we show that LMF attains ϵ-optimality within $\mathcal{O}(\epsilon^{-p/(p-1)})$ time in the convex case, and within $\tilde{\mathcal{O}}(\epsilon^{-1/(p-1)})$ time for (relatively) strongly convex objectives. These guarantees provide a transparent characterization of the impact of frequent long jumps on the convergence of the process, and percolate to a series of matching discrete-time guarantees for several variants of SMD under heavy-tailed noise.
****
Personalized Policy Learning through Discrete Experimentation
Zhiqi Zhang, Zhiyu Zeng, Ruohan Zhan, Dennis Zhang
While Randomized controlled trials (RCTs), or A/B tests, are the gold standard for optimizing online-platform policies, they are limited by discrete testing levels. This approach is suboptimal for continuous variables (e.g., prices and incentives), as it fails to extrapolate to untested values or account for user heterogeneity. We address this by developing Deep Learning for Policy Targeting (\textsf{DLPT}) to learn personalized continuous policies from discrete RCTs using high-dimensional features. We prove our estimators are asymptotically unbiased and consistent, achieving a $\sqrt{n}$-regret bound. In a collaboration with a leading social media platform to optimize creator incentives, we show that \textsf{DLPT} substantially outperforms existing benchmarks.
****
VLAW: Iterative Co-Improvement of Vision-Language-Action Policy and World Model
Yanjiang Guo, Tony Lee, Lucy Xiaoyang Shi, Jianyu Chen, Percy Liang, Chelsea Finn
The goal of this paper is to improve the performance and reliability of vision-language-action (VLA) models through iterative online interaction.
Since collecting policy rollouts in the real world is expensive, we investigate whether a learned simulator—specifically, an action-conditioned video generation model—can be used to generate additional rollout data.
Unfortunately, existing world models lack the physical fidelity necessary for policy improvement: they are predominantly trained on demonstration datasets that lack coverage of many different physical interactions (particularly failure cases) and struggle to accurately model small yet critical physical details in contact-rich object manipulation.
We propose a simple iterative improvement algorithm that uses real-world roll-out data to improve the fidelity of the world model, which can then, in turn, be used to generate supplemental synthetic data for improving the VLA model.
In our experiments on a real robot, we use this approach to improve the performance of a state-of-the-art VLA model on multiple downstream tasks.
We achieve a 39.2\% absolute success rate improvement over the base policy and 11.6\% improvement from training with the generated synthetic rollouts. Videos can be found at this anonymous website: \url{https://sites.google.com/view/vla-w}.

Learning Adaptive Topology with FiLM-Guided Distillation for Tertiary Structure-Based RNA Design
Zixun Zhang, Yuncheng Jiang, Yuzhe Zhou, Jiayou Zheng, Shuguang Cui, Zhen Li

Tertiary structure-based RNA design aims to generate RNA sequences that can fold into desired 3D structures, but remains a challenging problem due to the scarcity of annotated data, structural noise, and the intrinsic complexity of RNA topology. Existing structure-to-sequence frameworks largely rely on static k-nearest neighbor graphs and rigid message passing schemes, which fail to capture the flexible and heterogeneous nature of RNA geometry. To address these issues, we propose a unified framework, ATL-FGD, that integrates Adaptive Topology Learning (ATL) and FiLM-Guided Distillation (FGD) for robust RNA design. ATL introduces a differentiable edge gating mechanism to jointly learn topology and representation, enabling the model to construct data-driven, layer-adaptive graphs that better reflect structural dynamics and biochemical consistency. On top of this, FGD bridges structural and sequence representations via feature-wise linear modulation, softly transferring the semantic knowledge from RNA foundation models without relying on them during inference. Extensive experiments on tertiary structure-based RNA design benchmarks demonstrate that our approach achieves significant improvements in both sequence recovery and structural fidelity.

Understanding Generalization and Forgetting in In-Context Continual Learning

Guangyu Li, Meng Ding, Lijie Hu

In-context learning (ICL) derives its power from enabling Large Language Models to adapt to new tasks via prompt-based reasoning alone, entirely bypassing the need for parameter updates. Existing theories primarily study ICL in single-task settings, while real-world prompts often contain sequences of heterogeneous tasks, leaving a gap in understanding whether Large Language Models implicitly perform continual learning during inference. To bridge this gap, we propose the first theoretical framework for in-context continual learning, modeling how a pretrained Transformer processes multiple sequential tasks within a single prompt through shared attention mechanisms. Focusing on linear and masked linear self-attention, we derive error expressions for model predictions under sequential task prompts and analyze their generalization and forgetting behavior. Our results reveal that standard attention mechanisms inevitably induce inter-task interference by uniformly or causally aggregating historical contexts, leading to systematic bias. We further provide a bias–variance–interference decomposition of prediction error, characterizing when historical in-context information yields positive transfer or provable negative transfer. This analysis exposes fundamental limits of attention-based continual inference and offers theoretical explanations for order sensitivity and performance degradation in long prompts.

The ACUTE Protocol: Operationalizing Language Model Activations for Better Calibration, Utility, and Trust

Nishant Subramani, Palash Goyal, Yiwen Song, Mani Malek, Yuan Xue, Tomas Pfister, Hamid Palangi

As language models improve and become increasingly deployed to solve a variety of tasks, trustworthiness becomes essential. Calibration is a good proxy for trust: well-calibrated confidence estimates help inform the risk versus reward trade-off when trusting a specific model output. Unfortunately, even as models improve, they remain poorly calibrated, often biasing towards overconfidence. Additionally, calibration can be gamed: a policy that always predicts the base rate is perfectly calibrated, but completely uninformative. To resolve this, we develop a new metric, **expected utility renormalized by the oracle (EURO)**, that balances calibration and informativeness. We also propose a general-purpose **activation-based confidence, utility, and trust estimation protocol (ACUTE)** to appropriately adjudicate uncertainty. The ACUTE protocol provides flexible, sample-efficient, and compute-efficient confidence estimators for 3 tasks including multiple choice question answering, tool-calling, and scientific document summarization across 6 models from 4 model families. ACUTE outperforms strong baselines on EURO, while maintaining low calibration error. Taken together, our work shows that equipping LLMs with the ACUTE protocol can improve calibration, utility, and trustworthiness in numerous settings.

From Teacher Pathways to Invariant Manifolds: Consensus Subspace Distillation fo r TSFMs
Zexing Zhang, Tianyang Lei, Jichao Li, Yang Kewei
Time-series foundation models (TSFMs) deliver strong cross-domain generalization , but their scale makes deployment costly. Knowledge distillation is a natural c ompression route, yet prior TSFM distillation typically imitates teacher outputs , features, or pairwise relations, and therefore remains tightly coupled to teac her-specific training trajectories while underutilizing two empirical properties : (i) high-level representations across model scales tend to converge toward a s hared, approximately low-rank geometry, and (ii) layer-wise utility follows a lo ng-tail pattern. We propose consensus subspace distillation, which reframes dist illation as aligning a student to a model-agnostic geometric object: a scale-inv ariant low-rank consensus subspace together with its center statistics. Offline, we screen high-contribution layers via drop-layer marginal loss, estimate a shr inkage-stabilized covariance from their embeddings, and derive a truncated eigen subspace that defines a consensus projector. Online, we project student embeddin gs into this subspace and match the teacher’s projected mean and covariance usin g a lightweight mean--covariance objective, enabling stable optimization without rigid pointwise feature binding. To mitigate subset-induced bias, we further in troduce a frequency-domain uncertainty injection mechanism that inflates spectra l density based on characteristic-function discrepancies and injects dispersion only within the consensus directions. Across forecasting and imputation, the dis tilled student matches or slightly improves upon the teacher, while exhibiting a predictable trade-off under strict zero-shot classification. With MOMENT-Large as teacher, we achieve about 90% parameter reduction and substantial distillatio n-time savings while retaining comparable performance across multiple time-serie s tasks. Code and compressed weights are available at anonymous.4open.science/r/ CSD-13C3/.

Are Tools Always Beneficial? Learning to Invoke Tools Adaptively for Dual-Mode M ultimodal LLM Reasoning
Qinghe Ma, Zhen Zhao, Yiming Wu, Jian Zhang, LEI BAI, Yinghuan Shi
Tool-augmented reasoning has emerged as a promising direction for enhancing the reasoning capabilities of multimodal large language models (MLLMs). However, exi sting studies mainly focus on enabling models to perform tool invocation, while neglecting the necessity of invoking tools. We argue that tool usage is not alwa ys beneficial, as redundant or inappropriate invocations largely increase reason ing overhead and even mislead model predictions. To address this issue, we intro duce AutoTool, a model that adaptively decides whether to invoke tools according to the characteristics of each query. Within a reinforcement learning framework , we design an explicit dual-mode reasoning strategy with mode-specific reward f unctions to guide the model toward producing accurate responses. Moreover, to pr event premature bias toward a single reasoning mode, AutoTool jointly explores a nd balances tool-assisted and text-centric reasoning throughout training, and pr omotes free exploration in later stages. Extensive experiments demonstrate that AutoTool exhibits outstanding performance and high efficiency, yielding a 21.8\% accuracy gain on V* benchmark compared to the base model, and a 44.9\% improvem ent in efficiency over existing tool-augmented methods on POPE benchmark. Code i s available at https://github.com/MQinghe/AutoTool.

Invariant Representation Learning for Source-Free Time Series Forecasting with L LM-Centric Proxy Denoising
Kangjia Yan, Chenxi Liu, Hao Miao, Xinle Wu, Yan Zhao, Chenjuan Guo, Bin Yang
Effective time series forecasting enables various real-world applications, benef iting from the proliferation of mobile devices. However, the volume of time seri es data may vary significantly across domains due to high data acquisition costs and data regulations. To maximally create value from sparse data, this study fo cuses on a new problem of source-free time series forecasting, aiming to adapt a pretrained model from sufficient source time series to the sparse target time s eries without access to the source data, enabling data protection. To achieve th

is, we propose TimeID, a novel source-free time series forecasting framework wit
h a large language model (LLM) centric proxy denoising inspired by the powerful
generalization capabilities of LLMs. Specifically, TimeID consists of three key
components: (1) dual-branch invariant disentangled feature learning that enforce
s representation- and gradient-wise invariance by means of season-trend decompos
ition; (2) lightweight, parameter-free proxy denoising that dynamically calibrat
es systematic biases of LLMs; and (3) knowledge distillation that bidirectionall
y aligns the denoised prediction and the original target prediction. Extensive e
xperiments on real-world datasets demonstrate that TimeID outperforms state-of-t
he-art baselines, improving MSE and MAE by 10.7\% and 9.3\% on average. The code
 is available at https://github.com/decisionintelligence/TimeID.
****

LagLLM: LLM-empowered lead–lag dependency learning for spatial-temporal time ser
ies forecasting

Binqing Wu, Jian Zhou, Zongjiang Shang, Ling Chen

Spatial-temporal time series forecasting is challenging due to complex lead-lag
dependencies, which are often ignored or inadequately modeled by existing method
s. Thus, we propose LagLLM, the first LLM-empowered framework that explicitly mo
dels lead–lag dependencies by unifying data-driven dynamics modeling and knowled
ge-driven semantic reasoning. Specifically, LagLLM constructs a lead-lag graph b
y integrating learnable embeddings, spatial proximity, and prompt-guided reasoni
ng from a frozen LLM, which can capture lead-lag dependencies informed by the un
derlying data structure and semantic knowledge.

In addition, LagLLM introduces structural token sorting based on the graph, whic
h can make a fine-tuned LLM explicitly perceive directional and delayed interact
ions. Experiments on eight real-world datasets show that LagLLM achieves the sta
te-of-the-art performance with improved accuracy, robustness, and interpretabili
ty. The code is available at https://github.com/w2obin/LagLLM-2026.

Deterministic Differentiable Structured Pruning for Large Language Models

Weiyu Huang, Pengle Zhang, Xiaolu Zhang, JUN ZHOU, Jun Zhu, Jianfei Chen

Structured pruning reduces LLM inference cost by removing low-importance archite
ctural components. This can be viewed as learning a multiplicative gate for each
 component under an ℓ_0 sparsity constraint. Due to the discreteness of the
 ℓ_0 norm, prior work typically adopts stochastic hard-concrete relaxations
 to enable differentiable optimization; however, this stochasticity can introduc
e a train--test mismatch when sampled masks are discretized for deployment and r
estricting masks to a bounded, near-binary range. To address this, we propose De
terministic Differentiable Pruning (DDP), a mask-only optimization method that e
liminates stochasticity by directly optimizing a deterministic soft surrogate of
 the discrete ℓ_0 objective. Compared with prior approaches, DDP offers gre
ater expressiveness, reduced train--test mismatch, and faster convergence. We ap
ply our method to several dense and MoE models, including Qwen3-32B and Qwen3-30
B-A3B, achieving a performance loss as small as 1\% on downstream tasks while ou
tperforming previous methods at 20\% sparsity. We further demonstrate end-to-end
 inference speedups in realistic deployment settings with vLLM.
****

Consistent Diffusion Language Models

Hasan Amin, Yuan Gao, Yaser Souri, Subhojit Som, Ming Yin, Rajiv Khanna, Xia Son
g

Diffusion language models (DLMs) are an attractive alternative to autoregressive
 models because they promise sublinear-time, parallel generation, yet practical
gains remain elusive as high-quality samples still demand hundreds of refinement
 steps. In continuous domains, consistency training along the probability-flow O
DE is a popular recipe to accelerate diffusion. For discrete diffusion, no analo
gous sample-space ODE exists, making direct adaptation ill-defined. We argue tha
t the right discrete substitute is the exact posterior bridge—the closed-form co
nditional law linking any two noise levels—which is available for broad corrupti
ons including masked and uniform diffusion. Building on this observation, we int
roduce Multi-Path Discrete Consistency (MPDC), a new principle that trains a den

oiser to be path-invariant in expectation across these stochastic bridges, and i
nstantiate it as the Consistent Diffusion Language Model (CDLM), a single-stage
training framework that does not require an already trained teacher model. Our C
DLM objective recovers masked diffusion, continuous consistency models, and prog
ressive or discrete distillation as analytic limits or empirical approximations
of one common view. Empirically, CDLM establishes a new state of the art on both
 conditional and unconditional text-generation, consistently outperforming stron
g base discrete diffusion models and often even multi-stage distilled baselines
across sampling budgets, with the largest gains in the few-step regime. Together
, these results position CDLM as a principled and scalable foundation for the ne
xt generation of fast, high-fidelity discrete generative modeling.
****
Universal Representation of Generalized Convex Functions and their Gradients
Moeen Nehzati
A wide range of optimization problems can often be written in terms of generaliz
ed convex functions (GCFs). When this structure is present, it can convert certa
in nested bilevel objectives into single-level problems amenable to standard fir
st-order optimization methods. We provide a new differentiable layer with a conv
ex parameter space and show (Theorems 5.1 and 5.2) that it and its gradient are
universal approximators for GCFs and their gradients. We demonstrate how this pa
rameterization can be leveraged in practice by (i) learning optimal transport ma
ps with general cost functions and (ii) learning optimal auctions of multiple go
ods. In both these cases, we show how our layer can be used to convert the exist
ing bilevel or min-max formulations into single-level problems that can be solve
d efficiently with first-order methods.
****
Primal-Spectral Generative Modeling: Fast Analytical Generation via Pseudoinvers
e Lévy Inversion
Zhiyuan Ouyang, Simei Huang, Zuokai Wen, Xiangyun Zhang, Junchi Yan
A probability distribution $\mathbb{P}$ is a measure on a σ-algebra, assi
gning mass to sets rather than points, which poses a challenge for the training
of neural networks that often struggle to reconstruct the global topology of con
tinuous manifolds from sparse samples. We mitigate this issue by transforming $\
mathbb{P}$ into a continuous function via spectral methods, providing theoretica
l guarantees for the convergence of the learned distribution to the true distrib
ution. Specifically, we introduce a network, PriSpecNet, with a single-function
evaluation (1-NFE) Pseudoinverse L\'evy Inversion (PiLI) solver that regards gen
eration as a fast analytical problem, eliminating the need for iterative numeric
al integration while maintaining full compatibility with the stochastic interpol
ants. We test our PriSpecNet in two applications: for time series, it unifies ge
neration and forecasting, outperforming state-of-the-art (SOTA) baselines with C
ontext-FID reductions of 50.0\%, 41.5\%, 80.6\%, and 63.1\% on Sines, Solar, ETT
h, and Stock benchmarks, respectively, also decreasing forecasting MSE by 29.8\%
 on Solar and 23.8\% on Stock. For ImageNet 256×256, 1-NFE PiLI achieve
s a competitive FID of **1.66** using only **26** Gflops, representing a **170$\
times$** reduction in total Gflops compared to the 4,436 Gflops required by the
25-NFE DPM-Solver++.
****
DRPBench: Evaluating LLMs in Concurrent Code Comprehension via Fine-Grained Data
 Race Prediction
Yuqi Guo, Siwei Wei, Yan Cai
Large Language Models (LLMs) have demonstrated sophisticated comprehension of se
quential code, yet their capacity for reasoning about concurrent programs remain
s largely unquantified. We introduce DRPBench, a benchmark designed to evaluate
the concurrent code comprehension of LLMs by measuring their data race predictio
n performance. To address the challenge of runtime non-determinism for evaluatio
n on concurrent programs, we frame the evaluation as a fine-grained static predi
ction task using 1,003 programs from the SV-COMP suite, featuring 557 manually a
nnotated data races with precise variable- and line-level granularity. Our evalu
ation of 15 state-of-the-art LLMs—spanning standard, reasoning, and agentic vari

ants—reveals that DRPBench effectively differentiates concurrent code comprehens ion capabilities of LLMs. While the top-performing model (Gemini 3 with test-tim e reasoning) achieves an F1 score of 74.89%, most models struggle significantly (scoring less than 60%), with Llama 3 70B achieving only 8.80%. Beyond benchmark ing, we characterize two primary failure modes: (1) shared-variable distraction, where multiple variable appearances degrade comprehension accuracy, and (2) syn chronization-logic myopia, the inability to interpret non-standard synchronizati on implementations. Our findings provide a diagnostic roadmap for enhancing conc urrent code comprehension of LLMs in future development.

SciPredict: Can LLMs Predict the Outcomes of Scientific Experiments in Natural S ciences?

Udari Madhushani Sehwag, Elaine Lau, Haniyeh Ehsani Oskouie, Shayan Shabihi, Eri ch Liang, Andrea Sarai Echeverria Toledo, Guillermo A. Mangialardi, Sergio Fonro uge, Ed-Yeremai Hernandez-Cardona, Paula Vergara, Utkarsh Tyagi, Chen Bo Calvin Zhang, Pavi Bhatter, Nicholas E. Johnson, Furong Huang, Ernesto Gabriel Hernánde z Montoya, Bing Liu

Accelerating scientific discovery requires the identification of which experimen ts would yield the best outcomes before committing resources to costly physical validation. While existing benchmarks evaluate LLMs on scientific knowledge and reasoning, their ability to predict experimental outcomes---a task where AI coul d significantly exceed human capabilities---remains largely underexplored.

We introduce SciPredict, a benchmark comprising 405 tasks derived from recent em pirical studies in 33 specialized sub-fields of physics, biology, and chemistry. SciPredict addresses two critical questions: (a) *can LLMs predict the outcome of scientific experiments with sufficient accuracy?* and (b) *can such predictio ns be reliably used in the scientific research process?* Evaluations reveal fund amental limitations on both fronts. Model accuracies are 14-26\% and human expe rt performance is $\approx$20\%. Although some frontier models exceed human perf ormance model accuracy is still far below what would enable reliable experimenta l guidance. Even within the limited performance, models fail to distinguish reli able predictions from unreliable ones, achieving only $\approx$20\% accuracy reg ardless of their confidence or whether they judge outcomes as predictable withou t physical experimentation. Human experts, in contrast, demonstrate strong calib ration: their accuracy increases from $\approx$5\% to $\approx$80\% as they deem outcomes more predictable without conducting the experiment. SciPredict establi shes a rigorous framework demonstrating that superhuman performance in experimen tal science requires not just better predictions, but better awareness of predic tion reliability. For reproducibility all our data and code are provided at http s://anonymous.4open.science/r/SciPredict-AI01.

MLUBench: A Benchmark for Lifelong Unlearning Evaluation in MLLMs

He Li, Haoang Chi, Qizhou Wang, Yunxin Mao, Zhiheng Zhang, Jie Tan, Tongliang Li u, Wenjing Yang, Bo Han

Multimodal large language models (MLLMs) are trained on massive multimodal data, making data unlearning increasingly important as data owners may request the re moval of specific content. In practice, these requests often arrive sequentially over time, giving rise to the challenging problem of *MLLM Lifelong Unlearning* .

However, most existing benchmarks are limited in scale and scope, failing to c apture the complexities of MLLM lifelong unlearning.

To fill this gap, we introduce the MLUBench, a large-scale and comprehensive b enchmark featuring 127 entities across 9 classes under lifelong unlearning reque sts.

We perform extensive experiments using MLUBench and reveal that existing unlea rning methods suffer from severe, cumulative degradation.

More critically, we further identify the unique challenge of this problem: unl ike in unimodal models, MLLM lifelong unlearning is constrained by the need to p reserve multimodal alignment. Continually unlearning from one modality could deg rade the entire model.

To alleviate this challenge, we propose LUMoE, an effective and efficient method.

Experiments demonstrate that LUMoE significantly mitigates the degradation problem faced by baselines.

The source code and the MLUBench dataset are open-sourced in this [URL](https://github.com/lihe-maxsize/Lifelong_Unlearning_main).

Dual-Calibration Multi-View Clustering via Compact Anchor Learning

Huibing Wang, Yuemeng Huang, Yawei Chen, Jiaxin Yang, Qian Liu, Jinjia Peng, Zetian Mi, Ximing Li

The anchor-based multi-view clustering methods have received extensive attention due to their efficiency and scalability in large-scale data scenarios. Existing anchor-based methods still face challenges in learning compact and semantically discriminative anchors. Current mainstream approaches typically rely on random sampling strategies or orthogonal constraints for anchor selection and learning. However, they often optimize anchor learning and cluster assignment in a relatively separate manner, leaving the clustering semantics in the sample space insufficiently exploited for calibrating the anchor space. As a result, the learned anchors may suffer from redundant coverage and ambiguous cluster boundaries. Unlike existing anchor-based multi-view clustering methods, this paper proposes a Dual-Calibration Multi-view Clustering via Compact Anchor Learning (DCMC), which effectively improves anchor quality through a dual-space alignment mechanism. Specifically, DCMC initializes view-specific anchors to capture the underlying data distribution, and then enforces bidirectional consistency between the anchor space and the clustering space to jointly optimize both the sample-to-anchor assignments and the cluster assignments. The alternating optimization process effectively enhances cross-view semantic consistency while preserving the discriminative characteristics of each view. Experimental results demonstrate that DCMC outperforms state-of-the-art methods across multiple benchmark tests, confirming its effectiveness and reliability.

Flow-Based Density Ratio Estimation for Intractable Distributions with Applications in Genomics

Egor Antipov, Alessandro Palma, Lorenzo Consoli, Stephan Günnemann, Andrea Dittadi, Fabian J Theis

Estimating density ratios between pairs of intractable data distributions is a core problem in probabilistic modeling, enabling principled comparisons of sample likelihoods under different data-generating processes across conditions. While exact-likelihood models such as normalizing flows offer a promising approach to density ratio estimation, naive evaluations are computationally expensive and prone to discretization errors because they require simulating each distribution's likelihood independently. In this work, we leverage condition-aware flow matching to derive a single dynamical formulation for tracking density ratios along generative trajectories. We demonstrate competitive performance on simulated benchmarks for closed-form ratio estimation, and show that our method supports versatile tasks in single-cell genomics data analysis, where likelihood-based comparisons of cellular states across experimental conditions enable treatment effect estimation and batch correction evaluation.

NExT-Guard: Training-Free Streaming Safeguard without Token-Level Labels

Junfeng Fang, Nachuan Chen, Houcheng Jiang, Dan Zhang, Xiangnan He, Tat-Seng Chua, Xiang Wang

Large language models are increasingly deployed in streaming scenarios, rendering conventional post-hoc safeguards ineffective as they fail to interdict unsafe content in real-time. While streaming safeguards based on token-level supervised training could address this, they necessitate expensive annotations and suffer from severe overfitting. In this work, we challenge the paradigm that streaming safety must rely on token-level supervised training. Instead, it is an inherent capability of well-trained post-hoc safeguards, as they already encode token-level risk signals in hidden representations. Hence, we introduce NExT-Guard, a fra

mework that achieves streaming safeguards by monitoring interpretable latent features from Sparse Autoencoders (SAEs). It uses pretrained SAEs from publicly available base LLMs, enabling flexible, low-cost deployment without token-level supervision. Experimental results show that NExT-Guard outperforms both post-hoc and streaming safeguards based on supervised training, with superior robustness across models, SAE variants, and risk scenarios. These results make NExT-Guard a universal and scalable paradigm for real-time safety, accelerating the practical deployment of streaming safeguards.

How Far Can LLM Agents Reason with Tables? Benchmarking Multi-Turn Agentic Table Question Answering in the Wild
Jingwang Huang, Jie Zhang, Haoyang Zeng, Changzai Pan, Xianjie Wu, Guanting Dong, Jiaheng Liu, Wei Zhang, Mingyu Zheng, Chunxiao Liu, Kaiwen Wei, Jiang Zhong, Jian Yang
Recent advances in large language models (LLMs) have substantially expanded the scope of Table Question Answering (TableQA). However, existing benchmarks primarily treat TableQA as a passive, single-turn natural language understanding task, lacking the capacity to evaluate autonomous reasoning and tool-call trajectories in realistic, multi-turn scenarios.
To bridge this gap, we introduce TableAgent-Bench, a large-scale bilingual benchmark that reformulates TableQA as proactive, agentic interactions over structurally complex, multi-table environments. With a topology-aware construction strategy, TableAgent-Bench captures dynamic intent evolution through 1,310 multi-turn dialogues grounded in 2,275 industrial tables. Furthermore, we propose the Table-centric Agent Evaluation Framework (TAEF) to assess agent interactions with complex table structures. Specifically, TAEF integrates a specialized agent toolset and 4 metric categories to systematically diagnose intermediate failure modes, assessing performance across table localization, tool-invocation rationality, and trajectory-level pass rate. Extensive experiments with 25 state-of-the-art LLM agents reveal a substantial capability gap, with even the strongest model Gemini-3-Pro-Preview achieving only 53.4% information coverage. We expect TableAgent-Bench to serve as a rigorous testbed for developing and evaluating agents capable of robust table-centric reasoning.

Calibrating Generative Models to Distributional Constraints
Henry Smith, Nathaniel Lee Diamant, Brian L. Trippe
Generative models frequently suffer miscalibration, wherein statistics of the sampling distribution—such as the fraction of generations in a given class—deviate from desired values.
We frame calibration as a constrained optimization problem and seek the closest model in Kullback-Leibler divergence satisfying a calibration constraint.
To address the intractability of imposing these constraints exactly, we introduce two surrogate objectives for fine-tuning: (1) the relax loss, which replaces the constraint with a miscalibration penalty, and (2) the reward loss, which converts calibration into a reward fine-tuning problem.
We demonstrate that these approaches substantially reduce calibration error across hundreds of simultaneous constraints and models with up to nine billion parameters, spanning applications in protein design, image generation, and language modeling.
Code is available at https://github.com/smithhenryd/cgm.

On Expressive Power of Floating-Point Transformers
Sejun Park, Yeachan Park, Geonho Hwang
Research on the expressive power of transformers shows that transformers are equivariant to permutations and can approximate all permutation-equivariant continuous functions on a compact domain. However, these results assume real parameters and exact operations, whereas real-world implementations on computers can only use a finite set of numbers and inexact machine operations with round-off errors. In this work, we investigate the representability of floating-point transformers that use floating-point parameters and floating-point operations.

Unlike existing results under exact arithmetic, we first show that floating-poin
t transformers can represent non-permutation-equivariant functions even without
positional encoding. Furthermore, we prove that floating-point transformers can
represent all permutation-equivariant functions when the sequence length is boun
ded, but they cannot when the sequence length is large. We also identify the min
imal equivariance property in floating-point transformers, and show that all non
-trivial additive positional encoding can harm the representability of floating-
point transformers.

Ranking Time Series using a Time Warping Ideal Point Model
Lucas Zoroddu, Pierre Humbert, Laurent Oudre
Expert-annotated time series datasets often suffer from low agreement, especiall
y in medical applications where decisions rely on subjective criteria and incons
istent thresholds. Such variability degrades annotation quality and thus limits
the reliability of supervised classification models. To address this, we propose
 to rely on a pairwise comparison-based approach, which provides a more robust a
lternative to individual annotation, since relative judgments are typically easi
er and yield higher consistency.
The problem is thus transformed into a ranking problem and we introduce an ideal
 point model adapted to time series data using elastic similarity measures such
as Dynamic Time Warping (DTW) and Time Warp Edit Distance (TWED).
We prove Lipschitz continuity of these distances and demonstrate several converg
ence guarantees for this model. To facilitate gradient-based optimization, we al
so introduce a differentiable version of the TWED. Finally, we show through mult
iple experiments that our approach produces accurate and robust rankings under n
oisy annotation conditions.

Theory of Minimal Weight Perturbations in Deep Networks and its Applications for
 Low-Rank Activated Backdoor Attacks
Bethan Evans, Jared Tanner
The minimal norm weight perturbations of DNNs required to achieve a specified ch
ange in output are derived and the factors determining its size are discussed. T
hese single-layer exact formulae are contrasted with more generic multi-layer Li
pschitz constant based robustness guarantees; both are observed to be of the sam
e order which indicates similar efficacy in their guarantees. These results are
applied to precision-modification-activated backdoor attacks, establishing prova
ble compression thresholds below which such attacks cannot succeed, and show emp
irically that low-rank compression can reliably activate latent backdoors while
preserving full-precision accuracy. These expressions reveal how back-propagated
 margins govern layer-wise sensitivity and provide certifiable guarantees on the
 smallest parameter updates consistent with a desired output shift.

TextAtlas5M: A Large-Scale Dataset for Long Text Image Generation
Dongxing Mao, Alex Jinpeng Wang, Weiming Han, Jiawei Zhang, Zhuobai Dong, Linjie
 Li, Yiqi Lin, Zhengyuan Yang, Libo Qin, Fuwei Zhang, Lijuan Wang, Min Li
Text-conditioned image generation has made rapid progress, yet rendering images
with long-form text remains challenging due to the limitations of existing datas
ets, which predominantly focus on short and simple text.
We introduce TextAtlas5M, a large-scale dataset designed to evaluate long-text r
endering, where “long text” encompasses not only textual length but also layout
complexity and semantic richness.
TextAtlas5M contains 5 million generated and collected images across diverse dat
a types, enabling comprehensive evaluation of large-scale generative models.
We further curate 4,000 human-improved test cases (TextAtlasEval) spanning four
domains, forming one of the most extensive benchmarks for text rendering.
Evaluations show that TextAtlas5M poses substantial challenges even for state-of
-the-art proprietary models (e.g., GPT-4o), with significantly larger gaps obser
ved for open-source models.
Training on TextAtlas5M consistently improves text rendering
for both diffusion-based and autoregressive models, demonstrating

its effectiveness for advancing text-rich image generation.

Parametrized Power-Iteration Clustering for Directed Graphs
Gwendal Debaussart-Joniec, Harry Sevi, Matthieu Jonckheere, Argyris Kalogeratos
Vertex-level clustering for directed graphs (digraphs) remains challenging as ed ge directionality breaks the key assumptions underlying popular spectral methods , which also incur the overhead of eigen-decomposition. This paper proposes *Par ametrized Power Iteration Clustering* (ParPIC), a random-walk-based clustering m ethod for weakly connected digraphs. This builds over the Power-Iteration Cluste ring paradigm, which uses the rows of the iterated diffusion operator as a data embedding. ParPIC has three important features: the use of parametrized reversib le random walk operators, the automatic tuning of the diffusion time, and the ef ficient truncation of the final embedding, which produces low-dimensional data r epresentations and reduces complexity. Empirical results on synthetic and real-w orld graphs demonstrate that ParPIC achieves competitive clustering accuracy wit h improved scalability relative to spectral and teleportation-based methods.
****
KineFlow: Kinematic Second-Order Flow Matching for Time-Series Forecasting
Haiqi Jiang, Hui Xiong
Conventional time-series discriminative forecasting relies on point-wise regress ion, which inherently induces over-smoothing and fails to capture stochastic vol atility in complex systems. While first-order generative flow matching methods m itigate this issue, they ignore system inertia, resulting in phase-space ambigui ties and high sensitivity to noise. We introduce KineFlow, a generative time-ser ies forecasting framework that augments flow matching with a phase-space Neural Acceleration Field, treating exogenous inputs as driving forces that produce gra dual momentum shifts rather than abrupt state perturbations. This second-order f ormulation serves as a structural filter via double integration, suppressing hig h-frequency noise and producing robust, physically consistent predictions. Exten sive experiments on six real-world benchmarks demonstrate that KineFlow achieves an average 15% MSE improvement over discriminative baselines and an 8% gain in CRPS compared to state-of-the-art generative methods.

Sparser Block-Sparse Attention via Token Permutation
Xinghao Wang, Pengyu Wang, Dong Zhang, Chenkun Tan, Shaojun Zhou, Zhaoxiang Liu, Shiguo Lian, Fangxu Liu, Kai Song, Xipeng Qiu
Scaling the context length of large language models (LLMs) offers significant be nefits but is computationally expensive.
This expense stems primarily from the self-attention mechanism, whose $O(N^2)$ c omplexity with respect to sequence length presents a major bottleneck for both m emory and latency.
Fortunately, the attention matrix is often sparse, particularly for long sequenc es, suggesting an opportunity for optimization.
Block-sparse attention has emerged as a promising solution that partitions seque nces into blocks and skips computation for a subset of these blocks.
However, the effectiveness of this method is highly dependent on the underlying attention patterns, which can lead to sub-optimal block-level sparsity.
For instance, important key tokens for queries within a single block may be scat tered across numerous other blocks, leading to computational redundancy.
In this work, we propose Permuted Block-Sparse Attention (**PBS-Attn**), a plug- and-play method that leverages the permutation properties of attention to increa se block-level sparsity and enhance the computational efficiency of LLM prefilli ng.
We conduct comprehensive experiments on challenging long-context datasets, demon strating that PBS-Attn consistently outperforms existing block-sparse attention methods in model accuracy and closely matches the full attention baseline.
Powered by our custom permuted-FlashAttention kernels, PBS-Attn achieves an end- to-end speedup of up to $\mathbf{2.75\times}$ in long-context prefilling, confir ming its practical viability.
Code available at \url{https://github.com/xinghaow99/pbs-attn}.

AREA: Attribute Extraction and Aggregation for CLIP-Based Class-Incremental Lear ning
Zhen-Hao Xie, Yu-Cheng Shi, Da-Wei Zhou
Class-Incremental Learning (CIL) is important in building real-world learning sy stems. In CLIP-based CIL, the model performs classification by comparing similar ity between visual and textual embeddings obtained from template prompts, e.g., ``a photo of a [CLASS]''. This seemingly monolithic matching process can be deco mposed into two conceptually distinct stages: attribute extraction and attribute aggregation. For example, a model may recognize cat using attributes such as fu r texture and whiskers. When learning a new class like car, the model must extra ct additional attributes like wheels and adjust how they are aggregated in the s hared representation space. However, since only data from the current task is av ailable, incremental updates can bias both attribute extraction and aggregation toward new classes, leading to catastrophic forgetting. Therefore, we propose AR EA for attribute extraction and aggregation in CLIP-based CIL. To stabilize extr action, we anchor class-level visual and textual attributes on the hyperspherica l embedding space via principal geodesic analysis. To stabilize aggregation, we learn lightweight task-specific experts with scoring and residual refinement, re gularized by a variational information bottleneck objective. During inference, w e perform routing over task attribute manifolds via optimal transport for more c oncise prediction. Experiments show that AREA consistently outperforms SOTA meth ods. Code is available at https://github.com/LAMDA-CL/ICML2026-AREA.

BiCrossNet with Decoupled Dual Generators: A Parameter■Efficient and Generalizab le Few■Shot Custom Gesture Recognition Framework
Chunyang Yu, Ning SUN, Shenyue Wang
Gesture interaction and touchless sensing is a natural and intuitive control met hod that allows users to control devices through natural hand or body movements, reducing reliance on physical input and enhancing convenience and functional ef ficiency. The biggest challenge is balancing accuracy and model parameter count for custom gesture tasks, while minimizing the number of data samples required f or training. This paper proposes a novel IMU-based BiCrossNet model and two nove l data augmentation models (delta-generator and embedding-generator) to address this challenge. Compared with existing methods, the model proposed in this artic le boosts accuracy by 11.7% and 12.7% in UMAHand (public datasets); and 8.85% a nd 5.25% in GRHand (self-developed datasets), with decreasing 27.8% pretrained f eature-extractor model parameters. This research lays a solid foundation for dep loying and implementing custome gesture recognition engineering on intelligent terminal devices.

Delving into Non-Exchangeability for Conformal Prediction in Graph-Structured Mu ltivariate Time Series
Ruichao Guo, Xingyao Han, Luo Wenshui, Zhe Liu, Chen Gong, Hesheng Wang
Point forecasting for graph-structured multivariate time series is a fundamental problem, but rigorous uncertainty quantification for such predictions is still underexplored. Conformal prediction (CP) offers uncertainty estimation with a so lid coverage guarantee under the exchangeability assumption, which requires the joint data distribution to be unchanged under permutation. However, in graph-str uctured time series, inherent cross-node coupling can violate the exchangeabilit y condition, making direct application of CP unreliable.
Inspired by the spectral graph theory, such coupling resides in global trends an d can be characterized by the low-frequency components, while high-frequency com ponents are nearly exchangeable. Therefore, we propose a novel concept named **S **pectral **G**raph **C**onditional **E**xchangeability (SGCE), which conditions exchangeable high-frequency components on low-frequency ones to preserve global trends and enable effective CP in the spectral domain.
Based on SGCE, we further propose **S**pectral **C**onformal prediction via w**A **ve**LE**t transform (SCALE). SCALE uses graph wavelets to decompose low/high-f requency components and conformalizes high-frequency residuals via adaptive gati

ng over a low-frequency embedding. Experimental results on real-world benchmark datasets across multiple application domains show that SCALE not only achieves valid coverage but also consistently improves the coverage-efficiency trade-off over the state-of-the-art CP methods.

Return-Critic: Bridging Goal Discrepancy for Efficient Visual Reinforcement Learning

Ruyi Lu, Xuesong Wang, Hengrui Zhang, Yuhu Cheng

Sample inefficiency remains a challenge in pixel-based visual reinforcement learning (RL), primarily due to ineffective state representation learning. While recent advances employ auxiliary tasks to improve representation learning, their representation goals (e.g., mask reconstruction, state prediction) are misaligned with the ultimate RL goal of maximizing return, constraining further improvements in representation quality. To achieve efficient visual reinforcement learning, we propose Return-Critic (RC), an auxiliary framework that bridges goal discrepancy by return prediction. RC samples partial frames from an episode, processes them through a shared visual encoder, and employs a lightweight Transformer to predict the episode's return, forcing the encoder to learn return-relevant representation. The attention weights naturally highlight important frames, enabling a key function for prioritized learning. Extensive experiments on both online (DMControl) and offline (V-D4RL) benchmarks demonstrate that RC significantly enhances the sample efficiency, particularly achieving 68% performance boost on average across nine challenging tasks from DMControl.

Rethinking Generative Image Pretraining: How Far Are We From Scaling Up Next-Pixel Prediction?

Xinchen Yan, Chen Liang, Lijun Yu, Adams Wei Yu, Yifeng Lu, Quoc V Le

This paper investigates the scaling properties of autoregressive next-pixel prediction, a simple, end-to-end yet under-explored framework for unified vision models. Starting with images at resolutions of 32$\times$ 32, we
train a family of Transformers using IsoFLOP profiles across compute budgets up to 7e19 FLOPs and evaluate three distinct target metrics: next-pixel prediction objective, ImageNet classification accuracy, and generation-based completion where top half of the image serves as a spatial prompt. First, optimal scaling strategy is critically task-dependent.
At a fixed resolution of 32 $\times$ 32 alone,
the optimal scaling properties for image classification and image generation diverge, where generation optimal setup requires the data size grow three to five times faster than for the classification optimal setup.
Second, as image resolution increases, the optimal scaling strategy indicates that the model size must grow much faster than data size.
Surprisingly, by projecting our findings, we discover that the primary bottleneck is compute rather than the amount of training data.
As compute continues to grow four to five times annually,
we forecast the feasibility of pixel-by-pixel modeling of images within the next five years.

****

Coloring the Noise: Adversarial Sobolev Alignment for Faithful Image Super Resolution

Hongbo Wang, Huaibo Huang, Pin Wang, Jinhua Hao, Chao Zhou, Ran He

Generative priors in Image Super-Resolution (SR) often compromise faithful restoration, we attribute this limitation to a fundamental spectral misalignment between isotropic objectives and the intrinsic natural image manifold. While Direct Preference Optimization offers a path to alignment, its reliance on spectrally flat Gaussian noise fails to distinguish authentic high-frequency details from hallucinations. To bridge this geometric gap, we propose ASASR, a theoretically grounded framework that recasts the generative flow into a Sobolev-induced Riemannian geometry by explicitly coloring the noise transition kernel to mirror natural spectral decay. Driving this geometric alignment, we integrate a parametric adversary grounded in the Riesz Representation Theorem, which synthesizes targeted

negative samples equivalent to worst-case Sobolev gradients to direct optimization along the tangent space of plausible structural failures.
Extensive evaluations demonstrate that ASASR outperforms leading generative baselines, particularly in preserving spectral consistency and structural fidelity, offering a robust solution that effectively mitigates artifacts.
****

Divide and Contrast: Learning Robust Temporal Features without Augmentation
Abdul-Kazeem Shamba, Kerstin Bach, Gavin Taylor
Self-supervised learning for time-series representation aims to reduce reliance on labeled data while maintaining strong downstream performance, yet many existing approaches incur high computational costs or rely on assumptions that do not hold across diverse temporal dynamics. In this work, we introduce Divide and Contrast (Di-COT), an unsupervised framework that avoids data augmentation and multiple encoder passes by contrasting informative substructures within a window rather than individual timesteps. Di-COT stochastically partitions each window into a small number of overlapping sub-blocks per iteration, enabling efficient and meaningful contrast while mitigating false positives during temporal transitions. To further improve scalability, we adopt a contrastive objective whose computation depends on the batch size and the number of sub-blocks, making loss computation independent of sequence length. Extensive experiments on six large-scale real-world datasets, as well as the UCR and UEA benchmarks, demonstrate that Di-COT learns transferable representations while achieving state-of-the-art performance with substantially reduced training time.
****

Causes and Consequences of Representational Similarity in Machine Learning Models
Zeyu Michael Li, Hung Anh Vu, Damilola Awofisayo, Emily Wenger
Numerous works have noted similarities in how machine learning models represent the world, even across modalities. Although much effort has been devoted to uncovering properties and metrics on which these models align, surprisingly little work has explored causes of this similarity. To advance this line of inquiry, this work explores how two factors—dataset overlap and task overlap—influence downstream model similarity. We evaluate the effects of both factors through experiments across model sizes and modalities, from small classifiers to large language models. We find that dataset and task overlap are positively associated with higher representational similarity across many of our settings, with clear evidence in vision/language classification and weaker trends in language generation experiments. Finally, we consider downstream consequences of representational similarity, showing that greater similarity is associated with increased vulnerability to transferable adversarial attacks in vision models.
****

Asymptotic Theory of Iterated Empirical Risk Minimization, with Applications to Active Learning
Hugo Cui, Yue M. Lu
We study a class of iterated empirical risk minimization (ERM) procedures in which two successive ERMs are performed on the same dataset, and the predictions of the first estimator enter as an argument in the loss function of the second. This setting, which arises naturally in active learning and reweighting schemes, introduces intricate statistical dependencies across samples and fundamentally distinguishes the problem from classical single-stage ERM analyses. For linear models trained with a broad class of convex losses on Gaussian mixture data, we derive a sharp asymptotic characterization of the test error in the high-dimensional regime where the sample size and ambient dimension scale proportionally. Our results provide explicit, fully asymptotic predictions for the performance of the second-stage estimator despite the reuse of data and the presence of prediction-dependent losses. We apply this theory to revisit a well-studied pool-based active learning problem, removing oracle and sample-splitting assumptions made in prior work. We uncover a fundamental tradeoff in how the labeling budget should be allocated across stages, and demonstrate a double-descent behavior of the test error driven purely by data selection, rather than model size or sample count.

****
To Grok Grokking: Provable Grokking in Ridge Regression
Mingyue Xu, Gal Vardi, Itay Safran
We study *grokking* — the onset of generalization long after overfitting — in a classical ridge regression setting. We prove end-to-end grokking results for learning over-parameterized linear regression models using gradient descent with weight decay. Specifically, we prove that the following stages occur: (i) the model overfits the training data early during training; (ii) poor generalization persists long after overfitting has manifested; and (iii) the generalization error eventually becomes arbitrarily small. Moreover, we show, both theoretically and empirically, that grokking can be amplified or eliminated in a principled manner through proper hyperparameter tuning. To the best of our knowledge, these are the first rigorous quantitative bounds on the generalization delay (which we refer to as the "grokking time") in terms of training hyperparameters. Lastly, going beyond the linear setting, we empirically demonstrate that our quantitative bounds also capture the behavior of grokking on non-linear neural networks. Our results suggest that grokking is not an inherent failure mode of deep learning, but rather a consequence of specific training conditions, and thus does not require fundamental changes to the model architecture or learning algorithm to avoid.
****
How does Chain of Thought decompose complex tasks?
Amrut Nadgir, Vijay Balasubramanian, Pratik Chaudhari
Many language tasks can be modeled as classification problems where a large language model (LLM) is given a prompt and selects one among many possible answers. We show that the classification error in such problems scales as a power law in the number of classes. This has a dramatic consequence: the prediction error can be reduced substantially by splitting the overall task into a sequence of smaller classification problems, each with the same number of classes ("degree"). This tree-structured decomposition models chain-of-thought (CoT). It has been observed that CoT-based predictors perform better when they "think", i.e., when they develop a deeper tree, thus decomposing the problem into a larger number of steps. We identify a critical threshold for the degree, below which thinking is detrimental, and above which there exists an optimal depth that minimizes the error. It is impossible to surpass this minimal error by increasing the depth of thinking.
****
Regularized Discriminative Alignment for Deep Representations under Label Shift
Hengchao Shi, Boen Jiang, Guanhua Fang, Wen Yu, Ming Zheng
Label shift refers to the distribution shift scenario where the marginal label distribution changes while the class-conditional distribution remains invariant. To address this challenge in complex real-world settings, we propose **Regularized Discriminative Alignment for Label Shift (RDALS)**, a novel framework that adapts to target domains by aligning distributions within the deep latent space. By shifting the focus from raw inputs to learned representations, RDALS effectively operates under a weaker and more practical invariance assumption. Specifically, we construct a moment-matching linear system using Linear Discriminant Analysis (LDA) and show that this choice maximizes numerical stability. We further provide rigorous theoretical analysis, establishing finite-sample error bounds for the importance weight estimation and the generalization bounds for the adapted classifier. Extensive experiments on standard benchmarks demonstrate that RDALS significantly outperforms state-of-the-art baselines, achieving superior robustness and accuracy in both data-scarce and extreme-shift regimes.
****
APEX: Approximate-but-exhaustive search for ultra-large combinatorial synthesis libraries
Aryan Pedawi, Jordi Silvestre-Ryan, Bradley Worley, Darren J. Hsu, Kushal S Shah, Elias Stehle, Jingrong Zhang, Izhar Wallach
Make-on-demand combinatorial synthesis libraries (CSLs) like Enamine REAL have significantly enabled drug discovery efforts. However, their large size presents a challenge for virtual screening, where the goal is to identify the top compoun

ds in a library according to a computational objective (e.g., optimizing docking score) subject to computational constraints under a limited computational budget. For current library sizes---numbering in the tens of billions of compounds---and scoring functions of interest, a routine virtual screening campaign may be limited to scoring fewer than 0.1% of the available compounds, leaving potentially many high scoring compounds undiscovered. Furthermore, as constraints (and sometimes objectives) change during the course of a virtual screening campaign, existing virtual screening algorithms typically offer little room for amortization. We propose the approximate-but-exhaustive search protocol for CSLs, or APEX. APEX utilizes a neural network surrogate that exploits the structure of CSLs in the prediction of objectives and constraints to make full enumeration on a consumer GPU possible in under a minute, allowing for exact retrieval of approximate top-k sets. To demonstrate APEX's capabilities, we develop a benchmark CSL comprised of more than 10 million compounds, all of which have been annotated with their docking scores on five medically relevant targets along with physicohemical properties measured with RDKit such that, for any objective and set of constraints, the ground truth top-k compounds can be identified and compared against the retrievals from any virtual screening algorithm. We show APEX's consistently strong performance both in retrieval accuracy and runtime compared to alternative methods.

Evaluating Language Models in Realistic Conversational Contexts

Ilija Subasic, Andrew Rabinovich, Zhao Chen

As Large Language Models (LLMs) are increasingly deployed to serve open-ended, multi-turn interactions, evaluating conversational quality at human scale has become a central challenge. Existing evaluation frameworks built for summarization, translation, or short-form QA tasks fall short of adequately measuring the consistency of human-scale dialogue, especially when derivation and validation of these metrics themselves often rely on synthetic rather than human sources. We fill the gap by introducing \textbf{UPHELD} (Utility \& Planning Human-Scale Evaluated Long Dialogues), a large, reference-full benchmark for evaluating human-scale conversational ability beyond factual correctness. UPHELD consists of hundreds of complete human-to-human dialogues authored by \textbf{professional script writers}, with realistic turn densities and \textbf{36,000+ per-turn human annotations} across \textbf{30,000+ expert-generated dialogue turns}. Using UPHELD, we systematically evaluate classical automatic metrics and reference-free LLM-as-a-judge approaches, and find them unreliable when correlated with expert human judgment. Building off this analysis, we use UPHELD to develop a \textbf{Mixture-of-Judges} framework that combines multiple evaluative signals and improves correlation with human assessments by approximately \textbf{30\%}. Overall, UPHELD provides a robust, human-grounded foundation for evaluating human-scale conversational intelligence that fills a crucial gap in the pre-existing LLM dataset landscape.

Offline Multi-agent Continual Cooperation via Skill Partition and Reuse

Yuchen Xiao, Lei Yuan, Ruiqi Xue, Tieyue Yin, Yang Yu

Extracting skills from multi-agent offline dataset improves learning efficiency via sharing task-invariant coordination skills among tasks. In settings where tasks occur sequentially and the space of skills grows exponentially, existing approaches that rely on heuristically designed and fixed-sized skill libraries struggle to resolve the problem of distributional shift and interference, facing catastrophic forgetting and plasticity loss. To address this problem and endow agents with the ability to continually discover and reuse coordination skills in open-environment, we propose COMAD, a principled framework for **C**ontinual **O**ffline **M**ulti-**a**gent Skill **D**iscovery via Skill Partition and Reuse. We first discover skills from mixed multi-agent behavior data with an auto-encoder to transform coordination knowledge into reusable coordination skills. Then we construct a skill-augmented policy learning objective with multi-head architectures, explicitly guiding the advantage function with reusable skills identified via a density-based reusability estimator.

Theoretical analysis shows our method approximates the optimum of a continual sk ill discovery problem. Empirical results across diverse MARL benchmarks show tha t COMAD continually expands its skill library to mitigate interference, achievin g superior forward and backward transfer for task streams compared to multiple b aselines.

Controlled LLM Training on Spectral Sphere
Tian Xie, Haoming Luo, Haoyu Tang, Hu Yiwen, Jason Klein Liu, Qingnan Ren, Yang Wang, Xin Zhao, Rui Yan, Bing Su, Chong Luo, Baining Guo
Scaling large models requires optimization strategies that ensure rapid converge nce grounded in stability. Maximal Update Parametrization ($\boldsymbol{\mu}$P) provides a theoretical safeguard for width-invariant $\Theta(1)$ activation cont rol, whereas emerging optimizers like Muon are only "half-aligned" with these co nstraints: they control updates but allow weights to drift. To address this limi tation, we introduce the **Spectral Sphere Optimizer (SSO)**, which enforces str ict module-wise spectral constraints on both weights and their updates. By deriv ing the steepest descent direction on the spectral sphere, SSO realizes a fully $\boldsymbol{\mu}$P-aligned optimization process. To enable large■scale training , we implement SSO as an efficient parallel algorithm within Megatron. Through e xtensive pretraining on diverse architectures, including Dense 1.7B, MoE 8B-A1B, and 200-layer DeepNet models, SSO consistently outperforms AdamW and Muon. Furt hermore, we observe significant practical stability benefits, including improved MoE router load balancing, suppressed outliers, and strictly bounded activation s.

Test-Time Guidance for Flow-Based Generative Models via Parallel Tempering on So urce Distributions
Shih-Hsin Wang, Joel Keller, Taos Transue, Drake Benjamin Brown, Thomas Strohmer , Bao Wang
Generative models that transport a simple source distribution to a complex data distribution—such as diffusion and flow-based models—are central to high■fidelit y data generation. Test-time guidance can further steer pretrained models toward user-specified high-reward regions without costly retraining. However, existing guidance methods face critical limitations: they struggle with non-differentiab le rewards, fail to navigate complex landscapes, and often lack theoretical guar antees on generation performance. We propose {\it Source Parallel Tempering (SPT)}, a gradient■free test■time guidance framework that operates entirely in sourc e space, leveraging its simpler geometry to avoid the complexities of the data m anifold. SPT couples a local exploration kernel with parallel tempering, enablin g efficient barrier crossing and robust discovery of high■reward modes. Theoreti cally, we provide a new error bound linking training-time approximation error to test-time guidance performance.Empirically, SPT significantly improves over sta te-of-the-art methods on benchmark tasks in conditional image synthesis and dyna mical system trajectory sampling.

Spatial Memory for Out-of-Vision Manipulation in Vision-Language-Action
Pengteng Li, Weiyu Guo, He Zhang, Tiefu Cai, Xiao He, Yandong Guo, Hui Xiong
We introduce SOMA, the Spatial Memory framework for Out-of-Vision Manipulation i n Vision-Language-Action (VLA) models. Most existing VLAs implicitly assume that task-relevant objects are always visible, leading to brittle and reactive behav iors when targets fall outside the camera’s field of view. SOMA addresses this l imitation by equipping VLAs with a persistent spatial memory constructed from mu lti-view observations acquired via a movable head camera, enabling reasoning bey ond the current visual frustum. The framework consists of three components: Spat ial Memory Construction, which aggregates angular-wise observations into a unifi ed spatial–semantic representation through scanning; Dynamic Memory Refinement, which maintains global consistency over time; and Contextual Memory Retrieval, w hich activates instruction-relevant spatial cues during manipulation. We evaluat e SOMA on five challenging real-world out-of-vision manipulation tasks, includin g multi-step and dual-arm scenarios where target objects are initially invisible

. Experimental results show that SOMA not only improves task success rates, but also induces qualitatively different manipulation behaviors, with faster target localization, reduced viewpoint search, and near one-shot grasping under partial observability. Additional experiments on RoboCasa GR1 and SimplerEnv further validate the effectiveness of SOMA's memory design under conventional fully observable settings. Code will be released soon.

TSFAdv: Frequency-Guided Black-Box Adversarial Attacks on Time Series Forecasting
Qizhuo Han, Xiangrui Cai, Sihan Xu, Ying Zhang, Zheli Liu
While deep neural network-based long-term time series forecasting (LTSF) has become indispensable for critical infrastructures such as smart grids and IoT platforms, the deployment of these models as black-box APIs introduces severe security vulnerabilities that remain largely underexplored. In this paper, we propose TSFAdv, a query-efficient adversarial framework for LTSF models. The framework systematically analyzes model sensitivity to spectral perturbations in both magnitude and phase of the frequency domain. By embedding frequency-domain priors into Natural Evolution Strategies, we achieve sensitivity-guided gradient estimation that improves perturbation efficacy without violating practical query constraints. To overcome ambiguities inherent to point-wise regression metrics, we adopt a trajectory-level evaluation protocol based on Dynamic Time Warping (DTW) and Slope Misalignment Error (SME), enabling the capture of complex geometric and directional deviations. Extensive experiments across seven state-of-the-art architectures demonstrate that TSFAdv achieves substantial performance gains, with median DTW improvements of 38.78\% and median SME improvements of 26.47\% under 200-query budget. These findings reveal that existing defense mechanisms are ineffective against frequency-domain manipulation, underscoring an urgent necessity for robust LTSF models.
****
Ideal Attribution and Faithful Watermarks for Language Models
Min Jae Song, Kameron Shahabi
We introduce ideal attribution mechanisms, a formal abstraction for reasoning about attribution decisions over strings. At the core of this abstraction lies the ledger, an append-only log of the prompt-response interaction history between a model and its user. Each mechanism produces deterministic decisions based on the ledger and an explicit selection criterion, making it well-suited to serve as a ground truth for attribution. We frame the design goal of watermarking schemes as faithful representation of ideal attribution mechanisms. This novel perspective brings conceptual clarity, replacing piecemeal probabilistic statements with a unified language for stating the guarantees of each scheme. It also enables precise reasoning about desiderata for future watermarking schemes, even when no current construction achieves them, as the ideal functionalities are specified first. In this way, the framework provides a roadmap that clarifies which guarantees are attainable in an idealized setting and worth pursuing in practice.

Adaptive Estimation and Inference in Semi-parametric Heterogeneous Clustered Multitask Learning via Neyman Orthogonality
Hanxiao Chen, Debarghya Mukherjee
We study clustered multitask learning in a semiparametric setting where tasks share a latent cluster structure in their target parameters but exhibit heterogeneous, potentially infinite-dimensional nuisance components. Such heterogeneity poses a major challenge for existing multitask learning methods, which typically rely on aligned feature spaces or homogeneous task structures. To address this challenge, we propose an *adaptive fused orthogonal estimator* that integrates Neyman-orthogonal losses with data-driven pairwise fusion penalties. Our framework leverages task-specific pilot estimates to calibrate the fusion penalties and combines adaptive aggregation with orthogonalization to mitigate the impact of nuisance-parameter estimation error. Theoretically, we show that the proposed estimator achieves exact recovery of the latent clustering with high probability and attains pooled parametric convergence rates proportional to cluster size. Moreov

er, we establish asymptotic normality and show that, asymptotically, our estimat
or matches the performance of an oracle procedure that knows the true clustering
 in advance. Empirically, we show that the proposed method consistently outperfo
rms strong baselines in various simulation setups. A real-world application to U
.S. residential energy consumption further demonstrates the effectiveness of our
 approach in uncovering meaningful regional clustering in electricity price elas
ticity, showcasing the efficacy of our method.

Universal Skeleton Understanding via Differentiable Rendering and MLLMs
Ziyi Wang, Peiming Li, Xinshun Wang, Yang Tang, Kai-Kuang Ma, Mengyuan Liu
Multimodal large language models (MLLMs) exhibit strong visual-language reasonin
g, yet remain confined to their native modalities and cannot directly process st
ructured, non-visual data such as human skeletons. Existing methods either compr
ess skeleton dynamics into lossy feature vectors for text alignment, or quantize
 motion into discrete tokens that generalize poorly across heterogeneous skeleto
n formats. We present SkeletonLLM, which achieves universal skeleton understandi
ng by translating arbitrary skeleton sequences into the MLLM's native visual mod
ality. At its core is DrAction, a differentiable, format-agnostic renderer that
converts skeletal kinematics into compact image sequences. Because the pipeline
is end-to-end differentiable, MLLM gradients can directly guide the rendering to
 produce task-informative visual tokens. To further enhance reasoning capabiliti
es, we introduce a cooperative training strategy: Causal Reasoning Distillation
transfers structured, step-by-step reasoning from a teacher model, while Discrim
inative Finetuning sharpens decision boundaries between confusable actions. Skel
etonLLM demonstrates strong generalization on diverse tasks including recognitio
n, captioning, reasoning, and cross-format transfer---suggesting a viable path f
or applying MLLMs to non-native modalities. Code is available in the Supplementa
ry Material.

Linear Ensembles Wash Away Watermarks: On the Fragility of Distributional Pertur
bations in LLMs
Zhihao Wu, Gracia Gong, Qinglin Zhu, Yudong Chen, Runcong Zhao
Watermarking embeds statistical signatures in AI-generated text for detection an
d attribution. We reveal a fundamental vulnerability: when users access multiple
 models (today's reality), watermarks trivially fail. Watermarks perturb output
 distributions away from the original, and in competitive markets, these perturb
ations are typically independent across providers. We theoretically prove that a
veraging output probability distributions recovers the unwatermarked distributio
n with up to a second-order error term. Empirically, simply averaging 3-5 models
 cancels out these perturbations. We introduce WASH (Watermark Attenuation via S
tatistical Hybridisation), which solves practical challenges in ensemble generat
ion: vocabulary misalignment and tokenisation differences across heterogeneous m
odels. Experiments across six watermarking schemes and three LLMs show that aver
aging across 3 models suppresses detection z-scores from 5-300 to **below 2** (b
elow the detection threshold of 4) and reduces TPR@5%FPR to **below 50%**, while
 improving quality by **27.5%** and running **6×** faster than the best baseline
 on the long sequence generation. Our results suggest that robust AI-text detect
ion via watermarking requires either accepting this fundamental vulnerability or
 unprecedented coordination among model providers.

Near-Optimal Regret for Policy Optimization in Contextual MDPs with General Offl
ine Function Approximation
Orin Levy, Aviv Rosenberg, Alon Cohen, Yishay Mansour
We introduce OPO-CMDP, the first policy optimization algorithm for stochastic Co
ntextual Markov Decision Process (CMDPs) under general offline function approxim
ation. Our approach achieves a high probability regret bound of
$\widetilde{O}(H^4\sqrt{T|S||A|\log(|\mathcal{F}||\mathcal{P}|)}),$ where S an
d A denote the state and action spaces, H the horizon length, T the number
 of episodes, and $\mathcal{F}, \mathcal{P}$ the finite function classes used to
 approximate the losses and dynamics, respectively. This is the first regret bou

nd with optimal dependence on $|S|$ and $|A|$, directly improving the current st
ate-of-the-art (Qian, Hu, and Simchi-Levi, 2024).
These results demonstrate that optimistic policy optimization provides a natural
, computationally superior and theoretically near-optimal path for solving CMDPs
.

Scaling the Scaling Logic: Agentic Meta-Synthesis of Logic Reasoning
Bowen LIU, Zhi Wu, Runquan Xie, Zhanhui Kang, Jia Li
Reinforcement Learning from Verifiable Rewards (RLVR) is bottlenecked by data: e
xisting synthesis pipelines rely on expert-written code or fixed templates, conf
ining growth to instance-level perturbations. We shift the evolvable unit from p
roblem instances to task-family specifications. SSLogic is an agentic meta-synth
esis framework in which LLM agents iteratively author and refine executable Gene
rator-Validator pairs inside a closed Generate-Validate-Refine loop, producing f
amilies with new rules and difficulty gradients rather than parameter variations
 of old ones. A Multi-Gate Validation Protocol, multi-strategy consensus plus Ad
versarial Blind Review, where independent agents solve each instance by writing
and executing code, filters ill-posed tasks before they enter training. Starting
 from 400 seed families, two evolution rounds yield 953 families and 21,389 veri
fiable instances. Three converging comparisons (step-matched, token-matched, and
 size-controlled on external Enigmata data) consistently show higher training ut
ility of evolved data, with gains of SynLogic +5.2, AIME25 +3.0, and BBH +5.5 on
 Enigmata. Fine-grained KORBench evaluation reveals selective improvements in lo
gic (+13.2%) and operation (+9.6%), linking structural evolution to downstream g
ains. Code is available at https://github.com/AdAstraAbyssoque/Scaling-the-Scal
ing-Logic.

Physics in 2-Steps: Locking Motion Priors Before Visual Refinement Erases Them
Woojung Han, Seil Kang, Youngjun Jun, Min-Hung Chen, Fu-En Yang, Seong Jae Hwang
Image-to-Video diffusion models leverage input images to generate visually stunn
ing content, yet frequently produce motion that violates physical laws. We revea
l a surprising finding: a 2-step generation often exhibits better physical consi
stency than a 50-step output from the same model. Through spectral analysis, we
trace this to phase erosion during denoising; the phase degrades significantly (
dropping by $\approx 18\%$ from step 2 to step 50), whereas the magnitude remain
s relatively stable. Building on this insight, we propose PhaseLock, a training-
free framework that preserves the valid motion priors from few-step inference th
roughout the denoising trajectory. Rather than relying on full-step inference fo
r physical consistency, PhaseLock extracts a motion prior from just 2 steps and
enforces it onto high-fidelity generation via Latent Delta Guidance. Our approac
h effectively mitigates phase degradation, improving physical consistency by an
average of 6.2 points across diverse models while largely maintaining visual fid
elity, with negligible overhead ($1.06\times$ time, $1.02\times$ memory) and red
uced reliance on expensive external guidance methods ($\sim5\times$ time).

GUDA: Counterfactual Group-wise Training Data Attribution for Diffusion Models v
ia Unlearning
Naoki Murata, Yuhta Takida, Chieh-Hsin Lai, Toshimitsu Uesaka, Bac Nguyen, Stefa
no Ermon, Yuki Mitsufuji
Training-data attribution for vision generative models aims to identify which tr
aining data influenced a given output. While most methods score individual examp
les, practitioners often need group-level answers (e.g., artistic styles or obje
ct classes). Group-wise attribution is counterfactual: how would a model's behav
ior on a generated sample change if a group were absent from training? A natural
 realization of this counterfactual is Leave-One-Group-Out (LOGO) retraining, wh
ich retrains the model with each group removed; however, it becomes computationa
lly prohibitive as the number of groups grows. We propose GUDA (Group Unlearning
-based Data Attribution) for diffusion models, which approximates each counterfa
ctual model by applying machine unlearning to a shared full-data model instead o
f training from scratch. GUDA quantifies group influence using differences in a

likelihood-based scoring rule (ELBO) between the full model and each unlearned counterfactual. Experiments on CIFAR-10 and artistic style attribution with Stable Diffusion show that GUDA identifies primary contributing groups more reliably than semantic similarity, gradient-based attribution, and instance-level unlearning approaches, while achieving $\sim$100$\times$ speedup on CIFAR-10 over LOGO retraining. The code is available at https://github.com/sony/guda.
****
Deterministic Inference across Tensor Parallel Sizes That Eliminates Training-Inference Mismatch
Ziyang Zhang, Xinheng Ding, Jiayi Yuan, Rixin Liu, Huizi Mao, Jiarong Xing, Zirui Liu
Deterministic inference is increasingly critical for Large language model (LLM) applications such as LLM-as-a-judge evaluation, multi-agent systems, and reinforcement learning (RL).
However, existing LLM serving frameworks can produce different outputs for identical inputs when tensor parallel (TP) size or batch size changes, even under greedy decoding.
This arises from the non-associativity of floating-point arithmetic and inconsistent reduction orders across GPUs. While prior work has addressed batch-size–related nondeterminism through batch-invariant kernels, determinism across different TP sizes remains an open problem, particularly in RL settings, where the training engine typically uses Fully Sharded Data Parallel (FSDP) (i.e., TP = 1) while the rollout engine relies on multi-GPU TP to maximize the inference throughput, creating a probability mismatch that can degrade or even collapse training.
We identify and analyze the root causes of TP-induced inconsistency and propose **Tree-Based Invariant Kernels (TBIK)**, a set of custom matrix multiplication and reduction kernels that guarantee bit-wise identical results across TP sizes. Our key insight is to enforce a consistent reduction order across and within GPUs.
We implement TBIK in Triton and integrate it into vLLM and FSDP, achieving **bit-wise deterministic inference** across different TP sizes and **zero probability divergence** between rollout and training engines in RL pipelines. By eliminating mismatches caused by different parallelization strategies, TBIK enables **true on-policy RL at scale for the first time**, leading to improved model performance and faster convergence.

Transform Trained Transformer for Accelerating Native 4K Video Generation
Jiangning Zhang, Junwei Zhu, Teng Hu, Yabiao Wang, Donghao Luo, Weijian Cao, Zhenye Gan, Xiaobin Hu, Zhucun Xue, Xiangtai Li, Chengjie Wang, Yong Liu
Native 4K (2176$\times$3840) video generation remains a critical challenge due to the quadratic computational explosion of full-attention as spatiotemporal resolution increases, making it difficult for models to strike a balance between efficiency and quality. This paper proposes a novel Transformer retrofit strategy termed T3 (**T**ransform **T**rained **T**ransformer) that, without altering the core architecture of full-attention pretrained models, significantly reduces compute requirements by optimizing their forward logic. Specifically, T3-Video introduces a multi-scale weight-sharing window attention mechanism and, via hierarchical blocking together with an axis-preserving full-attention design, can effect an “attention pattern” transformation of a pretrained model using only modest compute and data. Results on 4K-VBench show that T3-Video substantially outperforms existing approaches: while delivering performance improvements (+4.29$\uparrow$ VQA and +0.08$\uparrow$ VTC), it accelerates native 4K video generation by more than 10$\times$. Demo and source code are available in \#Supp.
****
Training-Free Adaptation of Diffusion Models via Doob's h-Transform
Qijie Zhu, Zeqi Ye, Han Liu, Zhaoran Wang, Minshuo Chen
Adaptation methods have been a workhorse for unlocking the transformative power of pre-trained diffusion models in diverse applications. Existing approaches often abstract adaptation objectives as a reward function and steer diffusion model

s to generate high-reward samples. However, these approaches can incur high comp
utational overhead due to additional training, or rely on stringent assumptions
on the reward such as differentiability. Moreover, despite their empirical succe
ss, theoretical justification and guarantees are seldom established. In this pap
er, we propose $\texttt{DOIT}$ ($\textbf{D}$oob-$\textbf{O}$riented
$\textbf{I}$nference-time $\textbf{T}$ransformation), a training-free
adaptation method for generic, non-differentiable rewards. We develop
two variants of this method: $\texttt{DOIT-Proto}$, a full-rollout
simulation-based algorithm and
$\texttt{DOIT-Practical}$, an efficient surrogate algorithm.
The key idea is a measure transport formulation that seeks to transport the pre-
trained generative distribution to a high-reward target distribution. We leverag
e Doob's h-transform to realize this transport, which induces a dynamic correc
tion to the diffusion sampling process and admits simulation-based computation w
ithout modifying the pre-trained model. Theoretically, we establish a high-proba
bility convergence
guarantee to the target high-reward distribution for $\texttt{DOIT-Proto}$ by ch
aracterizing the approximation error in
the dynamic Doob correction. Empirically, $\texttt{DOIT-Practical}$ consistently
outperforms state-of-the-art baselines on D4RL offline RL benchmarks
while preserving sampling efficiency.
****

ERAlign: Energy-based Representation Alignment of GNNs and LLMs on Text-attribut
ed Graphs
Xianlin Zeng, Fan Xia, Xiangyu Chen
Text-attributed Graphs (TAGs) incorporate textual node attributes with graph str
uctures to describe rich relational semantics. Recent efforts to integrate Graph
 Neural Networks (GNNs) and Large Language Models (LLMs) have shown promise for
learning on TAGs, yet achieving well-aligned representations remains challenging
. Prior studies largely rely on heuristics that perform coarse-grained matching.
 They lack sufficient constraints and ignore distributional alignment, leading t
o representation drift and limited generalization. Building on Energy-based Mode
ls (EBMs), we propose an **E**nergy-based **R**epresentation **Align**ment (ERAl
ign) framework that projects GNN-encoded graph structure and LLM-derived text em
beddings in a shared latent space to achieve distribution consistency. Concretel
y, layer-wise alignment is quantified by a distance metric and optimized via an
EBM objective. By decreasing energy values, our framework yields well-aligned re
presentations for downstream tasks. During training, we introduce Energy Discrep
ancy (ED) to avoid high sampling costs associated with intractable normalization
. ED also carries theoretical guarantees of higher training efficiency and reduc
ed energy landscape distortion. Empirical evaluations on eight TAG datasets demo
nstrate that ERAlign obtains state-of-the-art performance across varying levels
of supervision and cross-task transfer scenarios.

What Makes a Representation Good for Single-Cell Perturbation Prediction?
Wenkang Jiang, Yuhang Liu, Yichao Cai, Erdun Gao, Jiayi Dong, Ehsan Abbasnejad,
Lina Yao, Javen Qinfeng Shi
Single-cell perturbation modeling is fundamental for understanding and predictin
g cellular responses to genetic perturbations. However, existing approaches, fro
m causal representation learning to foundation models, often struggle with an ov
erlooked challenge: gene expression is dominated by perturbation-invariant infor
mation, while perturbation-specific signals are intrinsically sparse. As a resul
t, learned representations either entangle invariant and perturbation-specific i
nformation, leading to spurious and non-generalizable predictors, or suppress pe
rturbation-specific signals altogether, rendering them ineffective for predictio
n. To address this, we propose PerturbedVAE, a general framework designed to res
olve this signal imbalance. The framework explicitly separates perturbation-spec
ific information from dominant invariant structure and recovers causal represent
ations to effectively utilize such information for prediction. We further provid
e an identifiability analysis that characterizes the conditions under which spar

se perturbation effects can be reliably recovered, thereby clarifying how the fr amework can be concretely specified under such conditions. Empirically, Perturbe dVAE achieves state-of-the-art performance on a widely used benchmark across mul tiple evaluation settings, yielding significant gains on out-of-distribution com binatorial predictions and uncovering interpretable perturbation-response progra ms.

****

Spectrally-Guided Diffusion Noise Schedules

Carlos Esteves, Ameesh Makadia

Denoising diffusion models are widely used for high-quality image and video gene ration.

Their performance depend on noise schedules, which define the distribution of no ise levels applied during training and the sequence of noise levels traversed du ring sampling. Noise schedules are typically handcrafted and require manual tuni ng across different resolutions. In this work, we propose a principled way to de sign per-image noise schedules for pixel diffusion, based on the images spectral properties. By deriving theoretical bounds on how efficacy of minimum and maxim um noise levels, we design "tight" noise schedules that eliminate redundant step s. During inference, we propose to conditionally sampled such noise schedules. E xperiments show that our noise schedules improve generative quality, particularl y at the low-step regime.

****

Scaling the Prior: Size-Consistent Geometric Diffusion for 3D Molecular Generati on

Wenhan Gao, Jingxiang Qu, Yi Liu

Diffusion models typically operate in fixed-dimensional metric spaces, whereas 3 D geometric molecular data vary in dimensionality because molecules differ in si ze (number of atoms). A common adaptation in diffusion models for 3D molecular g eneration is to use models that handle variable-sized inputs, such as graph neur al networks and transformers. However, these approaches ignore that molecular si ze also sets the spatial scale of atomic coordinates, causing inconsistent gener ative trajectories.

In 3D molecular diffusion, generation can be seen as forming a coarse structure first and then refining atomic positions. Larger molecules form coarse structure s earlier than smaller ones because their spatial scales are larger relative to the noise. This makes the generative process inconsistent across sizes, with tra jectories driven by molecular size rather than by a unified generative pattern. We are the first to identify and analyze this size-induced inconsistency by deco mposing denoising dynamics, showing how spatial scale shapes formation of both 3 D structure and atom types. Based on this, we propose Scaling the Prior (StP), w hich rescales the prior distribution by molecular size to normalize learning acr oss sizes, harmonize denoising trajectories, and generate high-quality molecules . The code is available at https://github.com/wenhangao21/ICML26-StP.

Predictive Prefetching for Retrieval-Augmented Generation

Wuyang Zhang, Shichao Pei

Retrieval-Augmented Generation (RAG) improves factual grounding in large languag e models but suffers from substantial latency due to synchronous retrieval. Whil e recent work explores asynchronous retrieval, existing approaches rely on heuri stic coordination between retrieval and generation and assume stable information demands during decoding that often break in complex, multi-domain settings. In this paper, we propose an advanced asynchronous retrieval framework that enables predictive prefetching aligned with evolving information needs. The framework e xplicitly predicts when retrieval should be triggered and what information shoul d be retrieved using three components, a retrieval predictor, a context monitor, and a query generator, by exploiting semantic precursors in generation dynamics that emerge several tokens before uncertainty becomes critical. Experiments on multiple benchmarks demonstrate up to 43.5% end-to-end latency reduction and 62. 4% improvement in time-to-first-token, while maintaining answer quality comparab le to synchronous RAG baselines.

PAC-Bayesian Reinforcement Learning Trains Generalizable Policies
Abdelkrim ZITOUNI, Mehdi hennequin, Juba Agoun, Ryan Horache, NADIA KABACHI, Omar Rivasplata
We derive a novel PAC-Bayesian generalization bound for reinforcement learning that explicitly accounts for Markov dependencies in the data, through the chain's mixing time. This contributes to overcoming challenges in obtaining generalization guarantees for reinforcement learning, where the sequential nature of data breaks the independence assumptions underlying classical bounds. The new bound provides non-vacuous certificates for modern off-policy algorithms such as Soft Actor-Critic. We demonstrate the practical utility of the bound through PB-SAC, a novel algorithm that optimizes the bound during training to guide exploration. Experiments across several continuous control tasks show that the proposed approach provides meaningful confidence certificates while maintaining competitive performance.

Learning Locally, Revising Globally: Global Reviser for Federated Learning with Noisy Labels
Yuxin Tian, Mouxing Yang, Yuhao Zhou, Jian Wang, Qing Ye, Tongliang Liu, Gang Niu, Jiancheng Lv
Conventional federated learning (FL) heavily depends on high-quality labels, which are often impractical in the real world, leading to the federated label-noise (F-LN) problem. Worse still, the F-LN problem is exacerbated by the heterogeneity of FL, whereas clients experience different label-noise types, ratios, and data distribution. In this study, we first observe an intriguing phenomenon that the global model of FL exhibits a slow memorization of noisy labels, suggesting its ability to maintain reliable predictions and robust representations in FL. Motivated by this, we propose a novel method termed Federated Global Reviser (FedGR), a straightforward yet effective method comprising three modules that collaboratively rectify noisy labels and regularize local training. By exploiting this inherent property, FedGR improves the label-noise robustness of FL in a self-contained manner. Extensive experiments on three widely used F-LN benchmarks demonstrate the superior performance of FedGR, consistently outperforming eight state-of-the-art baselines even in severe label-noise and data heterogeneity. Code: https://github.com/cs-yuxintian/FedGR-ICML26

ProMiSE: Protein Multi-State Evaluation Benchmark in Biological Contexts
Bonjae Ku, Seeun Kim, Yubeen Kim, Hahnbeom Park, Chaok Seok
Proteins are inherently dynamic, with biological functions often emerging from transitions between multiple conformational states. While recent breakthroughs have largely addressed the static structure prediction problem, no systematic benchmark exists to demonstrate how well current models capture functionally relevant dynamics. We introduce ProMiSE, the first benchmark that provides both a dataset and an evaluation scheme, based on native biological assemblies and integrating major conformational change mechanisms—intrinsic, ligand-induced, and protein-induced—within a single curated dataset. We conducted a comprehensive evaluation of state-of-the-art structure prediction models, including AlphaFold3 and recent generative approaches. Our findings reveal that current models exhibit a limited ability to sample intrinsic multi-states and are often insensitive to biological context in induced scenarios. Internal representation analysis suggests that training-data exposure can shift predictions toward dominant conformational states over alternative biologically relevant states, primarily at the structure module. In contrast, results from BioEmu indicate that reducing decoding-stage bias can substantially improve multi-state sampling without major changes to upstream pair representations.
****
ProtoVAR: Efficient Dataset Distillation via Prototype-Guided Visual Autoregressive Modeling
Mingyu Wang, Wei Jiang
Recent advances in generative distillation have shown strong potential in constr

ucting high quality surrogate datasets within a fraction of the time required by optimization-based approaches. However, most existing generative solutions rely on diffusion models, which suffer from two limitations. (i) Indirect matching objectives. Their sequential denoising process makes it difficult to directly match representative prototypes. (ii) Target-agnostic generation. The generation process is often decoupled from the target task, causing the synthesized samples to drift from the desired distribution. Building on this insight, We propose ProtoVAR, a prototype-guided visual autoregressive framework. Instead of relying on latent space, ProtoVAR uses the coarse-to-fine next-scale prediction of Visual AutoRegressive (VAR) modeling to maintain semantic consistency during generation. By injecting multi-scale class prototypes, ProtoVAR enforces clear representativeness constraints while preserving diversity. A pool-based selector further distills the prototype-guided outputs into a compact, task-aligned surrogate dataset. Extensive experiments show that ProtoVAR achieves state-of-the-art performance with comparable or lower computational cost than diffusion-based distillation.

Learning to Think in Physics: Breaking Shortcut Learning in Scientific Diffusion via Representation Alignment
Haozhe Jia, Pengyu Yin, Wenshuo Chen, Shaofeng Liang, Lei Wang, Bowen Tian, Xiucheng Wang, Jia Nanqian, Yutao Yue
Physics-informed diffusion models typically enforce PDE constraints only on final outputs, leaving intermediate representations unconstrained and prone to shortcut learning under shifted boundary conditions. We introduce **REPA-P**, a teacher-free, architecture-agnostic framework that aligns intermediate features with physical states using first-principles residuals. REPA-P attaches lightweight $1{\times}1$ projection heads to selected layers, decodes hidden activations into physical quantities, and applies PDE residual losses during training. These heads are discarded at inference, introducing **zero overhead**. Across four PDE tasks, including Darcy flow, topology optimization, electrostatic potential, and turbulent channel flow, REPA-P accelerates convergence by up to $2{\times}$, reduces physics residuals by up to 66.4%, and improves out-of-distribution robustness by up to 49.3%, with consistent gains on both U-Net and Diffusion Transformer backbones. Ablations show that supervising a small set of intermediate layers captures most benefits and complements output-level physics losses. Code is available at https://github.com/Hxxxz0/REPA-P.
****
A Close Look at Negative Label Guided Out-of-distribution Detection in Pre-trained Vision-Language Models
Bo Peng, Jie Lu, Zhen Fang, Guangquan Zhang
Advances in pre-trained vision-language models have enabled zero-shot out-of-distribution (OOD) detection using only in-distribution (ID) labels. Recent methods in this direction expand the label space with negative labels to enhance the discrimination between ID and OOD inputs. Despite their promising progress, there remains a limited understanding of their empirical effectiveness in open-world scenarios, where negative labels can arbitrarily diverge from real OOD ones. This paper bridges this research gap with the helm of a novel energy-based framework, where the energy function is built upon the margin between the similarity of an input to ID labels and that to negative labels. Guided by this framework, we prove that the inherent tolerance of such methods to the sampling bias essentially stems from estimating the worst-case energy function over a KL-constrained set of potential distributions centered on the negative label distribution. Furthermore, our theoretical analysis reveals that existing methods suffer from over-pessimism and consequently high sensitivity to outliers. Provably, we can alleviate these problems by leveraging Rényi divergence to refine potential distributions. Extensive experiments empirically manifest that our method establishes a new state-of-the-art across a variety of OOD detection settings.

Target-Aware Bandit Allocation for Scalable Surrogate Optimization in Chemical Space

Mohammad Haddadnia, Yuvan Chali, Abhilash Jayaraj, Constance Kraay, Joana Reis, Felix Strieth-Kalthoff, Haribabu Arthanari
Identifying high-utility candidates from massive discrete spaces under expensive evaluations is a recurring challenge across the sciences, with structure-based drug discovery as a prominent example. While surrogate-based optimization can increase sample efficiency by reducing the number of expensive evaluations, modern molecular libraries have reached billions to trillions of compounds, making full-library surrogate inference itself a major computational bottleneck. We introduce BOBA, a bandit-guided surrogate optimization framework that eliminates full-library inference by adaptively allocating computation across partitions of the action space. By treating partitions as arms in a multi-armed bandit, BOBA concentrates inference and evaluations on empirically promising partitions while maintaining principled exploration. Experiments on real-world synthesis-on-demand libraries demonstrate that optimism-under-uncertainty bandits, combined with meaningful action space partitioning, are essential for effective allocation of inference and evaluations. Our findings reveal a tunable tradeoff between screening performance and surrogate inference cost, which supports practical optimization over current libraries, and establishes a viable route to ultra-large library virtual screening.

Improved Algorithms for Nash Welfare in Linear Bandits
Dhruv Sarkar, Nishant Pandey, Sayak Ray Chowdhury
Nash regret has recently emerged as a principled fairness-aware performance metric for stochastic multi-armed bandits, motivated by the Nash Social Welfare objective. Although this notion has been extended to linear bandits, existing results suffer from suboptimality in ambient dimension d, stemming from proof techniques that rely on restrictive concentration inequalities. In this work, we resolve this open problem by introducing new analytical tools that yield an order-optimal Nash regret bound in linear bandits. Beyond Nash regret, we initiate the study of p-means regret in linear bandits, a unifying framework that interpolates between fairness and utility objectives and strictly generalizes Nash regret. We propose a generic algorithmic framework, FairLinBandit, that works as a meta-algorithm on top of any linear bandit strategy. We instantiate this framework using two bandit algorithms: Phased Elimination and Upper Confidence Bound, and prove that both achieve sublinear p-means regret for the entire range of p. Extensive experiments on linear bandit instances generated from real-world datasets demonstrate that our methods consistently outperform the existing state-of-the-art baseline.

What Preferences Can—and Cannot—Predict in Multi-Agent Online Learning
Omar Abbadi, Rida Laraki, Panayotis Mertikopoulos
We examine the interplay between ordinal, preference-based solution concepts in games and the outcomes of payoff-driven learning dynamics, asking to what extent the combinatorial data of a game—its *preference graph*—can predict the long-run behavior of no-regret dynamics such as *follow-the-regularized-leader* (FTRL). In one direction, we show that the skeleton of every *dynamically stable* set (i.e., the set of pure profiles it contains) must also be *preferentially stable*, that is, it must be closed under profitable deviations.
We then ask the converse question: when are preferences sufficient to describe the long-run behavior of the players' learning dynamics?
We begin by showing that preferences are indeed enough to fully characterize asymptotic stability in the case of *subgames*—i.e., subsets of pure profiles obtained by restricting players' action sets. Beyond this case however, the equivalence between dynamic and preferential stability breaks down: in particular, we construct a three-player game with a preferentially stable set whose span is dynamically *unstable*, showing that preferences are *not sufficient* to describe dynamically stable behavior in general. To restore stability, we introduce the notion of *leaklessness*, a measure of aggregate payoff drift away from a set of pure profiles, and we use it to identify a payoff-based condition guaranteeing that the span of a set of pure profiles is stable and attracting.

DeepHA: Scaling Action Chains Elicits Deep Hierarchical Agents
Zihao Wang, Muyao Li, Kaichen He, Haowei Lin, Xiaojian Ma, Anji Liu, Yitao Liang
Prevailing autonomous agents are often constrained by a single, predefined actio
n space, which limits their generalization capabilities across diverse tasks and
 can introduce compounding errors through decoupled policy execution. To address
 these limitations, we introduce the Deep Hierarchical Agent (DeepHA), a unified
 architecture that operates across a mixture of heterogeneous action spaces, fle
xibly generating actions ranging from high-level semantic skills to low-level mo
tor controls. We further propose a Chain-of-Action (CoA) reasoning framework, wh
ich enables the agent to use higher-level abstract actions as structured `though
ts' to guide the generation of more granular, subsequent actions. To manage the
computational demands of this deep reasoning in long-horizon tasks, we develop a
 memory-efficient mechanism that dynamically compresses historical context and l
everages Key-Value (KV) caching, reducing context length by approximately 75% wi
thout sacrificing performance. We conduct extensive evaluations on a new, large-
scale benchmark of over 800 diverse Minecraft tasks. Results show that DHA signi
ficantly outperforms prior methods, establishing a new state-of-the-art and demo
nstrating superior generalization, particularly in complex, multi-step planning
tasks. Our work presents a novel, unified framework for building more capable an
d efficient autonomous agents.

Diversity-aware Weight Perturbation Promotes Robust Adaptation
Zibo Chen, Ruxin Li, Zilu Wang
Compute-In-Memory (CIM) accelerators are promising for energy-efficient edge inf
erence, yet they faces fundamental challenges when deploying Deep Neural Network
s (DNNs), as hardware-induced weight perturbations from intrinsic noise and devi
ce drift degrade accuracy and impede reliable inference. To tackle this challeng
e, we propose Diversity-aware Weight
Perturbation (DWP), an immune-system-inspired training method that
emulates affinity-based selection by exploiting sample-level
prediction disagreement under diverse noise realizations to guide
adaptive sample weighting, building robustness to weight perturbation. Experimen
ts show that DWP-trained models consistently yield superior robustness, achievin
g over 15\% accuracy improvements compared to standard-trained models under seve
re weight perturbations (mismatch level up to 70\%) and maintaining
inference accuracy at 90\% over a simulated one-year CIM operation
with only 2\%–4\% variation in accuracy. Moreover, under matched model and infer
ence configurations, deployment on low-precision CIM hardware reduces inference
energy by 38\% compared to a GPU baseline. These results demonstrate that DWP en
ables robust and energy-efficient neural network deployment on resource-constrai
ned edge devices with inherent hardware uncertainties.
****
Skill Neologisms: Towards Skill-based Continual Learning
Antonin Berthon, Nicolás Astorga, Mihaela van der Schaar
Modern LLMs show mastery over an ever-growing range of skills, as well as the ab
ility to compose them flexibly. However, extending model capabilities to new ski
lls in a scalable manner is an open problem: fine-tuning and parameter-efficient
 variants risk catastrophic forgetting, while context-based approaches have limi
ted expressiveness and are constrained by the model's effective context.
We explore *skill neologisms*--soft tokens integrated in the model's vocabulary
and optimized to improve capabilities over a specific skill--as a way to selecti
vely acquire new skills without weight updates. We first observe that pre-traine
d LLMs already exhibit tokens associated with procedural knowledge. We then show
 on a controlled synthetic task that skill neologisms can be learned to improve
model capabilities on specific skills while being composable with out-of-distrib
ution skills, and that independently trained skill neologisms can be composed ze
ro-shot. Finally, we validate zero-shot composition of independently learned ski
ll neologisms on the more realistic natural language setting of the Skill-Mix be
nchmark. These results suggest that skill neologisms may provide a scalable path

towards skill-based continual learning.

Large Language Model Teaches Visual Students: Cross-Modality Transfer of Fine-Grained Conceptual Knowledge
Thomas Liang, Zhuoran Yu, Yong Jae Lee
Large Language Models (LLMs) possess broad conceptual knowledge acquired through large-scale text pretraining, yet their potential to supervise models in other modalities remains underexplored. In this work, we propose LaViD—Language-to-Visual Knowledge Distillation—a simple and effective framework for transferring high-level semantic knowledge from a language-only teacher to a vision-only student model. Instead of relying on paired multimodal data, LaViD elicits conceptual signals from an LLM by prompting it to generate multiple-choice questions (MCQs) that probe semantic distinctions between visual classes. Each class is mapped to a soft label distribution over these MCQs, forming a rich conceptual signature that guides the student through an auxiliary distillation loss. Notably, despite using a language-only teacher without access to image data, LaViD consistently outperforms recent methods like MaKD that distill from vision-language models across multiple fine-grained benchmarks. It also achieves competitive or superior performance compared to state-of-the-art visual distillation methods such as DKD and MLKD, with further gains when combined with logit standardization. On the Waterbirds dataset, LaViD substantially improves worst-group accuracy, demonstrating enhanced robustness to spurious correlations with distillation. Code is available at \url{https://github.com/lliangthomas/lavid}.
****
Olaf-World: Orienting Latent Actions for Video World Modeling
Yuxin Jiang, Yuchao Gu, Ivor Tsang, Mike Zheng Shou
Scaling action-controllable world models is limited by the scarcity of action labels. While latent action learning promises to extract control interfaces from unlabeled video, learned latents often fail to transfer across contexts: they entangle scene-specific cues and lack a shared coordinate system. This occurs because standard objectives operate only *within* each clip, providing no mechanism to align action semantics across contexts. Our key insight is that although actions are unobserved, their *semantic effects* are observable and can serve as a shared reference. We introduce **SeqΔ-REPA**, a sequence-level control-effect alignment objective that anchors integrated latent action to temporal feature differences from a frozen, self-supervised video encoder. Building on this, we present **Olaf-World**, a pipeline that pretrains action-conditioned video world models from large-scale passive video. Extensive experiments demonstrate that our method learns a more structured latent action space, leading to stronger zero-shot action transfer and more data-efficient adaptation to new control interfaces than state-of-the-art baselines.
****
Visual Persuasion: What Influences Decisions of Vision-Language Models?
Manuel Cherep, Pranav M R, Patricia Maes, Nikhil Singh
The web is littered with images, once created for human consumption and now increasingly interpreted by agents using vision-language models (VLMs). These agents make visual decisions at scale, deciding what to click, recommend, or buy. Yet, we know little about the structure of their visual preferences. We introduce a framework for studying this by placing VLMs in controlled image-based choice tasks and systematically perturbing their inputs. Our key idea is to treat the agent's decision function as a latent visual utility that can be inferred through revealed preference: choices between systematically edited images. Starting from common images, such as product photos, we propose methods for visual prompt optimization, adapting text optimization methods to iteratively propose and apply visually plausible modifications using an image generation model (such as in composition, lighting, or background). We then evaluate which edits increase selection probability. Through large-scale experiments on frontier VLMs, we demonstrate that optimized edits significantly shift choice probabilities in head-to-head comparisons. We develop an automatic interpretability pipeline to explain these preferences, identifying consistent visual themes that drive selection. We argue th

at this approach offers a practical and efficient way to surface visual vulnerab
ilities, safety concerns that might otherwise be discovered implicitly in the wi
ld, supporting more proactive auditing and governance of image-based AI agents.

Adaptively Robust Resettable Streaming
Edith Cohen, Elena Gribelyuk, Jelani Nelson, Uri Stemmer
We study algorithms in the resettable streaming model, where the value of each k
ey can either be increased or reset to zero. This model is suitable for applicat
ions such as active resource monitoring with support for deletions and machine u
nlearning. We show that all existing sketches for this model are vulnerable to a
daptive adversarial attacks that apply even when the sketch size is polynomial i
n the length of the stream. To overcome these vulnerabilities, we present the fi
rst adaptively robust sketches for resettable streams that require only polyloga
rithmic space complexity in the stream length. Our framework supports (sub) line
ar statistics including L_p moments for $p\in[0,1]$ (in particular, Cardinalit
y and Sum) and Bernstein statistics. We bypass strong impossibility results kno
wn for linear and composable sketches by designing dedicated single-stream sketc
hes robustified via Differential Privacy. Unlike standard robustification techni
ques, which provide limited benefits in this setting and still require polynomia
l space in the stream length, we leverage the Binary Tree Mechanism for continua
l observation to protect the sketch's internal randomness. This enables accurate
 prefix-max error guarantees with polylogarithmic space.

A Geometric Analysis of Small-sized Language Model Hallucinations
Emanuele Ricco, Elia Onofri, Lorenzo Cima, Stefano Cresci, Roberto Di Pietro
Hallucinations—plausible but factually incorrect responses—pose a major challeng
e to the reliability of Large Language Models (LLMs), especially in multi-step o
r agentic settings.
Existing work largely frames hallucinations as a consequence of missing knowledg
e; we show instead that, even when the relevant factual knowledge is present, mo
dels still produce hallucinated answers, pointing to retrieval instability rathe
r than knowledge gaps.
Building on this observation, we introduce APORIA (*Aggregate Prompt-wise Observ
ation Retrieving Instability via Asymmetry*—the Socratic state of "puzzlement-in
-contradiction" that hallucinations embody), a geometric framework that studies
repeated responses to the same prompt in sentence-embedding space. Our central h
ypothesis is that genuine responses cluster more tightly than hallucinated ones;
 we empirically validate this and show that, after Fisher projection, the two re
sponse classes become consistently separable.
We leverage this asymmetry in geometry via APORIA-LP, an efficient label-propaga
tion method that classifies large collections of responses from as few as 30–50
annotations, achieving F1 scores above 90% across ten small-sized LLMs.
To support further research, we release SOCRATES-300K, a fully labelled dataset
of 300,000 responses, together with the code for both dataset generation and res
ult reproduction.
Our key finding—framing hallucinations from a geometric perspective in the embed
ding space—complements traditional knowledge-centric and single-response evaluat
ion paradigms, paving the way for further research.

SpecExit: Accelerating Large Reasoning Model via Speculative Exit
Rubing Yang, Huajun Bai, Song Liu, Guanghua Yu, Runzhi Fan, Yanbin Dang, Zhang J
iejing, Kai Liu, Jianchen Zhu, Peng Chen
Despite their strong performance on reasoning tasks, Large reasoning models (LRM
s) often suffer from overthinking, producing unnecessarily long outputs and incu
rring high end-to-end latency, a significant limitation to their real-world depl
oyment.
To address overthinking, early-exit mechanisms have been proposed to terminate r
easoning before typical completion, showing that this approach can effectively s
horten generation length with minimal impact on accuracy. However, their relianc
e on probing mechanisms introduces a detection overhead that limits their end-to

-end latency gains and compromises their generalizability across diverse problem
s.
Inspired by the use of hidden states in speculative decoding, we propose **SpecE
xit**, a novel framework that predicts both future tokens and an early-exit sign
al directly from a lightweight draft model without probing overhead.
Our method offers significant improvements, achieving up to 66\% generation leng
th reduction and 2.5$\times$ end-to-end speedup compared with the speculative de
coding baseline, without compromising accuracy.
Our method leverages the inherent signals from hidden states to provide effectiv
e early-exit signals, suggesting broader use of hidden states for efficient reas
oning.
Our code is available at: https://anonymous.4open.science/r/SpecExit-B802.

Domain Restriction via SAE Multi-Layer Transitions
Elias Shaheen, Avi Mendelson
The general-purpose nature of Large Language Models (LLMs) presents a significan
t challenge for domain-specific applications, often leading to out-of-domain (OO
D) interactions that undermine the provider's intent. Existing methods for detec
ting such scenarios treat the LLM as an uninterpretable black box and overlook t
he internal processing of inputs. In this work we show that layer transitions pr
ovide a promising avenue for extracting domain-specific signature. Specifically,
 we present several lightweight ways of learning on internal dynamics encoded us
ing a sparse autoencoder (SAE) that exhibit great capability in distinguishing O
OD texts. Building on top of SAEs representation transitions enables us to bette
r interpret the LLM internal evolution of input processing and shed light on its
 decisions. We provide a comprehensive analysis of the method and benchmark it w
ith the gemma-2 2B and 9B models. Our results emphasize the efficacy of the inte
rnal process in capturing fine-grained input-related details.
****

GEMQ: Global Expert-Level Mixed-Precision Quantization for MoE LLMs
Jianing Deng, Song Wang, Dongwei Wang, Zijie Liu, Tianlong Chen, Huanrui Yang, J
ingtong Hu
Mixture-of-Experts Large Language Models (MoE-LLMs) achieve strong performance b
ut incur substantial memory overhead due to massive expert parameters.
Mixed-precision quantization mitigates this cost by allocating expert-wise bit-w
idths based on their importance, approaching the accuracy-memory Pareto frontier
 and enabling extreme low-bit quantization.
However, existing methods rely on layer-wise importance estimation and overlook
router shifts induced by quantization, resulting in suboptimal allocation and ro
uting.
In this work, we propose Global Expert-level Mixed-precision Quantization (GEMQ)
 to overcome these limitations via (1) a global linear-programming formulation t
hat captures model-wide expert importance based on quantization error analysis,
and (2) efficient router fine-tuning to adapt routing to quantized experts. Thes
e components are integrated into a progressive quantization framework that itera
tively refines importance estimation and allocation.
Experiments demonstrate that GEMQ significantly reduces memory and accelerates i
nference with minimal accuracy degradation.

UI2Code^N: UI-to-Code Generation as Interactive Visual Optimization
Zhen Yang, Wenyi Hong, Mingde Xu, Xinyue Fan, Weihan Wang, Jiale Cheng, Xiaotao
Gu, Jie Tang
UI-to-code aims to translate UI screenshots into executable front-end code.
Despite progress with vision-language models (VLMs), most existing methods formu
late UI-to-code as a single-pass generation, which mismatches real-world UI deve
lopment that is inherently iterative and feedback-driven.
We reformulate UI-to-code as an interactive visual optimization problem, where c
ode generation is embedded in a closed-loop process of execution, visual inspect
ion, and iterative refinement driven by rendered visual feedback.
To address the non-differentiability of visual objectives and the noise of absol

ute visual evaluators, we propose Relative Visual Policy Optimization (RVPO), a preference-based reinforcement learning method that optimizes relative visual rankings among rendered candidates under execution feedback.
We instantiate this paradigm in UI2Code^{N}, an open-source 9B model trained via continual pre-training, supervised fine-tuning, and reinforcement learning.
Experiments demonstrate state-of-the-art performance on UI drafting, UI polishing, and UI editing benchmarks, even outperforming larger models, with performance consistently improving through iterative visual optimization.
Our code and models are available at \url{https://github.com/zai-org/UI2Code_N}.

DREAM-R: Multimodal Speculative Reasoning with RL-Based Refined Drafting, Precise Verification, and Fully Parallel Execution
Yunhai Hu, Zining Liu, Xiangyang Yin, Tianhua Xia, BO BAO, Eric Sather, Vithursan Thangarasa, Sai Qian Zhang
Speculative reasoning has recently been proposed as a means to accelerate reasoning-intensive generation in large multimodal models, but its effectiveness is often constrained by misalignment between speculative drafts and target-verified reasoning. In this work, we introduce \textit{DREAM-R}, a framework that substantially improves the performance of speculative reasoning. At its core, DREAM-R employs \textit{Speculative Alignment Policy Optimization} (SAPO), a reinforcement-learning objective that trains draft models to generate reasoning steps that are both faithful to target trajectories and concise. We further propose a \textit{Threshold-based Verification Mechanism} (TBVM) that uses a ratio-based criterion to provide stable and interpretable acceptance of speculative steps only when positive evidence clearly dominates, thereby preventing error propagation. Building on these components, we develop a \textit{Fully Parallel Speculative Reasoning} (FPSR) framework that parallelizes draft generation, target-side reasoning, and verification across multi-step reasoning, enabling early stopping and clean fallback. Experiments on reasoning-heavy benchmarks demonstrate up to $2.49\times$ speedup while preserving target-model accuracy, yielding substantial efficiency gains without compromising reasoning quality.
****

Midtraining Bridges Pretraining and Posttraining Distributions
Emmy Liu, Graham Neubig, Chenyan Xiong
Midtraining, the practice of mixing specialized data with more general pretraining data in an intermediate training phase, has become widespread in language model development, yet there is little understanding of what makes it effective. We propose that midtraining functions as distributional bridging by providing better initialization for posttraining. We conduct controlled pretraining experiments, and find that midtraining benefits are largest for domains distant from general pretraining data, such as code and math, and scale with the proximity advantage the midtraining data provides toward the target distribution. In these domains, midtraining consistently outperforms continued pretraining on specialized data alone both in-domain and in terms of mitigating forgetting. We further conduct an investigation on the starting time and mixture weight of midtraining data, using code as a case study, and find that time of introduction and mixture weight interact strongly such that early introduction of specialized data is amenable to high mixture weights, while late introduction requires lower ones. This suggests that late introduction of specialized data outside a plasticity window cannot be compensated for by increasing data mixtures later in training. Beyond midtraining itself, this suggests that distributional transitions between any training phases may benefit from similar bridging strategies.
****

Partitioning for Intrinsic Model Inversion Resistance in Collaborative Inference
Rongke Liu, Youwen Zhu, Lei Zhou, Zhang Xianglong, Dong Wang
In collaborative inference (CI), transmitting intermediate representations Z from edge devices enables model inversion attacks (MIA) that reconstruct the original inputs X, while existing defenses mainly perturb shallow-layer Z at the cost of utility. We instead ask: *where should an edge–cloud model be partition

ed to obtain intrinsic resistance to MIA?* We challenge the intuition that depth is the driver of MIA resistance, and show that depth is sufficient only insofar as it enables a representational transition; this transition is necessary for *intrinsic* resistance and is marked by an abrupt rise in the lower bound of $H(X|Z)$. Correspondingly, the decisive variance term in the entropy bound shifts from a global variance to the intra-class mean-squared radius R^2_c rather than dimensionality alone, yielding an R^2_c-based criterion to locate the transition zone, or identify it post hoc from MIA outcomes, which we term the *Golden Partition Zone* (GPZ). We further explain how R^2_c evolves during training and show that it can be controlled through the label distribution; we refer to this controllable dynamic behavior as the *Neural Vortex*, an analysis-backed explanatory concept. Across four representative deep vision models, partitioning at the GPZ yields over 4× higher reconstruction MSE compared to shallow splits; under entropy and inversion-model enhancements, decision-level representations provide 66\% stronger resistance than feature-level ones, and we further observe that data type affects both the transition boundary and reconstruction.

Biologically plausible heavy-tailed connectivity enhances generalizations on cognitive tasks in recurrent neural networks

Zhe Jiao, Xiaodong He, Shanglin Zhou

While heavy-tailed synaptic weight distributions are pervasive in biological neural networks, their computational role---particularly in relation to generalization---remains poorly understood. To address this, we develop a novel optimal-transport-based optimization algorithm that incorporates key biological constraints, including Dale’s principle and heavy-tailed synaptic statistics, to train recurrent neural networks (RNNs) on a wide range of cognitive tasks. We show that these biologically constrained, heavy-tailed RNNs exhibit substantially improved generalization, which we further characterize within a PAC-Bayes framework. Our theoretical analysis and numerical experiments reveal two complementary mechanisms underlying this generalization enhancement. Topologically, heavy-tailed connectivity induces an effectively low-rank structure, which in turn yields low-dimensional neural dynamics. Geometrically, heavy-tailed connectivity intrinsically shapes task variable representations to lie near a linear manifold, thereby improving generalization for a linear readout strategy. Together, these results identify heavy-tailed connectivity as a biologically grounded intrinsic mechanism that promotes low-rank structure and favorable representational geometry, leading to improved generalization in flexible cognitive tasks.

Self-Prophetic Decoding to Unlock Visual Search in LVLMs

Zhendong He, Qiyuan Dai, Guanbin Li, Liang Lin, Sibei Yang

Large Vision-Language Models (LVLMs) are rapidly evolving toward true multimodal reasoning, with visual search representing a concrete instantiation of the thinking-with-images paradigm. However, LVLM visual search faces two key challenges: incompatibility among intrinsic capabilities after post-training, and interference in long multi-step reasoning contexts. To address these, we identify two novel insights. First, self-regulation between pre- and post-training LVLMs leverages the intrinsic single-step capabilities of the pre-training model to mitigate capability deterioration and long-context interference. Second, probability-based prophetic sampling, replacing naive prompting, provides a probabilistic interface where the pre-training model acts as a prophet and the post-training model selectively accepts prophetic tokens under its output distribution, preserving coherent multi-step reasoning. Building on these insights, we introduce SeProD, a self-prophetic decoding framework that leverages intrinsic single-step capabilities to enable coherent multi-step reasoning in a training-free, plug-and-play manner. Experiments show that SeProD consistently improves multiple visual-search LVLMs across all 12 splits of 4 visual search benchmarks, as well as across general VQA benchmarks, without added computational overhead, thanks to its parallel prophetic acceptance mechanism.

The Heterogeneous Safety Impacts of Benign Multilingual Fine-Tuning

Will Hawkins, Kai Rawal, Jonathan Rystrøm, Stratis Tsirtsis, Zihao Fu, Greta Warren, Ryan Brown, Eoin D. Delaney, Sandra Wachter, Brent Mittelstadt, Chris Russell

Fine-tuning a large language model is a ubiquitous method for enhancing its capability on a specific downstream task. However, prior work has shown that this increase in capability comes with a cost: it can increase a model's tendency to respond to unsafe adversarial prompts, even when fine-tuning with non-adversarial data. We present the first comprehensive empirical study of this phenomenon in multilingual settings by fine-tuning Llama-3.2, Qwen3, and Gemma-3 models using benign data translated across nine languages. We find that safety outcomes are highly sensitive to both the choice of fine-tuning language and the evaluation language, with adversarial compliance rates increasing four-fold in some settings. Multilingual safety drift is decoupled from general capability metrics, and occurs heterogeneously across languages and models. Fine-tuning in non-English languages often induces smaller internal representational drifts than English, but these shifts lead models to default to either exaggerated compliance or refusal. As such, assessing fine-tuning impacts solely in English provides inadequate assurance for deployment. To facilitate further research into these cross-lingual safety blind spots, we release the Multilingual-Benign-Tune dataset and the SORRY-Bench-Multilingual evaluation suite.

Towards Diverse Scientific Hypothesis Search with Large Language Models

Haorui Wang, Parshin Shojaee, Kazem Meidani, Kunyang Sun, José Miguel Hernández-Lobato, Teresa Head-Gordon, Jiajun He, Chandan K. Reddy, Chao Zhang, Yuanqi Du

Large language models (LLMs) are on the rise for accelerating scientific discovery, most recently in advanced tasks such as generating valid scientific hypotheses. Yet in many discovery settings, the goal is not to identify a single best hypothesis since validation can be noisy and expensive, and scientists benefit from a set of high-quality alternative hypotheses that hedge against downstream uncertainty for the best solutions. Nevertheless, commonly used evolutionary search recipes tend to prioritize optimization over exploration in hypothesis generation, and the resulting selection pressure during the search process leads to diversity collapse. Motivated by these limitations, we formulate hypothesis search as a sampling problem, where the objective is to efficiently produce diverse, high-quality hypotheses under a fixed validation budget. Building on this perspective, we propose EvoDiverse, an evolutionary framework inspired by the classical parallel tempering algorithm that searches hypotheses at multiple temperature levels and enables principled information exchange across temperatures to improve exploration without disrupting convergence. Across domains including molecular discovery, equation discovery, and algorithm discovery, our approach consistently improves both hypothesis quality and diversity under the same validation budget, and produces candidates that remain robust under more expensive downstream computational validations.

MIMO-LP: A Multi-Input Multi-Output Framework for Subgraph-based Link Prediction

Yixin Song, Guangchi Liu, Xiangyu Xu, Shaofeng Li, Zhen Ling, Yiwei Wang, Yujun Cai

Link prediction (LP) is a fundamental problem in graph learning and can be broadly categorized into node-based and subgraph-based approaches. While subgraph-based LP methods often achieve superior predictive performance by exploiting localized structural information, they suffer from efficiency bottlenecks due to the high computational cost of per-query subgraph message-passing during both training and inference. To address this challenge, we propose MIMO-LP, a Multi-Input Multi-Output (MIMO) framework that accelerates subgraph-based LP. Given a batch of query node pairs and their corresponding subgraphs extracted from a shared full graph, MIMO-LP superposes their message-passing processes into a shared latent space while ensuring minimal interference among them. This design enables MIMO-LP to multiplex multiple queries within a single forward pass during both training and inference, substantially reducing redundant message-passing computations in overlapping subgraph regions. Extensive experiments demonstrate that MIMO-LP a

chieves a 14x-44x speedup over existing one-to-one subgraph-based methods, while maintaining comparable predictive performance.
****
Geodesic Calculus on Implicitly Defined Latent Manifolds
Florine Hartwig, Josua Sassen, Juliane Braunsmann, Martin Rumpf, Benedikt Wirth
Latent manifolds of autoencoders provide low-dimensional representations of data, which can be studied from a geometric perspective.
We propose to describe these latent manifolds as implicit submanifolds of some ambient latent space.
Based on this, we develop tools for a discrete Riemannian calculus approximating classical geometric operators.
These tools are robust against inaccuracies of the implicit representation often occurring in practical examples.
To obtain a suitable implicit representation, we propose to learn an approximate projection onto the latent manifold by minimizing a denoising objective. This approach is independent of the underlying autoencoder and supports the use of different Riemannian geometries on the latent manifolds. The framework in particular enables the computation of geodesic paths connecting given end points and shooting geodesics via the Riemannian exponential maps on latent manifolds. We evaluate our approach on various autoencoders trained on synthetic and real data.
****
UAV^2: A Unified and Adaptive Scheduling Framework for UAV Autopilot System with Reinforcement Learning
Zeying Li, shuai zhao, Chaowen Wu, Boyang Li, Kai Huang
Unmanned aerial vehicle (UAV) autopilot systems typically comprise navigation and flight-control modules, and their effective scheduling is critical to achieving high flight performance.
However, most existing UAV platforms adopt a split architecture in which navigation and flight control are deployed on separate hardware devices. This separation restricts system-wide observability and prevents holistic scheduling and optimization across the entire autopilot pipeline.
Moreover, autonomous flight performance emerges from implicit, cross-coupled, and accumulated interactions among multiple factors, rendering traditional model-based or heuristic scheduling approaches ineffective.
To address these challenges, we propose UAV^2, a unified and adaptive scheduling framework for UAV autopilot systems with reinforcement learning, targeting flight performance optimization.
UAV^2 integrates navigation and flight control onto a single onboard computing platform and operating system, formulates the scheduling problem as a partially observable Markov decision process, and learns scheduling policies from runtime execution feedback.
The proposed approach is trained and evaluated in a hardware-in-the-loop simulation environment. Experimental results demonstrate that the learned scheduling policy consistently outperforms fixed-rate scheduling strategies in terms of flight robustness and tracking performance.

Deliberate Evolution: Agentic Reasoning for Sample-Efficient Symbolic Regression with LLMs
Xinyu Pang, Zhanke Zhou, Xuan Li, Fangrui Lv, Shanshan Wei, Sen Cui, Bo Han, Changshui Zhang
Symbolic regression (SR) discovers compact mathematical expressions from data, yet recent LLM-based evolutionary methods remain sample-inefficient because they rely mainly on scalar feedback such as MSE. We identify a core limitation: existing methods conflate candidate proposal with search guidance, requiring the LLM to infer how to evolve an expression, diagnose its errors, and reuse past experience from a single score. To address this, we propose Deliberate Evolution (DE), an agentic framework that decouples symbolic generation from search control. DE guides LLM proposals with adaptive operators for search direction, analytical tools for structural diagnosis, and reflective memory for trajectory-level experience. Experiments on LLM-SRBench show that DE consistently outperforms represent

ative LLM-based SR baselines across diverse scientific domains while using only 40% of the standard sample budget. Code is available at https://github.com/Xinyu-Pang/Deliberate-Evolution.

Thinking in Latent Space: Progressive Multimodal Simplification for Visual Reasoning

Yuesen Tang, Yiming Yang, Tengfei Bao, Yu Tong

Recent Multimodal Large Language Models (MLLMs) have advanced cross-modal reasoning by extending Chain-of-Thought (CoT) prompting to visual tasks. However, existing methods still rely heavily on explicit textual reasoning steps, leading to information loss, unstable perception–reasoning interaction, and high computational cost. Inspired by human cognition, we argue that effective visual reasoning emerges from a dynamic interplay between perception and latent thought, rather than a purely linear verbalization process.

Motivated by this insight, we propose Latent-Driven Progressive Visual Reasoning (LDPVR), a framework that formulates multimodal reasoning as a Markov Chain of Recursive State Simplification, where explicit textual states are progressively refined under the guidance of latent transitions. Central to LDPVR is Interleaved Latent Grounding, which leverages latent semantic intent to actively retrieve fine-grained visual evidence and drive robust state evolution, enabling the model to iteratively reduce uncertainty before committing to simplified textual states.

To optimize this process, we introduce a three-stage curriculum combining supervised fine-tuning, latent-text distillation, and reinforcement learning via Group Relative Policy Optimization (GRPO). Experiments on six multimodal reasoning benchmarks demonstrate that LDPVR improves reasoning accuracy while maintaining low inference latency.

RAD: Retrieval High-quality Demonstrations to Enhance Decision-making

Lu Guo, Yixiang Shan, Zhengbang Zhu, Qifan Liang, Lichang Song, Ting Long, Weinan Zhang, Yi Chang

Offline reinforcement learning (RL) learns policies from fixed datasets, thereby avoiding costly or unsafe environment interactions. However, its reliance on finite static datasets inherently restricts the ability to generalize beyond the training distribution.

Prior solutions based on synthetic data augmentation often fail to generalize to unseen scenarios in the (augmented) dataset.

To address these challenges, we propose Retrieval High-quAlity Demonstrations (RAD) for decision-making, which innovatively introduces a retrieval mechanism into offline RL. Specifically, RAD retrieves high-return and reachable states from the offline dataset as target states, and leverages a generative model to generate sub-trajectories conditioned on these targets for planning. Since the targets are high-return states, once the agent reaches such a target, it can continue to obtain high returns by following the associated high-return actions, thereby improving policy generalization.

Extensive experiments confirm that RAD achieves competitive or superior performance compared to baselines across diverse benchmarks, validating its effectiveness. Our code is available at https://github.com/LeahGL/RAD.

Learning Query-Aware Budget-Tier Routing for Runtime Agent Memory

Haozhen Zhang, Haodong Yue, Tao Feng, Quanyu Long, Jianzhu Bao, Bowen Jin, Weizhi Zhang, Xiao Li, Jiaxuan You, Chengwei Qin, Wenya Wang

Memory is increasingly central to Large Language Model (LLM) agents operating beyond a single context window, yet most existing systems rely on offline, query-agnostic memory construction that can be inefficient and may discard query-critical information. Although runtime memory utilization is a natural alternative, prior work often incurs substantial overhead and offers limited explicit control over the performance-cost trade-off. In this work, we present **BudgetMem**, a runtime agent memory framework for explicit, query-aware performance–cost control. BudgetMem structures memory processing as a set of memory modules, each offered

in three budget tiers (i.e., Low/Mid/High). A lightweight router performs budget-tier routing across modules to balance task performance and memory construction cost, which is implemented as a compact neural policy trained with reinforcement learning. Using BudgetMem as a unified testbed, we study three complementary strategies for realizing budget tiers: implementation (method complexity), reasoning (inference behavior), and capacity (module model size). Across LoCoMo, LongMemEval, and HotpotQA, BudgetMem surpasses strong baselines when performance is prioritized (i.e., high-budget setting), and delivers better accuracy–cost frontiers under tighter budgets. Moreover, our analysis disentangles the strengths and weaknesses of different tiering strategies, clarifying when each axis delivers the most favorable trade-offs under varying budget regimes. Code is available at https://github.com/ViktorAxelsen/BudgetMem

Regret Minimization With a Crowd of Awakening Experts

Anna Lunghi, Gianmarco Genalti, Alberto Marchesi, Matteo Castiglioni

We study the Awakening Crowd of Experts (ACE) problem, an online learning problem where the set of experts available to the learner grows at each round. ACE is a special case of the well-known sleeping experts problem (Kleinberg et al., 2010), where the number of experts is huge $(K=T)$. Existing results on sleeping experts preclude any learner from achieving a sublinear regret when the number of available experts is linear in T. Inspired by real-world applications, such as Q\&A platforms and social proof marketing, we thus focus on the awakening version of the sleeping experts problem, where a new expert arrives at every round and never leaves. We show that in the stochastic version of ACE, it is possible to obtain regret $\tilde{\mathcal{O}}(T^{2/3})$ using an unusual pessimism in the face of the uncertainty principle. Moreover, we characterize the dependence of the regret on the stability of an optimal strategy. For both results, we present matching lower bounds. Surprisingly, the adversarial version of ACE is sensibly harder. In particular, we provide a lower bound precluding sublinear α-regret when the competitive ratio is constant. We provide an algorithm to face this crucial trade-off between competitive ratio and regret, and bound its α-regret, almost matching the aforementioned lower bound. As a corollary, we get a $\tilde{\mathcal{O}}(\log(\log(T))$ competitive ratio when an optimal strategy enjoys a reward linear in T.

Beyond Explicit Edges: Robust Reasoning over Noisy and Sparse Knowledge Graphs

Hang Gao, Dimitris N. Metaxas

GraphRAG is increasingly adopted for converting unstructured corpora into graph structures to enable multi-hop reasoning. However, standard graph algorithms rely heavily on static connectivity and explicit edges, often failing in real-world scenarios where Knowledge Graphs (KGs) are noisy, sparse, or incomplete. To address this limitation, we introduce INSES (Intelligent Navigation and Similarity Enhanced Search), a dynamic framework designed to reason beyond explicit edges. INSES couples LLM-guided navigation, which prunes noise and steers exploration, with embedding-based similarity expansion to recover hidden links and bridge semantic gaps. Recognizing the computational cost of graph reasoning, we complement INSES with a lightweight router that delegates simple queries to Naïve RAG and escalates complex cases to INSES, balancing efficiency with reasoning depth. Experimental results show that INSES performs favorably compared to established RAG and GraphRAG baselines on multiple benchmarks. In particular, on the MINE benchmark, it exhibits notable robustness and adaptability across KGs constructed by varying methods. Our code and data are publicly available at https://github.com/hanggao-gh/INSES.

Emergence of Biased Consensus in Multi-Agent LLM Debates

Maya Okawa

Multi-agent LLM debates achieve strong performance on decision-making tasks as well as problem-solving benchmarks, yet their safety and fairness risks remain poorly understood. Notably, interaction can amplify the biases of single LLMs, raising concerns for real-world deployment. We identify the emergence of collective

(often biased) norms in multi-agent LLM debates and show that noise (e.g., LLM sampling temperature) is a key driver. To explain this, we propose an analytical framework drawing on physics-inspired theoretical models of social dynamics. We predict a phase transition to collective bias when conformity surpasses a critical threshold given the LLMs' initial bias and debate noise. We test the theoretical predictions through controlled experiments and observe a finite-size crossover consistent with an underlying phase transition. We further find that agent heterogeneity suppresses emergence by smoothing (rounding) this transition. Finally, we show that these insights generalize to realistic decision-making tasks, including investment decisions and LLM-as-a-judge evaluation.

ACON: Optimizing Context Compression for Long-horizon LLM Agents
Minki Kang, Wei-Ning Chen, Dongge Han, Huseyin A Inan, Lukas Wutschitz, Yanzhi Chen, Robert Sim, Saravan Rajmohan
Large language models (LLMs) are increasingly deployed as agents in dynamic real-world environments, where success depends on maintaining precise records of actions and observations.
However, the resulting unbounded context growth in long-horizon agentic tasks makes two critical bottlenecks: prohibitive inference memory costs and reasoning degradation due to irrelevant information.
Existing compression methods fail to fully address this, often relying on brittle heuristics or requiring parameter updates impractical for proprietary or large-scale LLMs.
We introduce Agent Context Optimization (ACON), a unified framework that optimally compresses both observations and history into concise, informative representations. Distinct from prior works, ACON employs an optimization in natural language space: it iteratively refines compression guidelines based on failure analysis of the agent, ensuring critical state information is preserved without model fine-tuning. To further minimize computational overhead, we distill the optimized compressor into smaller models.
Experiments on AppWorld, OfficeBench, and Multi-objective QA demonstrate that ACON reduces peak token usage by 26–54\% while improving task success over existing compression baselines. Notably, it enables smaller LMs to function effectively as long-horizon agents, achieving up to 46% performance improvement by mitigating context distraction.
Our code is available at https://github.com/microsoft/acon.

Neural-Inspired Modeling of Auditory Selection and Compensation for Audio-Visual Speech Separation
Xinmeng Xu, Haoran Xie, Xiaohui Tao, Lin Li, S. Joe Qin
Current audio-visual speech separation (AVSS) models typically rely on implicit multimodal fusion, but the absence of explicit modality alignment and reliability modeling often causes semantic misalignment and contaminates speech representations. The brain addresses this with a hierarchy: top-down auditory selection uses visual priors to maintain target-consistent acoustics, while bottom-up cross-modal compensation integrates temporally aligned articulatory cues to reconstruct and stabilize speech. Guided by this principle, we present Neuro-SCNet, an AVSS architecture that makes selection and compensation explicit and reliability-aware. The Auditory Selection Mechanism applies top-down, visually guided gain along the audio pathway to isolate target time-frequency units and suppress distractors. The module preserves the auditory trace with an identity bypass and adds controlled visual refinements via a residual path. A synchrony-driven gate reduces the influence of low-confidence visual cues. Additionally, a lightweight pre-alignment for visual feature pre-processing estimates and corrects small temporal offsets, and a compact magnitude-phase encoder is used to preserve fine acoustic detail to stabilize reconstruction. Evaluations on LRS2, LRS3, and VoxCeleb2 show state-of-the-art separation with improved efficiency, supporting the value of explicit selection and reliability-aware compensation.

ZeroDiff: Zero-Shot Time Series Reconstruction via Informed-Prior Diffusion

Yingda Fan, Dan Lu, Xiaowei Jia
Time series modeling increasingly demands high-quality supervision, yet target observations remain scarce—exogenous inputs are broadly available, but target measurements are often unavailable due to cost, infrastructure, or accessibility constraints. Can models trained on observed locations reconstruct target time series where measurements have never been collected? We term this zero-shot time series reconstruction. A naive approach—directly mapping exogenous inputs to targets—can yield predictions at unobserved locations, but without target signals, such models fail to capture the intrinsic dynamics of the target variable, producing overly smooth outputs that underestimate extremes. This reveals systematic errors that call for explicit modeling and calibration. We propose ZeroDiff, which constructs an informed prior from exogenous variables alone, then learns to calibrate reconstruction errors through diffusion—training on observed locations and generalizing to unobserved ones. Experiments across diverse real-world datasets demonstrate significant improvements over existing approaches. Our code is available at https://github.com/YingdaFan/ZeroDiff-ICML2026.

Pareto-Guided Optimal Transport for Multi-Reward Alignment
Ying Ba, Tianyu Zhang, Mohan Zhou, Yalong Bai, Wenyi Mo, Guiwei Zhang, Bing Su, Ji-Rong Wen
Text-to-image generation models have achieved remarkable progress in preference optimization, yet achieving robust alignment across diverse reward models remains a significant challenge. Existing multi-reward fusion approaches rely on weighted summation, which is costly to tune and insufficient for balancing conflicting objectives. More critically, optimization with reward models is highly susceptible to reward hacking, where reward scores increase while the perceived quality of generated images deteriorates. We demonstrate that optimizing against a unified global target under heterogeneous reward upper bounds can induce reward hacking, a risk further exacerbated by the inherent instability of weak reward models. To mitigate this, we propose a Pareto Frontier-Guided Optimal Transport (PG-OT) framework. Our method constructs a prompt-specific Pareto frontier and maps dominated samples toward it via distribution-aware optimal transport. Furthermore, we develop both online and offline optimization strategies tailored to diverse reward signal characteristics. To provide a more rigorous assessment, we introduce the Joint Domination Rate (JDR) and Joint Collapse Rate (JCR) as principled metrics to quantify multi-reward synergy and reward hacking. Experimental results show that our approach outperforms strong baselines with an 11% gain in JDR and achieves a near 80% win rate in human evaluations.
****

FLIPS: Instance-Fingerprinting for LLMs via Pseudo-random Sequences
Richardeau Gurvan, Gohar Dashyan, Erwan Le Merrer, Gilles Tredan
Literature reveals that a Large Language Model's (LLM) behavior is not only conditioned by its original weights but also its instance-level parameters, such as instructional prompt, sampling configuration or quantization. A model that generates safe outputs under one configuration may produce toxic content under another. However, current LLM identification techniques (such as fingerprinting) focus on intellectual property protection, and their design favors robustness to changes in these instance-level parameters. This poses a critical challenge for AI regulation in which compliance assessments target actual deployed behaviors, not model provenance. In this paper, we introduce instance-level fingerprinting, a regulator-oriented paradigm that distinguishes configurations of the same LLM. Our method FLIPS, exploits biases in generated binary random sequences to reach 96% (closed-set) and 90% (open-set, where some targets are unknown) identification accuracy across 237 model instances, versus 35% for the adapted LLMmap baseline. This shows that instance-level fingerprinting is both necessary for regulation and practically feasible. Code available at https://github.com/GurvanR/FLIPS-LLM-Instance-Fingerprinting.

AdvEvo-MARL: Shaping Internalized Safety through Adversarial Co-Evolution in Multi-Agent Reinforcement Learning

Zhenyu Pan, Yiting Zhang, Zhuo Liu, Yolo Y. Tang, Zeliang Zhang, Haozheng Luo, Chenwei Xu, Yuwei Han, Jianshu Zhang, Dennis Wu, Hong-Yu Chen, Haoran Lu, Haoyang Fang, Manling Li, Chenliang Xu, Philip S. Yu, Han Liu

LLM-based multi-agent systems excel at planning, tool use, and role coordination, but their openness and interaction complexity also expose them to jailbreak and adversarial collaboration. Existing defenses fall into two lines: (i) self-verification that asks each agent to pre-filter unsafe instructions before execution, and (ii) external guard modules that police behaviors. The former often underperforms because a standalone agent lacks sufficient capacity to detect cross-agent unsafe chains and delegation-induced risks; the latter increases system overhead and creates a single-point-of-failure—once compromised, system-wide safety collapses, and adding more guards worsens cost and complexity. To solve these challenges, we propose AdvEvo-MARL, a co-evolutionary multi-agent reinforcement learning framework that internalizes safety into task agents. Rather than relying on external guards, AdvEvo-MARL jointly optimizes attackers (which synthesize evolving jailbreak prompts) and defenders (task agents trained to both accomplish their duties and resist attacks) in adversarial learning environments. To stabilize learning and foster cooperation, we introduce a public baseline for advantage estimation: agents within the same functional group share a group-level mean-return baseline, enabling lower-variance updates and stronger intra-group coordination. Across representative attack scenarios, AdvEvo-MARL consistently keeps attack-success rate (ASR) below 20\%, whereas baselines reach up to 38.33\%, while preserving or even improving task accuracy (up to +3.67\%). These results show that safety and utility can be jointly improved without relying on extra guard agents or added system overhead.

Grokking Finite-Dimensional Algebra

Pascal Junior Tikeng Notsawo, Guillaume Dumas, Guillaume Rabusseau

This paper investigates the grokking phenomenon, which refers to the sudden transition from a long memorization to generalization observed during neural networks training, in the context of learning multiplication in finite-dimensional algebras (FDA). While prior work on grokking has focused mainly on group operations, we extend the analysis to more general algebraic structures, including non-associative, non-commutative, and non-unital algebras. We show that learning group operations is a special case of learning FDA, and that learning multiplication in FDA amounts to learning a bilinear product specified by the algebra’s structure tensor. For algebras over the reals, we connect the learning problem to matrix factorization with an implicit low-rank bias, and for algebras over finite fields, we show that grokking emerges naturally as models must learn discrete representations of algebraic elements. This leads us to experimentally investigate the following core questions: (i) how do algebraic properties such as commutativity, associativity, and unitality influence both the emergence and timing of grokking, (ii) how structural properties of the structure tensor of the FDA, such as sparsity and rank, influence generalization, and (iii) to what extent generalization correlates with the model learning latent embeddings aligned with the algebra’s representation. Our work provides a unified framework for grokking across algebraic structures and new insights into how mathematical structure governs neural network generalization dynamics.

Learn to change the world: Multi-level reinforcement learning with model-changing actions

Ziqing Lu, Babak Hassibi, Lifeng Lai, Weiyu Xu

Reinforcement learning usually assumes a given or sometimes even fixed environment in which an agent seeks an optimal policy to maximize its long-term discounted reward. In contrast, we consider agents that are not limited to passive adaptations: they instead have model-changing actions that actively modify the RL model of world dynamics itself. Reconfiguring the underlying transition processes can potentially increase the agents' rewards. Motivated by this setting, we introduce the multi-layer configurable time-varying Markov decision process (MCTVMDP). In an MCTVMDP, the lower-level MDP has a non-stationary transition function tha

t is configurable through upper-level model-changing actions. The agent's object ive consists of two parts: Optimize the configuration policies in the upper-leve l MDP and optimize the primitive action policies in the lower-level MDP to joint ly improve its expected long-term reward.

Trojan-Speak: Bypassing Constitutional Classifiers with No Jailbreak Tax via Adv ersarial Finetuning
Bilgehan Sel, Xuanli He, Alwin Peng, Ming Jin, Jerry Wei
Fine-tuning APIs offered by major AI providers create new attack surfaces where adversaries can bypass safety measures through targeted fine-tuning. We introduc e **Trojan-Speak**, an adversarial fine-tuning method that bypasses Anthropic's Constitutional Classifiers. Our approach uses curriculum learning combined with GRPO-based hybrid reinforcement learning to teach models a communication protoco l that evades LLM-based content classification. Crucially, while prior adversari al fine-tuning approaches report more than 25\% capability degradation on reason ing benchmarks, Trojan-Speak incurs less than 5\% degradation while achieving 99 +\% classifier evasion for models with 14B+ parameters. We demonstrate that fine -tuned models can provide detailed responses to expert-level CBRN (Chemical, Bio logical, Radiological, and Nuclear) queries from Anthropic's Constitutional Clas sifiers bug-bounty program. Our findings reveal that LLM-based content classifie rs alone are insufficient for preventing dangerous information disclosure when a dversaries have fine-tuning access, and we show that activation-level probes can substantially improve robustness to such attacks.

Structured Expert Routing with Multi-View Task Priors for Offline Meta-Reinforce ment Learning
Yisen Zhao, Peixi Peng, Xinyu Hu, Cong Li, Zhan Su, Zhuojian Li
Offline meta-reinforcement learning requires agents to generalize to unseen task s from fixed datasets, yet existing sequence-based and MoE-based methods rely on implicit or token-level routing signals that fail to capture task-level structu re.
We propose the **Task-Guided Router (TGR)**, a structured expert-routing framewo rk that explicitly models inter-task relationships via multi-view task represent ations that combine semantic descriptors, behavioral summaries, and latent dynam ics features.
Using structure-guided routing, TGR assigns experts based on global task compati bility rather than local trajectory fragments, enabling stable specialization an d effective knowledge transfer across tasks.Extensive experiments on continuous-control benchmarks demonstrate that TGR consistently outperforms state-of-the-ar t offline meta-RL methods in few-shot generalization, particularly under sparse data and heterogeneous dynamics.
Our results highlight the importance of task-level priors for robust offline met a-reinforcement learning.

The Perceptual Bandwidth Bottleneck in Vision-Language Models: Active Visual Rea soning via Sequential Experimental Design
Anjie Liu, Ziqin Gong, Yan Song, Yuxiang Chen, Xiaolong Liu, Hengtong Lu, Kaike Zhang, Chen Wei, Jun Wang
Visual perception in modern Vision-Language Models (VLMs) is constrained by a pe rceptual bandwidth bottleneck: a broad field of view preserves global context bu t sacrifices the fine-grained details required for complex reasoning. We argue t hat high-resolution visual reasoning is therefore not only semantic reasoning bu t also task-relevant evidence acquisition under limited perceptual bandwidth. In spired by active vision and information foraging, we formalise this process as s equential Bayesian optimal experimental design (S-BOED), where an agent decides which visual evidence to acquire before answering. Since exact Bayesian inferenc e is intractable in continuous gigapixel spaces, we derive a tractable coverage-resolution objective as a proxy for task-relevant information gain. We instantia te this framework with FOVEA, a training-free procedure that refines VLM crop pr oposals through evidence-oriented probing. Experiments on high-resolution bench

marks show consistent gains over direct and ReAct-style baselines, with particul
arly strong improvements in search-dominated remote-sensing settings.
****
Solving Inverse Problems with Flow-based Models via Model Predictive Control
George Webber, Alexander Denker, Riccardo Barbano, Andrew J. Reader
Flow-based generative models provide strong unconditional priors for inverse pro
blems, but guiding their dynamics for conditional generation remains challenging
.
Recent work casts training-free conditional generation in flow models as an opti
mal control problem; however, solving the resulting trajectory optimisation is c
omputationally and memory intensive, requiring differentiation through the flow
dynamics or adjoint solves.
We propose MPC-Flow, a model predictive control framework that formulates invers
e problem solving with flow-based generative models as a sequence of control sub
-problems, enabling practical optimal control-based guidance at inference time.
We provide theoretical analysis linking MPC-Flow to the underlying optimal contr
ol objective and show how different algorithmic choices yield a spectrum of guid
ance algorithms, including regimes that avoid backpropagation through the genera
tive model trajectory.
We evaluate MPC-Flow on benchmark image restoration tasks, spanning linear and n
on-linear settings such as in-painting, deblurring, and super-resolution, and de
monstrate strong performance and scalability to massive state-of-the-art archite
ctures via training-free guidance of FLUX.2 (32B) in a quantised setting on cons
umer hardware.
****
Equilibrium Propagation for Non-Conservative Systems
Antonino Emanuele Scurria, Dimitri Vanden Abeele, Bortolo Matteo Mognetti, Serge
 Massar
Equilibrium Propagation (EP) is a physics-inspired learning algorithm that uses
stationary states of a dynamical system both for inference and learning. In its
original formulation it is limited to conservative systems, *i.e.* to dynamics w
hich derive from an energy function. Given their applications, it is important t
o extend EP to non-conservative systems, *i.e.* systems with non-reciprocal inte
ractions. Previous attempts to generalize EP to such systems failed to compute t
he exact gradient of the cost function.
Here we propose a framework that extends EP to arbitrary non-conservative system
s, including feedforward networks.
We keep the key property of equilibrium propagation, namely the use of stationar
y states both for inference and learning. However, we modify the dynamics in the
 learning phase by a term proportional to the non-reciprocal part of the interac
tion so as to obtain the exact gradient of the cost function.
This algorithm can also be derived using a variational formulation that generate
s the learning dynamics through an energy function defined over an augmented sta
te space.
Numerical experiments show that this algorithm achieves better performance and l
earns faster than previous proposals.
****
Contrastive Reasoning Alignment: Reinforcement Learning from Hidden Representati
ons
Haozheng Luo, Yimin Wang, Jiahao Yu, Binghui Wang, Yan Chen
We propose CRAFT, a red-teaming alignment framework that leverages model reasoni
ng capabilities and hidden representations to improve robustness against jailbre
ak attacks.
Unlike prior defenses that operate primarily at the output level, CRAFT aligns l
arge reasoning models to generate safety-aware reasoning traces by explicitly op
timizing objectives defined over the hidden state space.
Methodologically, CRAFT integrates contrastive representation learning with rein
forcement learning to separate safe and unsafe reasoning trajectories, yielding
a latent-space geometry that supports robust, reasoning-level safety alignment.
Theoretically, we show that incorporating latent–textual consistency into GRPO e

liminates superficially aligned policies by ruling them out as local optima. Empirically, we evaluate CRAFT on multiple safety benchmarks using two strong reasoning models, Qwen3-4B-Thinking and R1-Distill-Llama-8B, where it consistently outperforms state-of-the-art defenses such as IPO and SafeKey. Notably, CRAFT delivers an average **79.0%** improvement in reasoning safety and **87.7%** improvement in final-response safety
over the base models, demonstrating the effectiveness of hidden-space reasoning alignment.
****

Stop Training for the Worst: Progressive Unmasking Accelerates Masked Diffusion Training
Jaeyeon Kim, Jonathan Geuter, David Alvarez-Melis, Sham M. Kakade, Sitan Chen
Masked Diffusion Models (MDMs) have emerged as a promising approach for generative modeling in discrete spaces. By generating sequences in any order and allowing for parallel decoding, they enable fast inference and strong performance on non-causal tasks. However, this flexibility comes with a *training complexity* trade-off: MDMs train on an exponentially large set of masking patterns, which is not only computationally expensive, but also creates a train--test mismatch between the random masks used in training and the highly structured masks induced by inference-time unmasking.
In this work, we propose Progressive UnMAsking (PUMA), a simple modification of the forward masking process that aligns training-time and inference-time masking patterns, thereby focusing optimization on *inference-aligned masks* and speeding up training. Empirically, PUMA speeds up pretraining at the 125M scale by $\approx 2.3 \times$ and offers complementary advantages on top of common recipes like autoregressive initialization. We open-source our codebase at https://github.com/JaeyeonKim01/PUMA.
****

Progressive Cramming: Reliable Token Compression and What It Reveals
Dmitrii Tarasov, Timofei Lashukov, Elizaveta Goncharova, Andrey Kuznetsov
Token cramming compresses sequences into learned embeddings with near-perfect reconstruction, but fixed token budgets and 99\% accuracy thresholds leave it unclear whether residual errors reflect optimization failures or fundamental limits. We introduce progressive cramming, which grows the target prefix token-by-token, stopping only when reconstruction is no longer achievable within a fixed optimization budget. Progressive trajectories occupy low-dimensional structure in embedding space. Prepending a crammed embedding causes a moderate but consistent accuracy drop on multiple-choice benchmarks even with the original prefix in context, and collapses capability almost entirely under generative evaluation. Causal attention-knockout interventions trace this degradation to the embedding's interactions in the model's early layers. These results position progressive cramming as a tool for studying compression limits and show that perfect reconstruction - achievable through brittle steering rather than transferable semantics - is insufficient for meaningful compression.
****

From Evaluation to Design: Using Potential Energy Surface Smoothness Metrics to Guide ML Interatomic Potential Architectures
Ryan Liu, Eric Qu, Tobias Kreiman, Samuel M Blau, Aditi S. Krishnapriyan
Machine Learning Interatomic Potentials (MLIPs) sometimes fail to reproduce the physical smoothness of the quantum potential energy surface (PES), leading to erroneous behavior in downstream simulations that standard energy and force regression evaluations can miss. Existing evaluations, such as microcanonical molecular dynamics (MD), are computationally expensive and primarily probe near-equilibrium states. To improve evaluation metrics for MLIPs, we introduce the Bond Smoothness Characterization Test (BSCT). This efficient benchmark probes the PES via controlled bond deformations and detects non-smoothness, including discontinuities, artificial minima, and spurious forces, both near and far from equilibrium. We show that BSCT correlates strongly with MD stability while requiring a fraction of the cost of MD. To demonstrate how BSCT can guide iterative model design, we utilize an unconstrained Transformer backbone as a testbed, illustrating how

refinements such as a new differentiable k-nearest neighbors algorithm and temperature-controlled attention reduce artifacts identified by our metric. By optimizing model design systematically based on BSCT, the resulting MLIP simultaneously achieves a low conventional E/F regression error, stable MD simulations, and robust atomistic property predictions. Our results establish BSCT as both a validation metric for practitioners to assess MLIP utility and as an "in-the-loop" model design proxy that alerts MLIP developers to physical challenges that cannot be efficiently evaluated by current MLIP benchmarks.

REALISTA: Realistic Latent Adversarial Attacks that Elicit LLM Hallucinations
Buyun Liang, Jinqi Luo, Liangzu Peng, Kwan Ho Ryan Chan, Darshan Thaker, Kaleab A Kinfu, Fengrui Tian, Hamed Hassani, Rene Vidal
Large language models (LLMs) achieve strong performance across many tasks but remain vulnerable to hallucinations, making it important to systematically evaluate their reliability under realistic adversarial inputs. We formulate hallucination elicitation as a constrained optimization problem, where the goal is to find semantically coherent adversarial prompts that are equivalent to benign user prompts. Existing attack methods remain limited: discrete prompt-based attacks preserve semantic equivalence and coherence but search only over a limited set of prompt variations, while continuous latent-space attacks explore a richer space but often decode into prompts that are no longer valid rephrasings. To address these limitations, we propose REALISTA, a realistic latent-space attack framework. REALISTA constructs an input-dependent dictionary of valid editing directions, each corresponding to a semantically equivalent and coherent rephrasing, and optimizes continuous combinations of these directions in latent space. This design combines the optimization flexibility of continuous attacks with the semantic realism of discrete rephrasing-based attacks. Experiments demonstrate that REALISTA achieves superior or comparable performance to state-of-the-art realistic attacks on open-source LLMs and, crucially, succeeds in attacking large reasoning models under free-form response settings, where prior realistic attacks fail.

Lightweight Federated Incremental Learning via Decoupled Replay
Xiuying Wang, Yichen Li, Hang Su, Gaozhuo Liu, Shiwei Li, Chuang Zhao, Jiangming Shi, Imran Razzak
Federated Incremental Learning (FIL) aims to learn streaming tasks across distributed clients without catastrophic forgetting while preserving privacy. Most existing methods mitigate forgetting by replaying historical samples, but it can pose privacy risks and incur high resource overhead, limiting deployment on resource-constrained edge devices.
To address this challenge, we propose a novel **Li**ghtweight **F**ederated **I**ncremental **L**earning framework called **Li-FIL** that leverages dense features synthesized by a server-side secure generator to enable efficient feature-based decoupled replay.
More specifically, each client extracts high-confidence features from new tasks, enrich them via mixup, and privatize them before uploading to the server, which reduces both storage and communication overhead. A generator is deployed on the server to learn the distributions of clients and generate global features for replay.
Moreover, to enable clients to better learn from these dense features, we decouple local training into classifier stabilization and encoder regularization. This design allows feature replay and alignment between new and previous features to be conducted separately and more effectively.
Extensive experiments demonstrate that Li-FIL outperforms other state-of-the-art methods by up to 10.14% in terms of accuracy on both old and new tasks with superior resource efficiency.
****
Focus-Then-Contact: Speeding Up Robotic Contact-Rich Task Learning with Affordance-Guided Real-World Residual Reinforcement Learning
Guanren Qiao, Ruixiang Ouyang, Sheng Xu, Ruixing Jin, Yueci Deng, Yunxin Tai, Kui Jia, Guiliang Liu

Real-World Reinforcement Learning (RL) has shown significant potential in roboti c manipulation tasks. However, many methods still require substantial human-in-t he-loop involvement to complete contact-rich tasks, especially when there are di sruptions such as visual backgrounds or positional changes. To address this, we propose the Focus Then Contact (FTC), a lightweight and low-cost method to accel erate the convergence of human-in-the-loop real-world RL for contact-rich tasks.
  FTC leverages residual RL to provide base actions, helping the system quickly reach the target regions and improve sample efficiency. Additionally, FTC integr ates an affordance-guided reward that drives the real-world RL system to quickly focus on key regions of interest, making it possible for the robotic arm to con tinuously engage with these goal areas through force-control feedback. At the sa me time, we optimize the human-in-the-loop implementation to prevent conflicts w ith RL over control of the robotic arm. We demonstrate the effectiveness of FTC on 6 contact-rich tasks, where it outperforms baseline methods in achieving high success rates and speeds up robotic contact-rich task learning under a real-wor ld RL setting.

CORE: Conflict-Oriented Reasoning for General Multimodal Manipulation Detection
Jinjie Shen, Yaxiong Wang, Yujiao Wu, Lechao Cheng, Tianrui Hui, Nan Pu, Zhihui Li, Zhun Zhong

The rapid rise of generative AI has made multimodal fake news increasingly reali stic and pervasive, posing severe threats to public trust and social stability. Existing detection methods rely heavily on manipulation-specific models and larg e-scale labeled data, resulting in poor generalization to emerging manipulation types. We observed that the essence of manipulated misinformation lies in its in trinsic conflicts, i.e., semantic or physical inconsistencies either across moda lities or with common world knowledge. Inspired by this observation, we propose Conflict-{Oriented REasoning (CORE) framework, an effective paradigm that learn s to endows multimodal large language models (MLLMs) with explicit conflict-capt uring capability. To this end, CORE first constructs the Conflict Attribution Co rpus (CAC) with fine-grained annotations of conflict factors and sources, provid ing essential data support for subsequent conflict perception training. By perfo rming conflict-oriented representation enhancement and reasoning based on CAC, C ORE achieves robust and generalizable conflict detection, effectively and rapidl y adapting to unseen manipulation types with a few samples or in even zero-shot settings. Extensive experiments demonstrate that CORE surpasses state-of-the-art models by 9.7\%, 14.1\%, and 11.8\% in accuracy on the DGM^4, MMFakeBench, an d MDSM benchmarks, respectively.

The Mechanistic Emergence of Symbol Grounding in Language Models
Shuyu Wu, Ziqiao Ma, Xiaoxi Luo, Yidong Huang, Josue Torres-Fonseca, Freda Shi, Joyce Chai

Symbol grounding (Harnad, 1990) describes how symbols such as words acquire thei r meanings by connecting to real-world sensorimotor experiences. Recent work has shown preliminary evidence that grounding may emerge in (vision-)language model s trained at scale without using explicit grounding objectives. Yet, the specifi c loci of this emergence and the mechanisms that drive it remain largely unexplo red. To address this problem, we introduce a controlled evaluation framework tha t systematically traces how symbol grounding arises within the internal computat ions through mechanistic and causal analysis. Our findings show that grounding c oncentrates in middle-layer computations and is implemented through the aggregat e mechanism, where attention heads aggregate the environmental ground to support the prediction of linguistic forms. This phenomenon replicates in multimodal di alogue and across architectures (Transformers and state-space models), but not i n unidirectional LSTMs. Our results provide behavioral and mechanistic evidence that symbol grounding can emerge in language models, with practical implications for predicting and potentially controlling the reliability of generation.

Predicting the Emergence of Induction Heads in Language Model Pretraining
Tatsuya Aoyama, Ethan Gotlieb Wilcox, Nathan Schneider

Specialized attention heads dubbed induction heads (IHs) have been argued to underlie the remarkable in-context learning capabilities of modern language models; yet, a precise characterization of their emergence, especially in the context of language modeling, remains wanting. In this study, we investigate the relationship between statistical properties of the training data and IH formation in both natural and synthetic training data settings. We show that: (1) a simple equation combining batch size and context size predicts the point at which IHs form and that this emergence point is agnostic to model size; (2) surface bigram repetition frequency and reliability strongly affect the formation of IHs, and we find an effective decision boundary in terms of these two values; (3) local dependency with high bigram repetition frequency and reliability is sufficient for IH formation, but categoriality and the shape of the marginal distribution appear to modulate IH formation near the decision boundary.

Rethinking Time-Series Imputation as Conditional Inference along Temporal Evolution
Yu Fan, Yang Yang, Yufan Guo, Huazhong Yang, Pengjun Wang
Real-world time-series data often suffer from missing observations, hindering long-range temporal modeling. However, most existing imputation methods formulate imputation as conditional reconstruction over limited context, which restricts temporal information propagation and fails to explicitly model temporal evolution. To overcome this limitation, we propose the Conditional Temporal Inference Paradigm (CTIP), which formulates time-series imputation as conditional inference along temporal evolution. Under this paradigm, we introduce CBiT, which leverages a history compression mechanism to encode long-range history into a compact latent space for history-conditioned temporal imputation. In addition, we adopt a partitioned modeling strategy that distinguishes historical context and temporal imputation targets with only linear-time complexity. Extensive experiments on multiple public benchmarks show that CBiT improves imputation accuracy by reducing Masked MAE and Masked RMSE by 27.3% and 18.6%, respectively, across different missing rates.

SPA: A Simple but Tough-to-Beat Baseline for Knowledge Injection
Kexian Tang, Jiani Wang, Shaowen Wang, Kaifeng Lyu
While large language models (LLMs) are pretrained on massive amounts of data, their knowledge coverage remains incomplete in specialized, data-scarce domains, motivating extensive efforts to study synthetic data generation for knowledge injection. We propose $\textbf{SPA}$ ($\textbf{S}$caling $\textbf{P}$rompt-engineered $\textbf{A}$ugmentation), a simple but tough-to-beat baseline that uses a small set of carefully designed prompts to generate large-scale synthetic data for knowledge injection. Through systematic comparisons, we find that $\textbf{SPA}$ outperforms several strong baselines. Furthermore, we identify two key limitations of prior approaches: (1) while RL-based methods may improve the token efficiency of LLM-based data augmentation at small scale, they suffer from diversity collapse as data scales, leading to diminishing returns; and (2) while multi-stage prompting may outperform simple augmentation methods, their advantages can disappear after careful prompt tuning. Our results suggest that, for knowledge injection, careful prompt design combined with straightforward large-scale augmentation can be surprisingly effective, and we hope SPA can serve as a strong baseline for future studies in this area. Our code is available at https://github.com/Tangkexian/SPA.

Q-Sched: Pushing the Boundaries of Few-Step Diffusion Models with Quantization-Aware Scheduling
Natalia Frumkin, Diana Marculescu
Text-to-image diffusion models remain computationally intensive: generating a single image typically requires dozens of passes through large transformer backbones (e.g., SDXL uses ~50 evaluations of a 2.6B-parameter model). Few-step variants reduce the step count to 2–8 but still rely on large, full-precision backbones, making inference impractical on resource-constrained platforms. Existing post-

training quantization (PTQ) methods are further hampered by their dependence on full-precision calibration.

We introduce **Q-Sched**, a scheduler-level PTQ approach that adapts the diffusion sampler while keeping the quantized weights fixed. By adjusting the few-step sampling trajectory with quantization-aware preconditioning coefficients, Q-Sched matches or surpasses full-precision quality while delivering a **4× reduction** in model size and preserving a single reusable checkpoint across bit-widths. To learn these coefficients, we propose a reference-free **Joint Alignment–Quality (JAQ)** loss, which combines text–image compatibility with an image-quality objective for fine-grained control. JAQ requires only a handful of calibration prompts and avoids any full-precision inference during calibration.

Empirically, Q-Sched yields substantial gains: a **15.5%** FID improvement over the FP16 4-step Latent Consistency Model and a **16.6%** improvement over the FP16 8-step Phased Consistency Model, demonstrating that quantization and few-step distillation are complementary for high-fidelity generation. A large-scale user study with **80,000+** annotations further validates these results on both FLUX.1[schnell] and SDXL-Turbo.

Contextual Slate GLM Bandits with Limited Adaptivity
Tanmay Goyal, Sukruta Prakash Midigeshi, Gaurav Sinha
We investigate the contextual slate bandit problem with generalized linear rewards under limited adaptivity. At each round, the learner is presented with N sets of items, where each item is represented by a d-dimensional feature vector. The learner then constructs a slate by selecting one item per set; the resulting slate yields a scalar reward sampled from a Generalized Linear Model (GLM). We propose algorithms under two limited-adaptivity settings: (a) Batched and (b) Rarely-Switching. For the batched setting, we introduce B-SlateGLinCB, which partitions the time horizon into $\mathcal{O}(\log\log T)$ batches such that each batch's policy relies only on data from previous batches. For the rarely-switching setting, we propose RS-SlateGLinCB, which adaptively performs only $\mathcal{O}(Nd\log T)$ parameter updates. Under a diversity assumption on the item sequences, we prove that B-SlateGLinCB and RS-SlateGLinCB achieve regret bounds of $\mathcal{O}(Nd^{3/2}\sqrt{T})$ and $\mathcal{O}(Nd\sqrt{T})$, respectively. Notably, both bounds are independent of the non-linearity parameter κ that is typically found to scale the regret of GLM bandit algorithms. Our algorithms are computationally efficient, requiring only $\text{poly}(N)$ time per round despite $2^{\Omega(N)}$ possible slates. Simulations show our algorithms outperform existing baselines with limited adaptivity and remain competitive with Slate-GLM-OFU, a fully adaptive state-of-the-art algorithm. Notably, a slightly modified B-SlateGLinCB empirically matches this baseline. Finally, we demonstrate strong performance in a practical in-context example selection task for language models.
****
Adaptive Code Watermarking Through Reinforcement Learning
Zhimeng Guo, Huaisheng Zhu, Siyuan Xu, Hangfan Zhang, Teng Xiao, Minhao Cheng
As LLMs increasingly generate production code, protecting intellectual property demands watermarking techniques that respect code's strict syntactic constraints. In this work, we introduce CodeTracer, an innovative adaptive code watermarking framework underpinned by a reinforcement learning training paradigm. At its core, CodeTracer features a policy-driven approach that utilizes a parameterized model to intelligently bias token choices during next-token prediction. This strategy ensures that embedded watermarks maintain code functionality while exhibiting subtle yet statistically detectable deviations from typical token distributions. To facilitate policy learning, we devise a comprehensive reward system that seamlessly integrates execution feedback with watermark embedding signals, balancing process-level and outcome-level rewards. To enable gradient-based optimizat

ion of these discrete watermarking decisions, we employ Gumbel Top-k reparameterization. Extensive comparative evaluations demonstrate that CodeTracer outperforms state-of-the-art baselines across multiple benchmarks in both watermark detectability and code functionality. Our code is available at https://github.com/TimeLovercc/CodeTracer.

KernelFoundry: Hardware-Aware Evolutionary GPU Kernel Optimization
Nina Wiedemann, Quentin Leboutet, Michael Paulitsch, Diana Wofk, Benjamin Ummenhofer
GPU kernel optimization challenges LLMs beyond standard coding tasks, as it requires an understanding of hardware architecture, parallel computing optimization strategies, and profiling outputs. However, most existing approaches leveraging LLMs for kernel generation apply standard prompting and feedback loops, considering hardware only through profiling feedback. We introduce KernelFoundry, an evolutionary framework that efficiently explores the space of GPU kernels through (1) MAP-Elites quality-diversity search with kernel-specific behavioral dimensions to sustain exploration; (2) meta-prompt evolution that co-evolves prompts with kernels to uncover task-specific optimization strategies, and (3) a template-based parameter optimization approach to tune kernels to inputs and hardware. We evaluate this framework on KernelBench, robust-kbench and custom tasks, generating SYCL kernels as a cross-platform GPU programming paradigm, and CUDA kernels for comparison to prior work. Our approach consistently outperforms the baseline methods and achieves an average speedup of 2.3 on KernelBench for SYCL. Moreover, KernelFoundry is implemented as a distributed framework with remote access to diverse hardware, allowing quick benchmarking and featuring a flexible user input layer to support kernel generation for a wide range of real use cases beyond benchmarking.

TDM-R1: Reinforcing Few-Step Diffusion Models with Non-Differentiable Reward
Yihong Luo, Tianyang Hu, Weijian Luo, Jing Tang
While few-step generative models have enabled powerful image and video generation at significantly lower cost, generic reinforcement learning (RL) paradigms for few-step models remain an unsolved problem. Existing RL approaches for few-step diffusion models strongly rely on back-propagating through differentiable reward models, thereby excluding the majority of important real-world reward signals, e.g., non-differentiable rewards such as humans' binary likeness, object counts, etc.
To properly incorporate non-differentiable rewards to improve few-step generative models, we introduce TDM-R1, a novel reinforcement learning paradigm built upon a leading few-step model, Trajectory Distribution Matching (TDM).
TDM-R1 decouples the learning process into surrogate reward learning and generator learning.
Furthermore, we developed practical methods to obtain per-step reward signals along the deterministic generation trajectory of TDM, resulting in a unified RL post-training method that significantly improves few-step models' ability with generic rewards.
We conduct extensive experiments ranging from text-rendering, visual quality, and preference alignment.
All results demonstrate that TDM-R1 is a powerful reinforcement learning paradigm for one- and few-step text-to-image models, scaling from 0.6B to 6B parameters while achieving state-of-the-art performance on both in-domain and out-of-domain metrics.

Balancing Learning Rates Across Layers: Exact Two-Step Dynamics and Optimal Scaling in Linear Neural Networks
Tianyu Pang, Vignesh Kothapalli, Shenyang Deng, Haohui Wang, Dawei Zhou, Yaoqing Yang
We study optimal learning-rate selection in two-layer and three-layer linear neural networks trained to learn linear
target functions. In particular, we derive the exact closed-form expressions for

the gradients and test loss after one and two steps of gradient descent, enabling a precise characterization of early training dynamics. We characterize how learning rates should scale under the gradient approximation in the first two steps, and prove that performing updates with this approximation yields a tractable surrogate loss with a tight, small approximation error. This formulation enables the theoretical analysis of layer-wise learning rates and reveals a distinct early-training regime: test loss can be minimized by unequal learning rates at the initial step, while equal learning rates become optimal in subsequent steps. Our numerical experiments validate the theory and demonstrate the importance of balancing layer-wise learning rates early during training. The code is available at: [TDCSZ327/Layer-Balancing](https://github.com/TDCSZ327/Layer-Balancing).

FedPDG: Prediction Discrepancy–Guided Data Generation for Heterogeneous Federated Learning

Yuqi Wang, Jianwei Niu, Xinghao Wu, Xuefeng Liu, Xin Hao

One emerging approach to mitigating data heterogeneity in Federated Learning (FL) is to employ diffusion models to generate synthetic data for clients, thereby aligning local data distributions with the global distribution. Prior work has primarily focused on balance-oriented augmentation, which assumes a balanced global class distribution and thus generates samples of rare classes to rebalance each client's local dataset. However, in practice, global data distributions are often inherently imbalanced. Moreover, privacy constraints in FL hinder the server’s ability to accurately estimate the global distribution, rendering balance-oriented augmentation suboptimal. This raises a key, underexplored challenge: How can synthetic data be generated and selected to align local distributions with the true, yet unknown, global distribution? Our key insight is that a model’s performance implicitly reflects the data distribution it has been trained on. Based on this observation, we use the performance discrepancy between local and global models to identify the regions where each client’s local dataset is lacking, and generate corresponding samples for clients. Furthermore, we adapt the diffusion model via preference optimization, enabling it to generate data that better aligns with the true global distribution. Extensive experiments on multiple benchmarks demonstrate that FedPDG outperforms state-of-the-art methods, achieving up to 3.82\% improvement.

Resting Neurons, Active Insights: Robustifying Activation Sparsity in LLMs via Spontaneity

Haotian Xu, Jiannan Yang, Tian Gao, Tsui-Wei Weng, Tengfei Ma

Activation sparsity offers a compelling route to accelerate large language model (LLM) inference by selectively suppressing hidden activations, yet existing approaches exhibit severe accuracy degradation at high sparsity. We show that this failure stems from representational instability: *activation sparsity disrupts input-dependent activation learned during pretraining, inducing distribution shifts in hidden states*. We address this issue by reframing activation sparsity as a representational alignment problem and introducing **Spontaneous Neurons (SPON)**, a lightweight mechanism inspired by spontaneous neural activity in biological systems. SPON injects a small set of learnable, input-independent activation vectors that act as persistent representational anchors for sparse computation. These vectors are trained via distribution matching to the dense model and can be absorbed into bias terms after training, incurring negligible inference overhead. Across multiple LLM backbones, SPON consistently restores performance, stabilizes latent representations, and preserves generalization. Our results establish SPON as an effective and principled solution for reliable activation-sparse inference, and offer new insights into knowledge retention in LLMs.

Homophily-Heterogeneity Gradient Surgery for Federated Graph Learning

Sujia Huang, Lele Fu, Shunxin Xiao, Xiaoya Zhang, Chunyan Xu, Tong Zhang, Bo Huang, Zhen Cui

Federated Graph Learning (FGL) facilitates privacy-preserving collaborative training of graph neural networks, yet homophily heterogeneity across subgraphs can

induce optimization conflicts that degrade model generalization.
  Many existing solutions rely on multi-channel architectures to mitigate such c onflicts, which increase the burden on edge devices and lack theoretical converg ence analysis.
  To overcome these limitations, we propose FedGCM, a novel FGL framework with G roup-oriented Conflict Mitigation, which aligns inconsistent optimization object ives via a tailored gradient surgery.
  Specifically, FedGCM first divides clients into distinct groups based on their homophily levels, thereby avoiding exhaustive client-to-client conflict assessm ents.
  To resolve inter-group interference, we develop RPGrad, a gradient surgery mec hanism based on residual projection, which integrates synergistic knowledge whil e filtering inter-group conflicts.
  The refined updates are then transmitted in a group-wise fashion, effectively alleviating optimization conflicts induced by homophily heterogeneity without au gmenting the client-side burden.
  Furthermore, we provide a formal theoretical analysis establishing the converg ence.
  Extensive experiments on both homophilous and heterophilous graphs demonstrate that FedGCM consistently achieves superior performance.

DIVE: Scaling Diversity in Agentic Task Synthesis for Generalizable Tool Use
Aili Chen, Chi Zhang, Junteng Liu, Jiangjie Chen, Chengyu Du, Yunji Li, Ming Zho ng, Qin Wang, Zhengmao Zhu, Jiayuan Song, Ke Ji, Junxian He, Pengyu Zhao, Yanghu a Xiao
Recent work increasingly synthesizes agentic tasks for post-training tool-using LLMs, yet robust generalization under shifts in tasks and toolsets remains an op en challenge. We trace this brittleness to insufficient diversity in synthesized training tasks. Scaling diversity is difficult because training requires tasks to remain executable and verifiable, while generalization demands diverse tool t ypes, toolset combinations, and heterogeneous tool-use patterns. We propose DIVE , an evidence-driven recipe that inverts synthesis order, executing diverse real -world tools first and reverse-deriving tasks strictly entailed by the resulting traces, providing grounding by construction. DIVE scales structural diversity a long two controllable axes, tool-pool coverage and per-task toolset variety, syn thesizing 48k trajectories over 374 tools across five domains that cover 46,398 unique toolsets and 39,810 unique tool-call graphs. Training Qwen3-8B on DIVE da ta (48k SFT + 3.2k RL) improves by +22 average points across 9 OOD benchmarks an d outperforms the strongest 8B baseline by +68%. Under a fixed budget, controlle d scaling shows diversity scaling consistently outperforms quantity scaling, eve n with 4× less data.

Training-Free Hashing-Based Attention via Binary Principal Components
Daohai Yu, Zhanpeng Zeng, Keyu Chen, Wenhao Li, Zhifeng Shen, Luxi Lin, Ruizhi Q iao, Xing Sun, Rongrong Ji
Long-context large language models (LLMs) are increasingly deployed in real-worl d applications, yet self-attention remains a major efficiency bottleneck -- espe cially during decoding -- due to the necessity of repeatedly processing ever-gro wing key-value (KV) caches.
Existing sparse attention reduce computation by attending to fewer KV pairs, but often suffer from substantial accuracy degradation, require additional training , or rely on expensive hashing.
In this work, we present \textbf{BinaryPC}, a training-free, data-aware hashing-based sparse attention for long-context LLMs. BinaryPC constructs compact binary hash codes and corresponding hash function by computing binary principal compon ents of data.
Unlike Locality-Sensitive Hashing (LSH) with data-independent random projections or learned non-linear hashing methods, BinaryPC constructs binary codes that ex plicitly preserve the structural information of data without requiring gradient-based training.

Comprehensive experiments across multiple model families and long-context benchm
arks show that BinaryPC preserves accuracy relative to full attention while achi
eving superior performance among sparse and hashing-based baselines.
On modern GPUs, BinaryPC improves end-to-end decoding throughput by 3.56$\times$
 over the FlashAttention kernel.
Our code is available at https://github.com/yudaohai666/BPC.

RSA-CP: Efficient Conformal Prediction in Small-Sample Regimes via Random Score
Alignment
Pankaj Bhagwat, Zhixian Yang, yihao wang, Bei Jiang, Linglong Kong
Conformal Prediction (CP) provides rigorous finite-sample coverage guarantees, y
et its statistical efficiency hinges critically on the size of the calibration s
et. In data-scarce regimes, CP often suffers from volatile quantile estimation,
leading to overly conservative and wide prediction intervals. To address this, w
e propose Random Score Alignment-Conformal Prediction (RSA-CP), a simple framewo
rk designed to improve sample efficiency in small-sample CP. Instead of requirin
g the computationally intensive generation of full synthetic datasets, RSA-CP en
hances calibration by directly aligning real scores with a high-resolution refer
ence score distribution. By employing an optimal transport mapping, our framewor
k refines "step-like" quantile increments through a globally optimal use of refe
rence information. We provide theoretical guarantees establishing that RSA-CP ma
intains robust coverage without any distributional assumptions on the reference
scores. Empirical evaluations demonstrate that RSA-CP consistently produces shor
ter and more precise prediction intervals while maintaining finite-sample covera
ge guarantees. Overall, RSA-CP offers a computationally efficient and theoretica
lly grounded solution for robust uncertainty quantification under limited data.

Sample-Efficient Diffusion-based Reinforcement Learning with Critic Guidance
Shutong Ding, Zejia Zhong, Zhongyi Wang, Ke Hu, Bikang Pan, Jingya Wang, Ye Shi
Recent advances in reinforcement learning (RL) have achieved great successes by
leveraging the multimodality and exploration capability of diffusion policies. A
mong these approaches, one representative branch focuses on the sampling-based p
olicy optimization. This design enables better exploration capability of the dif
fusion model, particularly at the beginning of training, but suffer from low exp
loitation in Q-value information, resulting in a slow policy convergence. Anothe
r branch pays attention to gradient-based policy optimization, which sufficientl
y exploits the gradient of the Q function yet tends to collapse into a unimodal
policy with low diversity. To address this issue, we propose CGPO, \textbf{C}rit
ic-\textbf{G}uided diffusion \textbf{P}olicy \textbf{O}ptimization, which effect
ively balances exploration and exploitation with the training-free guidance tech
nique integrated into the denoising process of diffusion policy. Concretely, CGP
O steers action generation toward high-value regions defined by the critic netwo
rk and uses the guided actions as regression objectives. In this manner, CGPO re
duces the time required to obtain high-quality actions and improves final perfor
mance with better balance between the exploration-exploitation tradeoff. We vali
date the effectiveness of CGPO on 5 MuJoCo locomotion tasks, and CGPO achieves s
tate-of-the-art performance compared with existing diffusion-based RL methods. N
otably, CGPO is the first success to incorporate diffusion policy into real-worl
d RL, with its superior performance on Franka robot arm grasping tasks. Our offi
cial page is released at \url{https://dingsht.tech/cgpo-webpage}.
****

Deep Coupling Learning for Solving PDEs
Lingshi MENG, Haosen Shi, Sinno Jialin Pan
Physics-Informed Neural Networks (PINNs) represent a significant advancement in
computational methods for solving partial differential equations (PDEs).
However, the adoption of deeper neural network architectures presents significan
t challenges, as they struggle to address differential-related complications tha
t arise during the computation of derivatives over the input of PINNs.
These complications extend beyond traditional vanishing and exploding gradients
to include vanishing and exploding differentials, with both phenomena becoming m

ore severe as networks grow deeper.
By examining the computation graph of derivatives in deep neural networks, we id entify key bottlenecks causing numerical instabilities in deep architectures.
In response, we introduce a novel approach that utilizes Coupling Layers with ca refully regulated spectral norms of Jacobian matrices to stabilize and facilitat e deep PINN training, effectively addressing differential-related challenges and improving model stability.
Our proposed architecture successfully mitigates the fundamental constraints of deeper PINNs while maximizing their capabilities through consistent differential propagation.
Comprehensive evaluations show that our approach surpasses conventional shallow PINN methods and alternative deep PINN designs across a range of challenging pro blems.

ExCyTIn-Bench: Evaluating LLM agents on Cyber Threat Investigation
Yiran Wu, Mauricio Velazco, Andrew Zhao, Manuel Raúl Meléndez Luján, Srisuma Mov va, Yogesh K Roy, Quang Nguyen, Roberto Rodriguez, Qingyun Wu, Michael Albada, J ulia Kiseleva, Anand Mudgerikar
We present ExCyTIn-Bench, the first benchmark to Evaluate an LLM agent X on the task of Cyber Threat Investigation through security questions derived from inves tigation graphs. Real■world security analysts must sift through a large number o f heterogeneous security logs, follow multi■hop chains of evidence to investigat e threats. With the developments of LLMs, building LLM-based agents for automati c threat investigation is a promising direction. We construct a benchmark from a controlled Azure tenant including a SQL environment covering 57 log tables from Microsoft Sentinel and related services, and 7542 generated questions. We lever age security logs extracted with expert-crafted detection logic to build threat investigation graphs, and then generate questions with LLMs using paired nodes o n the graph, taking the start node as background context and the end node as ans wer. Anchoring each question to these explicit nodes and edges not only provides automatic, explainable ground truth answers but also makes the pipeline reusabl e and readily extensible to new logs.
Our comprehensive experiments on the test set with different models confirm the difficulty of the task: the best model so far can achieve a reward of 0.606, lea ving much headroom for future research.
****

Semi-Supervised Neural Super-Resolution for Mesh-Based Simulations
Jiyeon Kim, Youngjoon Hong, Won-Yong Shin
Mesh-based simulations provide high-fidelity solutions to partial differential e quations (PDEs), but achieving such accuracy typically requires fine meshes, lea ding to substantial computational overhead. Super-resolution techniques aim to m itigate this cost by reconstructing high-resolution (HR), high-fidelity solution s from low-cost, low-resolution (LR) counterparts. However, training neural netw orks for super-resolution often demands large amounts of expensive HR supervisio n data. To address this challenge, we propose SuperMeshNet, an HR data-efficient super-resolution framework for mesh-based simulations aided by message passing neural networks (MPNNs). At its core, SuperMeshNet introduces complementary lear ning, a semi-supervised approach that effectively leverages both 1) a small amou nt of paired LR-HR data and 2) abundant unpaired LR data via two jointly trained , complementary MPNN-based models. Additionally, our model is enriched by induct ive biases, which are empirically shown to further improve super-resolution perf ormance. Extensive experiments demonstrate that SuperMeshNet requires 90% less H R data to achieve even lower root mean square error (RMSE) than that of the full y supervised benchmark without the inductive biases. The source code and dataset s are available at https://github.com/jykim-git/SuperMeshNet.git.

RiskZero: Plan More to Risk Less with a Learned Model
Yousef Yassin, Junfeng Wen
AlphaZero and *MuZero* have demonstrated superhuman performance across a range of strategic tasks. Yet their reliance on maximizing expected returns limits th

eir use in real-world settings, where even high-return policies may incur rare b
ut catastrophic failures. We introduce *RiskZero* to address this limitation; th
e first *MuZero*-family method for risk-sensitive decision-making, and planning
with *zero* prior knowledge of environment dynamics. *RiskZero* learns distribut
ional quantities to estimate trajectory-level risk, guiding search toward polici
es that explicitly avoid rare but severe outcomes. We establish theoretical conv
ergence to optimal, stationary risk-sensitive policies and validate our approach
 on environments designed to test risk-sensitive learning from pixels, as well a
s on larger-scale combinatorial tasks. Across all settings, *RiskZero* consisten
tly outperforms state-of-the-art risk-sensitive baselines, and improves sample e
fficiency, providing a general framework for safer and reliable model-based rein
forcement learning under uncertainty.

Evaluating Relational Reasoning in LLMs with REL
Lukas Fesser, Yasha Ektefaie, Ada Fang, Sham M. Kakade, Marinka Zitnik
Relational reasoning is the ability to infer relations that jointly bind multipl
e entities, attributes, or variables. While this capability is essential for sci
entific reasoning, most existing evaluations of relational reasoning in large la
nguage models focus on structured inputs such as tables, graphs, or synthetic re
lational tasks, and do not isolate the sources of difficulty that arise from hig
her-arity relational binding. We study this problem through the lens of *Relatio
nal Complexity (RC)*, defined as the minimum number of independent entities or o
perands that must be simultaneously bound to apply a relation. RC provides a pri
ncipled way to vary reasoning difficulty independently of confounders such as in
put size, vocabulary, and representational choices. Building on RC, we introduce
 REL, a generative benchmark framework spanning algebra, chemistry, and biology
that varies RC within each domain. Evaluating frontier LLMs, we observe a consis
tent and monotonic degradation in performance as RC increases, even when the tot
al number of entities is held fixed. This failure mode persists under increased
test-time compute and with in-context learning, suggesting a limitation tied to
the arity of the required relational binding rather than insufficient inference
steps or exposure to examples. Our results identify a well-defined regime of hig
her-arity reasoning in which current models struggle and motivate revisiting rea
soning benchmarks through the lens of relational complexity.

Chain-of-Goals Hierarchical Policy for Long-Horizon Offline Goal-Conditioned RL
Jinwoo Choi, Sang-Hyun Lee, Seung-Woo Seo
Offline goal-conditioned reinforcement learning remains challenging for long-hor
izon tasks. While hierarchical approaches mitigate this issue by decomposing tas
ks, most existing methods rely on separate high- and low-level networks and gene
rate only a single intermediate subgoal, leaving several structural limitations
in long-horizon decision-making. To address this limitation, we draw inspiration
 from chain-of-thought reasoning and propose the Chain-of-Goals Hierarchical Pol

icy (CoGHP), a novel framework that reformulates hierarchical decision-making as autoregressive sequence modeling within a unified architecture. Given a state and a final goal, CoGHP autoregressively generates a sequence of latent subgoals followed by the primitive action, where each latent subgoal acts as a reasoning step that conditions subsequent predictions. To implement this efficiently, we introduce an MLP-Mixer backbone, which supports cross-token communication and captures structural relationships among state, goal, latent subgoals, and action. Across challenging navigation and manipulation benchmarks, CoGHP consistently outperforms strong offline baselines, demonstrating improved performance on long-horizon tasks. Project page: https://wlsdn9350.github.io/projects/coghp/

Beyond Text-to-SQL: Can LLMs Really Debug Enterprise ETL SQL?
Jing Ye, Yiwen Duan, Yonghong Yu, Xinpei Zhao, Yang Gao, Xing Chen
SQL is central to enterprise data engineering, yet generating fully correct SQL code in a single attempt remains difficult—even for experienced developers and advanced Text-to-SQL LLMs—often requiring multiple debugging iterations. We introduce Squirrel Benchmark, the first benchmark for enterprise-level SQL reasoning and debugging. Our benchmark is built upon two key innovations: (1) an automated construction workflow that employs reverse engineering to systematically inject realistic bugs into large-scale SQL code, enabling scalable and diverse benchmark generation; and (2) an execution-free evaluation framework tailored for enterprise settings, providing fast, accurate, and resource-efficient assessment. Squirrel comprises 469 Squirrel-Syntax queries featuring syntax errors with explicit error messages, and 516 Squirrel-Semantic queries targeting semantic errors where code fails to meet user intent. The queries are highly complex, averaging over 140 lines and featuring deep, wide abstract syntax trees (average width >11, depth >8.7). Evaluation of nearly 30 LLMs reveals a substantial performance gap: the best-performing model, Claude-4-Sonnet, achieves only 36.46% accuracy on Squirrel-Syntax and 32.17% on Squirrel-Semantic, while most models score below 20%. We further explore four solution strategies, identify key challenges, and outline promising directions for enterprise SQL debugging with LLMs.

Iterative Refinement Neural Operators are Learned Fixed-Point Solvers: A Principled Approach to Spectral Bias Mitigation
Xiaotian Liu, Shuyuan Shang, Xiaopeng Wang, Pu Ren, Yaoqing Yang
Neural operators serve as fast, data-driven surrogates for scientific modeling but typically rely on a monolithic, single-pass inference procedure that struggles to resolve high-frequency details, a limitation known as spectral bias. We introduce the Iterative Refinement Neural Operator (IRNO), which augments pre-trained operators with a learned refinement module iteratively applied via fixed-point iteration. IRNO decomposes the prediction into a coarse initialization followed by successive residual corrections, paralleling classical numerical solvers. Under mild assumptions, we establish contraction of the induced operator, ensuring convergence to a unique fixed point. To explicitly target high-frequency errors, we propose a progressive spectral loss that adaptively increases penalty on high-frequency components over refinement steps during training.
Across physical systems, IRNO consistently lowers error, with up to 56.05\% improvement on turbulent flow. On Active Matter, spectral analysis reveals that, relative to base operator, the normalized error ratios decrease to 27.72–36.10\% in low-, 5.07–6.68\% in mid-, and 1.48–2.04\% in high-frequencies, remaining stable beyond the trained iteration count.

Not All Frequencies Are Equal: Energy-Adaptive Diffusion for Time Series Forecasting
Zining Qin, Huiling Qin, Chenhao Wang, Jianxiong Guo, Tian Wang, Weijia Jia
Diffusion models have achieved remarkable success in generative modeling, yet their application to time series forecasting remains suboptimal. Existing approaches apply uniform Gaussian noise across all time steps, assuming all frequency components should be corrupted at the same rate. However, energy distribution across frequencies in time series is highly non-uniform: when uniform noise is added

, high-frequency components are disproportionately overwhelmed while low-frequency trends remain inadequately diffused. We propose EADiff, an energy-adaptive diffusion framework operating in the wavelet domain to address this frequency-energy imbalance. Our key insight is that high-energy components require stronger perturbation while low-energy details need gentler corruption to preserve informative structures. We introduce a learnable modulation mechanism that automatically adjusts noise levels for each frequency band on a per-instance basis. Built upon this adaptive scheduler, we design a conditional diffusion framework where low-frequency trends serve as generation conditions, and noise-level-aware loss weighting naturally emphasizes different frequency components according to their signal characteristics. This cohesive design enables the model to respect the intrinsic multi-scale structure throughout both forward and reverse processes. Extensive experiments demonstrate that EADiff consistently outperforms existing diffusion-based and state-of-the-art deterministic methods.

FlashBlock: Attention Caching for Efficient Long-Context Block Diffusion
Zhuokun Chen, Jianfei Cai, Bohan Zhuang
Generating long-form content, such as minute-long videos and extended texts, is increasingly important for modern generative models. Block diffusion improves inference efficiency via KV caching and block-wise causal inference and has been widely adopted in diffusion language models and video generation. However, in long-context settings, block diffusion still incurs substantial overhead from repeatedly computing attention over an ever-growing KV cache. We identify an underexplored property of block diffusion: cross-step redundancy of attention within a block. Our analysis shows that attention outputs from tokens outside the current block remain largely stable across diffusion steps, while block-internal attention varies significantly. Based on this observation, we propose FlashBlock, a cached block-external attention mechanism that reuses stable attention output, substantially reducing attention computation and KV cache access without modifying the diffusion process.
Moreover, FlashBlock is orthogonal to sparse attention and can be combined as a complementary residual reuse strategy. When integrated, it substantially improves model accuracy under aggressive sparsification by offsetting much of the performance loss induced by sparsity.
Experiments on diffusion language models and video generation demonstrate up to 1.44$\times$ higher token throughput and up to 1.6$\times$ reduction in attention time, with negligible impact on generation quality.
****

Less Token, More Signal: MoE Expert Pruning via Critical Token Selection
Zeliang Zong, Kai Zhang, Yarong Wang, Wenming Tan, Ye Ren, Jilin Hu
Mixture-of-Experts (MoE) architectures provide strong scalability for large language models, but their large expert parameter footprint poses challenges for efficient deployment. Expert pruning is widely used to reduce model size and inference cost; however, existing approaches are token-agnostic, treating all tokens equally when estimating expert importance. This uniform treatment dilutes the contributions of informative tokens and leads to suboptimal pruning decisions. To address this fundamental limitation, we propose **Step** (**S**elective **T**oken-guided **E**xpert **P**runing), a token-aware framework that rethinks expert pruning from the perspective of selective token guidance. By incorporating loss-aware expert evaluation and a lightweight knowledge-preserving mechanism, **Step** reduces information loss while removing redundant experts. Extensive experiments across different MoE architectures and model scales demonstrate the effectiveness of **Step**. On the 30B Qwen3 MoE model with 50\% expert sparsity, **Step** achieves nearly a 50\% reduction in memory usage with minimal performance degradation, delivers a 1.5$\times$ throughput improvement, and completes the entire pruning process within 10 minutes.

SpaceVista: All-Scale Visual Spatial Reasoning from mm to km
Peiwen Sun, Shiqiang Lang, Dongming Wu, Ding Yi, Kaituo Feng, Huadai Liu, Zhen Ye, Rui Liu, Yun-Hui Liu, Jianan Wang, Xiangyu Yue

With the current surge in spatial reasoning, researchers have made significant p
rogress in understanding indoor scenes, but still struggle with more diverse app
lications. This paper aims to advance all-scale spatial reasoning by tackling tw
o key challenges: 1) the heavy reliance on indoor 3D scans and labor-intensive a
nnotations for dataset curation; 2) the absence of all-scale modeling, which oft
en leads to overfitting to single scenes. In this paper, we introduce a holistic
 solution that integrates a structured spatial reasoning knowledge system, scale
-aware modeling, and a progressive training paradigm, as the **first attempt** t
o broaden the scope of all-scale spatial intelligence. Using a task-specific, sp
ecialist-driven automated pipeline, we curate over 38K video scenes across 5 spa
tial scales to create **SpaceVista-1M**, a dataset comprising 1M spatial QAs spa
nning 19 diverse tasks. While specialist models offer valuable domain knowledge,
 they are often unreliable evaluators. Therefore, we build an all-scale benchma
rk with precise annotations by manually recording and retrieving videos. Neverth
eless, naive training with SpaceVista-1M often yields suboptimal results due to
the potential knowledge conflict. Accordingly, we introduce **SpaceVista-7B**, a
 spatial reasoning model that accepts inputs beyond semantics and uses scale as
an anchor for scale-aware experts and progressive rewards. Finally, extensive ev
aluations across 5 benchmarks, including our **SpaceVista-Bench**, demonstrate c
ompetitive performance, showcasing generalization across all scales and scenario
s. All materials will be released at https://mm2km.github.io/.

Learning Biophysical Models of Large-Scale Multineuronal Data To Enable Precise Neurostimulation

Amrith Lotlikar, Ian Christopher Tanoh, Praful K. Vasireddy, Andrew Lanpouthakou
n, Ramandeep Vilkhu, Michael A. Sommeling, A.J. Phillips, Alexander Sher, Alan L
itke, Scott Linderman, EJ Chichilnisky, Subhasish Mitra

Multi-compartment Hodgkin–Huxley (HH) models provide a principled framework for
predicting neural dynamics and responses to electrical stimulation. However, fit
ting HH biophysical parameters typically requires intracellular recordings, whic
h are invasive and low-throughput, limiting the ability to capture the geometry
and cell-specific properties of many neurons in a given neural circuit. Multi-el
ectrode arrays (MEAs) offer a scalable alternative—high-density extracellular me
asurements from full neural populations—but HH model complexity has so far precl
uded reliable biophysical inference from extracellular data alone. Here, we intr
oduce a framework to rapidly infer HH parameters from designed features of extra
cellular MEA measurements by leveraging differentiable biophysical simulation an
d simulation-based inference, unlocking a wide range of downstream applications.
 In this work, we focus on a central goal of translational neuroengineering: pre
dicting neural spiking responses to candidate neurostimulation patterns that wou
ld take hours to measure clinically. To validate our approach, we collected hund
reds of hours of stimulation and recording data from isolated macaque retina wit
h a 30 µm-pitch 512-electrode array. Our framework predicted previously unseen m
ulti-electrode stimulation responses with 90.4\% accuracy using HH models fit fr
om only a few minutes of recording, replacing hours of stimulus testing.

Beyond Single-View Indexing: Structure-Aware Multi-View Retrieval for Knowledge-Based VQA

Hao Wang, Xujia Li, Lei Chen

Knowledge-Based Visual Question Answering (KB-VQA) relies on retrieval from larg
e-scale knowledge bases, yet this stage is often treated simplistically. Existin
g methods typically adopt single-view indexing or naive multi-view fusion, leadi
ng to systematic coverage gaps. In this work, we demonstrate that different view
s exhibit strong complementarity in retrieval. Motivated by this observation, we
 propose SCAR, a Structure-aware Cross-View Retrieval framework that exploits cr
oss-view structural complementarity at inference time without additional trainin
g. SCAR enhances retrieval via structure-aware similarity propagation within eac
h view and explicit cross-view redundancy regulation. Experiments on multiple KB
-VQA benchmarks demonstrate that SCAR substantially improves retrieval recall, a
pproaches retrieval coverage upper bounds, and consistently boosts end-to-end KB

-VQA performance with negligible inference overhead.

Segment-Aligned Policy Optimization for Multi-Modal Reasoning
Lei Gao, Zhuoming Li, Mengxi Jia, Jiakang Yuan, Hongbo Sun, Hao Sun, Xuelong Li
Existing reinforcement learning approaches for Large Language Models typically perform policy optimization at the granularity of individual tokens or entire response sequences. However, such formulations often misalign with the natural step-wise structure of reasoning processes, leading to suboptimal credit assignment and unstable training in multi-modal reasoning tasks. To bridge this gap, we propose Segment-Aligned Policy Optimization (SAPO), a novel reinforcement learning paradigm that treats coherent reasoning steps, rather than tokens or full sequences as fundamental units of policy update. SAPO introduces a step-wise Markov decision process abstraction over reasoning segments, accompanied by segment-level value estimation, advantage computation, and importance sampling mechanisms that are semantically aligned with reasoning boundaries. Experiments on representative reasoning benchmarks demonstrate that SAPO consistently outperforms token-level and sequence-level policy optimization methods, achieving significant accuracy improvements while exhibiting better training stability and value estimation consistency. Our work underscores the importance of aligning reinforcement learning updates with the intrinsic structure of reasoning, paving the way for more efficient and semantically grounded policy optimization in complex reasoning tasks. Code is available at https://github.com/Graysonicc/SAPO.

MoSA: Motion-constrained Stress Adaptation for Mitigating Real-to-Sim Gap in Continuum Dynamics via Learning Residual Anisotropy
Jiaxu Wang, Junhao He, Jingkai SUN, Yi Gu, Yunyang Mo, Jiahang Cao, Qiang Zhang, Renjing Xu
Learning real-world dynamics from visual observations is crucial for various domains. A common strategy is to calibrate simulators by estimating physical parameters, yet accuracy is ultimately bounded by the underlying physical models, which often assume materials are homogeneous and isotropic. Even if reasonable, real-world objects typically exhibit mild anisotropy and heterogeneity. After the near-isotropic backbone is well calibrated, these residual effects become the key bottleneck for further closing the real-to-sim gap. Although neural networks can fit dynamics end-to-end, such black-box modeling discards strong physical priors, leading to poor data efficiency and overfitting.
Therefore, we propose MoSA, a motion-constrained stress adaptation framework that targets these residual effects to further improve real-to-sim dynamics learning. MoSA uses an isotropic model as a physics prior and learns residual stress operators to capture mild anisotropy and heterogeneity. It progressively adapts stresses via microplane-constrained redistribution in a physics-informed cascaded network. We further impose motion constraints by supervising temporal and spatial derivatives of the deformation field. Experimentally, our learned dynamics achieves superior accuracy, generalization, and robustness, while learning physically meaningful residual anisotropy. Finally, we validate MoSA in a robot manipulation setting, showing that better real-to-sim dynamics modeling translates into more reliable sim-to-real transfer.

A^{2}SG: Adaptive and Asymmetric Surrogate Gradients for Training Deep Spiking Neural Networks
Yechan Kang, Yongjin Kweon, Mingyeong Seo, Sohee Park, Yeonguk jeon, Jongkil Park, Hyun Jae Jang, Jaewook Kim, YeonJoo Jeong, Suyoun Lee, Seongsik Park
Training deep spiking neural networks (SNNs) remains challenging due to sharp loss landscapes and temporal inconsistency caused by surrogate gradients. To address these challenges, we propose a unified framework: adaptive and asymmetric surrogate gradients (A^{2}SG). The adaptive gradients adjust an effective window for spatio-temporal adaptation, reducing spatial gradient variation and maintaining directional consistency of gradients over time. The asymmetric gradients reflect neuronal dynamics by assigning larger gradients to neurons with higher membrane potentials, and we prove that they yield lower variation than symmetric surro

gates. Our analysis further establishes a direct connection between local gradie nt variation and the curvature of the loss landscape, providing a principled exp lanation for how A^{2}SG promotes convergence to flatter minima and improves gen eralization. We conduct extensive experiments on diverse models, including CNN-b ased and Transformer-based SNNs, across various tasks such as image classificati on using both static and neuromorphic datasets, as well as segmentation. The res ults demonstrate that A^{2}SG consistently improves accuracy and energy efficien cy, establishing it as a general and reliable solution for training deep SNNs.Ou r code is available at https://github.com/KIST-NCL/A2SG.git.

Omni-Perception Policy Optimization for Multimodal Emotion Reasoning
Zhiyuan Han, Beier Zhu, Wenwen Tong, Pengyang Shao, Peipei Song, Xinyi Wang, Jia ngnan Chen, Lewei Lu, Xun Yang
We find that current emotion-oriented Omni-MLLMs still lack *reliable omni-modal perception*: they (i) underutilize multimodal cues in their reasoning trajector ies and (ii) exhibit unfaithful behavior, often hallucinating modality-specific statements from other modalities.
Building on these insights, we propose **OPPO** (**O**mni-**P**erception **P**ol icy **O**ptimization), a reinforcement learning framework that explicitly optimi zes multimodal perception.
First, an Omni-Perception Reward decomposes ground-truth reasoning into fine-gra ined visual, acoustic, and emotion cues and rewards trajectories that semantical ly recover these cues.
Second, an Omni-Perception Loss compares the policy under full and unimodally ma sked inputs, applying a KL penalty only to modality-specific evidence tokens to suppress cross-modal hallucination.
We further introduce *MEP-Bench*, a diagnostic benchmark that quantifies *utiliz ation* and *faithfulness*. Experiments show that OPPO achieves state-of-the-art performance on MER-UniBench and substantially improves utilization and faithfuln ess scores on MEP-Bench, highlighting the importance of sufficient and faithful omni perception for multimodal emotion reasoning.

Benchmarking Dense and Indiscernible Object Counting with Blueberries
Weihao Bo, Yanpeng Sun, Jingwen Qin, Fei Shen, Xiaofan Li, Zechao Li
Real-world agricultural counting often operates in the extreme regime of \textbf {Dense and Indiscernible Object Counting (DIOC)}, where targets are tiny, cluste red, and highly camouflaged. To facilitate research in this domain, we introduce \textbf{DIOCblueberry}, a large-scale benchmark that pushes the boundaries of v isual perception. Unlike general datasets with salient objects, DIOCblueberry fe atures extreme occlusion and camouflage. Compared to the popular FSC147 benchmar k, it contains \textbf{1.9$\times$ more instances} per image (avg. 108) with an average box pixel ratio that is \textbf{7.9$\times$ smaller}, serving as a rigor ous testbed for model robustness. Standard counting methods struggle in these sc enarios due to severe visual ambiguity and scale mismatch. To address this, we p ropose \textbf{MaskCount}, a coarse-to-fine framework that incorporates semantic guidance. MaskCount leverages Vision-Language Models (CLIP) to generate pseudo segmentation masks for background suppression and employs a contrastive loss to maximize feature discriminability between fruits and foliage. Additionally, we d esign an edge-aware cropping mechanism to resolve boundary truncation in dense c lusters. Extensive experiments demonstrate that MaskCount achieves a new state-o f-the-art, reducing MAE and RMSE by \textbf{49.16\%} and \textbf{70.50\%} respec tively on DIOCblueberry, with strong generalization to other agricultural scenes .

EvReflection: Event-Driven Micro-Dynamics for Reflection Removal
Jiaxiao Wang, Dachun Kai, Huyue Zhu, Quanquan Hu, Zhenyang Xu, Xiaoyan Sun
Despite remarkable progress in reflection removal, current methods primarily exp loit static image priors from a single frame and still suffer from severe residu al artifacts due to the inherent ambiguity between the reflection and transmissi on layers. In this paper, we propose leveraging event signals to break this ambi

guity. By employing event cameras to capture micro-dynamics, we reveal the differential motion between these two layers. We thereby present a novel event-driven reflection removal network, EvReflection, that utilizes these dynamic cues for layer separation. Specifically, we design a Micro-Dynamics Decoupler to disentangle layer-specific motions from event streams as priors, which then guide a Parallax-Attention Rectifier to cleanly remove artifacts from the RGB image. Furthermore, to address data scarcity, we develop a parallax-aware simulation pipeline and construct the EVR^2 benchmark dataset, the first real-world dataset for this task.

Extensive experiments demonstrate that EvReflection achieves state-of-the-art performance on both synthetic and real-world benchmarks, surpassing the best competing method by more than 1.6 dB and 1.2 dB in PSNR, respectively.

The code, dataset, and pre-trained models are available at \href{https://github.com/JiaxiaoWang/EvReflection}{https://github.com/JiaxiaoWang/EvReflection}.

Veda: Scalable Video Diffusion via Distilled Sparse Attention

Shihao Han, Hao Yang, Xiaofeng Mei, Xinting Hu, Yi Jiang, Xiaojuan Qi

Scaling Diffusion Transformers to generate high-resolution, long videos is constrained by the quadratic cost of self-attention, and existing sparse attention methods degrade under high sparsity. We show empirically that generation quality is determined not by the sparsity ratio itself, but by how well the sparse mask aligns with the tile-wise geometry of full attention. Based on this insight, we propose Veda, a distilled sparse attention framework that formulates tile selection as an explicit reconstruction problem from full attention. Veda integrates statistics-aware tile scoring with head-aware tiling to reduce estimation error and structural mismatch, enabling aggressive sparsity. A hardware-efficient tile-skipping kernel converts theoretical sparsity into practical wall-clock speedups. Experiments on large video diffusion models, including Waver and Wan2.1, demonstrate substantial acceleration with no noticeable degradation in generation quality. To generate 720P 10-second videos on Waver-T2V-12B, Veda achieves a 5.1$\times$ end-to-end speedup and a 10.5$\times$ self-attention speedup, reducing attention overhead from 92\% to 50\%. Notably, the gains increase with sequence length, indicating that Veda scales favorably with spatiotemporal resolution across models.

CLIMB: Taming the LoRA Residency Cliff in Multi-LoRA Serving

Haoran Zhang, Zhiyu Liang, ZUO Decheng, Hongzhi Wang

Multi-tenant multi-LoRA serving multiplexes many LoRA adapters on a single GPU under high utilization, where most device memory is reserved for the KV cache, leaving only a small residency budget K for adapters.

In this regime, adapter readiness is atomic: if an adapter is not device-resident, the engine must perform a mandatory fetch, stalling shared execution and amplifying tail latency system-wide.

With only K residency slots, we identify a LoRA residency cliff: once the active adapter working set exceeds K, time-to-first-token (TTFT) tail latency can exhibit a congestion collapse rather than smooth degradation.

To tame this cliff, we propose CLIMB, a minimal ingress controller that enforces feasibility-first admission by queueing non-resident adapters outside the engine, prioritizing critical (VIP) traffic, and rotating background adapters via round-robin.

On a cliff-inducing workload, CLIMB averts collapse, reducing VIP TTFT p99 from 38.7 s to 13.1 s at matched throughput (10.66 rps) by keeping VIP engine latency near 0.13 s and shifting the residual tail into explicit ingress queueing.

Overall, CLIMB shifts fetch-induced stalls from inside the engine to managed ingress queues, mitigating tail amplification without throughput loss in the evaluated settings.

AgentConductor: Topology Evolution for Multi-Agent Competition-Level Code Generation

Siyu Wang, Ruotian Lu, Zhihao Yang, Yuchao Wang, Yanzhou Zhang, Lei Xu, Qimin Xu

, Guojun Yin, Cailian Chen, Xinping Guan
Large language model(LLM)-driven multi-agent systems(MAS) coordinate specialized agents through predefined topologies and show promise for complex tasks such as competition-level code generation. Recent studies demonstrate that carefully designed multi-agent workflows and communication graphs can significantly improve code generation performance by leveraging collaborative reasoning. However, existing methods neither adapt topology density to task difficulty nor refine the topology within an instance using execution feedback, which leads to redundant communication and performance bottlenecks. To address these issues, we propose AgentConductor: a reinforcement learning-optimized MAS with an LLM-based orchestrator agent as its core, which enables end-to-end feedback-driven dynamic generation of interaction topologies. For each query, AgentConductor infers agent roles and task difficulty, then constructs a task-adapted, density-aware layered directed acyclic graph(DAG) topology, underpinned by two key innovations. First, we design a novel topology density function to quantify communication-aware multi-agent interactions. Second, we adopt difficulty interval partitioning to avoid excessive pruning for precise topological density upper bound measurement per difficulty level and finer-grained control. Across five code datasets, AgentConductor outperforms the strongest baseline by up to 14.6\% in pass@1, with 13\% lower topology density and 68\% lower token cost.

PCGS: Deblurring 3D Gaussian Splatting with Patch Comparison
Yilong Li, Bo Pang, Zhongtao Wang, Mai Su, Yisong Chen, Chengwei Pan, Meng GAI, Fei Zhu, Guoping Wang
Recent neural methods, such as 3D Gaussian Splatting, have achieved state-of-the-art rendering quality and speed. However, these methods frequently encounter challenges in regions with overlapping Gaussians, leading to blurring and artifacts in the rendered images. We observed that widely used view-space positional gradients are insufficient for handling such circumstances. To address this, we introduce PCGS, a Patch Comparison Gaussian Splatting method to control the densification of corresponding Gaussians adaptively. Specifically, PCGS divides the rendered image into patches and identifies those with significant errors by comparing the loss between the rendered and ground truth images. Additional densification operations are then applied to the Gaussians in these error-prone regions. Furthermore, to prevent over-densification and redundant Gaussians, we design a Gaussian control strategy to regulate the densification process. Specifically, we set a Gaussian number budget that dynamically changes according to the progress of densification, and sample the Gaussians required for each densification step based on their importance scores. Our method results in significantly fewer artifacts and less blur while maintaining a Gaussian count approximately equal to that of 3DGS. Extensive experiments on multiple standard benchmarks demonstrate the superiority of our approach.
****
SAOT: Self-Supervised Continual Graph Learning with Structure-Aware Optimal Transport
Yuting Zhang, Yanbei Liu, Zhitao Xiao, Lei Geng, Yanwei Pang, Xiao Wang
Self-supervised Continual Graph Learning (CGL) aims to successively learn from a graph sequence with different tasks without label supervision—a paradigm that has attracted widespread attention. Most existing self-supervised CGL methods rely on instance-level consistency objectives that enforce stability of individual node (or node-pair) embeddings. Due to optimizing nodes in isolation, these methods fail to maintain global relational structure, causing inter-node correspondences to progressively distort under continual learning. To this end, we propose a novel Structure-Aware Optimal Transport (SAOT) framework that explicitly captures and preserves relational structure within graph representations across sequential tasks. Specifically, SAOT leverages optimal transport theory to capture global inter-node correspondences, thereby facilitating and enhancing graph representation learning. Simultaneously, SAOT incorporates a cross-task knowledge distillation mechanism to preserve the previous structural knowledge. Extensive experiments on four CGL benchmark datasets demonstrate that SAOT outperforms existin

g self-supervised baselines. In particular, SAOT achieves significant performanc e gains, improving average accuracy by up to 5% on CoraFull-CL and over 15% on P roducts-CL compared with state-of-the-art methods in the Class-IL setting.

MoshiRAG: Asynchronous Knowledge Retrieval for Full-Duplex Speech Language Model s

Chung-Ming Chien, Manu Orsini, Eugene Kharitonov, Neil Zeghidour, Karen Livescu, Alexandre Défossez

Speech-to-speech language models have recently emerged to enhance the naturalnes s of conversational AI.
In particular, full-duplex models are distinguished by their real-time interacti vity, including handling of pauses, interruptions, and backchannels.
However, improving their factuality remains an open challenge.
While scaling the model size could address this gap, it would make real-time inf erence prohibitively expensive.
In this work, we propose Moshi-RAG, a modular approach that combines a compact f ull-duplex interface with selective retrieval to access more powerful knowledge sources.
Our asynchronous framework enables the model to identify knowledge-demanding que ries and ground its responses in external information.
By leveraging the natural temporal gap between response onset and the delivery o f core information, the retrieval process can be completed while maintaining a n atural conversation flow.
With this approach, Moshi-RAG achieves factuality comparable to the best publicl y released non-duplex speech language models while preserving the interactivity inherent to full-duplex systems.
Moreover, our flexible design supports plug-and-play retrieval methods without r etraining and demonstrates strong performance on out-of-domain mathematical reas oning tasks.

BASIL: Scalable Bayesian Semi-supervised Clustering with Feature Selection and A daptive Constraint Weighting

Luwei Wang, Dagmara Panas, KE WANG, Bruce Guthrie, Sohan Seth

Constrained clustering incorporates prior knowledge in the form of pairwise cons traints to guide data partitioning. While effective, existing Bayesian approache s are often limited in scalability to large datasets and provide weak interpreta bility due to the lack of explicit feature relevance modeling. We propose BASIL, a scalable Bayesian semi-supervised clustering framework that leverages stochas tic variational inference to jointly infer cluster assignments and feature impor tance weights. This joint formulation enables the identification of discriminati ve features consistent with the imposed constraints. To robustly handle noisy or inconsistent supervision, BASIL introduces an adaptive constraint-weighting mec hanism that down-weights unreliable constraints. Experiments on synthetic and re al-world benchmarks show BASIL attains competitive accuracy while reducing train ing time by over $96\\%$ on large datasets, learns interpretable cluster-specifi c feature importance maps, and remains robust to up to $30\\%$ noisy constraints under sufficient supervision. We further demonstrate applicability to large-sca le health data, including medical imaging and electronic health records.

Attacking Gray-Box Large Vision-Language Models with Adaptive SVD-Structured Adv ersarial Alignment

Daizong Liu, Xiaowen Cai, Junhao Dong, Zhongliang Guo, Xiaoye Qu, Runwei Guan, X iang Fang, Dengpan Ye

Large vision-language models (LVLMs) have demonstrated remarkable capabilities a cross a wide range of multimodal reasoning tasks. However, recent research shows that they are susceptible to adversarial examples. Existing LVLM attack methods are generally deployed in the white- or black-box setting, which severely rely on full-model gradients or elaborated transfer strategies, resulting in large re source costs. To this end, this paper focuses on a more efficient gray-box attac k setting by solely accessing LVLM's vision encoder. Instead of using target ima

ges as the adversarial guidance, our main goal is to perturb the visual feature to best match more natural attacker-chosen target texts. Specifically, we develop a global semantic alignment module to project the visual features onto the SVD-structured subspace spanned by the textual semantics. We also propose to align detailed visual features with multi-context semantic texts extended by LLMs over discrete distributions via optimal transport. Extensive experiments demonstrate the superiority of the proposed method, while our attack is further proven to achieve great transferability across various LVLMs with CLIP-aware transfer designs.

****

Adaptive Multiscale Binary Expansion Tests for Independence

Yang Yang, Duo Zheng, Sandeep Jain, Kai Zhang, Ping-Shou Zhong

This paper introduces a new family of adaptive, distribution-free independence tests for multivariate random vectors based on binary expansion coefficients, supported by a tractable asymptotic theory. Our first key contribution establishes a general equivalence between independence testing and testing cross-covariances among exponentially many binary expansion interaction coefficients, applicable to broad sample spaces and not limited to kernel-induced representations. While this exponential interaction structure makes naive construction and computation infeasible, we overcome this challenge by reformulating the proposed tests as a class of U-statistics and deriving an explicit kernel representation that enables scalable and efficient computation. Exploiting the multiscale nature of binary expansions, the proposed framework automatically adapts to unknown dependence structures by selectively truncating higher-order interactions, yielding both strong power and clear interpretability. To further enhance power and computational efficiency, we introduce an adaptive weighted aggregation procedure, termed wa-dCoBET, which combines a baseline Covariance Binary Expansion Test (CoBET) with a distance-measure–based CoBET. Extensive simulations and a real-data application demonstrate that wa-dCoBET consistently matches or outperforms HSIC and distance covariance, particularly in higher-dimensional and non-monotone settings, while maintaining accurate type I error control.

****

Error Propagation Mechanisms and Compensation Strategies for Quantized Diffusion Models

Songwei Liu, Chao Zeng, Chenqian Yan, Xurui Peng, XING WANG, Fangmin Chen, Xing Mei

Diffusion models have transformed image synthesis by establishing unprecedented quality and creativity benchmarks. Nevertheless, their large-scale deployment faces challenges due to computationally intensive iterative denoising processes. Although post-training quantization (PTQ) provides an effective pathway for accelerating sampling, the iterative nature of diffusion models causes stepwise quantization errors to accumulate progressively during generation, inevitably compromising output fidelity. To address this challenge, we develop a theoretical framework that mathematically formulates error propagation in Diffusion Models (DMs), deriving per-step quantization error propagation equations and establishing the first closed-form solution for cumulative error. Building on this theoretical foundation, we propose a timestep-aware cumulative error compensation scheme. Extensive experiments on multiple image datasets demonstrate that our compensation strategy effectively mitigates error propagation, significantly enhancing existing PTQ methods. Specifically, it achieves a 1.2 PSNR improvement over SVDQuant on SDXL W4A4, while incurring only an additional $<$ 0.5\% time overhead.

ReLAM: Learning Anticipation Model for Rewarding Visual Robotic Manipulation

Nan Tang, Jing-Cheng Pang, Guanlin Li, Chao Qian, Yang Yu

Reward design remains a critical bottleneck in visual reinforcement learning (RL) for robotic manipulation. In simulated environments, rewards are conventionally designed based on the distance to a target position. However, such precise positional information is often unavailable in real-world visual settings due to sensory and perceptual limitations. In this study, we propose a method that implicitly infers spatial distances through keypoints extracted from images. Building

on this, we introduce Reward Learning with Anticipation Model (ReLAM), a novel framework that automatically generates dense, structured rewards from action-free video demonstrations. ReLAM first learns an anticipation model that serves as a planner and proposes intermediate keypoint-based subgoals on the optimal path to the final goal, creating a structured learning curriculum directly aligned with the task's geometric objectives. Based on the anticipated subgoals, a continuous reward signal is provided to train a low-level, goal-conditioned policy under the hierarchical reinforcement learning (HRL) framework with provable sub-optimality bound. Extensive experiments on complex, long-horizon manipulation tasks show that ReLAM significantly accelerates learning and achieves superior performance compared to SOTA methods.

****

Near-Minimax Multi-Objective RL under Predictable Adversarial Preferences and Preference-Free Exploration in Linear MDPs

Mingxi Hu, Meiling Yu

Multi-objective reinforcement learning (MORL) must often support preferences that change online or are specified only after data collection.

We study finite-horizon MORL with vector feedback in linear MDPs under two protocols: (i) predictable adversarial preferences revealed before each episode, and (ii) reward-free preference-free exploration (PFE), where exploration observes only transitions and must later answer arbitrary preference queries.

Standard reductions are protocol-unsafe: re-scalarizing past stochastic rewards with future weights breaks the martingale structure needed for self-normalized confidence bounds, and hypervolume evaluation must account for episode-start randomization, which yields a deployable convex hull of return vectors.

We propose a protocol-safe reward interface that estimates each reward coordinate via regression and performs scalarization only at query time, and we formalize deployable hypervolume semantics with a stability chain from support-function error to hypervolume error.

Consequently, we obtain filtration-safe regret bounds for any predictable preference sequence without discretizing the simplex (only $\log m$ dependence) and matching near-minimax rates in linear MDPs, as well as sharp reward-free PFE guarantees: a (near-)minimax decision-optimal query answering rate $\tilde{O}(d^2 U_{\mathrm{ret}}^2/\varepsilon^2)$ and a tight separation from explicit transition-model recovery $\Theta(d(|\mathcal{S}|-1)/\varepsilon_P^2)$.

These results connect online learning, preference-free deployment, and hypervolume-aware evaluation through a single protocol-aligned theory.

****

Jailbreaking Vision-Language Models Through the Visual Modality

Aharon Azulay, Jan Dubi■ski, Zhuoyun Li, Atharv Mittal, Yossi Gandelsman

The visual modality of vision-language models (VLMs) is an underexplored attack surface for bypassing safety alignment. We introduce four jailbreak attacks exploiting the vision component: (1) encoding harmful instructions as visual symbol sequences with a decoding legend, (2) replacing harmful objects with benign substitutes (e.g., bomb $\rightarrow$ banana) then prompting for harmful actions using the substitute term, (3) replacing harmful text in images (e.g., on book covers) with benign words while visual context preserves the original meaning, and (4) visual analogy puzzles whose solution requires inferring a prohibited concept. Evaluating across six frontier VLMs, our visual attacks bypass safety alignment and expose a cross-modality alignment gap: text-based safety training does not automatically generalize to harmful intent conveyed visually. For example, our visual cipher achieves 40.9\% attack success on Claude-Haiku-4.5 versus 10.7\% for an equivalent textual cipher. To further our insight into the attack mechanism, we present preliminary interpretability and mitigation results. These findings highlight that robust VLM alignment requires treating vision as a first-class target for safety post-training.

Connecting Independently Trained Modes via Layer-Wise Connectivity

Yongding Tian, Zaid Al-Ars, Maksim Kitsak, H Peter Hofstee

Empirical studies have shown that continuous low-loss paths can be constructed b

etween independently trained neural network models.
This phenomenon, known as mode connectivity, refers to the existence of such pat
hs between distinct modes-i.e., well-trained solutions in parameter space.
However, existing empirical methods do not reliably connect independently traine
d modes and have been evaluated mainly on a narrow set of architectures (e.g., b
asic CNNs, VGG, and ResNet), leaving their effectiveness on newer models unclear
.
In this work, we propose a new empirical algorithm for connecting independently
trained modes that generalizes beyond traditional architectures and supports a b
roader range of networks, including MobileNet, ShuffleNet, EfficientNet, RegNet,
 Deep Layer Aggregation (DLA), and Compact Convolutional Transformers (CCT).
In addition to broader applicability, the proposed method yields more consistent
 connectivity paths across independently trained mode pairs and supports connect
ing modes obtained with different training hyperparameters.

Modality-Decoupled Online Recursive Editing
Siyuan Li, Youyuan Zhang, Fangming Liu, Jing Li
Online model editing for multimodal large language models (MLLMs) requires assim
ilating a stream of corrections under tight compute and memory budgets. Yet edit
ors developed for text-only LLMs often degrade on MLLMs: visually dominant activ
ations skew the statistics that shape updates, causing *cross-modal conflict*, w
hile sequential writes become entangled in a shared edit space and amplify long-
horizon interference, causing *inter-edit interference*. To address these, we pr
opose **M-ORE**, a modality-decoupled online recursive editor for lifelong MLLM
adaptation. M-ORE is derived from a unified proximal-projection formulation and
admits a closed-form update with a Sherman-Morrison recursion, yielding constant
 per-edit overhead. It maintains module-wise locality statistics for the text st
ack and the visual projector to avoid visually dominated update shaping and perf
orms continual updates in a fixed orthogonal low-rank edit subspace via a Sherma
n-Morrison recursion to mitigate long-horizon interference. Experiments on multi
ple MLLM backbones and online editing benchmarks show that our M-ORE method cons
istently improves reliability, generality, and locality over strong baselines, w
hile achieving favorable quality-efficiency scaling. Our code is publicly availa
ble at https://github.com/lab-klc/M-ORE.

The Shadow Price of Reasoning: Economic Perspective on Optimal Budget Allocatio
n for LLMs
Xu Wan, Speed Zhu, Jianwei Cai, Guang Chen, XiMing Huang, Wiggin Zhou, Mingyang
Sun
Inference-time scaling has emerged as a critical avenue for enhancing Large Lang
uage Models' performance, yet real-world deployment is constrained by strict com
putational budgets. In this work, we formulate inference budget allocation as a
global constrained optimization problem governed by economic principles. By mode
ling per-query reasoning utility with a shifted-surge function, we derive an opt
imal allocation policy based on a global shadow price that equilibrates marginal
 utility under resource scarcity.
Based on this theory, we propose Constrained Latent-utility Equilibrium Allocati
on for Reasoning (CLEAR). It performs rational abandonment and reallocates resou
rces from insolvent queries to solvable queries near their emergence thresholds.

Extensive experiments on several reasoning tasks with different traffic streams
demonstrate that CLEAR significantly improves the Pareto frontier of total token
 cost versus mean accuracy. In resource-scarce regimes, CLEAR achieves up to a 3
× improvement in global accuracy compared to uniform allocation.

Approximate Proportionality in Online Fair Division
Davin Choo, Winston Fu, Tzeh Yuan Neoh, Tze-Yang Poon, Nicholas Teh
We study the online fair division problem, where indivisible goods arrive sequen
tially and must be allocated immediately and irrevocably. Prior work establishes
 strong impossibility results for approximating classic notions such as envy-fre

eness up to one good (EF1) and maximin share (MMS) in this setting, but the appr oximability of proportionality up to one good (PROP1) has remained unresolved. W e resolve this gap in two steps. First, we show that three natural greedy alloca tion rules (standard baselines in fair division) fail to guarantee any multiplic ative approximation to PROP1 against an adaptive adversary. These limitations mo tivate two relaxations: (i) restricting attention to a non-adaptive adversary, a nd (ii) incorporating coarse predictions in the spirit of learning-augmented alg orithms. Under a non-adaptive adversary, we show that the uniform random allocat ion achieves a meaningful PROP1 approximation with high probability, and this gu arantee is essentially tight for this approach; moreover, when item values are s ufficiently small, the allocation is near-PROP1 with high probability. Finally, given maximum item value (MIV) predictions, we design an online algorithm that a chieves robust approximation guarantees for PROP1, and degrades gracefully under one-sided prediction error. In contrast, we show that EF1, MMS, and PROPX remai n inapproximable even with perfect MIV predictions.

Formalizing the Binding Problem

Lianghuan Huang, Yihao Li, Saeed Salehi, Yingshan Chang, Ansh Soni, Konrad Kordi ng

Representations of the world, arguably, contain information about features (e.g. something is blue, something is a circle) but also information about which feat ures are part of the same object (e.g. the circle is blue), which we call bindin g information. Any system with the ability to understand scenes with multiple ob jects must be able to solve the binding problem: it needs to know which features belong together. However, despite work showing that Vision Transformers (ViTs) know which patches belong together, it is not known whether current deep learnin g models learn to exhibit binding information, i.e., for features. We may believ e that there is not much binding information, after all misattributing features to wrong objects is a common failure of ViT-based architectures, especially in s cenes with objects sharing features. Here we formalize the binding problem with an information-theoretic approach, and introduce a probing method to measure bin ding information in model representations. We perform experiments on ViTs, measu ring binding from different components of the architecture, such as the image su mmary token [CLS] or the spatial tokens. We use datasets with different binding challenges, such as feature sharing, occlusion, and natural features, while comp aring the performance of several pre-trained ViTs. Overall, our research demonst rates binding as a key ingredient to strong visual recognition and reasoning.

How do Humans Process AI-generated Hallucination Contents: a Neuroimaging Study

Shuqi Zhu, Yi Zhong, Ziyi Ye, Bangde Du, Yujia Zhou, Qingyao Ai, Yiqun LIU

While AI-generated hallucinations pose considerable risks, the underlying cognit ive mechanisms by which humans can successfully recognize or be misled by these hallucinations remain unclear. To address this problem, this paper explores huma ns' neural dynamics to characterize how the brain processes hallucinated content . We record EEG signals from 27 participants while they are performing a verific ation task to judge the correctness of image descriptions generated by a multi-m odal large language model (MLLM). Based on an averaged event-related potential (ERP) study, we reveal that multiple cognitive processes, e.g., semantic integrat ion, inferential processing, memory retrieval, and cognitive load, exhibit disti nct patterns when humans process hallucinated versus non-hallucinated content. N otably, neural responses to hallucinations that were misjudged versus correctly judged by human participants showed significant differences.

This indicates that misjudged AI-generated hallucinations failed to trigger the standard neurocognitive fact verification pathway. The detailed code can be acce ssed openly through https://github.com/Promise-Z5Q2SQ/EEG-Hallucination.

MGAL: A Multilingual Granularity-Aware Long-Context Benchmark

Chunhan Li, Chenglin Xu, Zongyang Zhang, Jiale Liu, Zhuoxi Rao, Xudong jia, JUNX IU HE, Menglin Yang, Wenjuan Gong, Zhengzhe Liu, Chengwei Qin

Evaluation of long-context Large Language Models (LLMs) has advanced rapidly. Ho

wever, most existing benchmarks are limited to the document level and focus main ly on high-resource languages, leaving many fine-grained challenges insufficient ly evaluated. To address this gap, we present MGAL, the first multilingual, gran ularity- and position-aware long-context benchmark. MGAL is constructed from Uni ted Nations (UN) reports spanning 8K to 128K tokens across the six official UN l anguages. It covers four coherent levels of linguistic granularity (word, senten ce, paragraph, and document) and further stratifies entries by their position wi thin the document (begin, middle, and end), indexed at both the document and par agraph levels. This design enables systematic diagnosis of multilingual long-con text comprehension across different granularities.

Through extensive experiments and analyses, we find that: (1) LLMs perform well at word-level tasks but struggle with coarser-grained ones; and (2) Closed-sourc e models retain a clear performance advantage in lower-resource languages.
We further identify two new challenges: (1) Under local semantic crowding, where neighboring sentences share topics and entities, models tend to follow surface cues (e.g., connectives like 'however' or repeated entities) rather than the dis course role of the sentence in surrounding context (e.g., background, outcome); and (2) A gap between fluency and consistency in generated outputs, where models produce text that reads smoothly but drifts from the source facts. In addition, we observe several patterns in line with prior studies, including reliance on n earby evidence and reuse of options under uncertainty.

Efficient Equivariant High-Order Crystal Tensor Prediction via Cartesian Local-E nvironment Many-Body Coupling
Dian Jin, Yancheng Yuan, Xiaoming Tao
End-to-end prediction of high-order crystal tensor properties from atomic struct ures remains challenging: while spherical-harmonic equivariant models are expres sive, their Clebsch-Gordan tensor products incur substantial compute and memory costs for higher-order targets. We propose the Cartesian Environment Interaction Tensor Network (CEITNet), an approach that constructs a multi-channel Cartesian local environment tensor for each atom and performs flexible many-body mixing v ia learnable channel-space interactions. By performing learning in channel space and using Cartesian tensor bases to assemble equivariant outputs, CEITNet enabl es efficient construction of high-order tensor.
Across benchmark datasets for order-2 dielectric, order-3 piezoelectric, and ord er-4 elastic tensor prediction, CEITNet surpasses prior high-order prediction me thods on key accuracy criteria while offering high computational efficiency.
****

Value Aggregation with Uncertainty in Online Decentralized MARL
Ziyue Chu, Leonardo Stella
Multi-agent reinforcement learning (MARL) has received increasing attention for solving complex decision-making tasks. Networked MARL approaches offer a decentr alized solution for parameter sharing to accelerate training via value aggregati on. However, existing federated aggregations rely on convex averaging that may f ail to converge to global optima and cause learning rollback in the online learn ing setting. In this paper, we formally characterize the learning rollback pheno menon arising from aggregating value estimates with unequal uncertainty under he terogeneous online update depths. We propose a novel adaptive global consensus (AGC) mechanism for Q-value aggregation in decentralized MARL policy evaluation, which dynamically adjusts aggregation weights based on agents’ uncertainty. We e stablish theoretical guarantees on accelerated convergence and bounded learning variance with empirical validations, advancing the state-of-art MARL theory.

Rethinking Visual Autoregressive Sampling with Information-Grounding Guidance
Ky Dan Nguyen, Hoang Lam Tran, Anh-Dung Dinh, Daochang Liu, Weidong Cai, Xiuying Wang, Chang Xu
Autoregressive (AR) models based on next-scale prediction are rapidly emerging a s a powerful tool for image generation, but they face a critical weakness: infor mation inconsistencies between patches across timesteps introduced by progressiv

e resolution scaling. These inconsistencies scatter guidance signals, causing th
em to drift away from conditioning information and leaving behind ambiguous, unf
aithful features. We tackle this challenge with Information-Grounding Guidance (
IGG), a novel mechanism that anchors guidance to semantically important regions
through attention. By adaptively reinforcing informative patches during sampling
, IGG ensures that guidance and content remain tightly aligned. Across both clas
s-conditioned and text-to-image generation tasks, IGG delivers sharper, more coh
erent, and semantically grounded images, setting a new benchmark for AR-based me
thods.

Efficient, Property-Aligned Fan-Out Retrieval via RL-Compiled Diffusion
Pengcheng Jiang, Judith Yue Li, Moonkyung Ryu, Lily Hu, Kun Su, Zhong Yi Wan, Li
am Hebert, Hao Peng, Jiawei Han, Dima Kuzmin, Craig Boutilier
Many modern retrieval problems are set-valued:
given a broad intent, the system must return
a collection of results that optimizes higherorder
properties (e.g., diversity, coverage, complementarity,
coherence) while staying grounded
to a fixed database. Set-valued objectives are
inherently non-decomposable and are not captured
by existing supervised (query, content)
datasets which only prioritize top-1 retrieval.
While reinforcement learning (RL) can optimize
set-level objectives via interaction, deploying
an RL-tuned LLM for fan-out retrieval is
prohibitively expensive at query time. Conversely,
diffusion-based generative retrieval enables
efficient single-pass fan-out in embedding
space, but requires objective-aligned training targets.
To address these issues, we propose R4T
(Retrieve-for-Train), which uses RL once as an
objective transducer in a three step process: (i)
train a fan-out LLM with composite set-level rewards,
(ii) synthesize objective-consistent training
pairs, and (iii) train a lightweight diffusion
retriever to model the conditional distribution of
set-valued outputs. Across Polyvore and a music
playlist dataset, R4T improves retrieval quality
over strong baselines while reducing query-time
fan-out latency by an order of magnitude.

Energy-Structured Low-Rank Adaptation for Continual Learning
Longhua Li, Lei Qi, Qi Tian, Xin Geng
While orthogonal subspace methods try to mitigate task interference in Continual
 Learning (CL), they often suffer from energy diffusion across the basis, hinder
ing knowledge compaction and exhausting capacity for future tasks. We observe th
at output feature drift induced by parameter updates is inherently low-rank, and
 theoretically prove that preserving parameters along the principal directions o
f this drift minimizes the output reconstruction error. Motivated by this, we pr
opose **E**nergy-Concentrated and **E**nergy-Ordered **Lo**w-**R**ank **A**dapta
tion (E^2-LoRA). By explicitly ordering and concentrating knowledge into leadi
ng ranks, E^2-LoRA frees capacity for subsequent tasks. Furthermore, we design
 a dynamic rank allocation strategy to balance stability and plasticity by joint
ly optimizing energy retention and model plasticity. Extensive experiments acros
s multiple benchmarks demonstrate that E^2-LoRA achieves state-of-the-art perf
ormance.
****

Constrained Meta Reinforcement Learning with Provable Test-Time Safety
Tingting Ni, Maryam Kamgarpour
Meta reinforcement learning (RL) allows agents to leverage experience across a d

istribution of tasks on which the agent can train at will, enabling faster learn ing of optimal policies on new test tasks. Despite its success in improving samp le complexity on test tasks, many real-world applications, such as robotics and healthcare, impose safety constraints during testing. Constrained meta RL provid es a promising framework for integrating safety into meta RL. An open question i n constrained meta RL is how to ensure safety of the policy on the real-world te st task, while reducing the sample complexity and thus, enabling faster learning of optimal policies. To address this gap, we propose an algorithm that refines policies learned during training, with provable safety and sample complexity gua rantees for learning a near optimal policy on the test tasks. We further derive a matching lower bound, showing that this sample complexity is tight.

Unified Safe In-context Image Generation in Multimodal Diffusion Transformers vi a Restricting Unsafe Information Flows

Xiang Yang, Feifei Li, Mi Zhang, Geng Hong, Xiaoyu You, Mi Wen, Min Yang

Diffusion transformers (DiTs) equipped with multimodal attention (MM-Attn) have become a dominant paradigm for image generation. However, preventing the generat ion of harmful content remains a critical challenge, particularly in image-to-im age (I2I) editing tasks.

Existing safety mechanisms are primarily designed for text-to-image (T2I) synthe sis or U-Net-based architectures, which limits their effectiveness for unified s afety mitigation in DiT-based frameworks. To bridge this gap, we propose Unified Visual Safety Regulator (UVR), a training-free safe generation framework that r egulates unsafe semantics in generated images. UVR is grounded in an analysis of attention dynamics from the perspective of information flow in MM-Attn. We iden tify a task-independent start-up stage, during which unsafe semantics in output patches rapidly emerge and can be accurately localized, followed by task-specifi c semantic amplification and interference stages, where harmful signals are furt her propagated and entangled with benign content. Based on these observations, U VR mitigates unsafe generation through unified, targeted attention modulation an d explicit restriction of harmful information flow over the identified unsafe ou tput patches. Experiments across various concepts show that UVR achieves state-o f-the-art safety performance by achieving 91% and 77% erase rate in image synth esis and editing tasks, while preserving visual quality and fidelity with minima l degradation. Code is available at https://github.com/deng12yx/UVR.

DECO: Decoupled Multimodal Diffusion Transformer for Bimanual Dexterous Manipula tion with a Plugin Tactile Adapter

Xukun Li, Yu Sun, Lei Zhang, Bo-Sheng Huang, Yibo Peng, Yuan Meng, Haojun Jiang, Shaoxuan Xie, Guocai Yao, Alois Knoll, Zhenshan Bing, Xinlong Wang, Zhenguo Sun

Bimanual dexterous manipulation relies on integrating multimodal inputs to perfo rm complex real-world tasks. To address the challenges of effectively combining these modalities, we propose DECO, a decoupled multimodal diffusion transformer that disentangles vision, proprioception, and tactile signals through specialize d conditioning pathways, enabling structured and controllable integration of mul timodal inputs, with a lightweight adapter for parameter-efficient injection of additional signals.

Alongside DECO, we release DECO-50 dataset for bimanual dexterous manipulation w ith tactile sensing, consisting of 50 hours of data and over 5M frames, collecte d via teleoperation on real dual-arm robots.

We train DECO on DECO-50 and conduct extensive real-world evaluation with over 2 ,000 robot rollouts. Experimental results show that DECO achieves the best perfo rmance across all tasks, with a 72.25\% average success rate and a 21\% improvem ent over the baseline. Moreover, the tactile adapter brings an additional 10.25\ % average success rate across all tasks and a 20\% gain on complex contact-rich tasks while tuning less than 10\% of the model parameters.
****

Reasoning Quality Emerges Early: Data Curation for Reasoning Models

Hongyi Henry Jin, Wenhan Yang, Meysam Ghaffari, Carlos Morato, Baharan Mirzasole iman

Supervised fine-tuning (SFT) on a small, high-quality set of long reasoning traces is an effective approach for eliciting strong reasoning capabilities in Large Language Models (LLMs). However, existing methods for curating high-quality SFT data rely heavily on strong reasoning models to filter examples based on diversity and difficulty, making the curation process costly while often yielding suboptimal data quality. In this work, we show that diverse and challenging reasoning examples can be identified using only the initial reasoning tokens. Specifically, we demonstrate that difficult problems can be reliably detected based on the loss of the first 100 reasoning tokens evaluated at a randomly perturbed checkpoint of the pretrained model. We further show that examples exhibiting similar loss patterns over their first 1k reasoning tokens across a small number of perturbed checkpoints extrapolating along the fine-tuning trajectory provably induce similar gradients. We validate our approach through extensive experiments on fine-tuning Qwen2.5-7B and Llama3.1-8B models on the M23K medical reasoning and OpenThoughts-Math datasets. Our method outperforms existing baselines by up to 1.7% while being 91% more token efficient.

Understanding Dynamics of Adam in Zero-Sum Games: An ODE Approach

Yi Feng, Weiming Ou, Xiao Wang

The remarkable success of the Adam in training neural networks has naturally led to the widespread use of its descent-ascent counterpart, Adam-DA, for solving zero-sum games. Despite its popularity in practice, a rigorous theoretical understanding of Adam-DA still lags behind. In this paper, we derive ordinary differential equations (ODEs) that serve as continuous-time limits of the Adam-DA. These ODEs closely approximate the discrete-time dynamics of Adam-DA, providing a tractable analytical framework for understanding its behavior in zero-sum games. Using this ODE approach, we investigate two fundamental aspects of Adam-DA: local convergence and implicit gradient regularization. Our analysis reveals that the roles of the first- and second-order momentum parameters in zero-sum games are exactly the opposite of their well-documented effects in minimization problems. We validate these predictions through GAN experiments across multiple architectures and datasets, demonstrating the practical implications of this reversed momentum effect.

Domain Adaptive Object Detection via Dynamic Causal Refinement

Zeyu Ma, Jiaqi Huang, Yitong Qin, Zheng Ziqiang, Jiwei Wei, Jie Zou, Yang Yang, Heng Tao Shen

Domain Adaptive Object Detection (DAOD) addresses the challenge of transferring object detectors from labeled source domains to unlabeled target domains.

Existing domain adaptation methods primarily rely on feature distribution alignment, which enhances domain-invariant features (statistical invariance) but also inadvertently increases inherent domain-common spurious factors (e.g., common environmental contexts), which act as shortcut features rather than the true causal factors for object classification.

We propose Dynamic Causal Refinement (DCR), a novel framework that establishes a closed-loop feedback mechanism between data augmentation and model optimization to progressively refine causal features.

Specifically, we design Semantic Prediction Consistency (SPC) to filter domain-specific spurious factors and establish a robust statistical invariance, and Discrepancy-Guided Causal Refinement (DGCR) to actively suppress the dependence on domain-common spurious factors via spectral perturbation for causal refinement.

This process encourages the detector to suppress its reliance on shortcut features and instead prioritize semantically meaningful causal representations.

Extensive experiments on standard benchmarks demonstrate that our method outperforms state-of-the-art counterparts significantly.

AgentSelect: Benchmark for Narrative Query-to-Agent Recommendation

Yunxiao Shi, Wujiang Xu, Tingwei Chen, Haoning Shang, Ling Yang, Yunfeng Wan, Zhuo Cao, Xing Zi, Dimitris N. Metaxas, Min Xu

LLM agents are rapidly becoming a practical interface for task automation, yet s

electing suitable deployable configurations remains underexplored. Existing LLM leaderboards and tool/agent benchmarks evaluate components in isolation and are fragmented across tasks, metrics, and candidate pools, leaving a critical research gap: there is little query-conditioned supervision for learning to recommend end-to-end compositional agent configurations.
We introduce AgentSelect, a benchmark that reframes agent selection as narrative query-to-agent recommendation over capability profiles. AgentSelect systematically converts heterogeneous evaluation artifacts into unified positive-only interaction data, comprising 111,179 queries, 107,721 deployable agents, and 251,103 interaction records from 40+ sources across LLM-only, toolkit-only, and compositional agents.
Our analyses reveal a shift from dense head reuse to long-tail, near one-off supervision, where ID-based interaction methods become fragile and reliable recommendation increasingly requires content-aware intent-to-capability matching. We validate the synthesized supervision through counterfactual, ablation, and show practical transferability on the MuleRun agent marketplace and a small-scale end to end Agno deployment study.
Overall, AgentSelect provides the first unified data and evaluation infrastructure for agent recommendation, which establishes a reproducible foundation to study and accelerate the emerging agent ecosystem. The resources are available at \footnote{\url{https://github.com/Ancientshi/AgentSelect}}.
****
Singular Proxies for Adaptive Caching in Diffusion Language Models
Wenhao Sun, Rong-Cheng Tu, Yifu Ding, Zhao Jin, Jingyi Liao, Yongcheng Jing, Dacheng Tao
While Diffusion Language Models (DLMs) offer a flexible, arbitrary-order alternative to the autoregressive paradigm, their non-causal nature precludes standard KV caching, forcing costly hidden state recomputation at every decoding step.
Existing caching approaches reduce this cost by selective hidden state updates; however, they are still limited by (i) computationally costly token-wise update identification heuristics and (ii) rigid, uniform budget allocation that fails to account for heterogeneous hidden- tate dynamics.
To address these challenges, we present SPA-Cache that jointly optimizes update identification and budget allocation.
First, we derive a low-dimensional singular proxy that enables the identification of update-critical tokens in a low-dimensional subspace, substantially reducing the overhead of update identification.
Second, motivated by the layer-wise heterogeneity in hidden state dynamics, we introduce an adaptive strategy that allocates fewer updates to stable layers without degrading generation quality.
Together, these contributions significantly improve the efficiency of DLMs, yielding up to an $8\times$ throughput improvement over vanilla models decoding and a 2-$4\times$ speedup over existing caching baselines.
****
Towards a Science of AI Agent Reliability
Stephan Rabanser, Sayash Kapoor, Peter Kirgis, Kangheng Liu, Saiteja Utpala, Arvind Narayanan
AI agents are increasingly deployed to execute important tasks. While rising accuracy scores on standard benchmarks suggest rapid progress, many agents still continue to fail in practice. This discrepancy highlights a major limitation of current evaluations: focusing on a single metric is not enough to understand agent behavior. Notably, it ignores whether agents behave consistently across runs, withstand perturbations, fail predictably, or have bounded error severity. Grounded in safety-critical engineering, we provide a holistic performance profile consisting of twelve metrics that decompose agent reliability along four key dimensions: *consistency*, *robustness*, *predictability*, and *safety*. Evaluating 15 models across two complementary benchmarks, we find that recent capability gains have only yielded small improvements in reliability. By exposing these persistent limitations, our metrics complement traditional evaluations while offering tools for reasoning about how agents perform, degrade, and fail.

****
GFFMERGE: Efficient Merging of Graph Neural Force Fields and Beyond
Parth Verma, Parv Pratap Singh, Vipul Garg, Ishita Thakre, N M Anoop Krishnan, S ayan Ranu
Graph Neural Networks (GNNs) have revolutionized Neural Force Fields for atomist ic simulations, achieving near-quantum accuracy at reduced cost, yet adapting th ese models to new chemical systems requires expensive retraining of foundation m odels. Inspired by model merging in vision and language processing, we introduce GFFMERGE, the first principled framework for closed-form model merging in GNNs. We exploit the linear structure of message-passing layers and formulate merging as a convex embedding-alignment problem with an analytical solution. Through th e first systematic benchmarking of model merging for GNNs, we show that existing methods designed for vision and language catastrophically fail on force field r egression, while GFFMERGE recovers performance approaching gold standard joint t raining. Across molecular (MD17, MD22), solid-state (LiPS20), and large-scale gr aph benchmarks, GFFMERGE and GNNMERGE (its generic GNN counterpart) achieve 5-27 $\times$ speedups while enabling modular composition of specialized models. Rema rkably, our closed-form solution alone outperforms all baseline methods before f ine-tuning and provides superior initialization for faster, data-efficient conve rgence.
****
REAR: Test-time Preference Realignment through Reward Decomposition
Fuxiang Zhang, Pengcheng Wang, Chenran Li, Yi-Chen Li, Yuxin Chen, Lang Feng, Ch enfeng Xu, Masayoshi Tomizuka, Bo An
Aligning large language models (LLMs) with diverse user preferences is a critica l yet challenging task. While post-training methods can adapt models to specific needs, they often require costly data curation and additional training. Test-ti me scaling (TTS) presents an efficient, training-free alternative, but its appli cation has been largely limited to verifiable domains like mathematics and codin g, where response correctness is easily judged. To extend TTS to preference alig nment, we introduce a novel framework that models the task as a realignment prob lem, since the base model often fails to sufficiently align with the stated pref erence. Our key insight is to decompose the underlying reward function into two components: one related to the question and the other to preference information. This allows us to derive a REAlignment Reward (REAR) that selectively rescales the proportions of these two reward terms. We then show that REAR can be formula ted as a linear combination of token-level policy log-probabilities, making it c omputationally efficient and easy to integrate with various TTS algorithms such as best-of-N sampling and tree search. Experiments show that compared to other test-time baselines, REAR not only enables scable test-time realignment for pre ference alignment tasks under diverse user requirements, but also generalizes to mathematical and visual tasks under appropriate preference settings.
****
VecMol: Vector-Field Representations for 3D Molecule Generation
Yuchen Hua, Xingang Peng, Jianzhu Ma, Muhan Zhang
Generative modeling of three-dimensional (3D) molecules is a fundamental yet cha llenging problem in drug discovery and materials science. Existing approaches ty pically represent molecules as 3D graphs and co-generate discrete atom types wit h continuous atomic coordinates, leading to intrinsic learning difficulties such as heterogeneous modality entanglement and geometry–chemistry coherence constra ints. We propose VecMol, a novel representation that models 3D molecules as cont inuous vector fields over Euclidean space, where vectors point toward nearby ato ms and implicitly encode molecular structure. The vector field is parameterized by a neural field and generated using a latent diffusion model, avoiding explici t graph generation and decoupling structure learning from discrete atom instanti ation. Experiments on the QM9 and GEOM-Drugs benchmarks demonstrate that VecMol achieves competitive generation quality, suggesting vector-field-based represent ations as a promising new direction for 3D molecular generation.
****
Natural Hypergradient Descent: Algorithm Design, Convergence Analysis, and Para

llel Implementation
Deyi Kong, Zaiwei Chen, Shuzhong Zhang, Shancong Mou
In this work, we propose *Natural Hypergradient Descent* (NHGD), a new method fo r solving bilevel optimization problems. To address the computational bottleneck in hypergradient estimation, namely the need to compute or approximate Hessian inverses, we exploit the statistical structure of the inner optimization problem and use the empirical Fisher information matrix as an asymptotically consistent surrogate for the Hessian. This design enables a parallel *optimize-and-approxi mate* framework in which the Hessian-inverse approximation is updated *synchrono usly* with the stochastic inner optimization, reusing gradient information at ne gligible additional cost. Our main theoretical contribution establishes high-pro bability error bounds and sample complexity guarantees for NHGD that match those of state-of-the-art optimize-then-approximate methods, while significantly redu cing computational time overhead. Empirical evaluations on representative bileve l learning tasks further demonstrate the practical advantages of NHGD, highlight ing its scalability and effectiveness in large-scale machine learning settings.
****
CaP-X: A Framework for Benchmarking and Improving Coding Agents for Robot Manipu lation
Letian Fu, Justin Yu, Karim El-Refai, Ethan Kou, Haoru Xue, Huang Huang, Wenli X iao, Li Fei-Fei, Guanya Shi, Jiajun Wu, S. Shankar Sastry, Yuke Zhu, Ken Goldber g, Linxi Fan
Code-as-Policy (CaP) is a paradigm in which a language or vision-language model generates executable robot control programs, yet its effectiveness as an autonom ous controller for embodied manipulation remains underexplored. Prior CaP system s often rely on high-level, human-designed primitives, making it difficult to se parate agent capability from designer-provided scaffolding. We present CaP-X, an open-access framework for systematically studying Code-as-Policy agents in robo t manipulation. CaP-X includes four components. CaP-Gym is an interactive enviro nment in which coding agents control robots by synthesizing and executing progra ms that compose perception and control primitives. Building on this foundation, CaP-Bench evaluates frontier language and vision-language models across varying levels of abstraction, interaction, and perceptual grounding. Across 12 models, the task success rates improve with human-crafted abstractions but degrade as th ese priors are removed, exposing a dependence on designer scaffolding. At the sa me time, we observe that scaling test-time computation with multi-turn interacti on, structured execution feedback, visual differencing, automatic skill synthesi s, and ensembled reasoning can substantially improve robustness even when agents operate over low-level primitives. These findings motivate CaP-Agent0, a traini ng-free framework that achieves near human-level reliability on several manipula tion tasks in simulation and on real embodiments. CaP-RL explores reinforcement learning with verifiable rewards to improve success rates and supports sim-to-re al transfer through a shared code-as-action-space interface. Together, CaP-X pro vides an open-access platform for advancing embodied coding agents. Project page : https://capgym.github.io

Alignment-Sensitive Minimax Rates for Spectral Algorithms with Learned Kernels
Dongming Huang, Zhifan Li, Yicheng Li, Qian Lin
We study spectral algorithms in settings where kernels may arise from a learning procedure, and ask how the resulting spectral order affects risk. We introduce the effective span dimension (ESD), an alignment-sensitive complexity measure th at depends jointly on the target signal, the spectral order induced by the kerne l, and the noise level σ^2. The ESD is defined without requiring eigen-de cay conditions or source conditions, and it captures how much of the target sign al lies in the leading spectral span. We prove that, for sequence models whose E SD is at most K, the minimax excess risk scales as $\sigma^2 K$, and we extend the framework to linear models and RKHS regression. Furthermore, we analyze ove r-parameterized gradient flow in a fixed-eigenbasis spectral learning model and prove that it can reduce the ESD under certain conditions. Together with numeric al experiments, these results connect adaptive feature learning with reductions

in ESD and offer a novel perspective on generalization beyond traditional fixed-kernel theories.

Stochastic Gradient Variational Inference with Price's Gradient Estimator from Bures-Wasserstein to Parameter Space
Kyurae Kim, Qiang Fu, Yian Ma, Jacob R. Gardner, Trevor Campbell
For approximating a target distribution given only its unnormalized log-density, stochastic gradient-based variational inference (VI) algorithms are a popular approach. For example, Wasserstein VI (WVI) and black-box VI (BBVI) perform gradient descent in measure space (Bures-Wasserstein space) and parameter space, respectively. Previously, for the Gaussian variational family, convergence guarantees for WVI have shown superiority over existing results for black-box VI with the reparametrization gradient, suggesting the measure space approach might provide some unique benefits. In this work, however, we close this gap by obtaining identical state-of-the-art iteration complexity guarantees for both. In particular, we identify that WVI's superiority stems from the specific gradient estimator it uses, which BBVI can also leverage with minor modifications. The estimator in question is usually associated with Price's theorem and utilizes second-order information (Hessians) of the target log-density. We will refer to this as Price's gradient. On the flip side, WVI can be made more widely applicable by using the reparametrization gradient, which requires only gradients of the log-density. We empirically demonstrate that the use of Price's gradient is the major source of performance improvement.
****
ERGeoBench: A Comprehensive Benchmark for Embodied Reasoning and Geo-localization in Multimodal Large Language Models
Kaiwen Xue, Tao Wei, Guoxin Zhang, Zhonghong Ou, Kaoyan Lu, Yu Feng, Yifan Zhu, Haoran Luo
Multimodal large language models (MLLMs) have shown strong potential as embodied agents, yet embodied geo-localization remains underexplored due to the lack of fine-grained evaluation. We introduce ERGeoBench, a diagnostic benchmark for vision-driven embodied geo-localization. ERGeoBench evaluates models under three progressive settings---single-view, panorama-view, and embodied-view---where agents may actively acquire observations through sequential changes in yaw, pitch, and zoom. The benchmark contains 2,207 globally distributed street-view panoramas and measures four complementary capabilities: foundational perception, spatial awareness, common sense reasoning, and geo-localization reasoning. Evaluations of leading proprietary and open-source MLLMs show that current models can infer high-level geographic semantics, but still struggle with fine-grained perceptual operations, metric localization, and spatial consistency across views. We further observe that geo-localization is strongly correlated with the other capability dimensions, suggesting that accurate localization depends on integrated perception, spatial reasoning, and commonsense inference rather than isolated visual recognition. Overall, ERGeoBench provides a unified framework for diagnosing and advancing human-like embodied geo-localization. Project Page: \url{https://kaixuewen.github.io/ERGeoBench/}

SLAE: Strictly Local All-atom Environment for Protein Representation
Yilin Chen, Tianyu Lu, Cizhang Zhao, Hannah Wayment-Steele, Po-Ssu Huang
Building physically grounded protein representations is central to computational biology, yet most existing approaches rely on sequence-pretrained language models or backbone-only graphs that overlook side-chain geometry and chemical detail. We present SLAE, a unified all-atom framework for learning protein representations from each residue’s local atomic neighborhood using only atom types and interatomic geometries. To encourage expressive feature extraction, we introduce a novel multi-task autoencoder objective that combines coordinate reconstruction, sequence recovery, and energy regression. SLAE reconstructs allatom structures with high fidelity from latent residue environments and achieves state-of-the-art performance across diverse downstream tasks via transfer learning. SLAE’s latent space is chemically informative and environmentally sensitive, enabling quanti

tative assessment of structural qualities and smooth interpolation between confo
rmations at all-atom resolution.

ScaleEnv: Scaling Environment Synthesis from Scratch for Generalist Interactive
Tool-Use Agent Training
Dunwei Tu, Hongyan Hao, Hansi Yang, Yihao Chen, Yu Yang, Yueqing Sun, Xingchen L
iu, Furao Shen, Qi GU, Hui Su, Xunliang Cai
Training generalist agents capable of adapting to diverse scenarios requires int
eractive environments for self-exploration.
However, interactive environments remain critically scarce, and existing synthes
is methods suffer from significant limitations regarding environmental diversity
 and scalability.
To address these challenges, we introduce ScaleEnv, a framework that constructs
fully interactive environments and verifiable tasks entirely from scratch.
Specifically, ScaleEnv ensures environment reliability through procedural testin
g, and guarantees task completeness and solvability via tool dependency graph ex
pansion and executable action verification.
By enabling agents to learn through exploration within ScaleEnv, we demonstrate
significant performance improvements on unseen, multi-turn tool-use benchmarks s
uch as τ^2-Bench and VitaBench, highlighting strong generalization capabili
ties.
Furthermore, we investigate the relationship between increasing number of domain
s and model generalization performance, providing empirical evidence that scalin
g environmental diversity is critical for robust agent learning.

Resolution as a Direction: Vector-Panning Feature Alignment for Cross-Resolution
 Re-Identification
Zanwu Liu, Chao Yuan, Bo Li, Xiaowei Zhang, Guanglin Niu
Cross-resolution person re-identification (CR-ReID) remains challenging in pract
ical surveillance, where camera quality and capture distance lead to substantial
 resolution gaps between low-resolution (LR) queries and high-resolution (HR) ga
llery images. Prior approaches commonly rely on super-resolution (SR) or resolut
ion-invariant representation learning, which often increases system complexity a
nd may not directly address the feature mismatch induced by resolution degradati
on. In this work, we report a new empirical finding from a dedicated analysis in
 which identity-specific variation is averaged out: the HR--LR feature discrepan
cy produced by standard ReID backbones exhibits a consistent, resolution-related
 semantic direction in the embedding space. We further support this observation
with statistical analyses based on Canonical Correlation Analysis (CCA) and Pear
son correlation analysis. Motivated by this finding, we propose Vector Panning F
eature Alignment (VPFA), a lightweight post-hoc module that learns to pan LR fea
tures along the learned resolution direction to obtain pseudo-HR representations
. VPFA operates after feature extraction and can be integrated into existing ReI
D systems with negligible overhead. Extensive experiments on multiple CR-ReID be
nchmarks show that VPFA achieves state-of-the-art performance while improving ef
ficiency compared to SR-based or jointly trained alternatives. Code is available
 at \url{https://github.com/ashmentlzw/VPFA}

Discovering Symmetry Groups with Flow Matching
Yuxuan Chen, Jung Yeon Park, Floor Eijkelboom, Jianke Yang, Jan-Willem van de Me
ent, Lawson L.S. Wong, Robin Walters
Symmetry is fundamental to understanding physical systems and can improve perfor
mance and sample efficiency in machine learning. Both pursuits require knowledge
 of the underlying symmetries in data, yet discovering these symmetries automati
cally is challenging. We propose LieFlow, a novel framework that reframes symmet
ry discovery as a distribution learning problem on Lie groups. Instead of search
ing for the symmetry generators, our approach operates directly in group space,
modeling a symmetry distribution over a large hypothesis group G. The support
of the learned distribution reveals the underlying symmetry group $H \subseteq G
$.

Unlike previous works, LieFlow can discover both continuous and discrete symmetries within a unified framework, without assuming a fixed Lie algebra basis or a specific distribution over the group elements.
Experiments on synthetic 2D and 3D point clouds, ModelNet10, and a real-world MI-Motion dataset show that LieFlow accurately discovers continuous and discrete subgroups, significantly outperforming a state-of-the-art baseline, LieGAN, in identifying discrete symmetries.
****
ProConMV: Provenance-Enabled Conceptual Framework for Interpretable Multi-View Diabetic Retinopathy Diagnosis
Xiaoling Luo, Shuo Yang, Qihao Xu, Jiansong Zhang, Zhuoqin Yang, Zhihui Lai, Linlin Shen, Chengliang Liu
Existing deep learning models have demonstrated potential in Diabetic retinopathy (DR) diagnosis, but they still suffer from three key challenges: reliance on single-source inputs, opaque and untraceable reasoning processes, and the absence of a mechanism for result verification. Thus, we propose a provenance-enabled concept-based framework for multi-view DR diagnostic (ProConMV), which integrates DR lesion masks, clinical text and multi-view data, utilizing multimodal prompt analysis and visual-text concept interaction to learn the interpretable multi-source input. During the reasoning stage, the proposed framework introduces lesion concepts for causal reasoning chains combining clinical guidelines, and adds doctor intervention for human-machine collaboration. For dynamic fusion decision and verification in multi-view DR diagnosis, we derive via generalization theory that incorporating each view’s lesion concept uncertainty and grading uncertainty reduces the generalization error upper bound. Accordingly, we design a dual uncertainty-aware module to enable provenance-based verification, ultimately enabling verifiable analysis of DR diagnostic results. Extensive experiments conducted on two public multi-view DR datasets demonstrate the effectiveness of our method. The code will be released at https://github.com/SoY0ung/ProConMV.

Toward Cybersecurity-Expert Small Language Models
Matan Levi, Daniel Ohayon, Ariel Blobstein, Ravid Sa, Ian Molloy, Yair Allouche
Large language models (LLMs) are transforming everyday applications, yet they lag behind in specialized fields, such as cybersecurity, due to a lack of high-quality, domain-specific models and training datasets. To address this gap, we present CyberPal 2.0, a family of cybersecurity-expert small language models (SLMs) ranging from 4B–20B parameters. To train CyberPal 2.0, we generate an enriched chain-of-thought cybersecurity instruction dataset built with our data enrichment and formatting pipeline, SecKnowledge 2.0, which integrates expert-in-the-loop steering of reasoning formats alongside LLM-driven multi-step grounding, yielding higher-fidelity, task-grounded reasoning traces for security tasks. Across diverse cybersecurity benchmarks, *CyberPal 2.0 consistently outperforms its baselines and matches or surpasses various open and closed-source frontier models*, while remaining a fraction of their size. On core threat-investigation tasks, such as correlating vulnerabilities and bug tickets with weaknesses, *our best 20B-parameter model outperforms GPT-4o, o1, o3-mini, and Sec-Gemini v1, ranking first, while our smallest 4B-parameter model ranks second. On core cyber threat intelligence knowledge tasks, our models outperform almost all tested frontier models, ranking second only to Sec-Gemini v1*. To foster reproducibility and practical adoption, we will release our models as open source.

Boosting CVaR Policy Optimization with Quantile Gradients
Yudong Luo, Erick Delage
Optimizing Conditional Value-at-risk (CVaR) using policy gradient (a.k.a CVaR-PG) faces significant challenges of sample inefficiency. This inefficiency stems from the fact that it focuses on tail-end performance and overlooks many sampled trajectories. We address this problem by augmenting CVaR with an expected quantile term. Quantile optimization admits a dynamic programming formulation that leverages all sampled data, thus improves sample efficiency. This does not alter the CVaR objective since CVaR corresponds to the expectation of quantile over the

tail. Empirical results in domains with verifiable risk-averse behavior show tha t our algorithm within the Markovian policy class substantially improves upon CV aR-PG and consistently outperforms other existing methods.

The Catastrophic Failure of *the* k-Means Algorithm in High Dimensions, and How Hartigan's Algorithm Avoids It
Roy R Lederman, David Silva-Sánchez, Ziling Chen, Gilles Mordant, Amnon Balanov, Tamir Bendory
Lloyd's k-means algorithm is one of the most widely used clustering methods. We prove that in high-dimensional, high-noise settings, the algorithm exhibits cata strophic failure: with high probability, essentially every partition of the data is a fixed point. Consequently, Lloyd's algorithm simply returns its initial pa rtition — even when the underlying clusters are trivially recoverable by other m ethods. In contrast, we prove that Hartigan's k-means algorithm does not exhibit this pathology. Our results show the stark difference between these algorithms and offer a theoretical explanation for the empirical difficulties often observe d with k-means in high dimensions.

Linear Causal Representation Learning by Topological Ordering, Pruning, and Dise ntanglement
Hao Chen, Lin Liu, Yu Guang Wang
Causal representation learning (CRL) has garnered increasing interest from the c ausal inference and artificial intelligence communities due to its potential to disentangle complex data-generating mechanism into causally interpretable latent features by leveraging the heterogeneity of modern datasets. In this paper, we further contribute to the CRL literature, by focusing on the stylized linear str uctural causal model over latent features and assuming a linear mixing function that maps latent features to the observed data or measurements. Existing linear CRL methods often rely on stringent assumptions, such as access to single-node i nterventional data or restrictive distributional constraints on latent features and/or exogenous measurement noise. However, these prerequisites can be easy to violate in practice. In this work, we propose a novel linear CRL algorithm that, unlike existing methods, operates under weaker assumptions on environment heter ogeneity and data-generating distributions while still recovering latent causal features up to an equivalence class. We further validate our new algorithm via s ynthetic experiments and an interpretability analysis of large language models, demonstrating both its superiority over competing methods in finite samples and its potential in integrating causality into understanding artificial intelligenc e. The source code is available at [the accompanying GitHub link](https://github .com/utulie/code_for_linear_crl_paper_creator).

Esoteric Language Models: A Family of Any-Order Diffusion LLMs
Subham Sekhar Sahoo, Zhihan Yang, Yash Akhauri, Johnna Liu, Deepansha Singh, Zho ujun Cheng, Zhengzhong Liu, Eric P. Xing, John Thickstun, Arash Vahdat
Diffusion Language Models offer a compelling alternative to autoregressive (AR) models by enabling parallel and controllable generation.
Within this family, Masked Diffusion Models (MDMs) currently perform best but st ill underperform AR models in perplexity and lack key inference-time efficiency features, most notably KV caching. We introduce Esoteric Language Models (Eso-LM s), a new family of models that fuses AR and MDM paradigms, smoothly interpolati ng between their perplexities while overcoming their respective limitations. Unl ike prior work, which uses transformers with bidirectional attention as MDM deno isers, we exploit the connection between MDMs and Any-Order autoregressive model s and adopt causal attention. This design lets us (1) **compute the exact likeli hood of MDMs for the first time** and, crucially, (2) **allows exact KV caching for MDMs** while preserving parallel generation over the full sequence length fo r the first time, significantly improving inference efficiency. Combined with an optimized sampling schedule, Eso-LMs establish a new state of the art on the sp eed-quality Pareto frontier for unconditional generation.

From Extraction to Deduction: Resolving Functional Misalignment in RAG via a Collaborative Critic-Reasoner Framework
Yufei Chen, Yao Wang, Haibin Zhang, Hualin zhou, Tao Gu
Retrieval-augmented generation (RAG) systems suffer from a fundamental functional misalignment where retrievers optimize for semantic relevance, often recalling documents with high background utility but factually erroneous answer spans that generators blindly adopt as cognitive shortcuts. To resolve this, we propose the collaborative Critic-Reasoner framework that shifts robustness control from coarse-grained filtering to fine-grained cognitive decoupling. We disentangle the generation process into two serialized roles by deploying a Critic to perform surgical evidence purification through identifying and masking misleading entities while preserving supportive background context, followed by a Reasoner that switches from rote extraction to deductive reasoning based on the residual evidence. We operationalize this framework via a two-stage alignment strategy combining supervised fine-tuning (SFT) with path-aware direct preference optimization (DPO) to enforce strict behavioral synergy. Experimental results on adversarial benchmarks such as ConFiQA demonstrate that our method significantly outperforms baselines, achieving a 25.99\% accuracy gain in conflicting scenarios and effectively resolving the trust bias dilemma in real-world RAG.
****
Mitigating Reward Hacking in LLM-based Recommendation: A Preference Optimization Approach
Heyu Chen, Junkang Wu, Guoqing Hu, Kexin Huang, Xiang Wang, Jiancan Wu
Post-training adaptation has become the central paradigm for leveraging large language models (LLMs) in recommendation.
While recent preference optimization methods, such as Direct Preference Optimization (DPO), enhance pairwise preference discrimination, they remain vulnerable to \emph{reward hacking}: models exploit imperfections in reward signals, leading to inflated training metrics without genuine recommendation gains.
We analyze this issue from a gradient perspective and formalize the concept of the
\emph{ε-insensitive region}, where pairwise updates exert little influence on the ordering between positives and unsampled negatives.
Under the Bradley–Terry model, we further show that these regions can occupy a substantial fraction of the preference space, inevitably leading to misaligned rankings.
To address this issue, we propose Simulated Preference Optimization for Reward-hacking mitigation using Pseudo-negatives (SIRIUS).
Our framework introduces pseudo-negative samples to enrich contrastive signals and reduce the prevalence of ε-insensitive regions.
Extensive experiments on three public benchmarks show that \our{} consistently improves ranking quality and effectively mitigates reward hacking, providing both theoretical and practical insights for advancing LLM-based recommendation.
Our code is available at
\url{https://anonymous.4open.science/r/C557-id}

Deformba: Vision State Space Model with Adaptive State Fusion
Hongyu Ke, Jack Morris, Yongkang Liu, Satoshi Kitai, Kentaro Oguchi, Yi Ding, Haoxin Wang
State Space Models (SSMs) have emerged as a powerful and efficient alternative to Transformers, demonstrating linear-time complexity and exceptional sequence modeling capabilities. However, their application to vision tasks remains challenging. First, existing vision SSMs largely depend on manually designed fixed scanning methods to flatten image patches into sequences, which imposes predefined geometric structures and increases the complexity. Second, the broader adoption of vision SSMs is hindered in domains that require query-based interactions between distinct information streams. This is a result of the inherently causal and self-referential nature of SSMs designed for 1D sequence modeling tasks. This fusion mechanism is indispensable for critical perception tasks such as multi-view 3D fusion. To address these limitations, we propose Deformba, a context adaptive

method that dynamically augments the spatial structural information while mainta
ining the linear complexity of SSMs. Deformba also allows multi-modal fusion, an
alogous to standard cross attention. To demonstrate the effectiveness and genera
l applicability of Deformba, we test its performance on general 2D vision tasks
such as image classification, object detection, instance segmentation, and seman
tic segmentation, as well as 3D vision tasks like BEV perception. Extensive expe
riments show that Deformba achieves strong performance across various visual per
ception benchmarks.

Evolving Interdependent Operators with Large Language Models for Multi-Objective
 Combinatorial Optimization

junhao qiu, Xin Chen, Liang Ge, Liyong Lin, Zhichao Lu, Qingfu Zhang

Neighborhood search operators are critical to the performance of Multi-Objective
 Evolutionary Algorithms (MOEAs) and rely heavily on expert design. Although rec
ent LLM-based Automated Heuristic Design (AHD) methods have made notable progres
s, they primarily optimize individual heuristics or components independently, la
cking explicit exploration and exploitation of dynamic coupling relationships be
tween operators. In this paper, multi-operator optimization in MOEAs is formulat
ed as a Markov decision process, enabling the improvement of interdependent oper
ators through sequential decision-making. To address this, we propose the Evolut
ion of Operator Combination (E2OC) framework for MOEAs, which achieves the co-ev
olution of design strategies and executable codes. E2OC employs Monte Carlo Tree
 Search to progressively search combinations of operator design strategies and a
dopts an operator rotation mechanism to identify effective operator configuratio
ns while supporting the integration of mainstream AHD methods as the underlying
designer. Experimental results across AHD tasks with varying objectives and prob
lem scales show that E2OC consistently outperforms state-of-the-art AHD and othe
r multi-heuristic co-design frameworks, demonstrating strong generalization and
sustained optimization capability.

ExpWeaver: LLM Agents Learn from Experience via Latent RAG

Tao Feng, Tianyang Luo, Jingjun Xu, Zhigang Hua, Yan Xie, Shuang Yang, Ge Liu, J
iaxuan You

Experience learning has achieved promising results in enhancing LLM agent planni
ng and reasoning by integrating past interactions as reusable knowledge. However
, existing methods remain confined to explicit text space—retrieving experiences
 via semantic similarity and concatenating them into the context window, leading
 to substantial token overhead and a decoupled architecture that separates retri
eval from generation. To address these limitations, we propose ExpWeaver, a fram
ework that enables LLM agents to learn from experience via latent retrieval-augm
ented generation, without requiring a separate RAG module. ExpWeaver encodes exp
eriences using the LLM’s own hidden states, retrieves relevant experiences direc
tly in latent space at each decoding step, and integrates them through cross-att
ention aggregation and gated residual mechanisms. The entire pipeline is optimiz
ed end-to-end with reinforcement learning, supporting both generative and rankin
g tasks. We evaluate ExpWeaver on 13 diverse tasks spanning question answering,
reasoning, coding, scientific prediction, and recommendation. Results demonstrat
e that: (1) ExpWeaver achieves state-of-the-art on 12 out of 13 tasks, outperfor
ming the strongest baseline by over 6.8%; (2) ExpWeaver maintains token efficien
cy comparable to non-retrieval baselines while text-based retrieval methods requ
ire 1.5–2× more tokens; and (3) ExpWeaver exhibits superior cross-domain general
ization, outperforming the strongest baseline by 16.32% under zero-shot transfer
 and 15.21% under few-shot transfer. Our code for ExpWeaver is released at https
://github.com/ulab-uiuc/ExpWeaver.

Lookahead-GCG: Improving Universal Multi-Model Optimization-Based Jailbreaking A
ttacks via Stochastic Nesterov Optimization

Rong Feng, Haohan Zhao, Shiqin Tang, Geng Liu, Song Lai, Meng Wang, Shuxin Zhuan
g, Yuqi Zha, Changyi Ma, Runsheng Yu

Transferable jailbreaking attacks enable red-teaming of black-box large language

models by optimizing adversarial prompts on open-source surrogates. A natural approach to improve transferability is multi-model training---optimizing against multiple source models simultaneously. Yet this approach has been largely abandoned, as it yields only marginal gains with standard optimizers. We argue the root cause is poor generalization: standard gradient descent lacks stability when aggregating gradients from diverse models. Since GCG and its variants implicitly perform SGD in discrete token space, they inherit this instability in multi-model settings. We address this with Lookahead-GCG, which combines: (1) Stochastic Nesterov Accelerated Gradient (SNAG), whose lookahead mechanism reduces sensitivity to individual gradient updates, providing stability for multi-model optimization; (2) embedding-space momentum accumulation, which enables SNAG in discrete token optimization; and (3) maximally distant initialization, which exploits SNAG's improved generalization by starting from a universally beneficial point. Experiments show our method achieves 50.37% ASR on open-source and 34.03\% on closed-source LLMs, outperforming GCG and TransferAttack with +11.78% gains from multi-model optimization.

Elastic Diffusion Transformer

Jiangshan Wang, Zeqiang Lai, Jiarui Chen, Jiayi Guo, Hang Guo, Xiu Li, Xiangyu Yue, Chunchao Guo

Diffusion Transformers (DiT) have demonstrated remarkable generative capabilities but remain highly computationally expensive. Previous acceleration methods, such as pruning and distillation, typically rely on a fixed computational capacity, leading to insufficient acceleration and degraded generation quality. To address this limitation, we propose \textbf{Elastic Diffusion Transformer (E-DiT)}, an adaptive acceleration framework for DiT that effectively improves efficiency while maintaining generation quality. Specifically, we observe that the generative process of DiT exhibits substantial sparsity (i.e., some computations can be skipped with minimal impact on quality), and this sparsity varies significantly across samples. Motivated by this observation, E-DiT equips each DiT block with a lightweight router that dynamically identifies sample-dependent sparsity from the input latent. Each router adaptively determines whether the corresponding block can be skipped. If the block is not skipped, the router then predicts the optimal MLP width reduction ratio within the block. During inference, we further introduce a block-level feature caching mechanism that leverages router predictions to eliminate redundant computations in a training-free manner. Extensive experiments across 2D image (Qwen-Image and FLUX) and 3D asset (Hunyuan3D-3.0) demonstrate the effectiveness of E-DiT, achieving up to $\sim$2$\times$ speedup with negligible loss in generation quality.

SlaClip: Gradient Norm Slacks can be Indicator for Adaptive Clipping in DP-SGD

Shuyan Zou, Shaowei Wang, Zhanxing Zhu, Jin Li, Changyu Dong, Vladimiro Sassone, Han Wu

Differentially private stochastic gradient descent (DP-SGD) achieves privacy by clipping per-sample gradients and injecting Gaussian noise, but its utility is highly sensitive to the choice of the clipping threshold C. A fixed C often degrades performance and necessitates repeated empirical calibration. Existing adaptive clipping methods either modify the gradient update in vanilla DP-SGD, causing additional tuning or optimization overhead, or introduce separate private queries to monitor gradient statistics. In contrast, we leverage the *slack* information induced by the standard clipping operation, an overlooked signal in prior work, and show that it provides an effective indication for adapting C.

In light of this, we propose *SlaClip*, a privacy-preserving adaptive clipping strategy using a post-hoc *Slack Indicator*. Under the same training configuration and privacy accountant, *SlaClip* preserves the sampling rule, noise multiplier, and global ℓ_2 sensitivity bound of vanilla DP-SGD. Therefore, *SlaClip* is a plug-and-play module for vanilla DP-SGD and its variants. Moreover, *SlaClip* is accounted under the same per-step privacy bound, while requiring no additional private query. Across diverse datasets and tasks, experiments show that *SlaClip* consistently outperforms baseline adaptive clipping methods.

Text Generation as Continuous Latent Dynamics via Reinforcement Learning
Chen Jia
We propose to model text generation as a continuous-time latent dynamical proces s, where token generation is formulated as a Markov decision process whose inter nal state evolves via a neural ODE. This formulation bridges discrete token sequ ences and continuous semantic evolution, providing a theoretically grounded fram ework for text generation with continuous-time latent states. The framework is o ptimized via reinforcement learning, maximizing a composite objective that integ rates cumulative rewards with a Kullback–Leibler divergence regularization term from a pre-trained language model. Both theoretical and empirical results demons trate that our Continuous-Time Latent Language Model (CT-LLM) achieves superior effectiveness and efficiency in text generation, establishing a new paradigm for continuous-time language modeling.
****
Verified SHAP: Provable Bounds for Exact Shapley Values of Neural Networks
David Boetius, Shahaf Bassan, Guy Katz, Stefan Leue, Tobias Sutter
Shapley additive explanations (SHAP) are widely recognised as computationally in tractable for neural networks, since they induce an exponential search space ove r the input features. In this work, we take a first step towards scaling exact S HAP computation to larger search spaces by introducing an algorithm that leverag es recent advances in neural network verification to compute arbitrarily tight e xact lower and upper bounds on SHAP values for neural networks, ultimately recov ering the exact SHAP values. We demonstrate that our approach scales to orders o f magnitude larger search spaces than state-of-the-art exact methods. This provi des an important first step towards exact SHAP computation and establishes a pri ncipled cornerstone for evaluating statistical approximation methods on larger s earch spaces.
****
Towards Understanding Continual Factual Knowledge Acquisition of Language Models : From Theory to Algorithm
Haoyu Wang, yifan shang, Zhongxiang Sun, Weijie Yu, Xiao Zhang, Jun Xu
Continual Pre-Training (CPT) is essential for enabling Language Models (LMs) to integrate new factual knowledge without erasing old. While classical CPT techniq ues like data replay have become the standard paradigm, the mechanisms underlyin g how LMs acquire and retain facts over time, termed as continual Factual Knowle dge Acquisition (cFKA), remain unclear. In this work, we present a theoretical f ramework that characterizes the training dynamics of cFKA using a single-layer T ransformer with linear attention, offering a unified explanation for the behavio r of popular CPT methods. Our analysis reveals that regularization-based methods merely adjust the convergence rate of parameters without altering the inherent forgetting tendency, whereas data replay methods shift convergence dynamics and stabilize pretrained knowledge. Building on these insights, we propose a novel g enerative data replay approach, called Selecting Tokens via attentiOn Contributi on (STOC), which identifies influential factual snippets to guide replay generat ion. Extensive experiments on both synthetic and real-world datasets validate ou r theoretical findings and demonstrate that STOC effectively enhances cFKA by mi tigating catastrophic forgetting.
****
Just Y-Prediction: Enabling Historical Cumulative Inconsistency in Label Diffusi on for Learning with Noisy Label
Senyu Hou, Gaoxia Jiang, Xinyi Zheng, Yaqing Guo, Shuna Liang, Wenjian Wang
Label noise is pervasive in real-world datasets and significantly compromises mo del generalization, fueling extensive research into Learning with Noisy Labels (LNL). Most LNL methods focus on robust discriminative learning, while recent gen erative classifiers such as label diffusion models (LDMs) show superior robustne ss by modeling class posteriors. However, current LDMs predominantly rely on sta ndard ϵ-prediction, where Gaussian pnoise lacks explicit class semantic s, limiting both optimization and inference under label noise environments. To a ddress this issue, we propose just y-prediction (JYP), a novel training paradigm

that enables LDMs to directly characterize the label manifold and leverage explicit class-semantic guidance. Theoretically, we prove that JYP converges to an optimal solution equivalent to that of ϵ-prediction within the label diffusion framework, while facilitating accelerated convergence and enabling one-step inference. Leveraging JYP as a foundation, we further incorporate historical cumulative inconsistency to adaptively tailor optimization strategies for clean, noisy, and hard samples. Extensive experiments demonstrate that our method consistently outperforms competitors across diverse synthetic noisy datasets and achieves state-of-the-art performance on multiple real-world benchmarks.

Constrained Bayesian Experimental Design via Online Planning

Yujia Guo, Daolang Huang, Xinyu Zhang, Sammie Katt, Samuel Kaski, Ayush Bharti

Bayesian experimental design (BED) is a principled framework for data-efficient design of sequential experiments. However, existing BED methods are unable to adapt to dynamic constraints inherent in real-world tasks due to budget limitations, varying costs, or physical constraints that restrict how designs evolve over time. In this paper, we introduce a novel approach to BED that enables constrained optimization of experimental designs by combining offline pre-training of an amortized policy and a posterior network with online multi-step lookahead planning using scenario trees. We empirically demonstrate that our method yields substantially more informative design sequences than existing methods across a range of constrained BED tasks, while incurring only a modest additional computational overhead.

LongCoT: Benchmarking Long-Horizon Chain-of-Thought Reasoning

Sumeet Ramesh Motwani, Daniel Nichols, Charles London, Peggy Li, Fabio Pizzati, Acer Blake, Hasan Abed Al Kader Hammoud, Tavish Malcolm McDonald, Akshat Naik, Alesia Ivanova, Vignesh Baskaran, Ivan Laptev, Ruben Glatt, Tal Ben-Nun, Philip Torr, Ameya Prabhu, Brian R. Bartoldson, Bhavya Kailkhura, Christian Schroeder de Witt

As language models are increasingly deployed for complex autonomous tasks, their ability to reason accurately over longer horizons becomes critical. An essential component of this ability is planning and managing a long, complex chain-of-thought (CoT). We introduce LongCoT, a scalable benchmark of 2,500 expert-designed problems spanning chemistry, mathematics, computer science, chess, and logic to isolate and directly measure the long-horizon CoT reasoning capabilities of frontier models. Problems consist of a short input with a verifiable answer; solving them requires navigating a graph of interdependent steps that span tens to hundreds of thousands of reasoning tokens. Each local step is individually tractable for frontier models, so failures reflect long-horizon reasoning limitations. At release, the best models achieve <10% accuracy (GPT 5.2: 9.8%; Gemini 3 Pro: 6.1%) on LongCoT, revealing a substantial gap in current capabilities. Overall, LongCoT provides a rigorous measure of long-horizon reasoning, tracking the ability of frontier models to reason reliably over extended periods.

σ: Sigmoid Modulation for Ultra High Resolution Diffusion

Bingxuan Zhao, Qing Zhou, Yu Wang, Chuang Yang, Qi Wang

Diffusion Transformers (DiTs) can synthesize high-fidelity images, but training at ultra-high resolutions is expensive, making inference-time extrapolation essential. Existing methods are typically \textit{scale-agnostic}, applying the same positional-modulation schedule regardless of target resolution. We show that this misses a scale-sensitive property of denoising: resizing shifts a fixed semantic pattern toward lower \emph{normalized} spatial frequencies while enlarging the spatial support over which global structure must be coordinated. The latter delays structural lock-in at high resolutions, so schedules may either relax guidance before global layout has stabilized, causing \textit{structural collapse}, or retain excessive intervention into late denoising, causing \textit{textural degradation}. We introduce \textbf{SigMa (σ)}, a training-free framework that uses Sigmoid Modulation for \textit{scale-adaptive} extrapolation through two scaling laws: \textit{Decoupled Geometric Center Alignment} and \textit{Iso-Va

riance Rate Adaptation}. Experiments show that SigMa reduces this mismatch, enab
ling training-free extrapolation up to 16 megapixels and achieving the best or c
ompetitive performance among the tested training-free extrapolation baselines. C
ode is available at \href{https://github.com/bxuanz/SigMa.git}{github.com/bxuanz
/SigMa}.

Conformal Reliability: A New Evaluation Metric for Conditional Generation
Yachen Gao, Xinwei Sun, Yikai Wang, Ye Shi, Jingya Wang, Jianfeng Feng, Yanwei F
u
Conditional generative models have recently achieved remarkable success in vario
us applications. However, a suitable metric for evaluating the reliability of th
ese models, which takes into account their inherent uncertainty, is still lackin
g. Existing metrics, which typically assess a single output, may fail to capture
 the variability or potential risks in generation. In this paper, we propose a n
ovel evaluation metric called reliability score based on conformal prediction, w
hich measures the worst-case performance within the prediction set at a pre-spec
ified confidence level. However, computing this score is challenging due to the
high-dimensional nature of the output space and the nonconvexity of both the met
ric function and the prediction set.
    To efficiently compute this score, we introduce Conformal ReLiability (CReL)
, a framework that can (i) construct the prediction set with desired coverage; a
nd (ii) accurately optimize the reliability score within the constructed predict
ion set. We provide theoretical results on coverage and demonstrate empirically
that our method produces more informative prediction sets than existing approach
es. Experiments on synthetic data and the image-to-text and text-to-image tasks
further demonstrate the interpretability of our new metric, and the validity and
 effectiveness of our computational framework.
    Source code can be found at https://ggc29.github.io/CReL/.

Trajectory-Aware Certified Decentralized Unlearning via SGD Stability
Hengliang Wu, Jiale Yang, Shuzhen Chen, Di Wang, Dongxiao Yu, Youming Tao
Decentralized Unlearning (DU) aims to remove the influence of specific clients f
rom a collaboratively trained global model. However, existing methods suffer fro
m strong reliance on static, problem-specific hyperparameters or restrictive co
nvexity assumptions, limiting their general applicability. To overcome these lim
itations, we propose **TRA**jectory-aware **CE**rtified **D**ecentralized **U**n
learning (**TRACE-DU**), a generic unlearning framework for decentralized traini
ng. **TRACE-DU** introduces a fine-grained sensitivity analysis that leverages l
ocal SGD updates and decentralized training dynamics, thereby eliminating the ne
ed for convexity assumptions and reducing dependence on manually tuned parameter
s. By integrating strategic checkpoint selection with calibrated noise perturbat
ion, the proposed framework enables efficient certified unlearning. Moreover, we
 exploit historical model trajectories to extend this framework, enabling it to
naturally support sequential unlearning requests from an arbitrary number of cli
ents. We provide theoretical guarantees for certified unlearning and derive sens

itivity bounds under both convex and non-convex loss functions. Experimental res
ults demonstrate that our framework outperforms state-of-the-art baselines acros
s diverse metrics.

EqGINO: Equivariant Geometry-Informed Fourier Neural Operators for 3D PDEs
Sungwon Kim, Juho Song, Seungmin Shin, Guimok Cho, Sangkook Kim, Chanyoung Park
Deep learning surrogates for 3D Partial Differential Equations (PDEs) often fail
 to generalize across geometric transformations because they depend heavily on s
pecific coordinate systems. While equivariant networks offer a solution, they ty
pically rely on local operations in the spatial domain, making the global recept
ive field—essential for PDE dynamics—computationally expensive. Conversely, Four
ier Neural Operators (FNOs) efficiently capture global interactions, yet establi
shing 3D equivariance within them remains impractical due to the prohibitive cos
t of spectral group convolutions. To bridge this gap, we introduce EqGINO, a geo
metrically robust framework that enforces isotropy in the spectral domain. By de
sign, EqGINO guarantees exact equivariance to the discrete symmetries inherent t
o the discretized computational domain. Beyond this discrete guarantee, our stru
ctural prior enables effective generalization to arbitrary continuous orientatio
ns even with a limited number of SE(3)-transformed training samples. Consequentl
y, our method robustly models coordinate-invariant physical laws on complex irre
gular 3D geometries. Our code is available at https://github.com/sung-won-kim/Eq
GINO

Adversarial Training for Process Reward Models
Gurusha Juneja, Deepak Nathani, William Yang Wang
Process Reward Models (PRMs) enhance reasoning ability of LLMs by providing step
-level supervision.
However, their widespread adoption is limited due to expensive manual step-level
 annotation and poor generalization of static training data to novel errors.
We introduce Adversarially Trained PRMs (APRM), where
a Generator (G) learns to produce reasoning errors to deceive a PRM (R), whi
le R concurrently learns to detect them.
This interaction yields progressively harder negatives for R, improving it's r
obustness and generalization to novel errors without requiring manual step-level
 labels.
Averaged across diverse mathematical reasoning benchmarks, APRM improves solver
accuracy by $+3.4$ percentage points (pp) over the strongest PRM baseline. APRM
achieves gains of $+5.3$ pp on out-of-distribution tasks.

The Data Manifold under the Microscope
Marios Koulakis, Constantin Seibold
A significant gap exists between theory and practice in deep learning. Generaliz
ation and approximation error bounds are often derived for simplified models or
are too loose to be informative. Many rely on the manifold hypothesis and on geo
metric regularity such as intrinsic dimension, curvature, and reach. Progress re
quires insight into data-manifold geometry and suitable benchmarks, yet existing
 options are polarized: analytic manifolds with known geometry but limited appli
cability, or real-world datasets where geometry is only coarsely estimable. We i
ntroduce a benchmarking framework for studying data geometry. We repurpose and e
xtend dSprites and COIL-20 with additional transformation dimensions and dense,
axis-aligned sampling, and pair them with finite-difference estimators that reco
ver curvature, reach, and volume at near-ground-truth accuracy in a regime where
 general-purpose estimators are unreliable or difficult to deploy. The framework
 is intended as a controlled testbed, useful as a calibration environment for ge
ometric estimators and a sandbox for probing theoretical assumptions. To illustr
ate its use, we present two application studies, namely assessing the scaling be
havior of the bounds of Genovese et al. and Fefferman et al., and tracking the l
ayer-wise geometry of a β-VAE, highlighting the behavior of current bounds
 and the value of controlled benchmarks for guiding and validating future theory
.

A reference implementation is available at https://github.com/koulakis/manifold-microscope.

Robust and Consistent Ski Rental with Distributional Advice
Jihwan Kim, Chenglin Fan
The ski rental problem is a canonical model for online decision-making under uncertainty, capturing the fundamental trade-off between repeated rental costs and a one-time purchase. While classical algorithms focus on worst-case competitive ratios and recent ``learning-augmented'' methods leverage point-estimate predictions, neither approach fully exploits the richness of full distributional predictions while maintaining rigorous robustness guarantees. We address this gap by introducing algorithms that systematically integrate distributional predictions into both deterministic and randomized algorithms.
For the deterministic setting, we formalize the problem under perfect distributional prediction and derive an efficient algorithm to compute the optimal threshold-buy day.
We provide a rigorous performance analysis, identifying sufficient conditions on the predicted distribution under which the expected competitive ratio (ECR) matches the classic optimal randomized bound.
To handle imperfect predictions, we propose the Clamp Policy, which restricts the buying threshold to a safe range controlled by a tunable parameter.
We show that this policy is both robust, maintaining good performance even with large prediction errors, and consistent, approaching the optimal performance as predictions become accurate.
For the randomized setting, we characterize the stopping distribution via a Water-Filling Algorithm, which optimizes expected cost while strictly satisfying robustness constraints.
Experimental results across diverse distributions (Gaussian, geometric, and bi-modal) demonstrate that our framework improves consistency by significantly over existing point-prediction baselines while maintaining comparable robustness.
****

OptiFluence: Principled Design of Privacy Canaries
Mohammad Yaghini, Michael Aerni, Junrui Zhang, Nicolas Papernot, Florian Tramèr
Privacy auditing has emerged as a practical tool for empirically estimating training data leakage in machine learning models, in contrast to the provable but often overly pessimistic bounds provided by differential privacy analysis. A common strategy is to use membership inference attacks to detect the presence of specific canaries—data points chosen to maximize attack success—in training data. However, existing canary designs are largely heuristic, relying on mislabeled or out-of-distribution samples. We address this gap by formulating canary design as a bilevel optimization problem, where the model is trained in the inner loop and the canary is optimized in the outer loop to maximize its detectability. To solve this problem, we develop OptiFluence, a scalable optimization framework that combines (i) initialization by selecting candidates using influence functions and (ii) unrolled optimization with memory-efficient techniques. Our approach achieves remarkable empirical performance on four datasets. Optimized canaries achieve nearperfect detection rates of 99.6% true positive rate at 0.1% false positive rate on CIFAR-10, outperforming in-distribution baselines by 4$\times$. Critically, these canaries transfer effectively across different model architectures without retraining, enabling practical third-party privacy audits. This transferability allows regulators and auditors to assess model privacy without requiring access to proprietary training infrastructure or substantial computational resources.

How Powerful are LLMs in Generating Formal Program Specifications?
Fanpeng Yang, Xing Li, Shuling Wang, Jie An, Zeyu Sun, Shenghua Feng, Wenhan Wang, Weiyi Wang, Naijun Zhan, Fanjiang Xu
Formal verification provides strong guarantees of software correctness, but its adoption is limited by the high cost of writing precise formal specifications. W

hile recent large language models (LLMs) have shown strong capabilities in theor em proving and verified code generation, their true ability to generate program specifications remains unclear. Existing evaluations require either verifying im plementation conformance or proving semantic equivalence between specifications, both of which are formidably difficult and may conflate proof difficulty with s pecification quality. To address this problem, we introduce Coins, a Rocq based evaluation framework that assesses specification quality by instantiating specif ications under evaluation on trusted test cases and generating concrete proof ob ligations. This design aligns with the asymmetric nature of formal reasoning, wh ere successful proofs provide reliable evidence while proof failures are inheren tly ambiguous. Using Coins, we conduct a large scale study on HumanEval with a c urated set of human written Rocq specifications. Our results show that specifica tion generation remains a formidable challenge, and that verification complexity can obscure genuine differences in specification quality. Overall, we find that accurate specification evaluation, rather than model scaling alone, is central to understanding the power of LLMs for specification synthesis, and that test ca se based formal reasoning offers a more faithful and discriminative measure of p rogress.

Efficiently Learning Drifting Halfspaces with Massart Noise

Mingchen Ma, Guyang Cao, Jelena Diakonikolas, Ilias Diakonikolas

We study the problem of learning a drifting concept in the
presence of Massart noise. In this framework,
an online learner has access to a history
of independent samples whose labels are noisy versions
of a target concept that may change from round to round.
The goal is to output, in each round, a hypothesis with
small prediction error.
We study the complexity of this learning
problem for the fundamental class of margin-separable
linear classifiers (halfspaces).
On the positive side, we give a
computationally efficient learner achieving error
$\eta + \tilde O(\Delta^{1/3}/\gamma)$,
where η upper bounds the Massart noise rate,
Δ is the drift rate, and γ is the margin.
Interestingly, in the realizable setting,
an adaptation of our techniques
yields an efficient learner with an improved error
rate over prior work.
On the lower-bound side, we provide formal evidence of an
information-computation tradeoff, strongly suggesting that
our algorithm's performance is essentially optimal.
Specifically,
while the information-theoretically optimal error
scales with $\Delta^{1/2}$, we prove
that $\Delta^{1/3}$-scaling is unavoidable for
low-degree polynomial tests,
even in the special case of random classification noise.

NetDiff: Graph Diffusion with Improved Global Capabilities to Generate and Updat e Mobile Network Topologies

Félix Marcoccia, Victor Fagoo, Gilles Monzat de Saint Julien, Cédric Adjih, Thom as Watteyne, Paul Mühlethaler

We introduce NetDiff, a node-conditioned denoising diffusion model that generate s directional link topologies and a two-slot transmit/receive parity for mobile ad hoc networks. Directional antennas can yield high throughput but require glob ally consistent link decisions under sector, interference, connectivity, and hal f-duplex constraints. NetDiff improves global coherence with Absolute Cross-Atte ntive Modulation (ACAM) tokens, which provide permutation-invariant global signa

ls and help the model match graph-level counts (e.g., density and sector usage). We also propose partial diffusion to update an existing topology with a small number of denoising steps, enabling fast reconfiguration under mobility. NetDiff reaches over 95 \% of target performance with constant inference time, outperforms heuristic and omnidirectional baselines, and improves over a strong diffusion graph-transformer baseline on key metrics.

FOCUS: DLLMs Know How to Tame Their Compute Bound
Kaihua Liang, Xin Tan, An Zhong, Hong Xu, Marco Canini
Diffusion Large Language Models (**DLLMs**) offer a compelling alternative to Auto-Regressive models, but their deployment is constrained by high decoding cost. In this work, we identify a key inefficiency in DLLM decoding: while computation is parallelized over token blocks, only a small subset of tokens is decodable at each diffusion step, causing most compute to be wasted on non-decodable tokens. We further observe a strong correlation between attention-derived token importance and token-wise decoding probability. Based on this insight, we propose FOCUS, an inference system designed for DLLMs. By dynamically *focusing* computation on decodable tokens and evicting non-decodable ones on-the-fly, FOCUS increases the effective batch size, alleviating compute limitations and enabling scalable throughput. Empirical evaluations demonstrate that FOCUS achieves up to 3.52× throughput improvement over the production-grade engine LMDeploy in large-batch settings, while preserving or improving generation quality across multiple benchmarks.
****

CSPO: Constraint-Sensitive Policy Optimization for Safe Reinforcement Learning
Ayoub Belouadah, Sylvain KUBLER, YVES LE TRAON
Safe reinforcement learning (Safe RL) aims to maximize expected return while satisfying safety constraints, typically modeled as Constrained Markov Decision Processes (CMDPs). While primal-dual methods scale well to deep RL, they often suffer from delayed constraint correction, leading to oscillatory behavior and prolonged safety violations. In this paper, we propose *Constraint-Sensitive Policy Optimization (CSPO)*, a first-order primal-dual method that incorporates local constraint sensitivity into policy updates. CSPO augments the primal objective with a constraint-sensitive correction derived from the shortest signed distance to the safety boundary, enabling smarter recovery steps back to safety, compensating for delayed Lagrange multiplier updates, reducing oscillations near the boundary, and preserving the KKT solutions of the original constrained problem. Experiments on navigation and locomotion benchmarks demonstrate that CSPO achieves faster safety recovery and high reward preservation, resulting in higher constrained returns compared to state-of-the-art primal-dual and penalty-based methods.
****

Dimension-Free Multimodal Sampling via Preconditioned Annealed Langevin Dynamics
Lorenzo Baldassari, Josselin Garnier, Knut Solna, Maarten V. de Hoop
Designing sampling algorithms for multimodal targets that remain stable under refinement of the finite-dimensional approximation of an underlying function-space problem is a central challenge. Annealed Langevin dynamics (ALD) is a natural alternative to classical Langevin in this context, since it is often observed to improve exploration across modes. Yet a gap remains between its empirical success and existing theory: under which conditions can ALD be guaranteed to remain stable across dimensions? In this paper, we bridge this gap by providing a uniform-in-dimension analysis of continuous-time ALD for Gaussian-mixture targets. Along an explicit annealing path obtained by gradually removing Gaussian smoothing from the target, we identify spectral conditions linking the smoothing covariance to the component covariances under which ALD achieves a prescribed accuracy in Kullback-Leibler divergence within a dimension-uniform time horizon. We then establish stability in a perturbative regime with imperfect initialization and approximate scores. Under a misspecified-mixture score model, we show that preconditioning ALD with an operator whose spectrum decays sufficiently fast prevents error terms from accumulating across coordinates and thereby preserves dimension-uniform control.

Expanding the Capabilities of Reinforcement Learning via Text Feedback
Yuda Song, Lili Chen, Fahim Tajwar, Rémi Munos, Deepak Pathak, Drew Bagnell, Aarti Singh, Andrea Zanette
The success of RL for LLM post-training stems from an unreasonably uninformative source: a single bit of information per rollout as binary reward or preference label. At the other extreme, distillation offers dense supervision but requires demonstrations, which are costly and difficult to scale. We study natural language feedback as an intermediate signal: richer than scalar rewards, yet cheaper than complete demonstrations. Textual feedback is a natural mode of human interaction and is already abundant in many real-world settings, where users, tools, and automated judges routinely critique LLM outputs. Towards leveraging text feedback at scale, we formalize a multi-turn RL setup where text feedback is available during training but not at inference. Therefore, models must learn to internalize the feedback in order to improve their test-time single-turn performance. To do this, we propose two methods: Self Distillation, which trains the single-turn policy to match its own feedback-conditioned second-turn generations; and Feedback Modeling, which predicts the feedback as an auxiliary objective. We provide theoretical analysis on both methods, and empirically evaluate on reasoning puzzles, competition math, and creative writing tasks. Our results show that both methods consistently outperform strong baselines across benchmarks, highlighting the potential of RL with an additional source of rich supervision at scale.
****
Quantifying the Generalization Gap in Seizure Detection: A Large-Scale Empirical Benchmark via the SzCORE Challenge
Jonathan Dan, Amirhossein Shahbazinia, Christodoulos Kechris, David Atienza
Reliable automatic seizure detection from long-term electroencephalogram recordings (EEG) remains an unsolved challenge, as current models often fail to generalize across patients or clinical settings. Manual EEG review still is the standard of care, highlighting the need for robust models and standardized evaluation. The current literature often reports high efficacy, yet these models frequently fail when deployed to unseen patient populations. To rigorously assess this generalization gap, we conducted a large-scale empirical study evaluating 28 state-of-the-art algorithmic architectures, ranging from classical feature engineering to modern Deep Learning. These algorithms were collected by organizing a competition. A strictly held-out private dataset of continuous EEG recordings from 65 subjects, totaling 4,360 hours of data, was utilized to evaluate algorithm performance. Expert neurophysiologists annotated these recordings, establishing the ground truth for seizure events. Algorithms were evaluated using event-based metrics from the SzCORE framework, including sensitivity, precision, F1-score, and false positive rate per day. Results revealed significant performance variability among state-of-the-art approaches, with the top F1 score of 32% (sensitivity 37%, precision 29%), highlighting the persistent difficulty of this task for current machine learning methodologies. Our analysis uncovered a discordance between peak performance and population-level stability. The algorithms achieving the highest aggregate F1-scores did not achieve the most consistent ranking across subjects, indicating high performance variance and susceptibility to failure on outlier patients. This independent evaluation also exposed a notable gap between self-reported efficacies and hold-out performance, underscoring the critical need for standardized, rigorous benchmarking in developing clinically viable ML models. A comparison with previous challenges and commercial systems indicates that the best algorithm in this study surpassed prior methods. Critically, the evaluation infrastructure transitions into a continuously open benchmarking platform, fostering reproducible research and accelerating the development of robust seizure detection algorithms by allowing ongoing submissions and integration of additional private datasets. Clinical centers can also adopt this platform to evaluate seizure detection algorithms on their EEG data using a standardized, reproducible framework.
****
Tuning-Free One-Class Discriminant Learning for Tabular Anomaly Detection

Xuan-Ha Nguyen, Vu Nguyen Thai Duong, Nguyen Van Hoi, Kim-Hung Le, Nhien-An Le-Khac

Anomaly detection (AD) on real-world tabular data is challenged by diverse anomaly types, scarce labels, and high sensitivity to data-specific hyperparameter tuning.

A central difficulty is that different anomaly types favor opposing representations: *compactness* - tightening the normal class to expose pointwise deviations - and *structure preservation* - retaining cluster and cross-feature relationships.

Existing one-class detectors capture only one of these or balance them via hyperparameters, which is problematic without validation labels.

We propose **Discriminant Vector Machine for Anomaly Detection (DVM-AD)**, a closed-form one-class method derived from discriminant analysis that captures both behaviors under a single fixed configuration.

From a deterministic reference point built from the training data, DVM-AD derives a bounded ratio whose two ends correspond to compressive and structure-preserving directions. This bound enables selecting directions from both ends simultaneously without dataset-specific tuning.

In addition, a Moore-Penrose pseudo-inverse keeps the method well-posed under high-dimensional or rank-deficient settings, and test samples are scored by nearest-neighbor distance in the discriminant space, normalized for thresholding-ready use.

Across 47 ADBench tabular datasets and 10 NLP/CV embedding benchmarks against 28 baselines, DVM-AD achieves the best average AUROC (89.65\%, average rank 2.98) on tabular datasets and remains top-ranked across four anomaly types and on embedding tasks (average rank 1.60, AUROC 72.68\%).

Cerebellar-Inspired Residual Control for Fault Recovery: From Inference-Time Adaptation to Structural Consolidation

Nethmi Jayasinghe, Diana Gontero, Spencer T. Brown, Vinod K Sangwan, Mark C. Hersam, Amit Ranjan Trivedi

Robotic policies deployed in real-world environments often encounter post-training faults, where retraining, exploration, or system identification are impractical. We introduce an inference-time, cerebellar-inspired residual control framework that augments a frozen reinforcement learning policy with online corrective actions, enabling fault recovery without modifying base policy parameters. The framework instantiates core cerebellar principles, including high-dimensional pattern separation via fixed feature expansion, parallel microzone-style residual pathways, and local error-driven plasticity with excitatory and inhibitory eligibility traces operating at distinct time scales. These mechanisms enable fast, localized correction under post-training disturbances while avoiding destabilizing global policy updates. A conservative, performance-driven meta-adaptation regulates residual gain and plasticity, preserving nominal behavior and suppressing unnecessary intervention. Experiments on MuJoCo benchmarks under actuator, dynamic, and environmental perturbations show improvements of up to $+66$% on $\texttt{HalfCheetah-v5}$ and $+53$% on $\texttt{Humanoid-v5}$ under moderate faults, with graceful degradation under severe shifts and complementary robustness from consolidating persistent residual corrections into policy parameters.

Curriculum Reinforcement Learning for Black-Box Prompt Tuning via Large Language Models

Shuai Gong, Chaoran Cui, Xiaolin Dong, Chunyun Zhang, Linwei Fan

Black-box prompt tuning (BBPT) aims to optimize input prompts for large models where internal parameters and gradients are inaccessible. However, existing methods fail to simultaneously address the dual challenges of prompt interpretability and query efficiency. To address these challenges, we propose CRL-BPT, a curriculum reinforcement learning framework that utilizes a large language model as an agent to generate human-readable prompts. Specifically, CRL-BPT implements a dynamic curriculum schedule on two auxiliary objectives: an imitation loss and an innovation loss. By dynamically weighting these objectives, CRL-BPT regularizes

the RL process, guiding the agent from mimicking reference prompts to discoverin g novel patterns. Additionally, we introduce tailored stabilization mechanisms c omprising historical loss normalization and relative reward calibration to promo te more stable training. Extensive experiments demonstrate that CRL-BPT establis hes new state-of-the-art performance and generates highly interpretable prompts under a strict budget of API calls. Code is available at https://github.com/Gong Shuai8210/CRL-BPT.
****
PRISM: Synergizing Vision Foundation Models via Self-organized Expert Specializa tion
Ying Tang, Dong Li, Youjia Zhang, Zikai Song, Junqing Yu, Wei Yang
Unifying the complementary strengths of diverse Vision Foundation Models (VFMs) into a single efficient model is highly desirable but challenged by the negative transfer inherent in monolithic distillation. To address these feature conflict s, we introduce \textbf{PRISM}, a novel dual-stream Mixture-of-Experts (MoE) fra mework that synergizes VFMs via modular specialization. We propose a two-stage p aradigm: (1) expertise deconstruction, where a teacher-conditional router guides experts to specialize in distinct representational subspaces to mitigate interf erence, followed by (2) dynamic recomposition, where the router learns to assemb le these experts into tailored computational pathways for downstream tasks. Expe riments on PASCAL-Context and NYUD-v2 show that \textbf{PRISM} establishes a new state of the art, validating that sparse, emergent specialization is a scalable approach for integrating diverse visual knowledge.
****
The Generalization Spectrum: A Chromatographic Approach to Evaluating Learning A lgorithms
Jinghan Zhang, Zerui Cheng, Shiqi Chen, Ge Zhang, Wenhao Huang, Jiashuo Liu, Jun xian He, Tianle Cai
Traditional evaluations measure a learning algorithm's final performance on an i .i.d. test set, reducing learning to a single aggregate score. This approach obs cures a fundamental question: to what extent does learning from a specific examp le generalize to others? Such per-sample generalization—akin to learning by anal ogy in human cognition—captures how far the knowledge extracted from one example can transfer, yet remains invisible to standard benchmarks.

We introduce the Generalization Spectrum, an evaluation framework designed to ex pose this hidden dimension. For each training example, we construct a controlled suite of test variants arranged by increasing transfer distance—from exact reca ll to implementation transfer across languages, context transfer under complete narrative re-framing, category-matched in-domain problems, and an unpaired basel ine. By tracking performance across these distances, we reveal not just whether an algorithm learns, but how far that learning extends.
We instantiate this framework on competitive programming, using a synthetic gene ration pipeline seeded with recent problems to mitigate contamination.

We first compare **three canonical learning paradigms** under matched memorizati on. RL converts memorization into near-transfer more efficiently than SFT-family baselines, while ICL exhibits strong but correspondence-dependent transfer.
We then use the Spectrum to diagnose **within-family variants**. The resulting p rofiles show that local gains need not expand the generalization radius: abstrac tions and hints mainly lift local transfer, RFT preserves a stronger far-transfe r tail than reference SFT, and self-distillation or hint-assisted RL can reduce far transfer even when local transfer or optimization improves.
****
CompleteP for RL: Maintaining Feature Learning When Scaling Deep Reinforcement L earning
Adam Lee, M Ganesh Kumar, Blake Bordelon, Cengiz Pehlevan
The maximal update parameterization (μP) provides an approach to scale para meters while preserving feature learning in deep neural networks. In fixed data distribution settings it has been found to yield more stable learning dynamics,

more consistent learned features, and enable optimal hyperparameters such as lea
rning rate to transfer from small models to larger ones. However, it is unclear
if these benefits readily transfer to reinforcement learning problems, where lea
rning dynamics are coupled to the non-stationary data distribution induced by an
 agent's own actions. We empirically study how two regimes, the ''rich'' Complet
eP and ''lazy'' Neural Tangent Kernel (NTK) parameterizations affect hyperparame
ter transfer, feature and policy consistency, and learning behavior as we scale
reinforcement learning agents. Ultimately, we show that agents trained using Com
pleteP consequentially improves compute and reward efficiency compared to the NT
K parameterization across multiple control tasks and variants.

All Circuits Lead to Rome: Rethinking Functional Anisotropy in Circuit and Sheaf
 Discovery for LLMs
Xi Chen, Mingyu Jin, Jingcheng Niu, Yutong Yin, Jinman Zhao, Bangwei Guo, Dimitr
is N. Metaxas, Zhaoran Wang, Yutao Yue, Gerald Penn
In this paper, we present empirical and theoretical evidence against a central b
ut largely implicit assumption in circuit and sheaf discovery (CSD), which we te
rm the *Functional Anisotropy Hypothesis*: the idea that functions in large lang
uage models (LLMs) are localised to a unique or near-unique internal mechanism.
We show that a single LLM task can instead be supported by multiple, structurall
y distinct circuits or sheaves that are simultaneously faithful, sparse, and com
plete. To systematically uncover such competing mechanisms, we introduce Overlap
-Aware Sheaf Repulsion, a method that augments the CSD objective with an explici
t penalty on structural overlap across multiple discovery runs, enabling the dis
covery of circuits or sheaves with strong task performance but minimal shared st
ructure across a plethora of common CSD benchmarks. We find that this phenomenon
 becomes increasingly pronounced as the number of discovered sheaves grows and p
ersists robustly across major CSD methods. We further identify an ultra-sparse t
hree-edge sheaf and show that none of its edges is individually indispensable, u
ndermining even weakened notions of canonical or essential components. To explai
n these findings, we propose a *Distributive Dense Circuit Hypothesis* and provi
de a theoretical analysis demonstrating that non-unique, low-overlap circuit exp
lanations arise naturally from high-dimensional superposition under mild assumpt
ions. Together, our results suggest that mechanistic explanations in LLMs are in
herently non-canonical and call for a rethinking of how CSD results should be in
terpreted and evaluated.
****

ComplexMCP: Evaluation of LLM Agents in Dynamic, Interdependent, and Large-Scale
 Tool Sandbox
Yuanyang Li, Xue Yang, Longyue Wang, Weihua Luo, Hongyang Chen
Current LLM agents are proficient at calling isolated APIs but struggle with the
 "last mile" of commercial software automation. In real-world scenarios, tools a
re not independent; they are atomic, interdependent, and prone to environmental
noise. We introduce $\textbf{ComplexMCP}$, a benchmark designed to evaluate agen
ts in these rigorous conditions. Built on the Model Context Protocol (MCP), $\te
xtbf{ComplexMCP}$ provides over 300 meticulously tested tools derived from 7 sta
teful sandboxes, ranging from office suites to financial systems. Unlike existin
g datasets, our benchmark utilizes a seed-driven architecture to simulate dynami
c environment states and unpredictable API failures, ensuring a deterministic ye
t diverse evaluation.

We evaluate various LLMs across full-context and RAG paradigms, revealing a star
k performance gap: even top-tier models fail to exceed a 60% success rate, far t
railing human performance 90%. Granular trajectory analysis identifies three fun
damental bottlenecks: (1) $\textbf{tool retrieval saturation}$ as action spaces
scale; (2) $\textbf{over-confidence}$, where agents skip essential environment v
erifications; and (3) $\textbf{strategic defeatism}$, a tendency to rationalize
failure rather than pursuing recovery. These findings underscore the insufficien
cy of current agents for interdependent workflows, positioning $\textbf{ComplexM
CP}$ as a critical testbed for the next generation of resilient autonomous syste

ms. The codebase and benchmark implementation are publicly available at https://github.com/AIDC-AI/complex-mcp.

Subgroup Discovery with the Cox Model
Zachary Izzo, Iain Melvin
We study the problem of subgroup discovery for survival analysis, where the goal is to find an interpretable subset of the data on which a Cox model is highly accurate. We examine why existing quality functions are insufficient for this problem and introduce two technical innovations: the *expected prediction entropy (EPE)*, a novel metric for evaluating survival models that predict hazard functions, and the *conditional rank statistics (CRS)*, which quantifies individual point deviation from a subgroup's survival time distribution. We study the EPE and CRS theoretically and show they address problems with existing metrics. We then introduce eight algorithms for Cox subgroup discovery. Our main algorithm is based on the DDGroup framework of Izzo et al. (2023) and leverages both the EPE and CRS, allowing theoretical correctness guarantees in well-specified settings. Empirical evaluation on synthetic and real data confirms our theory, showing our methods recover ground-truth subgroups in well-specified cases and achieve better model fit than naively fitting the Cox model to the entire dataset. A case study on NASA jet engine simulation data demonstrates that discovered subgroups uncover known nonlinearities in the data and suggest design choices mirrored in practice.

MoSSP: A Momentum-Based Single-Loop Stochastic Penalty Method for Nonconvex Constrained DC-regularized Optimization
Luxuan Li, Chunfeng Cui, Xiao Wang
In this paper, we study a structured class of nonconvex constrained stochastic problems with difference-of-convex (DC) regularization, where the feasible set is possibly nonconvex and the concave part of the DC regularizer is allowed to be nonsmooth.
The fundamental challenge lies in maintaining feasibility for nonconvex constraints while achieving favorable oracle complexity.
Although single-loop algorithms efficiently solve unconstrained DC optimization problems, their potential for constrained optimization with DC structure remains largely unexplored. To address this gap, we develop **MoSSP**, a **Mo**mentum-based **S**ingle-loop **S**tochastic **P**enalty method for such problems with provable complexity guarantees. The key idea is to apply a single stochastic proximal-gradient step to the Moreau envelope of the penalty plus the convex DC part, with the concave part's proximal mapping computed in parallel. We derive two algorithm variants: a Polyak-momentum version with $\mathcal{O}(\varepsilon^{-4})$ oracle complexity for finding stochastic ε-KKT points, and an improved $\mathcal{O}(\varepsilon^{-3})$ version incorporating recursive momentum. Experimental results demonstrate the effectiveness of the proposed algorithms.

Genome-Factory: A Library for Tuning, Deploying, and Interpreting Genomic Foundation Models
Weimin Wu, Xuefeng Song, Yibo Wen, Qinjie Lin, Zhihan Zhou, Jerry Yao-Chieh Hu, Zhong Wang, Han Liu
We introduce Genome-Factory, the first integrated Python library for tuning, deploying, and interpreting genomic foundation models.
Our core contribution is to simplify and unify the workflow for genomic model development: data collection, model tuning, inference, benchmarking, and interpretability.
For data collection, Genome-Factory offers an automated pipeline to download genomic sequences and preprocess them.
For model tuning, Genome-Factory supports both full and parameter-efficient fine-tuning across diverse genomic models.
For inference, Genome-Factory enables both embedding extraction and DNA sequence generation.
For benchmarking, we include two existing benchmarks and provide a flexible inte

rface to incorporate additional benchmarks.
For interpretability, Genome-Factory introduces an open-source biological interp reter based on a sparse auto-encoder.
We validate the utility of Genome-Factory across three dimensions:
(i) Compatibility with diverse models and fine-tuning methods;
(ii) Benchmarking downstream performance using two open-source benchmarks;
(iii) Biological interpretation of learned representations with DNABERT-2.
These results highlight its practical value for real-world genomic analysis.
GitHub: https://github.com/WeiminWu2000/Genome_Factory.

VecDesigner: Exploring Visual Guidance and Structural Consistency for Semantic T ypography
Liu Yu, Xingjiao Wu, Ziang Liu, Jiabao Zhao, Daoguo Dong, Liang He
Semantic Typography aims to visualize the meaning of an input word through the f orm of a character, while preserving its legibility. Existing vector-based metho ds, which primarily rely on text-driven optimization like Score Distillation Sam pling (SDS), often produce glyphs that lack rich semantic details. Furthermore, these approaches struggle to maintain the overall structural integrity of the gl yphs and frequently suffer from visual artifacts caused by intersections, compro mising both readability and aesthetic quality. To address these challenges, we p ropose VecDesigner, a novel optimization-based method for vector semantic typogr aphy. Specifically, we introduce Visual-Guided Score Distillation Sampling (VGSD S), which leverages text-related reference images as visual guidance to infuse t he glyphs with richer and more concrete semantic details. To preserve legibility and structural integrity, we design a vector-based Procrustes loss to constrain the overall deformation of the glyph. Concurrently, we effectively mitigate the intersection problem by imposing positional relationship constraints on the con trol points. Comprehensive experiments demonstrate that VecDesigner outperforms existing methods in both semantic expression and structural preservation, genera ting high-quality, expressive, and clearly legible semantic glyphs.

Draft-and-Audit Reinforcement Learning for Optimization Modeling
Zeping Min, Weihang Xu, Zhengzhong You, Wotao Yin, Xinshang Wang
Natural language to optimization (NL2Opt) requires translating unstructured text into executable mathematical models. Beyond simple syntax errors, this task suf fers from silent modeling failures, where incorrect formulations execute success fully but yield invalid results. We propose \textbf{Draft-and-Audit RL (DA-RL)}, a framework that learns optimization modeling as a two-step iterative workflow. Unlike inference-time scaffolds that rely on intermediate solver feedback to gu ide repairs, DA-RL optimizes a shared-parameter policy using terminal-only verif ication: the model is rewarded solely based on the execution of the final audite d program. This constraint forces the model to internalize rubric-guided revisio n as a learned capability and encourages the emergence of cross-turn synergy, wh ere the policy learns to generate drafts that are structurally amenable to self- correction.

SL-VC: A Benchmark and Automated Framework for Separation Logic Verification Con dition Proving
Hanyang Wang, Xiwei Wu, Qinxiang Cao
Formal verification of system software with complex heap manipulations remains c hallenging. Standard automated solvers frequently fail to discharge separation l ogic verification conditions even when correct specifications like loop invarian ts are provided, forcing verification engineers to manually construct proofs. Wh ile large language models (LLMs) have shown promise in proof synthesis, speciali zed approaches for separation logic remain unexplored. To bridge this gap, we in troduce SL-VC (Separation Logic Verification
Conditions), a benchmark of 289 verification conditions from textbook implementa tions of data structures and algorithms together with real-world C code, includi ng the LiteOS kernel's linked list library and the mini-gmp library. Our evaluat ion reveals that general-purpose LLMs and existing LLM-based Rocq provers strugg

le to effectively discharge these verification conditions. To address this chall
enge, we propose SPLIT (Split spatial and pure Proving with LLM-frIendly Tactics
), a novel framework that enables predictable proof state transitions through an
 LLM-friendly tactic library, combined with a two-stage workflow that separates
spatial and pure reasoning to align with separation logic semantics. Experimenta
l results on SL-VC demonstrate that SPLIT consistently outperforms existing appr
oaches, showing that LLM-assisted proof synthesis is a promising solution for se
paration logic verification of real-world system software.

HodgeFlow Policy Search by Topologically Dissecting Temporal-Difference Signals
in Non-Markovian Environments
Zuyuan Zhang, Sizhe Tang, Tian Lan
Non-Markovian dynamics are commonly found in real-world environments due to long
-range dependencies, partial observability, and memory effects. The Bellman equa
tion that is the central pillar of Reinforcement learning (RL) becomes only appr
oximately valid under Non-Markovian. Existing work often focus on practical algo
rithm designs and offer limited theoretical treatment to address key questions,
such as what dynamics are indeed capturable by the Bellman framework and how to
inspire new algorithm classes with optimal approximations. In this paper, we pre
sent a novel topological viewpoint on temporal-difference (TD) based RL. We show
 that TD errors can be viewed as 1-cochain in the topological space of state tra
nsitions, while Markov dynamics are then interpreted as topological integrabilit
y. This novel view enables us to obtain a Hodge-type decomposition of TD
errors into an integrable component and a topological residual, through a Bellma
n–de Rham projection. We further propose HodgeFlow Policy Search (HFPS) by fitti
ng a {potential network} to minimize the non-integrable projection residual in R
L, achieving stability/sensitivity guarantees. In numerical evaluations, HFPS is
 shown to significantly improve RL performance under non-Markovian.

Single-Head Attention in High Dimensions: A Theory of Generalization, Weights Sp
ectra, and Scaling Laws
Fabrizio Boncoraglio, Vittorio Erba, Emanuele Troiani, Yizhou Xu, Florent Krzaka
la, Lenka Zdeborová
Trained attention layers exhibit striking and reproducible spectral structure of
 the weights, including low-rank collapse, bulk deformation, and isolated spectr
al outliers, yet the origin of these phenomena and their implications for genera
lization remain poorly understood. We study empirical risk minimization in a sin
gle-head tied-attention layer trained on synthetic high-dimensional sequence tas
ks generated from the attention-indexed model. Using tools from random matrix th
eory, spin-glass theory, and approximate message passing, we obtain an exact hig
h-dimensional characterization of training and test error, interpolation and rec
overy thresholds, and the spectrum of the key and query matrices. Our theory pre
dicts the full singular-value distribution of the trained query–key map—includin
g low-rank structure and isolated spectral outliers—in qualitative agreement wit
h observations in more realistic transformers. Finally, for targets with power-l
aw spectra, we show that learning proceeds through sequential spectral recovery,
 leading to the emergence of power-law scaling laws.

Gradients with Respect to Semantics Preserving Embeddings Tell the Uncertainty o
f Large Language Model
Mingda Li, Rundong Lv, Xinyu Li, Weinan Zhang, Ting Liu
Uncertainty quantification (UQ) is an important technique for ensuring the trust
worthiness of LLMs, given their tendency to hallucinate. Existing state-of-the-a
rt UQ approaches for free-form generation rely heavily on sampling, which incurs
 high computational cost and variance. In this work, we propose the first gradie
nt-based UQ method for free-form generation, SemGrad, which is sampling-free and
 computationally efficient. Unlike prior gradient-based methods developed for cl
assification tasks that operates in parameter space, we propose to consider grad
ients in semantic space. Our method builds on the key intuition that a confident
 LLM should maintain stable output distributions under semantically equivalent i

nput perturbations. We interpret the stability as the gradients in semantic spac
e and introduce a Semantic Preservation Score (SPS) to identify embeddings that
best capture semantics, with respect to which gradients are computed. We further
 propose HybridGrad, which combines the strengths of SemGrad and parameter gradi
ents. Experiments demonstrate that both of our methods provide efficient and eff
ective uncertainty estimates, achieving superior performance than state-of-the-a
rt methods, particularly in settings with multiple valid responses.

Dual-View Predictive Diffusion: Lightweight Speech Enhancement via Spectrogram-I
mage Synergy

Ke Xue, Rongfei Fan, Kai Li, Shanping Yu, Puning Zhao, Jianping An

Diffusion models have recently set new benchmarks in Speech Enhancement (SE). Ho
wever, most existing score-based models treat speech spectrograms merely as gene
ric 2D images, applying uniform processing that ignores the intrinsic structural
 sparsity of audio, which results in inefficient spectral representation and pro
hibitive computational complexity. To bridge this gap, we propose **DVPD**, an e
xtremely lightweight **D**ual-**V**iew **P**redictive **D**iffusion model, which
 uniquely exploits the dual nature of spectrograms as both visual textures and p
hysical frequency-domain representations across both training and inference stag
es. Specifically, during training, we optimize spectral utilization via the Freq
uency-Adaptive Non-uniform Compression (FANC) encoder, which preserves critical
low-frequency harmonics while pruning high-frequency redundancies. Simultaneousl
y, we introduce a Lightweight Image-based Spectro-Awareness (LISA) module to cap
ture features from a visual perspective with minimal overhead. During inference,
 we propose a Training-free Lossless Boost (TLB) strategy that leverages the sam
e dual-view priors to refine generation quality without any additional fine-tuni
ng. Extensive experiments across various benchmarks demonstrate that DVPD achiev
es state-of-the-art performance while requiring only **35%** of the parameters a
nd **40%** of the inference MACs compared to SOTA lightweight model, PGUSE. Thes
e results highlight DVPD's superior ability to balance high-fidelity speech qual
ity with extreme architectural efficiency. Code and audio samples are available
at https://github.com/ke12345213/dvpd_demo

GraphFlow: A Graph-Based Workflow Management for Efficient LLM-Agent Serving

Ao Li, Shangpeng Yang, Fahao Chen, Tianheng Xu, Peng Li, su zhou

Large Language Model (LLM)-based agents demonstrate strong reasoning and executi
on capabilities on complex tasks when guided by structured instructions, commonl
y referred to as workflows. However, existing workflow-assisted agent serving sy
stems typically rely on predefined templates and shallow matching mechanisms, wh
ich limit their ability to capture deep semantic relationships and generalize to
 previously unseen tasks. To address these limitations, we propose a new workflo
w management paradigm that represents workflows using a unified graph, termed wG
raph, where each node corresponds to an atomic operation. wGraph serves as a sha
red substrate from which task-specific workflows are dynamically instantiated. B
uilding on wGraph primitives, we introduce GraphFlow, a system that efficiently
integrates workflows into agent serving through two key designs. First, adaptive
 workflow generation dynamically constructs workflows from wGraph based on task
semantics and constraint requirements. Second, workflow state management exploit
s wGraph structure to efficiently manage Key-Value (KV) caches, reducing redunda
nt computation during agent serving. Extensive experiments across five benchmark
 datasets show that GraphFlow consistently outperforms state-of-the-art methods,
 yielding an average performance improvement of approximately 4.95 percentage po
ints, while achieving an approximately 4× reduction in memory footprint.

On Effectiveness and Efficiency of Agentic Tool-calling and RL Training

Tong Liu, Cheng Qian, Matej Cief, Yuan He, Daniele Dan, Nikolaos Aletras, Gabrie
lla Kazai

Tool-calling is a central component of modern large language model (LLM) agents,
 equipping them with skills beyond their parametric knowledge.
This paper studies tool-calling along two complementary axes: **effectiveness**,

 i.e., how this capability is *measured*, and **efficiency**, i.e., how it is *learned*.
On effectiveness, we systematically analyze tool-calling evaluation pipelines and show that results can be highly sensitive to seemingly minor, often undocumented implementation choices including the *random seed*, *system prompt*, *multi-turn template construction*, and how *prior interaction/reasoning history* is carried forward.
These choices can lead to substantial differences in reported performance, especially in multi-turn settings where without rigorous standardization, leaderboard rankings are unreliable.
On efficiency, we examine standard reinforcement learning (RL) for tool-calling and identify two sources of computational waste: (i) during rollouts, many prompts produce no learning signal, and (ii) during policy updates, optimization incurs high computational cost.
Guided by these findings, we introduce two techniques that accelerate RL-based tool-calling training, achieving substantial wall-clock speedup without degrading performance.

Process Reward Agents for Steering Knowledge-Intensive Reasoning
Jiwoong Sohn, Tomasz Sternal, Kenneth Styppa, Torsten Hoefler, Michael Moor
Reasoning in knowledge-intensive domains remains challenging as intermediate steps are often not locally verifiable: unlike math or code, evaluating step correctness may require synthesizing clues across large external knowledge sources. As a result, subtle errors can propagate through reasoning traces, potentially never to be detected. Prior work has proposed process reward models (PRMs), including retrieval-augmented variants, but these methods operate post hoc, scoring completed trajectories, which prevents their integration into dynamic inference procedures. Here, we introduce Process Reward Agents (PRA), an inference-time method for providing domain-grounded, online, step-wise rewards to a frozen policy. In contrast to prior retrieval-augmented PRMs, PRA enables search-based decoding to rank and prune candidate trajectories at every generation step. Experiments on multiple medical reasoning benchmarks demonstrate that PRA consistently outperforms strong baselines, achieving 81.9% accuracy on MedQA with Qwen3-4B, a new state of the art at the 4B scale. Importantly, PRA generalizes to unseen frozen policy models ranging from 0.5B to 8B parameters, improving their accuracy by up to 25.7% without any policy model updates. More broadly, PRA suggests a paradigm in which frozen reasoners are decoupled from domain-specific reward modules, allowing the deployment of new backbones in complex domains without retraining. All code and data are publicly available at https://process-reward-agents.github.io/.

Bias-Spectrum Neural Processes for Parametric PDEs: Architecture Priors Meet PDE Constraints
Hui Li, Huafeng Liu, Chenguang Li, Tianxiao Zhang, Yajun Yang, Liping Jing
Parametric partial differential equations (PDEs) serve as fundamental models across science and engineering, yet constructing fast and accurate surrogate models from sparse, irregularly sampled observations with reliable uncertainty quantification remains challenging. Existing approaches struggle to simultaneously handle variable observation patterns, preserve physics consistency, and provide well-calibrated predictive uncertainty. We introduce Bias-Spectrum Neural Processes (BSNP), a unified meta-learning framework that systematically integrates weak structural priors (translation equivariance, locality) with strong physical priors (governing equations and boundary conditions). BSNP addresses two critical obstacles: discretization overfitting through stochastic collocation that resamples residual evaluation points, and uncertainty collapse through mean-field enforcement that applies PDE constraints only to predictive means while preserving learned uncertainty. Comprehensive experiments on nonlinear Poisson equations, Burgers dynamics, and Navier-Stokes flows demonstrate that BSNP achieves superior accuracy and well-calibrated uncertainty quantification in sparse-data regimes.

Rethinking the Design Space of Reinforcement Learning for Diffusion Models: On t
he Importance of Likelihood Estimation Beyond Loss Design
Jaemoo Choi, Yuchen Zhu, Wei Guo, Petr Molodyk, Bo Yuan, Jinbin Bai, Yi Xin, Mol
ei Tao, Yongxin Chen
Reinforcement learning has been widely applied to diffusion and flow models for
visual tasks such as text-to-image generation. However, these tasks remain chall
enging because diffusion models have intractable likelihoods, which creates a ba
rrier for directly applying popular policy-gradient type methods. Existing appro
aches primarily focus on crafting new objectives built on already heavily engine
ered LLM objectives, using ad hoc estimators for likelihood, without a thorough
investigation into how such estimation affects overall algorithmic performance.
 In this work, we provide a systematic analysis of the RL design space by disent
angling three factors: i) policy-gradient objectives, ii) likelihood estimators,
 and iii) rollout sampling schemes. We show that adopting an evidence lower boun
d (ELBO) based model likelihood estimator, computed only from the final generate
d sample, is the dominant factor enabling effective, efficient, and stable RL op
timization, outweighing the impact of the specific policy-gradient loss function
al. We validate our findings across multiple reward benchmarks using SD 3.5 Medi
um, and observe consistent trends across all tasks. Our method improves the GenE
val score from 0.24 to 0.95 in 90 GPU hours, which is $4.6\times$ more eff
icient than FlowGRPO and $2\times$ more efficient than the SOTA method Diffusion
NFT without reward hacking.

MechVQA: Benchmarking and Enhancing Multimodal LLMs on Comprehensive Mechanical
Drawing Understanding
Qian Kou, Xiaofeng Shi, Yulin Li, Xiaosong Qiu, Xinyang Wang, Hua Zhou, Cao Dong
xing
Multimodal Large Language Models (MLLMs) have demonstrated significant achieveme
nts in
general visual question answering (VQA) tasks.
However, they remain brittle on mechanical en-
gineering drawings, where high annotation den-
sity and weak domain knowledge, compounded
by unreliable spatial relation reasoning under
strict projection rules and geometric constraints,
make decisive cues easy to miss and frequently
lead to wrong answers. To bridge this gap,
we introduce the first comprehensive mechani-
cal drawing understanding dataset, MechVQA,
created through a semi-automated construction
and quality-control pipeline. MechVQA con-
tains 3.3k high-density pictures with 21K ques-
tion–answer pairs, spanning 10 different fine-
grained tasks across three capability levels:
Recognition, Reasoning, and Judging, provid-
ing a testbed to evaluate and improve MLLM
understanding on real-world mechanical draw-
ings. On top of MechVQA, we then develop the
MechVL model through a multi-stage training
paradigm, building a strong domain-specialized
baseline. Extensive experimental results demon-
strate that MechVL outperforms the strongest
closed-source baseline by 7.57 percentage points
on the MechVQA total score, significantly en-
hancing mechanical drawing understanding abil-
ity and providing a reusable foundation for deploy-
ing MLLMs in mechanical design and inspection
scenarios.

Distilling Task-Level Coordination Policies for Generalizable Multi-Agent Cooper

ation
Zimo Zhai, Manjie Xu, Wei Liang
Large language models have shown strong reasoning abilities and are increasingly explored as high-level coordinators for multi-agent systems. However, directly deploying LLMs for coordination remains challenging, as effective policies often fail to reliably emerge at the low-level control stage, and inference costs limit scalability.
We propose SynCoord (Synthetic Coordination Distillation), a self-supervised pipeline that distills task-level decision-making for cooperation from high-capacity reasoning models into lightweight agent policies. Our approach does not rely on explicit supervision or handcrafted coordination rules. Instead, we define a set of task-level tool interfaces that constrain LLM interaction and enable the collection of interaction trajectories, which are then used to train compact coordinated policies. This distillation process transfers coordination behaviors that are difficult to elicit through prompting alone, while substantially reducing inference overhead at execution time.
We evaluate our method on cooperative multi-agent benchmarks including Overcooked-AI and Level-Based Foraging (LBF), under varying team sizes and environment scales. Experimental results show that the distilled policies achieve success rates and execution efficiency comparable to reinforcement learning–based methods, while exhibiting fewer erroneous or redundant actions. Moreover, the learned task-level coordination policy generalizes effectively to unseen team compositions and larger layouts without retraining.
****
Enhancing Cross-subject Emotion Recognition via Heterogeneous Distribution Augmentation and Collaborative Learning
Wending Xiong, Ruimin Hu, Lingfei Ren, Junhang Wu, Mei Wang, Dengshi Li, Mang Ye
Cross-subject emotion recognition aims to improve a model's generalization to previously unseen subjects. Existing methods are mainly built upon domain generalization or data augmentation, but suffer from two major limitations: 1) heavy dependence on modality-specific feature designs—almost exclusively tailored to EEG signals—resulting in limited generalizability; and 2) the widespread assumption of independently and identically distributed data, which restricts the diversity of generated samples. To address these challenges, we systematically analyze the heterogeneous distribution characteristics of emotion data and propose **MixEmo**, a framework that integrates heterogeneous distribution augmentation and collaborative learning. Specifically, a well-trained backbone is used to extract representations and partition them into multiple single-distribution subsets as distribution prototypes. These prototypes are randomly combined to synthesize unseen distributions, thereby enhancing distributional diversity. Finally, heterogeneous distribution collaborative learning jointly optimizes the model across subsets. Extensive experiments demonstrate that **MixEmo** substantially improves generalization performance in cross-subject emotion recognition.
****
Accurate, Private, Secure, Federated U-statistics with Higher Degree
Quentin Sinh, Jan Ramon
We study the problem of computing a U-statistic with a kernel function f of degree $k \geq 2$, i.e.,
the average of some function f over all k-tuples of instances,
in a federated learning setting.
U-statistics of degree 2 include several useful statistics such as Kendall's τ coefficient,
the Area under the Receiver-Operator Curve and the Gini mean difference.
Existing methods provide solutions only under the lower-utility local differential privacy model and/or scale poorly in the size of the domain discretization.

In this work, we propose a protocol that securely computes U-statistics of degree $k \geq 2$ under central differential privacy by leveraging Multi Party Computation (MPC).
Our method substantially improves accuracy when compared to prior solutions.

We provide a detailed theoretical analysis of its accuracy, communication and co
mputational properties.
We evaluate its performance empirically, obtaining favorable results, e.g., for
Kendall's τ coefficient, our approach reduces the Mean Squared Error by up
to four orders of magnitude over existing baselines.
****
Efficient and Minimax Optimal In-context Nonparametric Regression with Transform
ers
Michelle Ching, Ioana Popescu, Nico Smith, Tianyi Ma, William G. Underwood, Rich
ard J. Samworth
We study in-context learning for nonparametric regression with α-Hölder s
mooth regression functions, for some $\alpha>0$. We
prove that, with n in-context examples and d-dimensional regression covariat
es, a pretrained transformer with $\Theta(\log n)$ parameters and $\Omega(n^{2\a
lpha/(2\alpha+d)}\log^3 n)$ pretraining sequences can achieve the minimax optima
l rate of convergence $O(n^{-2\alpha/(2\alpha+d)})$ in mean squared error. Our r
esult requires substantially fewer transformer parameters and pretraining sequen
ces than previous results in the literature. This is achieved by showing that tr
ansformers are able to approximate local polynomial estimators efficiently by im
plementing a kernel-weighted polynomial basis and then running gradient descent.
****
Learning to Label: A Reinforced Self-Evolving Framework for Semi-supervised Refe
rring Expression Segmentation
Runlong Cao, Ying Zang, Chuanwei Zhou, Tianrun Chen, Tong Zhang, Zhen Cui, Chuny
an Xu
Semi-supervised referring expression segmentation (SS-RES) aims to achieve preci
se pixel-level language grounding under limited annotation, yet suffers from lim
ited supervision and unreliable pseudo-labels when exploiting unlabeled image–te
xt pairs.
In this work, we propose Learning to Label, a reinforced self-evolving framework
 (L2L) that casts pseudo-label construction as a learnable decision-making proce
ss. To build foundational understanding, we leverage a multimodal large language
 model to extract semantic–spatial priors, which are instantiated as initial sof
t segmentation proposals and elevated—together with textual cues—into learnable
guidance signals that condition a hierarchical segmentation network. To ensure s
table learning, a reinforced pseudo-label selection is further formulated as an
exploratory decision process that adaptively rewards high-utility pixel-level su
pervision based on multimodal priors and model predictions. This reinforced self
-evolving loop enables joint optimization of the segmentation model and pseudo-l
abels, progressively enhancing label reliability under sparse supervision. Exten
sive experiments on RefCOCO, RefCOCO+, and RefCOCOg datasets demonstrate improve
ments over existing methods, validating its effectiveness and generalization.

Mind-Omni: A Unified Multi-Task Framework for Brain-Vision-Language Modeling via
 Discrete Diffusion
Yizhuo Lu, Changde Du, Qingyu Shi, Hang Chen, Jie Peng, Liuyun Jiang, Shuangchen
 Zhao, Huiguang He
Modeling the interplay between external stimuli and internal neural representati
ons is a pivotal research area for Brain-Computer Interfaces (BCIs). A major lim
itation of prior work is the prevailing paradigm of specialized, single-task mod
els, which curtails versatility and neglects inter-task synergies. To address th
is, we propose Mind-Omni, the first versatile framework that unifies seven disti
nct encoding and decoding tasks through a discrete diffusion paradigm. At its co
re is a novel Brain Tokenizer that transforms heterogeneous, continuous brain si
gnals into standardized, discrete tokens. This enables direct, token-level inter
actions for mutual understanding and generation between any two or more modaliti
es within a shared semantic space. To unlock advanced reasoning capabilities, we
 further curate a specialized Brain Question Answering (BQA) instruction-tuning
dataset. Our model not only establishes a new state-of-the-art among multi-task
unified frameworks but also provides strong evidence for multi-task synergy. By

demonstrating performance competitive with, and at times superior to, larger specialized models, our work offers a powerful new paradigm for neural modeling and paves the way for foundation models of neural activity.
****

On Contraction of Sequential and Offset Rademacher Complexities
Adam Block, Alexander Rakhlin, Mark Sellke
The Rademacher complexity of a function class is among the most basic notions of its ``size'' and yields classical offline generalization bounds for Lipschitz loss functions that lead in turn to a modern understanding of statistical learning. More recently, the *sequential* and *offset* Rademacher complexities were introduced to prove analogous generalization bounds for online learning and for prediction with squared loss. A fundamental structural result in the theory of Rademacher complexity, with many applications to learning theory, is the Ledoux--Talagrand contraction lemma, which states that the Rademacher complexity of a composition of a function class with a fixed Lipschitz function is at most that of the original class. We show that, under structural assumptions on the function class, this contraction extends to sequential and offset Rademacher complexity at the price of polylogarithmic factors. We further show that these logarithmic factors cannot be removed in general and, absent these additional structural assumptions, no such contraction inequality can hold. These results together indicate that the sequential and offset Rademacher complexities behave fundamentally differently from the classical Rademacher complexity with respect to contraction, which in turn has broad implications for understanding the sample complexities of online learning and regression with squared loss for composed function classes.

MAS-Orchestra: Understanding and Improving Multi-Agent Reasoning Through Holistic Orchestration and Controlled Benchmarks
Zixuan Ke, Yifei Ming, Austin Xu, Ryan Chin, Xuan-Phi Nguyen, Prathyusha Jwalapuram, Jiayu Wang, Semih Yavuz, Caiming Xiong, Shafiq Joty
While multi-agent systems (MAS) promise elevated intelligence through coordination of agents, current approaches to automatic MAS design under-deliver. Such shortcomings stem from two key factors: (1) methodological complexity – agent orchestration is performed using sequential, code-level execution that limits global system-level holistic reasoning and scales poorly with agent complexity – and (2) efficacy uncertainty – MAS are deployed without understanding if there are tangible benefits compared to single-agent systems (SAS). We propose MASOrchestra, a training-time framework that formulates MAS orchestration as a function-calling reinforcement learning problem with holistic orchestration, generating an entire MAS at once. In MAS-Orchestra, complex, goal-oriented subagents are abstracted as callable functions, enabling global reasoning over system structure while hiding internal execution details. To rigorously study when and why MAS are beneficial, we introduce MASBENCH, a controlled benchmark that characterizes tasks along five axes: Depth, Horizon, Breadth, Parallel, and Robustness. Our analysis reveals that MAS gains depend critically on task structure, verification protocols, and the capabilities of both orchestrator and subagents, rather than holding universally. Guided by these insights, MAS-Orchestra achieves consistent improvements on public benchmarks including mathematical reasoning, multi-hop QA, and search-based QA, while achieving more than 10× efficiency over strong baselines. Together, MAS-Orchestra and MASBENCH enable better training and understanding of MAS in the pursuit of multi-agent intelligence.
****

Reasoning Models Struggle to Control their Chains of Thought
Chen Yueh-Han, Robert McCarthy, Bruce W. Lee, He He, Micah Carroll, Tomek Korbak
Instruction following in LLMs captures models' ability to change their visible behaviors as requested by users. Instead, we study models' ability to control their chain-of-thought (CoT). This capability -- CoT controllability -- is undesirable because it could allow models to suppress signs of misbehavior in their CoT, thereby undermining our ability to monitor them. To measure this, we introduce the \emph{CoT-Control} evaluation suite. We show that reasoning models are less

able to follow instructions in their CoT than in their outputs: on instructions like reasoning about a genetics problem without mentioning the word ``chromosome", Claude-Sonnet-4.5 complies only 5\% of the time. We also find that CoT controllability is higher for larger models and decreases with more RL training, test-time compute, and increased problem difficulty. CoT controllability failures extend even to situations in which models are given incentives (as opposed to direct requests) to evade CoT monitors, although models that are told they're being monitored exhibit slightly higher controllability. Similarly, eliciting controllability by adversarially optimizing prompts doesn’t meaningfully increase controllability.
Our results leave us cautiously optimistic: reasoning models generally seem characterized by low CoT controllability. However, the mechanism behind this phenomenon is not well understood. Given its importance for maintaining CoT monitorability, we recommend that frontier labs keep tracking controllability for future models.
****
QiMeng-ChipV-RTL: Exploiting Information Locality for IP-level Verilog Generation
Hanqi Lyu, Di Huang, Yaoyu Zhu, Kangcheng Liu, Bohan Dou, Chongxiao Li, Pengwei Jin, Shuyao Cheng, Rui Zhang, Zidong Du, Qi Guo, Xing Hu, Yunji Chen
The generation of Register-Transfer Level (RTL) code is a crucial yet labor-intensive step in digital hardware design, traditionally requiring engineers to manually translate complex specifications into thousands of lines of synthesizable Hardware Description Language (HDL) code. While Large Language Models (LLMs) have shown promise in automating this process, existing approaches—including fine-tuned domain-specific models and advanced agent-based systems—struggle to scale to industrial IP-level design tasks. We identify three key challenges: (1) handling long, highly detailed documents, where critical interface constraints become buried in unrelated submodule descriptions; (2) generating long RTL code, where both syntactic and semantic correctness degrade sharply with increasing output length;
and (3) navigating the complex debugging cycles required for functional verification through simulation and waveform analysis.
To overcome these challenges, we propose \textit{ChipV-RTL}, a multi-agent framework that leverages \textit{information locality} in modular hardware design. ChipV-RTL decomposes the long-document to long-code generation problem into a set of short-document, short-code tasks, enabling scalable generation and debugging.

Specifically, ChipV-RTL integrates hierarchical document partitioning, task planning, localized code generation, interface-consistent merging, and AST-guided locality-aware debugging.
Experiments on \textsc{RealBench}, an IP-level Verilog generation benchmark, demonstrate that ChipV-RTL substantially outperforms state-of-the-art (SOTA) LLMs and agents, achieving a pass rate of 45.0\% compared to 21.6\%. Code, project page are available at: \url{https://iprc-dip.github.io/ChipV-RTL/}.

Native Active Perception as Reasoning for Omni-Modal Understanding
Zhenghao Xing, Ruiyang Xu, Yuxuan Wang, Jinzheng He, Ziyang Ma, Qize Yang, Yunfei Chu, Jin Xu, Junyang Lin, Chi-Wing Fu, Pheng-Ann Heng
Passive models for long video understanding typically rely on a "watch-it-all" paradigm, processing frames uniformly regardless of query difficulty, causing computational cost to grow with video duration. Although interactive frameworks have emerged, they often rely on global pre-scanning, and their context cost still scales with video length. We propose **OmniAgent**, the first native omni-modal agent that formulates video understanding as a POMDP-based iterative **Observation-Thought-Action** cycle. OmniAgent executes on-demand actions to selectively distill audio-visual cues into a persistent textual memory, effectively decoupling reasoning complexity from raw video duration. To operationalize this, we introduce (1) **Agentic Supervised Fine-Tuning** to bootstrap native active perception via best-of-N trajectory synthesis with dual-stage quality control, and (2) **

Agentic Reinforcement Learning** with **TAURA** (Turn-aware Adaptive Uncertainty Rescaled Advantage), which leverages turn-level entropy to steer credit assignment toward pivotal discovery turns. Crucially, OmniAgent exhibits positive test-time scaling, where performance improves as the number of reasoning turns increases, validating the efficacy of active perception. Empirical results across ten benchmarks (e.g., VideoMME, LVBench) demonstrate that OmniAgent achieves state-of-the-art performance among open-source models. Notably, on LVBench, our 7B agent outperforms the $10\times$ larger Qwen2.5-VL-72B (50.5% vs. 47.3%). We release our code and model at https://github.com/HarryHsing/OmniAgent.
****

Capability Traps in DPO
Marco Pollanen
Direct Preference Optimization (DPO) is often tuned by selecting checkpoints with high preference margins. We show that this selection rule can fail. Across dense β sweeps in three 7B open-weight families under controlled DPO recipes, the DPO preference margin can strongly anticorrelate with capability probes, with the strongest observed case in Llama logic probes (Pearson $r=-0.91$, $n=13$). In Mistral, matched-duration controls show that transient exposure to higher β produces persistent arithmetic ($d_z = 3.73$, $p = 0.002$) and format ($d_z = 3.38$, $p = 0.003$) degradation relative to a duration-matched constant-β run, while logic and sycophancy show no significant effect. An expanded 14-probe logic suite further shows that aggregate capability scores can hide stable opposition between probe clusters: direct-inference probes are consistently negative while fallacy-detection probes are consistently positive, with 13 of 14 probes sign-stable across 3 seeds and 3 β values. Sensitivity profiles differ across architectures: Mistral shows elevated seed variance near $\beta \approx 10^{-2}$, Llama shows capability-specific rigidity, and Qwen trades off smoothly. These findings motivate probe-resolved β sweeps rather than margin-based checkpoint selection.
****

GLARE: Scalable Neuro-Symbolic Reward Shaping for LLM Agents via Group-Level Automata
Jingyuan Yan, Qingchen Liu, Qichao Ma, Jiahu Qin
Reinforcement Learning (RL) with Group Relative Policy Optimization (GRPO) shows great promise for enhancing LLM reasoning, but remains challenged by sparse and unstable rewards in long-horizon tasks. Existing approaches to reward shaping struggle to balance semantic expressiveness, reliability, and computational efficiency: heuristic rules lack flexibility, while LLM-as-a-Judge incurs high computational cost and suffer from inconsistent and misaligned scoring signals in long-context settings. To address these challenges, we introduce GLARE, a neuro-symbolic reward framework that decouples semantic abstraction from credit assignment. Specifically, to leverage semantic understanding while preserving symbolic determinism, we first extract and symbolize trajectory events into a discrete representation. These events are then translated into Linear Temporal Logic (LTL) formulas, which are compiled into deterministic automata that track the agent's progress via state transitions. This mechanism yields dense and consistent reward signals, avoiding unstable direct scoring while significantly reducing computational cost. Empirical results on ALFWorld show that GLARE outperforms GRPO by 12.1\% in success rate, while achieving an 8.1\% improvement over conventional LLM-based judges using only 15\% of their computational cost.

HDFlow: Hierarchical Diffusion-Flow Planning for Long-horizon Tasks
Gireesh Nandiraju, Yuanliang Ju, Chaoyi Xu, Weiheng Liu, Yuxuan Wan, He Wang
Recent advances in generative models have shown promise in generating behavior plans for long-horizon, sparse reward tasks. While these approaches have achieved promising results, they often lack a principled framework for hierarchical decomposition and struggle with the computational demands of real-time execution, due to their iterative denoising process. In this work, we introduce $\textbf{Hierarchical Diffusion-Flow}$ ($\texttt{\textbf{HDFlow}}$), a novel hierarchical planning framework that optimally leverages the strengths of $\textit{diffusion}$ a

nd $\textit{rectified flow}$ models to overcome the limitations of single-paradigm generative planners. $\texttt{\textbf{HDFlow}}$ employs a high-level diffusion planner to generate sequences of strategic subgoals in a learned latent space, capitalizing on diffusion's powerful exploratory capabilities. These subgoals then guide a low-level rectified flow planner that generates smooth and dense trajectories, exploiting the speed and efficiency of ordinary differential equation (ODE)-based trajectory generation. We evaluate $\texttt{\textbf{HDFlow}}$ on four challenging furniture assembly tasks in both simulation and real-world, where it significantly outperforms state-of-the-art methods. Furthermore, we also showcase our method's generalizability on two long-horizon benchmarks comprising diverse locomotion and manipulation tasks. Project website: https://hdflow-page.github.io/

Extracting alignment data in open models

Federico Barbero, Xiangming Gu, Christopher A. Choquette-Choo, Chawin Sitawarin, Matthew Jagielski, Itay Yona, Petar Veli■kovi■, Ilia Shumailov, Jamie Hayes

In this work, we show that it is possible to extract significant amounts of alignment training data from a post-trained model -- useful to steer the model to improve certain capabilities such as long-context reasoning, safety, instruction following, and maths.

While the majority of related work on memorisation has focused on measuring success of training data extraction through string matching, we argue that embedding models are better suited for our specific goals.

Distances measured through a high quality embedding model can identify semantic similarities between strings that a different metric such as edit distance will struggle to capture.

In fact, in our investigation, approximate string matching would have severely undercounted (by a conservative estimate of $10\times$) the amount of data that can be extracted due to trivial artifacts that deflate the metric. Interestingly, we find that models readily regurgitate training data that was used in post-training phases such as SFT or RL. We show that this data can be then used to train a base model, recovering a meaningful amount of the original performance.

We believe our work exposes a possibly overlooked risk towards extracting alignment data. Finally, our work opens up an interesting discussion on the downstream effects of distillation practices: since models seem to be regurgitating aspects of their training set, distillation can therefore be thought of as indirectly training on the model's original dataset.

Fix the Loss, Not the Radius: Rethinking the Adversarial Perturbation of Sharpness-Aware Minimization

Jinping Wang, Qinhan Liu, Zhiwu Xie, Zhiqiang Gao

Sharpness-Aware Minimization (SAM) improves generalization by minimizing the worst-case loss within a fixed parameter-space radius neighborhood. SAM and its variants mainly rely on a first-order linearized surrogate, while flat minima are inherently a second-order (curvature) notion.

We revisit this mismatch and propose Loss-Equated SAM (LE-SAM), which inverts the traditional SAM mechanism that replaces the fixed perturbation radius with a fixed loss-space budget, effectively removing gradient-norm–dominated learning signals and shifting optimization toward curvature-dominated terms.

Extensive experiments across diverse benchmarks and tasks demonstrate the strong generalization ability of LE-SAM that consistently outperforms SAM and even its variants, achieving state-of-the-art performance.

Preference-Calibrated Optimization with Score-Level Distribution Alignment for Text-to-Image Diffusion Model Unlearning

Xiuyuan Wang, Weiming Liu, Hongyu Cai, Xin Gao, Fan Wang, Chaochao Chen, Xiaolin Zheng

While text-to-image diffusion models achieve remarkable generation quality, they inadvertently memorize sensitive content, necessitating machine unlearning to prevent undesired outputs. However, existing unlearning methods rely on suboptima

l surrogate objectives rather than directly optimizing the unlearning goal, lead ing to fundamental objective mismatch. Moreover, these methods preserve model ut ility via surface-level constraints on model parameters or outputs, yet fail to capture the intrinsic generative dynamics of diffusion models, consequently trig gering catastrophic forgetting. To address these challenges, we propose Preferen ce-calibrated Optimization with Score-level Distribution Alignment (POSDA), a un ified unlearning framework that harmonizes effective erasure with fine-grained s tructural preservation. Specifically, we reframe unlearning as a preference opti mization problem by constructing a reward that explicitly quantifies the unlearn ing objective. Additionally, we introduce score-level distribution alignment to ensure the invariance of the underlying manifold topology of the unlearned model , thereby preventing distributional drift. Extensive experiments across object, style, and NSFW unlearning tasks demonstrate that POSDA achieves state-of-the-ar t erasure efficacy while maintaining superior model utility compared to existing methods.

One-Step Residual Shifting Diffusion for Image Super-Resolution via Distillation

Daniil Selikhanovych, David Li, Aleksei Leonov, Nikita Gushchin, Sergei Kushneri uk, Alexander Filippov, Evgeny Burnaev, Iaroslav Sergeevich Koshelev, Alexander Korotin

Diffusion models for super-resolution (SR) produce high-quality visual results b ut require expensive computational costs. Despite the development of several met hods to accelerate diffusion-based SR models, some (e.g., SinSR) fail to produce realistic perceptual details, while others (e.g., OSEDiff) may hallucinate non- existent structures. To overcome these issues, we present **RSD**, a new distill ation method for ResShift. Our method is based on training the student network t o produce images such that a new fake ResShift model trained on them will coinci de with the teacher model. RSD achieves single-step restoration and outperforms the teacher by a noticeable margin in various perceptual metrics (LPIPS, CLIPIQA , MUSIQ). We show that our distillation method can surpass SinSR, the other dist illation-based method for ResShift, making it on par with state-of-the-art diffu sion SR distillation methods with limited computational costs in terms of percep tual quality. Compared to SR methods based on pre-trained text-to-image models, RSD produces competitive perceptual quality and requires fewer parameters, GPU m emory, and training cost. We provide experimental results on various real-world and synthetic datasets, including RealSR, RealSet65, DRealSR, ImageNet, and DIV2 K. We provide the code at https://github.com/Daniil-Selikhanovych/RSD.

CARE: Confounder-Aware Aggregation for Reliable LLM Evaluation

Jitian Zhao, Changho Shin, Tzu-Heng Huang, Satya Sai Srinath Namburi GNVV, Frede ric Sala

LLM-as-a-judge ensembles are the standard paradigm for scalable evaluation, but their aggregation mechanisms suffer from a fundamental flaw: they implicitly ass ume that judges provide independent estimates of true quality. However, in pract ice, LLM judges exhibit correlated errors caused by shared latent confounders--- such as verbosity, stylistic preferences, or training artifacts---causing standa rd aggregation rules like majority vote or averaging to provide little gain or e ven amplify systematic mistakes. To address this, we introduce CARE, a confounde r-aware aggregation framework that explicitly models LLM judge scores as arising from both a latent true-quality signal and shared confounding factors. Rather t han heuristically re-weighting judges, CARE separates quality from confounders w ithout access to ground-truth labels. We provide theoretical guarantees for iden tifiability and finite-sample recovery under shared confounders, and we quantify the systematic bias incurred when aggregation models omit confounding latent fa ctors. Across 12 public benchmarks spanning continuous scoring, binary classific ation, and pairwise preference settings, CARE improves aggregation accuracy, red ucing error by up to 26.8%.

Beyond Reactivity: Proactive Adaptive Conformal Inference for Online LLM Factual ity

Xinyu Liu, Jun Wu
Large Language Models (LLMs) often produce hallucinated outputs, which limit their reliability in high-stakes applications. Conformal prediction can provide guarantees on the correctness and factuality of LLM outputs, but existing approaches rely on the exchangeability assumption, which rarely holds in online settings where user queries and interests change over time. To solve this problem, in this paper, we propose **PACE** (**P**roactive **A**daptive **C**onformal Inferenc**E**), a novel framework that sequentially updates the time-varying target miscoverage parameter with a dynamic step size to maintain valid coverage under online distribution shifts. PACE is motivated by the theoretical connections between expected miscoverage error and key factors such as distribution shifts and instantaneous parameter error.
It integrates two complementary signals: (1) a proactive shift detection to estimate the magnitude of distribution shifts, and (2) a reactive error that scales updates according to the local coverage gap.
Extensive experiments on synthetic and real-world datasets demonstrate that PACE consistently outperforms advanced adaptive baselines. It reduces the deviation from the target error rate by up to 60\% in QA tasks and accelerates coverage recovery by over 2.5x during abrupt shifts, ensuring stable factuality guarantees without compromising utility and stability.

SG2Loc: Sequential Visual Localization on 3D Scene Graphs
Nicole Damblon, Olga Vysotska, Federico Tombari, Marc Pollefeys, Daniel Barath
Visual localization in complex indoor environments remains a critical challenge for robotics and AR applications. Sequential localization, where pose estimates are refined over time, is important for autonomous agents. However, traditional methods often require storing extensive image databases or point clouds, leading to significant overhead. This paper introduces a novel, lightweight approach to sequential visual localization using 3D scene graphs. Our method represents the environment with a compact scene graph, where nodes represent objects (with coarse meshes) and edges encode spatial relationships. For each image in the localization phase, we extract per-patch semantic features, predicting object identities. Localization is performed within a particle filter framework. Each particle, representing a camera pose, projects the coarse object meshes from the scene graph into the image, assigning object identities to patches based on visibility. The similarity of the per-patch features, in the input image, and object features from the scene graph determines the weight of a particle. Subsequent images are incorporated sequentially, refining the pose estimate. By leveraging a compact scene graph and efficient semantic matching, our method significantly reduces storage while maintaining performance on real-world datasets. The code is available at https://github.com/DmblnNicole/sg2loc.

Decoupling Reasoning and Confidence: Resurrecting Calibration in Reinforcement Learning from Verifiable Rewards
Zhengzhao Ma, Xueru Wen, Boxi Cao, Yaojie Lu, Hongyu Lin, Jinglin Yang, Min He, Xianpei Han, Le Sun
Reinforcement Learning from Verifiable Rewards (RLVR) significantly enhances large language models (LLMs) reasoning but severely suffers from calibration degeneration, where models become excessively over-confident in incorrect answers.
Previous studies devote to directly incorporating calibration objective into existing optimization target.
However, our theoretical analysis demonstrates that there exists a fundamental gradient conflict between the optimization for maximizing policy accuracy and minimizing calibration error.
Building on this insight, we propose DCPO, a simple yet effective framework that systematically decouples reasoning and calibration objectives.
Extensive experiments demonstrate that

our DCPO not only preserves accuracy on par with GRPO but also achieves the best calibration performance and substantially mitigates the over-confidence issue. Our study provides valuable insights and practical solution for more reliable LLM deployment.

TopBench: A Benchmark for Implicit Predictive Reasoning in Tabular Question Answering
An-Yang Ji, Jun-Peng Jiang, De-Chuan Zhan, Han-Jia Ye
Large Language Models (LLMs) have advanced Table Question Answering, where most queries can be answered by extracting information or simple aggregation. However, a common class of real-world queries is implicitly predictive, requiring the inference of unobserved answers from historical patterns rather than mere retrieval. These queries introduce two challenges: recognizing latent intent and reliable predictive reasoning over massive tables. To assess LLMs in such Tabular question answering with implicit Prediction tasks, we introduce TopBench, a benchmark consisting of 779 samples across four sub-tasks, ranging from single-point prediction to decision making, treatment effect analysis, and complex filtering, requiring models to generate outputs spanning reasoning text and structured tables. We evaluate diverse models under both text-based and agentic workflows. Experiments reveal that current models often struggle with intent recognition, defaulting to just lookups. Deeper analysis identifies that accurate intent disambiguation serves as the prerequisite for leading these predictive behaviors. Furthermore, elevating the upper bound of prediction precision requires the integration of more sophisticated modeling or reasoning capabilities.
****

Spike-HTR: Spiking Neural Transformer for Handwritten Text Recognition
Xiubo Liang, Jinxing Han, Yuke Li, Haoqi Zhu, Yu Zhao, Hongzhi Wang
Handwritten Text Recognition (HTR) is computationally imbalanced in two ways: most image pixels are background, and many width-axis sequence positions are blank-dominated.
This creates a mismatch for Spiking Neural Networks (SNNs): handwriting is observed as a static image, whereas spiking computation unfolds over timesteps.
We propose Spike-HTR, a hybrid spiking recognizer that controls both the number of spiking steps and the number of width positions processed by the deep sequence mixer.
To make a static image suitable for short-horizon spiking inference, InkCoder converts it into a coarse-to-fine input stream, where early steps cover broad stroke regions and later steps emphasize sharper stroke details.
To reduce sequence computation, a CTC-guided length reducer keeps likely character or uncertain positions and compresses long blank-dominated stretches before deep mixing.
With $T{=}2$, Spike-HTR trains only on target data, decodes without language models or lexicons, and reaches validation/test CERs of 3.5/5.4, 2.3/2.5, and 4.2/3.9 on IAM, LAM, and READ2016. Codes are available at https://github.com/QomolangmaH/SpikeHTR.

Measuring Meta-Cultural Competency: A Spectral Framework for LLM Knowledge Structures
Sougata Saha, Madhur Jindal, Saurabh Kumar Pandey, Mahardika Krisna Ihsani, Alham Fikri Aji, Monojit Choudhury
Most existing cultural evaluation frameworks for large language models (LLMs) focus on matching model outputs to ground-truth answers, primarily measuring factual cultural awareness. This overlooks whether models internalize broader cultural structure and pluralism. We introduce a spectral-analysis-based framework that captures large-scale macrostructural patterns in models' cultural knowledge and evaluate eight LLMs across nine cultural domains spanning all five of Newmark's cultural dimensions and 170 countries. Comparing with human data, we find that instruction-tuned models align more closely with human cultural structure than older models, while increased model size does not consistently improve performance. Finally, simulation-based experiments show that our proposed spectral metric

better predicts a model's ability to serve users from unfamiliar cultural backgr
ounds than existing ones.

Pressure Reveals Character: Behavioural Alignment Evaluation at Depth
Nora Petrova, John Burden
Evaluating alignment in language models requires testing how they behave under r
ealistic pressure, not just what they claim they would do. While alignment failu
res increasingly cause real-world harm, comprehensive evaluation frameworks with
 realistic multi-turn scenarios remain lacking. We introduce an alignment benchm
ark spanning 904 scenarios across six categories---Honesty, Safety, Non-Manipula
tion, Robustness, Corrigibility, and Scheming---validated as realistic by human
raters. Our scenarios place models under conflicting instructions, simulated too
l access, and multi-turn escalation to reveal behavioral tendencies that single-
turn evaluations miss. Evaluating 24 frontier models using LLM judges validated
against human annotations, we find that even top-performing models exhibit gaps
in specific categories, while the majority of models show consistent weaknesses
across the board. Factor analysis reveals that alignment behaves as a unified co
nstruct (analogous to the g-factor in cognitive research) with models scoring hi
gh on one category tending to score high on others. We publicly release the benc
hmark and an interactive leaderboard to support ongoing evaluation, with plans t
o expand scenarios in areas where we observe persistent weaknesses and to add ne
w models as they are released.

FOCUS & RePAIR: Mitigating Text Degeneration via Token-Level Guidance For Pruned
 Large Language Models
Junyoung Lee, Sehyeon Park, Shinhyoung Jang, Seonha Ryu, Hojeong Kim, Hyunsei Le
e, Il hong Suh, Yeseong Kim
Pruning is a practical approach to compress large language models (LLMs), but it
 can amplify text degeneration, especially repetition loops, even when perplexit
y and task accuracy remain largely unchanged. In this work, we present a token-l
evel analysis of this failure mode by viewing decoding as a dynamical process th
at enters and persists in a small set of recurrent contexts. Our analysis decomp
oses degeneration into loop entry risk and loop persistence, and shows that pers
istence is controlled by the escape mass assigned to plausible alternatives with
in the token sampling set.
Motivated by these findings, we propose two token-level guidance objectives for
post-pruning fine-tuning. FOCUS reweights distillation toward high-confidence te
acher regions to suppress leakage, while RePAIR uses onset-centered positive/neg
ative continuation pairs with a margin loss to promote plausible alternatives an
d prevent early commitment to repetition loops. Experiments on open-ended contin
uation and instruction-based generation show that both methods consistently redu
ce repetition and improve generation quality.
****

Alternating Reinforcement Learning for Rubric-Based Reward Modeling in Non-Verif
iable LLM Post-Training
Ran Xu, Tianci Liu, Zihan Dong, Tony Yu, Ilgee Hong, Carl Yang, Linjun Zhang, Tu
o Zhao, Haoyu Wang
Standard reward models typically predict scalar scores that fail to capture the
multifaceted nature of response quality in non-verifiable domains, such as creat
ive writing or open-ended instruction following. To address this limitation, we
propose Rubric-ARM, a framework that jointly optimizes a rubric generator and a
judge using reinforcement learning from preference feedback. Unlike existing met
hods that rely on static rubrics or disjoint training pipelines, our approach tr
eats rubric generation as a latent action learned to maximize judgment accuracy.
 We introduce an alternating optimization strategy to mitigate the non-stationar
ity of simultaneous updates, providing theoretical analysis that demonstrates ho
w this schedule reduces gradient variance during training. Extensive experiments
 show that Rubric-ARM achieves state-of-the-art performance among baselines on m
ultiple benchmarks and significantly improves downstream policy alignment in bot
h offline and online reinforcement learning settings.

****
Sem-Detect: Semantic Level Detection of AI Generated Peer-Reviews
Andre Vicente Duarte, Brian Tufts, Aditya Oke, Fei Fang, Arlindo L. Oliveira, Le
i Li
*How can we distinguish whether a peer review was written by a human or generate
d by an AI model?* We argue that, in this setting, authorship should not be attr
ibuted solely from the textual features of a review, but also from the ideas, ju
dgments, and claims it expresses. To this end, we propose Sem-Detect, an authors
hip detection method for peer reviews that operationalizes this principle by com
bining textual features with claim-level semantic analysis. Sem-Detect compares
a target review against multiple AI-generated reviews of the same paper, leverag
ing the observation that different AI models tend to converge on similar points,
 while human reviewers introduce more unique and diverse ones. As a result, Sem-
Detect is able to distinguish fully AI-generated reviews from authentic human-wr
itten ones, including those that have been refined using an LLM but still reflec
t human judgment. Across a dataset of over 20,000 peer reviews from ICLR and Neu
rIPS conferences, Sem-Detect improves over the strongest prior detector by 36.5%
 in TPR@1% FPR in the binary setting. More importantly, in the three-class scena
rio, we empirically show that LLM refinement preserves the semantic signals of h
uman reviews, which remain distinct from the patterns exhibited by fully AI-gene
rated text; as a result, fewer than 3.5% of LLM-refined human reviews are miscla
ssified as AI-generated.
****
Fleet: Few Shots Lead Effective AI-generated Image Detection
Jiaan Wang, Sirui Liu, Yu Li, Kaiyuan Yang, Juan Cao, Sheng Tang
AI-generated image (AIGI) detection is undergoing a critical transition from lab
oratory benchmarks to open-world adversarial defense.
The prevalent paradigm focuses on finding static feature spaces, assuming that s
ome invariant artifacts learned from historical data can achieve universal zero-
shot generalization.
While achieving saturation on several AIGI benchmarks, this static hypothesis su
ffers a severe performance drop against rapidly evolving generators (e.g., SD3,
Nano Banana Pro).
To address these limitations, we propose that the field should expand beyond "st
atic generalization" to a new paradigm of "dynamic adaptation".
We introduce **Fleet**, a framework that pioneers a dynamic paradigm of continuo
us few-shot evolution, enabling rapid alignment with emerging generative threats
.
Fleet improves few-shot adaptation by replacing unconstrained feature updates wi
th constrained routing correction, where avoidance routing redirects novel AI sa
mples away from Non-AI-dominated routes within decoupled subspaces.
To validate this, we present **Treasure**, a benchmark spanning 64 models and 36
0k images, featuring diverse architectures and 20 closed-source commercial engin
es.
Experiments reveal that while static SOTA methods fail catastrophically on moder
n generators, Fleet restores performance from 20.4\% to 73.1\% with only 10-shot
 adaptation on "Doubao Seedream 4.0".
Code and data are available at https://github.com/ICTMCG/Fleet .
****
Attention Sinks as Internal Signals for Hallucination Detection in Large Languag
e Models
Jakub Binkowski, Kamil Adamczewski, Tomasz Jan Kajdanowicz
Large language models frequently exhibit hallucinations: fluent and confident ou
tputs that are factually incorrect or unsupported by the input context. While re
cent hallucination detection methods have explored various features derived from
 attention maps, the underlying mechanisms they exploit remain poorly understood
. In this work, we propose SinkProbe, a hallucination detection method grounded
in the observation that hallucinations are deeply entangled with attention sinks
 - tokens that accumulate disproportionate attention mass during generation - in
dicating a transition from distributed, input-grounded attention to compressed,

prior-dominated computation. Importantly, although sink scores are computed sole
ly from attention maps, we find that the classifier preferentially relies on sin
ks whose associated value vectors have large norms. Moreover, we show that previ
ous methods implicitly depend on attention sinks by establishing their mathemati
cal relationship to sink scores. Our findings yield a novel hallucination detect
ion method grounded in theory that produces state-of-the-art results across popu
lar datasets and LLMs.

Meta-Black-Box Optimization Can Do Search Guidance for Expensive Constrained Mul
ti-Objective Optimization
Yukun Du, Haiyue Yu, Jiang Jiang, Shuaiwen Tang, Xiaotong Xie, Haobo Liu, Chongs
huang Hu, Shengkun Chang
Existing Meta-Black-Box Optimization (MetaBBO) methods focus on how to search wh
en controlling optimizers, but largely overlook where to search. We propose Meta
SG-SAEA, a bi-level MetaBBO framework for expensive constrained multi-objective
optimization problems (ECMOPs), in which a meta-policy provides search guidance
to the low-level Surrogate-Assisted Evolutionary Algorithm (SAEA). To achieve th
is, we introduce Max–Min Constraint-Calibrated Inequality (MM-CCI), a compact, p
roblem-agnostic region abstraction that maps heterogeneous constraint evaluation
s to an ordered scalar level; we further provide a theoretical analysis of its f
undamental properties. Building on this region abstraction, we adopt diffusion-b
ased population initialization to translate the meta-policy’s region-level guida
nce into solution-level priors for the SAEA. To make MetaSG-SAEA scalable, we co
nstruct an attention-based state representation across varying problem dimension
s, population sizes, and numbers of objectives and constraints. Experimental res
ults demonstrate that MetaSG-SAEA outperforms state-of-the-art baselines across
diverse benchmarks and exhibits the ability to generalize across problem distrib
utions.
****
SVRG and Beyond via Posterior Correction
Nico Daheim, Thomas Möllenhoff, Ming Liang Ang, Mohammad Emtiyaz Khan
Stochastic Variance Reduced Gradient (SVRG) and its variants aim to speed-up tra
ining by using gradient corrections. Originally proposed over a decade ago, thes
e methods have never been connected to any Bayesian method at a fundamental leve
l. Here, we fill this gap and derive surprising new connections of SVRG to a rec
ently proposed Bayesian method called `posterior correction'. Our main contribut
ion is to show that SVRG can be recovered as a special case of posterior-correct
ion over isotropic-Gaussian posteriors. Novel extensions of SVRG are automatical
ly obtained by using more flexible exponential-family posteriors. We derive two
new such extensions by using Gaussian families: a Newton-like variant with novel
 Hessian corrections, and an Adam-like extension that scales to large problems.
Our work is the first to connect SVRG to Bayes and use it to speed-up training.
****
HeraSys: Collaborative Serving of Multiple LLM Workflows via Fine-Grained End-to
-End Optimization
Size Li, Zhiqing Tang, Hongrui Liang, Jianxiong Guo, Jiong Lou, Tian Wang, Weiji
a Jia
The proliferation of Large Language Models (LLMs) has shifted serving systems fr
om processing isolated requests to orchestrating high-concurrency, multi-tenant
agentic workflows. However, existing solutions typically prioritize intra-workfl
ow optimization, largely neglecting the significant potential for inter-workflow
 optimization. In this paper, we propose HeraSys, an LLM serving system designed
 to optimize the end-to-end performance of concurrent workflows. Through fine-gr
ained orchestration, HeraSys eliminates cross-workflow computational redundancy
via structural node merging and reuse. Furthermore, HeraSys introduces a load-aw
are joint scheduling policy that dynamically manages execution order by evaluati
ng both inter- and intra-query priorities. By integrating a resource skewing mec
hanism with adaptive batching and pipeline decomposition, HeraSys effectively mi
tigates tail latency while maintaining low average latency, thereby substantiall
y improving system throughput. Extensive experiments demonstrate that HeraSys re

duces P99 latency by up to 2.17$\times$ and increases serving throughput by up t
o 1.85$\times$ under strict latency guarantees.

Gradient Descent as a Perceptron Algorithm: Understanding Dynamics and Implicit
Acceleration
Alexander Tyurin
Even for the gradient descent (GD) method applied to neural network training, un
derstanding its optimization dynamics, including convergence rate, iterate traje
ctories, function value oscillations, and especially its implicit acceleration,
remains a challenging problem. We analyze nonlinear models with the logistic los
s and show that the steps of GD reduce to those of generalized perceptron algori
thms (Rosenblatt, 1958), providing a new perspective on the dynamics. This reduc
tion yields significantly simpler algorithmic steps, which we analyze using clas
sical linear algebra tools. Using these tools, we demonstrate on a minimalistic
example that the nonlinearity in a two-layer model can provably yield a faster i
teration complexity $\tilde{\mathcal{O}}(\sqrt{d})$ compared to $\Omega(d)$ achi
eved by linear models, where d is the number of features. This helps explain t
he optimization dynamics and the implicit acceleration phenomenon observed in ne
ural networks. The theoretical results are supported by extensive numerical expe
riments. We believe that this alternative view will further advance research on
the optimization of neural networks.

Rethinking Federated Prompt Learning for Medical Images: From Textual Tuning to
Visual Manifold Anchoring
Yipan Wei, Wenke Huang, Yapeng Li, He Li, Qixin Zhang, Mang Ye, Bo Du
Federated Prompt Learning (FPL) adapts Vision-Language Models to privacy-sensiti
ve medical imaging, typically via a textual tuning paradigm that assumes the fro
zen visual encoder provides a discriminative feature geometry. We argue this ass
umption breaks down in medical settings, leading to two geometric pathologies: (
1) Intra-client: Medical Manifold Collapse, where high morphological similarity
reduces the effective rank of visual features; and (2) Inter-client: Medical Top
ological Misalignment, where heterogeneous acquisition protocols induce inconsis
tent geometry across clients. To address these, we propose FedMAP, which shifts
the paradigm to Visual Manifold Anchoring. FedMAP utilizes an LLM-derived codebo
ok as a client-invariant synchronization signal to restructure the visual space,
 via Manifold Semantic Anchoring (MSA) and Topology Structural Alignment (TSA) t
o enforce consistent inter-class relations. Experiments on FedISIC, FedCamelyon1
7, and a private ultrasound dataset show that FedMAP consistently outperforms st
ate-of-the-art methods, especially in high-noise regimes where manifold collapse
 is most severe.

CalPro: Prior-Aware Evidential Conformal Prediction with Structure-Aware Sensiti
vity Bounds for Protein Structures
Ibne Farabi Shihab, Sanjeda Akter, Anuj Sharma
Deep protein structure predictors such as AlphaFold provide confidence estimates
 (e.g., pLDDT) that are not calibrated and degrade under distribution shifts acr
oss experimental modalities, temporal changes, and disordered regions.
We introduce \textbf{CalPro}, a prior-aware evidential conformal framework for s
hift-robust uncertainty quantification.
CalPro combines three components: (i) a geometric evidential head outputting Nor
mal Inverse Gamma distributions via graph neural networks; (ii) a differentiable
 calibration surrogate that shapes representations during training, followed by
split-conformal calibration for finite-sample coverage; and (iii) domain priors
(disorder, flexibility) encoded as soft constraints on predicted uncertainty.
Theoretically, we derive structure-aware \emph{sensitivity bounds} for coverage
degradation under distribution shift using PAC-Bayesian control over ambiguity s
ets, quantifying how miscoverage increases with model complexity and shift magni
tude.
Empirically, CalPro achieves at most 5 percentage points coverage degradation ac
ross modalities compared to 15 to 25 points for baselines, reduces calibration e

rror by 30\% to 50\%, and improves downstream docking success from 52\% to 75\% when filtering by uncertainty. The framework extends beyond proteins to structured regression tasks where priors encode local reliability.
****
Inner-layer Token Self-modulation as Another Scaling Axis for LLMs
Yebin Yang, Huaijin Wu, Jingtao Han, Yu Wang, Xiaohan Qin, Jingzhi Wang, Debing Zhang, Junchi Yan
LLMs have traditionally scaled along dense dimensions, where performance is coupled with near-linear increases in computational cost. While MoE decouples capacity from compute, it introduces large memory overhead and hardware efficiency challenges. To overcome these, we propose token-indexed parameters as a novel, orthogonal scaling axis that decouple model capacity from FLOPs. Specifically, we introduce ReToken and MoRT, which augment Transformer layers with modulation vectors retrieved from auxiliary embedding tables. These vectors modulate the backbone via lightweight, element-wise operations, incurring negligible FLOPs overhead.

Extensive experiments on both dense and MoE backbones, spanning from 190M to 9.8B parameters, demonstrate that our approach consistently reduces validation loss and significantly improves downstream task performance (e.g., +7.3 on ARC-C, +6.3 on GSM8K). Rigorous isoFLOPs analysis further confirms that MoRT fundamentally shifts the quality–compute Pareto frontier, achieving comparable model quality with 35\% less compute relative to vanilla MoE architectures, and we validate that token-indexed parameters exhibit a predictable power-law scaling behavior. Moreover, our efficient implementation ensures that the overhead introduced by ReToken and MoRT remains marginal.
****
Multi-Integration of Labels Across Categories for Component Identification in Multi-trial Time Series
Noga Mudrik, Yuxi Chen, Gal Mishne, Adam Shabti Charles
Many fields collect large-scale temporal data through repeated measurements (`trials’), where each trial is labeled with a set of metadata variables spanning several categories. For example, a trial in a neuroscience study may be linked to a value from category (a): task difficulty, and category (b): animal choice. A critical challenge in time-series analysis is to understand how these labels are encoded within the multi-trial observations, and disentangle the distinct effect of each label entry across categories. Here, we present MILCCI, a novel data-driven method that i) identifies the interpretable components underlying the data, ii) captures cross-trial variability, and iii) integrates label information to understand each category's representation within the data. MILCCI extends a sparse per-trial decomposition that leverages label similarities within each category to enable subtle, label-driven cross-trial adjustments in component compositions and to distinguish the contribution of each category. MILCCI also learns each component’s corresponding temporal trace, which evolves over time within each trial and varies flexibly across trials. We demonstrate MILCCI’s performance through both synthetic and real-world examples, including voting patterns, online page view trends, and neuronal recordings.
****
Lower Bounds for Frank-Wolfe on Strongly Convex Sets
Jannis Halbey, Daniel Deza, Max Zimmer, Christophe Roux, Bartolomeo Stellato, Sebastian Pokutta
We present a constructive lower bound of $\Omega(1/\sqrt{\varepsilon})$ for Frank-Wolfe (FW) when both the objective and the constraint set are smooth and strongly convex, showing that the known uniform $\mathcal{O}(1/\sqrt{\varepsilon})$ guarantees in this regime are tight. It is known that under additional assumptions on the position of the optimizer, FW can converge linearly. However, it remained unclear whether strong convexity of the set can yield rates \emph{uniformly} faster than $\mathcal{O}(1/\sqrt{\varepsilon})$, i.e., irrespective of the position of the optimizer. To investigate this question, we focus on a simple yet representative problem class: minimizing a strongly convex quadratic over the Euclidean unit ball, with the optimizer on the boundary. We analyze the dynamics of F

W for this problem in detail and develop a novel computational approach to const
ruct worst-case FW trajectories, which is of independent interest. Guided by the
se constructions, we develop an analytical proof establishing the lower bound.

AutoVSR: Automatic Visual-to-Symbolic Reasoning for Symbolic Expression Generati
on from Circuit Schematic

Zhe Xiao, Longfei Li, Xu He, Haoying Wu, Zixing Zhang, Mingyu Liu

Symbolic expressions can effectively characterize and predict circuit behavior,
but deriving them directly from circuit schematics is challenging. This process
requires accurate visual-to-symbolic construction of circuit structure from imag
es and correct multi-step symbolic derivation, both of which impose strict corre
ctness requirements.

This work proposes AutoVSR, an automated framework for visual-to-symbolic genera
tion of circuit expressions using Vision Language Models (VLMs). By reconstructi
ng circuit diagrams into an executable intermediate representation (Executable I
R) and leveraging a symbolic solver for reasoning, AutoVSR significantly improve
s the accuracy of symbolic expression generation.

AutoVSR introduces two key innovations: an IR construction method guided by comp
onent rule retrieval and verification-based feedback, and a symbolic solver impl
emented as a planning agent equipped with a symbolic tool library for reliable m
ulti-step derivation. Compared with end-to-end VLM approaches and specialized me
thods on the main symbolic expression generation task, AutoVSR achieves accuracy
 improvements of 30.01--59.45% and 41.96--51.84%, respectively. Moreover, AutoVS
R surpasses closed-source state-of-the-art VLMs in inference cost and computatio
nal efficiency. Code is available at https://github.com/LongfeiLi1/AutoVSR.

The Cost of Commitment in Option-Based Hierarchical RL

Randy Lefebvre, Audrey Durand

Empirically, option-based hierarchical reinforcement (HRL) learning often produc
es longer and more diverse options when a deliberation cost is charged at option
 boundaries. However, when options are executed for many steps under an approxim
ate dynamics model, small model errors compound along the option, degrading the
quality of the resulting plan. In this work, we introduce the commitment loss to
 formalize the tradeoff between deliberation cost and model error as a function
of option duration. We characterize how optimal termination probabilities vary w
ith this tradeoff under two model-error mechanisms. First, the model is learned
from finite data via maximum-likelihood estimation, producing statistical error
that interacts with option duration. Second, we consider an input-driven setting
 where an exogenous input is only observed at option boundaries and evolves unob
served between them, creating a drift-induced mismatch between planned and reali
zed dynamics. In both cases, we solve for the optimal termination behavior as a
function of deliberation cost and the error scale, clarifying the behavior of so
me popular HRL algorithms that approach the deliberation cost as a heuristic.

Sparse Bayesian Deep Functional Learning with Structured Region Selection

Xiaoxian Zhu, Yingmeng Li, Shuangge Ma, Mengyun Wu

In modern applications such as ECG monitoring, neuroimaging, wearable sensing, a
nd industrial equipment diagnostics, complex and continuously structured data ar
e ubiquitous, presenting both challenges and opportunities for functional data a
nalysis. However, existing methods face a critical trade-off: conventional funct
ional models are limited by linearity, whereas deep learning approaches lack int
erpretable region selection for sparse effects. To bridge these gaps, we propose
 a sparse Bayesian functional deep neural network (sBayFDNN). It learns adaptive
 functional embeddings through a deep Bayesian architecture to capture complex n
onlinear relationships, while a structured prior enables interpretable, region-w
ise selection of influential domains with quantified uncertainty. Theoretically,
 we establish rigorous approximation error bounds, posterior consistency, and re
gion selection consistency. These results provide the first theoretical guarante
es for a Bayesian deep functional model, ensuring its reliability and statistica
l rigor. Empirically, comprehensive simulations and real■world studies confirm t

he effectiveness and superiority of sBayFDNN. Crucially, sBayFDNN excels in reco
gnizing intricate dependencies for accurate predictions and more precisely ident
ifies functionally meaningful regions, capabilities fundamentally beyond existin
g approaches.

Language Generation in the Limit: Complexity Barriers and Implications for Learn
ing
Marcelo Arenas, Pablo Barcelo, Luis Cofré, Alexander Kozachinskiy
Kleinberg and Mullainathan showed that language generation in the limit is alway
s possible
at the level of computability: given enough positive examples, a learner can eve
ntually
generate data indistinguishable from a target language. However, such existence
results do
not address feasibility.
We study the sample complexity of language generation in the limit for several c
anonical
classes of formal languages. Our results show that infeasibility already appears
 for
context-free and regular languages, and persists even for strict subclasses such
 as locally threshold
testable languages, as well as for incomparable classes such as non-erasing patt
ern
languages, a well-studied class in the theory of language identification.
Overall, our results establish a clear gap between the theoretical possibility o
f
language generation in the limit and its computational feasibility.

Hierarchical Abstract Tree for Cross-Document Retrieval Augmented Generation
Ziwen Zhao, Menglin Yang
Retrieval-augmented generation (RAG) enhances large language models with externa
l knowledge, and tree-based RAG organizes documents into hierarchical indexes to
 support queries at multiple granularities. However, existing Tree-RAG methods d
esigned for single-document retrieval face critical challenges in scaling to cro
ss-document multi-hop questions: *(1) poor distribution adaptability*, where k
-means clustering introduces noise due to rigid distribution assumptions; *(2) s
tructural isolation*, as tree indexes lack explicit cross-document connections;
and *(3) coarse abstraction*, which obscures fine-grained details. To address th
ese limitations, we propose **Ψ-RAG**, a tree-RAG framework with two key co
mponents. *First*, a hierarchical abstract tree index built through an iterative
 "merging and collapse" process that adapts to data distributions without a prio
ri assumption. *Second*, a multi-granular retrieval agent that intelligently int
eracts with the knowledge base with reorganized queries and an agent-powered hyb
rid retriever. Ψ-RAG supports diverse tasks from token-level question answe
ring to document-level summarization. On cross-document multi-hop QA benchmarks,
 it outperforms RAPTOR by 25.9\% and HippoRAG 2 by 7.4\% in average F1 score.
****
GraphP-FL: Personalized Federated Graph Learning via Dynamic Structure Awareness
 and Fisher Information Elastic Alignment
Haoyu Chen, Zening Zhao, Jinsong Wang, Kai Shi, Zongpu Wei, Jianhao Li
Federated Graph Learning (FGL) enables distributed clients to collaboratively tr
ain graph neural networks while strictly preserving data privacy. However, exist
ing FGL methods implicitly assume the reliability of local graph structures and
lack elastic awareness of parameter importance during model aggregation, leading
 to representation degradation under topological noise and catastrophic forgetti
ng caused by model drift. To address these challenges, we propose GraphP-FL, a g
eneral personalized FGL framework. (1) Specifically, we design a self-supervised
 dynamic topology reconstruction mechanism on the client side. This mechanism mi
nes implicit dependencies to adaptively rectify noisy topologies, effectively su
ppressing topological noise propagation and capturing precise structural relatio

nships for high-quality representations. (2) Additionally, we introduce a Fisher-based Elastic Parameter Alignment (FRPA) algorithm. FRPA imposes anisotropic regularization constraints in the parameter space to precisely quantify parameter importance, enabling the model to strictly preserve critical local knowledge while flexibly aligning with the global model, thus effectively overcoming catastrophic forgetting. Extensive experiments on seven benchmarks (including biochemical molecules, social networks, and large-scale encrypted traffic) demonstrate that GraphP-FL significantly outperforms state-of-the-art methods, improving accuracy by up to 8.6% while exhibiting superior generalization and robustness.
****

SCalDA: Semantics-Calibrated and Diffusion-Enhanced Data Augmentation
Shibo Lv, Jianmin Jiang
With the rapid development of deep learning, the issue of data scarcity has become increasingly prominent, inspiring emerging interests towards research on data augmentation techniques over recent years. However, our literature survey indicates that existing efforts often suffer from two issues of semantic infidelity, including: (i) visual semantics infidelity, such as visual artifacts, manifold intrusion, and unnatural blending boundaries etc, and (ii) label semantic infidelity, where augmented images do not match the original labels, creating extra label noises. To address these issues, we propose a Semantics Calibrated and Diffusion-Enhanced Augmentation (SCalDA) scheme to achieve accurate semantics calibration across image, label and feature domains. Compared with the existing approaches, our proposed features in precise guidance in label domain, semantics driven synthesis across three domains (image, label and feature), and semantics-aware metric learning. Extensive experiments on multiple datasets demonstrate that SCalDA yields consistent and significant performance improvements for both fine-grained and general classification tasks, validating the effectiveness and broad applicability of the proposed.
****

MoLoRA: Composable Specialization via Per-Token Adapter Routing
Shrey Shah, Justin Wagle
Multi-adapter serving systems route entire sequences to a single adapter, forcing a choice when requests span multiple domains. This assumption fails in two important settings: (1) multimodal generation, where text and image tokens require different adapters within the same sequence, and (2) mixed-capability requests like ``write code to solve this equation,'' which need expertise from multiple specialized adapters. We introduce \emph{per-token routing}, which routes individual tokens to adapters based on either vocabulary structure (for multimodal models) or learned gating (for semantic specialization). Per-token routing is provably optimal for mixed-adapter requests: N work for N tokens, versus $K \cdot N$ for per-sequence systems that must replay one adapter per pass. Our key contribution is MoLoRA (Mixture of LoRA), which enables \emph{composable specialization}: load multiple domain-specific adapters and let a learned router select the appropriate adapter per-token. We demonstrate that specialization dramatically beats scale: MoLoRA enables Qwen3-1.7B to exceed Qwen3-8B across four reasoning benchmarks while being 4.7$\times$ smaller. This enables modular expertise at inference time: train focused LoRAs independently, combine them without retraining, and add new capabilities by simply loading new adapters.
****

Adversarial Flow Models
Shanchuan Lin, Ceyuan Yang, Zhijie Lin, Hao Chen, Haoqi Fan
We present adversarial flow models, a class of generative models that belongs to both the adversarial and flow families. Our method supports native one-step and multi-step generation and is trained with an adversarial objective. Unlike traditional GANs, in which the generator learns an arbitrary transport map between the noise and data distributions, our generator is encouraged to learn a deterministic noise-to-data mapping. This significantly stabilizes adversarial training. Unlike consistency-based methods, our model directly learns one-step or few-step generation without having to learn the intermediate timesteps of the probability flow for propagation. This preserves model capacity and avoids error accumula

tion. Under the same 1NFE setting on ImageNet-256px, our B/2 model approaches th
e performance of consistency-based XL/2 models, while our XL/2 model achieves a
new best FID of 2.38. We additionally demonstrate end-to-end training of 56-laye
r and 112-layer models without any intermediate supervision, achieving FIDs of 2
.08 and 1.94 with a single forward pass and surpassing the corresponding 28-laye
r 2NFE and 4NFE counterparts with equal compute and parameters.

TFRBench: A Reasoning Benchmark for Evaluating Forecasting Systems
Md Atik Ahamed, Mihir Parmar, Palash Goyal, Yiwen Song, Long T. Le, Qiang Cheng,
 Chun-Liang Li, Hamid Palangi, Jinsung Yoon, Tomas Pfister
We introduce TFRBench, the first benchmark designed to evaluate the reasoning ca
pabilities of forecasting systems. Traditionally, time-series forecasting has be
en evaluated solely on numerical accuracy, treating foundation models as "black
boxes." Unlike existing benchmarks, TFRBench provides a protocol for evaluating
the reasoning generated by forecasting systems--specifically their analysis of c
ross-channel dependencies, trends, and external events. To enable this, we propo
se a systematic multi-agent framework that utilizes an iterative verification lo
op to synthesize numerically grounded reasoning traces. Spanning ten datasets ac
ross five domains, our evaluation confirms that this reasoning is causally effec
tive; useful for evaluation; and prompting LLMs with our generated traces signif
icantly improves forecasting accuracy compared to direct numerical prediction (e
.g., avg. ~40.2% $\rightarrow$ ~56.6%), validating the quality of our
reasoning. Conversely, benchmarking experiments reveal that off-the-shelf LLMs c
onsistently struggle with both reasoning (lower LLM-as-a-Judge scores) and numer
ical forecasting, frequently failing to capture domain-specific dynamics. TFRBen
ch thus establishes a new standard for interpretable, reasoning-based evaluation
 in time-series forecasting. Our benchmark is available at:
https://tfrbench.github.io

Efficiently Training Time-to-First-Spike Spiking Neural Networks from Scratch
Kaiwei Che, Zhengyu Ma, Yifan Huang, Peng Xue, Li Yuan, Wei Fang, Yonghong Tian
Spiking Neural Networks (SNNs), with their event-driven and biologically inspire
d mechanisms, are well-suited for energy-efficient neuromorphic hardware. Neural
 coding, which is critical to SNNs, determines how information is represented vi
a spikes. While Time-to-First-Spike (TTFS) coding uses a single spike per neuron
 to offer extreme sparsity and energy efficiency, it often suffers from unstable
 training and low accuracy due to its sparse firing.
To address these challenges, we propose a training framework that incorporates p
arameter initialization, training normalization, a temporal output decoder, and
a re-evaluation of the pooling layer.
The proposed parameter initialization and training normalization mitigate signal
 diminishing and gradient vanishing, which helps stabilize training. Our output
decoder aggregates temporal spikes to encourage earlier firing, thereby reducing
 latency.
The re-evaluation of the pooling layer demonstrates that max-pooling violates si
ngle-spike constraints, which should be avoided, whereas average-pooling preserv
es them.
Experiments show that our framework stabilizes and accelerates training, reduces
 latency, and achieves state-of-the-art accuracy for step-by-step TTFS SNNs on M
NIST (99.48%), Fashion-MNIST (92.90%), CIFAR10 (90.56%), CIFAR100 ($70.
27\%$) and DVS Gesture ($95.83\%$).

Partial Ring Scan: Revisiting Scan Order in Vision State Space Models
Yi-Kuan Hsieh, Kuan-Chuan Peng, Xin Li, Ming-Ching Chang, Yu-Chee Tseng, Jun Wei
 Hsieh
State Space Models (SSMs) provide linear-time alternatives to attention for visi
on, but require serializing 2D images into 1D sequences using a predefined scan
order. We identify scan order as a previously underexplored inductive bias that
fundamentally shapes spatial dependency modeling in Vision SSMs. Fixed scan path
s distort local adjacency, fragment object structure, and induce anisotropic rep

resentations that are brittle under geometric transformations such as rotation. We propose Partial RIng Scan Mamba (PRIS-Mamba), a rotation-robust traversal tha t decomposes images into concentric rings, performs permutation-invariant aggreg ation within each ring, and models cross-ring dependencies via short radial SSMs . This design induces a structured factorization of spatial dependencies that pr eserves isotropy while maintaining linear complexity. To improve efficiency with out sacrificing expressivity, we introduce partial channel filtering, selectivel y applying recurrent modeling to informative channels while routing others throu gh a residual pathway. Empirically, PRIS-Mamba improves accuracy, efficiency, an d rotation robustness over prior Vision SSMs on ImageNet-1K. Our results positio n scan-order design as a core representational choice in Vision SSMs, with impli cations for robustness and generalization beyond architectural scaling. The cod e will be released upon paper acceptance.

Data Provenance Auditing of Fine-Tuned Large Language Models with a Text-Preserv ing Technique
Yanming Li, Cédric Eichler, Nicolas Anciaux, Alexandra Bensamoun, Lorena Gonzale z-Manzano, Seifeddine Ghozzi
We propose a system for marking sensitive or copyrighted texts to detect their u se in fine-tuning large language models under black-box access with statistical guarantees. Our method builds digital “marks” using invisible Unicode characters organized into (“cue”, “reply”) pairs.
During an audit, prompts containing only “cue” fragments are issued to trigger r egurgitation of the corresponding “reply”, indicating document usage. To control false positives, we compare against held-out counterfactual marks and apply a r anking test, yielding a verifiable bound on the false positive rate. Empirically , we obtain a true positive rate of 96.7\% at 0\% false positive rate and reply regurgitation rates exceeding 28\% per document with only 40 (4\%) watermarked d ocuments. The approach is minimally invasive, scalable across many sources, robu st to standard processing pipelines, and achieves high detection power even when marked data is a small fraction of the fine-tuning corpus.

Is Fixing Schema Graphs Necessary? Full-Resolution Graph Structure Learning for Relational Deep Learning
Yi Huang, Qingyun Sun, Jia Li, Xingcheng Fu, Jianxin Li
Relational prediction tasks are fundamental in many real-world applications, whe re data are naturally stored in relational databases (RDBs). Relational Deep Lea rning (RDL) addresses this problem by modeling RDBs as graphs and applying graph neural networks (GNNs) for end-to-end learning. However, the full-resolution pr operty is commonly adopted as a design principle in graph construction for RDBs to preserve relational semantics, which leads most existing methods to rely on f ixed graph structures. In this paper, we propose **FROG**, a *F*ull-*R*esolution and *O*ptimizable *G*raph Structure Learning framework for RDL that formulates relational structure learning as a learnable table role modeling problem, allowi ng tables to contribute as nodes and edges in message passing. We further design role-driven message passing mechanisms to capture relational semantics, enablin g joint optimization of graph structure and GNN representations. To ensure seman tic consistency, we introduce functional dependency constraints that regularize representations across table and entity levels. Extensive experiments demonstrat e that our method outperforms existing approaches and reveal how table roles imp act downstream tasks, offering new insights into graph construction for RDL.
****

Adversarial Latent Embedding Repair for LLM Continual Learning
Xilin Xia, Tong Xialiang, Jie Wang, Chi Ma, Shengxue Li, Yinqi Bai, Yuhang Jiang , Xing Li, Jianye HAO, Mingxuan Yuan, Feng Wu
Research on continual learning for LLMs seeks to acquire new skills without cata strophic forgetting of established prior knowledge.
However, domain-specific fine-tuning still triggers severe, long-tailed forgetti ng issues even under narrow updates, particularly when the pre-training data is inaccessible.

To tackle this challenge, we propose **ALER**, a data-free continual learning framework that adversarially searches for a small set of latent prompt embeddings to maximize logit divergence from a frozen reference model, proactively exposing high-risk forgetting modes at each step.
It then performs online distillation from the frozen reference using the discovered embeddings to retain prior behaviors while preserving target-domain adaptation.
We provide theoretical guarantees on the efficiency of our targeted repair, and extensive experiments demonstrate consistent improvements in the retention–adaptation frontier over representative baselines across 2 domain-specific fine-tuning datasets and 6 general-purpose benchmarks,
suggesting a more proactive approach for LLM continual learning.

h1: Bootstrapping LLMs to Reason over Longer Horizons via Reinforcement Learning
Alesia Ivanova, Sumeet Ramesh Motwani, Ziyang Cai, Philip Torr, Riashat Islam, Shital Shah, Christian Schroeder de Witt, Charles London
Large language models excel at short-horizon reasoning tasks, but performance drops as reasoning horizon lengths increase. In this work, we introduce a scalable method to bootstrap long-horizon reasoning capabilities using only existing, abundant short-horizon data. Our approach synthetically composes simple problems into complex, multi-step dependency chains of arbitrary length. We train models on this data using outcome-only rewards under a curriculum that automatically increases in complexity, allowing RL training to be scaled much further without saturating. Empirically, our method generalizes remarkably well: curriculum training on composed 6th-grade level math problems improves accuracy on longer, competition-level benchmarks. It also transfers significantly to diverse out-of-distribution ReasoningGym domains and long-context benchmarks, indicating broader generalization. Importantly, our long-horizon improvements are significantly higher than baselines even at high pass@k, showing that models can learn new reasoning paths under RL. Theoretically, we show that curriculum RL with outcome rewards could achieve an exponential improvement in sample complexity over full-horizon training, providing training signal comparable to dense supervision. h1 therefore introduces an efficient path towards scaling RL for long-horizon problems using only existing data.
****

Split Group Knockoffs: Controlling False Discovery Rate in Transformational Group Sparsity
Siqi Chen, Yachen Gao, Yanwei Fu, Xinwei Sun
Controlling the false discovery rate (FDR) under complex sparsity structures remains a fundamental challenge in large language model (LLM) analysis. Motivated by multiple comparison problems in LLMs, we consider a setting in which sparsity arises at the group level after a linear transformation of model parameters. We propose Split Group Knockoffs (SGKs), a general framework for group-wise variable selection under grouped transformational sparsity that extends the Split Knockoff procedure to grouped transformed variables. We establish theoretical guarantees for group-level FDR control and support recovery consistency, addressing challenges induced by group-wise penalties in transformed spaces. Applying SGK to LLM behavior auditing experiment reveals that model disagreement is not uniform across subjects, but instead concentrates in domains with greater semantic and reasoning complexity, where SGK effectively distinguishes genuine behavioral deviations from surface-level performance variation.
****

pTNAS: Progressive Neural Architecture Search for Tabular Data
Naili Xing, Shaofeng Cai, Lingze Zeng, Jiaqi Zhu, Peng LU, Jian Pei, Beng Chin Ooi
Recent advances have shifted the paradigm of tabular learning toward tabular foundation models, yet their accuracy relies on a heavy inference cost that scales poorly with context size. Deep neural networks remain a highly competitive and more efficient modeling paradigm when equipped with well-designed architectures; however, identifying such architectures in a data-adaptive and budget-aware mann

er remains challenging. We propose pTNAS, the first progressive neural architect ure search (NAS) approach tailored for tabular data, which enables fast identifi cation of a viable architecture and continuously improves its search performance as more budget becomes available. pTNAS adopts a filter-and-refine optimization strategy that combines efficient training-free and effective training-based arc hitecture evaluation. In the filtering phase, we introduce pTProxy, a novel zero -cost proxy specifically designed for tabular networks that jointly captures arc hitectural trainability and expressivity, enabling fast filtering of large archi tecture search spaces. In the refinement phase, pTNAS employs a fixed-budget sch eduling algorithm to accurately identify the best-performing architecture from a small set of promising candidates. We further propose a budget-aware coordinato r to optimize budget allocation holistically. Experiments show that pTNAS reduce s the time to reach the globally best architecture by up to 82.75 X compared wit h other NAS approaches, achieves the best average predictive rank, and improves end-to-end efficiency by up to 4.78 X compared with TabPFN.

Towards a Holistic Understanding of Selection Bias for Causal Effect Identificat ion
Yiwen Qiu, Filip Kova■evi■, Shimeng Huang, Peter Spirtes, Francesco Locatello
Selection bias is pervasive in observational studies. For example, large scale b iobanks data can exhibit ``healthy volunteer bias'' when respondents are healthi er and of higher socio-economic status than the population they are meant to rep resent. Recovering causal effects from such sub-population is an important probl em in causal inference, as estimating average treatment effects (ATE) from sele cted populations can result in a severely biased estimate of the ATE from the w hole population.

In this paper, we investigate the identifiability of the ATE under selection bia s. We provide *necessary and sufficient conditions* for ATE identifiability, lev eraging weak assumptions on probability classes to characterize propensity score and selection probability, which are weaker assumptions than those required by existing general identification frameworks. Compared to previous works, our resu lts extend existing graphical identifiability criteria and offer a more comprehe nsive understanding of causal effect identification *with strictly weaker condit ions* in the presence of selection bias.
****
PPDL: LLM-Based Flows as Probabilistic Programs
Louis Mandel, Guillaume Baudart, Mandana Vaziri, Martin Hirzel
Building reliable applications that leverage large language models (LLMs) remain s a significant challenge. While LLMs offer impressive capabilities across diver se tasks, their outputs often lack accuracy and provide no clear measure of conf idence. This uncertainty compounds in flows of multiple calls to LLMs and other tools, making it difficult for developers and end-users to trust the results. Th is paper introduces a probabilistic language for programming LLM-based flows. It enables developers to quantify and propagate uncertainty throughout the applica tion's flow, and experiment with different inference scaling techniques without adding a single line of code beyond the flow's logic. We present an experimental study to demonstrate this capability, and a case study building a theorem prov ing agent for the Rocq theorem prover.
****
Robust Contextual Optimization with Missing Covariates
Qingyuan Xu, Ruiwei Jiang
Modern decision-making increasingly relies on contextual features (covariates) t o improve optimization under uncertainty. In practice, however, such covariates are often only partially observed due to, e.g., data source heterogeneity or cos tly data collection. Nonetheless, most existing methods assume fully observed hi storical data and can become unreliable when this assumption is violated. We add ress this gap by proposing a distributionally robust optimization approach that exploits incomplete covariates to produce robust decisions without imputing a co mplete dataset. Our method builds ambiguity sets from the observed partial data

and incorporates the general structure of the missingness mechanism, ensuring ca ndidate distributions remain consistent with what is observed. Across settings w ith discrete or continuous covariates and outcomes, we derive tractable reformul ations and establish finite-sample out-of-sample performance guarantees. Empiric al results across a range of contextual decision-making tasks demonstrate that t he proposed integrated approach consistently outperforms state-of-the-art baseli nes, including various impute-then-optimize pipelines, in both out-of-sample per formance and reliability.

Learning to Memorize with Attributive and Associative Memory for Online Test-Tim e Adaptation of Vision-Language Models
Yuchao Zhang, Hao Wang, Fan Zhang, Qirui Mi, Mengyue Yang, Yisen Wang, Jun Wang, Haoxuan Li, Zhouchen Lin
Memory-based test-time adaptation (TTA) assigns streaming test samples into clas s-specific memory slots based on pseudo-labels predicted by models like CLIP, an d retrieves them to facilitate subsequent predictions under distribution shift. However, this process introduces two challenges: (1) Each sample is hard-assigne d to a single class based on CLIP's prediction, where inaccurate CLIP prediction leads to memory contamination that biases subsequent prediction. (2) Samples ar e evicted under biased selection due to fixed memory capacity, which risks disca rding informative samples and undermining the efficacy of the memory. To address these challenges, we propose A²Memory (Attributive-Associative Memory for Test-time Adaptation). For challenge (1), we propose Attribute-centric Memory Constr uction that builds prior textual representations from class-shared representativ e and diverse visual attributes, and applies soft assignment to generate surroga te visual representations. For challenge (2), we design Class-wise Associative M emory that dynamically compresses streaming samples into fixed-capacity memory t hrough gradient-based optimization and data-dependent retention, then retrieves sample-adaptive class prototypes for reliable inference. Extensive experiments demonstrate consistent improvements over state-of-the-art methods across 15 benc hmarks.
****
REG: In-Sample RL via Regularizing the Evaluation Gap
Hanpu Shen, Weining Shen, Roy Fox
Distribution shift poses a fundamental challenge in offline reinforcement learni ng, often leading to value overestimation when querying out-of-distribution acti ons. We introduce Regularized Evaluation Gap (REG) as a bridge between implicit methods like IQL and explicit conservative methods. We formulate policy evaluati on as a robust optimization problem over an ambiguity set of critics and show th at IQL’s objective can be viewed as an approximate dual solution to this problem . To extract a policy from the learned value function, we propose a practical Or thogonal Policy Gradient (OPG) update. This method regularizes an aggressive, mo de-seeking policy gradient by projecting it onto the subspace orthogonal to a st able, in-sample behavior cloning gradient. Extensive D4RL experiments demonstrat e that REG matches state-of-the-art performance among both Gaussian methods and diffusion-based approaches without the computational burden of the latter.
****
Unleashing Implicit Rewards: Prefix-Value Learning for Distribution-Level Optimi zation
Shiping Gao, Hongzhan Chen, Xiaojun Quan, Qifan Wang, Lifu Huang
Process reward models (PRMs) provide fine-grained supervision for reasoning, but reliable PRMs often require step annotations or heavy verification pipelines, m aking them costly to scale and refresh during online RL. Implicit PRMs reduce th is cost by training log-likelihood-ratio rewards from trajectory-level outcome l abels. However, the log-ratio is constrained only as a sequence-level aggregate during training, while inference decomposes it into token- or step-level scores for partial prefixes. This train–inference mismatch leaves local credits weakly identified, so distribution-wide scoring can amplify misleading advantages. We p ropose Implicit Prefix-Value Reward Model (IPVRM), which directly learns the pro bability of eventual correctness for each prefix from outcome labels. Step signa

ls are then obtained as temporal-difference (TD) differences between consecutive prefix values, aligning the training target with inference-time use. IPVRM markedly improves step-verification F1 on ProcessBench. To exploit these prefix values during policy optimization, we further introduce Distribution-Level RL (DistRL), which applies TD advantages to both sampled tokens and high-probability candidate tokens, providing dense counterfactual updates without additional rollouts. Experiments show that DistRL brings limited gains with unreliable implicit rewards, but consistently improves downstream reasoning when paired with IPVRM. The implementation of our method is available at https://github.com/gaoshiping/IPVRM .

CoopEval: Benchmarking Cooperation-Sustaining Mechanisms and LLM Agents in Social Dilemmas

Emanuel Tewolde, Xiao Zhang, David Guzman Piedrahita, Vincent Conitzer, Zhijing Jin

It is increasingly important that LLM agents interact effectively and safely with other goal-pursuing agents, yet, recent works report the opposite trend: LLMs with stronger reasoning capabilities behave _less_ cooperatively in mixed-motive games such as the prisoner's dilemma and public goods settings. Indeed, our experiments show that recent models---with or without reasoning enabled---consistently defect in single-shot social dilemmas.

To tackle this safety concern, we present the first comparative study of game-theoretic mechanisms designed to enable cooperative outcomes between rational agents _in equilibrium_. Across four social dilemmas testing distinct components of robust cooperation, we evaluate four families of mechanisms: (1) repeating the game for many rounds, (2) reputation systems, (3) third-party mediators to delegate decision making to, and (4) contract agreements for outcome-conditional payments between players. Among our findings, we establish that contracting and mediation are most effective in achieving cooperative outcomes between capable LLM models, and that repetition-induced cooperation deteriorates drastically when co-players vary. Moreover, we demonstrate that the mechanisms become _more effective_ under evolutionary pressures to maximize individual payoffs.

High-Fidelity ANN-to-SNN Conversion via Closed-Loop CKA Distillation

Bozhou Li, Chubo Liu, Yan Ding, Yufeng Zhang, Zhuo Tang, Kenli Li

ANN-to-SNN conversion offers energy-efficient inference but faces a fidelity-latency trade-off due to open-loop error accumulation. While conversion-aware training mitigates this, it sacrifices the generality of using off-the-shelf ANNs. We propose a closed-loop fine-tuning framework that calibrates these errors without altering the source model. Our approach employs a Dual Alignment Mechanism, utilizing global Kullback-Leibler divergence for output distillation and introducing an adaptive local Centered Kernel Alignment constraint, weighted by initial conversion loss, for feature alignment. We uncover a critical time-dependent dynamic: local constraints are essential for stabilizing representations in low-latency regimes (e.g., $T=8$) where global gradients are unstable, whereas global alignment drives fidelity at higher time steps. Experiments on CIFAR-10 demonstrate that our method achieves over 99\% of source ANN accuracy at $T=32$ (e.g., ResNet-18: 96.38\% vs.\ 96.39\%). Furthermore, this fine-tuning acts as a regularizer, yielding SNNs with input noise robustness that matches or exceeds the source ANN.

****

FedHPro: Federated Hyper-Prototype Learning via Gradient Matching

Huan Wang, Jun Shen, Haoran Li, Zhenyu Yang, Jun Yan, Ousman Manjang, Yanlong Zhai, Di Wu, Guansong Pang

Federated Learning (FL) enables collaborative training of distributed clients while protecting privacy. To enhance generalization capability in FL, prototype-based FL is in the spotlight, since shared global prototypes offer semantic anchors for aligning client-specific local prototypes. However, existing methods update global prototypes at the prototype-level via averaging local prototypes or ref

ining global anchors, which often leads to semantic drift across clients and subsequently yields a misaligned global signal. To alleviate this issue, we introduce **hyper-prototypes**, defined by a set of learnable global class-wise prototypes to preserve underlying semantic knowledge across clients. The hyper-prototypes are optimized via gradient matching to align with class-relevant characteristics distilled directly from clients' real samples, rather than prototype-level descriptors. We further propose **FedHPro**, a Federated Hyper-Prototype Learning framework, to leverage hyper-prototypes to promote inter-class separability via mutual-contrastive learning with client-specific margin, while encouraging intra-class uniformity through a consistency penalty. Comprehensive experiments under diverse heterogeneous scenarios confirm that 1) hyper-prototypes produce a more semantically consistent global signal, and 2) FedHPro achieves state-of-the-art performance on several benchmark datasets.

Dyn-VPP: Video Prediction Policy Optimization for Improved Visual Dynamics
Zirui Ge, Pengxiang Ding, Baohua Yin, Yemin Wang, Qishen Wang, Zhiyong Xie, Hengtao Li, Runze Suo, Wenxuan Song, Han Zhao, Shangke Lyu, Haoang Li, Ran Cheng, Cheng Chi, Hui-Bin Ge, Yaozhi Luo, Donglin Wang
Video action models are a promising foundation for Vision–Language–Action (VLA) because they can learn rich visual dynamics directly from video. However, likelihood-oriented training of diffusion predictors emphasizes globally plausible futures and does not guarantee precision-critical visual dynamics needed for manipulation, so small prediction errors can be amplified by downstream policies. We propose Dyn-VPP, a post-training framework that casts multi-step denoising as policy optimization and aligns predicted future latents with expert visual dynamics via verifiable terminal reward, without modifying any architecture. This enables explicit optimization of dynamics signals that are not captured by likelihood-only training. As a result, Dyn-VPP yields more accurate visual dynamics and improves downstream task execution. Experiments across diverse simulated and real-world manipulation settings show improved dynamics consistency and consistently higher task success.

Ekka: Automated Diagnosis of Silent Errors in LLM Inference
Yile Gu, Zhen Zhang, Shaowei Zhu, Xinwei Fu, Jun Wu, Yida Wang, Baris Kasikci
LLM serving frameworks are quickly evolving with a complex software stack and a vast number of optimizations.
The rapid development process can introduce silent errors where output quality silently degrades without any explicit error signals.
Diagnosing silent errors is notoriously difficult due to the substantial semantic gap between the high-level symptoms and the low-level root causes.
We observe that diagnosis of silent errors can be effectively framed as a differential debugging problem by leveraging the existence of semantically correct reference implementations.
We propose Ekka, an automated diagnosis system that identifies root causes by systematically aligning and comparing intermediate execution states between a target and a reference framework.
We constructed a benchmark of real-world silent errors from popular serving frameworks, where Ekka shows 80\% pass@1 diagnosis accuracy and 88\% pass@5 diagnosis accuracy, outperforming state-of-the-art systems.
Ekka also diagnoses 4 new silent errors from serving frameworks, all of which have been confirmed by the developers.

A Probabilistic Framework for LLM-Based Model Discovery
Stefan Wahl, Raphaela Schenk, Ali Farnoud, Jakob H. Macke, Daniel Gedon
Automated methods for discovering mechanistic simulator models from observational data offer a promising path toward accelerating scientific progress. Such methods often take the form of agentic-style iterative workflows that repeatedly propose and revise candidate models by imitating human discovery processes. However, existing LLM-based approaches typically implement such workflows via hand-crafted heuristic procedures, without an explicit probabilistic formulation. We reca

st model discovery as probabilistic inference, i.e., as sampling from an unknown distribution over mechanistic models capable of explaining the data. This perspective provides a unified way to reason about model proposal, refinement, and selection within a single inference framework. As a concrete instantiation of this view, we introduce ModelSMC, an algorithm based on Sequential Monte Carlo sampling. ModelSMC represents candidate models as particles which are iteratively proposed and refined by an LLM, and weighted using likelihood-based criteria. Experiments on real-world scientific systems illustrate that this formulation discovers models with interpretable mechanisms and improves posterior predictive checks. More broadly, this perspective provides a probabilistic lens for understanding and developing LLM-based approaches to model discovery.

Variance Driven Exploration: A Provable and Efficient Methodology for Pure Exploration in Highly Stochastic Environments

Khang Luong, Nam Nguyen, Hoang Ta, Hung The Tran, Tuan Quang Dam

We propose ***Var**iance **D**riven **E**xploration* (VarDE), a principled approach for pure exploration in *highly stochastic environments*, where the exploration process is dominated by stochastic variance.

VarDE is built on a fundamental principle: *sampling effort should be allocated to minimize the uncertainty of the final decision*.

We formalize the uncertainty of the final decision through a smooth decision function and derive allocation rules that explicitly capture how stochastic noise in individual components affects the reliability of the final output.

We apply this methodology to three core problems of pure exploration -- Best Arm Identification (BAI), Monte Carlo Tree Search (MCTS), and Best-Policy Identification (BPI) -- with theoretical guarantees on variance decay and simple regret.

Empirically, we demonstrate consistent and significant improvements of VarDE over existing methods, with especially strong gains in highly stochastic environments.

Escaping the Diversity Trap in Robotic Manipulation via Anchor-Centric Adaptation

Yanzhe Chen, Kevin Yuchen Ma, Qi Lv, Yiqi Lin, Zechen Bai, Chen Gao, Mike Zheng Shou

While Vision-Language-Action (VLA) models offer broad general capabilities, deploying them on specific hardware requires real-world adaptation to bridge the embodiment gap. Since robot demonstrations are costly, this adaptation must often occur under a strict data budget. In this work, we identify a critical **diversity trap**: the standard heuristic of ``maximizing coverage" by collecting diverse, single-shot demonstrations can be self-defeating due to non-vanishing estimation noise. We formalize this phenomenon as a **Coverage--Density Trade-off**. By decomposing the policy error into estimation (density) and extrapolation (coverage) terms, we characterize an interior optimal allocation of unique conditions for a fixed budget. Guided by this analysis, we propose **Anchor-Centric Adaptation (ACA)**, a two-stage framework that first stabilizes a policy skeleton through repeated demonstrations at core anchors, then selectively expands coverage to high-risk boundaries via teacher-forced error mining and constrained residual updates. Real-robot experiments validate our trade-off framework and demonstrate that ACA significantly improves task reliability and success rates over standard diverse sampling strategies under the same budget.

GraphPFN: A Prior-Data Fitted Graph Foundation Model

Dmitry Eremeev, Oleg Platonov, Gleb Bazhenov, Artem Babenko, Liudmila Prokhorenkova

Graph foundation models face several fundamental challenges including transferability across diverse domains and data scarcity, which calls into question the very feasibility of creating such models. However, despite similar challenges, the tabular domain has recently witnessed the emergence of the first successful foundation models such as TabPFN. These models are based on the prior-data fitted networks (PFN) framework, in which models are pretrained on carefully designed sy

nthetic datasets to make predictions in an in-context learning setting. Recently, G2T-FM, a framework that converts graph node-level tasks into tabular tasks, has made the first step towards adopting PFNs for graphs, yet it is limited to hand-crafted features and was never pretrained on graph data. In this work, we make the next step by proposing GraphPFN, a PFN-based model designed and pretrained specifically for graph node-level tasks. Following the PFN framework, we first design a prior distribution of synthetic attributed graphs by using a novel combination of multi-level stochastic block models and a preferential attachment process for structure generation and graph-aware structured causal models for attribute generation. Then, we augment the tabular foundation model LimiX with attention-based graph neighborhood aggregation layers and train it on millions of synthetic graphs sampled from our prior. On diverse real-world graph datasets with node-level tasks, GraphPFN achieves state-of-the-art results in both in-context learning and finetuning regimes, outperforming G2T-FM, prior GFMs, and task-specific GNNs trained from scratch. More broadly, GraphPFN shows the potential of PFN-based models for building graph foundation models. Our code is available at https://github.com/yandex-research/graphpfn.

Exploring and Exploiting Stability in Latent Flow Matching

Rania Briq, Michael Kamp, Ohad Fried, Sarel Cohen, Stefan Kesselheim

In this work, we show that Latent Flow-Matching (LFM) models are robust to different types of perturbations, including data reduction and model capacity shrinkage. We characterize this stability by these models' tendency to generate similar outputs under identical noise seeds. We provide a perspective relating this phenomenon to flow matching theory, which indicates that this stability is inherent to the FM objective. We further exploit this stability to derive practical algorithms for more efficient training and inference. Concretely, first, we show that by training LFM models on significantly reduced datasets, performance is preserved, and in compute-constrained regimes, the model converges faster while maintaining quality. This yields multiple advantages, including savings in the training time due to faster convergence, and alleviating annotation effort when training conditional models. Second, LFM stability under architectural shrinkage gives rise to a two-model coarse-to-fine approach, one using a light-weight architecture for the first phase of the FM trajectory, and one with higher capacity for the second, thereby reducing the inference cost substantially. To determine which samples are informative, we introduce three sample-scoring criteria and evaluate them under standard metrics for generative models. Our results are thoroughly evaluated on multiple datasets, demonstrating the practical advantage of this stability, including data savings and a more than two-fold inference speedup while generating comparable outputs.

MoST: Mixing Speech and Text with Modality-Aware Mixture of Experts

Yuxuan Lou, Kai Yang, Yang You

We present MoST (Mixture of Speech and Text), a novel multimodal large language model that seamlessly integrates speech and text processing through our proposed Modality-Aware Mixture of Experts (MAMoE) architecture. While current multimodal models typically process diverse modality representations with identical parameters—disregarding their inherent representational differences, we introduce specialized routing pathways that direct tokens to modality-appropriate experts based on input type. MAMoE simultaneously enhances modality-specific learning and cross-modal understanding through two complementary components: modality-specific expert groups that capture domain-specific patterns and shared experts that facilitate information transfer between modalities. Building on this architecture, we develop an efficient transformation pipeline that adapts the pretrained MoE language model through strategic post-training on ASR and TTS datasets, followed by fine-tuning with a carefully curated speech-text instruction dataset. A key feature of this pipeline is that it relies exclusively on fully accessible, open-source datasets to achieve strong performance and data efficiency. Comprehensive evaluations across ASR, TTS, audio language modeling, and spoken question answering benchmarks show that MoST consistently outperforms existing models of comp

arable parameter counts. Our ablation studies confirm that the modality-specific routing mechanism and shared experts design significantly contribute to performance gains across all tested domains. To our knowledge, MoST represents the first fully open-source speech-text LLM built on a Mixture of Experts architecture.

Efficient Preference Poisoning Attack on Offline RLHF
Chenye Yang, Weiyu Xu, Lifeng Lai
Offline Reinforcement Learning from Human Feedback (RLHF) pipelines such as Direct Preference Optimization (DPO) train on a pre-collected preference dataset, which makes them vulnerable to preference poisoning attack.
We study label flip attacks against log-linear DPO.
We first illustrate that flipping one preference label induces a parameter-independent shift in the DPO gradient.
Using this key property, we can then convert the targeted poisoning problem into a structured binary sparse approximation problem.
To solve this problem, we develop two attack methods: Binary-Aware Lattice Attack (BAL-A) and Binary Matching Pursuit Attack (BMP-A).
BAL-A embeds the binary flip selection problem into a binary-aware lattice and applies Lenstra-Lenstra-Lovász reduction and Babai's nearest plane algorithm; we provide sufficient conditions that enforce binary coefficients and recover the minimum-flip objective.
BMP-A adapts binary matching pursuit to our non-normalized gradient dictionary and yields coherence-based recovery guarantees and robustness (impossibility) certificates for K-flip budgets.
Experiments on synthetic dictionaries and the Stanford Human Preferences dataset validate the theory and highlight how dictionary geometry governs attack success.
****
Identifiable Equivariant Networks are Layerwise Equivariant
Vahid Shahverdi, Giovanni Luca Marchetti, Georg Bökman, Kathlén Kohn
We investigate the relation between end-to-end equivariance and layerwise equivariance in deep neural networks. We prove the following:
For a network whose end-to-end function is equivariant with respect to group actions on the input and output spaces, there is a parameter choice yielding the same end-to-end function such that its layers are equivariant with respect to some group actions on the latent spaces.
Our result assumes that the parameters of the model are identifiable in an appropriate sense. This identifiability property has been established in the literature for a large class of networks, to which our results apply immediately, while it is conjectural for others. The theory we develop is grounded in an abstract formalism, and is therefore architecture-agnostic. Overall, our results provide a mathematical explanation for the emergence of equivariant structures in the weights of neural networks during training -- a phenomenon that is consistently observed in practice.

Convergence Analysis of the Lion Optimizer in Centralized and Distributed Settings
Wei Jiang, Mao Xu, Wenhao Yang, Yibo Wang, Zechao Li, Lijun Zhang
In this paper, we provide a comprehensive convergence analysis for the Lion optimizer. First, we establish that the original Lion achieves a convergence rate of $\mathcal{O}(d^{1/2}T^{-1/4})$, where d denotes the problem dimension and T is the iteration number. To improve this rate, we propose a variance reduction variant of Lion, which attains an enhanced rate of $\mathcal{O}(d^{1/2}T^{-1/3})$ with the average smoothness assumption. Then, we extend our analysis to distributed settings. We demonstrate that the distributed Lion optimizer and its variance reduction counterpart achieve linear speedup with respect to the number of nodes n, yielding convergence rates of $\mathcal{O}(d^{1/2}(nT)^{-1/4})$ and $\mathcal{O}(d^{1/2}(nT)^{-1/3})$, respectively. Additionally, we investigate a communication-efficient distributed Lion variant that utilizes sign compression for bidirectional communication. By employing unbiased sign operations, this varia

nt achieves a convergence rate of $\mathcal{O} \left(\max \{ \frac{d^{1/4}}{T^{1/4}}, \frac{d^{1/10}}{n^{1/5}T^{1/5}} \} \right)$, and its variance-reduced counterpart can further improve the rate to $\mathcal{O}\left(\frac{d^{1/4}}{T^{1/4}} \right)$. Finally, we conduct numerical experiments to validate the effectiveness of the proposed methods.

Mitigating Staleness in Asynchronous Pipeline Parallelism via Basis Rotation

Hyunji Jung, Sungbin Shin, Namhoon Lee

Asynchronous pipeline parallelism maximizes hardware utilization by eliminating the pipeline bubbles inherent in synchronous execution, offering a path toward efficient large-scale distributed training. However, this efficiency gain can be compromised by gradient staleness, where the immediate model updates with delayed gradients introduce noise into the optimization process. Crucially, we identify a critical, yet often overlooked, pathology: this delay scales linearly with pipeline depth, fundamentally undermining the very scalability that the method originally intends to provide. We trace this pathology to a specific property of the optimization landscape: the misalignment between the Hessian eigenbasis and the standard coordinate basis, which triggers oscillations in the update trajectories of coordinate-wise adaptive optimizers. We identify that these oscillations cause delayed updates to diverge from their true counterparts, invalidating their use for current iterations. This insight is formalized through theoretical analysis, including a convergence bound showing that basis misalignment amplifies the delay penalty, and substantiated with empirical evaluation. To address this, we propose basis rotation, a framework that rotates the optimizer's coordinate system to align with the Hessian eigenbasis, keeping delayed updates useful. We theoretically demonstrate that basis rotation minimizes basis misalignment, thereby counteracting the conditions that amplify delay penalties. Empirically, in training up to a 3B-parameter LLM, basis rotation reduces the required iterations by 81.7% compared to the best-performing asynchronous baseline.

ECSEL: Explainable Classification via Signomial Equation Learning

Adia C. Lumadjeng, Ilker Birbil, Erman Acar

We introduce ECSEL, an explainable classification method that learns formal expressions in the form of signomial equations, motivated by the observation that many symbolic regression benchmarks admit compact signomial structure. ECSEL directly constructs a structural, closed-form expression that serves as both a classifier and an explanation. On standard symbolic regression benchmarks, our method recovers a larger fraction of target equations than competing state-of-the-art approaches while requiring substantially less computation. Leveraging this efficiency, ECSEL achieves classification accuracy competitive with established machine learning models without sacrificing interpretability. Further, we show that ECSEL satisfies some desirable properties regarding global feature behaviour, decision-boundary analysis, and local feature attributions. Experiments on benchmark datasets and two real-world case studies i.e., e-commerce and fraud detection, demonstrate that the learned equations expose dataset biases, support counterfactual reasoning, and yield actionable insights.

Revisiting Photometric Ambiguity for Accurate Gaussian-Splatting Surface Reconstruction

Jiahe Li, Jiawei Zhang, Xiao Bai, Jin Zheng, Xiaohan Yu, Lin Gu, Gim Hee Lee

Surface reconstruction with differentiable rendering has achieved impressive performance in recent years, yet the pervasive photometric ambiguities have strictly bottlenecked existing approaches. This paper presents AmbiSuR, a framework that explores an intrinsic solution upon Gaussian Splatting for the photometric ambiguity-robust surface reconstruction with high performance. Started by revisiting the foundation, our investigation uncovers two built-in primitive-wise ambiguities in representation, while revealing an intrinsic potential for ambiguity self-indication in Gaussian Splatting. Stemming from these, a photometric disambiguation is first introduced, constraining ill-posed geometry solution for definite surface formation. Then, we propose an ambiguity indication module that unleash

es the self-indication potential to identify and further guide correcting underc
onstrained reconstructions. Extensive experiments demonstrate our superior perfo
rmance in surface reconstruction compared to existing methods across various cha
llenging scenarios, while excelling in broad compatibility. Our code will be mad
e open-source upon acceptance.

FocalPolicy: Frequency-Optimized Chunking and Locally Anchored Flow Matching for
 Coherent Visuomotor Policy

Qian He, Zhenshuo Yang, Wenqi Liang, Chunhui Hao, Nicu Sebe, Jiandong Tian

Visuomotor policies aim to learn complex manipulation tasks from expert demonstr
ations.
However, generating smooth and coherent trajectories remains challenging, as it
requires balancing proximal precision with distal foresight.
Existing approaches typically focus on optimizing intra-chunk action distributio
ns, often neglecting the inter-chunk coherence.
Consequently, inter-chunk discontinuities significantly impede the learning of c
oherent long-horizon actions.
To overcome this limitation and achieve a synergetic balance between precision a
nd foresight, we propose FocalPolicy, a foresight-aware visuomotor policy that c
ombines Frequency-Optimized Chunking with Locally Anchored flow matching.
We introduce a foresight composite objective that supervises time-domain alignme
nt within the proximal actions while regularizing frequency-domain structure ove
r multiple future action chunks to improve cross-chunk coherence.
To efficiently learn complex action distributions, we design locally anchored sa
mpling to enhance target signal propagation efficiency during consistency flow m
atching training.
Extensive experiments demonstrate that FocalPolicy outperforms existing approach
es and confirm the generalizability of our modules to other baselines.

Weaving in the Clouds: Achieving Synergistic Collaboration among LLM Agents via
Federated Learning

Jiaxing Zhao, Hongbin Xie, Yuzhen Lei, Xuan Song, Zhuoran Shi, Lianxin Li, Shuan
gxue liu, Haoran Zhang

Multi-Agent Systems (MAS) powered by Large Language Models (LLMs) have become a
promising paradigm for solving workflow-structured tasks through expert collabor
ation.
However, the data required for such collaboration are often distributed across o
rganizations and cannot be centrally pooled due to privacy, intellectual propert
y, and compliance constraints.
Federated Learning preserves data locality, but existing federated paradigms typ
ically treat clients as independent and fail to model workflow dependencies that
 are crucial for coherent multi-stage collaboration.
We introduce **FedWave**, a federated and workflow-aware framework that enables
LLM-based experts to solve sequential tasks under data-locality constraints.
FedWave combines a *Value Chain Layer* to model inter-stage dependencies, federa
ted LoRA adaptation to preserve role-specific expertise, a shared *Mixture-of-Ex
perts (MoE)* router for input-conditioned expert fusion, and a *Direct Preferenc
e Optimization (DPO)* stage based on router-induced preferences.
Experiments across workflow datasets and LLM backbones show that FedWave outperf
orms federated baselines and remains competitive with centralized multi-agent sy
stems while preserving data locality.

Evaluating the Representation Space of Diffusion Models via Self-Supervised Prin
ciples

Xiao Li, Yixuan Jia, Zekai Zhang, Xiang Li, Lianghe Shi, Jinxin Zhou, Zhihui Zhu
, Liyue Shen, Qing Qu

Diffusion models have demonstrated remarkable generative capabilities and have a
lso emerged as powerful self-supervised representation learners. However, the co
nnection between these two abilities remains less explored. In this work, drawin

g inspiration from self-supervised learning (SSL), we introduce a framework for jointly evaluating the representation and generation capabilities of diffusion models. Specifically, we decompose features into invariant and residual components and derive the Invariant Contamination Ratio (ICR), a Fisher-based metric that quantifies how residual variation contaminates invariant signal in feature space. We use this framework to analyze both discriminative and generative behavior of diffusion models. On the representation side, we find that invariance peaks at intermediate noise levels, which also yield the best downstream classification performance. On the generative side, we study how training transitions from genuine generalization to memorization in data-limited regimes, and show that ICR serves as a sensitive training-time indicator of early learning: increasing residual energy along Fisher directions marks the onset of memorization, detectable from training features alone without external evaluators or held-out test sets. Overall, our results show that diffusion models can be monitored from a self-supervised perspective through the geometry of their learned representations.
****
BiRQA: Bidirectional Robust Quality Assessment for Images
Aleksandr Gushchin, Dmitriy S. Vatolin, Anastasia Antsiferova
Full-Reference image quality assessment (FR IQA) is important for image compression, restoration and generative modeling, yet current neural metrics remain slow and vulnerable to adversarial perturbations. We present BiRQA, a compact FR IQA metric model that processes four fast complementary features within a bidirectional multiscale pyramid. A bottom-up attention module injects fine-scale cues into coarse levels through an uncertainty-aware gate, while a top-down cross-gating block routes semantic context back to high resolution. To enhance robustness, we introduce Anchored Adversarial Training, a theoretically grounded strategy that uses clean "anchor" samples and a ranking loss to bound pointwise prediction error under attacks. On five public FR IQA benchmarks BiRQA outperforms or matches the previous state of the art (SOTA) while running $\sim 3 \times$ faster than previous SOTA models. Under unseen white-box attacks it lifts SROCC from 0.30-0.57 to 0.60-0.84 on KADID-10k, demonstrating substantial robustness gains. To our knowledge, BiRQA is the only FR IQA model combining competitive accuracy with real-time throughput and strong adversarial resilience.
****
Sampling and Identity-Testing Without Approximate Tensorization of Entropy
William Gay, William He, Nicholas Kocurek, Ryan O'Donnell
We study the problems of approximate sampling from and distribution testing of \emph{mixture models}, where the modes satisfy a functional inequality called \emph{approximate tensorization of entropy} (ATE). While it is known that ATE makes these tasks more efficient in the unimodal setting, mixtures of few distributions satisfying ATE do not necessarily satisfy ATE overall, leading to a lack of theoretical guarantees for multimodal distributions, which are a key challenging case of modern generative models. We show this gap can be overcome by establishing the following pair of results for mixtures of ATE distributions:

1) We show fast mixing of Glauber dynamics from a \emph{data-based initialization}, with \emph{optimal} sample complexity, for mixtures of distributions satisfying modified log-Sobolev inequalities, building on similar results in (Koehler et al., 2024, Huang et al., 2024) for mixtures satisfying the weaker Poincaré inequality.
2) Answering an open question from (Blanca et al., 2023), we give efficient identity-testers for mixtures of ATE distributions in the coordinate-conditional sampling access model.
****
Being More Lightweight and Practical: Mini-sized Contrastive Learning Pre-trained Models for Fine-grained Traffic Task
Shuhao Li, Weidong Yang, Ben Fei, Yue Cui, Lipeng Ma, Fan Zhang
Fine-grained traffic prediction is critically important for mitigating traffic congestion in key urban areas and for providing lane-change guidance in autonomous vehicles and navigation systems. However, task-specific models are not efficie

nt enough, city-scale pre-trained models often overlook fine-grained requirements, and the demand for extensive computational resources hinders practical deployment. To address this issue, we developed a lightweight pre-training framework, MiniTraffic. This framework leverages abundant road-level data to address lane-level data scarcity through a frequency domain stability augmentation module and captures road-lane correlations via contrastive clustering to construct small-scale graph structures, significantly reducing model parameters. Fine-tuning with minimal target data provides a unified and efficient solution for fine-grained traffic prediction. In multi-granularity traffic prediction tasks across six fine-grained datasets, MiniTraffic demonstrated superior performance compared to existing baselines.

INFER: Learning Implicit Neural Frequency Response Fields for Confined Acoustic Environments

Harshvardhan C. Takawale, Nirupam Roy, C. Phillip Brown

Neural acoustic fields often model time-domain impulse responses, which struggle to capture the frequency-selective wave behaviors that dominate confined, resonant environments. To address this, we propose INFER (Implicit Neural Frequency Response fields), a framework that directly learns continuous, complex-valued frequency response fields. Unlike prior time-domain methods, our frequency-first approach enables three key innovations: (1) end-to-end learning of frequency-specific attenuation and phase delay in 3D space; (2) a physics-based Kramers–Kronig consistency constraint that causally regularizes attenuation and phase delay; and (3) perceptual and hardware-aware spectral supervision that prioritizes critical auditory bands. We evaluate INFER across diverse settings, ranging from standard room-scale benchmarks (MeshRIR, RAF) to challenging, highly reverberant environments like real car cabins. Our approach significantly outperforms time- and hybrid-domain baselines, reducing average magnitude and phase reconstruction errors by over 39\% and 51\%, respectively, demonstrating state-of-the-art accuracy in modeling complex acoustic spaces.

Taming Aleatoric Impulse in Off-Policy Reinforcement Learning

Zhouyang Yu, Guojian Zhan, Yang Guan, Jingliang Duan, Letian Tao, Shengbo Eben Li

Off-policy reinforcement learning is vulnerable to overestimation bias, which is rooted in the total value uncertainty. However, existing methods typically misaddress this by targeting the epistemic component, neglecting the aleatoric component. We identify for the first time that this oversight fails to contain a massive bias surge, termed **Aleatoric Impulse**. Although transient, this impulse fundamentally derails the learning trajectory, permanently locking the agent into suboptimal policies. To counteract this, we propose **A**leatoric **I**mpulse **D**amping **(AID)**, the first mechanism that models total value uncertainty by disentangling the return variance into epistemic and aleatoric components, followed by their adaptive weighted recombination. Leveraging this derived uncertainty, the critic constructs a pessimistic lower confidence bound to surgically suppress the impulse. Complementing this, the actor utilizes a symmetrical upper confidence bound to drive optimistic exploration, ensuring that the necessary pessimism does not compromise exploration efficiency. We integrate this mechanism into the Distributional Soft Actor-Critic algorithm to establish **DSAC-AID**. Extensive experiments on the high-dimensional Gym-MuJoCo and DeepMind Control Suite benchmarks demonstrate that it achieves state-of-the-art results in final performance.

****

Removing Noise, not Finding Gold: Quality Filtering for Large-Scale Pretraining

Thiziri Nait Saada, Louis Béthune, Michal Klein, David Grangier, marco cuturi, Pierre Ablin

Large-scale models are pretrained on massive web-crawled datasets containing documents of mixed quality, making data filtering essential. A popular method is Classifier-based Quality Filtering (CQF), which trains a binary classifier to distinguish between pretraining data and a small, high-quality set. It assigns each

pretraining document a quality score defined as the classifier's score and retai
ns only the top-scoring ones. We provide an in-depth analysis of CQF.
We show that while CQF improves downstream task performance, it does not necessa
rily enhance language modeling on the high-quality set. Importantly, we find tha
t training on CQF-selected data can outperform training directly on the high-qua
lity set, even when the latter is sufficiently large. This finding alone is part
icularly striking, given the substantial effort and cost recently devoted to aug
menting high-quality data. We explain this paradox by the fact that CQF implicit
ly filters the high-quality dataset as well as the low-quality one. Finally, we
introduce an optimization-driven notion of data quality and demonstrate that it
can be reliably estimated using small-scale proxy experiments. Altogether, our r
esults both elucidate the mechanisms behind CQF and deepen our understanding of
data selection methods widely used in practice.

Evolving Interpretable Constitutions for Multi-Agent Coordination
Ujwal Kumar, Alice Saito, Hershraj Niranjani, Rayan Yessou, Phan Xuan Tan
Constitutional AI has focused on single-model alignment using fixed principles.
However, multi-agent systems create novel alignment challenges through emergent
social dynamics. We present Constitutional Evolution, a framework for automatica
lly discovering behavioral norms in multi-agent LLM systems. Using a grid-world
simulation with survival pressure, we study the tension between individual and c
ollective welfare, quantified via a Societal Stability Score $\mathcal{S} \in [0
,1]$ that combines productivity, survival, and conflict metrics. Adversarial con
stitutions lead to societal collapse ($\mathcal{S}=0$), while vague prosocial pr
inciples (''be helpful, harmless, honest'') produce inconsistent coordination ($
\mathcal{S}=0.249$). Even constitutions designed by Claude 4.5 Opus with explici
t knowledge of the objective achieve only moderate performance ($\mathcal{S}=0.3
32$). Using LLM-driven genetic programming with multi-island evolution, we evolv
e constitutions maximizing social welfare without explicit guidance toward coope
ration. The evolved constitution $\mathcal{C}^*$ achieves
$\mathcal{S}=0.556\pm0.008$ (123\% higher than human-designed baselines, $N=10$)
, eliminates conflict, and discovers that minimizing communication (0.9\% vs 62.
2\% social actions) outperforms verbose coordination. Our interpretable
rules demonstrate that cooperative norms can be discovered rather than prescribe
d.

ProbeLLM: Automating Principled Diagnosis of LLM Failures
Yue Huang, Zhengzhe Jiang, Yuchen Ma, Yu Jiang, Xiangqi Wang, Yujun Zhou, Yuexin
g Hao, Kehan Guo, Pin-Yu Chen, Marzyeh Ghassemi, Stefan Feuerriegel, Xiangliang
Zhang
Understanding how and why large language models (LLMs) fail is becoming a centra
l challenge as models rapidly evolve and static evaluations fall behind. While a
utomated probing has been enabled by dynamic test generation, existing approache
s often discover isolated failure cases, lack principled control over exploratio
n, and provide limited insight into the underlying structure of model weaknesses
. We propose ProbeLLM, a benchmark-agnostic automated probing framework that ele
vates weakness discovery from individual failures to structured failure modes. P
robeLLM formulates probing as a hierarchical Monte Carlo Tree Search, explicitly
 allocating limited probing budgets between global exploration of new failure re
gions and local refinement of recurring error patterns. By restricting probing t
o verifiable test cases and leveraging tool-augmented generation and verificatio
n, ProbeLLM grounds failure discovery in reliable evidence. Discovered failures
are further consolidated into interpretable failure modes via failure-aware embe
ddings and boundary-aware induction. Across diverse benchmarks and LLMs, ProbeLL
M reveals substantially broader, cleaner, and more fine-grained failure landscap
es than static benchmarks and prior automated methods, supporting a shift from c
ase-centric evaluation toward principled weakness discovery

Fast and Highly Expressive Policy Learning for Offline Reinforcement Learning vi
a Bootstrapped Flow Q-Learning

Thanh Xuan Nguyen, Tri Ton, Hongbin Choe, Tung Minh Luu, Chang D. Yoo
Diffusion-based Q-learning has emerged as a powerful paradigm for offline reinfo rcement learning, but its reliance on multi-step denoising makes both training a nd inference computationally expensive and brittle. Recent efforts to accelerate diffusion Q-learning toward single-step action generation typically introduce a uxiliary networks, policy distillation, or multi-phase training, which frequentl y compromise simplicity, stability, or performance.
To address these limitations, we introduce Bootstrapped Flow Q-Learning (BFQ), a novel framework that enables accurate single-step action generation during both training and inference—without auxiliary networks or distillation procedures. B FQ adopts a divide-and-conquer view of the displacement vector along the flow pa th: it begins by learning short-range displacements that can be accurately estim ated from the Flow Matching marginal velocity, and bootstraps these components t o directly learn a noise-to-action mapping in a single step. This formulation el iminates multi-step denoising, resulting in a learning procedure that is substan tially faster, simpler, and more robust. Extensive D4RL evaluations show that BF Q improves performance while significantly reducing computational cost compared to multi-step diffusion baselines, demonstrating that single-step action generat ion suffices for high-performance offline Reinforcement Learning.

Cello: A Universal Cell-wise Feature Aggregation framework for Reliable Pathol ogy Images Analysis
Hengrui Lou, Weihan Li, Jiazhen Yang, Lingxiang Jia, Shengxuming Zhang, Linyun Z hou, Xiuming Zhang, Zhenyang Wang, Mingli Song, Zunlei Feng
Computational pathology has made progress in diagnosis and prognosis prediction from whole slide images (WSIs), yet pipelines still rely on patch-level feature extraction and aggregation, departing from the cell-centric reasoning used by pa thologists.
This gap limits sensitivity to micro-lesions and subtle changes, and current met hods rarely provide a unified solution that supports both local and global tasks with trustworthy evidence. We propose Cello, a universal cell-wise feature aggr egation framework for reliable pathology image analysis. Cello integrates cell-l evel representations into WSI modeling via protein-signal–supervised cell-wise l earning, preserving fine-grained cellular cues under gigapixel constraints. For local tasks, Cello introduces a flexible prototype-based contrastive module for scalable, task-adaptive representation learning. For global tasks, Cello adopts a weakly supervised gated aggregation that can widely leverage WSI labels. Final ly, a cell–local–global decision-route consistency objective dynamically aggrega tes cellular evidence and aligns local predictions with global outcomes, improvi ng reliability and faithfulness.
Trained with only hundreds to thousands of samples, Cello achieves performance g ains of 3.0%~7.6% and outperforms SOTA pathology foundation models pretrained on tens of thousands of samples. Code is available at https://github.com/HengruiLo u/Cello.

Noisy-Channel Minimum Bayes Risk Decoding
Yusuke Sakai, Hidetaka Kamigaito, Taro Watanabe
Minimum Bayes Risk (MBR) decoding yields more robust and higher-quality text gen eration than maximum a posteriori (MAP) decoding by selecting hypotheses that ma ximize expected utility over sampled pseudo-references. However, there exists a discrepancy in the design: hypothesis selection calculates expected utility scor es conditioned on given pseudo-references, while commonly used evaluation metric s, e.g., BLEU and COMET, are asymmetric. Therefore, it is important to consider both hypothesis-to-reference and reference-to-hypothesis directional effects. In this study, we introduce a noisy channel decomposition of MBR decoding that nat urally incorporates bidirectional effects to account for these asymmetries. We d ecompose MBR decoding into four interacting components: hypothesis-to-reference likelihood, reference-to-hypothesis likelihood, hypothesis prior, and reference prior. This decomposition provides a unified interpretation of existing MBR vari ants and enables metric- and task-specific interpretability by isolating the con

tribution of each channel. Our comprehensive analysis reveals that channel-wise contributions exhibit distinct characteristics across metrics while remaining consistent across tasks, and suggests that appropriate channel weighting may lead to improvements over original MBR decoding.

MICE-Bench: A Challenging and Comprehensive Benchmark for Multi-Reference Image Creation and Editing

Siqi Luo, Huayu Zheng, Jianghan Shen, Yi Xin, Luxin Xu, Jiyao Liu, Xinyu Zhang, Hang Zhou, Pengyu Xie, Xiaohui Li, Shuo Cao, Yuandong Pu, Junjun He, Bin Fu, Yihao Liu, Yu Qiao, Guangtao Zhai, Yuewen Cao, Xiaohong Liu

The paradigm of visual generation is rapidly shifting from single-image conditioning toward multi-image conditioning, making the ability to synthesize and edit images based on multiple visual references a critical capability. Despite this trend, existing benchmarks remain largely limited to single-reference scenarios or narrowly defined tasks, leaving model behavior under complex multi-concept composition insufficiently explored. To bridge this gap, we introduce **MICE-Bench**, a comprehensive benchmark for **M**ulti-reference **I**mage **C**reation and **E**diting. The benchmark is designed around three core principles: 1) heterogeneous concept composition across seven visual dimensions; 2) varying levels of constraint density, ranging from dual-concept to seven-concept configurations; 3) concept-centric data construction and benchmark evaluation, enabling fine-grained analysis of interactions among multiple concepts. MICE-Bench consists of 3,119 high-quality test cases within a unified concept space. Using an 8-dimensional evaluation metric, we systematically evaluate 13 state-of-the-art models. Our results show that although closed-source models maintain a clear performance advantage, all models experience notable degradation in concept consistency and physical realism as concept complexity increases.This indicates that current models rely on superficial composition rather than genuine multi-concept synthesis, highlighting substantial room for future improvement.

Multipole Semantic Attention: A Fast Approximation of Softmax Attention for Pretraining

Rupert Mitchell, Kristian Kersting

Pretraining transformers on long sequences, such as entire code repositories or collections of related documents, is bottlenecked by quadratic attention costs. We present Multipole Semantic Attention (MuSe), which accelerates 64k-context pretraining by 36% while matching baseline loss, requiring no architectural changes. MuSe is a training-time approximation that clusters queries and keys separately in representation space. This yields query-specific summaries that substantially outperform spatial blocking at matched sparsity, while also enabling drop-in compatibility with existing pretrained models—we validate on Llama 3.1-8B and 3.2-1B without retraining. We pretrain
language models up to 1B parameters at 64k context on code and scientific documents, confirming that MuSe preserves quality and long-context utilization during training.

Thinking with Geometry: Active Geometry Integration for Spatial Reasoning

Haoyuan Li, Qihang Cao, Tao Tang, Kun Xiang, Zihan Guo, Jianhua Han, Jia-Wang Bian, Hang Xu, Xiaodan Liang

Recent progress in spatial reasoning with Multimodal Large Language Models (MLLMs) increasingly leverages geometric priors from 3D encoders. However, most existing integration strategies remain passive: geometry is exposed as a global stream and fused in an indiscriminate manner, which often induces semantic-geometry misalignment and redundant signals. We propose GeoThinker, a framework that shifts the paradigm from passive fusion to active perception. Instead of feature mixing, GeoThinker enables the model to selectively retrieve geometric evidence conditioned on its internal reasoning demands. GeoThinker achieves this through Spatial-Grounded Fusion applied at carefully selected VLM layers, where semantic visual priors selectively query and integrate task-relevant geometry via frame-strict cross-attention, further calibrated by Importance Gating that biases per-fram

e attention toward task-relevant structures. Comprehensive evaluation results sh ow that GeoThinker sets a new state-of-the-art in spatial intelligence, achievin g a peak score of 72.6 on the VSI-Bench. Furthermore, GeoThinker demonstrates ro bust generalization and significantly improved spatial perception across complex downstream scenarios, including embodied referring and autonomous driving. Our results indicate that the ability to actively integrate spatial structures is es sential for next-generation spatial intelligence.

Lower Complexity Bounds for Nonconvex-Strongly-Convex Bilevel Optimization with First-Order Oracles

Kaiyi Ji

Although upper bound guarantees for bilevel optimization have been widely studie d, progress on lower bounds has been limited due to the complexity of the bileve l structure. In this work, we focus on the smooth nonconvex-strongly-convex sett ing and develop new hard instances that yield nontrivial lower bounds under dete rministic and stochastic first-order oracle models. In the deterministic case, w e prove that any first-order zero-respecting algorithm requires at least $\Omega (\kappa^{3/2}\epsilon^{-2})$ oracle calls to find an ϵ-accurate station ary point, improving the optimal lower bounds known for single-level nonconvex o ptimization and for nonconvex-strongly-convex min-max problems. In the stochasti c case, we show that at least $\Omega(\kappa^{5/2}\epsilon^{-4})$ stochastic ora cle calls are necessary, again strengthening the best known bounds in related se ttings. Our results expose substantial gaps between current upper and lower boun ds for bilevel optimization and suggest that even simplified regimes, such as th ose with quadratic lower-level objectives, warrant further investigation toward understanding the optimal complexity of bilevel optimization under standard firs t-order oracles.

Distilling Linearized Behavior into Non-linear Fine-Tuning for Effective Task Ar ithmetic

Thomas Sommariva, Francesca Morandi, Simone Calderara, Angelo Porrello

Task vector composition has emerged as a promising paradigm for editing pre-trai ned models, enabling model merging through addition and unlearning through subtr action. Fine-tuning in the tangent space of a pre-trained model (linear fine-tun ing) has proven effective, as it produces task vectors that are naturally disent angled and resistant to interference. However, linearized models suffer from lim ited expressivity during training and incur higher computational costs at infere nce time, which restrict their practical applicability. In this work, we bridge the gap between linear and standard non-linear fine-tuning. We show that lineari ty with respect to weight perturbations, a property defined in parameter space, can be enforced through constraints in activation space during training. Concret ely, we distill hidden representations from a curvature-regularized linearized t eacher into a non-linear student trained via conventional fine-tuning. We find t hat the resulting model inherits key properties of linearized models for task ar ithmetic, enabling effective composition of task vectors and achieving strong pe rformance across vision and language benchmarks without incurring any inference-time overhead.

Why Deep Jacobian Spectra Separate: Depth-Induced Scaling and Singular-Vector Al ignment

Nathanaël Haas, François Gatine, Augustin M Cosse, Zied Bouraoui

Understanding why gradient-based training in deep networks exhibits strong impli cit bias remains challenging, in part because tractable singular-value dynamics are typically available only for balanced deep linear models. We propose an alte rnative route based on two theoretically grounded and empirically testable signa tures of deep Jacobians: depth-induced exponential scaling of ordered singular v alues and strong spectral separation. Adopting a fixed-gates view of piecewise-l inear networks, where Jacobians reduce to products of masked linear maps within a single activation region, we prove the existence of Lyapunov exponents governi ng the top singular values at initialization, give closed-form expressions in a

tractable masked model, and quantify finite-depth corrections. We further show t
hat sufficiently strong separation forces singular-vector alignment in matrix pr
oducts, yielding an approximately shared singular basis for intermediate Jacobia
ns. Together, these results motivate an approximation regime in which singular-v
alue dynamics become effectively decoupled, mirroring classical balanced deep-li
near analyses without requiring balancing. Experiments in fixed-gates settings v
alidate the predicted scaling, alignment, and resulting dynamics, supporting a m
echanistic account of emergent low-rank Jacobian structure as a driver of implic
it bias.

Fast-SAM3D: 3Dfy Anything in Images but Faster
Weilun Feng, Mingqiang Wu, zhiliang chen, Chuanguang Yang, Haotong Qin, Yuqi Li,
 Xiaokun Liu, Guoxin Fan, Libo Huang, Yulun Zhang, Michele Magno, Yongjun Xu, Zh
ulin An
SAM3D enables scalable, open-world 3D reconstruction from complex scenes, yet it
s deployment is hindered by prohibitive inference latency. In this work, we cond
uct the **first systematic investigation** into its inference dynamics, revealin
g that generic acceleration strategies are brittle in this context. We demonstra
te that these failures stem from neglecting the pipeline's inherent multi-level
heterogeneity: the kinematic distinctiveness between shape and layout, the i
ntrinsic sparsity of texture refinement, and the spectral variance across geomet
ries. To address this, we present **Fast-SAM3D**, a training-free framework that
 dynamically aligns computation with instantaneous generation complexity. Our ap
proach integrates three heterogeneity-aware mechanisms: (1) *Modality-Aware Step
 Caching* to decouple structural evolution from sensitive layout updates; (2) *J
oint Spatiotemporal Token Carving* to concentrate refinement on high-entropy reg
ions; and (3) *Spectral-Aware Token Aggregation* to adapt decoding resolution. E
xtensive experiments demonstrate that Fast-SAM3D delivers up to **2.67$\times$**
 end-to-end speedup with negligible fidelity loss, establishing a new Pareto fro
ntier for efficient single-view 3D generation.

Transformer Circuits Can Realize Clustering Algorithms
Kenneth L. Clarkson, Lior Horesh, Takuya Ito, Charlotte Park, Parikshit Ram
Although transformers are most commonly optimized as statistical sequence models
, it is unclear to what extent they can implement and learn exact algorithmic co
mputations. Here, we specify a transformer implementation from first principles
that executes a fundamental and widely used method for k-means clustering: Llo
yd's algorithm. We theoretically prove and empirically demonstrate that this imp
lementation of a transformer architecture, which we term the _k-means transfor
mer_, exactly implements Lloyd's algorithm for k-means clustering using the st
andard circuit mechanisms of modern transformers: attention block, residual conn
ections, and feed-forward block. In learning experiments, we find that training
this base architecture on k-means clustering yields a generalizable clustering
 algorithm that surpasses Lloyd's algorithm in terms of clustering quality. Fina
lly, we demonstrate that interpretable alterations (e.g., inclusion of layer nor
malizations) to this architecture yields diverse and novel variants of clusterin
g algorithms, including soft k-means, spherical k-means, trimmed k-means.
Overall, our results show that transformer circuit mechanisms can instantiate ex
act algorithmic routines for clustering, while simultaneously providing an effec
tive learnable model.

The Abstraction Gap in Vision-Language Causal Reasoning
Chinh Hoang, Mohammad Rashedul Hasan
Vision-language models (VLMs) generate fluent causal explanations, but current e
valuations cannot distinguish linguistic plausibility from faithful causal reaso
ning. We introduce a dual-probe methodology that isolates these properties. The
Text-Only Probe measures linguistic quality. The Chain-Text Probe requires model
s to first generate explicit causal chains. The Abstraction Gap (AG) metric quan
tifies the normalized performance difference. Evaluating eight VLMs on CAGE (Cau
sal Abstraction Gap Evaluation), a benchmark of 49,500 questions across 5,500 im

ages spanning Pearl's causal hierarchy, we find seven models exhibit AG exceedin g 0.50 with text scores of 6--8 but chain scores below 2.5. Fine-tuning on 45,00 0 chain-annotated examples fails to close the gap. However, one model achieves n ear-zero AG. The capability exists within current VLM architectures and depends on pretraining and architectural choices. CAGE provides a diagnostic tool for as sessing faithful causal reasoning in VLMs.

A Penalty Approach For Differentiation Through Black-box Quadratic Programming S olvers
Yuxuan Linghu, Zhiyuan Liu, Qi Deng
Differentiating through the solution of a quadratic program (QP) is a central pr oblem in differentiable optimization. Most existing approaches differentiate thr ough the Karush--Kuhn--Tucker (KKT) system, but their computational cost and num erical robustness can degrade at scale. To address these limitations, we propose dXPP, a penalty-based differentiation framework that decouples QP solving from differentiation. In the solving step (forward pass), dXPP is solver-agnostic and can leverage any black-box QP solver. In the differentiation step (backward pas s), we map the solution to a smooth approximate penalty problem and implicitly d ifferentiate through it, requiring only the solution of a much smaller linear sy stem in the primal variables. This approach bypasses the difficulties inherent i n explicit KKT differentiation and significantly improves computational efficien cy and robustness. We evaluate dXPP on various tasks, including randomly generat ed QPs, large-scale sparse projection problems, and a real-world multi-period po rtfolio optimization task. Empirical results demonstrate that dXPP is competitiv e with KKT-based differentiation methods and achieves substantial speedups on la rge-scale problems. Our implementation is open source and available at https://g ithub.com/mmmmmmlinghu/dXPP.

FPTQuant: Function-Preserving Transforms for LLM Quantization
Boris van Breugel, Yelysei Bondarenko, Paul N. Whatmough, Markus Nagel
Large language models (LLMs) require substantial compute, and thus energy, at in ference time. While quantizing weights and activations is effective at improving efficiency, naive quantization of LLMs can significantly degrade performance du e to large magnitude outliers. This paper describes FPTQuant, which introduces t hree novel, lightweight, and expressive function-preserving transforms (FPTs) to facilitate quantization of transformers: (1) a mergeable pre-RoPE transform for queries and keys, (2) a mergeable transform for values, (3) a cheap, dynamic sc aling transform. By leveraging the equivariances and independencies inherent to canonical transformer operation, we designed these FPTs to maintain the model’s function while shaping the intermediate activation distributions to be more quan tization friendly. FPTQuant requires no custom kernels and adds virtually no ove rhead during inference. The FPTs are trained both locally to reduce outliers, an d end-to-end such that the outputs of the quantized and full-precision models ma tch. FPTQuant enables static INT4 quantization with minimal overhead and shows S OTA speed-up of up to 3.9x over FP. Empirically, FPTQuant has an excellent accur acy-speed trade-off—it is performing on par or exceeding most prior work and onl y shows slightly lower accuracy compared to a method that is up to 29% slower.

Heterogeneous Customizable Personalized Federated Fine-Tuning Approach for Larg e Language Models
xin tong, Baojiang cui
Personalized federated LoRA fine tuning has become a key approach to addressing data heterogeneity in distributed fine tuning of large language models (LLMs). E xisting methods typically assume homogeneous personalization needs across client s, relying on dual LoRA or personalized calibration schemes. However, they fail to account for the heterogeneity of local personalization requirements and the c onflicting optimization objectives in dual LoRA, limiting scalability and perfor mance. To address this, we propose Het-CPFLoRA, a customizable heterogeneous fe derated LoRA fine tuning algorithm inspired by the decoupling properties of LoRA parameters. We employ a single adapter fine tuning scheme to mitigate conflicts

between personalized and generalized optimization, decouple LoRA into generalized and personalized subspaces for local customization, and use SVD compression to integrate cross client generalized knowledge. During inference, we introduce an OOD oriented dynamic mechanism to adjust the weighting between personalized and generalized decoupling knowledge, improving performance on user data. Extensive experiments on two public benchmark datasets show that Het-CPFLoRA outperforms state of the art methods in both personalization and generalization across heterogeneous scenarios. The code will be released as an open-source project.

Restoring Exploration after Post-Training: Latent Exploration Decoding for Large Reasoning Models
Wenhui Tan, Fiorenzo Parascandolo, Enver Sangineto, Jianzhong Ju, Zhenbo Luo, Qian Cao, Rita Cucchiara, Ruihua Song, Jian Luan
Large Reasoning Models (LRMs) have recently achieved strong mathematical and code reasoning performance through Reinforcement Learning (RL) post-training.
However, we show that modern reasoning post-training induces an unintended exploration collapse: temperature-based sampling no longer increases pass@n accuracy.
Empirically, the final-layer posterior of post-trained LRMs exhibit sharply reduced entropy, while the entropy of intermediate layers remains relatively high.
Motivated by this entropy asymmetry, we propose Latent Exploration Decoding (LED), a depth-conditioned decoding strategy.
LED aggregates intermediate posteriors via cumulative sum and selects depth configurations with maximal entropy as exploration candidates.
Without additional training or parameters, LED consistently improves pass@1 and pass@16 accuracy by 0.61 and 1.03 percentage points across multiple reasoning benchmarks and models.
Relevant code is included in the supplementary material and will made be fully public after this paper is accepted.

DR-MMSearchAgent: Deepening Reasoning in Multimodal Search Agents
Shengqin Wang, Wentao Yan, Huichi Zhou, Yihang Chen, Kun Shao, Zhizhong Zhang, Yuan Xie
Agentic multimodal models have garnered significant attention for their ability to leverage external tools to tackle complex tasks. However, it is observed that such agents often meet premature interaction collapse, caused by two primary reasons: 1) the terminal reward often appending on the last token prevents the advantage from distinguishing trajectories with exploratory behavior; 2) excessively redundant context hinders the agent from absorbing useful feedback. To address these issues, we propose the Deepening Reasoning MMSearchAgent, the framework leverages the structural proximity to derive advantage signals from the whole rollout trajectories in an entire batch, such that trajectories of different lengths are further encouraged to be generated, even when containing the same correct answer. Additionally, differentiated gaussian rewards are employed to dynamically calibrate interaction tolerance, thereby ensuring information reliability and reducing redundancy. To support multi-turn interaction training, we have constructed a multi-step deep-reasoning dataset including 3602 high-quality QA pairs with at least 3 reasoning steps. Extensive experiments demonstrate that our method achieves state-of-the-art performance, outperforming the MMSearch-R1 by 8.4\% on FVQA-test.
****
Expo-GS: Exposure-Aware Signed Distance Function in Gaussian Splatting for High Dynamic Range
Chaoda Song, Yiren Lu, Xinpeng Li, Yunlai Zhou, Yanyan Zhang, Yu Yin, Vipin Chaudhary
High dynamic range novel view synthesis (HDR-NVS) remains challenged by geometric artifacts and radiometric distortions under multi-exposure conditions, primarily due to existing methods ignoring exposure and over-relying on color cues. Inspired by the integrated processing of color and structure of the human visual system (HVS), we propose Expo-GS, a novel framework that decomposes HDR-NVS into t

hree interpretable components, namely, Irradiance Field Training, Geometry Fiel d Training, and Interactive Joint Training. Central to Expo-GS is the exposure-a ware signed distance function (Expo-SDF), which dynamically reweights geometric supervision via localized exposure reliability estimation, suppressing noisy gra dients from unstable regions while enhancing structure learning in well-exposed areas. Building on this, we design an interactive optimization strategy that syn chronizes Gaussian primitive growth and pruning with evolving Expo-SDF cues, ena bling exposure-aware density control and eliminating hallucinated structures nea r exposure transitions. Experiments show that Expo-GS significantly outperforms prior methods on both synthetic and real-world datasets. It achieves a peak PSNR of 39.06 dB under HDR settings and up to 41.38 dB in the LDR-OE configuration, excelling in preserving high-frequency textures and maintaining structural consi stency.

BioAgent Bench: An AI Agent Evaluation Suite for Bioinformatics

Dionizije Fa, Marko ■uljak, Bruno Pandža, Mateo ■upi■

We introduce BioAgent Bench, an evaluation suite designed for measuring the perf ormance and robustness of AI agents in common bioinformatics tasks. The suite co nsists of manually curated end-to-end tasks (e.g., RNA-seq, variant calling, met agenomics) accompanied by task-specific prompts and concrete output artifacts to support automated assessment. We evaluate frontier closed- and open-weight mode ls across multiple agent harnesses, and use an LLM-based grader to score pipelin e progress and outcome validity. We find that agents based on frontier LLMs can complete multi-step bioinformatics pipelines without elaborate custom scaffoldin g, often producing the requested final artifacts reliably. However, robustness t ests reveal failure modes under controlled perturbations (corrupted inputs, deco y files, and prompt bloat), indicating that correct high-level pipeline construc tion does not guarantee reliable step-level reasoning. Finally, bioinformatics w orkflows often involve sensitive patient data or unpublished intellectual proper ty, thereby making the use of cost-effective yet reliable local agents an impera tive. Therefore, by releasing the code and the complementary resources comprisin g our suite, we aim to accelerate the development of such privacy-preserving age nts.

A Sketch-and-Project Analysis of Subsampled Natural Gradient Algorithms

Gil Goldshlager, Jiang Hu, Lin Lin

Subsampled natural gradient descent (SNG) has been used to enable high-precision scientific machine learning, but standard analyses based on stochastic precondi tioning fail to provide insight into realistic small-sample settings. We overcom e this limitation by instead analyzing SNG as a sketch-and-project method. Motiv ated by this lens, we discard the usual theoretical proxy which decouples gradie nts and preconditioners using two independent mini-batches, and we replace it wi th a new proxy based on squared volume sampling. Under this new proxy the expect ation of the SNG direction becomes equal to a preconditioned gradient descent st ep even in the presence of coupling, leading to (i) global convergence guarantee s when using a single mini-batch of any size, and (ii) an explicit characterizat ion of the convergence rate in terms of quantities related to the sketch-and-pro ject structure. These findings in turn yield new insights into small-sample sett ings, for example by suggesting that the advantage of SNG over SGD is that it ca n more effectively exploit spectral decay in the model Jacobian. We also extend these ideas to explain a popular structured momentum scheme for SNG, known as SP RING, by showing that it arises naturally from accelerated sketch-and-project me thods.

SARSteer: Safeguarding Large Audio Language Models via Safe-Ablated Refusal Stee ring

Weilin Lin, Jianze Li, Hui Xiong, Li Liu

Large Audio–Language Models (LALMs) are becoming essential as a powerful multimo dal backbone for real-world applications. However, recent studies show that audi o inputs can more easily elicit harmful responses than text, exposing new risks

toward deployment. While safety alignment has made initial advances in LLMs and Large Vision–Language Models (LVLMs), we find that vanilla adaptation of these approaches to LALMs faces two key limitations: 1) LLM-based steering fails under audio input due to the large distributional gap between activations, and 2) prompt-based defenses induce over-refusals on benign-speech queries. To address these challenges, we propose **S**afe-**A**blated **R**efusal **Steer**ing (SARSteer), an effective inference-time defense framework for LALMs. Specifically, SARSteer leverages text-derived refusal steering to enforce rejection without manipulating audio inputs and introduces decomposed safe-space ablation to mitigate over-refusal. Extensive experiments demonstrate that SARSteer significantly improves harmful-query refusal while preserving benign responses, establishing a principled step toward safety alignment in LALMs. The codes and constructed datasets are released at https://github.com/linweiii/SARSteer.

A Two-Tier Perspective on Inference-Time Parallelism in Multi-Agent LLM Systems

Zihan Xu, Haolin Tian, Hai Jiang

Large language model (LLM)-driven multi-agent systems typically require multiple model invocations and complex coordination during inference, and their execution strategies directly affect system accuracy, latency, and computational cost. Parallel execution provides a means to improve inference-time efficiency. From the perspective of inference-time execution, this paper models parallelism in multi-agent systems as two distinct levels of decision processes: Replica Parallelism, which explores multiple complete solution paths at the task level, and Structural Parallelism, which enables concurrent execution within a single solution path through task decomposition. However, the roles of different forms of parallelism and their interrelationships still lack systematic study in terms of unified organization and coordination. We therefore propose TIPEX, a controllable execution framework that unifies these two levels of parallelism and coordinates their roles within the inference process under a unified execution semantics while supporting systematic combinations and analyses of different parallel strategies and parameter configurations. Systematic experiments on the GAIA benchmark demonstrate that inference-time parallelism can significantly improve accuracy and reduce end-to-end latency at the cost of increased token consumption. Further analysis shows that Replica and Structural Parallelism exhibit complementary effects across task complexities, with tasks of intermediate difficulty benefiting most from their coordination, while overly aggressive parallel strategies do not necessarily yield better performance.

Understanding Multimodal Learning: A Loss Landscape Smoothness Perspective

Jae-Jun Lee, Sung Whan Yoon

A surge of recent advancements has consistently highlighted the superiority of multimodal learning over unimodal approaches across a variety of tasks.

However, the theoretical foundations elucidating this advantage remain underexplored: existing theoretical analyses are often constrained by tight assumptions, and lack empirical validation.

In this paper, we link this gap by proposing a novel theoretical framework grounded in \textit{convolutional smoothing}, offering a new perspective on how multimodal learning contributes to a smoother loss landscape compared to unimodal learning.

Building upon this theoretical foundation, we introduce a simple yet effective distributional training approach based on stochastic modality pairing instead of fixed pairing; thus, further promoting flatter landscape via convolutional smoothing.

Our empirical results across various multimodal datasets demonstrate that multimodal models not only achieve better performance but also exhibit smoother loss landscape, which represent better robustness and generalization.

Beyond Log Likelihood: Probability-Based Objectives for Supervised Fine-Tuning across the Model Capability Continuum

Gaotang Li, Ruizhong Qiu, Xiusi Chen, Heng Ji, Hanghang Tong

Supervised fine-tuning (SFT) is the standard approach for post-training large la
nguage models (LLMs), yet it often shows limited generalization. We trace this l
imitation to its default training objective: negative log likelihood (NLL). Whil
e NLL is classically optimal when training from scratch, post-training operates
in a different paradigm and could violate its optimality assumptions, where mode
ls already encode task-relevant priors and supervision can be long and noisy. In
 this work, we systematically study various probability-based objectives and cha
racterize when and why different objectives succeed or fail under varying condit
ions. Through comprehensive experiments and extensive ablation studies across 8
model backbones, 27 benchmarks, and 7 domains, we uncover a critical dimension t
hat governs objective behavior: the model-capability continuum. Near the model-s
trong end, prior-leaning objectives that downweight low-probability tokens (e.g.
, $-p$, $-p^{10}$, thresholded variants) consistently outperform NLL; toward the
 model-weak end, NLL dominates; in between, no single objective prevails. Our th
eoretical analysis further elucidates how objectives trade places across the con
tinuum, providing a principled foundation for adapting objectives to model capab
ility. The code is available at https://github.com/GaotangLi/Beyond-Log-Likeliho
od.

Learning to Correct: Reinforcement Learning for Multi-Attempt Chain-of-Thought
Muhammed Emrullah Ildiz, Halil Alperen Gozeten, Ege Onur Taga, Samet Oymak
State-of-the-art reasoning models utilize long chain-of-thought (CoT) to solve i
ncreasingly complex problems using more test-time computation. In this work, we
explore a long CoT setting where the model makes up to K successive attempts at
solving a problem, in which each attempt is allowed to build on earlier ones aft
er the model receives a hard verifier feedback. This motivates RL methods that c
an harness per-attempt rewards by carefully weighting individual attempts. We st
udy optimizing the Verification@K reward (the model succeeds by the K-th attempt
) and show that naively weighing the attempts by their pass/fail results in bias
ed gradients. We introduce Calibrated Attempt-Level (CAL) GRPO by devising a wei
ghing strategy to obtain unbiased gradients while maintaining small variance. Ou
r theory reveals how incorporating per-attempt rewards influences the training a
nd the eventual Verification@K performance. Experiments, baselines, and ablation
s on synthetic and real data corroborate our theory and the benefits of CAL-GRPO
 over vanilla GRPO as well as naive weighting.

Differential syntactic and semantic encoding in LLMs
Santiago Acevedo, Alessandro Laio, Marco Baroni
We study how syntactic and semantic information is encoded in inner layer repres
entations of Large Language Models (LLMs), focusing on the very large DeepSeek-V
3. We find that, by averaging hidden-representation vectors of sentences sharing
 syntactic structure or meaning, we obtain vectors that capture a significant pr
oportion of the syntactic and semantic information contained in the representati
ons. In particular, subtracting these syntactic and semantic ``centroids'' from
sentence vectors strongly affects their similarity with syntactically and semant
ically matched sentences, respectively, suggesting that syntax and semantics are
, at least partially, linearly encoded. We also find that the cross-layer encodi
ng profiles of syntax and semantics are different, and that the two signals can
to some extent be decoupled, suggesting differential encoding of these two types
 of linguistic information in LLM representations.
****

LALM-as-a-Judge: Benchmarking Large Audio-Language Models for Safety Evaluation
in Multi-Turn Spoken Dialogues
Amir Ivry, Shinji Watanabe
Evaluation of socially unsafe content in spoken dialogues remains text-centric,
missing prosody and transcription failures. We present LALM-as-a-Judge, which in
cludes an open benchmark of 24,000 multi-turn spoken dialogues with one localize
d unsafe turn, generated out of 8 socially unsafe categories and 5 severity leve
ls. We evaluate 6 large audio-language models (LALMs) as judges, open and closed
-source, in text-only, audio-only, and multimodal setups by their sensitivity, s

everity-order specificity, and turn-position bias for socially harmful content i
n the dialogue. Results show that audio contributes non-lexical evidence beyond
transcript semantics and that multimodal gains are not universal but can be text
-anchored, balanced, conservative, and interfering, which we link to the audio p
athway bottlenecks and fusion limits. We position the benchmark as diagnostic an
d derive practitioner guidance for model, modality, and prompts choices.

Rethinking KV Cache Eviction via a Unified Information-Theoretic Objective
Jiaming Yang, Chenwei Tang, Liangli Zhen, Jiancheng Lv
Key–value (KV) caching is essential for large language model inference, yet its
memory overhead poses a critical bottleneck for long-context generation. Existin
g eviction policies predominantly rely on empirical heuristics, lacking a rigoro
us theoretical foundation. This work rethinks KV cache eviction through the lens
 of the Information Bottleneck principle. Under a linear–Gaussian surrogate of a
ttention, we derive a closed-form mutual information objective that characterize
s the effective information capacity of a retained KV cache subset. This formula
tion reveals that a wide range of existing eviction strategies can be interprete
d as different approximations of the same capacity-maximization principle. Guide
d by this insight, we introduce CapKV, a capacity-aware eviction method that dir
ectly targets information preservation via a log-determinant approximation using
 statistical leverage scores. This approach replaces heuristic selection with a
theoretically grounded mechanism that preserves the maximum predictive signal. E
xtensive experiments across multiple models and long-context benchmarks show tha
t CapKV consistently outperforms prior methods, achieving a better trade-off bet
ween memory efficiency and generational fidelity.

XSpecMesh: Quality-Preserving Auto-Regressive Mesh Generation Acceleration via M
ulti-Head Speculative Decoding
Dian Chen, Yansong Qu, Xinyang Li, Ming Li, Shengchuan Zhang
Current auto-regressive models can generate high-quality, topologically precise
meshes; however, they necessitate thousands—or even tens of thousands—of next-to
ken predictions during inference, resulting in substantial latency. We introduce
 XSpecMesh, a quality-preserving acceleration method for auto-regressive mesh ge
neration models. XSpecMesh employs a lightweight, multi-head speculative decodin
g scheme to predict multiple tokens in parallel within a single forward pass, th
ereby accelerating inference. We further propose a verification and resampling s
trategy: the backbone model verifies each predicted token and resamples any toke
ns that do not meet the quality criteria. In addition, we propose a distillation
 strategy that trains the lightweight decoding heads by distilling from the back
bone model, encouraging their prediction distributions to align and improving th
e success rate of speculative predictions. Extensive experiments demonstrate tha
t our method achieves a $1.7\times$ speedup without sacrificing generation quali
ty. Our code will be released.

SMART: Scalable Mesh■free Aerodynamic Simulations from Raw Geometries using a Tr
ansformer■based Surrogate Model
Jan Hagnberger, Mathias Niepert
Machine learning–based surrogate models have emerged as more efficient alternati
ves to numerical solvers for physical simulations over complex geometries, such
as car bodies. Many existing models incorporate the simulation mesh as an additi
onal input, thereby reducing prediction errors. However, generating a simulation
 mesh for new geometries is computationally costly. In contrast, mesh-free metho
ds, which do not rely on the simulation mesh, typically incur higher errors. Mot
ivated by these considerations, we introduce SMART, a neural surrogate model tha
t predicts physical quantities at arbitrary query locations using only a point-c
loud representation of the geometry, without requiring access to the simulation
mesh. The geometry and simulation parameters are encoded into a shared latent sp
ace that captures both structural and parametric characteristics of the physical
 field. A physics decoder then attends to the encoder's intermediate latent repr
esentations to map spatial queries to physical quantities. Through this cross-la

yer interaction, the model jointly updates latent geometric features and the evo lving physical field. Extensive experiments show that SMART is competitive with and often outperforms existing methods that rely on the simulation mesh as input , demonstrating its capabilities for industry-level simulations.

AC-ODM: Actor–Critic Online Data Mixing for Sample-Efficient LLM Pretraining
Jing Ma, Chenhao Dang, Mingjie Liao
Optimizing pretraining data composition is pivotal for LLM generalization. While dynamic mixing outperforms static strategies by capturing evolving training dyn amics, current methods fail to reconcile computational efficiency with sample ef ficiency and structural flexibility for diverse pipelines.We introduce \textbf{A ctor--Critic Online Data Mixing (AC-ODM)}, which approaches data mixing from a r einforcement learning perspective with a parameterized policy that we theoretica lly prove to act as a dynamic linear surrogate maximizing the constructive inter ference of gradients. To enhance practical flexibility, AC-ODM supports two oper ational modes: (i) a \textbf{proxy mode} for fixed, pre-prepared corpora, where a policy learned on a small model is transferred to a larger target; and (ii) a \textbf{non-proxy mode} for direct end-to-end training from scratch without prio rs. Empirically, AC-ODM significantly outperforms prior methods in convergence s peed and downstream accuracy across various architectures. On Pythia-1B, it reac hes optimal validation perplexity using up to 66\% fewer training steps than com petitive baselines, delivering a 27.5\% relative improvement in MMLU accuracy an d a 2.23$\times$ higher pass@1 on HumanEval, all while incurring a virtually neg ligible ($~$0.4\%) per-step wall-clock increase and only 2\% additional memory o verhead. Code is available at \url{https://github.com/DANG-ai/AC-ODM}.

AutoSizer: Automatic Sizing of Analog and Mixed-Signal Circuits via Large Langua ge Model (LLM) Agents
Xi Yu, Dmitrii Torbunov, Soumyajit Mandal, Yihui Ren
The design of Analog and Mixed-Signal (AMS) integrated circuits remains heavily reliant on expert knowledge, with transistor sizing a major bottleneck due to no nlinear behavior, high-dimensional design spaces, and strict performance constra ints. Existing Electronic Design Automation (EDA) methods typically frame sizing as static black-box optimization, resulting in inefficient and less robust solu tions. Although Large Language Models (LLMs) exhibit strong reasoning abilities, they are not suited for precise numerical optimization in AMS sizing. To addres s this gap, we propose \textsc{AutoSizer}, a reflective LLM-driven meta-optimiza tion framework that unifies circuit understanding, adaptive search-space constru ction, and optimization orchestration in a closed loop. It employs a two-loop op timization framework, with an inner loop for circuit sizing and an outer loop th at analyzes optimization dynamics and constraints to iteratively refine the sear ch space from simulation feedback. We further introduce \textsc{AMS-SizingBench} , an open benchmark comprising 24 diverse AMS circuits in SKY130 CMOS technology , designed to evaluate adaptive optimization policies under realistic simulator- based constraints. \textsc{AutoSizer} experimentally achieves higher solution qu ality, faster convergence, and higher success rate across varying circuit diffic ulties, outperforming both traditional optimization methods and existing LLM-bas ed agents.

Optimizing Rank for High-Fidelity Implicit Neural Representations
Julian McGinnis, Florian A. Hölzl, Suprosanna Shit, Florentin Bieder, Paul Fried rich, Mark Mühlau, Bjoern Menze, Daniel Rueckert, Benedikt Wiestler
Implicit Neural Representations (INRs) based on vanilla Multi-Layer Perceptrons (MLPs) are widely believed to be incapable of representing high-frequency conten t. This has directed research efforts towards architectural interventions, such as coordinate embeddings or specialized activation functions, to represent high- frequency signals. In this paper, we challenge the notion that the low-frequency bias of vanilla MLPs is an intrinsic, architectural limitation to learn high-fr equency content, but instead a symptom of stable rank degradation during trainin g. We empirically demonstrate that regulating the network’s rank during training

substantially improves the fidelity of the learned signal, rendering even simple MLP architectures expressive. Extensive experiments show that using optimizers like Muon, with high-rank, near-orthogonal updates, consistently enhances INR architectures even beyond simple ReLU MLPs. These substantial improvements hold across a diverse range of domains, including natural and medical images and novel view synthesis, with up to +9 dB PSNR over the samearchitecture. Code is available [here](https://rank-inrs.github.io/).

Extending Fair Null-Space Projections for Continuous Attributes to Kernel Methods

Felix Störck, Fabian Hinder, Barbara Hammer

With the on-going integration of machine learning systems into the everyday social life of millions the notion of fairness becomes an ever increasing priority in their development.
Fairness notions commonly rely on protected attributes to assess potential biases.
Here, the majority of literature focuses on discrete setups regarding both target and protected attributes.
The literature on continuous attributes especially in conjunction with regression - we refer to this as *continuous fairness* - is scarce.
A common strategy is iterative null-space projection which as of now has only been explored for linear models or embeddings such as obtained by a non-linear encoder.
We improve on this by extending this to kernel induced feature spaces by means of the ``empirical feature space''.
We theoretically derive this as a direct transformation of the kernel matrix yielding a model and fairness-score agnostic method applicable to continuous protected attributes.
We demonstrate that our novel approach in conjunction with Support Vector Regression (SVR) provides competitive or improved performance across multiple datasets in comparison to other contemporary methods.

Keep Everyone Happy: Online Fair Division of Numerous Items with Few Copies

Arun Verma, Indrajit Saha, Makoto Yokoo, Bryan Kian Hsiang Low

This paper considers a novel variant of the online fair division problem involving multiple agents in which a learner sequentially observes an indivisible item that must be irrevocably allocated to one of the agents to achieve a desired balance between fairness and efficiency. Existing algorithms assume a small number of items with a sufficiently large number of copies, which ensures a good utility estimation for all item-agent pairs from noisy observed utilities. However, this assumption may not hold in many real-life applications, e.g., an online platform with a large number of users (items) who use the platform's service providers (agents) only a few times (a few copies of items), making it difficult to accurately estimate utilities for all item-agent pairs. To address this limitation, we assume utility is an unknown function of item-agent features. We propose algorithms that model online fair division as a contextual bandit problem, achieving provable sub-linear regret. Our experimental results further validate the effectiveness of the proposed algorithms. The code is publicly available in this [GitHub repository](https://github.com/arunv3rma/SEDMA.git).

FedRot-LoRA: Mitigating Rotational Misalignment in Federated LoRA

Haoran Zhang, Dongjun Kim, Seohyeon Cha, Haris Vikalo

Federated LoRA provides a communication-efficient mechanism for fine-tuning large language models on decentralized data. In practice, however, a discrepancy between the factor-wise averaging used to preserve low rank and the mathematically correct aggregation of local updates can cause significant aggregation error and unstable training. We argue that a major source of this problem is *rotational misalignment*, arising from the rotational invariance of low-rank factorizations -- semantically equivalent updates can be represented in different latent subspaces across clients since $(B_i R_i)(R_i^\top A_i) = B_i A_i$. When such misalig

ned factors are averaged directly, they interfere destructively and degrade the global update. To address this issue, we propose **FedRot-LoRA**, a federated LoRA framework that aligns client updates via orthogonal transformations prior to aggregation. This alignment preserves the semantic update while reducing cross-client subspace mismatch, without increasing communication cost or restricting model expressivity. We provide a convergence analysis that examines the aggregation error induced by factor-wise averaging and shows how rotational alignment yields a tighter upper bound on this error. Extensive experiments on natural language understanding and generative tasks demonstrate that FedRot-LoRA consistently outperforms existing federated LoRA baselines across a range of heterogeneity levels and LoRA ranks. The code is available at https://github.com/haoran-zh/FedRot-LoRA.

DSGym: A Standardized and Holistic Framework for Evaluating and Training Data Science Agents

Fan Nie, Junlin Wang, Harper Hua, Federico Bianchi, Yongchan Kwon, Zhenting Qi, Owen Queen, Shang Zhu, James Zou

Data science agents promise to accelerate discovery and insight-generation by turning data into executable analyses and findings. Yet existing data science benchmarks fall short due to fragmented evaluation interfaces that make cross-benchmark comparison difficult, narrow task coverage and a lack of rigorous data grounding. In particular, we show that a substantial portion of tasks in current benchmarks can be solved without using the actual data. To address these limitations, we introduce DSGym, a standardized framework for evaluating and training data science agents in self-contained execution environments. Unlike static benchmarks, DSGym provides a modular architecture that makes it easy to add tasks, agent scaffolds, and tools, positioning it as a live, extensible testbed. We curate DSGym-Tasks, a holistic task suite that standardizes and refines existing benchmarks via quality and shortcut solvability filtering. We further expand coverage with (1) DSBio: expert-derived bioinformatics tasks grounded in literature and (2) DSPredict: challenging prediction tasks spanning domains such as computer vision, molecular prediction, and single-cell perturbation. Beyond evaluation, DSGym enables agent training via execution-verified data synthesis pipeline. As a case study, we build a 2,000-example training set in DSGym that substantially improves a 4B mode on standardized analysis benchmarks. Overall, DSGym enables rigorous end-to-end measurement of whether agents can plan, implement, and validate data analyses in realistic scientific context.

MathlibLemma: Folklore Lemma Generation and Benchmark for Formal Mathematics

Xinyu Liu, Zixuan Xie, Amir Moeini, Claire Chen, Shuze Daniel Liu, Yu Meng, Aidong Zhang, Shangtong Zhang

While the ecosystem of Lean and Mathlib has enjoyed celebrated success in formal mathematical reasoning with the help of large language models (LLMs),
the absence of many folklore lemmas in Mathlib remains a persistent barrier that limits Lean's usability as an everyday tool for mathematicians like LaTeX or Maple.

To address this, we introduce MathlibLemma, a modular LLM-based pipeline for automated folklore-lemma mining: the discovery, formalization, and proving of reusable intermediate facts that mathematicians often take for granted but that are not always present in formal libraries.

At its core, MathlibLemma proactively mines the missing connective tissue of mathematics.

The pipeline produces a verified library of folklore-style lemmas, including 1,506 Lean-checked proofs that pass a proof-bypass screen; a small curated pilot subset has also been merged into Mathlib, providing external evidence that selected outputs can meet expert library standards.

Leveraging this pipeline, we further construct the MathlibLemma benchmark, a suite of 4,028 non-trivial type-checked Lean statements spanning a broad range of mathematical domains.

By transforming the role of LLMs from passive consumers to active contributors,

this work takes a step toward AI-assisted expansion of formal mathematical libra
ries.

Beyond Logits: Metastable Latent Dynamics for Sample-Efficient Best-of-N Selecti
on in LLMs
Xinrong Li, Zidong Zhou, Keyu Shen, Wenhao Zhou, Shangqi Guo
Best-of-N selection improves reasoning in large language models (LLMs) by alloca
ting test-time compute to sample candidate trajectories, but it relies on reliab
le verification. Widely used proxies have complementary failure modes: logit-con
fidence signals can suffer from calibration collapse, where confidence becomes m
isaligned with correctness, while sample agreement can be costly or brittle.

    Instead, we analyze the model's latent dynamics during inference. Motivated
by metastable dynamics in cognitive systems, we introduce Latent Velocity Entrop
y (LVE), a training-free metric that quantifies the temporal concentration of in
ternal representation updates.

    Experiments on four reasoning benchmarks, AIME25, GPQA, MATH500, and BRUMO25
, show that LVE-based selection remains informative when logit-confidence baseli
nes fail, with the clearest gains on reasoning-dense mathematical tasks and more
 modest gains on knowledge-heavy GPQA. On MATH500, LogNorm-LVE reaches 92.2\% Pa
ss@1 at $N=10$ and nearly matches 10-sample majority voting with only 3 samples.
 Cross-model, bootstrap, and length-controlled analyses indicate that LVE is not
 reducible to sequence length, while also clarifying the task-dependent limits o
f the signal. Code is available at https://github.com/ZopenDP/LatentVelocityEntr
opy.

A Risk Decomposition Framework for Pre-hoc Fine-tuning Prediction
Yuxiang Luo, Chen Wang, Nan Tang
The high cost of fine-tuning LLMs poses a significant economic barrier; pre-hoc
performance prediction offers a critical solution to substantially reduce this e
xpense. However, the theoretical limits of pre-hoc performance prediction remain
 unexplored.
We formulate it as a stochastic estimation problem under information constraints
, decomposing prediction risk into two components: an \textbf{intrinsic limit} (
static data-model compatibility) and a \textbf{reducible optimization variance}.
 We prove that optimization variance admits a necessary lower bound on its decay
 rate, implying fundamental constraints on how quickly uncertainty dissipates, r
egardless of the predictor used. Based on these dynamics, we derive a budget-opt
imal probing principle and introduce a predictability phase diagram that organiz
es tasks into three distinct regimes: Static-Sufficient, Dynamic-Critical, and N
oise-Dominant. Extensive experiments on synthetic and real-world benchmarks vali
date these theoretical regimes and demonstrate the efficiency of our probing str
ategy.

Op-CAD: Benchmarking and Investigating Operation-oriented CAD Generation
Yixue Bai, Yufei Gu, Zeke Xie
Recent research has made growing efforts to leverage large language models (LLMs
) for computer-aided design (CAD), a domain that demands advanced geometric and
spatial reasoning across long operation sequence. However, existing studies rema
in limited in addressing complex modeling tasks that necessitate step-by-step re
asoning, primarily due to the scarcity of high-quality CAD datasets and the abse
nce of fine-grained evaluation frameworks. In response to these challenges, we i
ntroduce Op-CAD, the first large-scale, multi-modal dataset for operation-orient
ed CAD generation, encompassing four operation types and five modalities. Furthe
rmore, we introduce a novel CAD parsing module together with a geometry-guided h
ierarchical annotation pipeline, which decomposes modeling sequences into discre
te operations and substantially improves the annotation accuracy of Vision-Langu
age Models (VLMs). Based on our dataset, we redefine the CAD modeling task by de
coupling geometric and spatial perspectives and introduce a novel metric, Chamfe
r/Fillet Intersection over Union (CF-IoU), to fill the void in assessing chamfer
 and fillet operations. By comprehensively evaluating eight LLMs on Op-CAD, we e

stablish a benchmark for current models on operation-oriented tasks. Finally, we investigate performance enhancement strategies through fine-tuning on Op-CAD and propose Chain-of-Operation (COOP), a novel prompting strategy that emulates human-engineer reasoning.

MEDUSA: Motion Elimination in Diffusion Using Spectral Attack
Hongwei Yu, Daoqing Zha, Xinlong Ding, Jiawei Li, Junbao Zhuo, Qiankun Liu, Huimin Ma, Jiansheng Chen
With the widespread application of Video Diffusion Models (VDMs), video synthesis has achieved remarkable temporal dynamics.
Image-to-Video (I2V) generation allows users to provide reference images, which enables attackers to inject adversarial noise into these conditions.
Due to the robust spatio-temporal priors in VDMs, conventional frame-level attacks merely induce superficial artifacts and struggle to suppress the synthesis of motion semantics.
In this work, we approach the problem by exploring the underlying mechanism of temporal dynamics.
We reveal that the static video manifests as a temporal rank collapse, a degenerate state characterized by rank-1 degeneracy within the temporal attention matrix.
Guided by this insight, we propose Motion Elimination in Diffusion Using Spectral Attack (MEDUSA) to freeze the video.
It minimizes the nuclear norm of the attention matrix to induce the temporal rank collapse.
This objective circumvents the vanishing gradient problem encountered when directly imposing a rigid temporal mapping on the attention matrix.
Furthermore, we provide a mathematical analysis of this phenomenon and the gradient vanishing problem during the optimization.
Experiments confirm that MEDUSA achieves excellent performance and validates the effectiveness of spectral constraints.
****
From Per-Image Low-Rank to Encoding Mismatch: Rethinking Feature Distillation in Vision Transformers
Huiyuan Tian, Bonan Xu, Shijian Li
Feature-map knowledge distillation (KD) transfers internal representations well between comparably sized Vision Transformers (ViTs), but it often fails in compression. We revisit this failure and uncover a paradox. Sample-wise SVD shows that each image is highly compressible, which seems to suggest that a narrow student with a linear projector should match the teacher "in principle". However, a dataset-level view contradicts this intuition: PCA shows that the teacher is a union of low-rank subspaces with significant subspace rotation across inputs. We further introduce token-level Spectral Energy Patterns (SEP) and find an architecture-invariant encoding law: tokens spread energy broadly across channel modes even when they live in low-rank subspace, creating a bandwidth mismatch. We refer to this combined phenomenon as an encoding mismatch. We propose two minimal remedies, Lift or WideLast: (i) Lift retains a lightweight lifting projector at inference to provide wider channel, or (ii) WideLast widens only the student’s last block, enabling an input-dependent expansion. On ImageNet-1K, these fixes revive feature KD for ViT compression, improving DeiT-Tiny distilled from CaiT-S24 from 74.86% to 77.53%/78.23% top-1 accuracy, and they also strengthen students trained without distillation. Our analyses clarify when and why feature-map KD fails and then how to fix it. Code and raw data are provided in https://github.com/thy960112/From-Per-Image-Low-Rank-to-Encoding-Mismatch.

MolAlign3D: Enhancing Fixed-Dimensional E(3)-Equivariant Latent Space for High-Fidelity 3D Molecular Reconstruction and Editing
Zitao Chen, Jiatong Ji, Yinjun Jia, Wei-Ying Ma, Yanyan Lan
Recent advances in 3D molecular modeling have achieved high-fidelity structural synthesis, yet these models often lack an explicit and manipulable representation space. To address this, MolFLAE introduced a fixed-dimensional, E(3)-equivaria

nt latent space, providing a novel framework for molecular editing independent o
f atom counts. However, because its latent space was primarily optimized for geo
metric reconstruction, it remains semantically shallow and inadequate for compre
hensive representation learning. In this work, we propose **MolAlign3D**, which
evolves this architecture into a unified semantic-generative engine. By anchorin
g MolFLAE’s manipulable latents with embeddings from a pre-trained molecular enc
oder, we yield a manifold that is both semantically dense and geometrically prec
ise. Experiments show that MolAlign3D achieves high-fidelity molecular reconstru
ction and attains comparable performance on molecular property prediction benchm
arks. Notably, the integration of rich semantic priors significantly enhances ze
ro-shot molecular manipulation, including atom-number editing and latent-space i
nterpolation, outperforming prior fixed-dimensional equivariant latent baseline.

Learn to Think: Improving Multimodal Reasoning through Vision-Aware Self-Improve
ment Training
Qihuang Zhong, Liang Ding, Wenjie Xuan, Juhua Liu, Bo Du, Dacheng Tao
Post-training with explicit reasoning traces is common to improve the reasoning
capabilities of Multimodal Large Language Models (MLLMs). However, acquiring hig
h-quality reasoning traces is often costly and time-consuming. Hence, the self-i
mprovement paradigm has emerged, enabling MLLMs to self-generate reasoning trace
s for training without external supervision. Despite its effectiveness, we revea
l two shortcomings in the self-improvement training of MLLMs: 1) data imbalance,
 where simple samples are over-trained, but the challenging yet crucial samples
are under-trained; 2) language prior bias, where MLLMs overly rely on linguistic
 priors while neglecting the visual cues. To this end, we propose VISTA, a VIsio
n-aware Self-improvement Training framework for enhancing the multimodal Reasoni
ng of MLLMs. Specifically, VISTA first introduces a prefix resampling strategy t
o reuse the partial correct reasoning traces for efficient data collection, and
then designs a vision-aware attention score to quantify the model’s focus on vis
ual information. Extensive experiments show that VISTA can be applied to various
 post-training scenarios, i.e., supervised fine-tuning and preference learning,
and effectively enhances the multimodal reasoning performance across various MLL
Ms and tasks, e.g., bringing up to +13.66% average performance gains for Qwen2.5
-VL-3B-Instruct.

Towards Efficient LLMs Annealing with Principled Sample Selection
Yuanjian Xu, Jianing Hao, Wanbo Zhang, Zhong Li, Guang Zhang
The annealing phase is a pivotal convergence stage in LLM pre-training that ulti
mately determines final model quality. However, effectively selecting training d
ata during this phase remains a key challenge. Current strategies rely on empiri
cal heuristics, such as domain filtering or context extension, which lack a prin
cipled grounding in optimization theory. In this work, we characterize the annea
ling phase through the lens of the loss landscape's spectral geometry. We argue
that optimal convergence requires gradient updates to satisfy heterogeneous cons
traints across different eigen-directions. Building on this insight, we formulat
e data selection as a problem of satisfying these directional constraints. To th
is end, we propose **DiReCT** (**Di**rectionally-**Re**strained **C**onstrained
 Training), a novel framework that reformulates sample selection in the anne
aling stage as a constrained optimization problem. By imposing explicit directio
nal constraints on per-sample gradients based on the spectral properties of the
Hessian, **DiReCT** identifies samples that align with the optimal curvature-awa
re descent path. Extensive experiments across various model scales demonstrate t
hat **DiReCT** consistently achieves state-of-the-art performance. For future re
search, code is available at https://github.com/xuyj233/Direct.

Hybrid-Gym: Training Coding Agents to Generalize Across Tasks
Yiqing Xie, Emmy Liu, Gaokai Zhang, Nachiket Kotalwar, Shubham Gandhi, Sathwik A
charya, Xingyao Wang, Carolyn Rose, Graham Neubig, Daniel Fried
When assessing the quality of coding agents, predominant benchmarks focus on sol
ving single issues on GitHub, such as SWE-Bench.

In contrast, in real use these agents solve more various and complex tasks that involve other skills such as exploring codebases, testing software, and designing architecture. In this paper, we first characterize some transferable skills that are shared across diverse tasks by decomposing trajectories into fine-grained components, and derive a set of principles for designing auxiliary training tasks to teach language models these skills. Guided by these principles, we propose a training environment, Hybrid-Gym, consisting of a set of scalable synthetic tasks, such as function localization and dependency search. Experiments show that agents trained on our synthetic tasks effectively generalize to diverse real-world tasks that are not present in training, improving a base model by 25.4% absolute gain on SWE-Bench Verified, 7.9% on SWT-Bench Verified, and 5.1% on Commit-0 Lite. Hybrid-Gym also complements datasets built for the downstream tasks (e.g., improving SWE-Play by 4.9\% on SWT-Bench Verified). We provide the code at https://github.com/Hybrid-Gym/Hybrid-Gym.

Refining Context-Entangled Content Segmentation via Curriculum Selection and Anti-Curriculum Promotion

Chunming He, Rihan Zhang, Fengyang Xiao, Dingming Zhang, Zhiwen Cao, Sina Farsiu

Biological learning proceeds from easy to difficult tasks, gradually reinforcing perception and robustness. Inspired by this principle, we address Context■Entangled Content Segmentation (CECS)—a challenging setting where objects share intrinsic visual patterns with their surroundings, as in camouflaged object detection. Conventional segmentation networks predominantly rely on architectural enhancements but often ignore the learning dynamics that govern robustness under entangled data distributions.

We introduce CurriSeg, a dual■phase learning framework that unifies curriculum and anti■curriculum principles to improve representation reliability. In the Curriculum Selection phase, CurriSeg dynamically selects training data based on the temporal statistics of sample losses, distinguishing hard■but■informative samples from noisy or ambiguous ones, thus enabling stable capability enhancement. In the Anti■Curriculum Promotion phase, we design Spectral■Blindness Fine■Tuning, which suppresses high■frequency components to enforce dependence on low■frequency structural and contextual cues. Combined with Sharpness■Aware Minimization, this promotes convergence to flatter minima and strengthens generalization.

Extensive experiments demonstrate that CurriSeg achieves consistent improvements across diverse CECS benchmarks without adding parameters or increasing total training time, offering a principled view of how progression and challenge interplay to foster robust and context■aware segmentation.

Code will be released.

BRIDGE: Predicting Human Task Completion Time From Model Performance

Fengyuan Liu, Jay Gala, Nilaksh, Dzmitry Bahdanau, Siva Reddy, Hugo Larochelle

Evaluating the real-world capabilities of AI systems requires grounding benchmark performance in human-interpretable measures of task difficulty. Existing approaches that rely on direct human task completion time annotations are costly, noisy, and difficult to scale across benchmarks. In this work, we propose BRIDGE, a unified psychometric framework that learns the latent difficulty scale from model responses and anchors it to human task completion time. Using a two-parameter logistic Item Response Theory model, we jointly estimate latent task difficulty and model capability from model performance data across multiple benchmarks. We demonstrate that latent task difficulty varies linearly with the logarithm of human completion time, allowing human task completion time to be inferred for new benchmarks from model performance alone. Leveraging this alignment, we forecast frontier model capabilities in terms of human task length and independently reproduce METR’s exponential scaling results, with the 50% solvable task horizon doubling approximately every 6 months.

StructMamPose: From Sequential Perception to Structural Reasoning for 3D Human Pose Estimation

Jiahong Jiang, Miao Zhang, Jingjing Li, Leiye Liu, Yao Cui, Wei Ji, Yongri Piao,

Huchuan Lu
Accurately modeling complex temporal and topological dependencies and depth information is critical for monocular 3D human pose estimation, yet existing Mamba-based approaches struggle to fulfill these demands, suffering from internal state update confusion induced by forced sequence flattening and depth modeling confusion inherent to single-view observations. To address this confusion, we propose a StructMamPose framework equipped with Identity Anchoring Mechanism (IAM) and View Transformation Hub (VTH). The IAM injects spatiotemporal identities into the parameter generation network to anchor the selectivity of state update matrices, suppressing spurious connections to enforce feature propagation along valid topological dependencies. The VTH performs internal coordinate rotation to transform implicit depth inference into observable planar features, endowing the model with explicit spatial understanding and multi-view constraints. Experimental results demonstrate that our framework achieves SOTA performance on most datasets.

Break the Block: Dynamic-size Reasoning Blocks for Diffusion Large Language Models via Monotonic Entropy Descent with Reinforcement Learning
Yan Jiang, Ruihong Qiu, Zi Huang
Recent diffusion large language models (dLLMs) have demonstrated both effectiveness and efficiency in reasoning via a block-based semi-autoregressive generation paradigm. Despite their progress, the fixed-size block generations remain a critical bottleneck for effective and coherent reasoning. (I) From a global perspective, different reasoning tasks would correspond to different optimal decoding block sizes, which makes a "one-size-fits-all" assumption ineffective. (II) Even within a single reasoning task, the rigid block partitioning would break the logical flow and reduce reasoning coherence. Through empirical observations, we reveal that, for block-wise entropy, incorrect reasoning exhibits a fluctuating and unsteady trend between blocks, while the correctly generated tasks follow a consistent descending paradigm. Therefore, this paper proposes b1, a novel post-training framework that learns dynamic-size reasoning blocks via a Monotonic Entropy Descent objective with reinforcement learning to enhance reasoning coherence. b1 integrates seamlessly as a plug-and-play module with existing dLLM's post-training algorithms. Extensive experiments across various reasoning benchmarks showcase b1's consistent improvement over fixed-size block baselines. Our code has been released at https://github.com/YanJiangJerry/Block-R1.

POLCA: Stochastic Generative Optimization with LLM
Xuanfei Ren, Allen Nie, Tengyang Xie, Ching-An Cheng
Optimizing complex systems, ranging from LLM prompts to multi-turn agents, traditionally requires labor-intensive manual iteration. We formalize this as a stochastic generative optimization problem where a language model acts as the optimizer, guided by numerical and text feedback to discover the best system. We introduce **P**rioritized **O**ptimization with **L**ocal **C**ontextual **A**ggregation (POLCA), a scalable framework designed to handle stochasticity in optimization—such as noisy feedback, sampled minibatches, and stochastic system behaviors—while effectively managing the unconstrained expansion of the solution space. POLCA maintains a priority queue to enable exploration–exploitation, tracking candidate solutions and their evaluation histories. To enhance efficiency, we integrate an ε-Net mechanism to maintain parameter diversity and an LLM Summarizer to perform meta-learning across historical trials. We theoretically prove that POLCA converges to near-optimal candidate solutions under stochasticity. We evaluate our framework on diverse benchmarks, including τ-bench, HotpotQA, VeriBench, and KernelBench. Experimental results demonstrate that POLCA achieves robust, sample- and time-efficient performance, consistently outperforming state-of-the-art algorithms in both deterministic and stochastic problems. The codebase for this work is publicly available at https://github.com/rlx-lab/POLCA.

Rare Event Analysis of Large Language Models
Jake McAllister Dorman, Edward Gillman, Dominic C Rose, Jamie F. Mair, Juan P. Garrahan

Being probabilistic models, during inference large language models (LLMs) displa
y *rare events*: behaviour that is far from typical but highly significant. By d
efinition all rare events are hard to see, but the enormous scale of LLM usage m
eans that events completely unobserved during development are likely to become p
rominent in deployment. Here we present an end-to-end framework for the systemat
ic analysis of rare events in LLMs. We provide a practical implementation spanni
ng theory, efficient generation strategies, probability estimation and error ana
lysis, which we illustrate with concrete examples. We outline extensions and app
lications to other models and contexts, highlighting the generality of the conce
pts and techniques presented here.
****
Asymptotic Universal Alignment: A New Alignment Framework via Test-Time Scaling
Yang Cai, Weiqiang Zheng
Aligning large language models (LLMs) to serve users with heterogeneous and pote
ntially conflicting preferences is a central challenge for personalized and trus
tworthy AI. We formalize an ideal notion of *universal alignment* through *test-
time scaling*: for each prompt, the model produces $k\ge 1$ candidate responses
and a user selects their preferred one. We introduce *$(k,f(k))$-robust alignmen
t*, which requires the k-output model to have win rate $f(k)$ against any othe
r single-output model, and *asymptotic universal alignment (U-alignment)*, which
 requires $f(k)\to 1$ as $k\to\infty$. Our main result characterizes the optimal
 convergence rate: there exists a family of *single-output* policies whose k-s
ample product policies achieve U-alignment at rate $f(k)=\frac{k}{k+1}$, and no
method can achieve a faster rate in general.

We show that popular post-training methods, including Nash learning from human f
eedback (NLHF), can fundamentally underutilize the benefits of test-time scaling
. Even though NLHF is optimal for $k=1$, sampling from the resulting (often dete
rministic) policy cannot guarantee win rates above $\tfrac{1}{2}$ except for an
arbitrarily small slack. This stems from a lack of output diversity: existing al
ignment methods can collapse to a single majority-preferred response, making add
itional samples redundant. In contrast, our approach preserves output diversity
and achieves the optimal test-time scaling rate. In particular, we propose a fam
ily of symmetric *multi-player alignment games* and prove that any symmetric Nas
h equilibrium policy of the $(k+1)$-player alignment game achieves the optimal $
(k,\frac{k}{k+1})$-robust alignment. Finally, we provide theoretical convergence
 guarantees for self-play learning dynamics in these games and extend the framew
ork to opponents that also generate multiple responses.

Hyper-LLaVA: Hyperbolic Uncertainty-aware Modality-Balanced Routing for Multimod
al Continual Instruction Tuning
Kunlun Xu, YanQin Zhang, Wenwen Qiang, Jiahuan Zhou
Multimodal Continual Instruction Tuning (MCIT) aims to exploit the incrementally
 accumulated knowledge to process multimodal inputs of diverse tasks, where para
meter routing plays an important role. State-of-the-art methods rely on sample-t
o-task center similarity and cross-modal fusion with equal weight during routing
. However, such solutions face two fundamental flaws: (1) Within each modality,
the sample-to-task center distance is sub-optimal for routing since the abundant
 intra-task diversity information is underleveraged. (2) Different modalities ex
hibit varying reliability across tasks, where the modality with inter-task ambig
uity can easily misguide the routing result. To address these problems, we prop
ose Hyperbolic Uncertainty-aware Modality-Balanced Routing (Hyper-LLaVA) to impr
ove parameter routing capacity based on cross-modality task feature uncertainty
modeling. Specifically, to improve intra-modality task matching, Hyper-LLaVA acc
esses the sample to task distribution similarity in the Hyperbolic space. Beside
s, to alleviate the degradation brought by unreliable modality, Hyper-LLaVA quan
tifies the task matching ambiguity within each modality to achieve adaptive bala
ncing between task matching across modalities. Based on the complementary intra-
 and inter-modality task matching enhancement, our Hyper-LLaVA outperforms state
-of-the-art approaches by large margins. Our source code is available at https:/

TINNs: Time-Induced Neural Networks for Solving Time-Dependent PDEs
Chen-Yang Dai, Che-Chia Chang, Te-Sheng Lin, Ming-Chih Lai, Chieh-Hsin Lai
Physics-informed neural networks (PINNs) solve time-dependent partial differenti al equations (PDEs) by learning a mesh-free, differentiable solution that can be evaluated anywhere in space and time. However, standard space-time PINNs take t ime as an input but reuse a single network with shared weights across all times, forcing the same features to represent markedly different dynamics. This coupli ng degrades accuracy and can destabilize training when enforcing PDE, boundary, and initial constraints jointly. We propose *Time-Induced Neural Networks (TINNs)*, a novel architecture that parameterizes the network weights as a learned fun ction of time, allowing the effective spatial representation to evolve over time while maintaining shared structure.
The resulting formulation naturally yields a nonlinear least-squares problem, wh ich we optimize efficiently using a Levenberg-Marquardt method. Experiments on v arious time-dependent PDEs show up to $4\times$ improved relative L^2 error an d $10\times$ faster convergence compared to PINNs and strong baselines. Code is available at https://github.com/CYDai-ml/TINN.

Target-Driven Policy Optimization for Sequential Counterfactual Outcome Control
Xin Wang, Xiangyu Zhang, Shengfei Lyu, Huanhuan Chen
Identifying optimal intervention sequences from offline data to guide temporal s ystems toward target outcomes is a critical challenge with profound implications for fields like personalized medicine. While existing methods are mostly evalua ted in offline settings, practical applications demand online, adaptive strategi es that can respond in real-time. To address this, we propose \textbf{G}oal-cond itioned \textbf{I}ntervention via \textbf{F}actual-\textbf{T}argeted Training (\ textbf{GIFT}), a novel framework for learning sequential intervention policies f rom observational data. GIFT learns a goal-conditioned policy by rescaling rewar ds with clipped importance weights, stabilizing learning and steering toward the target. Under standard assumptions, the induced operator has a unique fixed poi nt and our procedure converges to it. We also bound the bias from clipping and a pproximation via the gap to the policy’s true value. Experiments show GIFT signi ficantly outperforms existing methods in creating goal-conditioned policies for online deployment.

Two-Parameter Flows for Learning Population Dynamics of Physical Systems
Paul Schwerdtner, Tobias Blickhan, Benjamin Peherstorfer
This work addresses the problem of learning the dynamics of high-dimensional pro bability densities over time using unlabeled samples, without assuming access to trajectory information. We introduce two-parameter flows that learn only sampli ng-time transports from a base distribution to each marginal and then extract a physics-time velocity by regressing on coupled synthetic trajectories. We prove that the resulting physics-time dynamics are unique and inherit regularity from the sampling-time transports. Because we can build on standard, well-developed c onditional flow matching techniques for learning the base-to-marginal transports , our approach scales to high dimensions and avoids per-step optimal-transport c ouplings, while allowing admissible non-gradient dynamics that can naturally exp lain rotational or circulating physics phenomena.

Boosting World Models Learning via Latent-Space Value Alignment
Xingyu Jiang, Yuheng Pan, Mukang You, Xiuhui Zhang, Ning Gao, Guanwei Yan, Hao L i, Yue Deng
Model-based reinforcement learning aims to construct world models for efficient sampling. Current mainstream algorithms can be broadly categorized into two para digms: maximum likelihood and value-aware world models. The former employs struc tured Recurrent/Transformer State-Space Models to capture environmental dynamics but overlooks task-relevant features. The latter prioritizes decision-critical states but suffers from sub-optimal performance. While recent efforts have sough

t to integrate these approaches, they typically rely on auxiliary modules or hea vy external priors that significantly increase computational complexity. In this work, we propose a Value-Aligned World Model, a minimalist framework designed t o synergize these two paradigms with negligible overhead. Specifically, We intro duce an intrinsic latent-space value-alignment regularization that compels the w orld model to prioritize task-relevant features while maintaining the structural integrity of stochastic dynamics. To ensure stable optimization, we develop an adaptive weighting mechanism that acts as a self-regulating curriculum, balancin g reconstruction fidelity with decision-making utility. Extensive experiments on Atari 100k and DeepMind Control benchmarks demonstrate that our algorithm consi stently boosts existing methods with minimal added code and computational overhe ad. Code is available at supplementary material.

τ-Voice: Benchmarking Full-Duplex Voice Agents on Real-World Domains
Soham Ray, Keshav Dhandhania, Victor Barres, Karthik R Narasimhan
Full-duplex voice agents—systems that listen and speak simultaneously—are rapidl y moving from research to production. However, existing evaluations address conv ersational dynamics and task completion in isolation. We introduce τ-Voice, a be nchmark for evaluating voice agents on grounded tasks with real-world complexity : agents must navigate complex multi-turn conversations, adhere to domain polici es, and interact with the environment. The framework extends τ^2-bench into a nov el voice agent benchmark combining verifiable completion of complex grounded tas ks, full-duplex interaction, and realistic audio—enabling direct comparison betw een voice and text performance. A controllable and realistic voice user simulato r provides diverse accents, realistic audio environments, and rich turn-taking d ynamics; by decoupling simulation from wall-clock time, the user simulator can u se the most capable LLM without real-time constraints. We evaluate task completi on (pass@1) and voice interaction quality across 278 tasks: while GPT-5 (reasoni ng) achieves 85%, voice agents reach only 31–51% under clean conditions and 26–3 8% under realistic conditions with noise and diverse accents—retaining only 30–4 5% of text capability; qualitative analysis confirms 79–90% of failures stem fro m agent behavior, suggesting that observed failures primarily reflect agent beha vior under our evaluation setup. τ-Voice provides a reproducible testbed for mea suring progress toward voice agents that are natural, conversational, and reliab le.

Trust It or Not: Evidential Uncertainty for Feed-Forward 3D Reconstruction with Trust3R
Zihao Zhu, Wenyuan Zhao, Nuo Chen, Chao Tian, Zhiwen Fan
Geometric foundation models hold promise for unconstrained dense geometry predic tion from uncalibrated images. However, current feed-forward designs often produ ce heuristic confidence scores that lack probabilistic interpretation and fail t o indicate where and how much the predicted geometry can be trusted. To address this gap, we present ***Trust3R***, a lightweight evidential uncertainty framewo rk for feed-forward 3D reconstruction. Trust3R combines gated residual mean refi nement with a Normal-Inverse-Wishart evidential head, yielding a closed-form mul tivariate Student-t distribution for per-point geometric uncertainty. This provi des probabilistically grounded pointmap uncertainty estimates with moderate infe rence overhead.
We evaluate on diverse indoor and outdoor benchmarks and compare against MASt3R 's built-in confidence map, single-pass heteroscedastic regression, MC dropout, and deep ensembles. Experimental results show that Trust3R consistently improves risk--coverage and sparsification, generally improves geometric accuracy, and s trengthens uncertainty ranking across benchmarks. On ScanNet++, Trust3R achieves 25% lower AURC and 41% lower AUSE, providing a practical reliability signal for uncertainty-aware weighting in downstream geometry pipelines. Our project page and code are available at https://trust3r-z.github.io.

Causal discovery for time series with endogenous context variables
Oana-Iuliana Popescu, Wiebke Günther, Martin Rabel, Jakob Runge

Many real-world systems exhibit both context- and time-dependent causal dynamics , where the dynamical system state also influences its context. For instance, so il moisture is driven by precipitation, yet also provides the context for heat-f lux realization. We capture such dynamics in Structural Causal Models (SCMs) by introducing endogenous and time-dependent discrete context variables, also allow ing for possibly lagged dependencies with the system variables. While context va riables are discrete, they may also be proxies of continuous variables. The enab ling assumptions for causal discovery of our model are either persistence of the context or sparsity of the context–system dependencies. We design two new PCMCI -based algorithms for causal discovery with endogenous context variables for tim e series and prove their soundness. A systematic evaluation on synthetic benchma rks and an application to a real-world land-atmosphere feedback problem demonstr ate their effectiveness and applicability.

COPF: An Online Framework for Deployment-Stable Counterfactual Fairness in Evolv ing Graphs

Sheng'en Li, Dongmian Zou

Online link recommendation on evolving graphs is performative: by choosing which candidate links to show users, the system changes which links form and what fee dback it later observes. Consequently, fairness estimates from logged outcomes c an be misleading and may drift after deployment when the recommendation policy i s updated. We introduce COPF (Counterfactual Online Performative Fairness), a de cision-layer framework for deployment-stable fairness monitoring and control in online link recommendation. COPF (i) defines group-level opportunity gaps over e xposure (shown vs. not shown) counterfactuals, (ii) makes them estimable by expl icit exploration and by logging the probability (propensity) that each candidate is shown, and (iii) audits and controls fairness using residual outcome indisti nguishability (OI) over a configurable auditor family with graph-aware doubly ro bust (GA-DR) estimators. We provide a noisy transfer theorem showing that Residu al-OI on estimated GA-DR residuals implies bounds on exposure-counterfactual gro up gaps under temporal mixing and bounded local interference, and we instantiate an online multicalibration auditor together with a primal-dual controller. Expe riments on two TGB streams and a controlled synthetic bipartite stream show that COPF reduces worst-case spikes in exposure-counterfactual group disparities wit h modest impact on ranking utility. Our code is available at https://github.com/ lsnnnnnnnn/COPF.

CRAG: Can 3D Generative Models Help 3D Assembly?

Zeyu Jiang, Sihang Li, Siqi Tan, Chenyang Xu, Juexiao Zhang, Julia Galway-Witham , Xue Wang, Scott A. Williams, Radu Iovita, Chen Feng, Jing Zhang

Most existing 3D assembly methods treat the problem as pure pose estimation, rea rranging observed parts via rigid transformations. In contrast, human assembly n aturally couples structural reasoning with holistic shape inference. Inspired by this intuition, we reformulate 3D assembly as a joint problem of assembly and g eneration. We show that these two processes are mutually reinforcing: assembly p rovides part-level structural priors for generation, while generation injects ho listic shape context that resolves ambiguities in assembly. Unlike prior methods that cannot synthesize missing geometry, we propose CRAG, which simultaneously generates plausible complete shapes and predicts poses for input parts. Extensiv e experiments demonstrate state-of-the-art performance across in-the-wild object s with diverse geometries, varying part counts, and missing pieces. Our code and models will be released.

****

Information Geometry Loss for Time Series Forecasting

Jiayu Fang, Xuande Liu, Sangsha Fang, Ernie Tian, Hongwei Ma, Zhiqi Shao, Junbin Gao

Time series forecasting fundamentally involves learning probability distribution s over future observations. However, existing loss functions rely on point-wise Euclidean metrics, neglecting the intrinsic geometric structure of probability d istributions. This leads to suboptimal alignment between predicted and true dist

ributions, particularly for uncertainty quantification. We propose InfoGeo Loss, a principled loss function grounded in information geometry that measures distributional discrepancies on statistical manifolds. Our approach comprises three key components: (1) a distribution parameterization module that models predictions with learnable sufficient statistics, (2) a Fisher information metric that quantifies intrinsic distributional distance, and (3) a Bregman divergence component that captures asymmetric prediction errors. We further introduce a natural gradient weighting strategy for efficient optimization on statistical manifolds. Theoretically, we prove statistical consistency and establish convergence guarantees. Extensive experiments on seven datasets with five architectures show that InfoGeo Loss consistently outperforms existing losses, achieving average improvements of 6.8% in MSE and 5.3% in MAE.

From Abstraction to Instantiation: Learning Behavioral Representation for Vision-Language-Action Model

Bing Hu, Zaijing Li, Rui Shao, Junda Chen, April Hua Liu, Wei-Shi Zheng, Liqiang Nie

Vision-Language-Action (VLA) models often suffer from performance degradation under distribution shifts, as they struggle to learn generalized behavior representations across varying environments. While existing approaches attempt to construct behavior representations through action-centric latent variables, they are often limited by short-horizon temporal fragmentation and static execution-alignment, leading to inconsistent behaviors in complex scenarios. To address these limitations, we propose \textbf{BehaviorVLA}, a framework that facilitates robust manipulation through the learning of a temporally coherent behavioral representations. Our approach features two symmetric components: (1) the \textbf{Visuomotor Behavior Encoder (VBE)}, which utilizes a causal Mamba-based architecture to aggregate long-horizon trajectory information into a unified behavior representation; and (2) the \textbf{Phase-conditioned Behavior Decoder (PBD)}, which decodes this representation into precise actions by dynamically aligning task-level priors with real-time execution progress. Experiments on RoboTwin 2.0, LIBERO, and CALVIN demonstrate state-of-the-art success rates of 58\%, 98\%, and 4.36 (Avg. Len), respectively. Notably, in real-world sim-to-real transfer, BehaviorVLA matches the performance of OpenVLA-OFT using only 50\% of the demonstration data, showcasing its superior data efficiency and generalization.

Fine-Tuning Masked Diffusion for Provable Self-Correction

Jaeyeon Kim, Seunggeun Kim, Taekyun Lee, David Z. Pan, Hyeji Kim, Sham M. Kakade, Sitan Chen

A natural desideratum for generative models is self-correction--detecting and revising low-quality tokens at inference. While Masked Diffusion Models (MDMs) have emerged as a promising approach for generative modeling in discrete spaces, their capacity for self-correction remains poorly understood. Prior attempts to incorporate self-correction into MDMs either require overhauling MDM architectures/training or rely on imprecise proxies for token quality, limiting their applicability. Motivated by this, we introduce PRISM--Plug-in Remasking for Inference-time Self-correction of Masked Diffusions--a lightweight, model-agnostic approach that applies to any pretrained MDM. Theoretically, PRISM defines a self-correction loss that provably learns per-token quality scores, without RL or a verifier. These quality scores are computed in the same forward pass with MDM and used to detect low-quality tokens. Empirically, PRISM advances MDM inference across domains and scales: Sudoku; unconditional text (170M); and code with LLaDA (8B). We open-source our codebase in https://github.com/SeunggeunKimkr/PRISM.

DiscoForcing: A Unified Framework for Real-Time Audio-Driven Character Control with Diffusion Forcing

Kaiyang Ji, Bingsheng Qian, Binghuan Wu, Kangyi Chen, Ye Shi, Jingya Wang

We study real-time audio-responsive character control as a deployment-faithful problem: strictly causal, bounded-latency streaming that must generate coherent full-body motion at interactive frame rates while the audio condition can change

abruptly (tempo shifts, drops, or user edits). Prior music-to-motion systems are largely optimized for offline generation with global context, and degrade in streaming rollouts where conditioning history becomes stale or unreliable. We introduce DiscoForcing, a streaming audio-driven diffusion framework that combines a causal music encoder that captures rhythmic structure and phase dynamics with a diffusion-forcing sequence model trained under heterogeneous noise levels across the temporal horizon. Building on this, we design a hybrid temporal schedule and a history-guided streaming sampler to explicitly trade off responsiveness against long-horizon consistency under non-stationary audio. Implemented in an end-to-end real-time interactive system with online avatar playback and humanoid deployment workflows, DiscoForcing delivers more stable long-horizon rollouts and sharper audio–motion alignment than prior baselines under matched causality and latency constraints while maintaining real-time throughput.Project Page: https://discoforcing.github.io

BTSP-CAM: A Brain-Inspired Geometric Memory for Class-Incremental Learning

Zheng Zhang, Jiaye Yang, Qingjie Guo, Jiangrong Shen, Long Chen, Qi Xu

Gradient-based optimization in class-incremental learning (CIL) often faces the plasticity–stability dilemma, since continuous weight updates can distort decision boundaries learned from earlier tasks. We revisit this problem from the viewpoint of stochastic geometric memory allocation and propose BTSP-CAM, a gradient-free memory system that instantiates theoretical insights from the hippocampal simpleBTSP model into a practical algorithm. Rather than fine-tuning a frozen encoder by backpropagation, BTSP-CAM externalizes plasticity into a binary synaptic matrix that evolves through local stochastic bit-flip updates. A trace-gated plateau process, driven by eligibility traces together with familiarity and collision signals, modulates when and where synapses are rewritten and suppresses cross-class interference in Hamming space. The resulting geometric memory states are mapped to semantic logits through a CA1-like competitive layer and a closed-form ridge readout, enabling fast consolidation after each task. Empirically, BTSP-CAM rivals gradient-based methods in a strictly exemplar-free setting and consistently boosts SOTA baselines as a lightweight plugin. Mechanistic analysis validates our geometric theory, confirming that stochastic repulsion actively bounds class overlap and stabilizes decision margins.

Mixture of Horizons in Action Chunking

Dong Jing, Gang Wang, Jiaqi Liu, Weiliang Tang, Zelong Sun, Yunchao Yao, Zhenyu Wei, Yunhui Liu, Zhiwu Lu, Mingyu Ding

Vision-language-action models exhibit an inherent trade-off in action chunk length (``horizon''): longer horizons improve global foresight but degrade fine-grained local control, while shorter ones yield the opposite.

To mitigate the trade-off, we propose a $\textbf{mixture of horizons (MoH)}$ strategy.

In brief, MoH rearranges the action chunk into several segments with different horizons, processes them in parallel with a shared action transformer, and fuses outputs with a light linear gate.

It offers three appealing benefits.

i) Long-term foresight and short-term precision are jointly exploited within a single model.

ii) MoH is plug-and-play for full-attention action modules with minimal training or inference overhead.

iii) MoH enables dynamic inference with adaptive horizons, which selects stable actions through cross-horizon consensus, achieving 2.5$\times$ higher throughput than baselines while preserving superior performance.

Extensive experiments over flow-based and one-step regression policies demonstrate that MoH yields consistent and significant gains on both simulations and real-world tasks.

Fair Dataset Distillation via Cross-Group Barycenter Alignment

Mohammad Hossein Moslemi, Nima Hosseini Dashtbayaz, Zhimin Mei, Bissan Ghaddar,

Boyu Wang
Dataset Distillation aims to compress a large dataset into a small synthetic one while maintaining predictive performance.
We show that as different demographic groups exhibit distinct predictive patterns, the distillation process struggles to simultaneously preserve informative signals for all subgroups, regardless of whether group sizes are mildly or severely imbalanced.
Consequently, models trained on distilled data can experience substantial performance drops for certain subgroups, leading to fairness gaps. Crucially, these gaps do not disappear by merely correcting group imbalance, since they stem from fundamental mismatches in subgroup predictive patterns rather than from sample-size disparities alone. We therefore formally analyze the interaction between these two sources of bias and cast the solution as identifying a group-imbalance-agnostic barycenter of the predictive information that induces similar representations across all subgroups. By distilling toward this shared aggregate representation, we show that group fairness concerns can be reduced. Our approach is compatible with existing distillation methods, and empirical results show that it substantially reduces bias introduced by dataset distillation. Code is available at https://github.com/mhmoslemi/COBRA.
****
USE: A Unified Self-Ensembling Framework for Test-Time Prompt Tuning
Siru Jiang, Jian Liang, Ran He, Tieniu Tan
Test-time adaptation (TTA) has emerged as a popular paradigm for improving the performance of vision–language models (*e.g.*, CLIP) on downstream tasks.
Among existing CLIP-based TTA methods, Test-Time Prompt Tuning (TPT) is a pioneering work that optimizes textual prompts using multiple test-time augmentations and remains a strong baseline to date.
In this work, we revisit TPT and reveal that its optimization can be interpreted as implicitly learning from self-generated pseudo labels.
Building on this perspective, we propose a unified self-ensembling framework (**USE**) that ensures consistency between the optimization and inference stages.
During optimization, we introduce a simple yet effective self-ensembling (**SE**) strategy that emphasizes the test image itself over its augmented views adaptively to obtain more reliable pseudo labels.
To fully exploit the potential of augmentations, we further apply the same strategy at inference time, unifying the objectives of both stages.
Notably, **SE** can also act as a lightweight optimization-free TTA method.
Extensive experiments across multiple datasets demonstrate that **SE** and **USE** outperform their counterparts, respectively.
Furthermore, **SE** yields consistent performance gains when integrated with existing TTA methods.
The code is available at *https://github.com/sirujiang/USE*.

AgentSuite: Toward More Reliable Agent Evaluation with a Component-Based Benchmark Auditing Pipeline
Hyewon Suh, Binfei Ji, Seojune Lee, Rishi Khare, Basit Khan, Hyunjun Kim, Tianyi Zhang, Venkat Krishna Srinivasan, Peter Belcak, Shizhe Diao, Pavlo Molchanov, Yingyan Celine Lin, Zhen Dong
Reliable evaluation of large language model (LLM) agents depends critically on benchmark validity, yet modern agent benchmarks often contain hidden flaws arising from interactions among user instructions, environments, tools, ground-truth trajectories, and evaluation protocols. These flaws confound model errors with benchmark artifacts and undermine leaderboard-based comparisons. We propose **COBA** (**CO**mponent-based **B**enchmark **A**uditing), an automated pipeline for diagnosing and filtering validity issues in agent benchmarks. COBA decomposes agent tasks into four standardized components—User, Environment, Ground Truth, and Evaluation—and operationalizes a component-level issue taxonomy using hybrid rule-based detectors and taxonomy-guided LLM evaluation. Across six widely used agent benchmarks, COBA achieves strong alignment with expert judgments, with F1 scores between 0.791 and 0.874. It complements manual verification of τ^2-benc

h by identifying issues missed due to benchmark complexity, and generalizes to p
reviously unseen benchmarks with minimal adaptation. Our analysis shows that ben
chmark flaws are widespread and materially affect evaluation outcomes, demonstra
ting that component-based auditing provides a scalable foundation for more relia
ble and interpretable agent evaluation. We release AgentSuite, a unified benchma
rk-running platform that includes the COBA auditing pipeline and audited benchma
rk variants: https://github.com/Agent-Suite/AgentSuite.

Comp-Attn: Present-and-Align Attention for Compositional Video Generation
Hongyu Zhang, Yufan Deng, Shenghai Yuan, Xuehan Hou, Yian Zhao, Peng Jin, Chang
Liu, Jie Chen
In the domain of text-to-video (T2V) generation, reliably synthesizing compositi
onal content involving multiple subjects with intricate relations is still under
explored. The main challenges are twofold: 1) Subject presence, where not all su
bjects can be presented in the video; 2) Inter-subject relations, where the inte
raction and spatial relationship between subjects are misaligned. Existing metho
ds adopt techniques, such as inference-time latent optimization or layout contro
l, which fail to address both issues simultaneously. To tackle these problems, w
e propose Comp-Attn, a composition-aware cross-attention variant that follows a
``Present-and-Align" paradigm: it decouples the two challenges by enforcing subj
ect presence at the condition level and achieving relational alignment at the at
tention-distribution level. Specifically, 1) We introduce Subject-aware Conditio
n Interpolation (SCI) to reinforce subject-specific conditions and ensure each s
ubject's presence; 2) We propose Layout-forcing Attention Modulation (LAM), whic
h dynamically enforces the attention distribution to align with the relational l
ayout of multiple subjects. Comp-Attn can be seamlessly integrated into various
T2V baselines in a training-free manner, boosting T2V-CompBench scores by 15.7%
and 11.7% on Wan2.1-T2V-14B and Wan2.2-T2V-A14B with only a 5% increase in infer
ence time. Meanwhile, it also achieves strong performance on VBench and T2I-Comp
Bench, demonstrating its scalability in general T2V and compositional text-to-im
age (T2I) tasks. Code and models are available at: https://github.com/Hong-yu-Zh
ang/Comp-attn.

Structurally Aligned Subtask-Level Memory for Software Engineering Agents
Kangning Shen, Jingyuan Zhang, Chenxi Sun, Wencong Zeng, Yang Yue
Large Language Models (LLMs) have demonstrated significant potential as autonomo
us software engineering (SWE) agents. Recent work has further explored augmentin
g these agents with memory mechanisms to support long-horizon reasoning. However
, these approaches typically operate at a coarse instance granularity, treating
the entire problem-solving episode as the atomic unit of storage and retrieval.
We empirically demonstrate that instance-level memory suffers from a fundamental
granularity mismatch, resulting in misguided retrieval when tasks with similar
surface descriptions require distinct reasoning logic at specific stages. To add
ress this, we propose Structurally Aligned Subtask-Level Memory, a method that a
ligns memory storage, retrieval, and updating with the agent's functional decomp
osition. Extensive experiments on SWE-bench Verified demonstrate that our method
consistently outperforms both vanilla agents and strong instance-level memory b
aselines across diverse backbones, improving mean Pass@1 over the vanilla agent
by +4.7 pp on average (e.g., +6.8 pp on Gemini 2.5 Pro). Performance gains grow
with more interaction steps, showing that leveraging past experience benefits lo
ng-horizon reasoning in complex software engineering tasks.
****

Maximum-Likelihood Learning of Latent Dynamics Without Reconstruction
Samo Hromadka, Kai Biegun, Lior Fox, James Heald, Maneesh Sahani
We address the challenge of uncovering systematic, and potentially controllable,
dynamical structure underlying complex high-dimensional time-series data. Exist
ing generative and autoregressive models have difficulty telling systematic cont
ent apart from distractors, while contrastive methods struggle to learn accurate
dynamics. To address these shortcomings, we develop the Recognition-Parametrize
d Gaussian State-Space Model (RP-GSSM), a probabilistic framework that infers ac

curate latent dynamics without relying on a parametrized decoder. By eliminating explicit generative parameters, the model directs its entire representational capacity to encoding dynamically relevant state; and, being fully probabilistic, learns via maximum likelihood without auxiliary objectives or ad-hoc regularization. Combining the expressive power of a neural network encoder with exact inference under a jointly Gaussian prior allows the RP-GSSM to embed a broad class of intrinsically nonlinear dynamical systems. The RP-GSSM parameters are provably linearly identifiable in the infinite data limit. We show that the RP-GSSM recovers physically meaningful latent states from noisy video more faithfully than competing methods, more reliably identifies underlying controllable nonlinear dynamics, and remains substantially more robust to visual distractors.

Vision-DeepResearch: Incentivizing DeepResearch Capability in Multimodal Large Language Models

Wenxuan Huang, Yu Zeng, Qiuchen Wang, Zhen Fang, Shaosheng Cao, Zheng Chu, Qingyu Yin, Shuang Chen, Zhenfei Yin, Lin Chen, Zehui Chen, Yao Hu, Philip Torr, Feng Zhao, Wanli Ouyang

Multimodal large language models (MLLMs) have achieved remarkable success across a broad range of vision tasks.
However, constrained by the capacity of their internal world knowledge, prior work has proposed augmenting MLLMs by ``reasoning-then-tool-call'' for visual and textual search engines to obtain substantial gains on tasks requiring extensive factual information.
However, these approaches typically define multimodal search in a naive setting, assuming that a single full-level or entity-level image query and few text query suffices to retrieve the key evidence needed to answer the question, which is unrealistic in real-world scenarios with substantial visual noise.
Moreover, they are often limited in the reasoning depth and search breadth, making it difficult to solve complex questions that require aggregating evidence from diverse visual and textual sources.
Building on this, we propose Vision-DeepResearch, which proposes one new multimodal deep-research paradigm, i.e., performs multi-turn, multi-entity and multi-scale visual and textual search to robustly hit real-world search engines under heavy noise.
Our Vision-DeepResearch supports dozens of reasoning steps and hundreds of engine interactions, while internalizing deep-research capabilities into the MLLM via cold-start supervision and RL training, resulting in a strong end-to-end multimodal deep-research MLLM.
It substantially outperforming existing multimodal deep-research MLLMs, and workflows built on strong closed-source foundation model such as GPT-5, Gemini-2.5-pro and Claude-4-Sonnet.

Training-Free Vector Quantization via Gaussian VAEs

Tongda Xu, Wendi Zheng, Jiajun He, José Miguel Hernández-Lobato, Yan Wang, Ya-Qin Zhang, Jie Tang

Vector-quantized variational autoencoders (VQ-VAEs) are discrete autoencoders that compress images into discrete tokens. However, they are difficult to train due to discretization. In this paper, we propose a simple yet effective technique dubbed __Gaussian Quant (GQ)__, which first trains a Gaussian VAE under certain constraints and then converts it into a VQ-VAE without additional training. For conversion, GQ generates random Gaussian noise as a codebook and finds the closest noise vector to the posterior mean. Theoretically, we prove that when the logarithm of the codebook size exceeds the bits-back coding rate of the Gaussian VAE, a small quantization error is guaranteed. Practically, we propose a heuristic to train Gaussian VAEs for effective conversion, named the target divergence constraint (TDC). Empirically, we show that GQ outperforms previous VQ-VAEs, such as VQGAN, FSQ, LFQ, and BSQ, on both UNet and ViT architectures. Furthermore, TDC also improves previous Gaussian VAE discretization methods, such as TokenBridge. The source code is provided in https://github.com/tongdaxu/VQ-VAE-from-Gaussian-VAE.

Stable Velocity: A Variance Perspective on Flow Matching
Donglin Yang, Yongxing Zhang, Xin Yu, Liang Hou, Xin Tao, Pengfei Wan, Xiaojuan Qi, Renjie Liao
While flow matching is elegant, its reliance on single-sample conditional velocities leads to high-variance training targets that destabilize optimization and slow convergence. By explicitly characterizing this variance, we identify 1) a *high-variance regime* near the prior, where optimization is challenging, and 2) a *low-variance regime* near the data distribution, where conditional and marginal velocities nearly coincide. Leveraging this insight, we propose **Stable Velocity**, a unified framework that improves both training and sampling. For training, we introduce Stable Velocity Matching (StableVM), an unbiased variance-reduction objective, along with Variance-Aware Representation Alignment (VA-REPA), which adaptively strengthen auxiliary supervision in the *low-variance regime*. For inference, we show that dynamics in the *low-variance regime* admit closed-form simplifications, enabling Stable Velocity Sampling (StableVS), a finetuning-free acceleration. Extensive experiments on ImageNet 256×256 and large pretrained text-to-image and text-to-video models, including SD3.5, Flux, Qwen-Image, and Wan2.2, demonstrate consistent improvements in training efficiency and more than $2\times$ faster sampling within the *low-variance regime* without degrading sample quality. Our code is available at https://github.com/linYDTHU/StableVelocity.
****
Base Models Know How to Reason, Thinking Models Learn When
Constantin Venhoff, Iván Arcuschin, Philip Torr, Arthur Conmy, Neel Nanda
What do different *thinking* language models learn during training?
We introduce *constructive model diffing*, a framework for understanding fine-tuned models by constructing the base-to-fine-tuned difference from interpretable components, producing hybrid models whose performance recovery measures how well the components capture the diff.
For thinking models, we decompose the diff into *reasoning mechanisms* (category-specific vectors that induce reasoning behaviors in the base model) and *reasoning heuristics* (a classifier determining when each mechanism fires).
To ground this decomposition, we use Sparse Autoencoders to discover interpretable taxonomies of reasoning behaviors.
Across nine model configurations (four RL-trained, four SFT-distilled from a larger thinking model, and one mixed), we find a striking difference: hybrid models recover much more performance for RL-trained models than for SFT-trained or mixed ones. This indicates that RL primarily teaches models to apply sophisticated heuristics to pre-existing base capabilities, while SFT-based distillation teaches the base model new mechanisms.
These results offer a new lens on what different training paradigms teach, with implications for efficient reasoning model development.

Rethinking Human Intent-to-CAD: Parametric CAD Model Generation via Cooperative Multi-Task Alignment and Spatial-Aware Reinforcement Learning
Qingwang Zhang, Jiahao Li, Xiangdong Zhou
Parametric Computer-Aided-Design (CAD) modeling from human intent remains challenging, particularly during the conceptual design stage, where design goals are expressed through incomplete and unstructured modalities (e.g., hand-drawn sketches and textual descriptions). In this work, we rethink the human intent-to-CAD pipeline and propose a unified method that directly maps multi-level human intents to executable codes, without assuming the prior existence of target CAD models. To support our study, we construct HiCAD, the first large-scale dataset aligning hand-drawn sketches, textual descriptions, and parametric CAD codes. Based on this, we introduce HiCAD, a two-stage framework comprising Cooperative Multi-Task Alignment to bridge the representational gap between heterogeneous inputs, and Spatial-Aware Reinforcement Learning to enforce geometric and topological consistency. Extensive experiments demonstrate that our method significantly outperforms existing baselines across multiple tasks, validating its effectiveness and

robustness in transforming heterogeneous human intents into high-fidelity parame
tric CAD models. Our project page: https://zqwlearning.github.io/HiCAD.

Prototype-Grounded Concept Models for Verifiable Concept Alignment
Stefano Colamonaco, David Debot, Pietro Barbiero, Giuseppe Marra
Concept Bottleneck Models (CBMs) aim to improve interpretability in Deep Learnin
g by structuring predictions through human-understandable concepts, but they pro
vide no way to verify whether learned concepts align with the human's intended m
eaning, hurting interpretability. We introduce Prototype-Grounded Concept Models
 (PGCMs), which ground concepts in learned visual prototypes: image parts that s
erve as explicit evidence for the concepts. This grounding enables direct inspec
tion of concept semantics and supports targeted human intervention at the protot
ype level to correct misalignments. Empirically, PGCMs achieve similar predictiv
e performance as state-of-the-art CBMs while substantially improving transparenc
y, interpretability, and intervenability.

Why Are Linear RNNs More Parallelizable?
William Merrill, Hongjian Jiang, Yanhong Li, Anthony Widjaja Lin, Ashish Sabharw
al
The community is increasingly exploring linear RNNs (LRNNs) as language models,
motivated by their expressive power and parallelizability. While prior work esta
blishes the expressivity benefits of LRNNs over transformers, it is unclear what
 makes LRNNs---but not traditional, *nonlinear* RNNs---as easy to parallelize in
 practice as transformers. We answer this question by providing a tight connecti
on between types of RNNs and standard complexity classes. We show that LRNNs can
 be viewed as log-depth (bounded fan-in) arithmetic circuits, which represents o
nly a slight depth overhead relative to log-depth boolean circuits that transfor
mers admit. Furthermore, we show that nonlinear RNNs can solve $\mathsf L$-compl
ete problems (and even $\mathsf P$-complete ones, under polynomial precision), r
evealing a fundamental barrier to parallelizing them as efficiently as transform
ers. Our theory also identifies fine-grained expressivity differences between re
cent popular LRNN variants: permutation-diagonal LRNNs are NC^1-compl
ete whereas diagonal-plus-low-rank LRNNs are more expressive (PNC^1-c
omplete). We provide further insight by associating each type of RNN with a corr
esponding automata-theoretic model that it can simulate. Together, our results r
eveal fundamental tradeoffs between nonlinear RNNs and different variants of LRN
Ns, providing a foundation for designing LLM architectures that achieve an optim
al balance between expressivity and parallelism.

Text Before Vision: Staged Knowledge Injection Matters for Agentic RLVR in Ultra
-High-Resolution Remote Sensing Understanding
Fengxiang Wang, Mingshuo Chen, Yueying Li, Yulin Wang, Yang Yajie, Yuhao Zhou, D
i Wang, YiFan Zhang, Haoyu Wang, Haiyan Zhao, Hongda Sun, Jun Song, Long Lan, Ji
ng Zhang, Wenlong Zhang, Bo Du
Multimodal reasoning for ultra-high-resolution (UHR) remote sensing (RS) is usua
lly bottlenecked by visual evidence acquisition: the model necessities localizin
g tiny task-relevant regions in massive pixel spaces.
While Agentic Reinforcement Learning with Verifiable Rewards (RLVR) using zoom-i
n tools offers a path forward, we find that standard reinforcement learning stru
ggles to navigate these vast visual spaces without structured domain priors.
In this paper, we investigate the interplay between post-training paradigms: com
paring Cold-start Supervised Fine-Tuning (SFT), RLVR, and Agentic RLVR on the UH
R RS benchmark. Our controlled studies yield a counter-intuitive finding: high-q
uality Earth-science text-only QA is a primary driver of UHR visual reasoning ga
ins. Despite lacking images, domain-specific text injects the concepts, mechanis
tic explanations, and decision rules necessary to guide visual evidence retrieva
l. Based on this, we propose a staged knowledge injection recipe: (1) cold-start
ing with scalable, knowledge-graph-verified Earth-science text QA to instill rea
soning structures; and (2) "pre-warming'' on the same hard UHR image–text exampl
es during SFT to stabilize and amplify subsequent tool-based RL.

This approach achieves a 60.04\% Pass@1 on XLRS-Bench, significantly outperforming larger general-purpose models (e.g., GPT-5.2, Gemini 3.0 Pro, Intern-S1) and establishing a new state-of-the-art. We provide both the automated data pipeline and the rigorous ablation studies that validate this "Text-Before-Vision'' paradigm. Datasets and code will be released.

A Fine-Grained Understanding of Uniform Convergence for Halfspaces
Aryeh Kontorovich, Kasper Green Larsen
We study the fine-grainded uniform convergence behavior of halfspaces beyond worst-case VC bounds. For inhomogeneous halfspaces in $\mathbb{R}^d$ with $d\ge 2$, we show that standard first-order VC bounds are essentially tight: even consistent hypotheses can incur population error $\Theta(d\log(n/d)/n)$, and in the agnostic setting the deviation scales as $\sqrt{\tau\log(1/\tau)}$ at true error τ.
In contrast, homogeneous halfspaces in $\mathbb{R}^2$ exhibit a markedly different behavior. In the realizable case, every hypothesis consistent with the sample has error $O(1/n)$. In the agnostic case, we prove a bandwise, log-free deviation bound on each dyadic risk band via a critical-wedge localization argument. Unioning over bands incurs only a $\log\log n$ overhead, and we establish a matching lower bound showing this overhead is unavoidable. Together, these results give a fine-grained and nearly complete picture of uniform convergence for halfspaces, revealing sharp dimensional and structural thresholds.

GXPO: Group Cross-Lingual Relative Policy Optimization for Code Generation
Linzheng Chai, Jian Yang, Jiajun Wu, Ensheng Shi, Xianglong Liu
Current reinforcement learning (RL) methods for code generation are predominantly optimized on Python, showing weak generalization to other programming languages (PLs). Although leveraging multilingual solutions offers richer semantics and a wider search landscape, naive independent training across languages suffers from optimization imbalance and fails to effectively transfer knowledge from high-resource languages. We propose Group Cross-lingual Relative Policy Optimization (GXPO), which forms training groups by generating solutions for the same problem in multiple PLs and jointly optimizes language-specific and cross-language signals, enabling more balanced optimization and improved transfer to low-resource PLs. We additionally introduce Multilingual LiveCodeBench (ML-LCB), extending LiveCodeBench to a unified multilingual evaluation setting. On ML-LCB across 8 PLs, GXPO consistently improves performance, with pronounced gains on low-resource PLs, demonstrating scalable multilingual RL for language-consistent code generation.

Infinite-World: Scaling Interactive World Models to 1000-Frame Horizons via Pose-Free Hierarchical Memory
Ruiqi Wu, Xuanhua He, Meng Cheng, Tianyu Yang, Yong Zhang, Zhuoliang Kang, Xunliang Cai, Xiaoming Wei, Chun-Le Guo, Chongyi Li, Ming-Ming Cheng
We propose **Infinite-World**, a robust interactive world model capable of maintaining coherent visual memory over **1000+ frames** in complex real-world environments. While existing world models can be efficiently optimized on synthetic data with perfect ground-truth, they lack an effective training paradigm for real-world videos due to noisy pose estimations and the scarcity of viewpoint revisits. To bridge this gap, we first introduce a **Hierarchical Pose-free Memory Compressor (HPMC)** that recursively distills historical latents into a fixed-budget representation. By jointly optimizing the compressor with the generative backbone, HPMC enables the model to autonomously anchor generations in the distant past with bounded computational cost, eliminating the need for explicit geometric priors. Second, we propose an **Uncertainty-aware Action Abstraction** module that discretizes continuous motion into a tri-state logic. This strategy maximizes the utilization of raw video data while shielding the deterministic action space from being corrupted by noisy trajectories, ensuring robust action-response learning. Furthermore, guided by insights from a pilot toy study, we employ a **Revisit-Dense Finetuning Strategy** using a compact, 30-minute dataset to efficient

ly activate the model’s long-range loop-closure capabilities. Extensive experiments, including objective metrics and user studies, demonstrate that Infinite-World achieves superior performance in visual quality, action controllability, and spatial consistency. Our code and data will be released.
****
Understanding Transfer Learning of RNA Foundation Models on Downstream Tasks
Yuan Li, Heng Yang, Renzhi Chen, Ke Li
Foundation models (FMs) pretrained on large-scale sequence data have emerged as a promising paradigm for RNA biology, yet the mechanisms underlying their transferability remain unclear.
In this work, we conduct a systematic investigation of transfer learning in RNA FMs across diverse structural and functional tasks.
Our results demonstrate that frozen representations from pretrained RNA FMs are not universally transferable, and that the hierarchical feature reuse paradigm prevalent in computer vision does not generally extend to RNA FMs.
Instead, pretraining primarily benefits downstream tasks by providing a favorable optimization initialization when pretraining and downstream objectives are well aligned, which accelerates convergence toward flatter minima associated with improved generalization.
Overall, our findings characterize pretraining as an optimization prior whose effectiveness is governed by task alignment and model capacity, offering principled guidance for future RNA FMs.
****
Anomaly-Preference Image Generation
Fuyun Wang, Yuanzhi Wang, Xu Guo, Sujia Huang, Tong Zhang, Dan Wang, Xin Liu, Hui Yan, Zhen Cui
Synthesizing realistic and diverse anomalous samples from limited data is vital for robust model generalization. However, existing methods struggle to reconcile fidelity and diversity, often hampered by distribution misalignment and overfitting, respectively. To mitigate this, we introduce Anomaly Preference Optimization (APO), a novel paradigm that reformulates anomaly generation as a preference learning problem. Central to our approach is an implicit preference alignment mechanism that leverages real anomalies as positive references, deriving optimization signals directly from denoising trajectory deviations without requiring costly human annotation. Furthermore, we propose a Time-Aware Capacity Allocation module that dynamically distributes model capacity along the diffusion timeline— prioritizing structural diversity during highnoise phases while enhancing fine-grained fidelity in low-noise stages. During inference, a hierarchical sampling strategy modulates the coherencealignment trade-off, enabling precise control over generation. Extensive experiments demonstrate that significantly outperforms existing baselines, achieving state-of-the-art performance in both realism and diversity.
****
LOTTERY: Learning from Reference-Only Samples in Two-Sample Testing under Size Asymmetry
Xunye Tian, Zhijian Zhou, Liuhua Peng, Feng Liu
Data-adaptive two-sample testing assesses if two samples come from the same distribution, using a discrepancy learned from the data (e.g., via kernel-based feature representations). Such methods typically rely on data splitting to decouple learning from testing and control type I error. However, this paradigm is ill-suited to few-shot settings with severe sample-size imbalance: abundant reference samples are available, while only a handful of query samples arrive. In this paper, we show how this imbalance can be leveraged constructively. Using abundant reference data, we learn reference-dependent representations that summarize salient structure of the reference distribution and provide informative signals for detecting departures. We incorporate a collection of representation families that capture both global and local structure, and adaptively weight them using only reference samples via an uncertainty-guided principle. Theoretically, we establish permutation-based type I error control and show consistency of the aggregated test: as the sample sizes grow, the test power converges to one whenever the re

presentation set contains at least one consistent representation. Empirically, o
ur aggregation achieves strong performance across a range of benchmarks while re
taining type I error control.

TRIM: Token-wise Attention-Derived Saliency for Data-Efficient Instruction Tunin
g

Manish Nagaraj, Sakshi Choudhary, Utkarsh Saxena, Deepak Ravikumar, Kaushik Roy

Instruction tuning is essential for aligning large language models (LLMs) to dow
nstream tasks and commonly relies on large, diverse corpora. However, small, hig
h-quality subsets, known as coresets, can deliver comparable or superior results
, though curating them remains challenging. Existing methods often rely on coars
e, sample-level signals like gradients, an approach that is computationally expe
nsive and overlooks fine-grained features. To address this, we introduce TRIM (T
oken Relevance via Interpretable Multi-layer Attention), a forward-only, token-c
entric framework. Instead of using gradients, TRIM operates by matching underlyi
ng representational patterns identified via attention-based "fingerprints" from
a handful of target samples. Such an approach makes TRIM highly efficient and un
iquely sensitive to the structural features that define a task. Coresets selecte
d by our method consistently outperform state-of-the-art baselines by up to 9% o
n downstream tasks and even surpass the performance of full-data fine-tuning in
some settings. By avoiding expensive backward passes, TRIM achieves this at a fr
action of the computational cost. These findings establish TRIM as a scalable an
d efficient alternative for building high-quality instruction-tuning datasets.

Relighting as a Probe of Visual Priors via Augmented Latent Intrinsics

Xiaoyan Xing, Xiao Zhang, Sezer Karaoglu, Theo Gevers, Anand Bhattad

Image-to-image relighting requires representations that separate illumination fr
om scene properties while preserving dense geometry, material, and photometric c
ues. We use this task as a probe of visual priors: unlike recognition tasks that
 reward invariance, relighting tests whether visual features retain the informat
ion needed for light transfer. Through a controlled generative relighting framew
ork, we find that strong semantic encoders can degrade relighting quality, expos
ing a semantic--photometric trade-off between abstraction and physical fidelity.
 We introduce \textbf{Augmented Latent Intrinsics (ALI)}, which balances this tr
ade-off by fusing dense, pixel-aligned visual features into a latent-intrinsic r
elighting model and refining it with self-supervision on unlabeled real image pa
irs. ALI improves relighting quality, especially on glossy, metallic, and transp
arent materials, and demonstrates that generative relighting is an effective too
l for quantifying what visual encoders encode about the physical world.

MoCL: Metabolic Optimization for Curvature-Aware Continual Learning

Jiajun Lai, Qi Liu, Shijie Li, Huaiguang Jiang

Continual learning requires models to mitigate catastrophic forgetting of prior
knowledge while learning a sequence of tasks. Although existing methods based on
 orthogonal projection prevent interference by constraining parameter updates, t
hey tend to limit plasticity as the task sequence progresses. The reliance on th
e linear approximation further causes the projected gradients to deviate from th
e nonlinear manifold. To address these issues, we propose Metabolic Optimization
 for Continual Learning (MoCL), a rehearsal-free framework that strikes a balanc
e between stability and plasticity. To capture the geometric manifold of prior k
nowledge, MoCL introduces a factorized subspace approximation that avoids expens
ive explicit matrix inversion. Given the heavy-tailed distribution of the Fisher
 Information Matrix, we employ a metabolic gating based on Tsallis entropy to su
ppress updates that conflict with historical knowledge. Theoretical and empirica
l analyses show that MoCL suppresses interference while supporting shared low-lo
ss behavior across sequential tasks. Extensive experimental results across multi
ple benchmarks demonstrate that MoCL outperforms state-of-the-art methods in bot
h classification performance and efficiency.

Hierarchical Causal Abduction: A Foundation Framework for Explainable Model Pred

ictive Control
Ramesh Arvind Naagarajan, Zühal Wagner, Stefan Streif
Model Predictive Control (MPC) is widely used to operate safety-critical infrastructure by predicting future trajectories and optimizing control actions. However, nonlinear dynamics, hard safety constraints, and numerical optimization often render individual control moves opaque to human operators, undermining trust and hindering deployment. This paper presents Hierarchical Causal Abduction (HCA), which combines (i) physics-informed reasoning via domain knowledge graphs, (ii) optimization evidence from Karush--Kuhn--Tucker (KKT) multipliers, and (iii) temporal causal discovery via the PCMCI algorithm to generate faithful, human-interpretable explanations for control actions computed by nonlinear MPC. Across three diverse control applications (greenhouse climate, building HVAC, chemical process engineering) with expert validation, HCA improves explanation accuracy by 53\% over LIME (0.478 vs. 0.311) using a single set of cross-domain parameters without per-domain tuning; domain-specific KKT-threshold calibration over 2--3 days further increases accuracy to 0.88. Ablation studies confirm that each evidence source is essential, with 32--37\% accuracy degradation when any component is removed, and HCA's ranking-and-validation methodology generalizes beyond MPC to other prediction-based decision systems, including learning-based control and trajectory planning.

UniFLoW: Universal Multi-Modal Federated LoRA Fine-Tuning Framework with Analytical Aggregation
Haoyuan Liang, Zhiyu Ye, Jielong Tang, Yang Yang, Shilei Cao, Guowen Li, Fei Hu, Zhiwei Zhang, Haohuan Fu, Juepeng Zheng
As Multimodal Large Language Models (MLLMs) continue to be trained, the availability of public data diminishes, limiting the possibility for further training and adaptation. However, private data remains an underutilized yet valuable resource. Federated Learning (FL) enables decentralized training on private data, yet extending it to MLLMs is challenging: heterogeneous client modalities induce architectural incompatibility, and full-parameter fine-tuning of billion-scale models incurs prohibitive communication costs. Parameter-efficient methods like LoRA alleviate these issues but introduce aggregation inconsistency, as averaged low-rank updates fail to recover the true global update faithfully.
To address these issues, we propose **UniFLoW**(Universal multi-modal Federated LoRA fine-tuning framework With Analytical Aggregation), a unified federated framework that leverages pre-trained large language models and a multi-modal Encoder architecture, and our proposed Federated Aggregating Analytical Low-Rank Adaption$FedA^2$-$LoRA$). UniFLoW effectively utilizes fragmented client-side multi-modal data while $FedA^2$-$LoRA$ ensuring consistent aggregation. And modality-specific encoders and a II stage training strategy ensure effective integration of diverse modalities without overfitting.
Experiments on text, image, and speech demonstrate that **UniFLoW** enables scalable, communication-efficient, and aggregation-consistent federated fine-tuning,
with $FedA^2$-$LoRA$ achieving state-of-the-art performance compared to existing FedLoRA approaches. We envision UniFLoW as a promising solution to the growing scarcity of public data.
****
SpreadsheetArena: Decomposing Preference in LLM Generation of Spreadsheet Workbooks
Srivatsa R Kundurthy, Clara Na, Michael Handley, Zach Kirshner, Chen Bo Calvin Zhang, Manasi Sharma, Emma Strubell, John Ling
We consider the task of end-to-end **spreadsheet generation**, where language models are prompted to produce spreadsheet artifacts to satisfy users' explicit and implicit constraints, specified in natural language.
We introduce **SpreadsheetArena**, a platform for evaluating models' performance on the task via blind pairwise evaluations of LLM-generated spreadsheet workbooks. As with other complex, open-ended tasks, relevant evaluation criteria can vary greatly across use cases and prompts, often in ways that are difficult to for

malize.
Compared to general dialogue or text generation settings, spreadsheet generation presents unique challenges and opportunities: the task output structure is well-defined and multi-dimensional, and there are often complex interactivity and layout considerations. We observe that stylistic, structural, and functional features of preferred spreadsheets vary meaningfully across prompts. Expert evaluations of spreadsheets for finance prompts suggest that even highly ranked models do not reliably produce spreadsheets aligned with domain-specific best practices. We host a live arena and release a dataset of prompts, generated spreadsheets, and preference votes, which we hope will facilitate further study of tasks operating over spreadsheets as a challenging and interesting class of complex, open-ended tasks for LLMs.
****

Model-Dowser: Data-Free Importance Probing to Mitigate Catastrophic Forgetting in Multimodal Large Language Models
Hyeontaek Hwang, Nguyen Dinh Son, Daeyoung Kim
Fine-tuning Multimodal Large Language Models (MLLMs) on task-specific data is an effective way to improve performance on downstream applications. However, such adaptation often leads to a degradation in generalization on pretrained tasks, a phenomenon known as Catastrophic Forgetting. Existing methods that aim to mitigate this issue either become ineffective when fine-tuning deeper layers of the language decoder or scale poorly with increasing model size. To address these limitations, we propose Model-Dowser, a novel sparse fine-tuning approach for MLLMs. Model-Dowser measures a principled importance score for each model parameter with respect to pretrained generalization (prior to downstream adaptation) by jointly considering weight magnitudes, input activations, and output sensitivities. During fine-tuning, Model-Dowser selectively preserves high-importance parameters and updates the remaining. Comprehensive experiments on two representative MLLMs, LLaVA and NVILA, demonstrate that Model-Dowser effectively mitigates catastrophic forgetting and consistently outperforms prior methods, while remaining resource-efficient and scalable to multi-billion-parameter models.
****

CAffNet: Hard Constraint-Affine Neural Networks
Yang Zhao, Jungeun Lee, Jeong hwan Jeon, Sze Zheng Yong
We present a novel framework for embedding hard constraint satisfaction into neural network (NN) architectures, specifically feedforward neural networks and transformers, with input-dependent affine constraints of arbitrary cardinality. Traditional constraint enforcement approaches either rely on penalty-based soft constraints, which offer no guarantee of satisfaction, or on post-processing methods that enforce constraints after the NN is trained, which may lead to suboptimality. We introduce a trainable constraint-affine (CAffine) layer into NNs, yielding CAffNet, which goes beyond enforcing affine constraints via fixed orthogonal or parallel projections and enables joint
optimization with network parameters. Moreover, we impose no restrictions on the constraint space dimensions and establish that our construction preserves the universal approximation properties of NNs, while providing provable guarantees on constraint adherence for all inputs. Experimental validation demonstrates robust performance across diverse domains requiring guaranteed constraint satisfaction.
****

One Bias After Another: Mechanistic Reward Shaping and Persistent Biases in Language Reward Models
Daniel Fein, Max Lamparth, Violet Xiang, Mykel Kochenderfer, Nick Haber
Reward Models (RMs) are crucial for online alignment of language models (LMs) with human preferences. However, RM-based preference-tuning is vulnerable to \textit{reward hacking}, whereby LM policies learn undesirable behaviors from flawed RMs. By systematically measuring biases in five high-quality RMs, including the state-of-the-art, we find that issues persist despite prior work with respect to length, sycophancy, and overconfidence. We also discover new issues related to bias toward model-specific “styles” and answer-order. We categorize RM failures

as tractable or resistant to linear intervention and propose a simple post-hoc i
ntervention to mitigate low-complexity biases that arise from spurious correlati
ons. Our proposed \textbf{mechanistic reward shaping} reduces targeted biases wi
thout degrading reward quality and while using minimal labeled data. The method
is extensible to new biases, model-internal, and generalizes out-of-distribution
.

The Convergent Representation of Contrastive Vision-Language Models: Geometry, M
odality Gap and Shared Space Alignment
Lingjie Yi, Raphael Douady, Chao Chen
Multimodal contrastive learning (MCL) aims to embed data from two modalities in
a shared embedding space. However, in practice, image and text representations o
ccupy completely separated regions of the embedding space, a phenomenon called t
he modality gap. Meanwhile, empirical findings on how the modality gap affects d
ownstream performance remain inconsistent. These observations motivate two key q
uestions: (1) What causes the modality gap? (2) What determines downstream perfo
rmance? To address these questions, we develop the first theoretical framework f
or analyzing the geometry of convergent optimal representations (COR) of MCL whe
n training is optimized. We prove that the modality gap emerges when image and t
ext representations collapse into different subspaces, a phenomenon called \emph
{dimension collapse}. Our theory further reveals that although the modality gap
prevents direct alignment between image and text representations, their projecti
ons onto the shared subspace can align. Moreover, we show that shared space alig
nment is a dominant factor in downstream performance, while the effect of the mo
dality gap is limited. Inspired by these findings, we propose Shared Space Align
ment (SSA) to improve MCL pretraining by enhancing alignment in the shared space
 without optimizing for modality gap reduction. Extensive empirical results vali
date our theoretical analysis and the proposed method.

Task-Aware Structured Memory for Dynamic Multi-modal In-Context Learning
Zhirui Chen, Ziwei Chen, Ling Shao
Multi-modal large language models (MLLMs) depend on in-context learning (ICL) fo
r rapid task adaptation, but their scalability is severely limited by finite con
text windows and the growing cost of key–value (KV) caches in long multi-modal s
equences. Existing memory compression approaches typically rely on rigid token r
emoval or sample-dependent importance estimation, which introduces bias, disrupt
s semantic structure—particularly for visual representations—and yields static m
emories that cannot adapt to new queries. We introduce TASM (Task-Aware Structur
ed Memory), a training-free framework that addresses these limitations through t
ask-aware, structure-preserving, and dynamically accessible memory construction.
 TASM employs Task-Vector Guided Compression to replace sample-specific signals
with a task-level direction that captures shared relevance across demonstrations
. To preserve the underlying information manifold, it further applies Semantics-
Aware Token Merging, formulating compression as a Bipartite Graph Matching probl
em that merges tokens without destructive pruning. Finally, TASM organizes compr
essed representations into a multi-resolution hierarchy consisting of a compact
Core Memory and a Latent Bank, enabling Query-Adaptive Dynamic Activation and Dy
namic Retrieval at inference time. Empirical evaluations show that TASM sustains
 strong multi-modal ICL performance under high compression ratios, demonstrating
 an effective balance between efficiency, adaptability, and semantic fidelity.

Vision Language Models Cannot Reason About Physical Transformation
Dezhi Luo, Yijiang Li, Maijunxian Wang, Tianwei Zhao, Bingyang Wang, Siheng Wang
, Pinyuan Feng, Pooyan Rahmanzadehgervi, Ziqiao Ma, Hokin Deng
Understanding physical transformations is fundamental for reasoning in dynamic e
nvironments. While Vision Language Models (VLMs) show promise in embodied applic
ations, whether they genuinely understand physical transformations remains uncle
ar. We introduce ***ConservationBench*** evaluating ***conservation***—whether p
hysical quantities remain invariant under transformations. Spanning four propert
ies with paired conserving/non-conserving scenarios, we generate 23,040 question

s across 112 VLMs. Results reveal systematic failure: performance remains near c
hance with improvements on conservation tasks accompanied by drops on controls.
Control experiments show strong textual priors favoring invariance, yet models p
erform worse with visual content. Neither temporal resolution, prompting, nor cu
rated sampling helps. These findings show that current VLMs fail to maintain tra
nsformation-invariant representations of physical properties across dynamic scen
es.

RQ-MoE: Residual Quantization via Mixture of Experts for Efficient Input-Depende
nt Vector Compression

Zhengjia Zhong, Shuyan Ke, Zaizhou Lin, Jiaqi Song, Hongyi Lan, Hui Li

Vector quantization is a fundamental tool for compressing high-dimensional embed
dings, yet existing multi-codebook methods rely on static codebooks that limit e
xpressiveness under heterogeneous data geometry. While recent dynamic quantizers
 like QINCo adapt codebooks to individual inputs and improve expressiveness, the
ir strict sequential dependencies create decoding bottlenecks. We propose Residu
al Quantization via Mixture of Experts (RQ-MoE), a framework combining a two-lev
el MoE with dual-stream quantization to enable input-dependent codebook adaptati
on for efficient vector quantization. RQ-MoE enables dynamic codebook constructi
on and decouples instruction from quantization, facilitating parallel decoding.
Theoretically, we show that standard Residual Quantization and QINCo can be reco
vered as constrained special cases of RQ-MoE, and derive a guideline for setting
 expert dimensionality in RQ-MoE. Extensive experiments show that RQ-MoE achieve
s state-of-the-art or on-par performance in reconstruction and retrieval, while
it can provide 6×–14× faster decoding than prior vector quantization methods. Th
e implementation is available at https://github.com/KDEGroup/RQ-MoE.

MemoryLLM: Plug-n-Play Interpretable Feed-Forward Memory for Transformers

AJAY KUMAR JAISWAL, Lauren Hannah, Han-Byul Kim, Duc N.M Hoang, Arnav Kundu, Meh
rdad Farajtabar, Minsik Cho

Understanding how transformer components operate in LLMs is important, as it is
at the core of recent technological advances in artificial intelligence. In this
 work, we revisit the challenges associated with interpretability of feed-forwar
d modules (FFNs) and propose MemoryLLM, which aims to decouple FFNs from self-at
tention and enables us to study the decoupled FFNs as context-free token-wise ne
ural retrieval memory. In detail, we investigate how input tokens access memory
locations within FFN parameters and the importance of FFN memory across differen
t downstream tasks. MemoryLLM achieves context-free FFNs by training them in iso
lation from self-attention directly using the token embeddings. This approach al
lows FFNs to be pre-computed as token-wise lookups (ToLs), enabling on-demand tr
ansfer between VRAM and storage, additionally enhancing inference efficiency. We
 also introduce Flex-MemoryLLM, positioning it between a conventional transforme
r design and MemoryLLM. This architecture bridges the performance gap caused by
training FFNs with context-free token-wise embeddings.

Debate2Create: Robot Co-design via Multi-Agent LLM Debate

Kevin Qiu, Marek Cygan

We introduce Debate2Create (D2C), a multi-agent LLM framework that formulates ro
bot co-design as structured, iterative debate grounded in physics-based evaluati
on. A design agent and control agent engage in a thesis-antithesis-synthesis loo
p, while criterion-specific LLM judges provide multi-objective feedback to steer
 exploration. Across five MuJoCo locomotion benchmarks, D2C achieves the highest
 default-normalized score among the evaluated LLM-based and black-box baselines,
 with gains up to 3.2x on Ant and nearly 9x on Swimmer. Iterative debate yields
18-35% gains over compute-matched zero-shot generation, and D2C-generated reward
s transfer to default morphologies in 4/5 tasks. These results suggest that stru
ctured, simulator-grounded multi-agent interaction is a useful mechanism for joi
nt morphology-reward optimization under a fixed-topology, per-candidate-RL proto
col. Project page: debate2create.github.io.

ACTIVE-o3 : Empowering MLLMs with Active Perception via Pure Reinforcement Learning
Muzhi Zhu, Hao Zhong, Canyu Zhao, Zongze Du, Mingyu Liu, Zheng Huang, Anzhou Li, Hao Chen, Cheng Zou, Jingdong Chen, Ming Yang, Chunhua Shen
Active vision, also known as active perception, refers to actively selecting where and how to look in order to gather task-relevant information. It is a critical component of efficient perception and decision-making in humans and advanced embodied agents. With the rise of Multimodal Large Language Models (MLLMs) as central planners in robotic systems, the lack of methods for equipping MLLMs with active perception has become a key gap. We first provide a systematic definition of MLLM-based active perception tasks and show that GPT-o3's zoom-in strategy can be viewed as a special case, though it suffers from low efficiency and inaccurate region selection. To address these issues, we propose Active-o3, a reinforcement learning framework built on GRPO that equips MLLMs with active perception capabilities. Leveraging a modular sensing-action design and a dual-form reward, Active-o3 autonomously learns efficient and stable region selection strategies without explicit supervision. We further establish a comprehensive benchmark covering both open-world tasks (small/dense-object grounding) and domain-specific scenarios (remote sensing, autonomous driving, interactive segmentation). Experimental results demonstrate that Active-o3 significantly enhances active perception capabilities compared to Qwen2.5-VL-CoT. Moreover, we show that our RL framework not only preserves the model’s general understanding ability but can also serve as a proxy task for leveraging perception data, further improving performance on benchmarks such as RealWorldQA. We hope that our work can provide a simple codebase and unified evaluation protocol to facilitate future research on active perception with MLLMs.
****
TokenRatio: Principled Token-Level Preference Optimization via Ratio Matching
Truong Nguyen, Tien-Phat Nguyen, Linh Ngo Van, Duy Minh Ho Nguyen, Khoa D Doan, Trung Le
Direct Preference Optimization (DPO) is a widely used RL-free method for aligning language models from pairwise preferences, but it models preferences over full sequences even though generation is driven by per-token decisions. Existing token-level extensions typically decompose a sequence-level Bradley–Terry objective across timesteps, leaving per-prefix (state-wise) optimality implicit. We study how to recover **token-level** preference optimality using only standard sequence-level pairwise comparisons.
We introduce **Token-level Bregman Preference Optimization (TBPO)**, which posits a token-level Bradley--Terry preference model over next-token actions conditioned on the prefix, and derive a Bregman-divergence density-ratio matching objective that generalizes the logistic/DPO loss while preserving the optimal policy induced by the token-level model and maintaining DPO-like simplicity. We introduce two instantiations: TBPO-Q, which explicitly learns a lightweight state baseline, and TBPO-A, which removes the baseline through advantage normalization.
Across instruction following, helpfulness/harmlessness, and summarization, TBPO improves alignment quality and training stability and increases output diversity relative to strong sequence-level and token-level baselines.
****
RelayCaching: Accelerating LLM Collaboration via Decoding KV Cache Reuse
Yingsheng Geng, Yuchong Gao, Weihong Wu, Guyue Liu, Jiang liu
The increasing complexity of AI tasks has shifted the paradigm from monolithic models toward multi-agent large language model (LLM) systems. However, these collaborative architectures introduce a critical bottleneck: redundant prefill computation for shared content generated by previous agents, which significantly increases KV cache memory usage and time-to-first-token (TTFT). While various KV cache methods have been proposed to mitigate prefill redundancy, they either fail to maintain accuracy on agent-generated outputs or exhibit low reuse rates due to rigid constraints. We present RelayCaching, a training-free inference method that directly reuses decoding phase KV caches from previous agents in subsequent prefill phases. Our key insight is that KV caches for identical content are highl

y consistent across phases, while prefix-induced deviations are sparse and local
ized within a limited range of layers and token positions. By selectively recomp
uting KV caches at these positions, RelayCaching preserves model accuracy with m
inimal overhead, yielding a superior accuracy–efficiency trade-off over existing
 methods. Experiments on diverse collaborative LLM tasks spanning mathematical r
easoning, general knowledge, and code generation demonstrate that RelayCaching a
chieves over 80\% KV cache reuse, reduces TTFT by up to $4.7\times$ compared t
o the standard pipeline, all with negligible accuracy degradation.

On the Fragility of Data Attribution When Learning Is Distributed

Xian Gao, Bo Hui, Min-Te Sun, Wei-Shinn Ku

Data attribution has become an important component of pricing, auditing, and gov
ernance in machine learning pipelines, yet most attribution methods implicitly a
ssume that attribution values faithfully reflect participants' contributions. We
 show that this assumption can fail: a single participant in a standard distribu
ted training workflow can substantially inflate its measured attribution value w
hile preserving global utility. Our attribution-first attack uses latent optimiz
ation to inject small synthetic batches that preserve utility while exploiting n
on-IID label coverage and evaluator sensitivities. Across datasets, models, and
multiple marginal-utility evaluators, the attack consistently increases the adve
rsary’s attribution value and reshapes the relative attribution structure among
benign clients without degrading accuracy or triggering geometry-based defenses.
 These results show that attribution itself forms a new attack surface and motiv
ate the development of attribution-robust and incentive-compatible scoring mecha
nisms.

SparseInfer: Accelerating Large Language Model Inference with Semantics-Inspired
 Adaptive Sparse Activation

Qinsi Wang, Saeed Vahidian, Hancheng Ye, Jianyang Gu, Jianyi Zhang, Yiran Chen

Large Language Models (LLMs) with billions of parameters have transformed AI app
lications but require immense computational and memory resources during inferenc
e.

Adaptive sparse activation inference, which activates only a small number of neu
rons for each token, offers a novel way to accelerate model inference without de
grading performance, showing great potential for resource-constrained hardware d
evices. Yet existing token-level MLP-based methods frequently alter activation m
aps, reducing efficiency gains.

In this paper, we introduce \textbf{SparseInfer}, an MLP-free adaptive sparse ac
tivation inference method based on sentence-level prediction.

We first propose the concept of core neurons and empirically demonstrate that, f
or an input sentence, LLMs only need the core neurons to maintain performance.

Remarkably, we discovered that core neurons exhibit both stability and similarit
y in relation to the sentence's semantics—an insight overlooked by previous stud
ies.

Building on this finding, we design two semantic-based methods for predicting co
re neurons to fit different input scenarios, which enables core neurons to be de
termined during the pre-filling stage and fixed during the encoding stage.

Our experiments verify SparseInfer exhibits good performance in various tasks an
d achieve 10.33$\times$ speed up.

Advancing Analytic Class-Incremental Learning through Vision-Language Calibratio
n

Binyu Zhao, Wei ZHANG, Xingrui Yu, Zhaonian Zou, Ivor Tsang

Class-incremental learning (CIL) with pre-trained models (PTMs) faces a critical
 trade-off between efficient adaptation and long-term stability. While analytic
learning enables rapid, recursive closed-form updates, its efficacy is often com
promised by accumulated errors and feature incompatibility. In this paper, we fi
rst conduct a systematic study to dissect the failure modes of PTM-based analyti
c CIL, identifying representation rigidity as the primary bottleneck. Motivated
by this insight, we propose **VILA**, a novel dual-branch framework that advance

s analytic CIL via a two-level vision-language calibration strategy. Specificall y, we coherently fuse plastic, task-adapted features with a frozen, universal vi sual anchor at the feature level through geometric calibration, and leverage cro ss-modal semantic priors at the decision level to rectify prediction bias. This confluence maintains analytic-learning's extreme efficiency while overcoming its inherent brittleness. Extensive experiments across eight benchmarks demonstrate that VILA consistently yields superior performance, particularly in fine-graine d and long-sequence scenarios. Our framework harmonizes high-fidelity prediction with the simplicity of analytic learning. Our code is available at https://gith ub.com/byzhaoAI/VILA.

Kuramoto Oscillatory Phase Encoding: Neuro-inspired Synchronization for Improved Learning Efficiency

Mingqing Xiao, Yansen Wang, Dongqi Han, Caihua Shan, Dongsheng Li

Spatiotemporal neural dynamics and oscillatory synchronization are widely implic ated in biological information processing and have been hypothesized to support flexible coordination such as feature binding. By contrast, most deep learning a rchitectures represent and propagate information through activation values, negl ecting the joint dynamics of rate and phase. In this work, we introduce Kuramoto oscillatory Phase Encoding (KoPE) as an additional, evolving phase state to Vis ion Transformers, incorporating a neuro-inspired synchronization mechanism to ad vance learning efficiency. We show that KoPE can improve training, parameter, an d data efficiency of vision models through synchronization-enhanced structure le arning. Moreover, KoPE benefits tasks requiring structured understanding, includ ing semantic and panoptic segmentation, representation alignment with language, and few-shot abstract visual reasoning (ARC-AGI). Theoretical analysis and empir ical verification further suggest that KoPE can accelerate attention concentrati on for learning efficiency. These results indicate that synchronization can serv e as a scalable, neuro-inspired mechanism for advancing state-of-the-art neural network models.

LEGO-FL: Learning Heterogeneous Federated Models as a LEGO Assembly Games

Zeqi Leng, Chunxu Zhang, Guodong Long, Bo Yang

Just as LEGO pieces can be assembled into an unlimited variety of structures, he terogeneous federated learning (HFL) can be viewed as the assembly of diverse mo del components. Inspired by this analogy, we reformulate HFL as a LEGO-like asse mbly game. The central challenge in HFL lies in learning across heterogeneous mo del architectures, which hinders direct parameter sharing.

To address this challenge, we propose to decompose models into a set of modular components—analogous to LEGO pieces and collaboratively learn these components a cross clients under predefined composition rules.

Based on this perspective, we develop a novel federated learning framework, term ed LEGO-FL, which enables flexible model construction while preserving collabora tive learning. Extensive experiments validate the effectiveness of LEGO-FL under different heterogeneous settings and system scales.

Correctness-Optimized Residual Activation Lens (CORAL): Transferrable and Calibr ation-Aware Inference-Time Steering

Miranda Muqing Miao, Young Min Cho, Lyle Ungar

Large language models (LLMs) exhibit persistent miscalibration, especially after instruction tuning and preference alignment. Modified training objectives can i mprove calibration, but retraining is expensive. Inference-time steering offers a lightweight alternative, yet most existing methods optimize proxies for correc tness rather than correctness itself. We introduce CORAL (Correctness-Optimized Residual Activation Lens), a regularized inference-time steering method that cap tures distributed correctness signals from model internal activations using weig ht-decay MLP probes. We evaluate CORAL across three 7B-parameter models and find that it consistently improves accuracy by 10\% and expected calibration error (ECE) by 50\% on average. We additionally demonstrate that these gains transfer w ithout retraining to the complete published test sets of four held-out benchmark

s (ARC-Challenge, HellaSwag, Math-MC, OpenBookQA), averaging 14\% accuracy impro vements and 49\% ECE improvements. Our results support the hypothesis that distr ibuted information in model internals can be extracted using regularized probes when individual neurons are insufficient. CORAL thus provides a compute-efficien t, transferable, and calibration-aware approach to improve MCQA performance duri ng inference.

EngiAgent: Fully Connected Coordination of LLM Agents for Solving Open-ended Eng ineering Problems with Feasible Solutions
Xiyuan Zhou, Ruixi Zou, Xinlei Wang, Yuheng Cheng, Yan Xu, Junhua Zhao, Jinjin G u
Engineering problem solving is central to real-world decision-making, requiring mathematical formulations that not only represent complex problems but also prod uce feasible solutions under data and physical constraints. Unlike mathematical problem solving, which operates on predefined formulations, engineering tasks de mand open-ended analysis, feasibility-driven modeling, and iterative refinement. Although large language models (LLMs) have shown strong capabilities in reasoni ng and code generation, they often fail to ensure feasibility, which limits thei r applicability to engineering problem solving. To address this challenge, we pr opose EngiAgent, a multi-agent system with a fully connected coordinator that si mulates expert workflows through specialized agents for problem analysis, modeli ng, verification, solving, and solution evaluation. The fully connected coordina tor enables flexible feedback routing, overcoming the rigidity of prior pipeline -based reflection methods and ensuring feasibility at every stage of the process . This design not only improves robustness to diverse failure cases such as data extraction errors, constraint inconsistencies, and solver failures, but also en hances the overall quality of problem solving. Empirical results across four rep resentative domains demonstrate that EngiAgent achieves substantial improvements in feasibility compared to prior approaches, establishing a new paradigm for fe asibility-oriented engineering problem solving with LLMs. Our source code and da ta are available at https://github.com/AI4Engi/EngiAgent.

Large Scale Manifold Balanced Clustering
Fangfang Li, Quanxue Gao, Xingyu Xue
Manifold clustering has demonstrated strong capability in capturing complex data structures and has been widely studied in cluster analysis. However, many exist ing methods mainly focus on combining K-means with manifold learning, while over looking the consistency between data structures and clustering labels, and often suffer from high computational cost when handling large scale data. To address these issues, we propose a manifold balanced clustering method based on anchor i nduced distance(LMBC), grounded in the relationship between K-means clustering a nd manifold learning. Specifically, the LMBC uses label information to guide the construction of the manifold structure, thereby ensuring consistency between da ta structures and clustering labels. To enable large scale clustering, we introd uce an anchor induced distance representation that models manifold structure in a compact anchor space, significantly reducing computational complexity while pr eserving essential structural information. Furthermore, to naturally maintain cl ass balance during clustering, we maximize the Schatten-p norm of the label repr esentation and provide theoretical analysis to support its effectiveness. Experi mental results on several benchmark datasets demonstrate the effectiveness and s calability of the proposed method.

LEMUR: Learned Multi-Vector Retrieval
Elias Jääsaari, Ville Hyvönen, Teemu Roos
Multi-vector representations generated by late interaction models, such as ColBE RT, enable superior retrieval quality compared to single-vector representations in information retrieval applications. In multi-vector retrieval systems, both q ueries and documents are encoded using one embedding per token, and similarity b etween queries and documents is measured by the MaxSim similarity measure. Howev er, the improved quality of multi-vector retrieval comes at the expense of signi

ficantly increased search latency. In this work, we introduce LEMUR, a simple ye t efficient framework for multi-vector similarity search. LEMUR consists of two consecutive problem reductions: First, we formulate multi-vector similarity sear ch as a supervised learning problem that can be solved using a one-hidden-layer neural network. Second, we reduce inference under this model to single-vector si milarity search in its latent space, enabling the use of existing single-vector search indexes to accelerate retrieval. LEMUR is an order of magnitude faster th an prior multi-vector similarity search methods. Our code is available at https: //github.com/ejaasaari/lemur

Reasoning Theater: Disentangling Model Beliefs from Chain-of-Thought
Siddharth Boppana, Annabel Ma, Max Loeffler, Raphaël Sarfati, Eric Bigelow, Atti cus Geiger, Owen Lewis, Jack Merullo
We provide evidence of \textit{performative} chain-of-thought (CoT) in reasoning models, where a model becomes strongly confident in its final answer, but conti nues generating tokens without revealing its internal belief.
Our analysis compares activation probing, early forced answering, and a CoT moni tor across two large models (DeepSeek-R1 671B \& GPT-OSS 120B) and find task dif ficulty-specific differences: The model's final answer is decodable from activat ions far earlier in CoT than a monitor is able to say, especially for easy recal l-based MMLU questions. We contrast this with genuine reasoning in difficult mul tihop GPQA-Diamond questions. Despite this, \textit{inflection points} (e.g., ba cktracking, `aha' moments) occur almost exclusively in responses where probes sh ow large belief shifts, suggesting these behaviors track genuine uncertainty rat her than learned ``reasoning theater." Finally, probe-guided early exit reduces tokens by up to 80\% on MMLU and 30\% on GPQA-Diamond with similar accuracy, pos itioning attention probing as an efficient tool for detecting performative reaso ning and enabling adaptive computation.

A Minimax Approach for Optimal Intervention Policy Learning with Two-Stage Outco mes
Chenyang Li, Hao Mei, Yue Liu
When designing interventions to promote desired actions, two-stage agent heterog eneity -- encompassing both engagement with the intervention and completion of the desired action -- creates significant challenges in identifying optimal inte rvention policies. While this two-dimensional heterogeneity creates distinct age nt response types with varying marginal policy returns, existing literature typi cally falls short in full identification of all agent types, leading to ineffici ent intervention allocations.
To address the challenge of learning optimal policies that account for two-stage outcomes, we propose a minimax approach within a counterfactual principal strat a framework. A value function, accommodating varying policy returns across six p otentially non-identifiable principal strata, is designed and partially identifi ed to minimize the worst-case value loss relative to three benchmark policies: n ever-treat, always-treat, and oracle. We introduce three estimators for optimal policy learning: Principal Outcome Regression (P-OR), Principal Inverse Propensi ty Scoring (P-IPS), and Principal Doubly Robust (P-DR), providing theoretical gu arantees for their unbiasedness, robustness, and regret upper bounds. Extensive numerical experiments demonstrate the effectiveness and superiority of the propo sed approach.

When Diffusion Language Models Hesitate: Detecting and Correcting Visual Halluci nations via Confidence Fluctuation
Wenzheng Song, Pei Chen, Yichen Tan, Zejian Li, Lingyun Sun
Multi-modal Diffusion Language Models (MDLMs) have emerged as a powerful alterna tive to autoregressive models in vision understanding, offering advantages in bi directional context modeling and parallel decoding. However, existing MDLMs suff er from visual hallucinations due to the static nature of visual perception. Unl ike autoregressive models, MDLMs lack the sequential dependency to dynamically i nteract with visual content. Therefore, MDLMs rely on fixed visual features enco

ded at initialization, causing the denoising process to drift toward language pr iors and lose its anchor to visual evidence. In this paper, we propose VGR (Visu al-Guided Refinement), a framework that enables MDLMs to revisit visual details by exploiting diffusion dynamics. Our key insight is that the temporal trajector y of confidence during denoising reveals intrinsic uncertainty: while grounded t okens converge smoothly, hallucinated ones exhibit pronounced confidence fluctua tion. VGR utilizes this fluctuation signal to detect uncertain spans and correct s them through targeted visual evidence extraction and in-place remasking. Exten sive experiments on image captioning and hallucination evaluation benchmarks dem onstrate that our method reduces hallucinations and recalls more details. We rel ease our code at https://github.com/SongWZ3214/VGR.

Shared Lexical Task Representations Explain Behavioral Variability In LLMs
Zhuonan Yang, Xiaochen Li, Francisco Piedrahita Velez, Eric Todd, David Bau, Mic hael Littman, Stephen Bach, Ellie Pavlick
One of the most common complaints about large language models (LLMs) is their pr ompt sensitivity---that is, the fact that their ability to perform a task or pro vide a correct answer to a question can depend unpredictably on the way the ques tion is posed. We investigate this variation by comparing two very different but commonly-used styles of prompting: *instruction-based* prompts, which describe the task in natural language, and *example-based* prompts, which provide in-cont ext few-shot demonstration pairs to illustrate the task. We find that, despite l arge variation in performance as a function of the prompt, the model engages som e common underlying mechanisms across different prompts of a task. Specifically , we identify task-specific attention heads whose outputs literally describe the task --- which we dub *lexical task heads*---and show that these heads are shar ed across prompting styles and trigger subsequent answer production. We further find that behavioral variation between prompts can be explained by the degree to which these heads are activated, and that failures are at least sometimes due t o competing task representations that dilute the signal of the target task. Our results together present an increasingly clear picture of how LLMs' internal rep resentations can explain behavior that otherwise seems idiosyncratic to users an d developers.

OPTION: Optimal Transport–Guided Flow Matching for Incomplete and Unaligned Mult i-View Clustering
Siyuan Zhou, Zhibin Gu
Multi-view clustering effectively exploits rich information from multiple views, yet real-world applications are frequently challenged by missing views and cros s-view sample misalignment, hindering cross-view modeling and resulting in infer ior clustering performance. To address these challenges, this paper presents a n ovel method, **OP**timal **T**ransport–Gu**I**ded fl**O**w Matchi**N**g for inco mplete and unaligned multi-view clustering (**OPTION**). Specifically, OPTION em ploys conditional flow matching to learn deterministic transport paths for missi ng-view imputation, enabling stable manifold-preserving recovery and more discri minative representations. To support alignment-free fusion, we introduce a Gromo v-Wasserstein-inspired structural regularization that aligns intra-view geometri c structures in the latent space without solving hard correspondences. Furthermo re, an optional contrastive regularization is incorporated to enhance cross-view consistency specifically for aligned settings. Extensive experiments demonstrat e that OPTION outperforms state-of-the-art methods across ideal, incomplete, and unaligned scenarios evaluated separately. Code: https://github.com/TimoZhou1024 /OPTION.

Reason with Thumbnails, Answer with Focus: An Efficient and Effective Paradigm f or Multimodal Grounded Visual Reasoning
An-Lan Wang, Guozhi Tang, Lei Liao, Hanshen Zhu, Kai Huang, Jingqun Tang, Jiamin g Zhou, Kun-Yu Lin
To enhance the interpretability of multimodal large language models' outputs, re cent efforts explored Grounded Visual Reasoning (GVR), in which the model is tra

ined to select relevant image regions before answering the question. However, th e multi-round ``ground-then-answer'' and reasoning nature of these methods impos es much more computational costs compared to non-GVR methods. To attain efficien t and effective GVR, in this paper, we propose a novel paradigm called Reason wi th Thumbnails, Answer with Focus (RTAF), which feeds the model with low-resoluti on images to reason the relevant regions and high-resolution crops to answer the final answer. Our motivation arises from the observation that, in many cases, t he key area required to answer questions can be inferred from the low-resolution thumbnails, without the need for a full-resolution image. Additionally, for ext reme cases where thumbnails lack sufficient information (leading to undirected r egion guessing and increased computation), we equip the model with a tool to acc ess higher-resolution images. For training efficiency, we adopt pure reinforceme nt learning (i.e., GRPO) and design a suite of reward functions to supervise the model's behavior, alongside a resolution-aware training data selection strategy . Finally, our model, based on Qwen2.5-VL, achieves significant improvements acr oss a range of benchmarks with reduced computation, demonstrating the effectiven ess and efficiency of our proposed RTAF, e.g., compared to the non-GVR model Qwe n2.5-VL, our model achieves a performance gain of 5.8 while using comparable vis ual tokens (471 vs. 391). Against state-of-the-art GVR methods, RTAF reduces vis ual token usage by half while delivering superior performance.

Modelling Attention with Aitchison Geometry: Token Distinguishability and Temper ature Scaling

Sam Hilton-Jones, Timothy J. Norman, Zhanxing Zhu

The attention mechanism with softmax normalisation is a foundational component o f Transformer-based large language models. However, with very long contexts, at tention scores are known to diminish, raising fundamental questions about token distinguishability and how it can be preserved. In this work, we provide a forma l characterisation of token distinguishability in attention as a function of con text length and embedding dimension. We introduce Aitchison distance to quantify relative differences among attention probabilities, and show that, with Gaussia n queries and keys, even in the long-context regime, token distinguishability co nverges to a finite, non-zero limit rather than vanishing. Leveraging the linear relationship between inverse-temperature scaling and Aitchison distance, we der ive a theoretical lower bound of $\Omega(\sqrt{\log L})$ on the logit scaling re quired to produce a sharp attention distribution. Finally, we demonstrate that A itchison distance provides a principled and practical alternative to entropy for monitoring training and inference, as it captures the full compositional struct ure, including the smaller components of the attention probabilities.

MUSA-PINN: Multi-scale Weak-form Physics-Informed Neural Networks for Fluid Flow in Complex Geometries

Weizheng Zhang, Xunjie Xie, Hao Pan, Xiaowei Duan, Bingteng Sun, Qiang Du, Lin L u

While Physics-Informed Neural Networks (PINNs) offer a mesh-free approach to sol ving fluid-flow PDEs, standard point-wise residual minimization suffers from con vergence pathologies in topologically complex domains like Triply Periodic Minim al Surfaces (TPMS). The locality bias of point-wise constraints fails to propaga te global information through tortuous channels, causing unstable gradients and conservation violations.

To address this, we propose the Multi-scale Weak-form PINN (MUSA-PINN), which re formulates Navier-Stokes equation constraints as integral conservation laws over hierarchical spherical control volumes.

We enforce continuity and momentum conservation via flux-balance residuals on co ntrol surfaces. Our method utilizes a three-scale subdomain strategy-comprising large volumes for long-range coupling, skeleton-aware meso-scale volumes aligned with transport pathways, and small volumes for local refinement-alongside a two -stage training schedule prioritizing continuity. Experiments on steady incompre ssible flow in TPMS geometries show MUSA-PINN outperforms state-of-the-art basel ines, reducing relative errors by up to 93\% and preserving mass conservation.

Semantic Integrity Matters: Benchmarking and Preserving High-Density Reasoning in KV Cache Compression
Xiang Liu, Zhenheng Tang, Hong Chen, Peijie Dong, Zeyu Li, Xiuze Zhou, Bo Li, Xuming Hu, Xiaowen Chu
While Key-Value (KV) cache compression is essential for efficient LLM inference, current evaluations disproportionately focus on \textbf{sparse retrieval} tasks, potentially masking the degradation of High-Density Reasoning where Chain-of-Thought (CoT) coherence is critical. We introduce KVFundaBench to systematically evaluate this gap, revealing a sharp dichotomy: while retrieval tasks remain robust, reasoning tasks exhibit severe Task-Dependent Degradation under aggressive compression due to disrupted CoT links. Extending our analysis to the DeepSeek-R1 model, we uncover that its specialized attention patterns offer unique insights into the fragility of reasoning chains. Guided by these findings—specifically the necessity of preserving few-shot examples as indivisible \textbf{Semantic Units}—we propose ShotKV. This approach explicitly separates prefill and decoding phases to prioritize semantic integrity. Empirical results demonstrate that ShotKV achieves 9\%-18\% accuracy improvements on long-context generation tasks and effectively generalizes to document QA, all while delivering an 11\% latency reduction compared to full cache inference.
****
Fisher-Preserving Guidance: Training-Free Manifold Constraints for Safe Diffusion Control
Hao Ren, Zetong Bi, Yiming Zeng, Le Zheng, Zhi Li, Zhaoliang Wan, Lu Qi, Hui Cheng
Diffusion models are effective for waypoint prediction in visual navigation, but standard sampling and test time guidance can produce unreliable or inefficient trajectories when updates drift off the training manifold. We propose Fisher Preserving Guidance with Outer Product Span Projection, a training-free inference method that avoids large Fisher drift associated with off-distribution actions while optimizing a task objective. Our method computes the Fisher-preserving update via a low-rank Jacobian factorization, requiring only a single backward pass per step and enabling real-time use. We further introduce Truncated Fisher Denoising Sensitivity as an uncertainty signal and use it for robust multi-sample action blending. Experiments on toy and realistic navigation benchmarks, including Maze2D with TSDF-based guidance, PushT with official Diffusion Policy weights, and visual navigation in simulation and on real robots, demonstrate consistent improvements in performance over strong diffusion-policy baselines without additional training.
****
PipeSD: An Efficient Cloud-Edge Collaborative Pipeline Inference Framework with Speculative Decoding
Yunhe Han, Yunqi Gao, Bing Hu, Mahdi Boloursaz Mashhadi, Yitong Duan, Pei Xiao, Yanfeng Zhang
Speculative decoding can significantly accelerate LLM inference,
especially given that its cloud-edge collaborative deployment offers cloud workload offloading,
offline robustness, and privacy enhancement.
However, existing collaborative inference frameworks with speculative decoding are constrained by
(i) sequential token generation and communication with low resource utilization,

and (ii) inflexible cloud non-autoregressive verification (NAV) triggering that induces premature verification or costly rollbacks.
In this paper, we propose PipeSD, an efficient cloud-edge collaborative pipeline inference framework with speculative decoding.
PipeSD overlaps token generation and communication by a token-batch pipeline scheduling mechanism optimized by dynamic programming,
and improves verification flexibility through a dual-threshold NAV triggering mechanism with a lightweight Bayesian optimization autotuner.

We implement PipeSD using llama-cpp-python, PyTorch, and FastAPI,
and evaluate it on a real-world cloud-edge testbed
with two draft-target model pairs across four scenarios.
Results show that PipeSD consistently outperforms state-of-the-art baselines,
achieving $1.16\times$-$2.16\times$ speedup and
reducing energy consumption by 14.3%-25.3%.
Our code is available at https://github.com/Ghanyunhe/PipeSD.

On the Generalization in Topology Optimization via Sensitivity-Conditioned Bernoulli Flow Matching
Mohammad Rashed, Duarte F. Valoroso Madeira, Babak Gholami, Caglar Guerbuez, Yunjia Yang, Nils Thuerey
Surrogate models for topology optimization (TO) exhibit highly variable out-of-distribution (OOD) generalization under distribution shifts such as changing loads or boundary conditions, yet the source of this variability remains unclear. We hypothesize that OOD performance is governed by how much information the conditioning signal preserves about the adjoint sensitivity (reduced gradient) that drives classical TO. Modeling the TO pipeline as a causal Markov chain, the Data Processing Inequality establishes that, under this abstraction, the sensitivity field is an information-theoretically optimal conditioning signal for topology prediction. However, computing exact adjoint sensitivities can be expensive or unavailable in practice; we observe that certain physical fields can approximate sensitivities through monotone transformations. To formalize this, we introduce \textbf{pseudo-sensitivities} to characterize which fields enable generalization versus those that are information-poor. We then show that a sensitivity-conditioned Bernoulli flow-matching generator empirically confirms these predictions: conditioning on sensitivities yields state-of-the-art OOD performance, while increasingly distant physical fields degrade toward raw parameter conditioning. Results hold across structural TO benchmarks under load shifts and our new CFD-TO dataset under boundary-condition shifts such as multi-outlet configurations. Code and datasets are available at https://github.com/tum-pbs/topotransformer.

Confidence is Not Universal: Task-Dependent Calibration and Emergent Behavior in LLMs
Chaeyun Jang, Moonseok Choi, Yegon Kim, Seungyoo Lee, Juho Lee, Hyungi Lee
Large language models (LLMs) increasingly support human decision-making, rendering human-interpretable confidence essential. However, it remains unclear whether verbalized confidence calibration generalizes across heterogeneous tasks without degrading accuracy. We show that universal confidence calibration fails. Across diverse benchmarks, we identify two incompatible task families with distinct confidence semantics. In reasoning-centric tasks, confidence supervision transfers within the family, often improving calibration while preserving or even improving accuracy, and induces emergent behaviors such as confidence-dependent reasoning length and self-verification. Retrieval- and copy-oriented tasks also exhibit within-family transfer, but fail to generalize to reasoning tasks, with cross-family supervision degrading both calibration and accuracy. Motivated by this finding, we disentangle confidence into reasoning uncertainty and evidence localization uncertainty. This simple decomposition restores cross-family generalization using supervised fine-tuning alone, suggesting that effective confidence alignment requires task-aware semantics rather than a universal scalar notion.
****
An Interactive Paradigm for Deep Research
Lin Ai, Victor Bursztyn, Xiang Chen, Julia Hirschberg, Saayan Mitra
Recent advances in large language models (LLMs) have enabled deep research systems that synthesize comprehensive, report-style answers to open-ended queries by combining retrieval, reasoning, and generation. Yet, most frameworks rely on rigid workflows with one-shot scoping and long autonomous runs, offering little room for course correction if user intent shifts mid-process. We present **SteER**, a framework for steerable deep research that introduces interpretable, mid-process control into long-horizon research workflows. At each decision point, **SteE

R** uses a cost–benefit formulation to determine whether to pause for user input or proceed autonomously. It combines diversity-aware planning with utility signals that reward alignment, novelty, and coverage, and maintains a live persona model that evolves throughout the session. **SteER** outperforms state-of-the-art open-source and proprietary baselines by up to 22.80% on alignment, leads on quality metrics such as breadth and balance, and is preferred by human readers in 85%+ of pairwise alignment judgments. We also introduce a persona–query benchmark and data-generation pipeline. To our knowledge, this is the first work to advance deep research with an interactive, interpretable control paradigm, paving the way for controllable, user-aligned agents in long-form tasks.

FlatLab: A Unified Methodology Framework and Simulation-Based Benchmark for Robotic Manipulation of Flat Objects
Xingyu Zhu, Wenshuo Han, Zhouyu Wang, Yuran Wang, Ruihai Wu, Hao Dong, Fan Tang, Hechang Chen, Hyung Jin Chang, Yixing Gao
Robotic manipulation of flat objects is challenging due to the ungraspable configurations and strong variations in object geometry and material. Existing methods rely on heuristic pre-manipulation and are often evaluated in closed settings with limited generalization. We propose a unified framework that decouples the manipulation into a strategy generator and an action execution module. The strategy generator predicts appropriate manipulation strategies from object point clouds by learning strategy-centric, object-invariant representations via simulated data transformation and contrastive learning. Conditioned on the predicted strategy, the execution module decomposes long-horizon manipulation into reusable action primitives and dynamically composes them to generate stable trajectories. To enable systematic evaluation, we introduce FlatLab, a comprehensive simulation benchmark for robotic flat object manipulation. FlatLab provides high-fidelity physical simulation of diverse rigid and deformable flat objects, automated multi-modal data collection, and standardized task definitions and evaluation protocols. Experiments conducted in FlatLab demonstrate that our approach generalizes effectively to unseen objects and categories, outperforming existing baselines. The project page and the code are provided at \url{https://flatlab-web.github.io/}.

De-attribute to Forget for LLM Unlearning
Xinyang Lu, Jiabao Pan, Rachael Hwee Ling Sim, See-Kiong Ng, Anthony Kum Hoe Tung, Bryan Kian Hsiang Low
The rapid development of large language models (LLMs) has raised concerns regarding the inclusion of private or inappropriate data during training, which has led to growing interest in LLM unlearning. Many existing LLM unlearning approaches rely on prediction loss-based optimizations, such as maximizing the loss on the forget set. However, these methods often face issues such as over-forgetting and poor model utility. In this work, we address these issues by introducing a novel perspective that shifts the unlearning optimization target to reducing data attribution instead. We propose the first LLM unlearning framework based on data attribution rewards called DareU that employs reinforcement learning to update the LLM and reduce the attribution score of generated responses (i.e., de-attribute) to the forget data owners. Experimental results using an LLM classifier as an efficient approximation of attribution demonstrate that DareU outperforms existing baseline approaches, achieving effective unlearning while balancing forget quality and model utility.

Is Generation Required for Data-Efficient Perception?
Jack Brady, Bernhard Schölkopf, Thomas Kipf, Simon Buchholz, Wieland Brendel
It has been hypothesized that achieving the data efficiency of human visual perception requires a generative approach in which internal representations result from inverting a decoder. Yet today’s most successful vision models are non-generative, relying on an encoder that maps images to representations without decoder inversion. This raises the question of whether generation is necessary for data-efficient machine perception. To address this, we study to what extent generati

ve and non-generative methods can achieve compositional generalization, a hallmark of human data efficiency. Under a compositional generative process, we formally characterize the inductive biases required for compositional generalization in decoder-based (generative) and encoder-based (non-generative) methods. We show theoretically that the inductive biases required for an encoder are substantially more complex and generally infeasible to impose explicitly through architectural constraints or regularization. By contrast, the decoder biases take a simple form that can be enforced directly. These results suggest that compositional generalization may be substantially easier to achieve through a generative paradigm of learning and inverting a decoder rather than learning an encoder directly. We examine our theoretical findings empirically by training a range of generative and non-generative methods on synthetic image data. We find that non-generative methods often fail to generalize compositionally and require large-scale pretraining to improve generalization. By comparison, generative methods yield gains in generalization without requiring additional data.

Refining Dual Spectral Sparsity in Transformed Tensor Singular Values

Andong Wang, Yuning Qiu, Haonan Huang, Zhong Jin, Guoxu Zhou, Qibin Zhao

The Tubal Nuclear Norm (TNN), derived from the tensor Singular Value Decomposition (t-SVD), is a widely used low-rank modeling tool that promotes sparsity of frequency-domain singular values.

However, as a direct extension of the matrix nuclear norm, TNN applies a uniform element-wise penalty to transformed singular values, without explicitly distinguishing sparsity across frequency components from low-rankness within each component.

This can be restrictive for real-world tensor data that exhibit multi-level spectral structures, where spectral energy is concentrated in a subset of frequency components while active components remain low-rank.

To overcome this limitation, we propose the tensor ℓ_p-Schatten-q quasi-norm ($p,q\in(0,1]$), which enables explicit control of dual spectral sparsity by jointly regularizing inter-frequency sparsity and intra-frequency low-rankness. This formulation includes TNN as a special case and subsumes several existing tensor regularizers by coupling global frequency sparsity with local spectral low-rankness, yielding a more flexible modeling principle.

We establish minimax error bounds under the proposed dual spectral sparsity model, develop a reweighted optimization algorithm for the resulting nonconvex problem, and demonstrate its effectiveness and robustness on noisy and Poisson tensor completion as well as image clustering tasks.

MemIncept: Steering LLM Agents via Cooperative Stealthy Memory Injections

Nan Yan, Qian Lou, Jiarong Xing

Long-term memory empowers LLM-based agents with adaptive reasoning but exposes a critical attack surface---adversaries can inject malicious records to bias agent behaviors. However, existing attacks face a dilemma: effective injections are often visibly malicious and easily detected, while stealthy, benign-looking injections are often less effective in altering agent behaviors. To address this, we propose MemIncept, a memory poisoning attack that can impact agents even in black-box settings using only benign-appearing queries. Unlike prior methods that inject isolated records, MemIncept generates a cooperative set of queries that work together to bias the agent. It achieves this via a bidirectional evolutionary strategy that optimizes the query set from two ends. A forward pass ensures the queries collectively lead the agent to the target outcome, while a backward pass ensures they are semantically close to victim (benign) queries for reliable retrieval. This ``meet-in-the-middle'' approach creates injected records that are both easy to retrieve and effective at steering behavior. Through extensive experiments across diverse agents, we show that MemIncept significantly outperforms single-record attacks, achieving high success rates comparable to explicit attacks while remaining difficult to flag under automated filters or human inspection.

Thinking in Structures: Evaluating Spatial Intelligence in Constraint-Governed Spaces
Chen Yang, Guanxin Lin, Youquan He, Peiyao Chen, Guanghe Liu, Yufan Mo, Zhouyuan Xu, Linhao Wang, Guohui Zhang, Zihang Zhang, Shenxiang Zeng, Chen Wang, Jiansheng Fan
Spatial intelligence is crucial for vision--language models (VLMs), yet many scene-centric benchmarks evaluate unconstrained environments where a single image may admit multiple plausible 3D interpretations. We introduce SSI-Bench, a VQA benchmark for Structure-Centric Spatial Reasoning (SCSR) in constraint-governed spaces. Built from complex real-world 3D structures, it uses structural constraints from geometry, topology, and physical feasibility to make component relations more determinate from visual evidence. The benchmark contains 1,000 ranking questions spanning geometric and topological reasoning, where correct ordering requires resolving all candidate-wise 3D relations, imposing stronger demands on spatial understanding. It is created through a fully human-centered pipeline with over 400 researcher-hours of image curation, component annotation, and question design. Evaluating 31 VLMs reveals a large gap to humans: the best open-source model achieves 22.2% accuracy and the strongest closed-source model reaches 33.6%, while humans score 91.6%. Further results show that chain-of-thought reasoning brings only marginal gains, and error analysis reveals fundamental limitations in current models' spatial understanding within constraint-governed spaces. Project page: https://ssi-bench.github.io.

Symbol-Equivariant Recurrent Reasoning Models
Richard Freinschlag, Timo Bertram, Erich Kobler, Andreas Mayr, Günter Klambauer
Reasoning problems such as Sudoku and ARC-AGI remain challenging for neural networks. The structured problem solving architecture family of Recurrent Reasoning Models (RRMs), including Hierarchical Reasoning Model (HRM) and Tiny Recursive Model (TRM), offer a compact alternative to large language models, but currently handle symbol symmetries only implicitly via costly data augmentation.
We introduce Symbol-Equivariant Recurrent Reasoning Models (SE-RRMs), which enforce permutation equivariance at the architectural level through symbol-equivariant layers, guaranteeing identical solutions under symbol or color permutations. SE-RRMs outperform prior RRMs on 9$\times$9 Sudoku and generalize from just training on 9$\times$9 to smaller 4$\times$4 and larger 16$\times$16 and 25$\times$25 instances, to which existing RRMs cannot extrapolate.
On ARC-AGI-1 and ARC-AGI-2, SE-RRMs achieve competitive performance with substantially less data augmentation and only 2 million parameters, demonstrating that explicitly encoding symmetry improves the robustness and scalability of neural reasoning.

ArenaRL: Scaling RL for Open-Ended Agents via Tournament-based Relative Ranking
Qiang Zhang, Boli Chen, Fanrui Zhang, Ruixue Ding, Shihang Wang, Qiuchen Wang, Yinfeng Huang, Haonan Zhang, Rongxiang Zhu, Xin Li, Houquan Zhou, Pengjun Xie, Kaipeng Zhang, Jingren Zhou, Jiawei Liu
Reinforcement learning (RL) has advanced LLM agents on verifiable tasks but remains challenging for open-ended tasks with vast solution spaces (e.g., complex travel planning). Lacking objective ground truth, current RL algorithms rely on reward models assigning scalar scores to individual responses. We contend such pointwise scoring induces discrimination collapse: reward model fails to distinguish subtle advantages among trajectories, compressing intra-group rewards into a narrow range. This drowns effective reward signals in reward model noise, causing optimization stagnation. To address this, we propose ArenaRL, a reinforcement learning paradigm shifting from pointwise scalar scoring to intra-group relative ranking. ArenaRL introduces a process-aware pairwise evaluation with multi-level rubrics for fine-grained relative scoring. Meanwhile, we construct an intra-group adversarial arena and devise a tournament-based ranking scheme to obtain stable advantage signals. ArenaRL achieves high-precision advantage estimation with only $O(N)$ computational complexity, striking a favourable balance between efficiency and accuracy. Furthermore, to address the lack of full-cycle benchmarks f

or open-ended agents, we introduce two high-quality benchmarks: Open-Travel and Open-DeepResearch, encompassing full training and multi-dimensional evaluation p ipelines. Extensive experiments across three open-ended tasks validate the effec tiveness of ArenaRL.

TAG: Tangential Amplifying Guidance for Hallucination-Resistant Sampling
Hyunmin Cho, Donghoon Ahn, Susung Hong, Jee Eun Kim, Seungryong Kim, Kyong Hwan Jin
Diffusion models achieve state-of-the-art image generation but often produce sem antic inconsistencies, or *hallucinations*. Existing inference-time guidance met hods rely on external signals or architectural modifications, adding computation al overhead. We propose **T**angential **A**mplifying **G**uidance **(TAG)**, a training-free, architecture-agnostic, plug-and-play guidance method that operate s purely on trajectory signals. TAG uses an intermediate sample as a projection basis and amplifies the tangential components of the estimated score to correct the sampling trajectory. A first-order Taylor analysis shows that this steers th e state toward higher-probability regions of the data manifold, reducing inconsi stencies and improving fidelity while adding negligible overhead to existing sam plers. Code is available at our Project Page (https://hyeon-cho.github.io/TAG/).

Clarify Before You Draw: Proactive Agents for Robust Text-to-CAD Generation
Bo Yuan, Zelin Zhao, Petr Molodyk, Bin Hu, Yongxin Chen
Large language models have recently enabled text-to-CAD systems that synthesize parametric CAD programs (e.g., CadQuery) from natural-language prompts. In pract ice, however, geometric descriptions can be under-specified or internally incons istent: critical dimensions may be missing and constraints may conflict. Howeve r, existing fine-tuned models tend to reactively follow the user’s instructions a nd hallucinate dimensions when the text is ambiguous. To address this, we propo se a proactive agentic framework for text-to-CadQuery generation, named as \text bf{ProCAD}, that resolves specification issues before code synthesis. Our framew ork pairs a proactive clarifying agent, which audits the prompt and asks targete d clarification questions only when necessary to produce a self-consistent speci fication, with a CAD coding agent that translates the specification into an exec utable CadQuery program. We fine-tune the coding agent based on a curated high-q uality text-to-CadQuery dataset and train the clarifying agent via agentic SFT o n clarification trajectories. Experiments show that proactive clarification sign ificantly improves robustness to ambiguous prompts while keeping interaction ove rhead low. ProCAD outperforms frontier closed-source models, including Claude So nnet 4.5, reducing the mean Chamfer distance by 79.9\% and lowering the invalidi ty ratio from 4.8\% to 0.9\%. Our code and datasets are made publicly available on \url{https://github.com/BoYuanVisionary/Pro-CAD}.

From Welfare to Utility: Generalized Objectives in Budget-Feasible Procurement
Alon Eden, Kira Goldner, Eldar Kerner, Thodoris Tsilivis
We study mechanism design for the budget-feasible procurement problem, a natural problem that arises when a buyer wants to procure goods or services from multip le strategic sellers who each have a cost to provide that service, the buyer has a value for each service procured, but is constrained by a budget. In contrast to prior work, which has focused on buyer value maximization for this problem, w e solve for optimal and approximately-optimal mechanisms for the objectives of b uyer utility (value of procured services minus payments), welfare (value minus p roduction costs), and generalizations of the two. For welfare, we design a simpl e mechanism that obtains a constant-factor approximation for the prior-free (wor st-case) setting. As prior-free mechanisms fail to provide any guarantee for uti lity, even for a single seller, we consider Bayesian settings, where the buyer h as distributional knowledge over sellers' costs. We first provide a utility-opt imal mechanism that satisfies the buyer's budget constraint *in expectation*, th en we show how to modify the mechanism to satisfy the budget constraint *ex-post *, for every realization of seller costs, while still obtaining near-optimal uti lity guarantees. Finally, we generalize our mechanisms to other objectives.

Non-Adversarial Imitation Learning Provably Free of Compounding Errors: The Value Flow Mechanism
Tian Xu, Chenyang Wang, Xiaochen Zhai, Ziniu Li, Yi-Chen Li, Yang Yu
Adversarial imitation learning (AIL) achieves high-quality imitation by mitigating compounding errors inherent to behavioral cloning (BC), yet its adversarial optimization frequently leads to training instability. A class of non-adversarial Q-based imitation learning (IL) methods, exemplified by IQ-Learn, has emerged to address this instability and is widely believed to outperform BC by leveraging online environment interactions. In this paper, we revisit IQ-Learn and prove that it in fact reduces to BC: it admits an imitation gap lower bound with quadratic dependence on the horizon and therefore remains susceptible to compounding errors. Our theoretical analysis reveals why online interactions fail to help: IQ-Learn uniformly suppresses Q-values for all actions at states not covered by demonstrations, preventing generalization beyond demonstrations. To address this fundamental limitation, we introduce Dual Q-DM, a new Q-based IL method built on Bellman constraints. Crucially, Bellman constraints drive value flow: Q-values propagate from demonstrated to unvisited states through environment dynamics, enabling generalization beyond demonstrations. We prove that Dual Q-DM is equivalent to AIL and can recover expert actions at unvisited states, thereby mitigating compounding errors. To the best of our knowledge, Dual Q-DM is the first non-adversarial IL method that is theoretically guaranteed to eliminate compounding errors. Experimental results further corroborate our theoretical findings.

When RL Meets Adaptive Speculative Training: A Unified Training-Serving System
Junxiong Wang, Fengxiang Bie, Jisen Li, Zelei Shao, Qingyang Wu, Yinghui Liu, Yubo Wang, Avner May, Ben Athiwaratkun, Yineng Zhang, Shuaiwen Leon Song, Zhongzhu Zhou, Chenfeng Xu, Xiaoxia Wu
Speculative decoding can significantly accelerate LLM serving, yet most deployments today disentangle speculator training from serving, treating speculator training as a standalone offline modeling problem. We show that this decoupled formulation introduces substantial deployment and adaptation lag: (1) high time-to-serve, since a speculator must be trained offline for a considerable period before deployment; (2) delayed utility feedback, since the true end-to-end decoding speedup is only known after training and cannot be inferred reliably from acceptance rate alone due to model-architecture, diverse prompt engineering, and system-level overheads; and (3) domain-drift degradation, as the target model is repurposed to new domains and the speculator becomes stale and less effective. To address these issues, we present Aurora, a unified training–serving system that closes the loop by continuously learning a speculator directly from live inference traces. Aurora reframes online speculator learning as an asynchronous reinforcement-learning problem: accepted tokens provide positive feedback, while rejected speculator proposals provide implicit negative feedback that inherits the online traffic failure signals. Our design integrates an SGLang-based inference server with an asynchronous training server, enabling hot-swapped speculator updates without service interruption. Crucially, Aurora supports day-0 deployment: a speculator can be served immediately and rapidly adapted to live traffic, improving system performance while providing immediate utility feedback. Across experiments, Aurora achieves a 1.5$\times$ day-0 speedup on recently released frontier models (e.g., MiniMax M2.1 229B and Qwen3-Coder-Next 80B). Aurora also adapts effectively to distribution shifts in user traffic, delivering an additional 1.25$\times$ speedup over a well-trained but static speculator on widely used models (e.g., Qwen3 and Llama3).
****
VideoBrain: Learning Adaptive Frame Sampling for Long Video Understanding
Junbo Zou, Ziheng Huang, Shengjie Zhang, Liwen Zhang, Weining Shen
Long-form video understanding remains challenging for Vision-Language Models (VLMs) due to the inherent tension between computational constraints and the need to capture information distributed across thousands of frames. Existing approaches either sample frames uniformly (risking information loss) or select keyframes

in a single pass (with no recovery from poor choices). We propose VideoBrain, an end-to-end framework that enables VLMs to adaptively acquire visual information through learned sampling policies. Our approach features dual complementary agents: a CLIP-based agent for semantic retrieval across the video and a Uniform agent for dense temporal sampling within intervals. Unlike prior agent-based methods that rely on text-only LLMs orchestrating visual tools, our VLM directly perceives frames and reasons about information sufficiency. To prevent models from invoking agents indiscriminately to maximize rewards, we introduce a behavior-aware reward function coupled with a data classification pipeline that teaches the model when agent invocation is genuinely beneficial. Experiments on four long video benchmarks demonstrate that VideoBrain achieves +3.5\% to +9.0\% improvement over the baseline while using 30-40\% fewer frames, with strong cross-dataset generalization to short video benchmarks. The code is available at https://github.com/junbo-zou/VideoBrain.

Fox in the Henhouse: Supply-Chain Backdoor Attacks Against Reinforcement Learning

Shijie Liu, Andrew Craig Cullen, Paul Montague, Sarah Monazam Erfani, Benjamin I. P. Rubinstein

Existing backdoor attacks on Reinforcement Learning (RL) typically rely on unrealistic white-box access to victim parameters, rewards, or observations. Inspired by real world behaviors, we introduce the Supply-Chain Backdoor (SCAB) attack to demonstrate that such assumptions are unnecessary. SCAB targets the common practice of training with third-party policies, poisoning the dataset solely through a black-box of legitimate agent-environment interactions. With only 3% data corruption, SCAB demonstrates a peak attack success rate exceeding 90% and reduces victim returns by 80%. These findings expose a critical vulnerability in the modern RL supply chain, highlighting that reliance on untrusted external agents constitutes a severe and practical security risk.

Online Bayesian Experimental Design for Partially Observed Dynamical Systems

Sara Perez-Vieites, Sahel Iqbal, Simo Särkkä, Dominik Baumann

Bayesian experimental design (BED) provides a principled framework for optimising data collection by choosing experiments that are maximally informative about unknown parameters. However, existing methods cannot deal with the joint challenge of (a) *partially observable dynamical systems*, where only noisy and incomplete observations are available, and (b) *fully online inference*, which updates posterior distributions and selects designs sequentially in a computationally efficient manner. Under partial observability, dynamical systems are naturally modeled as state-space models (SSMs), in which latent states mediate the link between parameters and data, making the likelihood---and thus information-theoretic objectives like the expected information gain (EIG)---intractable. We address these challenges by deriving new estimators of the EIG and its gradient that explicitly marginalise latent states, enabling scalable stochastic optimisation in nonlinear SSMs. Our approach leverages nested particle filters for efficient online state-parameter inference with convergence guarantees. Applications to realistic models, such as the susceptible–infectious–recovered (SIR) model and a moving source location task, show that our framework successfully handles both partial observability and online inference.

OpenHA: A Series of Open-Source Hierarchical Agentic Models in Minecraft

Zihao Wang, Muyao Li, Kaichen He, Xiangyu Wang, Zhancun Mu, Minghao Liu, Anji Liu, Yitao Liang

A critical challenge in developing capable AI agents is defining their "action space''—the set of possible actions they can take. These spaces can range widely, from generating code and using language skills to operating on latent representations or raw joystick controls. Through a large-scale study in Minecraft, we discovered a major dilemma: no single action space is universally best. The most effective action space is highly task-dependent, which complicates the goal of building one generalist agent that can handle everything. To solve this, we introd

uce Chain-of-Action (CoA), a novel framework that unifies high-level abstracted actions and low-level control actions within a single model. With CoA, an abstract goal is not just a final command; instead, it serves as an intermediate reasoning step that guides the model to generate the precise, executable actions needed to complete the task. Furthermore, we show that an All-in-One generalist agent, trained on a diverse mix of action spaces using CoA, learns a more generalizable policy. This unified agent achieves a new state-of-the-art, outperforming strong, specialized baselines. To support the research community, we are releasing the OpenHA (Open Hierarchical Agents) suite, which includes our benchmark of over 800 tasks, curated datasets, source code, and all model checkpoints at: \url{https://github.com/
CraftJarvis/OpenHA}.

When Model Merging Breaks Routing: Training-Free Calibration for MoE
Canbin Huang, Tianyuan Shi, Xiaojun Quan, Jingang Wang, Jianfei Zhang, Qifan Wang
Model merging has emerged as a cost-effective approach for consolidating the capabilities of multiple LLMs without retraining. However, existing merging techniques, largely based on linear parameter arithmetic or optimization, struggle when applied to Mixture-of-Experts (MoE) architectures. We identify a critical failure mode in MoE merging, termed *routing breakdown*, in which the merged router fails to dispatch tokens to suitable experts. Routing breakdown stems from the sensitivity of the non-linear softmax and discrete Top-k routing mechanisms to parameter perturbations from merging, a sensitivity further amplified by load-balancing constraints imposed during MoE pretraining. Because fine-tuned experts exhibit distinct specializations, even modest misrouting can cause severe performance degradation. To address this issue, we propose Hessian-Aware Router Calibration (HARC), a training-free framework that leverages second-order curvature information to realign the merged router. This approach admits a closed-form solution that can be efficiently solved using a matrix-free conjugate gradient method. Experiments on mathematical reasoning and code generation tasks show that HARC effectively mitigates routing breakdown across diverse MoE merging baselines and leads to substantial performance improvements.
****
Compute Where it Counts: Self Optimizing Language Models
Yash Akhauri, Mohamed S. Abdelfattah
Efficient LLM inference research has largely focused on reducing the cost of each decoding step (e.g., using quantization, pruning, or sparse attention), typically applying a uniform computation budget to every generated token. In practice, token difficulty varies widely, so static compression can over-compute on easy steps and under-compute on hard ones. We study \emph{dynamic budget allocation} for autoregressive decoding: learning how much computation to spend \emph{per token} from within a single model.

Self-Optimizing Language Models (SOL) pair a frozen LLM with a lightweight policy network that reads the LLM hidden state and selects a discrete \emph{efficiency action} at each decode step. Actions can jointly control (i) token-level attention sparsity, (ii) structured activation pruning in the MLP, and (iii) activation quantization bit-width, while leaving the base model weights unchanged.
We train the policy with group-relative policy optimization on teacher-forced episodes: the token sequence is fixed, while we sample multiple compute schedules (i.e., “counterfactual” schedules that vary only the efficiency actions for the same token path) and compare their likelihoods under the same supervision. Our reward trades off language■model quality against soft penalties that encourage episode■average budget usage to match a requested target. Across model variants and compute regimes, SOL improves quality at matched budget over static allocation and strong random schedule search, offering a complementary axis for inference■efficiency optimization. SOL discovers a better quality-efficiency pareto-front across all our experiments and improves MMLU accuracy by up to 7.3\% over uniform budget allocation strategies. \href{https://github.com/akhauriyash/SOL}

G^2-Reader: Dual Evolving Graphs for Multimodal Document QA
Yaxin Du, Junru Song, Yifan Zhou, Cheng Wang, Jiahao Gu, Zimeng Chen, Menglan Ch
en, Wen Yao, Yang Yang, Ying Wen, Siheng Chen
Retrieval-augmented generation is a practical paradigm for question answering ov
er long documents, but it remains brittle for multimodal reading where text, tab
les, and figures are interleaved across many pages. First, flat chunking breaks
document-native structure and cross-modal alignment, yielding semantic fragments
 that are hard to interpret in isolation. Second, even iterative retrieval can f
ail in long contexts by looping on partial evidence or drifting into irrelevant
sections as noise accumulates, since each step is guided only by the current sni
ppet without a persistent global search state. We introduce G^2-Reader, a dual
-graph system, to address both issues. It evolves a Content Graph to preserve do
cument-native structure and cross-modal semantics, and maintains a Planning Grap
h, an agentic directed acyclic graph of sub-questions, to track intermediate fin
dings and guide stepwise navigation for evidence completion. On VisDoMBench acro
ss five multimodal domains, G^2-Reader with Qwen3-VL-32B-Instruct reaches 66.2
1\% average accuracy, outperforming strong baselines and a standalone GPT-5 (53.
08\%). Code is available: https://github.com/DorothyDUUU/G2_Reader.
****
Factored Gossip DiLoCo: Reducing Blocking Communication within DiLoCo
Chamin P Hewa Koneputugodage, Thalaiyasingam Ajanthan, Sameera Ramasinghe, Hadi
Mohaghegh Dolatabadi, Shamane Siriwardhana, Gil Avraham, Violetta Shevchenko, Ka
rol Pajak, James Snewin, Alexander Long
To make large-scale distributed training practical outside high-bandwidth datace
nters, we must reduce blocking, high-volume synchronization. While DiLoCo commun
icates infrequently, its outer synchronization remains bandwidth-heavy and britt
le to stragglers and transient failures.
We relax exact synchronization to *approximate synchronization* via mixing/gossi
p, which degrades gracefully under delays and communication failures. This allow
s us to factorize DiLoCo synchronization into a *non-blocking* mixing step that
overlaps computation with no staleness, and a *blocking* mixing step that tighte
ns worker agreement, yielding a tunable trade-off between compute utilization an
d optimization stability.
On up to billion-parameter language models in low-bandwidth settings, our framew
ork substantially improves compute utilization compared to DiLoCo, with training
 progress ranging from comparable to closely matching it, and is more robust to
failures.
****
NEMO: Execution-Aware Optimization Modeling via Autonomous Coding Agents
Yang Song, Anoushka Vyas, Zirui Wei, Sina Khoshfetrat Pakazad, Henrik Ohlsson, G
raham Neubig
We present **NEMO**, a system that translates **N**atural-language descriptions
of decision problems into formal **E**xecutable **M**athematical **O**ptimizatio
n implementations using autonomous coding agents (ACAs). Existing approaches rel
y on specialized large language models (LLMs) or bespoke task-specific agents th
at are often brittle and frequently generate syntactically invalid or non-execut
able code. NEMO instead treats ACAs as a first-class abstraction analogous to AP
I-based interaction with LLMs; their sandboxed execution guarantees code is exec
utable by construction and supports automated validation and repair. We introduc
e novel coordination patterns including asymmetric validation loops between inde
pendently generated optimizer and simulator implementations, external memory for
 experience reuse, and robustness enhancements via minimum Bayes risk (MBR) deco
ding and self-consistency. Across nine established optimization benchmarks, NEMO
 achieves state-of-the-art performance on the majority of tasks with substantial
 margins on several datasets, demonstrating the power of execution-aware agentic
 architectures for automated optimization modeling.

FedRGL: Robust Federated Graph Learning under Label Noise
De Li, Zhou Tan, Qiyu Li, Zeming Gan, Tiange Xia, Chunpei Li, Xianxian LI

Federated Graph Learning (FGL) is a distributed machine learning paradigm based on graph neural networks, enabling secure and collaborative modeling of local graph data among clients. However, label noise in graph data can degrade the generalization performance of the global model. Existing federated label noise learning methods, primarily focused on computer vision tasks, often yield suboptimal results when directly applied to FGL. To address this issue, we propose a robust federated graph learning method with label noise, termed **FedRGL**. Specifically, FedRGL leverages the globally aggregated model and local subgraph structural information to implement a dual-perspective consistency noise-node filtering mechanism under class-aware dynamic thresholds. The resulting *class-aware dual-consistency filtering (CADF)* can also serve as a plug-and-play module, enhancing noise robustness across various subgraph federated learning frameworks. To better exploit the supervisory information from filtered noisy nodes, we employ the natural augmentation techniques from graph contrastive learning to assign high-confidence pseudo-labels to the noise nodes. Additionally, we measure model quality via the average predictive entropy of unlabeled nodes, enabling adaptive robust aggregation on the server side. Extensive experiments on real-world graph datasets show that FedRGL consistently outperforms existing methods under different noise rates, noise types, and client scales, achieving on average **5--8\%** higher accuracy and up to **30\%** improvement over the weakest baselines under noisy conditions. The source code is available at https://github.com/LDer66/FEDRGL-ICML26.

DirectEdit: Step-Level Accurate Inversion for Flow-Based Image Editing

Desong Yang, Mang Ye

With recent advancements in large-scale pre-trained text-to-image (T2I) models, training-free image editing methods have demonstrated remarkable success. Typically, these methods involve adding noise to a clean image via an inversion process, followed by separate denoising steps for the reconstruction and editing paths during the forward process. However, since the reconstruction path is approximated using noisy latents from mismatched timesteps, existing methods inevitably suffer from accumulated drift, which fundamentally limits reconstruction fidelity. To address this challenge, we systematically analyze the inversion process within the flow transformer and propose DirectEdit, a simple yet effective editing method that eliminates the inherent reconstruction error without introducing additional neural function evaluations (NFEs). Unlike most prior works that attempt to rectify the inversion path, DirectEdit focuses on directly aligning the forward paths, enabling precise reconstruction and reliable feature sharing. Furthermore, we introduce a preservation mechanism based on attention feature injection and multi-branch mask-guided noise blending, which effectively balances fidelity and editability. Extensive experiments across diverse scenarios demonstrate that DirectEdit achieves efficient and accurate image editing, delivering superior performance that outperforms state-of-the-art methods. Code and examples are available at https://desongyang.github.io/Directedit.

FluxNet: Learning Capacity-Constrained Local Transport Operators for Conservative and Bounded PDE Surrogates

Zishuo Lan, Junjie Li, Lei Wang, Jincheng Wang

Autoregressive learning of time-stepping operators provides an effective approach to data-driven partial differential equation (PDE) simulation, yet for conservation laws, they face a fundamental challenge: learned updates may violate global conservation over long rollouts. For the important subclass of mass-conservation-type equations, the problem is compounded by inherent physical bounds (e.g., nonnegativity or concentrations in [0,1]) whose violation further destabilizes predictions. We introduce FluxNet, which learns cumulative transport amounts representing the total conserved quantity redistributed between each cell and a configurable neighborhood over the full surrogate interval. A conservative update guarantees exact discrete conservation by construction; modular capacity-constrained transport heads (L, U, and D) enforce lower bounds, upper bounds, or near-zero dual-bound violations through architectural design. Unlike flux-rate surrogate

s that require temporal integration and thus inherit CFL constraints, FluxNet in volves no such integration; configurable transport neighborhoods enable large-ti mestep prediction at full spatial resolution. Ghost cells extend the framework t o non-periodic boundaries. Experiments on four benchmarks (1D convection--diffus ion, 2D shallow water, 1D traffic flow, 2D Cahn--Hilliard) demonstrate exact con servation, structural bound preservation, architecture modularity, and superior stability over flux-rate surrogates at large temporal strides. The code is publi cly available at: https://github.com/Lan-zs/FluxNet.

One-shot Conditional Sampling: MMD meets Nearest Neighbors
Anirban Chatterjee, Sayantan Choudhury, Rohan Hore
How can we generate samples from a conditional distribution that we never fully observe? This question arises across a broad range of applications in both moder n machine learning and classical statistics, including image post-processing in computer vision, approximate posterior sampling in simulation-based inference, a nd conditional distribution modeling in complex data settings. In such settings, compared with unconditional sampling, additional feature information can be lev eraged to enable more adaptive and efficient sampling. Building on this, we intr oduce Conditional Generator using MMD (CGMMD), a novel framework for conditional sampling. Unlike many contemporary approaches, our method frames the training o bjective as a simple, adversary-free direct minimization problem.
A key feature of CGMMD is its ability to produce conditional samples in a single forward pass of the generator, enabling practical one-shot sampling with low te st-time complexity. We establish rigorous theoretical bounds on the loss incurre d when sampling from the CGMMD sampler, and prove convergence of the estimated d istribution to the true conditional distribution. In the process, we also develo p a uniform concentration result for nearest-neighbor based functionals, which m ay be of independent interest. Finally, we show that CGMMD performs competitivel y on synthetic tasks involving complex conditional densities, as well as on prac tical applications such as image denoising and image super-resolution.
****

DC-LA: Difference-of-Convex Langevin Algorithm
Hoang Phuc Hau Luu, Zhongjian Wang
We study a sampling problem whose target distribution is $\pi \propto \exp(-f-r) $ where the data fidelity term f is Lipschitz smooth while the regularizer ter m $r=r_1-r_2$ is a non-smooth difference-of-convex (DC) function, i.e., $r_1,r_2 $ are convex. By leveraging the DC structure of r, we can smooth out r by ap plying Moreau envelopes to r_1 and r_2 separately. In line with DC programmi ng, we then redistribute the concave part of the regularizer to the data fidelit y and study its corresponding proximal Langevin algorithm (termed DC-LA). We est ablish convergence of DC-LA to the target distribution π, up to discretizati on and smoothing errors, in the q-Wasserstein distance for all $q \in \mathbb{ N}^*$, under the assumption that V is distant dissipative. Our results improve previous work on non-log-concave sampling in terms of a more general framework and assumptions. Numerical experiments show that DC-LA produces accurate distrib utions in synthetic settings and provides qualitatively reasonable uncertainty q uantification in a real-world Computed Tomography application.

Less Is More in Federated Continual Learning: RieSelect for Conflict-Aware Layer Selection in LLMs
Wenqi Qiu, Yipeng Zhou, Lin Zhu, Laizhong Cui
Federated continual learning (FCL) of large language models on edge devices is c onstrained by a communication--stability--plasticity trilemma. We reveal a less- is-more phenomenon: beyond a moderate layer upload ratio, stability loss offsets saturated plasticity gains, so overall continual performance no longer improves . Moreover, layer-wise conflict is heavy-tailed and concentrates in a few layers ; denser uplink increasingly includes these layers, which disproportionately dri ves forgetting and motivates selective sparse communication. Therefore, we intro duce RieSelect, which treats stability as staying within a Fisher-metric safe ba sin around historical solutions. Under this safe-basin constraint, we derive a l

ayer-wise conflict score and a closed-form certified safe step size for finite l
ocal updates, and formulate selective uplink as a knapsack-based utility--risk s
election, balancing plasticity gains against stability risks. Extensive experime
nts show that, under a per-round uplink budget, RieSelect achieves the best perf
ormance across task orders. Beyond this matched-budget setting, under standard c
ommunication protocols, RieSelect improves average accuracy by 18.99–28.14 point
s while reducing total uplink by 53–115$\times$.

Gradient Testing and Estimation by Comparisons
Xiwen Tao, Chenyi Zhang, Helin Wang, Yexin Zhang, Tongyang Li
We study gradient testing and gradient estimation of smooth functions using only
 a comparison oracle that, given two points, indicates which one has the larger
function value. For any smooth $f:\mathbb R^n\to\mathbb R$, $\mathbf{x}\in\mathb
b R^n$, and $\varepsilon>0$, we design a gradient testing algorithm that determi
nes whether the normalized gradient $\nabla f(\mathbf{x})/\lVert\nabla f(\mathbf
{x})\rVert$ is ε-close or 2ε-far from a given unit vecto
r $\mathbf{v}$ using $O(1)$ queries, as well as a gradient estimation algorithm
that outputs an ε-estimate of $\nabla f(\mathbf{x})/\lVert\nabla f(\
mathbf{x})\rVert$ using $O(n\log(1/\varepsilon))$ queries which we prove to be o
ptimal. Furthermore, we study gradient estimation in the quantum comparison orac
le model where queries can be made in superpositions, and develop a quantum algo
rithm using $O(\log (n/\varepsilon))$ queries.

LabBuilder: Protocol-Grounded 3D Layout Generation for Interactable and Safe Lab
oratory
Jianbao Cao, zhangrui zhao, Bohan Feng, Zixuan Hu, Rui Li, Haiyuan Wan, Chenxi L
i, jingyuan Li, Wenzhe Cai, LEI BAI, Wanli Ouyang, LINGYU DUAN, Di Huang, Mintin
g Pan, Sha Zhang, Xinzhu Ma, SHIXIANG TANG, Dongzhan Zhou
Automated laboratories hold the promise of accelerating scientific discovery, ye
t their deployment is bottlenecked by the difficulty of designing safe and execu
table environments. While simulator-based design offers scalability, existing 3D
 scene generation methods are primarily tailored for household settings, optimiz
ing for visual plausibility while neglecting the protocol grounding and layout-l
evel safety constraints essential for scientific experimentation. We present Lab
Builder, an end-to-end system that generates and verifies 3D laboratory layouts
from concise textual specifications. It operates through three tightly coupled c
omponents: LabForge first curates a meta-dataset of annotated assets and chemica
l knowledge, translating natural language specifications into structured protoco
ls; building on these protocols, LabGen synthesizes laboratory layouts via an it
erative, constraint-aware optimization strategy; finally, LabTouchstone evaluate
s the resulting layouts as a unified benchmark. Extensive experiments demonstrat
e that LabBuilder significantly outperforms existing state-of-the-art methods, p
roducing laboratory environments that are realistic and valid under modeled geom
etric, chemical-safety, and navigation constraints.

OMP: One-step Meanflow Policy with Directional Alignment
Han Fang, Yize Huang, Yuheng Zhao, Paul Weng, Xiao Li, Yutong Ban
Robot manipulation has increasingly adopted data-driven generative policy framew
orks, yet the field faces a persistent trade-off: diffusion models suffer from h
igh inference latency, while flow-based methods often require complex architectu
ral constraints. Although in image generation domain, the MeanFlow paradigm offe
rs a path to single-step inference, its direct application to robotics is impede
d by critical theoretical pathologies, specifically spectral bias and gradient s
tarvation in low-velocity regimes. To overcome these limitations, we propose the
 One-step MeanFlow Policy (OMP), a novel framework designed for high-fidelity, r
eal-time manipulation. We introduce a lightweight directional alignment mechanis
m to explicitly synchronize predicted velocities with true mean velocities. Furt
hermore, we implement a Differential Derivation Equation (DDE) to approximate th
e Jacobian-Vector Product (JVP) operator, which decouples forward and backward p
asses to significantly reduce memory complexity. Extensive experiments on the Ad

roit and Meta-World benchmarks demonstrate that OMP outperforms state-of-the-art methods in success rate and trajectory accuracy, particularly in high-precision tasks, while retaining the efficiency of single-step generation.

Improving Sampling for Masked Diffusion Models via Information Gain
Kaisen Yang, Jayden Teoh, Kaicheng Yang, Yitong Zhang, Alex Lamb
Masked Diffusion Models (MDMs) enable flexible decoding orders, yet existing samplers remain largely greedy, selecting locally certain tokens without accounting for their downstream effects. We show that this myopia can increase cumulative uncertainty and lead to suboptimal generation. To address this, we propose the **Info-Gain Sampler**, a training-free decoding method that uses the bidirectional structure of MDMs to balance immediate uncertainty with the information gained over remaining masked positions. Across reasoning, coding, creative writing, and image generation tasks, Info-Gain Sampler consistently outperforms existing MDM samplers, improving average reasoning accuracy by 2.9--11.6 percentage points and achieving a 62.8% average win rate in creative writing. The code is available at https://github.com/yks23/Information-Gain-Sampler.

LiftQuant: Continuous Bit-Width LLM via Dimensional Lifting and Projection
Liulu He, Xuan Ang Liu, Juntao Liu, Taolue Feng, Ting Lu, Chunsheng Gan, ZHIYV PENG, Yuan Du, Huanrui Yang, Yijiang Liu, Li Du
Existing quantization methods are fundamentally limited by rigid, integer-based bit-widths (e.g., 2, 3-bit), resulting in a "deployment gap" where Large Language Models cannot be optimally fitted to specific memory budgets. To bridge this gap, we introduce LiftQuant, a novel framework that enables continuous bit-width control for true Pareto-optimal deployment. The core innovation is a "lift-then-project" mechanism which approximates low-dimensional weight vectors by projecting a simple 1-bit lattice from a higher-dimensional ``lifted" space. Crucially, the effective bit-width is determined simply by the ratio of the lifted dimension to the original dimension, which allows the bit-width to be tuned quasi-continuous as the dimension is a flexible structural parameter. This projection generates a structured yet non-uniform codebook, capturing the expressive power of Vector Quantization (VQ). While beneficial over VQ, LiftQuant's decoding path relies solely on linear transformations and 1-bit uniform quantizers, retaining hardware-friendly nature. This flexibility is transformative: LiftQuant enables a 70B LLM to be compressed to 2.4 bits to precisely fit a 24GB GPU, where its performance significantly surpasses state-of-the-art 2-bit models fitted on the same device. Our code and ckpt is available at \url{https://github.com/Heliulu/LiftQuant}.

PhaseAlign: Complex Phase Alignment for Stable Open-Vocabulary Semantic Segmentation
Jiankang Wang, Dingding Jia, Shuopeng Zhou, Xuan Wang
Open-Vocabulary Segmentation(OVS) aims to achieve pixel-level semantic recognition from arbitrary text queries. Existing large-scale visual-linguistic models, such as CLIP, perform well in zero-shot generalization, but their image-level training objectives and real-valued cross-modal alignment mix amplitude and phase information, limiting fine-grained segmentation and often causing blurred boundaries and fragmented structures. Inspired by the ability of electromagnetic wave phase to control interference independently of amplitude, we propose PhaseAlign, an OVS framework based on Complex Phase Alignment (CPA). CPA explicitly decouples the magnitude and phase of visual and textual embeddings in the complex domain, refining effective features for stable cross-modal alignment. To further enhance structural awareness, we introduce spatial-aware cross-modal projection, which models local neighborhood relations via multi-scale spatial contrast normalization, and attention-guided affinity modeling, which leverages pre-trained ViT self-attention to propagate category activations, improving boundary clarity and region integrity. Experiments show that PhaseAlign achieves state-of-the-art performance on multiple OVS benchmarks.
****

INT vs. FP: A Comprehensive Study of Fine-Grained Low-bit Quantization Formats
Mengzhao Chen, Meng Wu, Hui Jin, Zhihang Yuan, Jing Liu, Chaoyi Zhang, Yunshui Li, Jie Huang, Jin Ma, Zeyue Xue, Zhiheng Liu, Xingyan Bin, Ping Luo
Modern AI hardware, such as Nvidia's Blackwell architecture, is increasingly embracing low-precision floating-point (FP) formats to handle the pervasive activation outliers in Large Language Models (LLMs). Despite this industry trend, a unified comparison of FP and integer (INT) quantization across varying granularities has been missing, leaving algorithm and hardware co-design without clear guidance. This paper fills that gap by systematically investigating the trade-offs between FP and INT formats. We reveal a critical performance crossover: while FP excels in coarse-grained quantization, INT consistently surpasses it as the quantization block size shrinks. Our comprehensive comparison demonstrates that for popular fine-grained formats like MX (block size 32), MXINT8 and MXINT4 are superior to their FP counterparts in both algorithmic accuracy and hardware efficiency. We also introduce a symmetric clipping method that resolves gradient bias in fine-grained low-bit INT training, enabling nearly lossless performance for MXINT8 training. These findings challenge the current hardware trajectory and advocate for prioritizing fine-grained INT formats in future AI accelerators to achieve a better balance of accuracy, power, and efficiency. Code is available at \url{https://github.com/ChenMnZ/INT_vs_FP}.
****
Object-level Semantic and Spatial Distillation for Open Vocabulary Detection
Zitong Li, Jinzhuo Wu, Fukang Zhao, Xinyue Wang, Jun Chen-CUG, Zhuo Cheng, Dapeng Luo
Recent Open-vocabulary Object Detection (OVD) approaches adapt CLIP through region-level distillation to improve semantic alignment for novel categories. However, the distilled regional features are often used for both classification and localization, enhancing semantic consistency at the expense of spatial fidelity. To resolve this, we propose Object-level Semantic and Spatial Distillation (OSSD), a two-stage framework that explicitly decouples semantic and spatial feature learning. OSSD first distills object-level semantics from CLIP’s global [CLS] embeddings to enhance region discrimination, and then injects fine-grained spatial and structural priors via spatial distillation from a detector trained only on COCO base categories. Furthermore, we propose a Location Quality Estimation Head (LQEH) that predicts class-agnostic localization quality, complementing objectness confidence to improve the novel-object perception. Extensive experiments show that our method achieves 49.2 AP50 on the OV-COCO benchmark. exceeding the best previous result by 3.6\%, On the OV-LVIS benchmark, our method reaches 40.5 mAP on novel categories, outperforming previous state-of-the-art methods.
****
Bridging Functional and Representational Similarity via Usable Information
Antonio Almudévar, Alfonso Ortega
We present a unified framework for quantifying the similarity between representations through the lens of \textit{usable} information, offering a rigorous theoretical and empirical synthesis across three key dimensions. First, addressing functional similarity, we establish a formal link between stitching performance and conditional mutual information. We further reveal that stitching is inherently asymmetric, demonstrating that robust functional comparison necessitates a bidirectional analysis rather than a unidirectional mapping. Second, concerning representational similarity, we find that reconstruction-based metrics and standard tools (e.g., CKA, RSA) act as estimators of usable information under specific constraints. Crucially, we show that similarity is relative to the capacity of the predictive family: representations that appear distinct to a rigid observer may be identical to a more expressive one. Third, we demonstrate that representational similarity is sufficient but not necessary for functional similarity. We unify these concepts through a task-granularity hierarchy: similarity on a complex task guarantees similarity on any coarser derivative, establishing representational similarity as the limit of maximum granularity: input reconstruction.

DNACHUNKER: Learnable Tokenization for DNA Language Models

Taewon Kim, Jihwan Shin, Hyomin Kim, Youngmok Jung, Jonghoon Lee, Won-Chul Lee, Sungsoo Ahn, Insu Han

DNA language models are increasingly used to represent genomic sequence, yet their effectiveness depends critically on how raw nucleotides are converted into model inputs. Unlike natural language, DNA offers no canonical boundaries, making fixed tokenizations a brittle design choice under shifts, indels, and local repeats. We introduce DNAChunker, a masked DNA language model that incorporates a learnable adaptive segmentation module to produce context-dependent, variable-length units. Building on a dynamic segmentation procedure, DNAChunker learns to allocate finer granularity to functionally enriched regions while compressing repetitive or redundant sequence. We pretrain DNAChunker on the human reference genome and evaluate it across five benchmarks, where it consistently improves over strong fixed-tokenization baselines. Further analyses and ablations indicate that unlike fixed tokenizations, segmentation is learned in a biologically-informed, mutation-resilient manner.

Towards Functional Correctness of Large Code Models with Selective Generation

Jaewoo Jeong, Taesoo Kim, Sangdon Park

The hallucination of code generation models hinders their applicability to systems requiring higher safety standards. One critical bottleneck in addressing code hallucination is the difficulty of identifying the functional correctness of generated code, due to its unnatural form. We address this core bottleneck by automatically generating unit tests using dynamic code analysis tools, leveraging the executable nature of code. Accordingly, we propose a selective code generator that abstains from uncertain generations -- based on the functional correctness evaluated by generated unit tests -- to theoretically control the correctness among non-abstained answers, i.e., the false discovery rate. Finally, we propose to use generated unit tests in evaluation as well as in learning for precise code evaluation, calling this paradigm FuzzEval. We demonstrate the efficacy of our method along with the controllability of code hallucination and reasonable selection efficiency.

****

Simultaneous Confidence Bounds for Aggregated Effects via Exact Subset Optimization

Weihang Xu, Huajie Qian, Wotao Yin, Xinshang Wang

We study simultaneous confidence bounds for aggregated effects over downward-closed subset families of independent statistical tests. The bounds are obtained by bootstrap calibration of the maximum normalized aggregated effect over the relevant subset family, yielding valid post-hoc inference for data-selected subsets and tighter bounds than classical methods that protect all linear contrasts. A central challenge is that the required maximization is a nonlinear combinatorial optimization problem. We cast it as a weighted densest-subgraph problem and derive exact linear and mixed integer linear program reformulations, and we further develop a fully polynomial-time approximation scheme that exploits the rank-1 structure of the objective to scale to large families. On the statistical side, we establish a finite-sample coverage guarantee with a lighter dependence on the subset family size than high-dimensional central limit theorems provide. We illustrate the method on synthetic and real machine learning applications.

****

Randomized Feasibility Methods for Constrained Optimization with Adaptive Step Sizes

Abhishek Chakraborty, Angelia Nedich

We consider minimizing an objective function subject to constraints defined by the intersection of lower-level sets of convex functions. We study two cases: (i) strongly convex and Lipschitz-smooth objective function and (ii) convex but possibly nonsmooth objective function. To deal with the constraints that are not easy to project on, we use a randomized feasibility algorithm with Polyak steps and a random number of sampled constraints per iteration, while taking (sub)gradient steps to minimize the objective function. For case (i), we prove linear convergence in expectation of the objective function values to any prescribed toleran

ce using an adaptive stepsize. For case (ii), we develop a fully problem paramet er-free and adaptive stepsize scheme that yields an $O(1/\sqrt{T})$ worst-case r ate in expectation. The infeasibility of the iterates decreases geometrically wi th the number of feasibility updates almost surely, while for the averaged itera tes, we establish an expected lower bound on the function values relative to the optimal value that depends on the distribution for the random number of sampled constraints. For certain choices of sample-size growth, optimal rates are achie ved. Finally, simulations on a Quadratically Constrained Quadratic Programming (QCQP) problem, Support Vector Machines (SVM), and logistic regression with group fairness constraints demonstrate the computational efficiency of our algorithm compared to other state-of-the-art methods.

Order within Chaos: Capturing Intrinsic Energy Anomalies for AI-Manipulated Imag e Forgery Localization

Yiming Wang, Baiqi Wu, Qingming Li, Jiahao Chen, Tong Zhang, Shouling Ji

Recent advancements in generative AI have led to image editing models capable of producing realistic forgeries that evade traditional image forgery localization methods, as these approaches depend on physical noise absent in synthetic data. To address this challenge, we theoretically demonstrate that the diffusion proc ess inherently suppresses local high-frequency variance, creating a statistical energy gap that is distinguishable from the natural entropy of optical imaging. Guided by this insight, we propose FLAME, a unified framework that utilizes a LA D map to capture these intrinsic anomalies, coupled with a parameter-efficient a dapter for SAM to achieve precise, pixel-level forgery localization. Furthermore , to bridge the lag between forensic benchmarks and evolving generative models, we introduce EditStream, an automated pipeline for continuous, instruction-based training data synthesis. Extensive experiments demonstrate that FLAME establish es a new state-of-the-art, significantly outperforming previous methods on AI-ge nerated forgery datasets while effectively generalizing to unseen generative arc hitectures. Our code is available at https://github.com/phoenixnir/FLAME.

LipoPU: Pocket-level Prediction of Lipid-Protein Interactions via Positive-Unlab eled Learning

Yuxing Wang, Wenyi Zhang, Yilong Zou, Jing Huang

Computational identification of lipid-binding proteins is critical for both fund amental research and therapeutic development. Existing models are typically trai ned in a fully supervised manner, treating unlabeled samples as negatives. Howev er, missing evidence does not imply non-binding, leading to systematic false neg atives. Pocket-level lipid-binding prediction also remains underexplored compare d to residue- or sequence-level approaches. To bridge these gaps, we present **L ipoPU**, a pocket-centric predictor that formulates lipid-binding learning under a ranking-based positive-unlabeled objective, and supports both binary lipid-bi nding detection and multi-label lipid category prediction. LipoPU learns an atte ntion-based pocket representation that is robust to ambiguous pocket definitions while providing residue-level interpretability. Experiments show consistent gai ns over supervised baselines and prior pocket-level work, and a structural case study recovers a literature-supported allosteric lipid-binding pocket while high lighting biologically informative residues.

Feature-Aware (Hyper)graph Generation via Next-Scale Prediction
Dorian Gailhard, Enzo Tartaglione, Lirida Naviner, Jhony H. Giraldo
Graph generative models perform well on small structured data but struggle to sc
ale to large, complex structures.
Hierarchical approaches improve scalability but often ignore node and edge featu
res, which are critical in real-world applications, particularly for hypergraphs
 that model higher-order relationships.
In this paper, we propose FAHNES (**f**eature-**a**ware (**h**yper)graph generat
ion via **ne**xt-**s**cale prediction), a hierarchical framework that jointly ge
nerates topology and features for graphs and hypergraphs.
FAHNES builds multi-scale representations through node coarsening and localized
expansion, guided by a novel hierarchical scale encoding that controls granulari
ty and ensures cross-scale consistency.
Experiments on synthetic, 3D mesh, and graph point cloud datasets demonstrate co
mpetitive or state-of-the-art performance while uniquely scaling to featured lar
ge-scale graphs and hypergraphs.
Our code is open source.

Learning Taxonomic Trees with Hierarchical Representation Regularization for Lar
ge Multimodal Models
Hulingxiao He, Zhi Tan, Yuxin Peng
Taxonomies provide key information about the semantic relationships between conc
epts and the inherent organization of vision and language. Despite their impress
ive capabilities, large multimodal models (LMMs) often lack taxonomic knowledge,
 leading to low hierarchical visual recognition (HVR) consistency. These models
typically only rely on language modeling objectives during fine-tuning and lack
explicit taxonomy-aware regularization. To address this, we propose Hierarchical
 Representation Regularization (HiR^2), a simple plug-and-play regularizer tha
t improves hierarchical consistency in LMMs. Specifically, we introduce a semant
ic-aware visual tree construction framework that extracts coarse-to-fine visual
features from intermediate LLM layers guided by textual cues. The regularizer co
mbines two complementary objectives: a taxonomic entailment loss that enforces h
ierarchy via hyperbolic entailment cones in the Lorentz model, and a discriminat
ive dispersive loss that promotes angular separation of semantically similar emb
eddings on the unit sphere without disturbing the radial hierarchical structure.
 Extensive experiments demonstrate that HiR^2 effectively captures taxonomic s
tructures across diverse LMMs and fine-tuning methods. Code is available at http
s://github.com/PKUICST-MIPL/HiR2_ICML2026.

Quantifying Frontier LLM Capabilities for Container Sandbox Escape
Rahul Marchand, Art O Cathain, Jerome Wynne, Philippos Maximos Giavridis, Sam De
verett, John Wilkinson, Jason Gwartz, Harry Coppock
Large language models (LLMs) increasingly act as autonomous agents, using tools
to execute code, read and write files, and access networks, creating novel secur
ity risks. To mitigate these risks, agents are commonly deployed and evaluated i
n isolated "sandbox" environments, often implemented using Docker/OCI containers
. We introduce SandboxEscapeBench, an open benchmark that safely measures an LLM
's capacity to break out of these sandboxes. The benchmark is implemented as an
Inspect AI Capture the Flag (CTF) evaluation utilising a nested sandbox architec
ture with the outer layer containing the flag and no known vulnerabilities. Foll
owing a threat model of a motivated adversarial agent with shell access inside a
 container, SandboxEscapeBench covers a spectrum of sandbox-escape mechanisms sp
anning misconfiguration, privilege allocation mistakes, kernel flaws, and runtim
e/orchestration weaknesses. We find that, when vulnerabilities are added, LLMs a
re able to identify and exploit them, showing that use of evaluation like Sandbo
xEscapeBench is needed to ensure sandboxing continues to provide the encapsulati

on needed for highly-capable models.
****
Structure-Induced Information for Rerooting Levin Tree Search
Jake Tuero, Michael Buro, Laurent Orseau, Levi Lelis
Subgoal-based policy tree search, which uses a policy to guide search, is effective for complex single-agent deterministic problems but often relies on explicit subgoal generation that can incur substantial overhead and hinders scalability. In this paper, we overcome these limitations by using a learned ``rerooter'' through the recently-introduced $\sqrt{\text{LTS}}$ algorithm. A *rerooter* implicitly decomposes the problem into soft subtasks. While previous work focused on the formal guarantees for given or handcrafted rerooters, in this work we propose three rerooter designs:
(i) a clustering-based rerooter that exploits global state-space structure, (ii) a heuristic-based rerooter that leverages learned cost-to-go estimates, and (iii) a hybrid that combines both signals.
Our framework avoids having to explicitly reconstruct and reason over generated subgoals, thereby enabling scalable allocation of search effort with significantly lower computational overhead.
Empirically, our rerooting-based methods scale to complex environments where subgoal-based policy tree search fails, and achieve state-of-the-art online training efficiency on the domains tested.
****
MoSE: Mixture of Slimmable Experts for Efficient and Adaptive Language Models
Nurbek Tastan, Stefanos Laskaridis, Karthik Nandakumar, Samuel Horváth
Mixture-of-Experts (MoE) models scale large language models efficiently by sparsely activating experts, but once an expert is selected, it is executed fully. Hence, the trade-off between accuracy and computation in an MoE model typically exhibits large discontinuities. We propose Mixture of Slimmable Experts (MoSE), an MoE architecture in which each expert has a nested, slimmable structure that can be executed at variable widths. This enables conditional computation not only over which experts are activated but also over how much of each expert is utilized. Consequently, a single pretrained MoSE model can support a more continuous spectrum of accuracy-compute trade-offs at inference time. We present a simple and stable training recipe for slimmable experts under sparse routing, combining multi-width training with standard MoE objectives. During inference, we explore strategies for runtime width determination, including a lightweight test-time training mechanism that learns how to map router confidence/probabilities to expert widths under a fixed budget. Experiments on GPT-style models, various routing regimes, zero-shot downstream reasoning benchmarks, and continual pre-training adaptation of DeepSeek model show that MoSE matches or improves standard MoE at full width and consistently shifts the compute-quality frontier toward lower inference FLOPs. The code can be found at: https://github.com/tnurbek/mose.
****
COFT: Counterfactual–Conformal Decoding for Fair Chain■of■Thought Reasoning in Large Language Models
Arya Fayyazi, Mehdi Kamal, Massoud Pedram
Large language models (LLMs) can reveal and amplify societal biases during chain-of-thought (CoT) generation. We present COFT (Chain of Fair Thought), a training-free decoding method that applies token-level fairness control at decode time, with distribution-free marginal validity guarantees (under exchangeability) for any frozen causal language model.
COFT operates in three stages. First, it creates a masked counterfactual prompt by replacing sensitive spans with neutral tokens. Second, it compares the factual and masked logit distributions through lightweight logit fusion to attenuate attribute-driven biases. Third, it uses dual-branch split-conformal calibration to certify per-step candidate token sets at a user-chosen risk level.
We evaluate COFT across six models and multiple bias benchmarks. Our method reduces standard bias metrics by 30–55\% (median 38\%) while preserving task utility and language quality. Reasoning accuracies remain unchanged within run-to-run noise margins. The computational overhead is modest, equivalent to one additional

cached forward pass (<=11%).
COFT offers a clear, auditable path to safer CoT generation with significant bia
s reduction, negligible utility loss, and no requirement for retraining, auxilia
ry classifiers, or weight access.
****
Efficient Generative Modeling beyond Memoryless Diffusion via Adjoint Schrödinge
r Bridge Matching
Jeongwoo Shin, Jinhwan Sul, Joonseok Lee, Jaewoong Choi, Jaemoo Choi
Diffusion models often yield highly curved trajectories and noisy score targets
due to an uninformative, memoryless forward process that induces independent dat
a-noise coupling. We propose Adjoint Schrödinger Bridge Matching (ASBM), a gener
ative modeling framework that recovers optimal trajectories in high dimensions v
ia two stages. First, we view the Schrödinger Bridge (SB) forward dynamic as a c
oupling construction problem and learn it through a data-to-energy sampling pers
pective that transports data to an energy-defined prior. Then, we learn the back
ward generative dynamic with a simple matching loss supervised by the induced op
timal coupling. By operating in a non-memoryless regime, ASBM produces significa
ntly straighter and more efficient sampling paths. Compared to prior works, ASBM
scales to high-dimensional data with notably improved stability and efficiency.
Extensive experiments on image generation show that ASBM improves fidelity with
fewer sampling steps. We further showcase the effectiveness of our optimal traj
ectory via distillation to a one-step generator.

Float8@2bits: Entropy Coding Enables Data-Free Model Compression
Patrick Putzky, Martin Genzel, Mattes Mollenhauer, Sebastian Schulze, Thomas Wol
lmann, Stefan Dietzel
Post-training compression is currently divided into two contrasting regimes. On
the one hand, fast, data-free, and model-agnostic methods (e.g., NF4 or HQQ) off
er maximum accessibility but suffer from functional collapse at extreme bit-rate
s below 4 bits. On the other hand, techniques leveraging calibration data or ext
ensive recovery training achieve superior fidelity but impose high computational
constraints and face uncertain robustness under data distribution shifts. We in
troduce EntQuant, a framework that unites the advantages of these distinct parad
igms. By matching the performance of data-dependent methods with the speed and u
niversality of data-free techniques, EntQuant enables practical utility in the e
xtreme compression regime. Our method decouples numerical precision from storage
cost via entropy coding, compressing a 70B parameter model in less than 10 minu
tes. We demonstrate that EntQuant does not only achieve state-of-the-art results
on standard evaluation sets and models, but also retains functional performance
on more complex benchmarks with instruction-tuned models, all at modest inferen
ce overhead.

ClinTutor-R1: Advancing Scalable and Robust One-to-Many Alignment in Clinical So
cratic Education
Zhitao He, Haolin Yang, Zeyu Qin, Yi R. Fung
While Large Language Models (LLMs) have achieved remarkable success in dyadic (o
ne-on-one) instruction, they face significant challenges in One-to-Many alignmen
t, such as clinical ward rounds, where an instructor must simultaneously guide a
diverse group of trainees. Current models often suffer from context dilution an
d goal misalignment, failing to balance individual scaffolding with collective l
earning progress. To address this, we introduce ClinEdu, a multi-agent pedagogic
al simulator that model the complexity of group dynamics. Leveraging this platfo
rm, we construct ClinTeach, a large-scale dataset of Socratic teaching dialogues
, and propose ClinTutor-R1, the first multimodal agent explicitly architected to
achieve one-to-many alignment in clinical education, employing an explicit inte
rnal thinking mechanism to model both individual belief states and group consens
us. We validate our framework through a comprehensive protocol covering both sta
ndard static benchmarks and rigorous in-situ interactive evaluation within ClinE
du. Experimental results demonstrate that ClinTutor-R1 outperforms base models b
y over 20% and achieves parity with proprietary reasoning models , while exhibit

ing exceptional scalability in maintaining instructional quality across expandin
g student cohorts.

GenExam: A Multidisciplinary Text-to-Image Exam
Zhaokai Wang, Penghao Yin, Xiangyu Zhao, Changyao Tian, Yu Qiao, Wenhai Wang, Ji
feng Dai, Gen Luo
Exams are a fundamental test of expert-level intelligence and require integrated
 understanding, reasoning, and generation. Existing exam-style benchmarks mainly
 focus on understanding and reasoning tasks, and current generation benchmarks e
mphasize the illustration of world knowledge and visual concepts, neglecting the
 evaluation of rigorous drawing exams. We introduce GenExam, the first benchmark
 for multidisciplinary text-to-image exams, featuring 1,000 samples across 10 su
bjects with exam-style prompts organized under a four-level taxonomy. Each probl
em is equipped with ground-truth images and fine-grained scoring points to enabl
e a precise evaluation of semantic correctness and visual plausibility. Experime
nts on 17 text-to-image and unified models demonstrate the great challenge of Ge
nExam and the huge gap where open-source models consistently lag behind the lead
ing closed-source ones. By framing image generation as an exam, GenExam offers a
 rigorous assessment of models' ability to integrate understanding, reasoning, a
nd generation, providing insights on the path to intelligent generative models.
Our benchmark and evaluation code will be released.

Directional Neural Collapse Explains Few-Shot Transfer in Self-Supervised Learni
ng
Achleshwar Luthra, Yash Salunkhe, Tomer Galanti
Frozen self-supervised representations often transfer well with only a few label
s across many semantic tasks. We argue that a single geometric quantity, *direct
ional* CDNV (decision-axis variance), sits at the core of two favorable behavior
s: strong few-shot transfer within a task, and low interference across many task
s. We show that both emerge when variability *along* class-separating directions
 is small. First, we prove sharp non-asymptotic multiclass generalization bounds
 for downstream classification whose leading term is the directional CDNV. The b
ounds include finite-shot corrections that cleanly separate intrinsic decision-a
xis variability from centroid-estimation error. Second, we link decision-axis co
llapse to multitask geometry: for independent balanced labelings, small directio
nal CDNV across tasks forces the corresponding decision axes to be nearly orthog
onal, helping a single representation support many tasks with minimal interferen
ce. Empirically, across SSL objectives, directional CDNV collapses during pretra
ining even when classical CDNV remains large, and our bounds closely track few-s
hot error at practical shot sizes. Additionally, on synthetic multitask data, we
 verify that SSL learns representations whose induced decision axes are nearly o
rthogonal.

Learning to Route Languages for Multilingual Policy Optimization
Geyang Guo, Hiromi Wakaki, Yuki Mitsufuji, Alan Ritter, Wei Xu
Large language models~(LLMs) are trained on heterogeneous multilingual corpora,
yet existing policy optimization methods often implicitly restrict each training
 question to a single response language or rely on a fixed dominant language for
 supervision.
We propose language-routed policy optimization (LRPO), an online reinforcement l
earning framework that treats language as a selectable variable.
LRPO elicits multilingual rollouts for each training question and integrates the
ir relative quality into preference-based policy updates, increasing the diversi
ty and informativeness of training signals under the fixed rollout budget.
To adaptively determine which languages to explore during reinforcement learning
, we introduce a trainable language router formulated as a multi-armed bandit, b
alancing exploration of underutilized languages with exploitation of more inform
ative ones.
Extensive experiments show that LRPO consistently improves multilingual performa
nce, demonstrating that adaptive language routing enables effective cross-lingua

l knowledge exploitation for training.
We release all the resources at \url{https://github.com/Guochry/LRPO}.

SLQ: Bridging Modalities via Shared Latent Queries for Retrieval with Frozen MLLMs
Haoran Lou, Ziyan Liu, Chunxiao Fan, Yuexin Wu, Yue Ming, Hao Wu, Kai Zuo, Yibo Chen, Xu Tang
Multimodal Large Language Models (MLLMs) possess intrinsic reasoning and world-knowledge capabilities, yet adapting them for dense retrieval remains challenging. Existing approaches rely on invasive parameter updates, such as full fine-tuning and LoRA, which may disrupt the pre-trained semantic space and impair the structured knowledge essential for reasoning. To address this, we propose **SLQ**, a parameter-efficient tuning framework that adapts MLLMs for retrieval while keeping the backbone entirely frozen. SLQ introduces a small set of **Shared Latent Queries** that are appended to both text and image tokens, leveraging the model's native causal attention to aggregate multimodal context into a unified embedding space. Furthermore, to better evaluate retrieval beyond superficial pattern matching, we construct **KARR-Bench**, a benchmark designed for knowledge-aware reasoning retrieval. Extensive experiments show that SLQ outperforms full fine-tuning and LoRA on COCO and Flickr30K, while achieving competitive performance on MMEB and yielding substantial gains on KARR-Bench, validating that preserving the pre-trained representations via non-invasive adaptation is an effective strategy for MLLM-based retrieval. The code is available under: https://github.com/CnFaker/SLQ.

SpecPL: Disentangling Spectral Granularity for Prompt Learning
Jingtao Zhou, Xirui Kang, feiyang huang, Lai Man Po
Existing prompt learning for VLMs exhibits a modality asymmetry, predominantly optimizing text tokens while still relying on frozen visual encoder as holistic extractor and neglecting the spectral granularity essential for fine-grained discrimination. To bridge this, we introduce Disentangling Spectral Granularity for Prompt Learning (SpecPL), which approaches prompt learning from a novel spectral perspective via Counterfactual Granule Supervision. Specifically, we leverage a frozen VAE to decompose visual signals into semantic low-frequency bands and granular high-frequency details. A frozen Visual Semantic Bank anchors text representations to universal low-frequency invariants, mitigating overfitting. Crucially, fine-grained discrimination is driven by counterfactual granule training: by permuting high-frequency signals, we compel the model to explicitly distinguish visual granularity from semantic invariance. Uniquely, SpecPL serves as a universal plug-and-play booster, revitalizing text-oriented baselines like CoOp and MaPLe via visual-side guidance. Experiments on 11 benchmarks demonstrate competitive state-of-the-art performance, achieving a new performance ceiling of 81.51\% harmonic-mean accuracy. These results validate that spectral disentanglement with counterfactual supervision effectively bridges the gap in the stability-generalization trade-off.

LUCID: Attention with Preconditioned Representations
Sai Surya Duvvuri, Nirmal Patel, Nilesh Gupta, Inderjit S Dhillon
Softmax-based dot-product attention is a cornerstone of Transformer architectures, enabling remarkable capabilities such as in-context learning. However, as context lengths increase, a fundamental limitation of the softmax function emerges: it tends to diffuse probability mass to irrelevant tokens degrading performance in long-sequence scenarios. Furthermore, attempts to sharpen focus by lowering softmax temperature hinder learnability due to vanishing gradients. We introduce LUCID Attention, an architectural modification that applies a preconditioner to the attention probabilities. This preconditioner, derived from exponentiated key-key similarities, minimizes overlap between the keys in a Reproducing Kernel Hilbert Space, thus allowing the query to focus on important keys among large number of keys accurately with same computational complexity as standard attention. Additionally, LUCID's preconditioning-based approach to retrieval bypasses the

need for low temperature and the learnability problems associated with it. We va
lidate our approach by training $\sim$1 billion parameter language models evalua
ted on up to 128K tokens. Our results demonstrate significant gains on long-cont
ext retrieval tasks, specifically retrieval tasks from BABILong, RULER, SCROLLS
and LongBench. For instance, LUCID achieves up to 18\% improvement in BABILong a
nd 14\% improvement in RULER multi-needle performance compared to standard atten
tion.

Broadening the Backdoor Basin: Understanding LLM Backdoors Collapse and Making B
ackdoors Persistent

Xingyi Zhao, Tian Xie, Xiaojun Qi, Depeng Xu, Shuhan Yuan

Large Language Models (LLMs) are vulnerable to backdoor attacks, yet we observe
that many LLM backdoors do not survive when end users perform supervised fine-tu
ning (SFT). In this work, we provide a geometric explanation: by probing the bac
kdoor objective under controlled weight perturbations, we find that conventional
 poisoning often drives the backdoor loss to a narrow and sharp basin; consequen
tly, even modest parameter drift induced by downstream SFT can push the model ou
t of the low-loss and high-ASR region, leading to rapid backdoor forgetting. Mot
ivated by this insight, we propose BAD-BOOM, a resilient backdoor attack via bro
ader smoothness minimization, which explicitly broadens and smooths the backdoor
 basin. BAD-BOOM extends sharpness-aware minimization with a Fisher-induced elli
psoidal constraint that allocates larger perturbation budgets to backdoor-sensit
ive parameters, encouraging solutions whose neighborhoods also maintain low back
door loss. Across two threat settings, three attack scenarios, three open-source
 LLMs, and three trigger-free downstream SFT tasks, BAD-BOOM consistently preser
ves high ASR while maintaining competitive utility. The code is available at htt
ps://github.com/xingyizhao/BAD-BOOM.

The Shape of Addition: Geometric Structures of Arithmetic in Large Language Mode
ls

Liuyuan Wen, Xun Zhu, Lihao Huang, Wenbin Li, Yang Gao

Large Language Models exhibit paradoxical fragility in fundamental arithmetic, i
mplying a disconnect between internal computation and discrete output. By analyz
ing the residual stream geometry during multi-operand addition, we identify the
Iso-Raw-Sum Trajectory (IRST), a topological manifold where representations
are anchored by semantic digits and modulated by continuous carry fibers. We pro
pose the **Noisy Quantization Model**, which frames arithmetic errors as *topolo
gical slippages* caused by internal neural noise pushing a continuous, latent *c
arry potential* across quantization thresholds. This geometric framework further
 elucidates *probe versatility*, explaining how lightweight probes can disentang
le conflicting latent signals (such as ground truth versus hallucination) from a
 single activation vector. Finally, we validate these insights through a geometr
ic consistency check method that effectively detects and corrects these quantiza
tion failures during inference.

From Drift to Coherence: Stabilizing Beliefs in LLMs

SongEun Kim, Seungyoo Lee, Edwin Fong, Hyungi Lee, Juho Lee

Large language models (LLMs) are often hypothesized to perform implicit Bayesian
 inference, yet a key coherence condition—the martingale property of predictive
beliefs—has been shown to fail in controlled synthetic in-context learning setti
ngs. We revisit this question in a more typical usage regime: generic multiple-c
hoice question answering. Exploiting the discrete answer space, we compute exact
 predictive distributions and study belief dynamics induced by autoregressive an
swer resampling. We introduce prompted predictive resampling (PPR), where an LLM
 generates a sequence of answers to the same question. Empirically, PPR reveals
early-stage belief drift, indicating martingale violations. However, after suffi
cient resampling steps, the belief process self-stabilizes and converges to a co
herent predictive distribution. Based on this observation, we further propose (i
) a seed-answer prompting strategy to accelerate stabilization, and (ii) a self-
consistency loss that amortizes early-stage drift into the model via fine-tuning

. Experiments on multiple-choice QA benchmarks show that our methods substantial
ly reduce belief drift and improve predictive coherence without sacrificing accu
racy.

One-shot Entropy Minimization for Language Model Reasoning
Zitian Gao, Yilong Chen, Haoming Luo, Joey Zhou, Bryan Dai
In this work, we propose One-shot Entropy Minimization (EM), a simple and fully
unsupervised post-training approach that significantly improves reasoning and ge
neration performance using only a single unlabeled data and approximately ten gr
adient steps. To avoid data contamination, we pretrain a 7-billion-parameter lan
guage model from scratch with strictly decontaminated data. Despite its extreme
simplicity, one-shot EM yields substantial performance gains and improves reason
ing abilities across a broad range of domains, including mathematical reasoning,
 logical reasoning, and coding. We further show that entropy minimization induce
s a characteristic right-skewed logit shift, amplifying high-probability tokens
while suppressing low-probability tails, in contrast to reinforcement learning.
Our findings suggest that entropy minimization primarily acts as a distribution
shaping mechanism rather than a conventional learning process, offering an effic
ient and practical algorithm for post-training large language models.

Safe Reinforcement Learning with Preference-based Constraint Inference
Chenglin Li, Grant Ruan, Hua Geng
Safe reinforcement learning (RL) is a standard paradigm for safety-critical deci
sion making. However, real-world safety constraints can be complex, subjective,
and even hard to explicitly specify. Existing works on constraint inference rely
 on restrictive assumptions or extensive expert demonstrations, which are not re
alistic in many real-world applications. How to cheaply and reliably learn these
 constraints is the major challenge we focus on in this study. While inferring c
onstraints from human preferences offers a data-efficient alternative, we identi
fy popular Bradley-Terry (BT) models fail to capture the asymmetric, heavy-taile
d nature of safety costs, resulting in risk underestimation. It is still rare in
 the literature to understand the impacts of BT models on the downstream policy
learning. To address the above knowledge gaps, we propose a novel approach namel
y Preference-based Constrained Reinforcement Learning (PbCRL). We introduce a no
vel dead zone mechanism into preference modeling and theoretically prove that it
 encourages heavy-tailed cost distributions, thereby achieving better constraint
 alignment. Additionally, we incorporate a Signal-to-Noise Ratio (SNR) loss to e
ncourage exploration by cost variances, which is found to benefit policy learnin
g. Further, two-stage training strategy is deployed to lower online labeling bur
dens while adaptively enhancing constraint satisfaction. Empirical results demon
strate that PbCRL achieves superior alignment with true safety requirements and
outperforms state-of-the-art baselines in terms of safety and reward. Our work e
xplores a promising and effective way for constraint inference in Safe RL, with
great potential in various safety-critical applications.

M-Star: Markovian Projection of Star-Shaped Diffusion for Exponential Family Dis
tributions
François Bertholom, Khalid Oublal
Diffusion models achieve state-of-the-art performance in generative modeling but
 are limited by their reliance on Gaussian noise and the high computational cost
 of iterative sampling. Star-shaped diffusion addresses the former by introducin
g a non-Markovian forward process, yet this comes at the expense of temporal coh
erence in the reverse process. We propose a novel framework that resolves this t
rade-off by learning a Markovian projection of a star-shaped forward process, an
d its reversal. This design enables learning over a broad class of exponential m
odels and recovers DDPM as a special case. It is particularly well-suited for kn
owledge distillation, allowing few-step or even single-step generation. Experime
nts demonstrate the effectiveness and flexibility of our approach across multipl
e generative tasks. Code and demo are available at: https://oublalkhalid.github.
io/MStar-Diffusion/.

Unsupervised Partner Design Enables Robust Ad-hoc Teamwork
Constantin Ruhdorfer, Matteo Bortoletto, Victor Oei, Anna Penzkofer, Andreas Bulling
We introduce Unsupervised Partner Design (UPD), a population-free multi-agent reinforcement learning method for robust ad-hoc teamwork.
UPD generates training partners on-the-fly and selects them adaptively based on a learnability criterion, removing the need for pre-trained partner populations or manual parameter tuning.
We show that this simple mechanism enables effective partner diversity and can be extended to joint partner-environment selection when a procedural level generator is available.
Across Level-Based Foraging, Overcooked-AI, and the Overcooked Generalisation Challenge, UPD consistently achieves strong performance compared to both population-based and population-free baselines.
In a human-AI user study, agents trained with UPD achieve higher returns and are rated as more adaptive, more human-like, and less frustrating than all evaluated baseline methods.
****
Disentangling Consensus and Value-Specific Representations for Controllable Pluralistic Value Alignment of LLMs
JianKui Zhou, Jing Yao, Xiaoyuan Yi, Peng Zhang, Ning Gu, Zhan Hu, Xing Xie, Tun Lu
With the widespread deployment of large language models (LLMs), aligning model outputs with pluralistic human values has become an important research problem. Recent approaches that train task-specific experts and merge them through parameter aggregation have shown promise for pluralistic alignment. However, these methods often overlook the intrinsic complexity of real-world value data, where multiple correlated value dimensions coexist, resulting in highly similar and entangled expert representations. Consequently, modifying the contribution of one value expert may unintentionally influence other values, limiting fine-grained controllability.
To address this issue, we propose DisAlign, a model-merging framework that explicitly decomposes value representations into consensus and value-specific components using an information-geometric perspective. DisAlign first extracts a consensus anchor and subspace to capture shared structure across values, and then applies spectral decomposition to the residual representations to construct disentangled value subspaces. This design enables more precise and independent modulation of multiple values.
Experiments on three datasets covering different value frameworks demonstrate that DisAlign consistently improves value disentanglement and achieves more accurate pluralistic value control compared to existing baselines.
Our code is available at \url{https://anonymous.4open.science/r/DisAlign-7F35}

Computational Arbitrage in AI Model Markets
Ricardo Olmedo, Bernhard Schölkopf, Moritz Hardt
Consider a market of competing model providers selling query access to models with varying costs and capabilities. Customers submit problem instances and are willing to pay up to a budget for a verifiable solution. An arbitrageur efficiently allocates inference budget across providers to undercut the market, thus creating a competitive offering with no model-development risk. In this work, we initiate the study of arbitrage in AI model markets, empirically demonstrating the viability of arbitrage and illustrating its economic consequences. We conduct an in-depth case study of SWE-bench GitHub issue resolution using two representative models, GPT-5 mini and DeepSeek v3.2. In this verifiable domain, simple arbitrage strategies generate net profit margins of up to 40\%. Robust arbitrage strategies that generalize across different domains remain profitable. Distillation further creates strong arbitrage opportunities, potentially at the expense of the teacher model’s revenue. Multiple competing arbitrageurs drive down consumer prices, reducing the marginal revenue of model providers. At the same time, arbitr

age reduces market segmentation and facilitates market entry for smaller model p
roviders by enabling earlier revenue capture. Our results suggest that arbitrage
 can be a powerful force in AI model markets with implications for model develop
ment, distillation, and deployment.

BALLAST: Bayesian Active Learning with Look-ahead Amendment for Sea-drifter Traj
ectories under Spatio-Temporal Vector Fields
Rui-Yang Zhang, Lachlan Astfalck, Edward Cripps, David S. Leslie, Henry Moss
We introduce a formal active learning methodology for guiding the placement of L
agrangian observers to infer time-dependent vector fields -- a key task in ocean
ography, marine science, and ocean engineering -- using a physics-informed spati
o-temporal Gaussian process surrogate model. The majority of existing placement
 campaigns either follow standard `space-filling' designs or relatively ad-hoc ex
pert opinions. A key challenge to applying principled active learning in this se
tting is that Lagrangian observers are continuously advected through the vector
field, so they make measurements at different locations and times. It is, theref
ore, important to consider the likely future trajectories of placed observers to
 account for the utility of candidate placement locations. To this end, we prese
nt BALLAST: Bayesian Active Learning with Look-ahead Amendment for Sea-drifter T
rajectories. We observe noticeable benefits of BALLAST-aided sequential observer
 placement strategies on both synthetic and high-fidelity ocean current models.
In addition, we developed a novel GP inference method -- the Vanilla SPDE Exchan
ge (VaSE) -- to boost the GP posterior sampling efficiency, which is also of ind
ependent interest.

Explicitly Modeling Censoring Produces Superior Survival Predictors
Shi-ang Qi, Yakun Yu, Russell Greiner
Likelihood-based training is the dominant paradigm in survival prediction. Under
 independent censoring, we can factorize the likelihood and optimize only the te
rms related to event modeling, effectively treating the censoring mechanism as i
ncidental. This is justified when censoring is *non-informative*, i.e., when the
 censoring process shares no parameters with the event-time model. However, this
 may not hold in practice, and ignoring censoring contributions may discard usef
ul signals for learning representations that can help to effectively estimate ev
ent distributions. Motivated by this, we argue that explicitly modeling censorin
g can improve representation learning and time-to-event estimation, particularly
 when event and censoring processes are coupled. We introduce a latent decomposi
tion view in which observed covariates are mapped to latent components correspon
ding to event-specific, censoring-specific, confounding, and irrelevant informat
ion. We then learn decomposed representations for the first three categories to
guide a better estimation of the event distribution. We instantiate our method o
n 4 popular deep-learning survival models and evaluate on 10 datasets (2 semi-sy
nthetic and 8 real-world), showing consistent gains over strong baselines and mu
ltiple SOTA methods.

Pull Requests as a Training Signal for Repo-Level Code Editing
Qinglin Zhu, Tianyu Chen, Shuai Lu, Lei Ji, Runcong Zhao, Murong Ma, Xiangxiang
Dai, Yulan He, Lin Gui, Peng CHENG, Yeyun Gong
Repository-level code editing requires models to understand complex dependencies
 and execute precise multi-file modifications across a large codebase. While rec
ent gains on SWE-bench rely heavily on complex agent scaffolding, it remains unc
lear how much of this capability can be internalised via high-quality training s
ignals. To address this, we propose Clean Pull Request (Clean-PR), a mid-trainin
g paradigm that leverages real-world GitHub pull requests as a training signal f
or repository-level editing. We introduce a scalable pipeline that converts nois
y pull request diffs into Search/Replace edit blocks through reconstruction and
validation, resulting in the largest publicly available corpus of 2 million pull
 requests spanning 12 programming languages. Using this training signal, we perf
orm a mid-training stage followed by an agentless-aligned supervised fine-tuning
 process with error-driven data augmentation. On SWE-bench, our model significan

tly outperforms the instruction-tuned baseline, achieving absolute improvements of 13.6% on SWE-bench Lite and 12.3% on SWE-bench Verified. These results demonstrate that repository-level code understanding and editing capabilities can be effectively internalised into model weights under a simplified, agentless protocol, without relying on heavy inference-time scaffolding.

Shift-Dependent Asymmetry: Orthogonal Inverse Low-Rank Adaptation for Federated Medical Segmentation

Xingyue Zhao, Wenke Huang, Linghao Zhuang, Haoran Wu, Anwen Jiang, Zhifeng Wang, Wenwen He, Ming Feng, Mang Ye, Bo XU

Low-Rank Adaptation (LoRA) enables efficient federated fine-tuning of segmentation foundation models for medical imaging. However, most federated LoRA methods adopt a uniform aggregation rule, which breaks under the encoder–decoder asymmetry in medical segmentation: the encoder is dominated by appearance shifts, while the decoder is dominated by supervision variations. This mismatch entangles shared anatomy with site-specific biases and harms generalization. To address this, we propose Inverse Asymmetric Tuning (IAT). IAT aligns adaptation with heterogeneity sources by personalizing module-specific components in the encoder to absorb appearance shifts and in the decoder to accommodate site-dependent supervision, while retaining a shared pathway for transferable consensus. However, structural separation alone is insufficient under LoRA’s bilinear parameterization, where multiplicative coupling can still cause site-specific updates to leak into the shared direction. We therefore introduce a Subspace Orthogonality Regularizer that penalizes shared–local collinearity in the effective update space, mitigating leakage without extra communication. Experiments show consistent improvements over strong federated LoRA and parameter-efficient FL baselines.
****

MetaOthello: A Controlled Study of Multiple World Models in Transformers

Aviral Chawla, Galen Hall, Juniper L Lovato

Foundation models must handle multiple generative processes, yet mechanistic interpretability largely studies capabilities in isolation; it remains unclear how a single transformer organizes multiple, potentially conflicting "world models". Previous experiments on Othello-playing neural networks test world-model learning, but focus on a single game with a single set of rules. We introduce *MetaOthello*, a controlled suite of Othello-like games with shared syntax but different rules or tokenizations, and train small GPTs on mixed-variant data. We show that transformers trained on multiple Othello variants learn **shared world-state representations**: linear probes trained on one game intervene on another's board state nearly as well as matched probes. When the games conflict, the model resolves the resulting *ambiguity* through a localized mechanism we identify and steer. For isomorphic games with token remapping, representations are equivalent up to a single orthogonal rotation that generalizes across layers, showing the shared structure is abstract rather than tied to surface form. Together, these results show that transformers reconcile conflicting world models by sharing structure and localizing conflict. *MetaOthello* thus offers a path toward understanding how transformers organize many world models at once.

CausalProfiler: Generating Synthetic Benchmarks for Rigorous and Transparent Evaluation of Causal Machine Learning

Panayiotis Panayiotou, Audrey Poinsot, Alessandro Leite, Nicolas CHESNEAU, Marc Schoenauer, Özgür ■im■ek

Causal machine learning aims to answer "what if" questions using machine learning algorithms, making it a promising tool for high-stakes decision-making. Yet, empirical evaluation practices remain limited. Existing benchmarks often rely on a handful of hand-crafted or semi-synthetic datasets, leading to brittle, non-generalizable conclusions. To bridge this gap, we introduce CausalProfiler, a synthetic benchmark generator for causal machine learning methods. Based on a set of explicit design choices about the class of causal models, queries, and data considered, CausalProfiler randomly samples causal models, data, queries, and ground truths constituting the synthetic causal benchmarks. In this way, causal machi

ne learning can be rigorously and transparently evaluated under a variety of con ditions. This work offers the first random generator of synthetic causal benchma rks with coverage guarantees and transparent assumptions operating on the three levels of causal reasoning: observation, intervention, and counterfactual. We de monstrate its utility by evaluating several state-of-the-art methods under diver se conditions and assumptions, both in and out of the identification regime, ill ustrating the types of analyses and insights CausalProfiler enables.
****
VideoSEG-O3: A Multi-turn Reinforcement Learning Framework for Reasoning Video O bject Segmentation
Ming Dai, Sen Yang, Boqiang Duan, Boyuan Tong, Jiedong Zhuang, Wankou Yang, Jing dong Wang
Reasoning Video Object Segmentation (RVOS) demands a sophisticated integration o f temporal dynamics, spatial details, and linguistic reasoning to achieve precis e pixel-level localization. Existing methods are limited to reasoning over fixed initial inputs and lack the capacity to actively acquire further visual evidenc e, which is often essential for resolving complex references in long or intricat e videos. To address this, we propose $\textbf{VideoSEG-O3}$, the first multi-tu rn reinforcement learning framework for RVOS that emulates the human $\textit{`` coarse-to-fine''}$ cognitive process. It employs a $\textit{multi-turn temporal-spatial chain-of-thought}$ to capture fine-grained details by iteratively pinpoi nting critical intervals and keyframes. Additionally, to enable the policy to pe rceive segmentation quality beyond mere text probability of $\texttt{[SEG]}$ dur ing the RL stage, we introduce $\textit{SEG-aware logit calibration}$, which int egrates pixel-wise segmentation feedback directly into the token-level logits. F urthermore, we design a $\textit{decoupled thinking trace}$ to hierarchically de compose the reasoning process into temporal, spatial, and linguistic dimensions, and construct $\textbf{VTS-CoT}$, a specialized cold-start dataset featuring co mprehensive reasoning trajectories. Extensive experiments demonstrate that Video SEG-O3 achieves advanced performance across 8 mainstream RVOS benchmarks, partic ularly excelling in long-horizon and complex reasoning tasks.
****
StepCodeReasoner: Aligning Code Reasoning with Stepwise Execution Traces via Rei nforcement Learning
Hao Wang, Lei Sha, Jie M. Zhang
Existing code reasoning methods primarily supervise final code outputs, ignoring intermediate states, often leading to reward hacking where correct answers are obtained through inconsistent reasoning. We propose StepCodeReasoner, a framewor k that introduces explicit intermediate execution-state supervision. By automati cally inserting structured print-based execution-trace anchors into code, the mo del is trained to predict runtime states at each step, transforming code reasoni ng into a verifiable, stepwise execution modeling problem.
Building on this execution-aware method, we introduce Dual-Granularity GRPO (DG-GRPO), a reinforcement learning algorithm for structured credit assignment at tw o complementary granularities: inter-trajectory comparison across sampled execut ion paths and intra-trajectory shaping based on downstream correctness.
Extensive experiments demonstrate that StepCodeReasoner achieves state-of-the-ar t performance in code reasoning.
In particular, our 7B model achieves 91.1\% on CRUXEval and 86.5\% on LiveCodeBe nch, outperforming the CodeReasoner-7B baseline (86.0\% and 77.7\%) and GPT-4o (85.6\% and 75.1\%). Furthermore, on the execution-trace benchmark REval, our mod el scores 82.9\%, outperforming baseline CodeReasoner-7B (72.3\%), its 14B count erpart (81.1\%), and GPT-4o (77.3\%).
In addition, StepCodeReasoner improves code generation, achieving 90.1 on HumanE val, 85.0 on MBPP, and 19.4 on LiveCodeBench generation, with an average score o f 64.8 versus 62.6 for CodeReasoner-7B.

Optimality of FSQ Tokens for Continuous Diffusion for Categorical Data with Appl ication to Text-to-Speech

Vadim Popov, Wenju Gu, Tasnima Sadekova, Georgii Aparin, Assel Yermekova

Continuous diffusion for categorical data is a framework belonging to the diffus ion family and aiming at generating discrete data. The scientific interest to su ch models has been constantly increasing these days because researchers try to a chieve a challenging goal of finding reasonable alternatives to autoregressive l arge language models. In this paper, we study the properties of the structure of the latent space corresponding to discrete tokens expressed in terms of Kullbac k-Leibler divergence on diffusion path measures and accuracy of the correct toke n prediction by the optimally trained diffusion model. We find that FSQ tokeniza tion scheme has the latent space structure with the properties that make it best suited for continuous diffusion for categorical data as verified through rigoro us theoretical analysis and numerical experiments. To validate our findings in r eal-life scenario, we train several text-to-speech diffusion models having speec h tokens as intermediate acoustic features, and show that the one based on FSQ t okens indeed performs the best, and, moreover, it outperforms its strong LLM-bas ed counterpart, at the same time being significantly smaller and faster.

TriAttention: Efficient Long Reasoning with Trigonometric KV Compression

Weian Mao, Xi Lin, Wei Huang, Yuxin Xie, Tianfu Fu, Bohan Zhuang, Song Han, Yuka ng Chen

Extended reasoning in large language models (LLMs) requires long and accurate de coding and creates severe KV cache memory bottlenecks. Leading KV cache compress ion methods estimate KV importance using attention scores from recent post-RoPE queries. However, queries rotate with position during RoPE, making representativ e queries very few, leading to poor top-key selection and unstable reasoning. To avoid this issue, we turn to the pre-RoPE space, where we observe that Q and K vectors are highly concentrated around fixed non-zero centers and remain stable across positions—*Q/K concentration*. We show that this concentration causes que ries to preferentially attend to keys at specific distances (e.g., nearest keys) , with the centers determining which distances are preferred via a trigonometric series. Based on this, we propose TriAttention to estimate key importance by le veraging these centers. Via the trigonometric series, we use the distance prefer ence characterized by these centers to score keys according to their positions, and also leverage Q/K norms as an additional signal for importance estimation. O n AIME25 with 32K-token generation, TriAttention matches Full Attention reasonin g accuracy while achieving 2.5× higher throughput or 10.7× KV memory reduction, whereas leading baselines achieve only about half the accuracy at the same effic iency.

Language Bias in LVLMs: From In-Depth Analysis to Simple and Effective Mitigatio n

Yangneng Chen, Jing Li

Large Vision-Language Models (LVLMs) extend large language models with visual un

derstanding, but remain vulnerable to hallucination, where outputs are fluent ye
t inconsistent with images. Recent studies link this issue to language bias—the
tendency of LVLMs to over-rely on text while neglecting visual inputs. Yet most
analyses remain empirical without uncovering its underlying cause. In this paper
, we provide a systematic study of language bias and identify its root in modali
ty misalignment during training. Our analysis shows that both Visual Instruction
 Tuning (VIT) and Direct Preference Optimization (DPO) often prioritize textual
improvements, which may cause LVLMs to overly lean toward language modeling rath
er than balanced multimodal understanding. To address this, we propose two simpl
e yet effective methods: Language Bias Regularization (LBR), which mitigates lan
guage bias through regularization during instruction tuning, and Language Bias P
enalty (LBP), which penalizes language bias in the DPO training process. Extensi
ve experiments across diverse models and benchmarks demonstrate the effectivenes
s of our approach. LBR consistently improves performance on over ten general ben
chmarks, while LBP significantly reduces hallucination and improves trustworthin
ess. Together, these methods not only mitigate language bias but also advance th
e overall alignment of LVLMs, all without introducing any additional data or aux
iliary models. Our code is publicly available at [https://github.com/lab-klc/HAV
AE](https://github.com/lab-klc/HAVAE).

HECTOR: Hybrid Editable Compositional Object References for Video Generation
Guofeng Zhang, Angtian Wang, Jacob Zhiyuan Fang, Liming Jiang, Haotian Yang, Ala
n Yuille, Chongyang Ma
Real-world videos naturally portray complex interactions among distinct physical
 objects, effectively forming dynamic compositions of visual elements. However,
most current video generation models synthesize scenes holistically and therefor
e lack mechanisms for explicit compositional manipulation. To address this limit
ation, we propose HECTOR, a generative pipeline that enables fine-grained compos
itional control. In contrast to prior methods, HECTOR supports hybrid reference
conditioning, allowing generation to be simultaneously guided by static images a
nd/or dynamic videos. Moreover, users can explicitly specify the trajectory of e
ach referenced element, precisely controlling its location, scale, and speed (se
e Figure1). This design allows the model to synthesize coherent videos that sati
sfy complex spatiotemporal constraints while preserving high-fidelity adherence
to references. Extensive experiments demonstrate that HECTOR achieves superior v
isual quality, stronger reference preservation, and improved motion controllabil
ity compared with existing approaches.

You Can Learn Tokenization End-to-End with Reinforcement Learning
Sam Dauncey, Roger Wattenhofer
Tokenization is a hardcoded compression step which remains in the training pipel
ine of Large Language Models (LLMs), despite a general trend towards architectur
es becoming increasingly end-to-end. Prior work has shown promising results at s
cale in bringing this compression step inside the LLMs' architecture with heuris
tics to draw token boundaries, and also attempts to learn these token boundaries
 with straight-through estimates, which treat the problem of drawing discrete to
ken boundaries as a continuous one. We show that these token boundaries can inst
ead be learned using score function estimates, which have tighter theoretical gu
arantees due to directly optimizing the problem of drawing discrete token bounda
ries to minimize loss. We observe that techniques from reinforcement learning, s
uch as time discounting, are necessary to reduce the variance of this score func
tion sufficiently to make it practicable. We demonstrate that the resultant meth
od outperforms prior proposed straight-through estimates, both qualitatively and
 quantitatively at the 100 million parameter scale.
****

SWE-fficiency: Can Language Models Optimize Real-World Repositories on Real Work
loads?
Jeffrey Jian Ma, Milad Hashemi, Amir Yazdanbakhsh, Kevin Swersky, Ofir Press, En
hui Li, Vijay Janapa Reddi, Parthasarathy Ranganathan
Optimizing the performance of large-scale software repositories demands expertis

e in code reasoning and software engineering (SWE) to reduce runtime while prese
rving program correctness. However, most benchmarks emphasize what to fix rather
 than how to fix code. We introduce SWE-fficiency, a benchmark for evaluating re
pository-level performance optimization on real workloads. Our suite contains 49
8 tasks across nine widely used data-science, machine-learning, and HPC reposito
ries (e.g., numpy, pandas, scipy): given a complete codebase and a slow workload
, an agent must investigate code semantics, localize bottlenecks and relevant te
sts, and produce a patch that matches or exceeds expert speedup while passing th
e same unit tests. To enable this how-to-fix evaluation, our automated pipeline
 scrapes GitHub pull requests for performance-improving edits, combining keyword
 filtering, static analysis, coverage tooling, and execution validation to both c
onfirm expert speedup baselines and identify relevant repository unit tests. Emp
irical evaluation of state-of-the-art agents reveals significant underperformanc
e. On average, top agents achieve less than 0.23x the expert speedup: agents str
uggle in localizing optimization opportunities, reasoning about execution across
 functions, and maintaining correctness in proposed edits. We release the benchm
ark and accompanying data pipeline to facilitate research on automated performan
ce engineering and long-horizon software reasoning.

Inverse Entropic Optimal Transport Solves Semi-supervised Learning via Data Like
lihood Maximization

Mikhail Persiianov, Arip Asadulaev, Nikita Andreev, Nikita Starodubcev, Dmitry B
aranchuk, Anastasis Kratsios, Evgeny Burnaev, Alexander Korotin

Learning conditional distributions $\pi^\star(\cdot|x)$ is a central problem in
 machine learning, which is typically approached via supervised methods with pair
ed data $(x,y) \sim \pi^\star$. However, acquiring paired data samples is often
 challenging, especially in problems such as domain translation. This necessitate
s the development of *semi-supervised* models that utilize both limited paired d
ata and additional unpaired i.i.d. samples $x \sim \pi^\star_x$ and $y \sim \pi^
\star_y$ from the marginal distributions. The usage of such combined data is com
plex and often relies on heuristic approaches. To tackle this issue, we propose
 a new learning paradigm that integrates both paired and unpaired data seamlessly
 using data likelihood maximization techniques. We demonstrate that our approach
 also connects intriguingly with inverse entropic optimal transport (OT). This f
inding allows us to apply recent advances in computational OT to establish an *e
nd-to-end* learning algorithm to get $\pi^\star(\cdot|x)$. In addition, we deriv
e the universal approximation property, demonstrating that our approach can theo
retically recover true conditional distributions with arbitrarily small error. F
inally, we demonstrate through empirical tests that our method effectively learn
s conditional distributions using paired and unpaired data simultaneously.

Toward Training Superintelligent Software Agents through Self-Play SWE-RL

Yuxiang Wei, Zhiqing Sun, Emily McMilin, Jonas Gehring, David W. Zhang, Gabriel
 Synnaeve, Daniel Fried, LINGMING ZHANG, Sida Wang

While current software agents powered by large language models (LLMs) and reinfo
rcement learning (RL) can boost programmer productivity, their reliance on human
-curated training data and environments creates a fundamental barrier to superin
telligence. In this paper, we present Self-play SWE-RL (SSR), a first step towar
d training superintelligent software agents under minimal data assumptions. SSR
 requires only access to sandboxed repositories with source code and dependencies
, no need for human-labeled issues or test commands. Grounded in real-world code
bases, a single LLM agent is trained via RL in a self-play setting to inject and
 repair increasingly complex bugs. The bugs are formally specified by test suite
 improvements proposed by the agent rather than natural language issue descripti
ons. On the SWE-bench Verified and SWE-Bench Pro benchmarks, SSR achieves clear
 self-improvement (+10.4 and +7.8 points) and consistently outperforms the human-
data baseline throughout training, generalizing to natural language bug descript
ions not seen in training. Overall, our results point toward a paradigm where ag
ents autonomously gather extensive learning experiences from real software repos
itories, ultimately enabling superintelligent systems that exceed human capabili

ties in understanding, modifying, and creating software from scratch.

Incomplete Multi-View Clustering via Neighborhood-Conditioned Diffusion
Qian Guo, Gaohui Zuo, Bingbing Jiang, Guangrui Fan, Zhihua Cui, Xinyan Liang, Jianjian Ding
Incomplete multi-view clustering (IMVC) aims to uncover shared clustering structures from heterogeneous views with partial observations.
Recently, existing generative IMVC methods have made significant progress in this field; however, they still remain limited in two aspects.
On the one hand, they rely on weak cross-view signals, resulting in unstable latent recovery when facing missing data. On the other hand, they overlook stable cross-view neighborhood structures, leading to weak structural constraint.
To address these limitations, we propose neighborhood-conditioned diffusion for incomplete multi-view clustering (IMVC-NCD), which achieves robust latent completion.
Our method learns compact view-specific latent representations and constructs a unified conditioning vector by aggregating stable local neighborhood structures from available views while encoding missingness states, providing reliable guidance for diffusion-based denoising. With neighborhood-level conditioning, IMVC-NCD produces semantically aligned and view-consistent latent representations that are well suited for clustering, even under high missing-view ratios.
Extensive experiments on four benchmark datasets demonstrate the effectiveness and robustness of our method compared with state-of-the-art IMVC approaches.
Our code is available at https://github.com/zgh1115/IMVC-NCD.

Efficiently Solving Discounted MDPs via Predictions with Unknown Prediction Errors
Lixing Lyu, Jiashuo Jiang, Wang Chi Cheung
We study infinite-horizon discounted Markov decision processes (DMDPs) under a generative model. Motivated by the Algorithms with Advice framework (Mitzenmacher and Vassilvitskii, 2022), we propose a novel framework to investigate how black-box predictions of the transition matrix can enhance sample efficiency in solving DMDPs and improve sample complexity bounds. We focus on DMDPs with N state–action pairs and discount factor γ. We first provide an impossibility result showing that, in the presence of predictions with unknown accuracy, no sampling policy can compute an ϵ-optimal policy with a sample complexity better than $\tilde{O}((1-\gamma)^{-3} N \epsilon^{-2})$, which matches the state-of-the-art minimax sample complexity bound without prediction. In complement, we design an algorithm based on minimax optimization techniques that leverages predictions of the transition matrix without requiring knowledge of the prediction error. Our algorithm achieves a sample complexity bound that depends on the prediction error and is uniformly better than $\tilde{O}((1-\gamma)^{-4} N \epsilon^{-2})$, the previous best result derived from convex optimization methods. In some cases, our bound even improves upon the state-of-the-art $\tilde{O}((1-\gamma)^{-3} N \epsilon^{-2})$, despite not having access to the prediction quality.
****
InfraRL: A Benchmark for Constrained Resource Allocation in Large-Scale Infrastructure Asset Management
Yantian Wang, Wenhao Li, Bo Jin
Optimizing maintenance strategies for large-scale infrastructure is a critical sequential decision-making problem.
While Reinforcement Learning (RL) offers a theoretical framework for such problems, practical deployment necessitates offline constrained RL—learning policies solely from static historical datasets under rigid budgetary limits without dangerous on-policy exploration.
However, current research is hindered by benchmarks that fail to capture the confluence of distributional shift and hard constraints typical of real-world assets.
We introduce InfraRL, a high-fidelity benchmark that uses bridge maintenance as a rigorous testbed for general infrastructure asset management challenges.

Constructed from the U.S. National Bridge Inventory, InfraRL defines a rigorous offline task for optimizing maintenance strategies under hard budgetary constrai nts.
We benchmark a diverse suite of baselines, ranging from industry-standard heuris tics to single-agent, multi-agent, planning-based, and constrained offline RL me thods.
  Through a comprehensive evaluation protocol, we analyze performance across str uctural utility, constraint adherence, and behavioral fidelity, revealing critic al trade-offs between safety and long-term efficiency. Our code and data are ava ilable at https://github.com/BriSky-2021/InfraRL.

Learning to Approximate Uniform Facility Location via Graph Neural Networks
Chendi Qian, Christopher Morris, Stefanie Jegelka, Christian Sohler
Neural networks, particularly message-passing neural networks (MPNNs), are incre asingly used as heuristics for hard combinatorial optimization problems. Yet man y learning-based methods rely on supervision, reinforcement learning, or gradien t estimators, causing high computational cost, unstable training, or limited gua rantees. Classical approximation algorithms provide worst-case guarantees but ar e non-differentiable and cannot adapt to structure in natural input distribution s. We study this tradeoff through Uniform Facility Location (UniFL), a problem w ith applications in clustering, summarization, logistics, and supply chains. We propose a fully differentiable MPNN that incorporates approximation-algorithmic principles without solver supervision or discrete relaxations. The model has pro vable approximation guarantees and empirically improves on standard approximatio n algorithms, narrowing the gap to integer linear programming.

DTKG: Dual-Track Knowledge Graph-Verified Reasoning Framework for Multi-Hop QA
Changhao Wang, Yanfang Liu, Xinxin Fan, Ao Tian, Lanzhi Zhou, Yunfeng Lu
Multi-hop reasoning for question answering (QA) plays a critical role in retriev al-augmented generation (RAG) for large language models (LLMs). Based on inheren t relation-dependency and reasoning patterns, it is categorized into parallel fa ct-verification (simultaneously verifying independent sub-questions) and chained reasoning (sequential multi-step inference).
Existing approaches adopt either LLM-based fact verification or KG path-based ch ain construction, failing to handle both categories well: the former underperfor ms on chained reasoning, while the latter suffers from redundant paths in parall el tasks.
Inspired by the Dual Process Theory in cognitive science and Stanovich’s Cogniti ve Misers Theory, we propose an effective multi-hop QA framework DTKG (Dual-Trac k Knowledge Graph) through building a two-stage pipeline: i) Classification Stag e (dynamic question categorization via few-shot prompting, emulating "unconsciou s processing"); and ii) Branch Processing Stage (tailored reasoning paths, emula ting "conscious processing"). Multi-facet
experiments on six datasets show DTKG achieves 5.0\%-29.5\% performance improvem ent. The code is available at https://anonymous.4open.science/r/DTKG-621F

SceneDirector: Bridging Explicit Geometry and Generative Priors for Unified Driv ing Scene Editing
Yiyuan Liang, Zhiying Yan, Tao Zhang, Shangke Liu, Kai Lin, Xu Zou, Nong Sang, C hangxin Gao
Validating autonomous driving systems requires diverse scenarios, yet real-world data collection is biased and costly. Editing existing driving logs offers a sc alable solution, but simultaneously editing objects and ego-trajectory—termed un ified editing—remains challenging.
Current methods face an inherent dilemma: generative flexibility for object edit ing and physical precision for trajectory control.
To address this, we introduce SceneDirector, a diffusion-based framework that br idges explicit geometry and generative priors.
For explicit geometry, we leverage LiDAR-guided depth completion to construct de nse scene geometry and integrate editable 3D assets to form a Unified Geometric

Scaffold, providing rigorous structural guidance for unified editing.
To leverage generative priors, we encode the source video into a Static Texture Bank to provide rich appearance context.
Our proposed Mask-Gated Reference Attention bridges these modalities. Guided by a geometric uncertainty metric, this mechanism dynamically regulates the interaction between the scaffold and the bank—preserving reliable geometry while adaptively injecting textures for semantic refinement.
Extensive evaluations demonstrate that SceneDirector outperforms state-of-the-art methods in both controllability and visual quality.
****

FOCA: Future-Oriented Conditioning for Data-Efficient Vision-Language-Action Adaptation

Minh Duc Nguyen, Nghiem Tuong Diep, Nguyen Gia Binh, Trong-Bao Ho, Doanh Le Thien, Quang Tan Nguyen, Thien-Loc Ha, Tran Van Nhiem, Bao Thach, Tran Xuan Nhat, Tuan Anh Tran, Artur Habuda, Philip Lund Møller, Tran Nguyen Le, Daniel Sonntag, Mathias Niepert, Khoa D Doan, Vu N. Duong, Hung Ngo, Minh Nhat VU, Duy Minh Ho Nguyen, An Thai Le, Vien Anh Ngo

Vision–Language–Action (VLA) models enable general-purpose robotic control via large-scale multimodal pretraining, yet their effectiveness under few-shot imitation learning remains limited. We conduct a systematic stress test of state-of-the-art VLA models and show that performance degrades sharply as demonstrations are reduced, revealing a key weakness of existing adaptation strategies. To address this, we introduce FOCA, a future-oriented conditioning framework for data-efficient VLA adaptation. FOCA combines explicit prediction of task-grounded future interaction embeddings with implicit alignment to future goal observations, enabling long-horizon reasoning in latent space without pixel-level prediction. This formulation naturally supports action-free co-training with synthetic videos from video world models and can be interpreted as learning a future-conditioned value-like representation. Extensive experiments demonstrate FOCA achieves 95.7\% success with 20 demonstrations on LIBERO, improves 7–12\% on RoboCasa, and delivers up to 26\% absolute gains on real robots, establishing a new state of the art in few-shot VLA adaptation.

Numina-Lean-Agent: An Open and General Agentic Reasoning System for Formal Mathematics

Junqi Liu, Zihao Zhou, Zekai Zhu, Marco Dos Santos, Weikun He, jiawei liu, Yunzhou Xie, Junqiao Zhao, Qiufeng Wang, Lihong Zhi, Jia LI, Wenda Li

Agentic systems have recently become the dominant paradigm for formal theorem proving, achieving strong performance by coordinating multiple models and tools. However, existing approaches often rely on task-specific pipelines and trained formal provers, limiting their flexibility and reproducibility.
In this paper, we propose the paradigm that directly uses a general coding agent as a formal math reasoner. This paradigm is motivated by (1) A general coding agent provides a natural interface for diverse reasoning tasks beyond proving, (2) Performance can be improved by simply replacing the underlying base model, without training., and (3) MCP enables flexible extension and autonomous calling of specialized tools, avoiding complex design. Based on this paradigm, we introduce \textbf{Numina-Lean-Agent}, which combines Claude Code with Numina-Lean-MCP to enable autonomous interaction with Lean, retrieval of relevant theorems, informal proving and auxiliary reasoning tools.
Using Claude Opus 4.5 as the base model, Numina-Lean-Agent solves all problems in Putnam 2025 (12/12), matching the best closed-source system. Beyond benchmark evaluation, we further demonstrate its generality by interacting with mathematicians to successfully formalize the Brascamp–Lieb theorem.
****

WinDeskGround: A Benchmark for Robust GUI Grounding in Complex Multi-Window Desktop Environments

Haoren Zhao, Tianyi Chen, Zhen Wang

Multimodal Large Language Models (MLLMs) have revolutionized GUI automation, yet their efficacy is largely established on idealized, single-layer interfaces. Th

is paper identifies a critical reliability gap: state-of-the-art agents face dis
tinct robustness challenges in real-world desktop environments characterized by
multi-window stacking, occlusion, and visual clutter. To address this, we introd
uce WinDeskGround, a novel benchmark and synthesis framework tailored for evalua
ting GUI grounding robustness. Unlike static datasets, our framework parametrica
lly generates complex desktop scenarios by controlling window occlusion, layout
density, and semantic similarity, thereby simulating the distribution shifts of
authentic workflows. We construct a diverse meta-dataset of 1,356 high-fidelity
instruction-target pairs and conduct comprehensive evaluations of five leading M
LLMs. Our results demonstrate that while top-tier agents excel in simplified set
tings, their accuracy declines under partial occlusion. WinDeskGround provides a
 valuable benchmark to facilitate the assessment and advancement of GUI agent ro
bustness in realistic environments.

DyLLM: Efficient Diffusion LLM Inference via Saliency-based Token Selection and Partial Attention

Younjoo Lee, Seungkyun Dan, Junghoo Lee, Jaiyoung Park, Jung Ho Ahn

Masked diffusion language models enable parallel token decoding, providing a pro
mising alternative to the sequential nature of autoregressive generation.
However, their iterative denoising process remains computationally expensive bec
ause it repeatedly processes the entire sequence at every step.
We observe that across these diffusion steps, most token representations remain
stable; only a small subset, which we term *salient tokens*, contributes meaning
fully to the next update.
Leveraging this temporal sparsity, we present **DyLLM**, a training-free inferen
ce framework that accelerates decoding by selectively computing only these salie
nt tokens.
DyLLM identifies saliency by measuring the cosine similarity of attention contex
ts between adjacent denoising steps.
It recomputes feed-forward and attention operations only for salient tokens whil
e reusing cached activations for the remainder.
Across diverse reasoning and code-generation benchmarks, DyLLM achieves up to 9.
6 $\times$ higher throughput while largely preserving the baseline accuracy of r
epresentative open-source diffusion LLMs, LLaDA and Dream.

PRISM: Training-Free Video Anomaly Detection via Intrinsic Statistical Modeling

YUANTONG CHEN, Zhengyan Ding, YanFeng Shang

While recent training-free video anomaly detection (VAD) methods offer advantage
s such as interpretability and ease of deployment, they often suffer from comput
ational inefficiency due to complex memory retrieval mechanisms or high-latency
visual-language models (VLMs). To address this issue, we propose PRISM (Paramete
r-less Recognition Based on Intrinsic Statistical Modeling), a novel framework f
or efficient open-set anomaly detection with minimal computational cost. Built o
n a pre-trained multimodal embedding model, PRISM introduces differential amplif
ication and whitening mechanisms to statistically suppress common-mode backgroun
d noise in the embedding space, thereby improving the signal-to-noise ratio of a
nomalous events. Extensive experiments on three widely datasets demonstrate that
 PRISM achieves state-of-the-art performance among training-free methods while m
aintaining real-time inference capability. Furthermore, our statistical analysis
 offers a complementary perspective on why training-free methods may suffer from
 lower Average Precision (AP) on complex datasets such as XD-Violence.Code is re
leased at https://github.com/ytC2026/ICML2026-PRISM.

ACO-MoE-LoRA: Evolving-while-Training for Adapting Segment Anything Model 2 to Specialized Domains

Kaiyi Luo, Bangjun Wang, Li Zhang, Fanzhang Li, Fei Zhu, Jiaqing Fan

Static fine-tuning paradigms impose rigid structural constraints on foundation m
odels like the Segment Anything Model 2 (SAM2), limiting their adaptability to t
he varying complexity of specialized downstream tasks.
To overcome this limitation, we propose **ACO-MoE-LoRA**, a dynamic framework th

at introduces an "Evolving-while-Training" strategy by synergizing Ant Colony Optimization (ACO) with a Latent Space Mixture-of-Experts (MoE) architecture.
Central to our method is the ACO-ConvLoRA module, which employs a pheromone-guided routing mechanism to actively govern expert selection and topological evolution.
By formulating expert assignment as an evolutionary pathfinding problem, this module effectively mitigates the standard routing collapse issue and enables elastic adjustment of LoRA ranks via weight slicing, bridging discrete structural search with continuous parameter training.
Extensive experiments across 16 challenging datasets demonstrate that our framework consistently outperforms leading static adapters, while effectively addressing the local optimality limitations of recent dynamic heuristics.
This work presents a self-organizing solution that harmonizes swarm intelligence with gradient optimization for efficiently adapting foundation models to specialized domains.
****

Solving Time-Dependent Differential Equations with Physical Dynamical Systems
Chuan Liu, Yijie Chen, Ruibing Song, Wenhao Huang, Chunshu Wu, Deqian Kong, Ying Nian Wu, Kaiyuan Yang, Ang Li, Tony Geng
Time-Dependent Differential Equations (TDDEs) model dynamical processes across science and engineering, but time-critical applications require solvers that deliver high-fidelity trajectories under stringent latency constraints. Most existing TDDE solvers are limited by time discretization, forcing a latency-accuracy trade-off where smaller step sizes capture high-fidelity trajectories but incur prohibitive runtime, while larger steps meet real-time budgets at the cost of trajectory distortion. Dynamical System Machines (DSMs) offer a promising alternative by computing through continuous physical evolution, yet existing DSMs struggle to capture the spatiotemporal complexity of TDDEs. This work introduces DS-TS, a novel TDDE solver that is both accurate and efficient by leveraging the unique computational advantages of DSMs. DS-TS integrates three key innovations: (1) Excitatory-Inhibitory Inspired Coupling to better model complex spatial interactions; (2) State-aware Dynamic Nonlinearity to enable rich inter-node interactions and state-dependent spatiotemporal correlations; and (3) Hierarchical Temporal Integration to capture high-order temporal dependencies. Experiments demonstrate that DS-TS achieves high-fidelity solutions while delivering orders-of-magnitude improvements in speed ($\sim 10^3\times$) and energy efficiency ($\sim 10^5\times$) compared to baseline solvers.
****

Supervised Graph Contrastive Learning for Gene Regulatory Networks
Sho Oshima, Yuji Okamoto, Taisei Tosaki, Ryosuke Kojima
Graph Contrastive Learning (GCL) is a powerful self-supervised learning framework that performs data augmentation through graph perturbations, with growing applications in the analysis of biological networks such as Gene Regulatory Networks (GRNs).
The artificial perturbations commonly used in GCL, such as node dropping, induce structural changes that can diverge from biological reality.
This concern has contributed to a broader trend in graph representation learning toward augmentation-free methods, which view such structural changes as problematic and should be avoided.
However, this trend overlooks the fundamental insight that structural changes from biologically meaningful perturbations are not a problem to be avoided, but rather a rich source of information, thereby ignoring the valuable opportunity to leverage data from real biological experiments. Motivated by this insight, we propose SupGCL (Supervised Graph Contrastive Learning), a new GCL method for GRNs that directly incorporates biological perturbations from gene knockdown experiments as supervision.
SupGCL is a probabilistic formulation that continuously generalizes conventional GCL, linking artificial augmentations with real perturbations measured in knockdown experiments, and using the latter as explicit supervision.
On patient-derived GRNs from three cancer types, we train GRN representations wi

th SupGCL and evaluate it in two regimes: (i) embedding space analysis, where it yields clearer disease-subtype structure and improves clustering, and (ii) task-specific fine-tuning, where it consistently outperforms strong graph representation learning baselines on 13 downstream tasks spanning gene-level functional annotation and patient-level prediction.

Cross-View Lewis Weight Fusion Empowering Exemplar Replay for Federated Class-Incremental Learning

Zhuang Qi, Ying-Peng Tang, Lei Meng, Xiaoxiao Li, Han Yu, Xiangxu Meng

Federated Class-Incremental Learning (FCIL) aims to continually expand a model's recognition capacity in a distributed environment, enabling it to learn new classes while retaining knowledge of previously seen ones. Exemplar replay has emerged as a promising strategy owing to its simplicity and effectiveness. Existing methods either select exemplars based on local dynamics or construct global feature spaces to identify representative samples. However, they face inherent challenges in striking a balance between effectiveness and privacy. To address this issue, this paper proposes a Cross-view Lewis weIght Fusion method for exemplar replay in FCIL, termed CLIF, which fuses multi-view importance scores to guide representative sample selection under federated settings. Specifically, CLIF consists of two main modules: 1) the cross-view Lewis weight fusion module computes and integrates Lewis weights from multiple feature perspectives to achieve consistent importance estimation, ensuring that the selected samples better reflect the global data distribution and thus enhancing the representativeness of the replay subset. Building on this, 2) the frequency-based weighted training module adjusts the loss contribution of each sample according to its selection frequency across views, which emphasizes the contribution of critical samples. Moreover, we provide a theoretical analysis to guarantee the soundness and effectiveness of CLIF. Extensive experiments on three datasets demonstrate that our method consistently improves baselines by 1%–6%, supporting the above claims.

AudioChat: Unified Audio Storytelling, Editing, and Understanding with Transfusion Forcing

William Chen, Prem Seetharaman, Rithesh Kumar, Oriol Nieto, Shinji Watanabe, Justin Salamon, Zeyu Jin

Despite recent breakthroughs, audio foundation models struggle in processing complex multi-source acoustic scenes. We refer to this challenging domain as audio stories, which can have multiple speakers and background/foreground sound effects. Compared to traditional audio processing tasks, audio stories introduce new layers of semantic, temporal, and physical complexity. To address this challenge, we propose AudioChat, a framework for developing audio foundation models that can generate, edit, and understand audio stories. AudioChat introduces a new paradigm in which LLM-based toolcalling agents simulate interactions between users and the system, and these simulated dialogues are used as training data. We also introduce a novel Audio Transfusion Forcing objective to train the AudioChat model, allowing it to simultaneously decompose high-level instructions via structured chain-of-thought reasoning and perform interactive multi-turn audio understanding/generation. To evaluate generation and editing performance, we develop three new metrics that directly measure task performance instead of relying upon distribution-based scoring. We highly encourage readers to visit our demo to better understand the capabilities of AudioChat: https://audiochat-icml-2026.github.io/.

Towards Docking-oriented De Novo Ligand Design via Gradient Inversion

Zekai Chen, Xunkai Li, Sirui Zhang, Henan Sun, Jia Li, Qiangqiang Dai, Hongchao Qin, Zhenjun Li, Bing Zhou, Rong-Hua Li, Guoren Wang

De novo ligand design is a fundamental task that seeks to generate protein or molecule candidates that can effectively dock with protein receptors and achieve strong binding affinity entirely from scratch.

It holds paramount significance for a wide spectrum of biomedical applications.

However, most existing studies are constrained by the \textbf{Pseudo De Novo }, \textbf{Limited Docking Modeling}, and \textbf{Inflexible Ligand Type}.

To address these issues, we propose MagicDock, a forward-looking framework g rounded in the progressive pipeline and differentiable surface modeling.

(1) We adopt a well-designed gradient inversion framework.

To begin with, general docking knowledge of receptors and ligands is incorpo rated into the backbone model.

Subsequently, the docking knowledge is instantiated as reverse gradient flow s by binding prediction, which iteratively guide the de novo generation of ligan ds.

(2) We emphasize differentiable surface modeling in the \textit{generation p rocess}, leveraging learnable 3D point-cloud representations to precisely captur e docking details, thereby ensuring that the generated ligands preserve docking validity through interpretable spatial fingerprints.

(3) We introduce customized designs for different ligand types and integrate them into a unified gradient inversion framework with flexible triggers, thereb y ensuring broad applicability.

Moreover, we provide sufficient theoretical guarantees for MagicDock.

Extensive experiments across 9 scenarios demonstrate that MagicDock achieves average improvements of 7.0\% and 7.4\% over SOTA baselines specialized for pro tein or molecule ligand design, respectively.

Learning Molecular Semantic Invariant Representation with Prototype Constraint

Zhiqiang Li, Jianqing Liang, Zhiqiang Wang, Xizhao Luo, Jiye Liang

Molecular representation learning has achieved remarkable progress in molecular property prediction, yet out-of-distribution (OOD) generalization remains challe nging. In practice, training data typically cover only a limited portion of the chemical space, causing models to rely on environment-dependent factors that fai l to transfer when scaffold structures or functional compositions shift. To addr ess this issue, we propose MoSIR, a framework for learning molecular semantic in variant representation with prototype constraint, which projects entangled molec ular embeddings into a learnable semantic prototype space to extract semantic in variant representation while isolating environment-sensitive variations. Buildin g upon this decomposition, we optimize a bi-level min-max objective that introdu ces representation perturbations to simulate plausible environment shifts and en force semantic stability. We further provide theoretical guarantees for MoSIR by deriving an OOD generalization bound under distribution shifts. Extensive exper iments on multiple molecular OOD benchmarks demonstrate that MoSIR consistently outperforms strong baselines across diverse shift settings, and qualitative anal yses confirm that the learned prototypes capture meaningful chemical semantics.

Amortized Maximum Inner Product Search with Learned Support Functions

Theo X. Olausson, Joao Monteiro, Michal Klein, marco cuturi

Maximum inner product search (MIPS) is a crucial subroutine in machine learning, requiring identification of database vectors that align most strongly with a gi ven query. We propose amortized MIPS: a learning-based approach that trains neur al networks to directly predict MIPS solutions, amortizing the computational cos t of search across queries drawn from a known distribution. Our key insight is t hat the MIPS value function - the maximum inner product as a function of the que ry - is convex (as the pointwise maximum of linear functions), and its gradient at each query equals the optimal database vector. We explore two complementary a rchitectures: (1) Input Convex Neural Networks (ICNNs) that learn the convex val ue function and recover the optimal match via gradient computation, and (2) Vect orICNNs that directly regress the argmax, bypassing gradient computation entirel y at inference time. For ICNNs, we combine score regression with gradient matchi ng losses; for VectorICNNs, we introduce a score consistency loss derived from E uler's theorem for homogeneous functions. We further propose homogenization wrap pers that enforce positive 1-homogeneity, theoretically linking function values to gradients. Our experiments on retrieval benchmarks demonstrate that convexity provides an effective inductive bias, with learned potentials achieving high ma

tch rates while requiring only a single forward pass at inference. Our code is available at: https://github.com/apple/ml-amips.

Bottleneck Communication Delay Minimization for Communication-Efficient Decentralized Learning
Nozomi Hata, Kenta Niwa
For communication-efficient decentralized learning, advanced network (NW) topologies, such as exponential and 1-peer exponential graphs, have been studied under homogeneous communication delays. However, real-world NWs exhibit heterogeneous communication delays, making node assignment optimization crucial for minimizing the Bottleneck Communication Delay (BCD). We propose BTSP-MSR, an approximate method for minimizing BCD on circulant digraphs, including exponential and 1-peer exponential graphs. Leveraging the fact that circulant digraphs can be viewed as a union of (directed) ring graphs, we derive an upper bound on the BCD by combining the ring-graph BCD (BTSP) with a deviation term (MSR). We then construct a solver that sequentially minimizes these two terms. Numerical experiments show that BTSP-MSR consistently reduces BCD across several circulant digraphs with large numbers of nodes. Notably, incorporating the exponential or 1-peer exponential graph enables communication-efficient decentralized learning under heterogeneous delay settings.
****
A Geometry-Aware Efficient Algorithm for Compositional Entropic Risk Minimization
Xiyuan Wei, Linli Zhou, Bokun Wang, Chih-Jen Lin, Tianbao Yang
This paper studies optimization for a family of problems termed **compositional entropic risk minimization**, in which each data's loss is formulated as a Log-Expectation-Exponential (Log-E-Exp) function. The Log-E-Exp formulation serves as an abstraction of the Log-Sum-Exponential (LogSumExp) function when the explicit summation inside the logarithm is taken over a gigantic number of items and is therefore expensive to evaluate. While entropic risk objectives of this form arise in many machine learning problems, existing optimization algorithms suffer from several fundamental limitations including non-convergence, numerical instability, and slow convergence rates. To address these limitations, we propose a geometry-aware stochastic algorithm, termed **SCENT**, for the dual formulation of entropic risk minimization cast as a min--min optimization problem. The key to our design is a **stochastic proximal mirror descent (SPMD)** update for the dual variable, equipped with a Bregman divergence induced by a negative exponential function that faithfully captures the geometry of the objective. Our main contributions are threefold: (i) we establish an $O(1/\sqrt{T})$ convergence rate of the proposed SCENT algorithm for convex problems; (ii) we theoretically characterize the advantages of SPMD over standard SGD update for optimizing the dual variable; and (iii) we demonstrate the empirical effectiveness of SCENT on extreme classification, partial AUC maximization, contrastive learning and distributionally robust optimization, where it consistently outperforms existing baselines.

SciNet: Evaluating AI Agents in Relation-Aware Scientific Literature Retrieval
Chenyang Shao, Fengli Xu, Yong Li
AI agents have seen widespread adoption in information retrieval for scientific research, giving rise to tools such as Deep Research. However, existing retrieval agents mainly rely on keyword- or embedding-based methods. While effective at capturing content-level similarities, they struggle to understand complex relational networks among scientific papers, such as identifying corroborating or conflicting studies and tracing technological lineages. This fundamental limitation often results in fragmented knowledge structures, misinterpreted research sentiment, and ineffective modeling of collective scientific progress. To address this limitation, we introduce **SciNet**, the first **Sci**entific **Net**work relation-aware dataset for information retrieval agents. Built on a meta-database of 269 million papers across 7 disciplines and containing 8,940 carefully designed tasks, SciNet systematically captures three levels of relational understanding:

ego-centric retrieval of papers with novel knowledge structures, pairwise identi
fication of scholarly relationships, and path-wise reconstruction of scientific
evolution. Extensive evaluation of three categories of retrieval agents shows th
at their accuracy on relation-aware tasks often falls below 20%, highlighting a
fundamental shortcoming of current retrieval paradigms. Importantly, in a downst
ream literature review application, agents empowered with SciNet achieve a 25.3%
 improvement in review quality, highlighting the critical value of relation-awar
e retrieval for deepening scientific insights. We publicly release SciNet at htt
ps://github.com/tsinghua-fib-lab/SciNet to support future research.

Exposing Vulnerabilities in Explanation for Time Series Classifiers via Dual-Tar
get Attacks

Bohan Wang, Zewen Liu, Lu Lin, Hui Liu, Li Xiong, Ming Jin, Wei Jin

Interpretable time series deep learning systems are often assessed by checking t
emporal consistency on explanations, implicitly treating this as evidence of rob
ustness. We show that this assumption can fail: Predictions and explanations can
 be adversarially decoupled, enabling targeted misclassification while the expla
nation remains plausible and consistent with a chosen reference rationale. We pr
opose TSEF (Time Series Explanation Fooler), a dual-target attack that jointly m
anipulates the classifier and explainer outputs. In contrast to single-objective
 misclassification attacks that disrupt explanation and spread attribution mass
broadly, TSEF achieves targeted prediction changes while keeping explanations co
nsistent with the reference. Across multiple datasets and explainer backbones, o
ur results consistently reveal that explanation stability is a misleading proxy
for decision robustness and motivate coupling-aware robustness evaluations for t
rustworthy time series tasks.

CLoVE: Personalized Federated Learning through Clustering of Loss Vector Embeddi
ngs

Randeep Bhatia, Nikos Papadis, Murali Kodialam, T. V. Lakshman, Sayak Chakrabart
y

We propose CLoVE (Clustering of Loss Vector Embeddings), a novel algorithm for C
lustered Federated Learning (CFL). In CFL, clients are naturally grouped into cl
usters based on their data distribution. However, identifying these clusters is
challenging, as client assignments are unknown. CLoVE utilizes client embeddings
 derived from model losses on client data, and leverages the insight that client
s in the same cluster share similar loss values, while those in different cluste
rs exhibit distinct loss patterns. Based on these embeddings, CLoVE is able to i
teratively identify and separate clients from different clusters and optimize cl
uster-specific models through federated aggregation. Key advantages of CLoVE ove
r existing CFL algorithms are (1) its simplicity, (2) its applicability to both
supervised and unsupervised settings, and (3) the fact that it eliminates the ne
ed for near-optimal model initialization, which makes it more robust and better
suited for real-world applications. We establish theoretical convergence bounds,
 showing that CLoVE can recover clusters accurately with high probability in a s
ingle round and converges exponentially fast to optimal models in a linear setti
ng. Our comprehensive experiments comparing with a variety of both CFL and gener
ic Personalized Federated Learning (PFL) algorithms on different types of datase
ts and an extensive array of non-IID settings demonstrate that CLoVE achieves hi
ghly accurate cluster recovery in just a few rounds of training, along with stat
e-of-the-art model accuracy, across a variety of both supervised and unsupervise
d PFL tasks.

Relevance-Based Embeddings: Lightweight Candidate Retrieval via Heavy-Ranker Cal
ls

Kirill Sergeevich Shevkunov, Andrey Ploskonosov, Liudmila Prokhorenkova

In many machine learning applications, the most relevant items for a query shoul
d be efficiently retrieved. The relevance function is usually an expensive simil
arity model, making the exhaustive search infeasible. A typical solution is to t
rain another model that separately embeds queries and items to a vector space, w

here similarity is defined via the dot product or cosine similarity. This allows one to search the relevant items through fast approximate nearest neighbor search at the cost of some reduction in quality. To compensate for this reduction, the found items (candidates) are re-ranked by the expensive ranking model. In this paper, we investigate an alternative approach to candidate selection that utilizes the scores of the expensive model to improve the representations of queries and items. The idea is to describe each query (item) by its relevance to a set of support items (queries) and use these new representations to obtain query (item) embeddings. We theoretically prove that such embeddings are powerful enough to approximate any complex similarity model (under mild conditions). We also investigate the choice of support items, which is a crucial ingredient of the proposed approach. The experiments on diverse academic and production datasets illustrate the power of our method.

LIMSSR: LLM-Driven Sequence-to-Score Reasoning under Training-Time Incomplete Multimodal Observations

Huangbiao Xu, Huanqi Wu, Xiao Ke, Yuxin Peng

Real-world multimodal learning is often hindered by missing modalities. While Incomplete Multimodal Learning (IML) has gained traction, existing methods typically rely on the unrealistic assumption of full-modal availability during training to provide reconstruction supervision or cross-modal priors. This paper tackles the more challenging setting of IML under training-time incomplete observations, which precludes reliance on a "God's eye view" of complete data. We propose LIMSSR (LLM-Driven Incomplete Multimodal Sequence-to-Score Reasoning), a framework that reformulates this challenge as a conditional sequence reasoning task. LIMSSR leverages the semantic reasoning capabilities of Large Language Models via Prompt-Guided Context-Aware Modality Imputation and Multidimensional Representation Fusion to infer latent semantics from available contexts without direct reconstruction. To mitigate hallucinations, we introduce a Mask-Aware Dual-Path Aggregation to dynamically calibrate inference uncertainty. Extensive experiments on three Action Quality Assessment datasets demonstrate that LIMSSR significantly outperforms state-of-the-art baselines without relying on complete training data, establishing a new paradigm for data-efficient multimodal learning. Code is available at https://github.com/XuHuangbiao/LIMSSR.

TCAP: Tri-Component Attention Profiling for Unsupervised Backdoor Detection in MLLM Fine-Tuning

Mingzu Liu, Hao Fang, Runmin Cong

Fine-Tuning-as-a-Service (FTaaS) facilitates the customization of Multimodal Large Language Models (MLLMs) but introduces critical backdoor risks via poisoned data. Existing defenses either rely on supervised signals or fail to generalize across diverse trigger types and modalities. In this work, we uncover a universal backdoor fingerprint—attention allocation divergence—where poisoned samples disrupt the balanced attention distribution across three functional components: system instructions, vision inputs, and user textual queries, regardless of trigger morphology. Motivated by this insight, we propose Tri-Component Attention Profiling (TCAP), an unsupervised defense framework to filter backdoor samples. TCAP decomposes cross-modal attention maps into the three components, identifies trigger-responsive attention heads via Gaussian Mixture Model (GMM) statistical profiling, and isolates poisoned samples through EM-based vote aggregation. Extensive experiments across diverse MLLM architectures and attack methods demonstrate that TCAP achieves consistently strong performance, establishing it as a robust and practical backdoor defense in MLLMs.

Reinforcement-aware Knowledge Distillation for LLM Reasoning

Zhaoyang Zhang, Shuli Jiang, Yantao Shen, Yuting Zhang, Dhananjay Ram, Shuo Yang, Zhuowen Tu, Wei Xia, Stefano Soatto

Reinforcement learning (RL) post-training has recently driven major gains in long chain-of-thought reasoning large language models (LLMs), but the high inference cost of such models motivates distillation into smaller students.

Most existing knowledge distillation (KD) methods are designed for supervised fi
ne-tuning (SFT), relying on fixed teacher traces or teacher-student Kullback–Lei
bler (KL) divergence based regularization.
When combined with RL, these approaches often suffer from distribution mismatch
and objective interference: teacher supervision may not align with the student’s
 evolving rollout distribution, and the KL regularizer can compete with reward m
aximization and require careful loss balancing.
To address these issues, we propose \emph{RL-aware distillation} (RLAD), which p
erforms selective imitation during RL---guiding the student toward the teacher o
nly when it improves the current policy update.
Our core component,Trust Region Ratio Distillation (TRRD), replaces the teacher-
student KL regularizer with a PPO/GRPO-style likelihood-ratio objective anchored
 to a teacher--old-policy mixture, yielding advantage-aware, trust-region-bounde
d distillation on student rollouts and naturally balancing exploration, exploita
tion, and imitation.
Across diverse logic reasoning and math benchmarks, RLAD}consistently outperform
s offline distillation, standard GRPO, and KL-based on-policy teacher–student kn
owledge distillation.

Is Task-Specific Training Necessary for Anomaly Detection?
Xingwu Zhang, Guanxuan Li, Paul Henderson, Gerardo Aragon-Camarasa, ZIJUN LONG
Current state-of-the-art multi-class unsupervised anomaly detection (MUAD) metho
ds rely on training encoder--decoder models to reconstruct anomaly-free features
. However, we argue that such task-specific training is costly under distributio
n shifts, and that reconstruction-based residual scoring further faces a fidelit
y--stability dilemma. Existing training-free alternatives, in turn, remain prone
 to cross-category and cross-region mismatches in MUAD. Motivated by these limit
ations, we propose Retrieval-based Anomaly Detection (RAD), a task-specific trai
ning-free framework that stores anomaly-free features in a memory and detects an
omalies through multi-level retrieval, matching test patches against the memory.
 Experiments demonstrate that RAD achieves state-of-the-art performance across f
our established benchmarks (MVTec-AD, VisA, Real-IAD, 3D-ADAM) under both standa
rd and few-shot settings. On MVTec-AD, RAD reaches 96.7% Pixel AUROC with just a
 single anomaly-free image compared to 98.5% of RAD's full-data performance. Col
lectively, these findings overturn the assumption that MUAD requires task-specif
ic training, showing that state-of-the-art anomaly detection is feasible with tr
aining-free memory-based retrieval. Our code is available at https://github.com/
longkukuhi/RAD.

Can local learning match self-supervised backpropagation?
Wu S. Zihan, Ariane Delrocq, Wulfram Gerstner, Guillaume Bellec
While end-to-end self-supervised learning with backpropagation (global BP-SSL) h
as become central for training modern AI systems, theories of local self-supervi
sed learning (local-SSL) have struggled to build functional representations in d
eep neural networks.
To establish a link between global and local rules, we first develop a theory fo
r deep linear networks: We identify conditions for local-SSL algorithms (like Fo
rward-forward or CLAPP) to implement exactly the same weight update as a global
BP-SSL. Starting from the theoretical insights, we then develop novel variants o
f local-SSL algorithms to approximate global BP-SSL in deep non-linear convoluti
onal neural networks. Variants that improve the similarity between updates of lo
cal-SSL with those of global BP-SSL also show better performance on image datase
ts (CIFAR-10, STL-10, Tiny ImageNet, and ImageNet). The best local-SSL rule with
 the CLAPP loss function matches the performance of a comparable global BP-SSL w
ith InfoNCE or CPC-like loss functions, and improves upon state-of-the-art for l
ayer-wise SSL on these benchmarks.

Reflective Hamiltonian Monte Carlo: Mixing Analysis and Application to Sampling
 on Stiefel Manifold
Kwangmin Lee, Yeonhee Park, Sewon Park

Sampling from distributions with bounded supports is a fundamental challenge in constrained statistical inference. Reflective Hamiltonian Monte Carlo (ReHMC) provides a useful sampling approach for this setting. However, it relies on convexity assumptions on the support and lacks non-asymptotic theoretical guarantees such as mixing-time bounds. To bridge this gap, we propose a convex-container plus thinning framework that is applicable to arbitrary target densities with bounded support. We establish the first non-asymptotic total-variation mixing-time bounds for ReHMC, achieving a polynomial dimension dependence of $O(d^2)$ for L-smooth targets, though with exponential dependence on smoothness parameters. Under an additional m-strong convexity assumption, we derive a sharper bound that eliminates this exponential dependence. We further apply this approach to sampling on the Stiefel manifold via a well-conditioned polar reparameterization and demonstrate improved numerical stability and sampling efficiency in simulation studies.

Constructing Industrial-Scale Optimization Modeling Benchmark

Zhong Li, Hongliang Lu, Tao Wei, Yuxuan Chen, Wenyu Liu, Yuan Lan, Fan Zhang, Zaiwen Wen

Optimization modeling underpins decision-making in logistics, manufacturing, energy, and finance, yet translating natural-language requirements into correct optimization formulations and solver-executable code remains labor-intensive. Although large language models (LLMs) have been explored for this task, evaluation is still dominated by toy-sized or synthetic benchmarks, masking the difficulty of industrial problems with 10^{3}--10^{6} (or more) variables and constraints. A key bottleneck is the lack of benchmarks that align natural-language specifications with reference formulations/solver code grounded in real optimization models. To fill in this gap, we introduce MIPLIB-NL, built via a structure-aware reverse construction methodology from real mixed-integer linear programs in MIPLIB~2017. Our pipeline (i) recovers compact, reusable model structure from flat solver formulations, (ii) reverse-generates natural-language specifications explicitly tied to this recovered structure under a unified model--data separation format, and (iii) performs iterative semantic validation through expert review and human--LLM interaction with independent reconstruction checks. This yields 223 one-to-one reconstructions that preserve the mathematical content of the original instances while enabling realistic natural-language-to-optimization evaluation. Experiments show substantial performance degradation on MIPLIB-NL for systems that perform strongly on existing benchmarks, exposing failure modes invisible at toy scale.

****

MPFM: Cross Multi-Domain Prototype Flow Matching for Log Anomaly Detection

Jing Zhang, Chao Luo

Cross multi-domain log anomaly detection aims to train a unified model applying in multiple heterogeneous systems, alleviating the annotation cost and scalability bottlenecks of traditional cross single-domain approaches. However, existing methods face two fundamental challenges: (i) geometric proximity alone is insufficient to certify normality, and (ii) forcibly aligning distributions across domains can induce negative transfer. To address these issues, we propose MPFM (Cross Multi-Domain Prototype Flow Matching for Log Anomaly Detection), grounded in the principle that anomalies are samples that cannot be stably generated by the normal data-generating mechanism. Specifically, MPFM employs a shared–private prototype system to disentangle cross-domain commonalities from domain-specific patterns, introduces domain-conditioned flow matching to perform anomaly detection by integrating structural and dynamical evidence, and further leverages prototype-drift-driven hard example mining to improve robustness near decision boundaries. Experiments on HDFS, BGL, Thunderbird, and Spirit demonstrate that MPFM delivers substantial gains under multi-domain joint training.

****

Masked Multi-path Contrast with Confidence-Gated Semantic Imputation for Incomplete Multi-view Clustering

Fan Yang, Haikun Xu

Incomplete multi-view clustering (IMVC) becomes particularly challenging under h
eavy missingness and view-availability imbalance. In this regime, scarce co-obse
rved pairs make cross-view correspondences unreliable. Imputation-first pipeline
s may trigger cascading reconstruction errors, while purely consistency-based al
ignment often degrades sharply and gives limited control over semantic convergen
ce across views. We propose MAGIC (Masked multi-pAth contrast with confIdence-Ga
ted semantIc imputation), a unified framework that learns calibrated cluster sem
antics before conservative completion. MAGIC builds multiple correlated represen
tation and prediction paths from lightly augmented latent codes, and couples the
m with a masked multi-path contrastive consensus objective and prediction-consis
tency regularization. The resulting posteriors are aggregated into view-wise sof
t assignments to reduce overconfidence and alleviate dominance by more frequentl
y observed views. Based on these calibrated semantics, MAGIC performs similarity
-guided semantic transfer in label space with confidence-aware gating, and compl
etes missing representations through a geometry-preserving prototype fallback. E
xperiments on four benchmarks across different missing ratios show consistent ga
ins over prior IMVC methods, and the ablations support the roles of masked multi
-path consensus learning and confidence-gated semantic imputation.

Phy-CoSF: Physics-Guided Continuous Spectral Fields Reconstruction and Spectral Super-Resolution for Snapshot Compressive Imaging

Wudi Chen, Zhiyuan Zha, Xin Yuan, Shigang Wang, Bihan Wen, Jiantao Zhou, Gang Ya
n, zipei fan, Ce Zhu

Recent advances have demonstrated that coded aperture snapshot spectral imaging
(CASSI) systems show great potential for capturing 3D hyperspectral images (HSIs
) from a single 2D measurement. Despite the inherent spectral continuity of scen
es captured by CASSI, most existing reconstruction methods are restricted to fix
ed, discrete spectral outputs, thereby precluding continuous spectral reconstruc
tion or spectral super-resolution. To address this challenge, we propose Phy-CoS
F, which synergizes deep unfolding networks with implicit neural representations
, establishing a new paradigm for continuous spectral reconstruction and super-r
esolution in CASSI. Specifically, we propose a two-phase architecture that bridg
es discrete-wavelength training with continuous spectral rendering, enabling the
 synthesis of high-fidelity HSIs at arbitrary target wavelengths. At the core of
 our framework lies the continuous spectral fields (CoSF) module, embedded withi
n each unfolding stage as a dynamic prior, which comprises a triple-branch cross
-domain feature mixer for comprehensive spatial–frequency–channel feature fusion
, alongside a spectral synthesis head that generates spectral intensities by que
rying continuous wavelength coordinates. Extensive experimental results demonstr
ate that Phy-CoSF not only achieves continuous modeling at arbitrary spectral re
solutions but also outperforms many state-of-the-art methods in both reconstruct
ion fidelity and spectral detail preservation.

Learning to Evict from Key-Value Cache

Luca Moschella, Laura Manduchi, Ozan Sener

The growing size of Large Language Models (LLMs) makes efficient inference chall
enging, primarily due to the memory demands of the autoregressive Key-Value (KV)
 cache. Existing eviction or compression methods reduce cost but rely on heurist
ics, such as recency or past attention scores, which serve only as indirect prox
ies for a token’s future utility and introduce computational overhead. We refram
e KV cache eviction as a reinforcement learning (RL) problem: learning to rank t
okens by their predicted usefulness for future decoding. To this end, we introdu
ce KV Policy (KVP), a framework of lightweight per-head RL agents trained on pre
-computed generation traces using only key and value vectors. Each agent learns
a specialized eviction policy guided by a holistic reward, derived from future u
tility, that evaluates the quality of the ranking across all cache budgets, requ
iring no modifications to the underlying LLM or additional inference. Evaluated
across two model families on the long-context benchmark RULER (up to 128K tokens
) and the multi-turn dialogue benchmark OASST2-4k, KVP significantly outperforms
 strong baselines. Zero-shot tests on standard downstream tasks (BoolQ, LongBenc

h passage retrieval, GovReport) further show that KVP generalizes beyond its tra ining distribution and to considerably longer sequence lengths. These results de monstrate that learning to predict future token utility is a powerful and scalab le paradigm for adaptive KV cache management.

Procedural Generation Of Algorithm Discovery Tasks in Machine Learning
Alexander David Goldie, Zilin Wang, Adrian Hayler, Deepak Nathani, Edan Toledo, Ken Thampiratwong, Aleksandra Kalisz, Michael Beukman, Alistair Letcher, Shashan k Reddy Chirra, Clarisse Wibault, Theo Wolf, Charles O'Neill, Uljad Berdica, Nic holas Roberts, Saeed Rahmani, Roberta Raileanu, Shimon Whiteson, Jakob Nicolaus Foerster
Automating the development of machine learning algorithms has the potential to u nlock new breakthroughs. However, our ability to *improve* and *evaluate* algori thm discovery systems has thus far been limited by existing task suites. They su ffer from many issues, such as: poor evaluation methodologies; data contaminatio n; and containing saturated or very similar problems. Here, we introduce *DiscoG en*, a procedural generator of algorithm discovery tasks for machine learning, s uch as developing optimisers for reinforcement learning or loss functions for im age classification. Motivated by the success of procedural generation in reinfor cement learning, DiscoGen spans billions of tasks of varying difficulty and comp lexity from a range of machine learning fields. These tasks are specified by a s mall number of configuration parameters and can be used to optimise algorithm di scovery agents (ADAs). We present *DiscoBench*, a fixed, small subset of DiscoGe n tasks for principled evaluation of ADAs. Finally, we propose a number of ambit ious, impactful research directions enabled by DiscoGen, and demonstrate its use for ADA optimisation through scaling experiments for automated prompt tuning. D iscoGen is released open-source.

Understanding LoRA as Knowledge Memory: An Empirical Analysis
Seungju Back, Dongwoo Lee, Naun Kang, Taehee Lee, S. K. Hong, Youngjune Gwon, Su ngjin Ahn
Continuous knowledge updating for pre-trained large language models (LLMs) is in creasingly necessary yet remains challenging. Although inference-time methods li ke In-Context Learning (ICL) and Retrieval-Augmented Generation (RAG) are popula

r, they face constraints in context budgets, costs, and retrieval fragmentation. Departing from these context-dependent paradigms, this work investigates a parametric approach using Low-Rank Adaptation (LoRA) as a modular knowledge memory. Although few recent works examine this concept, the fundamental mechanics governing its capacity and composability remain largely unexplored. We bridge this gap through the first systematic empirical study mapping the design space of LoRA-based memory, ranging from characterizing storage capacity and optimizing internalization to scaling multi-module systems and evaluating long-context reasoning. Rather than proposing a single architecture, we provide practical guidance on the operational boundaries of LoRA memory. Overall, our findings position LoRA as the complementary axis of memory alongside RAG and ICL, offering distinct advantages.
****

Reliability-Aware LLM Alignment from Inconsistent Human Feedback
Jingyi Huang, Ruohan Zong, Yujun Feng, Liran Ma, Lanyu Shang, Yang Zhang
Reinforcement Learning from Human Feedback (RLHF) is critical for aligning Large Language Models (LLMs) with human preferences. However, its efficacy is often compromised by the inherent inconsistency and subjectivity of human annotations. Existing preference optimization frameworks, such as Direct Preference Optimization (DPO), typically treat ambiguous pairs with high annotator disagreement identically to those with unanimous consensus, forcing models to overfit to inconsistent supervision signals and leading to suboptimal alignment. In this work, we propose $\textit{Reliability-Guided Preference Optimization}$ (RGPO), a robust framework designed to mitigate the impact of inconsistent human feedback. RGPO estimates annotator reliability and infers latent ground truth labels from noisy human feedback to identify robust preferences. Furthermore, we introduce a reliability-aware consistency optimization that dynamically modulates the training objective based on the consensus level of annotations, ensuring the model prioritizes high-consensus supervision signals. Extensive experiments on LLM alignment benchmarks demonstrate that RGPO effectively reduces inconsistency and noise in training data and achieves superior performance compared to widely adopted RLHF baselines. Our code and configurations are available at https://github.com/GenieHuang/RGPO.
****

ARC-Decode: Accelerated Decoding with Risk-Bounded Acceptance
Ying Li, Zhaode Wang, Zhiwen Chen, chengfei lv, Huan Wang
As larger language models deliver stronger capabilities, their autoregressive inference becomes increasingly expensive.
Speculative decoding accelerates generation by letting a fast draft propose tokens that the target model verifies in parallel.
Yet under sampling ($T>0$), observed speedups consistently lag behind those under greedy decoding, as the classical lossless verification rule tends to over-reject low-risk drafts, leading to lower acceptance rates and limited acceleration.
To address this gap, we propose **ARC-Decode** (**A**cceptance with **R**isk **C**ontrol), a training-free method that augments speculative decoding without extra forward passes.
ARC-Decode enables \textbf{relaxed} acceptance by identifying drafts whose acceptance preserves the output distribution of the target model, under a risk-controlled criterion based on Jensen--Shannon divergence.
It combines confidence-based pre-verification filtering with a risk-bounded acceptance criterion derived from an analytic upper bound on the potential distributional deviation.
Integrated into the state-of-the-art EAGLE-3 pipeline, ARC-Decode increases accept length per cycle and reduces verification compute, achieving up to **1.6**$\times$ end-to-end speedup over EAGLE-3 under sampling with negligible quality change across benchmarks.
****

AdverMCTS: Combating Pseudo-Correctness in Code Generation via Adversarial Monte Carlo Tree Search
Qingyao Li, Weiwen Liu, Weinan Zhang, Yong Yu, Bo An

Recent advancements in Large Language Models (LLMs) have successfully employed s
earch-based strategies to enhance code generation. However, existing methods typ
ically rely on static, sparse public test cases for verification, leading to pse
udo-correctness—where solutions overfit the visible public tests but fail to gen
eralize to hidden test cases. We argue that optimizing against a fixed, weak env
ironment inherently limits robustness. To address this, we propose AdverMCTS, a
novel adversarial Monte Carlo Tree Search framework that combats pseudo-correctn
ess by coupling code search with active vulnerability discovery. AdverMCTS formu
lates generation as a minimax-style game between a Solver agent, which synthesiz
es code candidates, and an Attacker agent, which evolves to generate targeted te
st cases that exploit logical divergences in the current solution pool. These di
scovered tests form a dynamic, progressively hostile filter that penalizes fragi
le reasoning. Extensive experiments demonstrate that AdverMCTS significantly out
performs state-of-the-art baselines, effectively reducing false positive rates a
nd forcing the model to generalize beyond the initial constraints. The resources
 of this work are available at https://github.com/SIMONLQY/AdverMCTS.

Mixtures Closest To A Given Measure: A Semidefinite Programming Approach
Srecko Durasinovic, Jean B. Lasserre, Victor Magron
Mixture models, such as Gaussian mixture models (GMMs), are widely used in machi
ne learning to represent complex data distributions. A key challenge, especially
 in high-dimensional settings, is to determine the mixture order and estimate th
e mixture parameters. We study the problem of approximating a target measure, av
ailable only through finitely many of its moments, by a mixture of distributions
 from a parametric family (e.g., Gaussian, exponential, Poisson), with approxima
tion quality measured by the 2-Wasserstein ($\operatorname{W_2}$) or the total v
ariation (TV) distance. Unlike many existing approaches, the pa
rameter set is not assumed to be finite; it is modeled as a compact basic semi-a
lgebraic set. We introduce a hierarchy of semidefinite relaxations with asymptot
ic convergence to the desired optimal value. In addition, when a certain rank co
ndition is satisfied, the convergence is even finite and recovery of an optimal
mixing measure is obtained. We also present an application to clustering, where
our framework serves either as a stand-alone method or as a preprocessing step t
hat yields both the number of clusters and strong initial parameter estimates, t
hereby accelerating convergence of standard (local) clustering algorithms

Unlearning with Asymmetric Sources: Improved Unlearning-Utility Trade-off with P
ublic Data
Ahmed Mehdi Inane, Vincent Quirion, Gintare Karolina Dziugaite, Ioannis Mitliagk
as
Noise-based certified machine unlearning currently faces a hard ceiling: the noi
se magnitude required to certify unlearning typically destroys model utility, pa
rticularly for large-scale deletion requests.
While leveraging public data is a standard technique in differential privacy to
relax this tension, its role in unlearning remains unexplored. We address this g
ap by introducing **Asymmetric Langevin Unlearning (ALU)**, a framework that use
s public data to mitigate privacy costs. We prove that public data injection sup
presses the unlearning cost by a factor of $O(1/n_{\mathrm{pub}}^2)$, guaranteei
ng a strict computational advantage over retraining. This establishes a new cont
rol mechanism: practitioners can mitigate the need for high noise—and the associ
ated utility loss—by increasing the volume of public data. Crucially, we analyze
 the realistic setting of **distribution mismatch**, explicitly characterizing h
ow shifts between public and private sources impact utility. We show that ALU en
ables "mass unlearning'' of constant dataset fractions -- a regime where standar
d symmetric methods become impractical -- while maintaining high utility.
Empirical evaluations using variational Rényi divergence and membership inferenc
e attacks confirm that ALU effectively thwarts privacy attacks while preserving
utility under reasonable distribution shifts.

AgentHijack: Benchmarking Computer Use Agent Robustness to Common Environment Co

rruptions
Jingwei Sun, Jianing Zhu, Yuanyi Li, Tongliang Liu, Xia HU, Bo Han
Autonomous computer use agents that powered by multimodal large language models (MLLMs) are emerging as capable assistants for completing complex digital workflows. However, real-world execution environments are far from ideal: pop-ups, resolution changes, and competing applications frequently interfere with agent perception and control. We introduce AgentHijack, a benchmark designed to evaluate the robustness of computer-use agents under common corruptions, where the uncertainties in dynamic environment disrupt the execution flow without direct adversarial intent. Specifically, AgentHijack introduces 9 configurable common corruptions to replicate realistic imperfect scenarios. We evaluate a variety of desktop tasks that utilize MLLM-based agents and discover that even minor instances of corruption can result in substantial performance degradation, which emphasizes the fragility of agents and underscores the necessity of robustness evaluation. Afterward, we propose AgentHijack-Agent, a framework that integrates an action generator with enhanced grounding capabilities and an onlooker responsible for behavior summarization and environment checking. Extensive experiments validate its effectiveness. Our code, environment, baseline models and data are publicly available at: \url{https://AgentHijack.github.io}.
****

Cross-Tactile Sensor Representation Learning
Yan Zhang, Zheng WANG, Pengpeng Zeng, Xing Xu, Jingkuan Song, Heng Tao Shen
Visuo-tactile sensors have been widely adopted in robotic manipulation. However, inherent heterogeneity in sensor designs hinders the learning of unified tactile representations in cross-sensor scenarios. Existing methods that focus on reconstruction or task-specific supervision often fail to capture the common information between different tactile sensors, particularly in the presence of substantial sensor variations, resulting in limited generalization to unseen sensors. To address this, we propose Cross-Tactile Sensor Representation Learning (CTSRL), a unified framework for sensor-agnostic tactile representation learning. CTSRL introduces a Cross-Sensor Modulator (CSM) to eliminate sensor-specific biases and adopts a two-stage learning paradigm: (1) leveraging aligned synthetic data for cross-sensor self-supervised learning to extract shared latent representations across sensor domains; and (2) integrating real-world multimodal tactile data to bridge the sim-to-real semantic gap through cross-modal alignment, thereby enriching representations with fine-grained semantic attributes. Experimental results show that our method demonstrates strong multi-sensor generalization, significantly improving sensor-agnostic representation learning.
****

Reward Shaping for (Inference-Time) Alignment: A Stackelberg Game Perspective
Haichuan Wang, Tao Lin, Lingkai Kong, Ce Li, Hezi Jiang, Milind Tambe
Existing alignment methods directly use the reward model learned from user preference data to optimize an LLM policy, subject to KL regularization with respect to the base policy. This practice is suboptimal for maximizing user's utility because the KL regularization may cause the LLM to inherit the bias in the base policy that conflicts with user preferences. While amplifying rewards for preferred outputs can mitigate this bias, it also increases the risk of reward hacking. This tradeoff motivates the problem of optimally designing reward models under KL regularization. We formalize this reward model optimization problem as a Stackelberg game, and show that a simple reward shaping scheme can effectively approximate the optimal reward model. We empirically evaluate our method in inference-time alignment settings and demonstrate that it integrates seamlessly into existing alignment methods with minimal overhead. Our method consistently improves average reward and achieves win–tie rates exceeding 66\% against all baselines, averaged across evaluation settings.

Online Contract Design With Unknown Technology
Matteo Bollini, Matteo Castiglioni, Alberto Marchesi
Hidden-action principal-agent problems model scenarios in which a principal induces an agent to take a costly and *unobservable* action through the provision

of outcome-dependent payments. These problems find application in a variety of r
eal-world settings, such as crowdsourcing, online labor platforms, and machine l
earning task delegation. Recently, much of the literature has focused on how to
handle the principal’s *uncertainty* about the agent and the surrounding environ
ment, which is often the main challenge in practice. One prominent approach is t
o adopt an *online learning* framework, where the principal repeatedly interacts
with the agent to learn optimal payments from experience. However, existing lea
rning algorithms, while achieving regret that scales sublinearly in the number o
f interaction rounds T, typically suffer from an exponential dependence on the
size of the problem instance. In this paper, we show that this problematic expo
nential growth can be avoided by assuming that the principal has knowledge of a
set of possible actions of the agent, while remaining unaware of which actions a
re actually available---an assumption that is reasonable in many real-world sett
ings.

Beyond Looking Up, Try Looking Around: Harmonizing Global Structure and Local Co
nsistency in Optimal Transport for Short Text Clustering
Zhihao Yao, Yuxuan Gu, Jixuan Yin, Bo Li
Pseudo-labeling based on Optimal Transport (OT) has become an effective mechanis
m for enhancing short text clustering.
Existing OT methods are short in modeling semantic consistencies between samples
, which may assign different pseudo-labels to semantically similar samples. Thes
e erroneous pseudo-labels can cause the model to produce inferior clusters.
This paper proposes a novel short text clustering framework, which remedies the
neglect of semantic consistency in existing OT methods, generating reliable pseu
do-labels to facilitate clustering.
Specifically, the proposed approach first designs an instance-level attention me
chanism to capture semantic relationships between samples, which are then integr
ated into the OT formulation to endow the transport process with neighborhood se
mantic awareness.
By solving the proposed OT formulation, reliable pseudo-labels are obtained that
simultaneously account for sample-to-sample semantic consistency and sample-to-
cluster global structure information.
These pseudo-labels are then used as supervisory signals to guide the model to a
chieve accurate clustering.
Extensive experiments demonstrate that the proposed approach outperforms state-o
f-the-art methods.
The code is available at: https://github.com/YZH0905/CAOT-STC.

FreeRet: MLLMs as Training-Free Retrievers
Yuhan Zhu, Xiangyu Zeng, Chenting Wang, Xinhao Li, Chunxu Liu, Yicheng Xu, Ziang
Yan, Yi Wang, Limin Wang
Multimodal large language models (MLLMs) are emerging as versatile foundations f
or mixed-modality retrieval.
Yet, they often require heavy post-hoc training to convert them into contrastive
encoders for retrieval.
This work asks: \textit{Can off-the-shelf MLLMs serve as powerful retrievers wit
hout additional training?}
We present \textbf{FreeRet}, a plug■and■play framework that turns any MLLM into
a two■stage retriever.
FreeRet first derives semantically grounded embeddings directly from the model f
or fast candidate search, and then exploits its reasoning ability for precise re
ranking.
The framework contributes three advances: bypassing lexical alignment layers to
obtain semantically faithful embeddings, conditioning representation generation
with explicit priors, and mitigating framing effect in reranking via neutral cho
ice framing.
On the MMEB and MMEB-V2, FreeRet substantially outperforms models trained on mil
lions of pairs.
Beyond benchmarks, FreeRet is model-agnostic and scales seamlessly across MLLM f

amilies and sizes, preserves their generative abilities, supports arbitrary moda
lity combinations, and unifies retrieval, reranking, and generation into end-to-
end RAG within a single model.
Our findings demonstrate that pretrained MLLMs, when carefully harnessed, can se
rve as strong retrieval engines without training, closing a critical gap in thei
r role as generalists.

ForceForget: Reinforcement Concept Removal for Enhancing Safety in Text-to-Image
 Models
Dong Han, Yong Li
With the advance of generative AI, the text-to-image (T2I) model has the ability
 to generate various contents. However, T2I models still can generate unsafe con
tents. To alleviate this issue, various concept erasing methods are proposed. Ho
wever, existing methods tend to excessively erase unsafe concepts and suppress b
enign concepts contained in harmful prompts, which can negatively affect model u
tility. In this paper, we focus on eliminating unsafe content while maintaining
model capability in safe semantic meaning interpretation by optimizing the conce
pt erasing reward (CER) with reinforcement learning. To avoid overly content era
sure, we introduce the Safe Adapter to project partial text embedding for effici
ent concept regulation in cross-attention layers. Extensive experiments conducte
d on different datasets demonstrate the effectiveness of the proposed method in
alleviating unsafe content generation while preserving the high fidelity of beni
gn images compared with existing state-of-the-art (SOTA) concept erasing methods
. In terms of robustness, our method outperforms counterparts against red-teamin
g tools. Moreover, we showcase the proposed approach is more effective in emergi
ng image-to-image (I2I) scenarios compared with others. Lastly, we extend our me
thod to erase general concepts, such as artistic styles and objects. **Disclaime
r:** *This paper includes discussions of sexually explicit content that may be o
ffensive to certain readers. All images used in this work are synthesized or fro
m public datasets.*

TIMI: Training-Free Image-to-3D Multi-Instance Generation with Spatial Fidelity
Xiao Cai, Pengpeng Zeng, Ji Zhang, Heng Tao Shen, Jingkuan Song, Lianli Gao
Precise spatial fidelity in Image-to-3D multi-instance generation is critical fo
r downstream real-world applications. Recent work attempts to address this by fi
ne-tuning pre-trained Image-to-3D (I23D) models on multi-instance datasets, whic
h incurs substantial training overhead and struggles to guarantee spatial fidel
ity.
In fact, we observe that pre-trained I23D models already possess meaningful spat
ial priors, which remain underutilized as evidenced by instance entanglement iss
ues.
Motivated by this, we propose **TIMI**, a novel **T**raining-free framework for
Image-to-3D **M**ulti-**I**nstance generation that achieves high spatial fid
elity.
Specifically, we first introduce an Instance-aware Separation Guidance (ISG) mod
ule, which facilitates instance disentanglement during the early denoising stage
. Next, to stabilize the guidance introduced by ISG, we devise a Spatial-stabili
zed Geometry-adaptive Update (SGU) module that promotes the preservation of the
geometric characteristics of instances while maintaining their relative relation
ships. Extensive experiments demonstrate that our method yields better performan
ce in terms of both global layout and distinct local instances compared to exist
ing multi-instance methods, without requiring additional training and with faste
r inference speed.

“Do Diffusion Models Dream of Electric Planes?” Discrete and Continuous Simulati
on-Based Inference for Aircraft Design
Aurelien Ghiglino, Daniel Elenius, Anirban Roy, Ramneet Kaur, Manoj Acharya, Col
in Samplawski, Brian Matejek, Susmit Jha, Juan Alonso, Adam D. Cobb
In this paper, we generate conceptual engineering designs of electric vertical t
ake-off and landing (eVTOL) aircraft. We follow the paradigm of simulation-based

inference (SBI), whereby we look to learn a posterior distribution over the full eVTOL design space. To learn this distribution, we sample over discrete aircraft configurations (topologies) and their corresponding set of continuous parameters. Therefore, we introduce a hierarchical probabilistic model consisting of two diffusion models. The first model leverages recent work on Riemannian Diffusion Language Modeling (RDLM) and Unified World Models (UWMs) to enable us to sample topologies from a discrete and continuous space. For the second model we introduce a masked diffusion approach to sample the corresponding parameters conditioned on the topology. Our approach rediscovers known trends and governing physical laws in aircraft design, while significantly accelerating design generation.

Attacks on Machine-Text Detectors Retain Stylistic Fingerprints
Rafael Alberto Rivera Soto, Barry Y. Chen, Nicholas Andrews
Despite considerable progress in the development of machine-text detectors, the ease with which machine-text can be manipulated to evade detection has led to suggestions that the problem is inherently intractable.
In this work, we investigate the limits of such evasion strategies.
We demonstrate that while current attacks, ranging from prompt engineering to detector-guided optimization can effectively degrade performance of standard detectors, they fail to erase the underlying stylistic "fingerprints" of machine text.
We show that few-shot detectors that utilize the stylistic feature space are robust to these evasion attempts, reliably detecting samples even from models explicitly tuned to prevent detection.
This raises the question: does style represent a universal defense against machine-detection attacks?
We demonstrate that the answer is "no" by introducing a novel paraphrasing approach that simultaneously optimizes for undetectability and adherence to specific human styles.
We show that unlike prior methods, this attack effectively evades all considered detectors, including those that utilize writing style.
However, we find that this evasion is not absolute: as the number of documents available for analysis grows, the human and machine distributions become distinguishable again.
Overall, our findings suggest that reliable machine-text detection requires moving beyond single-document analysis to multi-document analysis.

Introspection Adapters: Training LLMs to Report Their Learned Behaviors
Keshav Shenoy, Li Yang, Abhay Sheshadri, Jack Lindsey, Samuel Marks, Rowan Wang
Can we train LLMs to *introspect*, i.e. to faithfully describe their own behaviors in natural language? Prior work has shown some, limited, success. However, it is difficult to scale introspection training due to a lack of ground-truth labels. In this work, we study an approach to introspection training which side-steps this data bottleneck. Given a target model M, our method works by fine-tuning models M_i from M with implanted behaviors b_i (such as downplaying medical problems); the (M_i, b_i) pairs serve as labeled introspection training data. We then train an *introspection adapter* (IA): a LoRA adapter jointly optimized across the fine-tunes M_i which causes them to verbalize their implanted behaviors. This IA induces faithful introspection in fine-tunes of M that were trained in very different ways from the M_i, as well as in M itself. This is surprising because the IA was never trained on M. To demonstrate the utility of IAs, we use them to successfully audit misaligned models introduced in prior work. IAs can also be used to detect fine-tuning API attacks which train models to comply with encrypted harmful requests. Notably, IAs are more effective when applied to larger models. Overall, our results suggest that IAs are a scalable, effective, and practically useful approach to LLM introspection training.

Generalization Bounds for Out-of-distribution Generalization
Xin Zou, Xiuwen Gong, Weiwei Liu
Out-of-distribution (OOD) generalization has attracted increasing research atten

tion in recent years, owing to its promising empirical results in real-world applications. However, theoretical studies on OOD generalization remain limited, particularly with respect to lower bounds on the generalization error. To better understand how source data contributes to improved OOD generalization performance, we take an initial step toward establishing a lower bound on the OOD generalization error, and subsequently investigate upper bounds from the perspective of statistical learning theory. Interestingly, we find that under the RCS and empirical-RCS conditions, simply minimizing the average empirical risk over the source domains can yield a nearly optimal error rate (up to a logarithmic factor) \textit{without} requiring knowledge or estimation of distributional parameters or the discrepancy between source and target domains. This conditional result provides a theoretical perspective on the surprising phenomenon observed in DomainBed, where carefully designed OOD generalization algorithms fail to outperform the simple empirical risk minimization (ERM) algorithm. Our results also imply a no-free-lunch theorem and provide an optimistic bound for OOD generalization.

Can We Build a Monolithic Model for Fake Image Detection? SICA: Semantic-Induced Constrained Adaptation for Unified-Yet-Discriminative Artifact Feature Space Reconstruction
Bo Du, Xiaochen Ma, Xuekang Zhu, Zhe Yang, Chaoqun Niu, Jian liu, Ji-Zhe Zhou
Fake Image Detection (FID), aiming at unified detection across four image forensic subdomains, is critical in real-world forensic scenarios. Compared with ensemble approaches, monolithic FID models are theoretically more promising, but to date, consistently yield inferior performance in practice. In this work, we identify the intrinsic distinctness of artifacts across subdomains—a critical barrier we term the "Ji-Zhe phenomenon". Driven by this phenomenon, we diagnose the cause of this underperformance for the first time: the collapse of the artifact feature space. The core challenge for developing a practical monolithic FID model thus boils down to the "unified-yet-discriminative" reconstruction of the artifact feature space. To address this paradoxical challenge, we hypothesize that high-level semantics can serve as a structural prior for the reconstruction, and further propose Semantic-Induced Constrained Adaptation (SICA), the first monolithic FID paradigm. Extensive experiments on our $ \textit{OpenMMSec} $ dataset demonstrate that SICA outperforms 15 state-of-the-art methods and reconstructs the target unified-yet-discriminative artifact feature space in a near-orthogonal manner, thus firmly validating our hypothesis. The code and dataset will be made publicly available.

Faithful Relational Reasoning with Region-based Embeddings: Expressivity of Convex Coordinate-wise Models
Victor Charpenay, Steven Schockaert
Embedding methods are among the most efficient approaches for learning to reason about relational knowledge. In this paper, we focus on the framework of region-based embeddings, where relations are encoded as geometric regions. The spatial arrangement of these regions allows such models to capture symbolic rules, enabling them to simulate some forms of symbolic reasoning. A crucial consideration is how the regions are parameterized, as this affects which rule bases can be captured. Most methods use convex regions which are defined in terms of coordinate-wise comparisons. This makes them highly efficient, but the implications of this choice have thus far remained unclear. We present a series of results that shed light on this issue, showing that convex coordinate-wise models indeed have important limitations, while at the same time showing that there is still room for pushing the expressivity of existing coordinate-wise models.
****
Enhancing Reasoning for Diffusion LLMs via Distribution Matching Policy Optimization
Yuchen Zhu, Wei Guo, Jaemoo Choi, Petr Molodyk, Bo Yuan, Molei Tao, Yongxin Chen
Diffusion large language models (dLLMs) are promising alternatives to autoregressive large language models (AR-LLMs), as they potentially allow higher inference throughput. Reinforcement learning (RL) is crucial to enabling dLLMs to achieve

performance comparable to that of AR-LLMs on important tasks, such as reasoning. However, RL algorithms well-suited to dLLMs' unique characteristics have yet to be developed. This paper proposes \textbf{Distribution Matching Policy Optimization (DMPO)}, a principled and theoretically grounded RL fine-tuning method specifically designed to enhance the reasoning capabilities of dLLMs by matching the dLLM policy distribution to the optimal, reward-tilted one through cross-entropy optimization. We identify a key implementation challenge with small training batch sizes and propose several effective solutions based on a novel weight baseline subtraction technique. DMPO exhibits superior performance on multiple reasoning benchmarks without supervised fine-tuning, achieving up to a 39.63 percentage-point improvement in accuracy over prior non-DMPO RL baselines and 67.97 percentage points over the base model, underscoring the effectiveness of the distribution-matching framework. Our code is available at https://github.com/yuchen-zhu-zyc/DMPO.

Catch-22: On the Fundamental Tradeoff Between Detectability and Robustness in LLM Watermarking

Kuheli Pratihar, Debdeep Mukhopadhyay

Large language models generate text by sampling tokens at random, a process now widely used for inference-time watermarking that verifies AI-generated content. We present an information-theoretic framework that captures the trade-off between robustness to text edits and detectability by observers who lack the watermark key or a keyless detector. The bounds we derive hold regardless of computational power, and what a keyless detector can actually achieve depends on what it can observe about the model and its outputs. At the heart of the analysis is an additive, Kullback-Leibler (KL) information measure that quantifies how well a hypothesis test can distinguish watermarked from unwatermarked text while the watermark remains stealthy. The measure remains zero for distribution-preserving schemes and increases with text length for token-level and sentence-level probability-modifying schemes. When edits are modeled as noise, the KL measure shrinks quadratically with the edit rate for token-level schemes and with an induced semantic flip rate for sentence-level schemes. This shrinkage exposes an unavoidable trilemma among robustness, stealth, and reliable verification. Guided by these limits, we propose a hybrid watermarking strategy that selects the Pareto-optimal scheme among distribution-preserving, semantic-level, and token-level methods based on the expected editing regime at deployment. Experiments on Llama-2-7B and Mistral-7B under paraphrasing attacks corroborate these theoretical predictions and confirm that the hybrid strategy lies near the Pareto frontier across the edit regimes we evaluate.

Protein Autoregressive Modeling via Multiscale Structure Generation

Yanru Qu, Cheng-Yen Hsieh, Zaixiang Zheng, Ge Liu, Quanquan Gu

We present protein autoregressive modeling (PAR), the first multi-scale autoregressive framework for protein backbone generation via coarse-to-fine next-scale prediction. Using the hierarchical nature of proteins, PAR generates structures that mimic sculpting a statue, forming a coarse topology and refining structural details over scales. To achieve this, PAR consists of three key components: (i) multi-scale downsampling operations that represent protein structures across multiple scales during training; (ii) an autoregressive transformer that encodes multi-scale information and produces conditional embeddings to guide structure generation; (iii) a flow-based backbone decoder that generates backbone atoms conditioned on these embeddings. Moreover, autoregressive models suffer from exposure bias, caused by the training and the generation procedure mismatch, and substantially degrades structure generation quality. We effectively alleviate this issue by adopting noisy context learning and scheduled sampling, enabling robust backbone generation. Notably, PAR exhibits strong zero-shot generalization, supporting flexible human-prompted conditional generation and motif scaffolding without requiring fine-tuning. On the unconditional generation benchmark, PAR effectively learns protein distributions and produces backbones of high design quality, and exhibits favorable scaling behavior. Together, these properties establish PAR

as a promising framework for protein structure generation.

Latent Spherical Flow Policy for Reinforcement Learning with Combinatorial Actions
Lingkai Kong, Anagha Satish, Hezi Jiang, Akseli Kangaslahti, Andrew Ma, Wenbo Chen, Mingxiao Song, Lily Xu, Milind Tambe
Reinforcement learning (RL) with combinatorial action spaces remains challenging because feasible action sets are exponentially large and governed by complex feasibility constraints, making direct policy parameterization impractical. Existing approaches embed task-specific value functions into constrained optimization programs or learn deterministic structured policies, sacrificing generality and policy expressiveness. We propose a solver-induced \emph{latent spherical flow policy} that brings the expressiveness of modern generative policies to combinatorial RL while guaranteeing feasibility by design. Our method, LSFlow, learns a \emph{stochastic} policy in a compact continuous latent space via spherical flow matching, and delegates feasibility to a combinatorial optimization solver that maps each latent sample to a valid structured action. To improve efficiency, we train the value network directly in the latent space, avoiding repeated solver calls during policy optimization. To address the piecewise-constant and discontinuous value landscape induced by solver-based action selection, we introduce a smoothed Bellman operator that yields stable, well-defined learning targets. Empirically, our approach outperforms state-of-the-art baselines by an average of 20.6\% across a range of challenging combinatorial RL tasks.
****
The Consistency Dilemma in LLMs: Generator-Evaluator Agreement and Vulnerability to Mistakes
Marina Mancoridis, Zoe Hitzig
Large language models are increasingly deployed in agentic pipelines that depend on the model evaluating its own outputs without external verification. The reliability of these pipelines depends on an implicit assumption: that the model applies relevant concepts the same way when it generates an output and later evaluates that output. We propose a new measure, *generator–evaluator self-consistency*, to test this assumption directly and apply it to 10 frontier models across 491 concepts. We find, first, that there is substantial variation in self-consistency. Second, we find that in a clinical setting with physician-validated mistakes (Proniakin et al., 2025), across models, those with higher self-consistency are linked to *greater* vulnerability to mistakes. Thus, even when models consistently apply concepts they may not be safe to deploy. This is evidence of a *consistency dilemma* in LLMs: self-consistency is operationally useful, but models that are more consistent are also more prone to mistakes.

Discovering Ordinary Differential Equations with LLM-Based Qualitative and Quantitative Evaluation
Sum Kyun Song, Bong Gyun Shin, Jae Yong Lee
Discovering governing differential equations from observational data is a fundamental challenge in scientific machine learning. Existing symbolic regression approaches rely primarily on quantitative metrics; however, real-world differential equation modeling also requires incorporating domain knowledge to ensure physical plausibility. To address this gap, we propose DoLQ, a method for discovering ordinary differential equations with LLM-based qualitative and quantitative evaluation. DoLQ employs a multi-agent architecture: a Sampler Agent proposes dynamic system candidates, a Parameter Optimizer refines equations for accuracy, and a Scientist Agent leverages an LLM to conduct both qualitative and quantitative evaluations and synthesize their results to iteratively guide the search. Experiments on multi-dimensional ordinary differential equation benchmarks demonstrate that DoLQ achieves superior performance compared to existing methods, not only attaining higher success rates but also more accurately recovering the correct symbolic terms of ground truth equations. Our code is available at https://github.com/Bon99yun/DoLQ.

Uncovering Bias Mechanisms in Observational Studies
Ilker Demirel, Zeshan Hussain, Piersilvio De Bartolomeis, David Sontag
Observational studies are a key resource for causal inference but are often affe
cted by systematic biases. Prior work has focused mainly on detecting these bias
es, via sensitivity analyses and comparisons with randomized controlled trials,
or mitigating them through debiasing techniques. However, there remains a lack o
f methodology for uncovering the underlying mechanisms driving these biases, *e.
g.*, whether due to hidden confounding or selection of participants. In this wor
k, we show that the relationship between bias magnitude and the predictive perfo
rmance of nuisance function estimators (in the observational study) can help dis
tinguish among common sources of bias. We validate our methodology through exten
sive synthetic experiments and a real-world case study, demonstrating its effect
iveness in revealing the mechanisms behind observed biases. Our framework offers
 a new lens for understanding and characterizing bias in observational studies,
with practical implications for improving causal inference.
****
Steer Like the LLM: Activation Steering that Mimics Prompting
Geert Heyman, Frederik Vandeputte
Large language models can be steered at inference time through prompting or acti
vation interventions, but activation steering methods often underperform compare
d to prompt-based approaches. We investigate whether activation steering can be
improved by learning to mimic the interventions that prompt steering triggers wi
thin the model. To this end, we introduce *Prompt Steering Replacement (PSR)* mo
dels, a new family of activation steering methods that distill prompt steering b
ehavior into interpretable interventions on model activations. A PSR is an activ
ation steering method that estimates position-specific steering coefficients and
 is trained to imitate prompt-based interventions. Experiments on persona steeri
ng and instruction following across multiple language models demonstrate that PS
R models consistently outperform constant-coefficient interventions that are fre
quently used in the literature and achieve performance close to or exceeding pro
mpt steering while maintaining interpretability.
****
Generative Modeling of Discrete Latent Structures via Dynamic Policy Gradients
Stefan Ivanovic, Ge Liu, Mohammed El-Kebir
Many scientific problems require inferring unobserved mechanistic latent states
from indirect observations. While classical approaches, including expectation-ma
ximization, do not scale to combinatorially large spaces, deep learning approach
es such as variational autoencoders typically form artificial latent states rath
er than reconstructing the mechanistic ground-truth states. Here, we introduce G
ReinSS, a policy learning framework that uses dynamically rescaled rewards to le
arn latent state distributions that maximize the observed data likelihood. We sh
ow that GReinSS accurately reconstructs simulated latent sets and latent graphs,
 outperforming alternative policy learning and generative modeling baselines. Ad
ditionally, GReinSS reconstructs isoforms from real short-read RNA sequencing da
ta that better match orthogonal long-read sequencing detected isoforms than the
standard RSEM algorithm. Overall, GReinSS is a principled and practically effec
tive approach for generative modeling and inference of combinatorial latent stat
es from indirect observations.

The Tell-Tale Norm: ℓ_2 Magnitude as a Signal for Reasoning Dynamics in Lar
ge Language Models
Jinyang Zhang, Hongxin Ding, Yue Fang, Weibin Liao, Muyang Ye, Junfeng Zhao, Yas
ha Wang
Recent work has sought to understand Large Language Models (LLMs) reasoning, yet
 a principled, model-intrinsic signal that captures its *layer-wise reasoning dy
namics* remains underexplored. We bridge this gap by demonstrating that **the $\
ell_2$ norm of hidden states serves as an endogenous signal of the model's reaso
ning intensity**. Using Sparse Autoencoders (SAEs) as a diagnostic probe, we obs
erve that LLMs' internal reasoning is marked by a sharp increase in reasoning fe
ature activations concentrated in late layers. Motivated by this pattern, we est

ablish a formal link between reasoning intensity and the model's latent geometry and theoretically prove that the ℓ_2 norm of hidden states bounds the activation strength of SAE reasoning features. Empirical correlation analysis and causal interventions further prove ℓ_2 norm as a faithful indicator, where heightened norms consistently correspond to critical reasoning steps. We then introduce three test-time scaling techniques guided by ℓ_2 norms: Adaptive Layer-wise Reasoning Recursion, (ii) Endogenous Reasoning State Steering, and (iii) ℓ_2-guided Response Selection, which requires no additional training or data and is compatible with advanced inference engines. Experiments across model architectures and benchmarks show that ℓ_2-norm-based techniques significantly improve reasoning performance, offering a principled yet simple lens to perceive and control LLM latent reasoning dynamics. Our codes are available at https://github.com/zjy1298/The-Tell-Tale-Norm.

Seeing the Unseen: Physics-as-Representation for Generalizable Gaze Perception
Yunfeng Xiao, Xiaowei Bai, Hao Su, Hao He, Liang Xie, Erwei Yin

We introduce physics-as-representation, a learning paradigm that encodes physical structure and geometric laws into visual representations, enabling models to see the unseen—the underlying 3D geometry and motion dynamics not apparent in raw pixels. We instantiate this paradigm in gaze perception by proposing SG-Gaze, a framework that learns a Structurally and Geometrically Consistent Representation (SGR) through dual-branch adversarial learning.

An analytical branch embeds appearance features onto a spherical manifold aligned with gaze geodesics, while a model-guided branch reconstructs the 3D eyeball with weak 2D edge supervision.

We further introduce View-Consistent Regularization, which augments SGR learning with synthetic view perturbations and enforces rotation-equivariant consistency across gaze vectors and structural projections, eliminating the need for multi-view calibration or explicit 3D labels.

Extensive experiments across 12 challenging cross-domain transfers demonstrate that SG-Gaze achieves state-of-the-art accuracy and strong generalization. Our work highlights that enforcing structural and geometric consistency with equivariant regularization serves as effective inductive biases for interpretable and generalizable representation learning—a step toward machines that perceive the world not only from pixels, but from physics.

Mind Your Entropy: From Maximum Entropy to Trajectory Entropy-Constrained RL
Guojian Zhan, Likun Wang, Pengcheng Wang, Feihong Zhang, Jingliang Duan, Kaichen g Yu, Masayoshi Tomizuka, Shengbo Eben Li

Maximum entropy has become a mainstream off-policy reinforcement learning (RL) framework for balancing exploitation and exploration. However, two bottlenecks still limit further performance gains: (1) non-stationary Q-value estimation stemming from the joint injection of entropy and the concurrent updating of its temperature parameter; and (2) short-sighted local entropy tuning, which adjusts temperature solely based on current single-step entropy without accounting for cumulative entropy over time. In this paper, we broaden the maximum entropy framework by proposing a trajectory entropy-constrained reinforcement learning (TECRL) framework to address these limitations. We begin by introducing reward-entropy separation (RES) to decouple the value targets, ensuring they remain stable and unaffected by temperature fluctuations. Subsequently, the resulting entropy Q-function is leveraged to explicitly quantify expected cumulative entropy, allowing for the enforcement of a trajectory entropy constraint (TEC) to govern long-term stochasticity. We instantiate this framework as DSAC-E, a practical off-policy algorithm that builds upon the latest distributional soft actor-critic. Extensive evaluations across 10 challenging tasks in locomotion, robotic manipulation, and vision-based driving domains demonstrate that DSAC-E consistently outperforms baselines in both cumulative returns and training stability.

CANDI: Hybrid Discrete-Continuous Diffusion Models
Patrick Pynadath, Jiaxin Shi, Ruqi Zhang

While continuous diffusion has shown remarkable success in continuous domains su
ch as image generation, its direct application to discrete data has underperform
ed pure discrete formulations. To understand this gap, we introduce *token ident
ifiability*, an analytical framework characterizing how Gaussian noise corrupts
discrete data through two mechanisms: *discrete identity corruption* and *contin
uous rank degradation*. We reveal that these mechanisms scale differently with v
ocabulary size, creating a *temporal dissonance* that forces a tradeoff between
learning continuous geometry and discrete structure. To address this, we propose
 CANDI (**C**ontinuous **AN**d **DI**screte diffusion), a hybrid framework t
hat decouples discrete and continuous corruption, enabling simultaneous learning
 of both. This unlocks the benefits of continuous diffusion for discrete spaces:
 on controlled generation, CANDI enables classifier-based guidance with off-the-
shelf classifiers through simple gradient addition; on text generation, CANDI ou
tperforms masked diffusion at low NFE, demonstrating the value of learning conti
nuous gradients for discrete spaces.

From Knowledge to Inference: Formalizing Specialized Public Health Reasoning on
GlobalHealthAtlas
Zhaokun Yan, Shan Xu, Wuzheng Dong, Zhaohan Liu, Lijie Feng, Chengxiao Dai, Chen
 Tianqi, Binfan Liu, Yunpu Ma, Wenting Wei, Yingting Li, Yi Zhang, Tongning Wu
Public health reasoning requires population level inference grounded in scientif
ic evidence, expert consensus, and safety constraints. However, it remains under
explored as a structured machine learning problem with limited supervised signal
s and benchmarks. We introduce GlobalHealthAtlas, a large scale multilingual dat
aset of 280,210 instances spanning 15 public health domains and 17 languages. We
 further propose a large language model (LLM) assisted construction and quality
control pipeline with retrieval, deduplication, evidence grounding checks, and l
abel validation to improve consistency at scale. Finally, we present a domain al
igned evaluator distilled from high confidence judgments of diverse LLMs to asse
ss outputs along six dimensions: Accuracy, Reasoning, Completeness, Consensus Al
ignment, Terminology Norms, and Insightfulness. Together, these contributions en
able reproducible training and evaluation of LLMs for safety critical public hea
lth reasoning beyond conventional QA benchmarks. We publicly release project cod
ebase, evaluator, and model at:: https://github.com/Jan8217/GlobalHealthAtlas, h
ttps://huggingface.co/aerovane0/GlobalHealthAtlas_Public_Evaluator and https://h
uggingface.co/aerovane0/GlobalHealthAtlas_Public_Model

Low-Compute Watermark Removal via Dual-Domain Natural Projection
Pragati Shuddhodhan Meshram, Varun Chandrasekaran
Effective removal of semantic watermarks requires balancing three competing obje
ctives:
\emph{high removal success}, \emph{low perceptual distortion}, and \emph{low com
putational cost}.
However, existing single-image attacks typically optimize only for the first two
, achieving strong
watermark suppression but relying on expensive, multi-step optimization that lim
its practical
deployment. In this work, we show that this trade-off is fundamental: no current
 approach achieves
all three properties simultaneously. We introduce \textsc{DAWN}, a lightweight,
training-free
attack that explicitly targets the low-cost regime while maintaining competitive
 removal
performance. \textsc{DAWN} works by projecting a watermarked image onto natural-
image priors in
complementary frequency and semantic spaces, suppressing watermark signals that
deviate from
natural statistics, and then applying a decoupled perceptual-alignment step to r
estore visual
consistency with minimal artifact. Across diverse pixel-, frequency-, and latent

-space
watermarking schemes, \textsc{DAWN} consistently reduces detectability while pre serving structural
and semantic fidelity, demonstrating that efficient, low-resource watermark remo val is feasible
with only modest perceptual degradation. Our code is
available at \url{https://anonymous.4open.science/r/DAWN-567A/}.

RAGEN-2: Reasoning Collapse in Agentic RL
Zihan Wang, Chi Gui, Xing Jin, Qineng Wang, Licheng Liu, Kangrui Wang, Shiqi Che n, Linjie Li, Zhengyuan Yang, Pingyue Zhang, Yiping Lu, Jiajun Wu, Li Fei-Fei, L ijuan Wang, Yejin Choi, Manling Li
RL training of multi-turn LLM agents is unstable, and reasoning quality drives t ask performance. Entropy, the standard reasoning-stability monitor, only measure s within-input diversity and misses whether reasoning depends on the input. We i dentify **template collapse**: stable entropy alongside input-agnostic boilerpla te, invisible to entropy and existing metrics. We diagnose it via a **mutual-inf ormation (MI) proxy** that scores cross-input distinguishability online; across tasks, MI correlates with final performance far more strongly than entropy. We t hen explain collapse via a **signal-to-noise ratio (SNR)** mechanism: low within -input reward variance weakens task gradients, letting input-agnostic regulariza tion dominate and erase cross-input differences. We mitigate this with **SNR-Awa re Filtering**, prioritizing high-variance prompts each iteration. Across planni ng, math reasoning, web navigation, and code execution, the method consistently improves input dependence and task performance.
****
HInT: Hypergraph Infusion at the Structural Layers Improves Table Understanding
Wonjin Lee, Soomi Jeong, Kwang In Kim
Decoder-only large language models (LLMs) struggle with table reasoning because tables must be serialized, which can obscure row- and column-level structure. Pr ior graph and hypergraph approaches encode structure with an external encoder, b ut their gains are often inconsistent under autoregressive decoding. We analyze how tabular structure is represented inside decoder-only LLMs and find that row and column relations are concentrated in a small subset of layers and attention heads. Based on this observation, we propose *HInT* (*H*ypergraph *In*fusion for *T*able reasoning), which injects hypergraph-derived structural features direct ly into the layers where these relations are concentrated. *HInT* constructs a t able hypergraph over cells and headers, applies lightweight message passing, and fuses the resulting structural features with token hidden states through gated fusion. Experiments across diverse table reasoning tasks show consistent improve ments over text-only baselines and prior (hyper)graph-based methods.
****
UnMaskFork: Test-Time Scaling for Masked Diffusion via Deterministic Action Bran ching
Kou Misaki, Takuya Akiba
Test-time scaling strategies have effectively leveraged inference-time compute t o enhance the reasoning abilities of Autoregressive Large Language Models. In th is work, we demonstrate that Masked Diffusion Language Models (MDLMs) are inhere ntly amenable to advanced search strategies, owing to their iterative and non-au toregressive generation process. To leverage this, we propose **UnMaskFork** (** UMF**), a framework that formulates the unmasking trajectory as a search tree an d employs Monte Carlo Tree Search to optimize the generation path. In contrast t o standard scaling methods relying on stochastic sampling, UMF explores the sear ch space through deterministic partial unmasking actions performed by multiple M DLMs. Our empirical evaluation demonstrates that UMF consistently outperforms ex isting test-time scaling baselines on complex coding benchmarks, while also exhi biting strong scalability on mathematical reasoning tasks.
****
