Reinforcement learning with massively parallel simulations has become a standard framework for developing robust, deployable policies; however, most existing approaches still rely on simple Gaussian policy parameterizations. Diffusion models provide a more expressive policy class and have shown strong performance on challenging control problems, yet most diffusion-based RL methods are designed for offline or off-policy training. In this work, we ask whether diffusion policies can be trained effectively in the massively parallel, on-policy regime. To this end, we introduce Trust-region Diffusion Policies (TruDi), which enables diffusion policies for on-policy RL with massively parallel simulations. This setting is particularly challenging because the data distribution changes quickly across updates, making stable training with complex policies difficult. TruDi addresses this by integrating a trust-region optimization rule to enforce a KL-divergence constraint over the entire diffusion trajectory. Empirically, we evaluate TruDi on a diverse set of 4 massively parallel RL benchmarks comprising a total of 73 tasks. Across these tasks, TruDi consistently outperforms or is on-par with strong baselines on standard tasks and achieves clear gains on more challenging humanoid control tasks, establishing a strong new baseline for massively parallel on-policy RL.

MIRO: MultI-Reward cOnditioned pretraining improves T2I quality and efficiency

Nicolas Dufour, Lucas Degeorge, Arijit Ghosh, Vicky Kalogeiton, David Picard

The default paradigm of post-training text-to-image generators includes post-hoc selection of generated images, and subsequent training with one reward model to align the generator to the reward, typically user preference. This discards informative data as well as optimizes only for a single reward, hence harming diversity, semantic fidelity and efficiency. Instead, we propose MIRO, a method that conditions the model on multiple rewards during training, thus letting the model learn user preferences directly. MIRO pre-training both improves the visual quality of the generated images and speeds up the training, achieving state of the art on the GenEval compositional benchmark and user-preference scores (PickAScore, ImageReward, HPSv2).

Can I Have Your Order? Monte-Carlo Tree Search for Slot Filling Ordering in Diffusion Language Models

Joshua Ong Jun Leang, Yu Zhao, Mihaela C. Stoian, Wenda Li, Shay B Cohen, Eleonora Giunchiglia

While plan-and-infill decoding in Masked Diffusion Models (MDMs) shows promise for mathematical and code reasoning, performance remains highly sensitive to slot infilling order, often yielding substantial output variance. We introduce DiffuSearch, a framework that formulates slot selection as decision making and optimises infilling orders through Monte Carlo Tree Search (MCTS). DiffuSearch uses look-ahead simulations to evaluate partial completions before commitment, systematically exploring the combinatorial space of generation orders. Experiments show an average improvement of 3.2% over autoregressive baselines and 8.0% over baseline plan-and-infill, with notable gains of 19.5% on MBPP and 4.9% on MATH500. Our analysis reveals that while DiffuSearch predominantly follows sequential ordering, incorporating non-sequential generation is essential for maximising performance. We observe that larger exploration constants, rather than increased simulations, are necessary to overcome model confidence biases and discover effective orderings. These findings establish MCTS-based planning as an effective approach for enhancing generation quality in MDMs.

On the Accuracy of Newton Step and Influence Function Data Attributions
Ittai Rubinstein, Samuel B. Hopkins
Data attribution estimates how a trained model would change if a subset of train ing points were removed, and is a central primitive for tasks such as interpreta bility, data valuation, and machine unlearning. Despite its widespread use, our theoretical understanding of key data attribution methods -- Influence Functions (IF) and a single Newton Step (NS) -- remains limited: existing guarantees heav ily rely on *global* strong convexity and yield bounds with pessimistic dependen ce on the parameter dimension d and the number of removed samples k.
We give a new analysis of IF and NS for convex ERM that replaces global assumpti ons with *local* conditions: it suffices that the loss is strongly convex and su fficiently smooth only in a neighborhood of the first Newton step.
As a concrete validation, we analyze logistic regression with Gaussian features and show that our bounds capture the correct scaling up to polylogarithmic facto rs, yielding matching upper and lower bounds and explaining observed regimes in which NS is markedly more accurate than IF, thereby resolving open questions rai sed by (Koh et al., 2019).

mHC: Manifold-Constrained Hyper-Connections
Zhenda Xie, Yixuan Wei, Huanqi Cao, Chenggang Zhao, Chengqi Deng, Jiashi Li, Dam ai Dai, Huazuo Gao, Mingyu Xu, Kuai Yu, Liang Zhao, Shangyan Zhou, Zhean Xu, Zhe ngyan Zhang, Wangding Zeng, Shengding Hu, Yuqing Wang, Jingyang Yuan, Lean Wang, Wenfeng Liang
Recently, studies exemplified by Hyper-Connections (HC) have extended the ubiqui tous residual connection paradigm established over the past decade by expanding the residual stream width and diversifying connectivity patterns. While yielding substantial performance gains, this diversification fundamentally compromises t he identity mapping property intrinsic to the residual connection, which causes severe training instability and restricted scalability, and additionally incurs notable memory access overhead. To address these challenges, we propose Manifold -Constrained Hyper-Connections (mHC), a general framework that projects the resi dual connection space of HC onto a specific manifold to restore the identity map ping property, while incorporating rigorous infrastructure optimization to ensur e efficiency. Empirical experiments demonstrate that mHC is effective for traini ng at scale, offering tangible performance improvements and superior scalability . We anticipate that mHC, as a flexible and practical extension of HC, will cont ribute to a deeper understanding of topological architecture design and suggest promising directions for the evolution of foundational models.

A²RBench: An Automatic Paradigm for Formally Verifiable Abstract Reasoning Bench mark Generation
Qingchuan Ma, Yuexiao Ma, Yongkang Xie, Tianyu Xie, Xiawu Zheng, Rongrong Ji
Abstract reasoning ability reflects the intelligence and generalization capacity of LLMs to extract and apply abstract rules.
However, accurately measuring this ability remains challenging: existing benchma rks either rely on expensive manual annotation, limiting their scale, or risk me asuring memorization rather than genuine reasoning.
To address this, we introduce an automated pipeline named A^{2}RBench, encompass ing generation, expansion, evaluation, and analysis.
Specifically, in the generation stage, LLMs create diverse tasks demanding genui ne reasoning; in the expansion stage, LLMs reuse validated rules and expand new input spaces to generate task variations, achieving scaling.
However, such a process may cause hallucinations.
To eliminate it, we further establish a theoretical framework and prove that pro grammatic verification—testing whether the inverse operation perfectly reverses the forward operation (cycle consistency)—guarantees a unique solution.
Through extensive evaluations on mainstream LLMs, we find: (1) Current LLMs exhi bit fundamental deficiencies in abstract reasoning, with top models significantl y underperforming humans on a representative subset (39.8\% vs. 68.5\%). (2) Cur

rent LLMs fall far short of 2D and 1D in the complexity of generated 3D tasks, r
evealing their lack of understanding of high-dimensional tasks. (3) Counterintui
tively, inputs with higher information complexity can simplify the reasoning pro
cess.
Code and data are available at: https://github.com/MAC-AutoML/A2Rbench.

Dataset Distillation Efficiently Encodes Low-Dimensional Representations from Gr
adient-Based Learning of Non-Linear Tasks
Yuri Kinoshita, Naoki Nishikawa, Taro Toyoizumi
Dataset distillation, a training-aware data compression technique, has recently
attracted increasing attention as an effective tool for mitigating costs of opti
mization and data storage. However, progress remains largely empirical. Mechanis
ms underlying the extraction of task-relevant information from the training proc
ess and the efficient encoding of such information into synthetic data points re
main elusive. In this paper, we theoretically analyze practical algorithms of da
taset distillation applied to the gradient-based training of two-layer neural ne
tworks with width L. By focusing on a non-linear task structure called multi-i
ndex model, we prove that the low-dimensional structure of the problem is effici
ently encoded into the resulting distilled data. This dataset reproduces a model
with high generalization ability for a required memory complexity of $\tilde \T
heta(r^2d+L)$, where d and r are the input and intrinsic dimensions of the t
ask. To the best of our knowledge, this is one of the first theoretical works th
at include a specific task structure, leverage its intrinsic dimensionality to q
uantify the compression rate and study dataset distillation implemented solely v
ia gradient-based algorithms.

Cross-Chirality Generalization by Axial Vectors for Hetero-Chiral Protein-Peptid
e Interaction Design
Ziyi Yang, Zitong Tian, Yinjun Jia, Tianyi Zhang, Jiqing Zheng, Hao Wang, Yubu S
u, Juncai He, Lei Liu, Yanyan Lan
D-peptide binders targeting L-proteins have promising therapeutic potential. Des
pite rapid advances in machine learning-based target-conditioned peptide design,
generating D-peptide binders remains largely unexplored. In this work, we show
that by injecting axial features to E(3)-equivariant (polar) vector features, it
is feasible to achieve cross-chirality generalization from homo-chiral (L-L) tr
aining data to hetero-chiral (D-L) design tasks. By implementing this method wit
hin a latent diffusion model, we achieved D-peptide binder design that not only
outperforms existing tools in *in silico* benchmarks, but also demonstrates effi
cacy in wet-lab validation. To our knowledge, our approach represents the first
experimentally validated AI generative model for the *de novo* design of D-pepti
de binders, offering new perspectives on handling chirality in protein design. C
odes are available at [https://github.com/YZY010418/PepMirror](https://github.co

Hyperbolic Associative Memory Networks
Boliang Hao, Bailing Zhang, Fangyu Wu
Modern Hopfield Networks (MHNs) have achieved widespread success across various
domains but are confined to Euclidean/Hilbert spaces, failing to preserve the hi
erarchical structure of data due to geometric constraints—arbitrary tree structu
res cannot be embedded with low distortion, while hyperbolic spaces can naturall
y accommodate hierarchical structures through exponential volume growth. To addr
ess this issue, we propose Hyperbolic Associative Memory Networks (HAMNs), the f
irst framework to embed modern associative memory into hyperbolic space: we map
query and memory vectors from Euclidean space to a constant negative curvature m
anifold via exponential maps, define a regularized energy function based on the
Minkowski inner product, and adopt curvature-aware Riemannian optimization combi
ned with exponential map updates to achieve stable on-manifold retrieval. We put
forward a hierarchy-sensitivity hypothesis—HAMNs outperform Euclidean MHNs on d
ata with deep hierarchies but exhibit comparable performance on data with weak o
r shallow hierarchies, which is validated by depth-controlled experiments and cr

oss-level metrics. As a plug-and-play, model-agnostic module, HAMNs are suitable for the storage and retrieval of representations in task architectures requiring hierarchical understanding, instantiated with the Poincar\'e ball in experiments, and also applicable to any hyperbolic model with constant negative curvature.
The code is available at https://github.com/hbl66/HAMNs.

Provably Protecting Fine-Tuned LLMs from Training Data Extraction while Preserving Utility
Tom Segal, Yuval Elovici, Asaf Shabtai
Fine-tuning large language models (LLMs) on sensitive datasets raises privacy concerns, as training data extraction (TDE) attacks can expose highly confidential information.
Existing defenses against such attacks either lack formal privacy guarantees or incur substantial utility degradation.
We observe that fine-tuning induces widespread probability shifts, yet preserving only a small subset of influential token-level deviations is sufficient; the remaining shifts can be aggressively smoothed with minimal impact on utility.
Motivated by this insight, we propose SCP-Δ_r, a Near Access Freeness (NAF)-based algorithm that operates on relative probabilities and explicitly smooths low-impact tokens using a base model.
SCP-Δ_r achieves orders-of-magnitude better theoretical bounds than existing NAF based methods and provides strong empirical protection against TDE attacks with minimal performance loss.

Steady-State Behavior of Constant-Stepsize Stochastic Approximation: Gaussian Approximation and Tail Bounds
Yuyang Wang, Felix Wang, Zedong Wang, Ijay Narang, Yuzhou Wang, Siva Theja Maguluri
Constant-stepsize stochastic approximation is widely used in learning for computational efficiency. For a fixed stepsize, the iterates typically admit a stationary distribution that is rarely tractable. Prior work shows that as the stepsize $\alpha \downarrow 0$, the centered-and-scaled steady state converges weakly to a Gaussian limit. However, for fixed α, this weak convergence offers no usable error bound for approximating the steady-state by its Gaussian limit. This paper provides explicit, non-asymptotic error bounds for fixed α. We study (i) stochastic gradient descent on smooth strongly convex objectives, (ii) linear SA, and (iii) contractive nonlinear SA, and we treat both i.i.d. and Markovian noise models to ensure broad applicability. Our main results first give dimension- and stepsize-dependent, explicit bounds in Wasserstein distance between the centered-scaled steady state and its Gaussian limit, with errors that vanish as $\alpha \downarrow 0$. We further derive sharp tail control, comparing the steady-state tail probability to Gaussian tails with an explicit error term that decays in both the deviation level and α.
Our analysis combines steady-state Stein's method with moment bounds on the SA iterations, and uses Poisson equation techniques to manage temporal dependence in the Markovian noise setting. We adapt the same toolkit to SGD with general convex objectives and suggest non-Gaussian limiting behavior, which is validated in numerical experiments.

Distributional Active Inference
Abdullah Akgül, Gulcin Baykal, Manuel Haussmann, Mustafa Mert Çelikok, Melih Kandemir
Optimal control of complex environments with robotic systems faces two complementary and intertwined challenges: efficient organization of sensory state information and far-sighted action planning. Because the reinforcement learning framework addresses only the latter, it tends to deliver sample-inefficient solutions. Active inference is the state-of-the-art process theory that explains how biological brains handle this dual problem. However, its applications to artificial intelligence have thus far been limited to extensions of existing model-based appr

oaches. We present a formal abstraction of reinforcement learning algorithms tha t spans model-based, distributional, and model-free approaches. This abstraction seamlessly integrates active inference into the distributional reinforcement le arning framework, making its performance advantages accessible without transitio n dynamics modeling.
****
PowerFlow: Unlocking the Dual Nature of LLMs via Principled Distribution Matchin g
Ruishuo Chen, Yu Chen, Zhuoran Li, Longbo Huang
Unsupervised Reinforcement Learning from Internal Feedback (RLIF) has emerged as a promising paradigm for eliciting the latent capabilities of Large Language Mo dels (LLMs) without external supervision. However, current methods rely on heuri stic intrinsic rewards, which often lack a well-defined theoretical optimization target and are prone to degenerative biases. In this work, we introduce PowerFl ow, a principled framework that reformulates unsupervised fine-tuning as a distr ibution matching problem. By casting GFlowNet as an amortized variational sample r for unnormalized densities, we propose a length-aware Trajectory-Balance objec tive that explicitly neutralizes the structural length biases inherent in autore gressive generation. By targeting α-power distributions, PowerFlow enable s the directional elicitation of the dual nature of LLMs: sharpening the distrib ution ($\alpha > 1$) to intensify logical reasoning, or flattening it ($\alpha < 1$) to unlock expressive creativity. Extensive experiments demonstrate that Pow erFlow consistently outperforms existing RLIF methods, matching or even exceedin g supervised GRPO. Furthermore, by mitigating over-sharpening in aligned models, our approach achieves simultaneous gains in diversity and quality, shifting the Pareto frontier in creative tasks.

Geometry-Aware Image Flow Matching
Junho Lee, Kwanseok Kim, Joonseok Lee
Recent advances in generative models highlight the power of geometry-aware model ing in manifold-constrained settings. Yet, for natural images, the field remains confined to Euclidean assumptions, failing to exploit the potential of intrins ic geometric structures within the data. In this work, we investigate the geomet ry of natural images and observe that semantic information is predominantly enco ded in directional components, while norm components can be approximated by the global average. This property holds across both RGB and latent spaces, suggestin g that natural images can be effectively modeled on a hypersphere. Building on t his finding, we introduce Spherical Optimal Transport Flow Matching (SOT-CFM), w hich utilizes angular distance, and Spherical Flow Matching (SFM), which constra ins dynamics directly on the manifold. Our experiments demonstrate that these ge ometry-aware methods achieve superior performance against Euclidean baselines. U ltimately, this work provides a novel perspective that bridges the gap between R iemannian manifold-based modeling and natural image generation.
****
NorMuon: Making Muon more efficient and scalable
Zichong Li, Liming Liu, Chen Liang, Weizhu Chen, Tuo Zhao
The choice of optimizer significantly impacts the training efficiency and comput ational costs of large language models (LLMs). Recently, the Muon optimizer has demonstrated promising results by orthogonalizing parameter updates, improving o ptimization geometry through better conditioning.
Despite Muon’s emergence as a candidate successor to Adam, the potential for joi ntly leveraging their strengths—has not been systematically explored.
In this work, we bridge this gap by proposing NorMuon (Neuron-wise Normalized Mu on), an optimizer that synergistically combines orthogonalization with neuron-le vel adaptive learning rates. Our analysis reveals that while Muon effectively re duces condition numbers, the resulting updates exhibit highly non-uniform neuron norms, causing certain neurons to dominate the optimization process. NorMuon ad dresses this imbalance by maintaining second-moment statistics for each neuron a nd applying row-wise normalization after orthogonalization, ensuring balanced pa rameter utilization while preserving Muon's conditioning benefits. To enable pra

ctical deployment at scale, we develop an efficient distributed implementation u
nder the FSDP2 framework that distributes orthogonalization computations across
devices.
Experiments across multiple model scales demonstrate that NorMuon consistently o
utperforms both AdamW and Muon, achieving a 21.74\% reduction in training steps
relative to AdamW and an 11.31 percentage-point larger efficiency gain than Muon
 on 1.1B pretraining. Results suggest that orthogonalization and adaptive learni
ng rates are complementary rather than competing, opening new avenues for optimi
zer design in large-scale deep learning.

Bridging On-Device and Cloud LLMs for Collaborative Reasoning: A Unified Methodo
logy for Local Routing and Post-Training
Wenzhi Fang, Dong-Jun Han, Liangqi Yuan, Evan Chen, Christopher Brinton
Device-cloud collaboration holds promise for deploying large language models (LL
Ms), leveraging lightweight on-device models for efficiency while relying on pow
erful cloud models for superior reasoning. A central challenge in this setting i
s determining, for each incoming query, whether it should be processed locally o
r offloaded to the cloud. Existing approaches typically rely on external routers
, which often struggle to determine difficulty from the prompt itself, especiall
y for tasks involving complex reasoning. Motivated by this limitation, we propos
e enabling on-device LLMs to decide internally whether to invoke cloud assistanc
e at inference time, with this capability instilled through reinforcement learni
ng based post-training. Casting on-device LLM post-training as a reward maximiza
tion problem, we design hierarchical rewards to encourage local problem solving
and judicious cloud offloading. To solve the resulting problem, we develop an al
gorithm featuring a group-level policy gradient that stabilizes optimization, to
gether with adaptive prompt filtering that provides complementary learning signa
ls to mitigate policy collapse (i.e., exclusive local execution or exclusive clo
ud offloading). Extensive experiments on on-device-scale LLaMA and Qwen models a
cross multiple reasoning benchmarks show that our method consistently outperform
s baselines and significantly narrows the gap to full cloud LLMs.

DeCoDe: Decoupling Binding Position and Molecular Conformation in 3D Ligand Diff
usion for Structure-Based Drug Design
Julong Yang, Wen Huang, Junhui Chen, Jian Peng
Recent advances in diffusion models show promise for Structure-Based Drug Design
 (SBDD), which aims to generate 3D ligand molecules that bind tightly to specifi
c protein targets.
This involves jointly optimizing the ligand's 3D conformation and its binding po
sition within the protein pocket.
However, existing diffusion-based SBDD methods diffuse conformation and binding
position synchronously within a high-dimensional joint space, leading to ineffic
ient exploration and suboptimal generation quality in both aspects.
To address this, we propose **DeCoDe**, a novel diffusion framework that **decou
ples** the diffusion processes of the binding position and molecular conformatio
n.
Our key insight is to prioritize the perturbation of the ligand's internal confo
rmation in the early stages of the forward (noising) process, while accelerating
 the perturbation of its global binding position later.
This design guides the reverse (denoising) process to *first coarsely position*
the ligand within the pocket before *refining its detailed structure*, mimicking
 a more efficient, step-wise generation strategy.
Extensive experiments on the CrossDocked2020 benchmark show that DeCoDe achieves
 significantly higher structural fidelity (with an average improvement of 18%),
while maintaining competitive binding affinity and overall molecular properties
compared to state-of-the-art baselines.

Fair Classification with Efficient and Post-hoc Controllable Fairness-Accuracy T
rade-off
Maaya Sakata, Kazuto Fukuchi

Post-hoc controllability of fair machine learning models, the ability to control the trade-off between fairness and accuracy after training, is valuable for practical deployment. Existing post-processing methods provide such post-hoc controllability but often suffer from significant accuracy degradation, whereas in-processing methods achieve efficient trade-offs but require computationally expensive retraining for each change in trade-off ratio. To achieve both post-hoc controllability and efficient trade-offs, we propose a novel fair classification algorithm that learns effective feature representations to improve the trade-off efficiency of post-processing fair classifiers, by a gradient-based optimization approach. Experimental results on real-world datasets demonstrate that our method achieves trade-off efficiency comparable to, or even surpassing, in-processing methods, without requiring any retraining.

****

LAMP: Data-Efficient Linear Affine Weight-Space Models for Parameter-Controlled 3D Shape Generation and Extrapolation

Ghadi Nehme, Yanxia Zhang, Dule Shu, Matthew Klenk, Faez Ahmed

Generating high-fidelity 3D geometries under explicit parameter constraints is central to engineering design, yet current methods often require large datasets and fail to provide reliable control beyond the training distribution. We introduce LAMP, a data-efficient framework for controllable and interpretable 3D generation that aligns signed distance function (SDF) decoders by overfitting each exemplar from a shared initialization, then generates new designs by solving a parameter-constrained affine mixing problem in the aligned weight space. To improve reliability, we propose a linearity-mismatch safety metric that detects when mixed decoders leave the valid local regime. We evaluate LAMP on DrivAerNet++, BlendedNet, and additional industry-level vehicle families, including sports cars, SUVs, and convertibles. LAMP enables controlled interpolation with as few as 50 samples, safe extrapolation up to 100\% beyond training ranges, and performance-guided optimization under fixed parameters, outperforming conditional autoencoder and Deep Network Interpolation (DNI) baselines in extrapolation, data efficiency, and parameter fidelity. Our results demonstrate that LAMP advances controllable, data-efficient, and safe 3D generation for design exploration, dataset generation, and performance-driven optimization.

Categorical Reparameterization with Denoising Diffusion Models

Samson Gourevitch, Alain Oliviero Durmus, Eric Moulines, Jimmy Olsson, Yazid Janati

Learning models with categorical variables requires optimizing expectations over discrete distributions, a setting in which stochastic gradient-based optimization is challenging due to the non-differentiability of categorical sampling. A common workaround is to replace the discrete distribution with a continuous relaxation, yielding a smooth surrogate that admits reparameterized gradient estimates via the reparameterization trick. Building on this idea, we introduce ReDGE, a novel and efficient diffusion-based soft reparameterization method for categorical distributions. Our approach defines a flexible class of gradient estimators that includes the Straight-Through estimator as a special case. Experiments spanning latent variable models and inference-time reward guidance in discrete diffusion models demonstrate ReDGE consistently matches or outperforms existing gradient-based methods.

Knowledge Diversion for Efficient Morphology Control and Policy Transfer

Fu Feng, Ruixiao Shi, Yucheng Xie, Jianlu Shen, Jing Wang, Xin Geng

Universal morphology control aims to learn a universal policy that generalizes across heterogeneous robot morphologies, with Transformer-based controllers emerging as a dominant choice. However, such architectures incur substantial computational costs, resulting in high deployment overhead, and existing methods exhibit limited cross-task generalization, necessitating training from scratch for each new task. To this end, we propose DivMorph, a modular training paradigm that leverages knowledge diversion to learn *decomposable controllers*. DivMorph factorizes randomly initialized Transformer weights into *basic knowledge units* via S

VD and employs dynamic soft gating, conditioned on task and morphology embeddings, to adaptively modulate these units into universal *learngenes* and morphology- and task-specific *tailors* during training, thereby achieving knowledge disentanglement. By selectively activating relevant components, DivMorph adaptively recomposes the controller, enabling efficient policy deployment and effective policy transfer to novel tasks. Extensive experiments demonstrate that DivMorph achieves state-of-the-art performance, improving sample efficiency for cross-task transfer by 3.3$\times$ and reducing model size for single-agent deployment by 16.7$\times$.
****

LaST$_{0}$: Latent Spatio-Temporal Chain-of-Thought for Robotic Vision-Language-Action Model
Zhuoyang Liu, Jiaming Liu, Hao Chen, Jiale Yu, Ziyu Guo, Chengkai Hou, Chenyang Gu, Xiangju Mi, Renrui Zhang, Kun Wu, Zhengping Che, Jian Tang, Pheng-Ann Heng, Shanghang Zhang
Vision-Language-Action (VLA) models have recently shown strong generalization, with some approaches seeking to explicitly generate linguistic reasoning traces or predict future observations prior to execution. However, explicit reasoning typically incurs non-negligible inference latency, which constrains the temporal resolution required for robotic manipulation. Moreover, such reasoning is confined to the linguistic space, imposing a representational bottleneck that struggles to faithfully capture ineffable physical attributes. To mitigate these limitations, we propose LaST$_0$, a framework that enables efficient reasoning before acting through a Latent Spatio-Temporal Chain-of-Thought (CoT), capturing fine-grained physical and robotic dynamics that are often difficult to verbalize. Specifically, we introduce a token-efficient latent CoT space that models future visual dynamics, 3D structural information, and robot proprioceptive states, and further extends these representations across time to enable temporally consistent implicit reasoning trajectories. Furthermore, LaST$_0$ adopts a dual-system architecture implemented via a Mixture-of-Transformers design, where a reasoning expert conducts low-frequency latent inference and an acting expert generates high-frequency actions conditioned on robotics-oriented latent representations. To facilitate coordination, LaST$_0$ is trained with heterogeneous operation frequencies, enabling adaptive switching during deployment. Across 10 real-world tasks spanning tabletop, mobile, and dexterous hand manipulation, LaST$_0$ improves mean success rates by 13%, 14% and 14% over prior SOTA VLA methods, respectively.

TQL: Scaling Q-Functions with Transformers by Preventing Attention Collapse
Perry Dong, Kuo-Han Hung, Alexander Swerdlow, Dorsa Sadigh, Chelsea Finn
Despite scale driving substantial recent advancements in machine learning, reinforcement learning (RL) methods still primarily use small value functions. Naively scaling value functions -- including with a transformer architecture, which is known to be highly scalable -- often results in learning instability and worse performance. In this work, we ask what prevents transformers from scaling effectively for value functions? Through empirical analysis, we identify the critical failure mode in this scaling: attention scores collapse as capacity increases. Our key insight is that we can effectively prevent this collapse and stabilize training by controlling the entropy of the attention scores, thereby enabling the use of larger models. To this end, we propose Transformer Q-Learning (TQL), a method that unlocks the scaling potential of transformers in learning value functions in RL. Our approach yields up to a 43\% improvement in performance when scaling from the smallest to the largest network sizes, while prior methods suffer from performance degradation.
****

Partial Fusion of Neural Networks: Efficient Tradeoffs Between Ensembles and Weight Aggregation
Fabian Morelli, Stephan Eckstein
Ensembles of neural networks typically outperform individual networks but incur large computational costs, whereas weight aggregation produces less costly, yet also less accurate, aggregate models.

We introduce partial fusion of networks, which interpolates between ensembles an
d weight aggregation and thus allows for a flexible tradeoff between computation
al cost and performance.
A direct way to achieve this is to extend existing weight aggregation methods ba
sed on neuron-level similarity between different networks, where partial fusion
then only aggregates weights of neurons which are most similar.
We showcase one particular method to jointly identify which neurons are most sim
ilar and match them via partial optimal transport.
Further, we consider the more general perspective of weight aggregation and part
ial fusion as generalized pruning of ensemble models, where neurons cannot just
be deleted, but also linearly combined.
Finally, we show that generalized pruning applied to a single network yields sim
ilar benefits as partial fusion by allowing for a tradeoff between isolating, de
leting, and linearly combining neurons based on similarity.

PerceptionRubrics: Calibrating Multimodal Evaluation to Human Perception
Yana Wei, Hongbo Peng, Yanlin Lai, Liang Zhao, Kangheng Lin, En Yu, Keyu Lv, Han
Zhou, Yin Tang, Haodong Li, Mitt Huang, Hangyu Guo, Jianjian Sun, Zheng Ge, Xia
ngyu Zhang, Daxin Jiang, Vishal M. Patel
We introduce PerceptionRubrics, a rubric-based evaluation framework that address
es the dissonance between benchmark saturation and real-world brittleness. Shift
ing evaluation from holistic semantic matching to rigorous atomic auditing, Perc
eptionRubrics pairs 1,038 information-dense images with over 12,000 instance-spe
cific rubrics. These criteria are derived from golden captions that constructed
via a novel Circular Peer-Review consensus pipeline and then distilled into a du
al-stream system of Must-Right (essential facts) and Easy-Wrong (fine-grained de
tails) rubrics. Crucially, PerceptionRubrics implements a Gated Scoring mechanis
m: unlike linear averages, failure on mandatory visual facts triggers sharp bina
ry penalties. Extensive evaluation yields critical insights: (1) The Reliability
Gap: models often verify fragmented elements correctly yet fail strict conjunct
ive constraints, exposing brittleness in dense domains; (2) Open-Closed Stratifi
cation: contrary to reasoning trends, we reveal a persistent 5% perception defic
it between open-source and proprietary frontiers; and (3) Human-Aligned Rigor: o
ur gated metrics substantially out-align conventional benchmarks, validating tha
t strict perceptual fidelity is the prerequisite for reliable generation.
****

Kronecker Generative Networks: A General Neural Architecture for Parameter-Effic
ient Learning Across Classification Tasks
Yang Yang, Zhengmin Kong, Yuan Liu, Tao Huang, Wei Xiang
Modern neural networks derive much of their effectiveness from rich connectivity
patterns.
Yet, existing architectures often fix the topology at either the sparse or dense
extremes, thereby limiting structural flexibility and analysis.
We propose Kronecker Generative Networks (KGNs), an algebraic framework that con
structs neural network topologies via recursive generation rules, treating topol
ogy as a first-class design object.
KGNs generate families of directed acyclic graphs with controllable connectivity
complexity, enabling systematic interpolation between sparse and dense aggregat
ion regimes.
Under this formulation, architectures such as FractalNet and DenseNet arise as s
pecific instantiations corresponding to different generation rules.
We provide theoretical analysis of acyclicity, connectivity scaling, and express
iveness, and demonstrate experimentally that KGN instantiations achieve favorabl
e accuracy-efficiency trade-offs across multiple domains.

Context Forcing: Consistent Autoregressive Video Generation with Long Context
Shuo Chen, Cong Wei, Sun Sun, Tiancheng SHEN, Ping Nie, Kai Zou, Ge Zhang, Ming-
Hsuan Yang, Wenhu Chen
Recent approaches to real-time long video generation typically employ streaming
tuning strategies, attempting to train a long-context student using a short-cont

ext (memoryless) teacher. In these frameworks, the student performs long rollouts but receives supervision from a teacher limited to short 5-second windows. This structural discrepancy creates a critical **student-teacher mismatch**: the teacher's inability to access long-term history prevents it from guiding the student on global temporal dependencies, effectively capping the student's context length.
To resolve this, we propose **Context Forcing**, a novel framework that trains a long-context student via a long-context teacher. By ensuring the teacher is aware of the full generation history, we eliminate the supervision mismatch, enabling the robust training of models capable of long-term consistency. To make this computationally feasible for extreme durations (e.g., 2 minute), we introduce a context management system that transforms the linearly growing context into a **Slow-Fast Memory** architecture, significantly reducing visual redundancy.
Extensive results demonstrate that our method enables effective context lengths exceeding 20 seconds—$6\text{--}10\times$ longer than state-of-the-art methods like LongLive and Infinite-RoPE. By leveraging this extended context, Context Forcing preserves superior consistency across long durations, surpassing state-of-the-art baselines on various long video evaluation metrics.
****

EAPO: Enhancing Policy Optimization with On-Demand Expert Assistance
Siyao Song, Cong Ma, Zhihao Cheng, Shiye Lei, Minghao Li, Ying Zeng, Huaixiao Tou, Kai Jia
Large language models (LLMs) have recently advanced in reasoning when optimized with reinforcement learning (RL) under verifiable rewards. Existing methods primarily rely on outcome-based supervision to strengthen internal LLM reasoning, often leading to inefficient exploration and sparse rewards. To mitigate this issue, we propose Expert-Assisted Policy Optimization (EAPO), a novel RL framework that enhances exploration by incorporating multi-turn interactions with external experts during training. Unlike prior methods, where policies reason in isolation, EAPO incentivizes the policy to adaptively determine when and how to consult experts, yielding richer reward signals and more reliable reasoning trajectories. External assistance ultimately internalizes expert knowledge into the policy model, amplifying the model’s inherent reasoning capabilities. During evaluation, the policy model has been well-optimized to solve questions independently, producing improved reasoning paths and more accurate solutions. On AIME 2024/2025 and AIMO 2025, EAPO consistently outperforms expert-assisted, expert-distilled, and RL baselines, averaging a 5-point gain over self-exploration RL, and also generalizes to non-math benchmarks, including HumanEval, HLE, GPQA, MMLU, EvalPlus, HotpotQA, and SimpleQA.

Distributionally Robust Causal Abstractions
Yorgos Felekis, Theodoros Damoulas, Paris Giampouras
Causal Abstraction (CA) theory provides a principled framework for relating causal models that describe the same system at different levels of granularity while ensuring interventional consistency between them. Recent methods for learning CAs, however, assume fixed and well-specified exogenous distributions, leaving them vulnerable to environmental shifts and model misspecification. In this work, we address these limitations by introducing the first class of distributionally robust CAs and their associated learning algorithms. The latter cast robust causal abstraction learning as a constrained min-max optimization problem with Wasserstein ambiguity sets. We provide theoretical guarantees for both empirical and Gaussian environments, enabling principled selection of ambiguity-set radii and establish quantitative guarantees on worst-case abstraction error. Furthermore, we present empirical evidence across different problems and CA learning methods, demonstrating our framework’s robustness not only to environmental shifts but also to structural and intervention mapping misspecification.

RePro: Training Language Models to Faithfully Recycle the Web for Pretraining
Zichun Yu, Chenyan Xiong
High-quality data is a cornerstone of large language model (LLM) pretraining, ye

t its growth has not kept pace with the needs of frontier models. In this paper, we introduce RePro, a novel web recycling method that trains a relatively small LM with reinforcement learning to generate effective and faithful rephrasings of pretraining data. Specifically, we design one *quality* reward and three *faithfulness* rewards, optimizing the LM rephraser to convert organic data into high-quality rephrasings while maintaining its core semantics and structure. In our experiment, we train a rephraser as small as 1B parameters to recycle 72B tokens sampled from DCLM-RefinedWeb. Pretraining results on 400M, 1.4B, and 2.8B models demonstrate that RePro delivers 3.7\%-14.5\% relative accuracy gains over organic-only baseline on 22 downstream tasks, doubling the performance gains achieved by the state-of-the-art web recycling method that prompts a 70B rephraser. Experiments with different amounts of recycled data highlight that RePro improves organic data efficiency by 2-3$\times$. Individual and distributional analyses validate that RePro preserves more critical information and faithfully reflects the characteristics of organic data compared to prompting-based methods. Together, these results show that RePro provides an efficient and controllable path to effectively recycle organic data for pretraining. Our code is available at https://github.com/cxcscmu/RePro.

Entropy-informed Decoding: Adaptive Information-Driven Branching

Benjamin Patrick Evans, Sumitra Ganesh, Leo Ardon

Large language models (LLMs) achieve remarkable generative performance, yet their output quality is dependent on the decoding strategy. While sampling-based methods (e.g., top-k, nucleus) and search-and-select based methods (e.g., beam search, best-of-n, majority voting) can improve upon greedy decoding, both approaches suffer from limitations: sampling generally commits to a single path, while search often expends excessive computation regardless of task complexity. To address these, we introduce Entropy-informed DEcodiNg (EDEN), a plug-and-play, model-agnostic decoding framework that adaptively allocates computation based on the model’s own uncertainty, approximating higher-width beam search with *fewer expansions*. At each generation step, EDEN estimates the entropy of the output token distribution and adjusts the branching factor monotonically with the entropy, expanding more candidates in high-entropy regions and following a greedier path in low-entropy regions, improving token efficiency. Experiments across complex tasks, including mathematical reasoning, code generation, and scientific questions, demonstrate that EDEN consistently improves output quality over existing decoding strategies, achieving better accuracy-expansion trade-offs than fixed-width beam search. By treating next-token selection as a noisy maximisation problem, we prove that branching factors monotone in entropy are guaranteed to find better (i.e. more probable) continuations than any fixed branching factor within the same total expansion budget, and derive explicit regret rates characterising the benefit of the adaptive allocation.

Column Thresholding for Sparse Spiked Wigner Models: Improved Signal Strength Requirements

Jian-Feng Cai, Zhuozhi Xian, Jiaxi Ying

We study the sparse spiked Wigner model, where the goal is to recover an s-sparse unit vector $\boldsymbol{u} \in \mathbb{R}^d$ from a noisy observation $\boldsymbol{Y} = \beta \boldsymbol{u} \boldsymbol{u}^\top + \boldsymbol{W}$. While the information-theoretic threshold is $\beta = \widetilde{\Omega}(\sqrt{s})$, existing polynomial-time algorithms require $\beta = \widetilde{\Omega}(s)$, yielding a substantial computational-statistical gap. We propose a column thresholding method that attains the $\widetilde{\Omega}(\sqrt{s})$ scaling for both estimation and support recovery under the non-uniformity condition $|| \boldsymbol{u} ||_\infty = \Omega(1)$. This condition is not merely technical: it explicitly rules out uniform spikes, for which planted-clique-based hardness results apply, and identifies a concrete class of non-uniform spikes where the required signal strength can be reduced. Building on this initializer, we further develop a truncated power method that iteratively refines the estimate with provable linear convergence.

Learning Fingerprints for Medical Time Series with Redundancy-Constrained Information Maximization
Huayu Li, ZhengXiao He, Xiwen Chen, Jingjing Wang, siyuan tian, Jinghao Wen, Ao Li
Learning meaningful representations from medical time series (MedTS), such as ECG or EEG signals, is a critical challenge. These signals are often high-dimensional, variable-length, and rife with noise. Existing self-supervised approaches, such as Masked Autoencoders (MAEs), are highly effective for pre-training general-purpose encoders. However, they do not explicitly learn compact, fixed-size, or semantically interpretable latent representations, typically relying on heuristic aggregation strategies such as global average pooling or a designated [CLS] token. We propose a novel framework that compresses a variable-length MedTS into a fixed-size set of k latent Fingerprint Tokens. Our architecture employs a cross-attention bottleneck to generate these tokens and is trained with a dual-objective function. The first objective is a reconstruction loss, which ensures the tokens are \textit{sufficient statistics} for the original data. The second, a diversity penalty based on the Total Coding Rate (TCR), explicitly minimizes the redundancy between tokens, encouraging them to become statistically \textit{disentangled} representations. We present the theoretical justification for our method, framing it as a novel \textbf{Disentangled Rate-Distortion} problem. This approach produces a low-dimensional, interpretable, and sample-efficient representation, where each token is encouraged to capture an independent factor of variation, paving the way for more robust digital biomarkers.
****
Focus, Align, and Sustain: Counteracting Gradient Dilution in Incremental Object Detection
Aoting Zhang, Dongbao Yang, Chang Liu, Xiaopeng Hong, Yu ZHOU
Adapting Detection Transformers to Incremental Object Detection (IOD) poses a systemic challenge, as set-based optimization is inherently destabilized by sequential learning. In this work, we identify Gradient Dilution as the root cause of performance degradation, wherein optimization signals required to preserve old knowledge are progressively weakened. This phenomenon manifests as a cascading erosion of preservation gradients in magnitude, direction, and support coverage, driven by three tightly coupled factors: \textit{Signal Dispersion}, where foreground gradients are overwhelmed by background noise; \textit{Assignment Drift}, where stochastic query–target matching induces inconsistent gradient trajectories; and \textit{Support Attrition}, where gradients from retained samples insufficiently cover the old-class feature space, weakening decision boundaries under interference from new classes. To counteract this, we propose FAS, a unified framework that \underline{F}ocuses, \underline{A}ligns, and \underline{S}ustains gradient flow throughout incremental learning. Specifically, we introduce prior-injected queries to focus discriminative signals by filtering background interference at the source. We further propose deterministic anchor distillation to align query–target assignments and enforce semantic consistency across stages under unstable matching. Finally, we devise manifold-support replay to sustain distributional support of old classes, counteracting representational erosion induced by continual updates. Extensive experiments show that FAS restores robust optimization dynamics and outperforms state-of-the-art methods, achieving over 5.0 AP improvement in the challenging 40+10×4 incremental setting.

Interpretable Functional Koopman Learning with Non-Markovian Closure for Spatiotemporal Systems
Wanfeng Lu, He Ma, Wei Lin, Qunxi Zhu
Precise prediction of spatiotemporal dynamics over predictive horizons is constrained by the computational cost of high-fidelity solvers and the sparsity, noise, and irregularity of data. We introduce MERLIN, a Koopman-based framework that lifts dynamics to the evolution of learned *observation functionals* with near-linear progression, enabling full-field reconstruction at arbitrary resolutions. Theoretically, we develop a functional Koopman theory for PDEs and compensate fo

r the loss of finite-dimensional linear invariance via the Mori–Zwanzig formalis
m, which augments the linear backbone with non-Markovian memory terms to improve
 predictive accuracy. Practically, MERLIN employs discretization-invariant *func
tion encoders* that map partial, irregular observations to observables, and reso
lution-free *function decoders* that reconstruct states at arbitrary query point
s. Training under linear constraints yields an interpretable, low-dimensional mo
del
that captures principal modes and supports reduced-order modeling, while memory
correction further enables stable long-horizon rollouts even in ultra-low-dimens
ional
latent spaces. Our code is available at: https://github.com/RobinLufdu/MERLIN.

Minimum Distance Summaries for Robust Neural Posterior Estimation
Sherman Khoo, Dennis Prangle, Song Liu, Mark Beaumont
Simulation-based inference (SBI) enables amortized Bayesian inference by first t
raining a neural posterior estimator (NPE) on prior-simulator pairs, typically t
hrough low-dimensional summary statistics, which can then be cheaply reused for
fast inference by querying it on new test observations. Because NPE is estimated
 under the training data distribution, it is susceptible to misspecification whe
n observations deviate from the training distribution. Many robust SBI approache
s address this by modifying NPE training or introducing error models, coupling r
obustness to the inference network and compromising amortization and modularity.
 We introduce minimum-distance summaries, a post-hoc robust NPE method that adap
ts queried test-time summaries independently of the pretrained NPE. Leveraging t
he maximum mean discrepancy (MMD) as a distance between observed data and a summ
ary-conditional predictive distribution, the adapted summary displays strong rob
ustness properties due to the robustness of the MMD. We demonstrate that the alg
orithm can be implemented efficiently with random Fourier feature approximations
, yielding a lightweight, model-free test-time adaptation procedure. We provide
theoretical guarantees for the robustness of our algorithm and empirically evalu
ate it on a range of synthetic and real-world tasks, demonstrating substantial r
obustness gains compared with existing robust SBI methods with minimal additiona
l overhead.

Structured Multi-step Jailbreaking under a Hamiltonian Generative Formulation
Zihan Zhou, Yang Zhou, Jianghai Yu, Lingjuan Lyu, Longwei Wang, KC Santosh, Ruom
ing Jin, Dejing Dou
Recent work shows that even safety aligned large language models (LLM) can be pu
shed into unsafe behavior by carefully crafted jailbreak prompts. Existing jailb
reaking attack methods often rely on disfluent or incoherent prompts, which limi
t their success and make them easy to detect. We introduce SJA, a structured jai
lbreak attack built around two ideas. First, inspired by the logic of Spilsbury
puzzle, SJA decomposes a harmful query into a sequence of harmless sub-questions
 and reconstructs the original answer by combining the sub-question responses. S
econd, by leveraging the theory of Hamiltonian dynamics on hyperbolic space, we
propose a hyperbolic Hamiltonian dynamics-based sub-question generation framewor
k that effectively captures the structural and temporal dependencies. We provide
 a theoretical analysis of how each sub-question evolves along the trajectory an
d show that the hyperbolic Hamiltonian system effectively captures the underlyin
g semantic structure. Finally, we propose a hyperbolic narrative fusion mechanis
m built on fractional embedding and Möbius fusion. This mechanism integrates coh
erent narratives into sub-questions while preserving geometric consistency and i
mproving stealth performance. We theoretically validate that the combination of
the generated harmless sub-questions, guided by the stealthy narrative, can effe
ctively preserve the contextual semantics of the original harmful question.

ProRL: Effective Reinforcement Learning for Proactive Recommendation via Rectifi
ed Policy Gradient Estimation
Hongru Hou, Tiehua Mei, Denghui Geng, Jinhui Huang, Ao Xu, Hengrui Chen, Jiaqing
 Liang, Deqing Yang

Proactive Recommender Systems (PRSs) aim to guide user preference shift toward t
arget items by generating paths of intermediate recommendations. Reinforcement l
earning (RL) provides a principled framework for optimizing such sequential deci
sion tasks, as path rewards can naturally capture both short-term acceptance and
 long-term guidance effectiveness. However, naively applying policy gradients to
 PRS results in deficient gradient estimation. We identify two deficiencies: (1)
 path-level rewards decompose into step-level rewards with positive mean, creati
ng a *length-dependent bias* that causes gradients to favor path extension over
meaningful exploration; (2) weighting each step by the entire path-level reward
ignores the decomposition structure, leading to high gradient variance. To recti
fy these two deficiencies, we propose an effective RL framework **ProRL** with t
wo novel mechanisms for proactive recommendation. First, Stepwise Reward Centeri
ng subtracts expected rewards to neutralize length-dependent bias, ensuring that
 path extension yields zero expected gradient signal. Second, Position-Specific
Advantage Estimation leverages the reward decomposition structure to compute ste
p-dependent baselines, reducing gradient variance. Together, these mechanisms yi
eld policy gradients that precisely target path quality. Our experiments on thre
e real-world datasets demonstrate that ProRL significantly outperforms state-of-
the-art PRSs. Our code is available at https://github.com/hongruhou89/ProRL.

SEDRAS: Symbolically Evaluated Deep Research And Science
Fredrik Carlsson, Daniel Ward, Joseph Ortiz, Fangyu Liu, Joakim Nivre
As the reasoning capabilities of Large Language Models (LLMs) expand, evaluating
 true inductive generalization on entirely unseen data becomes increasingly chal
lenging. To this end, we introduce a modular in-context learning evaluation fram
ework, that is scalable and extendable across its separate modules. This is base
d upon the notion of synthetic scenarios with controllable complexity across thr
ee independent axes: 1) the logic of the underlying data distribution (UDD) 2) t
heir projection into diverse representations, and 3) the interaction dynamic det
ermining how the model accesses and explores the data. For these scenarios, the
model is tasked to perform in-context scientific discovery and produce an interp
retable theory in natural language that explains the observations. In a separate
 conversation, the model is then tasked to convert this generated theory into ex
ecutable code, which can be programmatically compared against the underlying dat
a distribution.
Using this modular framework we produce an initial suite of 600 diverse scenario
s that we use to evaluate and analyze various state-of-the-art LLMs.
Although these experiments show that Gemini 3.0 Pro achieves the best overall sc
ore, each model performs the best at different tasks. For example:
GPT 5.2 is the clear winner on pure symbolic data, Claude Opus 4.5 is the best a
t working with files, Gemini is the strongest model for the non-dynamic scenario
s, and Grok 4.1 is the strongest model when UDD complexity scales. Furthermore,
all models struggle with active exploration and are seemingly incapable of ident
ifying informative data points, resulting in less efficient exploration than a r
andom baseline.

ReCoG: Relational and Compact Context Graph Learning for Few-shot Molecular Prop
erty Prediction
Zeyu Wang, Xin Zheng, Yao Lu, Shanqing Yu, Qi Xuan, Shirui Pan
Few-shot molecular property prediction (FSMPP) is essential in drug discovery an
d materials design, where high-quality labeled data are often scarce and expensi
ve to obtain. Despite the promising performance of existing methods, especially
context-aware methods, they still face two-fold severe challenges with ${\rm \te
xtit{insufficient structural context modeling}}$ \& ${\rm \textit{redundant auxi
liary context learning}}$, leading to inadequate context graph exploration and i
neffective information utilization for effective molecule representation learnin
g.
To address these, in this paper, we propose a novel framework by learning on ${\
rm \mathbf{\underline{Re}}}$ational
and ${\rm \mathbf{\underline{C}}}$ompact c${\rm \mathbf{\underline{o}}}$ntext ${

\rm \mathbf{\underline{G}}}$raph, named ReCoG, to comprehensively exploit the co
ntext graph for expressive molecular property prediction.
Specifically, the proposed ReCoG contains two core modules: a **(1) cross-proper
ty relational learning module** to better model the structural and relational co
ntext information, and a **(2) context graph information bottleneck module** to
adaptively suppress irrelevant auxiliary signals for compact context information
 utilization, followed by a detailed theoretical demonstration regarding the imp
ortance of joint relational and compact knowledge extraction in context graphs.

Safe In-Context Reinforcement Learning
Amir Moeini, Minjae Kwon, Alper Kamil Bozkurt, Yuichi Motai, Rohan Chandra, Lu F
eng, Shangtong Zhang
In-context reinforcement learning (ICRL) is an emerging RL paradigm where an age
nt, after pretraining, can adapt to out-of-distribution test tasks without any p
arameter updates, instead relying on an expanding context of interaction history
. While ICRL has shown impressive generalization, safety during this adaptation
process remains unexplored, limiting its applicability in real-world deployments
 where test-time behavior is expected to be safe. In this work, we propose SCARE
D: Safe Contextual Adaptive Reinforcement via Exact-penalty Dual, the first meth
od that promotes safe adaptation of ICRL under the constrained Markov decision p
rocess framework. During the parameter-update-free adaptation process, our agent
 not only maximizes the reward but also keeps the accumulated cost within a user
-specified safety budget. We also demonstrate that the agent actively reacts to
the safety budget; with a higher safety budget, the agent behaves more aggressiv
ely, and with a lower safety budget the agent behaves more conservatively. Acros
s challenging benchmarks, SCARED consistently enables safe and robust in-context
 adaptation, outperforming existing ICRL and safe meta-RL baselines.

CyberJurors: A Multi-Agent Simulation Task for E-Commerce Disputes Verdict
Yanhui Sun, Wu Liu, Haifeng Ming, Xinru Wang, Hantao Yao, Yongdong Zhang
E-commerce platforms have begun recruiting crowdsourced jurors to adjudicate mas
sive volumes of transaction disputes.
Unlike formal legal judgment, E-commerce dispute verdicts require grounding pivo
tal clues from redundant, multi-round, multimodal evidence and making decisions
under flexible platform-specific conventions.
These characteristics render existing methods insufficient for this scenario.
To bridge this gap, we introduce a pioneering task, *E-commerce Dispute Verdicts
* (EDV), and present *VerdictBench*, a multimodal benchmark comprising 6,000 rea
l-world cases designed to reflect crowdsourced jury decisions. Building upon thi
s, we propose *CyberJurors*, a multi-agent framework to clarify the dispute logi
c and regulate the verdict process.
At the individual level, *Individual Verdict Chain-of-Thought* decomposes the ED
V task into four structured reasoning stages, enabling fine-grained clue percep
tion and clarifying causal logic between pivotal clues and the dispute focus.
At the collective level, *Jury Consensus Verdict* simulates multi-round discussi
on and voting among jurors, while incorporating verdict precedents to mitigate c
ognitive biases toward either disputant.
Experiments on *VerdictBench* show that *CyberJurors* outperforms state-of-the-a
rt LLMs, MLLMs, and court simulators, while achieving stronger alignment with re
al-world jury voting patterns.
Code and dataset are available at https://github.com/YanhuiS/CyberJurors and htt
ps://huggingface.co/datasets/piggi/VerdictBench.

TPGDiff : Hierarchical Triple-Prior Guided Diffusion for Image Restoration
Yanjie Tu, Qingsen Yan, Axi Niu, Jiacong Tang
All-in-one image restoration aims to address diverse degradation types using a s
ingle unified model. Existing methods typically rely on degradation priors to gu
ide restoration, yet often struggle to reconstruct content in severely degraded
regions. Although recent works leverage semantic information to facilitate conte
nt generation, integrating it into the shallow layers of diffusion models often

disrupts spatial structures (e.g., blurring artifacts). To address this issue, we propose a Triple-Prior Guided Diffusion (TPGDiff) network for unified image restoration. TPGDiff incorporates degradation priors throughout the diffusion trajectory, while introducing structural priors into shallow layers and semantic priors into deep layers, enabling hierarchical and complementary prior guidance for image reconstruction. Specifically, we leverage multi-source structural cues as structural priors to capture fine-grained details and guide shallow layers representations. To complement this design, we further develop a distillation-driven semantic extractor that yields robust semantic priors, ensuring reliable high-level guidance at deep layers even under severe degradations. Furthermore, a degradation extractor is employed to learn degradation-aware priors, enabling stage-adaptive control of the diffusion process across all timesteps. Extensive experiments on both single- and multi-degradation benchmarks demonstrate that TPGDiff achieves superior performance and generalization across diverse restoration scenarios.

Breaking Multi-Task Curse: Reward-Weighted Evolution for Black-Box Many-Task Optimization

Yanchi Li, Jiao Liu, Wenyin Gong, Qiong Gu, Yue Zhao, Yew-Soon Ong

Evolutionary multi-tasking accelerates black-box optimization via knowledge transfer but falters in scenarios involving many low-similarity tasks. We identify this scalability barrier as the *Multi-Task Curse*, driven by evaluation budget dispersion and negative transfer. To overcome this, we propose MES-RET (*M*any-task *E*volution *S*trategy with *R*eward-weighted *E*valuation and *T*ransfer), which combats budget dispersion via a reward-weighted evaluation scheme that guarantees superior expected improvement, while simultaneously mitigating negative transfer through a robust reward-weighted aggregation of mean and covariance statistics, ensuring a safe fallback to independent evolution. Furthermore, to handle neural dimensional mismatches in many-task policy search, we introduce a semantic parameter alignment strategy that bridges heterogeneous state-action spaces. Extensive experiments on synthetic benchmarks, real-world engineering problems, and reinforcement learning tasks demonstrate that MES-RET consistently outperforms state-of-the-art methods, notably enabling skill transfer across morphologically distinct policies.

Sharp description of local minima in the loss landscape of high-dimensional two-layer ReLU neural networks

Jie Huang, Bruno Loureiro, Stefano Sarao Mannelli

We study the population loss landscape of two-layer ReLU networks of the form $\sum_{k=1}^K \mathrm{ReLU}(w_k^\top x)$ in a realisable teacher–student setting with Gaussian covariates. We show that local minima admit an exact low-dimensional representation in terms of summary statistics, yielding a sharp and interpretable characterisation of the landscape. We further establish a direct link with one-pass SGD: local minima correspond to attractive fixed points of the dynamics in summary statistics space. This perspective reveals a hierarchical organisation of minima into discrete families and shows how overparameterisation changes their stability and reachability under gradient-based dynamics. In this overparameterised regime, global minima become increasingly accessible, attracting the dynamics and reducing convergence to spurious solutions. Overall, our results reveal intrinsic limitations of common simplifying assumptions, which may miss essential features of the loss landscape even in minimal neural network models.

Distributed Direct Preference Optimization

Zhanhong Jiang

Preference-based reinforcement learning (RL) is a key paradigm for aligning policies with human judgments, yet its theoretical behavior in distributed settings where preference data are fragmented across heterogeneous users remains poorly understood. Direct Preference Optimization (DPO) avoids explicit reward modeling but lacks convergence guarantees under federated and decentralized training, where communication constraints and non-IID preferences fundamentally alter optimiz

ation dynamics. We provide the first convergence and time-complexity analysis of DPO in distributed environments. Modeling personalized offline RL with user-specific preference distributions, we characterize the induced global optimization landscape. For federated DPO, we derive convergence rates that quantify the impact
of client drift, communication frequency, and preference heterogeneity; for decentralized DPO, we establish convergence over general communication graphs and show how spectral connectivity governs optimization speed and consensus. Empirically, we corroborate our theoretical insights on standard alignment benchmarks, demonstrating that our proposed methods not only enjoy strong theoretical guarantees but also deliver robust and scalable performance in practice. The code base is available here.

The Extra Tokens Matter: Disentangled Representation Learning with Vision Transformers
Maofeng Tang, Hairong Qi
Vision Transformers increasingly incorporate extra tokens beyond patch tokens—from class tokens for aggregation to register tokens for artifact mitigation. While effective for their intended purposes, these tokens typically lack semantic structure. We ask a more ambitious question: Can we design regularization constraints that transform extra tokens into disentangled representations, enabling them to decompose images into semantic parts (e.g., heads, bodies, legs) without explicit supervision?
We propose XTRA, an intuitive yet powerful framework that augments Vision Transformers with dedicated ``factor tokens'' and enforces disentanglement via a novel Minimum Volume Constraint (MVC). A multi-stage aggregation process further enforces these factor tokens into semantically pure components, preventing token collapse that often occurs when training with MVC alone. On ImageNet-1K, XTRA achieves superior disentanglement (8.4× improvement in SEPIN@1 over DINOv2)
while simultaneously improving representation quality: KNN accuracy improves by 5.8\% and
linear-probe accuracy by 2.3\%.
****

Navigating the Energy Landscape of Collaboration: Multi-Agent Communication Graph Generation via Score-Based Diffusion
GuanHao Zhao, Wenbo Lu, Cheng Cheng, Zhenya Huang, Wei Song, Zhiding Liu, Runze Wu, Enhong Chen
The collective intelligence of Large Language Model (LLM)-based Multi-Agent Systems (MAS) is fundamentally governed by the underlying communication graph. However, discovering task-adaptive structures within this combinatorial search space remains a significant challenge. Existing methods, ranging from heuristic pruning to autoregressive generation, often lack a unified theoretical framework to guide the self-organization of agents into efficient teams. In this paper, we bridge non-equilibrium thermodynamics and generative modeling to formalize multi-agent graph generation as an energy minimization process. Specifically, we frame the emergence of efficient collaboration as a thermodynamic "cooling" process, where initially stochastic interactions converge to a low-energy, structured equilibrium.
To implement this, We propose MAGE (Multi-Agent Communication Graph Generation), a score-based diffusion framework that constructs communication graphs by navigating the energy landscape via iterative denoising and first-order gradient guidance. Extensive experiments on representative benchmarks demonstrate that MAGE achieves state-of-the-art performance. Furthermore, qualitative analysis reveals that the generated graphs mirroring the functional specialization of human organizations, validating our thermodynamic hypothesis.

VlogReward: Learning Multi-Dimensional Evaluation for Vlog Editing
Yexiang Liu, Wen Zhong, Sijie Zhu, Xin Gu, Fan Chen, Junxian Duan, Jie Cao, Longyin Wen, Zhenfang Chen
The rapid rise of vlogs as a personalized storytelling medium has created a dema

nd for automated systems to evaluate and refine vlog editing plans. However, vlo
g assessment is highly subjective and remains challenging due to a lack of stand
ardized criteria, dataset and benchmark, and effective reward models. To address
 these challenges, we define a comprehensive vlog evaluation framework guided by
 professional vlog creators and product managers, establishing a taxonomy of six
 key dimensions, *i.e.*, *Creativity*, *Consistency*, *Concept Design*, *Cinemat
ography*, *Narration*, and *Pacing*. Subsequently, we curate a large-scale datas
et of 100k vlog edits and a dedicated benchmark, **VRMBench**, to evaluate the v
log rewarding capabilities of Multimodal Large Language Models (MLLMs). Finally,
 we present **VlogReward**, a robust vlog reward model that can provide both fin
e-grained multi-dimensional scores and actionable feedback for iterative refinem
ent.

  Technically, we enhance the Group Relative Policy Optimization (GRPO) framewor
k by introducing an adjustable inter-group comparison reward, which mitigates th
e "direction blindness" issue of standard GRPO and enables the model to better d
istinguish varied-quality edits.

  VlogReward achieves state-of-the-art results that significantly outperform exi
sting MLLMs, including GPT-5 and Gemini-3-Pro.

  We hope that our study can help vlog creators and foster automated vlog evalua
tion and refinement systems.

Equilibrium Reasoners: Learning Attractors Enables Scalable Reasoning
Benhao Huang, Zhengyang Geng, J Zico Kolter
Scaling test-time compute by iteratively updating a latent state has emerged as
a powerful paradigm for reasoning. Yet, the internal mechanisms that enable thes
e iterative models to generalize beyond memorized patterns remain fundamentally
unclear. We hypothesize that such generalizable reasoning arises from learning t
ask-conditioned attractors: a latent dynamical system where stable fixed points
correspond to valid solutions. We formalize this process by introducing Equilibr
ium Reasoners (EqR). EqR enables test-time scaling without relying on external v
erifiers or task-specific priors. Instead, our models scale internal dynamics al
ong two axes: depth by running more iterations and breadth by aggregating stocha
stic trajectories from multiple initializations. Empirically, performance gains
from scaling test-time compute are tightly coupled with better convergence to at
tractors. This attractor perspective allows neural networks to adaptively alloca
te test-time compute based on task difficulty. While simple cases converge withi
n 1 to 5 iteration steps, the hardest cases benefit from massive test-time scali
ng. By unrolling up to an equivalent of 40,000 layers, this scalable latent reas
oning boosts accuracy from 2.6% for feedforward models to over 99% on Sudoku-Ext
reme. We hope our attractor perspective sheds light on scalable reasoning.

World-R1: Reinforcing 3D Constraints for Text-to-Video Generation
Weijie Wang, Xiaoxuan He, Youping Gu, Yifan Yang, Zeyu Zhang, Yefei He, Yanbo Di
ng, Xirui Hu, Donny Y. Chen, Zhiyuan He, Yuqing Yang, Bohan Zhuang
Recent video foundation models demonstrate impressive visual synthesis but frequ
ently suffer from geometric inconsistencies. While existing methods attempt to i
nject 3D priors via architectural modifications, they often incur high computati
onal costs and limit scalability. We propose World-R1, a framework that aligns v
ideo generation with 3D constraints through reinforcement learning. To facilitat
e this alignment, we introduce a specialized pure text dataset tailored for worl
d simulation. Utilizing Flow-GRPO, we optimize the model using feedback from pre
-trained 3D foundation models and vision-language models to enforce structural c
oherence without altering the underlying architecture. We further employ a perio
dic decoupled training strategy to balance rigid geometric consistency with dyna
mic scene fluidity. Extensive evaluations reveal that our approach significantly
 enhances 3D consistency while preserving the original visual quality of the fou
ndation model, effectively bridging the gap between video generation and scalabl
e world simulation.
****

Open-Text Aerial Detection: A Unified Framework For Aerial Visual Grounding And

Detection
Guoting Wei, Xia Yuan, Yang Zhou, Haizhao Jing, Yu Liu, Xianbiao Qi, Chunxia Zhao, Haokui Zhang, Rong Xiao
Open-Vocabulary Aerial Detection (OVAD) and Remote Sensing Visual Grounding (RSVG) have emerged as two key paradigms for aerial scene understanding. However, each paradigm suffers from inherent limitations when operating in isolation: OVAD is restricted to coarse category-level semantics, while RSVG is structurally limited to single-target localization. These limitations prevent existing methods from simultaneously supporting rich semantic understanding and multi-target detection. To address this, we propose OTA-Det, the first unified framework that bridges both paradigms into a cohesive architecture. Specifically, we introduce a task reformulation strategy that unifies task objectives and supervision mechanisms, enabling joint training across datasets from both paradigms with dense supervision signals. Furthermore, we propose a dense semantic alignment strategy that establishes explicit correspondence at multiple granularities, from holistic expressions to individual attributes, enabling fine-grained semantic understanding. To ensure real-time efficiency, OTA-Det builds upon the RT-DETR architecture, extending it from closed-set detection to open-text detection by introducing several high efficient modules, achieving state-of-the-art performance on six benchmarks spanning both OVAD and RSVG tasks while maintaining real-time inference at 34 FPS.
****
Fast k-means Seeding Under The Manifold Hypothesis
Poojan Chetan Shah, Shashwat Agrawal, Ragesh Jaiswal
We study beyond worst case analysis for the k-means problem where the goal is to model typical instances of k-means arising in practice. Existing theoretical approaches provide guarantees under certain assumptions on the optimal solutions to k-means, making them difficult to validate in practice. We adopt the manifold hypothesis, where data obtained in ambient dimension D concentrates around a low dimensional manifold of intrinsic dimension d, as a reasonable assumption to model real world clustering instances. We identify key geometric properties of datasets which have theoretically predictable scaling laws depending on the quantization exponent $\varepsilon = 2/d$ using techniques from optimum quantization theory. We show how to exploit these regularities to design a fast seeding method called $\operatorname{Qkmeans}$ which provides $O(\rho^{-2} \log k)$ approximate solutions to the
k-means problem in time $O(nD \log k) + \widetilde{O}(\rho^{-1}k^{1+\gamma})$; where the exponent $\gamma = \varepsilon + \rho$ for an input parameter $\rho < 1$. This allows us to obtain new runtime - quality tradeoffs. We perform a large scale empirical study across various domains to validate our theoretical predictions and algorithm performance to bridge theory and practice for beyond worst case data clustering.
****
Convergence Rate of the Last Iterate of Stochastic Proximal Algorithms
Kevin Kurian Thomas Vaidyan, Michael Friedlander, Ahmet Alacaoglu
We analyze two classical algorithms for solving additively composite convex optimization problems where the objective is the sum of a smooth term and a nonsmooth regularizer. The first algorithm is the proximal stochastic gradient method for a single regularizer; the second is the randomized incremental proximal method, which uses the proximal operator of a randomly selected function when the regularizer is given as the sum of many nonsmooth functions. We focus on relaxing the bounded variance assumption that is common, yet stringent, for getting last iterate convergence rates. We prove the $\widetilde{O}(1/\sqrt{T})$ rate of convergence for the last iterate of both algorithms under componentwise convexity and smoothness, which is optimal up to log terms. Our results apply directly to graph-guided regularizers that arise in multi-task and federated learning, where the regularizer decomposes as a sum over edges of a collaboration graph.

WildCat: Near-Linear Attention in Theory and Practice
Tobias Schröder, Lester Mackey

We introduce WildCat, a high-accuracy, low-cost approach to compressing the atte
ntion mechanism in neural networks. While attention is a staple of modern networ
k architectures, it is also notoriously expensive to deploy due to resource requ
irements that scale quadratically with the input sequence length n. WildCat av
oids these quadratic costs by only attending over a small weighted coreset. Cruc
ially, we select the coreset using a fast but spectrally-accurate subsampling al
gorithm -- randomly pivoted Cholesky -- and weight the elements optimally to min
imise reconstruction error. Remarkably, given bounded inputs, WildCat approximat
es exact attention with super-polynomial $O(n^{-\sqrt{\log(\log(n))}})$ error de
cay while running in near-linear $O(n^{1+o(1)})$ time. In contrast, prior practi
cal approximations either lack error guarantees or require quadratic runtime to
guarantee such high fidelity. We couple this advance with a GPU-optimised PyTorc
h implementation and a suite of benchmark experiments demonstrating the benefits
of WildCat for image generation, image classification, and language model KV ca
che compression.

FlowCloud: Learning Continuous Spatiotemporal Dynamics from Unpaired Sparse Poin
t Cloud Snapshots

Yinbo Liu, Keyang Ye, Wenshan Sun, Handi Gao, Tian Tian

Reconstructing unified continuous dynamics from sparse, non-contiguous, and unpa
ired point cloud snapshots remains a fundamental challenge in spatiotemporal ana
lysis for computer vision and developmental biology. Existing methods, including
scene flow and Optimal Transport-based approaches, are limited either by explic
it reliance on point-wise correspondences or by cumulative errors from frame-to
-frame propagation and temporal discontinuity, and limited ability to model mult
i-attribute dynamics such as gene expression and population changes. We propose
FlowCloud, a variational Neural Ordinary Differential Equation (Neural ODE) gene
rative framework. FlowCloud aggregates information from all observed time points
into a joint latent representation that initializes a Neural ODE $z(t)$ enablin
g continuous spatiotemporal evolution modeling while mitigating propagation-indu
ced errors and preserving temporal consistency. Training is performed without pr
edefined correspondences using a multi-faceted objective with complementary role
s: Sinkhorn distance for global distribution alignment, Chamfer distance for loc
al geometric consistency, trajectory regularization to encourage smooth and phys
ically plausible dynamics, and supervised losses for multi-attribute prediction.
Experiments on human motion and developmental biology datasets demonstrate impr
oved interpolation accuracy and promising short-term extrapolation performance.
By unifying geometry, attributes, and population dynamics within a continuous la
tent framework, FlowCloud offers a novel and robust solution for continuous dyna
mic reconstruction from unstructured spatiotemporal observations.

HALO: A Unified Vision-Language-Action Model for Embodied Multimodal Chain-of-Th
ought Reasoning

Quanxin Shou, Fangqi Zhu, Shuang Chen, Puxin Yan, Zhengyang Yan, Yikun Miao, Xia
oyi Pang, Zicong Hong, Ruikai Shi, Hao HUANG, Jie ZHANG, Song Guo

Vision–Language–Action (VLA) models perform well in robotic manipulation, but of
ten struggle in long-horizon or out-of-distribution scenarios due to the lack of
explicit mechanisms for multimodal reasoning and anticipating how the world evo
lves under action.

Recent works introduce textual chain-of-thought or visual subgoal prediction wit
hin VLA models, but still fail to offer a unified human-like framework for joint
textual reasoning, visual foresight, and action prediction.

To this end, we propose HALO, a unified VLA model that enables embodied multimod
al chain-of-thought (EM-CoT) reasoning through textual reasoning, fine-grained v
isual subgoal prediction, and EM-CoT-augmented action prediction.

We instantiate HALO with a Mixture-of-Transformers (MoT) architecture that decou
ples semantic reasoning, visual foresight, and action prediction into specialize
d experts with seamless cross-expert collaboration.

To enable HALO learning at scale, we introduce an automated pipeline to synthesi
ze EM-CoT training data along with a carefully crafted training recipe.

Extensive experiments demonstrate that: (1) HALO achieves superior performance in both simulated and real world, surpassing baseline policy π_0 by 25.9\% on the RoboTwin benchmark; (2) all proposed components of the training recipe and EM-CoT design help improve task success rate; and (3) HALO exhibits strong generalization under aggressive unseen environment randomization with our proposed EM-CoT reasoning.

Same Question, Different Lies: Cross-Context Consistency (C³) for Black-Box Sandbagging Detection
Lin Yulong, Pablo Bernabeu-Perez, Benjamin Arnav, Lennie Wells, Mary Phuong
As language models grow more capable, accurate capability evaluation becomes essential for safety decisions. If models can deliberately underperform on dangerous capability evaluations—a behavior known as **sandbagging**—they may evade safety measures designed for their true capability level. We introduce Cross-Context Consistency (C^3), a general framework for unsupervised black-box sandbagging detection that exploits a fundamental asymmetry: when a model truly lacks capability, its confusion manifests consistently across paraphrased questions, but when a capable model feigns incompetence, its strategic choices about *how* to appear weak create detectable inconsistencies. The framework is agnostic to the specific consistency metric and aggregation method; we present a simple instantiation using embedding cosine distance and mean aggregation that requires no training data or model-specific adaptation. We evaluate C^3 across prompted and fine-tuned sandbagging scenarios, across instructed and more naturalistic setups, maintaining a classification signal where other black-box methods fail. Our findings show the limitations of existing sandbagging detection methods, and reveal the efficacy of consistency-checking as a detection mechanism for sandbagging.

d2: Improving Reasoning in Diffusion Language Models via Trajectory Likelihood Estimation
Guanghan Wang, Gilad Turok, Yair Schiff, Marianne Arriola, Volodymyr Kuleshov
While diffusion language models (DLMs) have achieved competitive performance in text generation, improving their reasoning ability with reinforcement learning remains an active research area. Here, we introduce d2, a reasoning framework tailored for masked DLMs. Central to our framework is a new policy gradient algorithm that relies on accurate estimates of the sampling trajectory likelihoods. Because computing these likelihoods naively is computationally expensive for masked DLMs, we develop a family of estimators tailored to distinct model classes. For DLMs that support a sampling algorithm called any-order decoding, we propose d2-AnyOrder, which achieves exact trajectory likelihood with a single model pass. Through an empirical study of widely used DLMs, we show that any-order decoding is not universally supported in practice. For standard masked diffusion models, we propose d2-StepMerge, which approximates the trajectory likelihood, trading off compute for approximation accuracy in an analytically tractable manner. Empirically, d2 significantly outperforms widely-used RL baselines when applied to popular DLMs, and sets a new state-of-the-art performance for DLMs on logical reasoning tasks (Countdown and Sudoku) and math reasoning benchmarks (GSM8K and MATH500). We provide the code along with a blog post on the project page: https://guanghanwang.com/d2

Attention Illuminates LLM Reasoning: The Uncovered Preplan-and-Anchor Rhythm Enables Fine-Grained Policy Optimization
Yang Li, Zhichen Dong, Yuhan Sun, Weixun Wang, Shaopan Xiong, Yijia Luo, Jiashun Liu, Han Lu, Jiamang Wang, Wenbo Su, Bo Zheng, Junchi Yan
The reasoning patterns of large language models (LLMs) remain opaque, and Reinforcement learning (RL) typically assigns uniform credit across an entire generation, blurring the distinction between pivotal and routine steps. This work treats attention as a natural substrate for interpreting LLM reasoning and a window for aligning optimization with its internal dynamics. We first distinguish attention heads between locally and globally focused information processing and reveal that locally focused heads produce a sawtooth pattern near the diagonal indicati

ng phrasal chunks, while globally focused heads expose tokens that exert broad d
ownstream influence over future tokens. We quantify these with two metrics measu
ring the extent of backward attention within a clipped window and the average at
tention a token receives from subsequent tokens, respectively. Taken together, t
hese signals indicate a recurring preplan-and-anchor regularity, where the model
 first performs a long-range contextual reference to generate an introductory to
ken, which is immediately followed by or coincides with a semantic anchor token
that organizes subsequent reasoning. Leveraging these insights, we introduce thr
ee novel RL strategies that dynamically perform targeted credit assignment to cr
itical nodes (preplan tokens, anchor tokens, and their temporal coupling) and sh
ow consistent performance gains across various reasoning tasks.

OPUS: Towards Efficient and Principled Data Selection in Large Language Model Pr
e-training in Every Iteration

Shaobo Wang, Xuan Ouyang, Tianyi Xu, Yuzheng Hu, Jialin Liu, Guo Chen, Tianyu Zh
ang, Junhao Zheng, Kexin Yang, Xingzhang Ren, Dayiheng Liu, Linfeng Zhang

As high-quality public text approaches exhaustion, a phenomenon known as the Dat
a Wall—LLM pre-training is shifting from more tokens to better tokens. However,
existing methods either rely on heuristic static filters that ignore training dy
namics, or use dynamic yet optimizer-agnostic criteria based on raw gradients. W
e propose OPUS (Optimizer-induced Projected Utility Selection), a dynamic framew
ork that defines utility in the optimizer-induced update space. OPUS scores cand
idates by projecting their effective updates, shaped by modern optimizers, onto
a target direction derived from a stable, in-distribution proxy. To ensure scala
bility, we employ Ghost technique with CountSketch for computational efficiency,
 and Boltzmann sampling for data diversity, incurring only 4.7% additional compu
te overhead. OPUS achieves remarkable results across diverse corpora, quality ti
ers, optimizers, and model scales. It also outperforms previous data selection m
ethods across different stages of training, including from-scratch pre-training
and also mid-training. Beyond online selection, the OPUS utility score also demo
nstrates potential as a static filter for flagging and removing toxic documents
from contaminated training corpora prior to training.

A Deep Learning Model of Mental Rotation Informed by Interactive VR Experiments

Raymond Khazoum, Daniela Fernandes, Aleksandr Krylov, Qin Li, Stephane Deny

Mental rotation—the ability to compare objects seen from different viewpoints—is
 a fundamental example of mental simulation and spatial world modeling in humans
. Here we propose a mechanistic model of human mental rotation, leveraging rece
nt advances in deep, equivariant, and neuro-symbolic learning. Our model consist
s of three stacked components: (1) an equivariant neural encoder, producing 3D s
patial representations of objects from images, (2) a neuro-symbolic object encod
er, deriving symbolic objects descriptions from these spatial representations, a
nd (3) a neural decision agent, comparing these symbolic descriptions to prescri
be rotation simulations in 3D latent space via a recurrent pathway. Our model de
sign is guided by the existing experimental literature on mental rotation, which
 we complemented with experiments in VR where participants could at times manipu
late the objects to compare. Our model captures well the performance, response t
imes and behavior of participants in our and others' experiments, and through ab
lation studies we demonstrate the necessity of each component. Our work adds to
a recent collection of deep neural models of human spatial reasoning, further de
monstrating the potency of integrating deep, equivariant, and symbolic represent
ations to model the human mind.

Meerkat-VL: Implicit Risk Safety Alignment in Multimodal LLMs via Perceptual Rea
soning and Self-Verification

Peicheng Zhou, Chuanbin Liu, Shancheng Fang, Bowei Pu, Yiwei Sun, Zhangchi Hu, H
ongtao Xie

Multimodal LLMs (MLLMs) are increasingly deployed across diverse applications, b
ut they pose significant safety concerns due to cross-modal interactions. To imp
rove model safety awareness, existing methods rely on explicit-risk preference d

atasets and reinforcement learning guided by safety rewards. While effective in improving models' safety awareness, these methods still face data scarcity and reward hacking in implicit-risk scenarios, leading to insufficient risk perception and harmful responses. To address these challenges, we propose Meerkat-VL, a framework that enables models to perceive and verify implicit risks while generating safe responses. First, we introduce Meerkat-Safe, the first training dataset with detailed labels for implicit risks. Second, we develop Normative Perceptual Self-Verification, which enables models to verify both perceptual reasoning and responses. This process provides denser and more reliable rewards for perception accuracy and answer safety, thereby mitigating reward hacking. Finally, we propose Dual-Objective Perceptual Consistency Alignment, encouraging models to generate safe responses by penalizing answers that follow safe templates without accurate risk perception. Extensive experiments show that Meerkat-VL consistently outperforms baselines on multimodal safety benchmarks, improving safety and helpfulness by 16% and 13%, and achieving a 32% safety gain on implicit-risk tasks. Our codes are available at https://github.com/Tunanzzz/Meerkat-VL.

VideoVeritas: AI-Generated Video Detection via Perception Pretext Reinforcement Learning

Hao Tan, jun lan, Senyuan Shi, Zichang Tan, Zijian Yu, Huijia Zhu, Weiqiang Wang, Jun Wan, Zhen Lei

The growing capability of video generation poses escalating security risks, making reliable detection increasingly essential. In this paper, we introduce **VideoVeritas**, a framework that integrates fine-grained perception and fact-based reasoning. We observe that while current multi-modal large language models (MLLMs) exhibit strong reasoning capacity, their granular perception ability remains limited. To mitigate this, we introduce *Joint Preference Alignment* and *Perception Pretext Reinforcement Learning (PPRL)*. Specifically, rather than directly optimizing for detection task, we adopt general spatiotemporal grounding and self-supervised object counting in the RL stage, enhancing detection performance with simple *perception pretext tasks*. To facilitate robust evaluation, we further introduce **MintVid**, a light yet high-quality dataset containing 3K videos from 9 state-of-the-art generators, along with a real-world collected subset that has factual errors in content. Experimental results demonstrate that existing methods tend to bias towards either *superficial* reasoning or *mechanical* analysis, while **VideoVeritas** achieves more balanced performance across diverse benchmarks.

UniRRM: Unified Reasoning Reward Models Across Languages and Evaluation Paradigms

Peng Lai, Yichao Du, Junchao Wu, Weibo Gao, Linan Yue, Longyue Wang, Weihua Luo, Derek F. Wong, Guanhua Chen

Reinforcement learning (RL) excels on tasks with verifiable rewards, but in open-ended tasks, the reliability of reward models remains a key challenge. Existing solutions either depend on costly proprietary LLM-as-a-Judge systems or opaque scalar reward models that lack interpretability. Recent works on generative reward models offer a promising alternative, but they remain constrained by static evaluation criteria, fragmented evaluation paradigms, and limited multilingual support. To address these challenges, we introduce MixReward, a large-scale multilingual dataset spanning six domains and 103 languages, containing both pairwise and listwise data, and propose UniRRM, a unified reasoning reward model supporting multiple languages and evaluation paradigms.

UniRRM uses a staged reasoning chain to dynamically generate task-generic and instruction-specific criteria, enabling fine-grained, input-adaptive judgments while maintaining consistency across languages. Experiments demonstrate that UniRRM-8B and UniRRM-14B achieve performance close to the state-of-the-art for models of comparable size across multiple benchmarks, and are effective for unseen evaluation paradigms. In addition, ablation studies validate the reliability and effectiveness of UniRRM.

Neural Honeytrace: Plug&Play Watermarking Framework against Model Extraction Attacks
Yixiao Xu, Binxing Fang, Rui Wang, Yinghai Zhou, Yuan Liu, Mohan Li, Zhihong Tian
Triggerable watermarking enables model owners to assert ownership against model extraction attacks. However, most existing approaches require additional training, which limits post-deployment flexibility, and the lack of clear theoretical foundations makes them vulnerable to adaptive attacks. In this paper, we propose Neural Honeytrace, a plug-and-play watermarking framework that operates without retraining. We redefine the watermark transmission mechanism from an information perspective, designing a training-free multi-step transmission strategy that leverages the long-tailed effect of backdoor learning to achieve efficient and robust watermark embedding. Extensive experiments demonstrate that Neural Honeytrace reduces the average number of queries required for a worst-case t-test-based ownership verification to as low as 2% of existing methods, while incurring zero training cost.
****
Conditional Diffusion Sampling
Francisco M Castro-Macías, Pablo Morales-Alvarez, Saifuddin Syed, Daniel Hernández-Lobato, Rafael Molina, José Miguel Hernández-Lobato
Sampling from unnormalized multimodal distributions with limited density evaluations remains a fundamental challenge in machine learning and natural sciences.
Successful approaches construct a bridge between a tractable reference and the target distribution.
Parallel Tempering (PT) serves as the gold standard, while recent diffusion-based approaches offer a continuous alternative at the cost of neural training.
In this work, we introduce Conditional Diffusion Sampling (CDS), a framework that combines these two paradigms.
To this end, we derive Conditional Interpolants, a class of stochastic processes whose transport dynamics are governed by an exact, closed-form stochastic differential equation (SDE), requiring no neural approximation.
Although these dynamics require sampling from a non-trivial initialization distribution, we show both theoretically and empirically that the cost of this initialization diminishes for sufficiently short diffusion times.
CDS leverages this by a two-stage procedure: (1) PT is used to efficiently sample the initial distribution, and then (2) samples are transported via the transport SDE.
This combination couples the robust global exploration of PT with efficient local transport.
Experiments suggest that CDS has the potential to achieve a superior trade-off between sample quality and density evaluation cost compared to state-of-the-art samplers.
****
Distributionally Robust Set Representation Learning Under Inference-Time Element Corruption
Yankai Chen, Hanrong Zhang, Bowei He, Philip S. Yu, Xue Liu
Standard Set Representation Learning methods typically excel on curated data but often overlook the challenge of Inference-time Element Corruption. This refers to scenarios where deployed models encounter element-level degradations, such as outliers or missing components, that may distort set representation and degrade performance. We propose SW-DRSO, a distributionally robust optimization framework tailored for sets. Rather than minimizing loss solely on observed training data, SW-DRSO optimizes a tractable surrogate of the
worst-case expected loss over a family of plausible inference-time variations. We introduce a barycentric adversary that approximates the intractable search over corrupted sets by a differentiable training-time optimization over simplex weights. Extensive experiments across four tasks demonstrate that SW-DRSO effectively enhances robustness against corruption while maintaining high overall performance.

Probability-Entropy Calibration: An Elastic Indicator for Adaptive Fine-tuning
Wenhao Yu, Shaohang Wei, Jiahong Liu, Yifan Li, Minda Hu, Aiwei Liu, Hao Zhang, Irwin King
Token-level reweighting is a simple yet effective mechanism for controlling supervised fine-tuning, but common indicators are largely one-dimensional: the ground-truth probability reflects downstream alignment, while token entropy reflects intrinsic uncertainty induced by the pre-training prior. Ignoring entropy can misidentify noisy or easily replaceable tokens as learning-critical, while ignoring probability fails to reflect target-specific alignment. RankTuner introduces a probability--entropy calibration signal, the **Relative Rank Indicator**, by comparing the rank of the ground-truth token with its expected rank under the predictiondiction distribution. The inverse indicator is used as a token-wise **Relative Scale** to reweight the fine-tuning objective, focusing updates on truly under-learned tokens without over-penalizing intrinsically uncertain positions. Experiments on multiple backbones show consistent improvements on mathematical reasoning benchmarks, transfer gains on out-of-distribution reasoning, and pre code generation performance over probability- or entropy-only reweighting baselines.
****

TraCeS: Learning Per-Timestep Constraint-Violation Credit from Sparse Trajectory-Level Labels
Siow Meng Low, Ze Gong, Akshat Kumar
Ensuring safe behavior in reinforcement learning (RL) is challenging when safety constraints are implicit and cannot be densely measured. In many settings, supervision is limited to coarse approvals or rejections of whole trajectories (e.g., whether a rollout remained within an unknown safety threshold). We propose **TraCeS** (Trajectory-based Constraint Estimation for Safety), a method for learning **per-timestep violation credit** from such sparse trajectory-level labels. **TraCeS** trains a sequential violation estimator whose per-step credits factorize the predicted probability that a trajectory has **not yet violated** the constraint, and integrates this learned signal into constrained policy optimization. The method requires neither a known cost function nor a known threshold, and remains compatible with standard continuous-control algorithms. We provide a theoretical analysis of the approximation gap introduced by the learning objective, and demonstrate empirically that **TraCeS** improves constraint satisfaction and feedback efficiency over baselines across multiple continuous-control benchmarks, including long-horizon tasks and settings with noisy or inconsistent labels.

Learning a Generative Meta-Model of LLM Activations
Grace Luo, Jiahai Feng, Trevor Darrell, Alec Radford, Jacob Steinhardt
Existing approaches for analyzing neural network activations, such as PCA and sparse autoencoders, rely on strong structural assumptions.
Generative models offer an alternative: they can uncover structure without such assumptions and act as priors that improve intervention fidelity.
We explore this direction by training diffusion models on one billion residual stream activations, creating "meta-models" that learn the distribution of a network's internal states. We find that diffusion loss decreases smoothly with compute and reliably predicts downstream utility. In particular, applying the meta-model's learned prior to steering interventions improves fluency, with larger gains as loss decreases. Moreover, the meta-model's neurons increasingly isolate concepts into individual units, with sparse probing scores that scale as loss decreases. These results suggest generative meta-models offer a scalable path toward interpretability without restrictive structural assumptions.
****

FairSSL: Fair Multimodal Self-Supervised Learning
Jiaee Cheong, Abtin Mogharabin, Paul Pu Liang, Hatice Gunes, Sinan Kalkan
Prevalent multimodal self-supervised learning (SSL) methods rely on the **redundancy assumption**: that different views share substantial task-relevant information. We argue that this assumption fails in complex, real-world settings characterized by heterogeneity (e.g., variable-length healthcare or behavioral data), where enforcing strict alignment can discard unique, modality-specific signals an

d inadvertently amplify bias. In this work, we propose **FairSSL**, a framework that leverages data heterogeneity as a resource for fairness rather than a hindrance. Unlike standard contrastive approaches, FairSSL uses a subject-aware Variance-Invariance-Covariance Regularization objective, where alignment is enforced across segments drawn from the same subject. We introduce a segment-based pooling strategy to handle variable-length modalities, and we regularize representations to encourage (i) sufficient within-subject variability, (ii) cross-modal and cross-subject invariance, and (iii) representation decorrelation. Theoretical analysis shows that our objective bounds the score gap between protected groups. Empirically, FairSSL significantly outperforms existing baselines on heterogeneous multimodal datasets, improving fairness without sacrificing downstream predictive performance. Code available at: https://github.com/abtinmU/FairSSL

Tight Stability Bounds for Robust Distributed Learning: Byzantine Failures Hurt Generalization More than Data Poisoning
Thomas Boudou, Batiste Le Bars, Nirupam Gupta, Aurélien Bellet
Robust distributed learning algorithms aim to maintain reliable performance despite the presence of misbehaving workers.
Such misbehaviors are commonly modeled as *Byzantine failures*, allowing arbitrarily corrupted communication, or as *data poisoning*, a weaker form of corruption restricted to local training data. While prior work shows similar optimization guarantees for both models, an important question remains: *How do these threat models impact generalization?* We show, for the first time, a fundamental gap in generalization guarantees between the two threat models: Byzantine failures yield strictly worse rates than those achievable under data poisoning. Our findings leverage a tight algorithmic stability analysis of robust distributed learning. Specifically, we prove that: *(i)* under data poisoning, the uniform algorithmic stability of an algorithm with optimal optimization guarantees degrades by an additive factor of $\Theta (\frac{f}{n-f})$, with f out of n workers misbehaving; whereas *(ii)* under Byzantine failures, the degradation is in $\Omega \big(\sqrt{ \frac{f}{n-2f}} \big)$.
****

Calibrating Decision Robustness via Inverse Conformal Risk Control
Wenbin Zhou, Shixiang Zhu
Robust optimization safeguards decisions against uncertainty by optimizing against worst-case scenarios, yet their effectiveness hinges on a prespecified robustness level that is often chosen ad hoc, leading to either insufficient protection or overly conservative and costly solutions. Recent approaches using conformal prediction construct data-driven uncertainty sets with finite-sample coverage guarantees, but they still fix coverage targets a priori and offer little guidance for selecting robustness levels. We propose a new framework that provides distribution-free, finite-sample guarantees on both miscoverage and regret for any family of robust predict-then-optimize policies. Our method constructs valid estimators that trace out the miscoverage--regret Pareto frontier, enabling decision-makers to reliably evaluate and calibrate robustness levels according to their cost--risk preferences. The framework is simple to implement, broadly applicable across classical optimization formulations, and achieves sharper finite-sample performance. This paper offers a principled data-driven methodology for guiding robustness selection and empowers practitioners to balance robustness and conservativeness in high-stakes decision-making.

From Poisoned to Aware: Fostering Backdoor Self-Awareness in LLMs
Guangyu Shen, Siyuan Cheng, Xiangzhe Xu, Yuan Zhou, Hanxi Guo, ZHUO ZHANG, Xiangyu Zhang
Backdoor attacks can introduce deceptive behaviors into large language models, causing them to execute prohibited actions only when specific secret triggers appear in the input. Existing safety training methods largely fail to address this vulnerability, due to the inherent difficulty of uncovering hidden triggers embedded within the model. Motivated by recent findings on LLMs' situational awareness, we propose a novel post-training framework that cultivates backdoor self-awa

reness, enabling a poisoned LLM to precisely articulate its own implanted trigge rs. At its core, our approach introduces an inversion-inspired reinforcement lea rning framework that encourages models to introspectively reason about their beh aviors and gradually reverse-engineer the triggers responsible for misaligned ou tputs. Building upon precise trigger articulation, we further present two comple mentary defense strategies for mitigating and detecting backdoor threats. Experi ments on five backdoor attacks, compared against six baseline methods, demonstra te that our approach has strong potential to improve the robustness of LLMs agai nst backdoor risks.

Online Learning with Recency: Algorithms for Sliding-window Streaming Multi-arme d Bandits
Vladimir Braverman, Chen Wang, Liudeng Wang, Samson Zhou
Motivated by the recency effect in online learning, we study algorithms for sing le-pass \emph{sliding-window streaming multi-armed bandits (MABs)} in this paper . In this setting, we are given n arms with unknown sub-Gaussian reward distri butions and a parameter W. The arms arrive in a single-pass stream, and only t he most recent W arms are considered valid. The algorithm is required to perfo rm pure exploration and regret minimization with \emph{limited memory}, \textcol or{red}{defined as the number of stored arms}. The model is a natural extension of the streaming multi-armed bandits model (without the sliding window) that has been extensively studied in recent years. We provide a comprehensive analysis o f both the pure exploration and regret minimization problems with the model. Fo r pure exploration, we prove that finding the best arm is hard with sublinear me mory while finding an \emph{approximate} best arm admits an efficient algorithm. For regret minimization, we explore a new notion of regret and give sharp memor y-regret trade-offs for any single-pass algorithms. We complement our theoretica l results with experiments, demonstrating the trade-offs between sample, regret, and memory.

BVS: Bayesian Visual Search with Multimodal Large Language Model for Fine-graine d Perception
Geng Li, Yuxin Peng
While Multimodal Large Language Models (MLLMs) demonstrate impressive general ca pabilities, they struggle with fine-grained perception in ultra-high-resolution (UHR) images, particularly for tiny objects in cluttered scenes. Existing method s face a dilemma: they either rely on inefficient prior-free scanning, or depend on static prior-driven heuristics that lack posterior correction to rectify ini tial model biases. To address this, we propose **BVS** (**B**ayesian **V**isual **S**earch), a framework that formulates perception as a global optimization pro blem over a continuous spatial-scale manifold. Specifically, BVS bridges prior g uidance with posterior correction: it utilizes an early-stop attention rollout o f MLLM to construct reasoning-aware priors, while employing a scale-aware non-st ationary kernel and GP-UCB to dynamically rectify noise and recover missing info rmation in the prior through iterative local observations. We provide theoretica l guarantees via sub-linear regret bounds, and extensive experiments demonstrate that BVS significantly outperforms state-of-the-art baselines with a superior t rade-off between accuracy and efficiency.

Vision Transformer Finetuning Benefits from Non-Smooth Components
Ambroise Odonnat, Laetitia Chapel, Romain Tavenard, Ievgen Redko
The smoothness of the transformer architecture has been extensively studied in t he context of generalization, training stability, and adversarial robustness. Ho wever, its role in transfer learning remains poorly understood. In this paper, w e analyze the ability of vision transformer components to adapt their outputs to changes in inputs, or, in other words, their *plasticity*. Defined as an averag e rate of change, it captures the sensitivity to input perturbation; in particul ar, a high plasticity implies a low smoothness. Our theoretical analysis and ext ensive experiments -- over $1,000$ finetuning runs on large-scale vision transfo rmers -- showcase that this perspective provides principled guidance in choosing

 the components to prioritize during adaptation. A key takeaway for practitioner
s is that the high plasticity of the attention modules and feedforward layers co
nsistently leads to better finetuning performance. Our findings depart from the
prevailing assumption that smoothness is desirable, offering a novel perspective
 on transformers' functional properties. The code is available at \url{https://g
ithub.com/ambroiseodt/vit-plasticity}.

Stable Localized Conformal Prediction via Transduction
Yinjie Min, Liuhua Peng, Changliang Zou
Existing evaluations of conformal prediction, such as prediction efficiency and
test-conditional coverage, are defined in expectation over the calibration data.
 In practice, when only one calibration set of limited size is available, predic
tion sets often exhibit high variability in size, especially for methods with lo
calization. We formalize this concern as set stability, defined as the variance
of the conditional expectation of the set size given the calibration data. To im
prove stability without requiring additional target-task labels, we propose Stab
le Conformal Prediction (StCP), a transfer learning approach that utilizes label
ed source-task data and unlabeled target data. Theoretically, we characterize th
e marginal coverage and stability of StCP; empirically, it delivers more stable
prediction sets than standard conformal prediction methods, especially for those
 with localization, when calibration data are limited.

Generative Representation Learning on Hyper-relational Knowledge Graphs via Mask
ed Discrete Diffusion
Jaejun Lee, Seheon Kim, Joyce Jiyoung Whang
Hyper-relational knowledge graphs (HKGs) effectively represent complex facts. Wh
ile inferring new knowledge in HKGs is a critical problem, current methods cast
it as a simple link prediction, assuming that nearly all entities and relations
within a fact are known, leaving only a single blank to be filled. However, this
 restricted assumption may not hold in real-world scenarios in which multiple, o
r even all, constituent components of a fact may be missing simultaneously. To b
ridge this gap, we introduce a task called fact generation: generating a valid h
yper-relational fact from an arbitrarily masked query, i.e., completing a partia
lly observed fact or generating a fact from scratch. We propose KREPE, the first
 generative representation learning method for HKGs that learns to model the pro
bability distributions of missing components conditioned on the local fact compo
nents and global structure of HKGs via a masked discrete diffusion. KREPE models
 both the intra-fact dependencies by contextual message passing and inter-fact c
orrelations by aggregating stochastically sampled contexts. KREPE seamlessly uni
fies link prediction and fact generation within a single training framework, ach
ieving state-of-the-art performance on standard HKG link prediction benchmarks a
nd outperforming LLM-based baselines in generating novel and correct facts.
****

Alignment-Aware Decoding
Frédéric Berdoz, Luca A Lanzendörfer, René Caky, Roger Wattenhofer
Alignment of large language models remains a central challenge in natural langua
ge processing. Preference optimization has emerged as a popular and effective me
thod for improving alignment, typically through training-time or prompt-based in
terventions. In this paper, we introduce alignment-aware decoding (AAD), a metho
d to enhance model alignment directly at inference. Theoretically, AAD can be in
terpreted as implicit reward optimization, yet it requires no specialized traini
ng beyond the standard DPO setup. Empirically, AAD consistently outperforms stro
ng baselines across diverse alignment benchmarks and model scales. Moreover, in
data-constrained settings, AAD can produce high-quality synthetic data to improv
e alignment under standard decoding, providing a practical solution when labeled
 data is limited.

g, Zilei Wang, Qiang Liu, Liang Wang, Junyang Lin, Binyuan Hui
The rapid evolution of Large Language Models (LLMs) has empowered even non-progr
ammers to create visually appealing frontend mini-games with a single instructio
n. However, open-source models significantly lag behind proprietary counterparts
 in this domain. The core bottleneck is the lack of an evaluation mechanism that
 balances reliability with scalability, as existing methods either fail to verif
y dynamic interactivity or incur prohibitive computational costs. To bridge this
 gap, we introduce ALIVE (Aligning LLMs via Interactive Visual Execution), a hig
h-throughput framework that leverages one-shot planning and DOM-based analysis t
o automatically evaluate generated games at scale. Extensive experiments demonst
rate that ALIVE significantly outperforms static judge baselines in identifying
functional flaws while remaining orders of magnitude more efficient than GUI age
nts. Functioning as a scalable `pre-flight' evaluation layer, it curates high-qu
ality data for Supervised Fine-Tuning (SFT) and provides a consistent reward sig
nal for Reinforcement Learning (RL). We leverage this pipeline to train ALIVE-Co
der, a model achieving superior performance in interactive frontend generation.
To the best of our knowledge, our work offers the first scalable path to evaluat
e and optimize interactive code, substantially advancing open-source capabilitie
s.

On the Plasticity and Stability for Post-Training Large Language Models
Wenwen Qiang, Ziyin Gu, Jiahuan Zhou, Jie Hu, Jingyao Wang, Changwen Zheng, Hui
Xiong
Training stability remains a critical bottleneck for Group Relative Policy Optim
ization (GRPO), often manifesting as a trade-off between reasoning plasticity an
d general capability retention. We identify a root cause as the geometric confli
ct between plasticity and stability gradients, which leads to destructive interf
erence. Crucially, we argue that deterministic projection methods are suboptimal
 for GRPO as they overlook the intrinsic stochasticity of group-based gradient e
stimates. To address this, we propose Probabilistic Conflict Resolution (PCR), a
 Bayesian framework that models gradients as random variables. PCR dynamically a
rbitrates conflicts via an uncertainty-aware ``soft projection'' mechanism, opti
mizing the signal-to-noise ratio. Extensive experiments demonstrate that PCR sig
nificantly smooths the training trajectory and achieves superior performance in
various reasoning tasks.

Giving Sensors a Voice: Multimodal JEPA for Semantic Time-Series Embeddings
Utsav Dutta, Gerardo Pastrana, Sina Khoshfetrat Pakazad, Henrik Ohlsson
Transformer-based architectures have advanced sequence modeling in language and
vision, yet general-purpose representation learning for heterogeneous multivaria
te time series remains underexplored. We introduce CHARM (Channel-Aware Represen
tation Model), which incorporates channel-level textual descriptions into a Tran
sformer encoder equivariant to channel order. CHARM is trained with a Joint Embe
dding Predictive Architecture (JEPA) and a novel loss promoting informative, tem
porally stable embeddings; latent-space prediction encourages robustness to sens
or noise while description-aware gating provides interpretability through learne
d inter-channel relationships. Across anomaly detection, classification, and sho
rt- and long-term forecasting, the learned embeddings achieve strong performance
 using only a linear probe. Performance is driven primarily by the JEPA objectiv
e and conditioning architecture, with text descriptions serving as channel ident
ifiers for cross-dataset generalization.

Scaling Long-Horizon Agent via Context Folding
Weiwei Sun, Miao Lu, Zhan Ling, Kang Liu, Xuesong Yao, Yiming Yang, Jiecao Chen
Large language model (LLM) agents are fundamentally constrained by context lengt
h on long-horizon tasks.
Existing agent frameworks usually rely on manually defined context engineering p
ipelines, such as multi-agent or post-hoc summary.
We introduce Context Folding, a framework that empowers agents to actively manag

e their working context.
An agent can procedurally branch into a sub-trajectory to handle a subtask and t hen fold it upon completion, collapsing the intermediate steps while retaining a concise summary of the outcome.
To make this behavior learnable, we propose FoldGRPO, an end-to-end reinforcemen t learning framework with specific process rewards to encourage effective task d ecomposition and context management.
On long-horizon tasks, our agent matches the performance of baselines while usin g an active context up to 10x smaller, and significantly outperforms models cons trained to the same context size.
Code is available at https://github.com/sunnweiwei/FoldAgent.

Learning Junta Distributions, Quantum Junta States, and QAC^0 Circuits
Jinge Bao, Francisco Escudero Gutiérrez
In this work, we consider the problems of learning junta distributions, their qu antum counterparts (quantum junta states), and QAC^0 circuits, which we show to be close to juntas.

(1) Junta distributions. A probability distribution $p:${-1,1}$^n\to \mathbb [0, 1]$ is a k-junta if it only depends on k bits. We show that they can be lear ned to within additive error ε in total variation distance from $O(2 ^k\log(n)/\varepsilon^2)$ samples, which quadratically improves the upper bound of Aliakbarpour et al. (COLT'16) and matches their lower bound in every paramete r.

(2) Junta states. We initiate the study of n-qubit states that are k-juntas, those that are the tensor product of a k-qubit state and an $(n-k)$-qubit max imally mixed state. We show that these states can be learned with error $\vareps ilon$ in trace distance with $O(12^{k}\log(n)/\varepsilon^2)$ single copies. We also prove a lower bound of $\Omega((4^k+\log (n))/\varepsilon^2)$ copies. Addit ionally, we show that, for constant k, $\widetilde{\Theta}(2^n/\varepsilon^2)$ copies are necessary and sufficient to test whether a state is ε-cl ose or 7ε-far from being a k-junta.

(3) QAC^0 circuits. We show that n-qubit QAC^0 circuits with size s, depth d and a auxiliary qubits can be learned from $2^{O(\log (s^22^a)^d)}\log(n)$ copies of the Choi state, improving the $n^{O(\log(s^22^a)^ d)}$ by Nadimpalli et al. (STOC'24).

Along the way, we give new proof of the optimal performance of Classical Shadows based on Pauli analysis. We also strengthen the lower bounds against $\mathsf{Q AC}^0$ to compute the address function.

Multimodal Crystal Flow: Any-to-Any Modality Generation for Unified Crystal Mode ling
Kiyoung Seong, Sungsoo Ahn, Sehui Han, Changyoung Park
Crystal modeling spans a family of conditional and unconditional generation task s, including crystal structure prediction (CSP) and *de novo* generation (DNG). While recent deep generative models have shown promising performance, they remai n largely task-specific, lacking a unified framework that shares crystal represe ntations across tasks. To address this limitation, we propose *Multimodal Crysta l Flow (MCFlow)*, a unified multimodal flow model that realizes multiple crystal generation tasks as distinct inference trajectories via independent time variab les for atom types and crystal structures. To enable multimodal flow in a standa rd transformer model, we introduce a composition- and symmetry-aware atom orderi ng with hierarchical permutation augmentation, injecting compositional and cryst allographic priors without explicit structural templates. Experiments on the MP-20 and MPTS-52 benchmarks show that a single MCFlow model is competitive with ta sk-specific baselines across CSP, DNG, and structure-conditioned atom type gener ation.

Categorical Flow Maps

Daan Roos, Oscar Davis, Floor Eijkelboom, Michael M. Bronstein, Max Welling, ■sm ail ■lkan Ceylan, Luca Ambrogioni, Jan-Willem van de Meent

We introduce Categorical Flow Maps, a flow-matching method for accelerated few-s tep generation of categorical data via self-distillation. Building on recent var iational formulations of flow matching and the broader trend towards accelerated inference in diffusion and flow-based models, we define a flow map towards the simplex that transports probability mass toward a predicted endpoint, yielding a parametrisation that naturally constrains model predictions. Since our trajecto ries are continuous rather than discrete, Categorical Flow Maps can be trained w ith existing distillation techniques, as well as a new objective based on endpoi nt consistency. This continuous formulation also automatically unlocks test-time inference: we can directly reuse existing guidance and reweighting techniques i n the categorical setting to steer sampling toward downstream objectives. Empiri cally, we achieve state-of-the-art few-step results on images, molecular graphs, and text, with strong performance even in single-step generation.

PLANTAIN: Plan-Answer Interleaved Reasoning

Anthony Liang, Jonathan Berant, Adam Fisch, Abhimanyu Goyal, Kalpesh Krishna, Ja cob Eisenstein

Reasoning models often spend significant time generating hidden reasoning before any visible response, which can waste user time when the model starts from a fa lse premise that could have been corrected early. Human speakers, in contrast, u se lightweight incremental check-ins to maintain common ground, motivating *inte rleaved reasoning* (IR), where a model alternates between internal thinking and visible intermediate responses. We instantiate this idea with PLAINTAIN (Plan-An swer Interleaved Reasoning), a post-training recipe that teaches a model to exte rnalize an explicit step-by-step plan before continuing its reasoning. This lear ned plan-first structure creates an interface for early feedback and interventio n while preserving space for subsequent reasoning. Across challenging math, codi ng, text-to-SQL, and reading-comprehension benchmarks, PLAINTAIN improves pass@1 by roughly 6% on average while reducing time-to-first-response by over 60% rela tive to think-then-answer baselines.

TileSparse: Arithmetic-Intensity-Aware Sparse Attention for Compute-Bound LLM De coding

Chao Wang, Pengfei Zuo, Zhangyu Chen, Qihui Zhou, Tsung-Yi Ho, Ming-Chang Yang

Sparse attention has emerged as a vital technique for long-context inference in Large Language Models (LLMs), effectively accelerating memory-bound decoding by reducing memory access for non-essential keys. However, the assumption that deco ding attention is memory-bound has been shattered. The proliferation of Multi-he ad Latent Attention (MLA) and Multi-Token Prediction (MTP) architectures has eff ectively rendered the process compute-bound. We observe that, in MLA, Q-heads ex hibit a degree of sparsity even when attending to the same key; consequently, tr aditional sparse attention algorithms introduce significant computational ineffi ciency in this new regime by rigidly computing interactions between all associat ed Q-heads and the retrieved keys.

To address this, we propose TileSparse, an arithmetic-intensity-aware (a.i.-awar e) algorithm for efficient attention in compute-bound settings. We first introdu ce a cost model that emphasizes compute budget (compute tile size) rather than m emory budget (fetched tokens) when evaluating sparse methods. Next, QK 2D Sparsi ty prunes unnecessary Q-head--key computations and uses the freed compute to ret rieve more semantically important tokens. Because Q-head sparsity differs across keys, we further propose Tiered QK 2D Sparsity and an AutoTuner to choose the b est pattern. Experiments show that under tight budgets our method improves accur acy by 40% over state-of-the-art dynamic K-only sparse methods. It also preserve s 99% of full-attention accuracy while cutting attention compute by 40.8%, outpe rforming prior sparse attention approaches.

Improving the Sensitivity of Backdoor Detectors via Class Subspace Orthogonalization
Guangmingmei Yang, David J. Miller, George Kesidis
Most post-training backdoor detection methods rely on attacked models exhibiting extreme outlier detection statistics for the target class of an attack, compared to non-target classes. However, these approaches may fail: (1) when some (non-target) classes are easily discriminable from all others, in which case they may _naturally_ achieve extreme detection statistics (e.g., decision confidence); and (2) when the backdoor is subtle, i.e., with its features weak relative to intrinsic class-discriminative features. A key observation is that the backdoor target class has contributions to its detection statistic from both the backdoor trigger _and_ from its intrinsic features, whereas non-target classes _only_ have contributions from their intrinsic features. To achieve more sensitive detectors, we thus propose to _suppress_ intrinsic features while optimizing the detection statistic for a given class. For non-target classes, such suppression will drastically reduce the achievable statistic, whereas for the target class the (significant) contribution from the backdoor trigger remains. In practice, we formulate a constrained optimization problem, leveraging a small set of clean examples from a given class, and optimizing the detection statistic while orthogonalizing with respect to the class's intrinsic features. We dub this approach ''class subspace orthogonalization'' (CSO). CSO can be ''plug-and-play'' applied to a wide variety of existing detectors. We demonstrate its effectiveness in improving several well-known detectors, comparing with a variety of baseline detectors, against a variety of attacks, on the CIFAR-10, GTSRB, and TinyImageNet domains. Moreover, to make the detection problem even more challenging, we also evaluate against a novel mixed clean/dirty-label poisoning attack that is more surgical and harder to detect than traditional dirty-label attacks. Finally, we evaluate CSO against an adaptive attack designed to defeat it, with promising detection results.
****
Vision2Web: A Hierarchical Benchmark for Visual Website Development with Agent Verification
Zehai He, Wenyi Hong, Zhen Yang, Ziyang Pan, Mingdao Liu, Xiaotao Gu, Jie Tang
Recent advances in large language models have improved the capabilities of coding agents, yet systematic evaluation of complex, end-to-end website development remains limited. To address this gap, we introduce Vision2Web, a hierarchical benchmark for visual website development, spanning from static UI-to-code generation, interactive multi-page frontend reproduction, to long-horizon full-stack website development. The benchmark is constructed from real-world websites and comprises a total of 193 tasks across 16 categories, with 918 prototype images and 1,255 test cases. To support flexible, thorough and reliable evaluation, we propose workflow-based agent verification paradigm based on two complementary components: a GUI agent verifier and a VLM-based judge. We evaluate multiple visual language models instantiated under different coding-agent frameworks, revealing substantial performance gaps at all task levels, with state-of-the-art models still struggling on full-stack development.
****
STAR-KV: Low-Rank KV Cache Compression via Soft Thresholding for Adaptive Rank Control
Priyansh Bhatnagar, Ashkan Moradifirouzabadi, Se-Hyun Yang, SeungJae Lee, Jungwook Choi, Mingu Kang
Low-rank projection has emerged as a promising approach for compressing the KV cache by exploiting hidden-dimension redundancy. However, prior methods rely on fixed or heuristic rank selection and struggle to achieve aggressive compression with minimal accuracy degradation. We propose STAR-KV, an adaptive low-rank KV cache compression framework with fine-grained rank control. STAR-KV encompasses 1) a differentiable thresholding mechanism that enables optimal rank selection at both attention-head and block levels, 2) a hybrid decomposition strategy that applies different low-rank factorizations according to the sensitivity of key and value projections, and 3) a low-rank--aware mixed precision quantization that

leverages data statistics for near lossless low-bit quantization. Evaluated acro ss multiple LLMs and benchmarks, STAR-KV achieves up to 75\% KV cache compressi on and up to 20$\times$ overall KV cache reduction when combined with quantizati on. Enabled by custom Triton-based GPU kernels, STAR-KV delivers up to 6.9$\time s$ speedup for the attention module and 3.1$\times$ end-to-end generation throug hput. Our code is publicly available at: https://github.com/PriyanshBhatnagar/ST AR-KV.

WinQ: Accelerating Quantization-Aware Training of Language Models Around Saddle Points

Dongyue Li, Zechun Liu, Kai Yi, Zhenshuo Zhang, Changsheng Zhao, Raghuraman Kris hnamoorthi, Harshit Khaitan, Hongyang R. Zhang, Steven Li

Quantization-aware training (QAT) is widely adopted to quantize language models by training full-precision weights using gradients from the quantized model. The main bottleneck is its slow convergence and early performance plateau, particul arly below 4-bit-widths. While this problem has been observed in prior work, its precise cause remains unclear. In this paper, we analyze the convergence of QAT by estimating the spectrum of the loss-surface Hessians. We find that the weigh ts converge to flat regions around saddle points, where a large fraction of the Hessian eigenvalues are both positive and negative. During training, an increasi ng fraction of Hessian eigenvalues concentrates around zero, whose magnitude dec reases. At lower bit-widths, the magnitude of eigenvalues in the Hessian spectru m is significantly smaller. To mitigate these issues, we propose an algorithm ca lled WinQ to accelerate QAT, which involves: (1) periodically resetting weights to the linear interpolation of full-precision and quantized weights, reducing th e distance to the quantization grid and increasing eigenvalue magnitude, and (2) computing gradients of noise-injected weights to regularize the Hessian. Extens ive experiments show that WinQ accelerates QAT by up to 4$\times$ across various quantization methods and models. Under the same training cost, WinQ improves st ate-of-the-art sub-4-bit quantization by up to 8.8%. These results are consisten t across 16 settings with different language models, quantization methods, and b it widths.

FIRE: Learning to Navigate and Act on Real-World Files via Stateful Reinforcemen t Learning

Jingyuan Ma, Zheng Li, Rui Li, Siyao Song, Ying Zeng, Minghao Li, Zhifang Sui

Large language models still struggle to reliably answer questions grounded in re al-world files like spreadsheets and slides, where evidence is scattered across irregular layouts and heterogeneous formats. We address this by formalizing File Reasoning, a setting where agents must interact directly with unprocessed files (XLSX, PDF, DOCX, PPTX) within a persistent sandbox. To support this, we introd uce a unified data pipeline and a high-difficulty benchmark of over 400 verifiab le questions that preserve native file structure. Furthermore, we propose a rein forcement learning framework grounded in stateful file execution. We train **FIR E** (**F**ile **I**nteractive **R**easoning **E**xpert), a family of models that learn to optimize long-horizon planning using genuine execution feedback. Unlik e stateless tool-use methods, this environmental persistence enables agents to i teratively recover from errors and adapt to structural ambiguities. Empirical re sults show that Qwen3-32B-FIRE achieves the strongest performance among the open -source models of comparable scale under identical execution constraints.

CURVE: Learning Causality-Inspired Invariant Representations for Robust Scene Un derstanding via Uncertainty-Guided Regularization

Yue Liang, Jiatong Du, Ziyi Yang, Yanjun Huang, Hong Chen

Scene graphs provide structured abstractions for scene understanding, yet they o ften overfit to spurious correlations, severely hindering out-of-distribution ge neralization. To address this limitation, we propose CURVE, a causality-inspired framework that integrates variational uncertainty modeling with uncertainty-gui ded structural regularization to suppress high-variance, environment-specific re lations. Specifically, we apply prototype-conditioned debiasing to disentangle i

nvariant interaction dynamics from environment-dependent variations, promoting a sparse and domain-stable topology. Empirically, we evaluate CURVE in zero-shot transfer and low-data sim-to-real adaptation, verifying its ability to learn domain-stable sparse topologies and provide reliable uncertainty estimates to support risk prediction under distribution shifts.

How can embedding models bind concepts?
Arnas Uselis, Darina Koishigarina, Seong Joon Oh
Humans easily determine which color belongs to which shape in multi-object scenes, an ability known as concept binding. Vision–language embedding models such as CLIP struggle with binding: they recognize individual concepts but fail to represent which concepts form which objects. Although CLIP behaves like a bag-of-concepts model in cross-modal retrieval, object information is recoverable from its image and text embeddings separately. We study this tension through the binding function, which maps concepts to scene embeddings.
We find that scene embeddings decompose additively into object representations, explaining why uni-modal probes can recover object information. However, CLIP’s binding function is high-complexity, which likely prevents the image and text encoders from learning a shared binding mechanism that generalizes to unseen concept combinations.
We then ask whether this limitation is fundamental. We show that it is not. In controlled transformer models trained from scratch, binding generalization emerges with sufficient data coverage. These models learn low-complexity binding functions characterized by multiplicative interactions between concepts, enabling systematic generalization.
****
Mind the Budget: Accelerating Deep Reinforcement Learning using Constrained Early Exit Neural Networks
Julien Brosseit, Jasper Hoffmann, Joschka Boedecker
Early exit neural networks, which adapt computation to input complexity, have proven effective in supervised learning but remain largely unexplored in deep reinforcement learning (DRL). In this paper, we propose Budgeted EXit Actor (BEXA), a novel actor-critic architecture that integrates early exit branches into the actor network. To ensure a mathematically principled trade-off between performance and inference expenditure, the exit decision is formulated as a constrained linear program during training, the solution of which is subsequently amortized to enable highly efficient runtime execution. BEXA is general, governed by an interpretable budget parameter, and compatible with any off-policy actor-critic method. We evaluate BEXA by integrating it with standard off-policy algorithms like SAC and TD3 on a suite of MuJoCo tasks. Our results demonstrate a substantial improvement in inference efficiency with minimal or no loss in performance. These findings highlight early exits as a promising direction for improving computational efficiency in DRL.
****
RLSF-V: Mitigating Hallucinations in MLLMs via Fuzzy Semantic Self-Feedback
Changhao He, Shuhao Yan, Shuxian Li, Xi Peng, Peng Hu
Multimodal large language models (MLLMs) extend large language models (LLMs) with visual perception for open-world understanding, but exacerbate LLMs' hallucinations, in which generated text contradicts visual evidence or common sense. To mitigate hallucinations, a dominant strategy is Direct Preference Optimization (DPO) using hallucination-labeled responses. Existing pipelines, however, face two key limitations: they either (i) rely on human inspection or proprietary models to correct hallucinated outputs, producing off-policy preference data that violate the assumptions of DPO, or (ii) depend on stronger models to evaluate responses, leading to an unfavorable trade-off between performance and scalability. Departing from these paradigms, we propose a reference-policy \emph{self-feedback} framework that constructs preference data for hallucination mitigation without any external supervision (\textit{e.g.}, large models or humans). Specifically, we present a novel \emph{local fuzzy semantic} evaluation paradigm that derives a hallucination-sensitive confidence signal directly from the internal logits, w

hich is then used to automatically rank diverse generated responses to build pre ference pairs for fine-tuning. Trained on a 10k-scale dataset, our method achiev es competitive performance on both generative and discriminative benchmarks comp ared to existing RLHF and RLAIF baselines.

Attention Sparsity is Input-Stable: Training-Free Sparse Attention for Video Gen eration via Offline Sparsity Profiling and Online QK Co-Clustering
Jiayi Luo, Jiayu Chen, Jiankun Wang, Cong Wang, Hanxin Zhu, Qingyun Sun, Chen Ga o, Zhibo Chen, Jianxin Li
Diffusion Transformers (DiTs) achieve strong video generation quality but suffer from high inference cost due to dense 3D attention, leading to the development of sparse attention technologies to improve efficiency. However, existing traini ng-free sparse attention methods in video generation still face two unresolved l imitations: *ignoring layer heterogeneity in attention pruning* and *ignoring qu ery-key coupling in block partitioning*, which hinder a better quality-speedup t rade-off. In this work, we uncover a critical insight that **the attention spars ity of each layer is its intrinsic property, with minor effects across different inputs**. Motivated by this, we propose **SVOO**, a training-free **S**parse at tention framework for fast **V**ideo generation via **O**ffline layer-wise spars ity profiling and **O**nline bidirectional co-clustering. Specifically, SVOO ado pts a two-stage paradigm: (i) offline layer-wise sensitivity profiling to derive intrinsic per-layer pruning levels, and (ii) online block-wise sparse attention via a novel bidirectional co-clustering algorithm. Extensive experiments on sev en widely used video generation models demonstrate that SVOO achieves a superior quality-speedup trade-off over state-of-the-art methods, delivering up to 1.93× speedup while maintaining a PSNR of up to 29 dB on Wan2.1.
****
Revisiting Uncertainty: On Evidential Learning for Partially Relevant Video Retr ieval
Jun Li, Peifeng Lai, Xuhang Lou, Jinpeng Wang, Yuting Wang, Ke Chen, Yaowei Wang , Shu-Tao Xia
Partially relevant video retrieval aims to retrieve untrimmed videos using text queries that describe only partial content. However, the inherent asymmetry betw een brief queries and rich video content inevitably introduces uncertainty into the retrieval process.
In this setting, vague queries often induce semantic ambiguity across videos, a challenge that is further exacerbated by the sparse temporal supervision within videos, which fails to provide sufficient matching evidence. To address this, we propose Holmes, a hierarchical evidential learning framework that aggregates mu lti-granular cross-modal evidence to quantify and model uncertainty explicitly.
At the inter-video level, similarity scores are interpreted as evidential suppor t and modeled via a Dirichlet distribution. Based on the proposed three-fold pri nciple, we perform fine-grained query identification, which then guides query-ad aptive calibrated learning.
At the intra-video level, to accumulate denser evidence, we formulate a soft que ry-clip alignment via flexible optimal transport with an adaptive dustbin, which alleviates sparse temporal supervision while suppressing spurious local respons es. Extensive experiments demonstrate that Holmes outperforms state-of-the-art m ethods. Code is released at https://github.com/lijun2005/ICML26-Holmes.

The Value Function Semi-Algebraic Set in Partially Observable Markov Decision Pr ocesses
Ryan A. Anderson, Guido Montufar
We study the geometry of feasible value functions in infinite-horizon partially observable Markov decision processes (POMDPs) under memoryless stochastic polici es. Our main contribution is a characterization of the feasible set of value fun ctions as a semi-algebraic set, defined by explicit polynomial inequalities dete rmined by the transition dynamics, observation kernel, and reward structure of t he POMDP. This result extends prior work for fully observable Markov decision pr ocesses, where the feasible set is known to be a polytope, to the substantially

more intricate partially observable setting. In contrast to the polyhedral structure arising in MDPs, partial observability induces fundamentally nonlinear constraints, leading to a richer and more complex geometric structure. Our geometric characterization provides new insight into the landscape of policy optimization in both MDPs and POMDPs, and reveals qualitative phenomena unique to partial observability, including the emergence of isolated local maximizers of the long-term reward and their dependence on the initial state distribution.
****
Does AI Reviewer See the Full Picture? Attacking and Defending Multimodal Peer Review
Xinyu Zhao, Rana Shahroz, Zhen Xu, Zhen Tan, Tianlong Chen
The integration of Large Language Models (LLMs) and Multimodal LLMs (MLLMs) into scientific peer-review workflows introduces novel and significant risks for adversarial manipulation, especially given the multimodal nature of scientific papers where figures, not just text, convey core evidence. This creates a significant gap: current robustness studies on AI peer-review are overwhelmingly text-only. Moreover, the problem is distinct from standard jailbreaking, as a peer-review attack seeks to induce a domain-specific, targeted failure (e.g., “inflate this score”) rather than a general safety policy violation, for which no practical defenses exist. To address this, we introduce PaperGuard, the first comprehensive benchmark designed to systematically evaluate and defend AI-generated peer-review against these domain-specific, cross-modal attacks. Our framework is built on three pillars: (1) a new multimodal peer-review dataset spanning multiple scientific domains; (2) a unified suite of attacks, including black-box prompt injections and white-box perturbations, specifically designed to target both text (GCG) and figures (PGD); and (3) a practical defense, motivated by the long-context challenge of academic papers, that uses chunk-based embedding search to efficiently localize and mitigate harmful instructions. Our extensive experiments, conducted across state-of-the-art models, confirm that AI reviewers are pervasively vulnerable. PaperGuard establishes the foundational benchmark, protocols, and actionable defense necessary to pioneer trustworthy, attack-resilient AI-assisted scholarly reviewing.

Chasing Moving Targets with Online Self-Play Reinforcement Learning for Safer Language Models
Mickel Liu, Liwei Jiang, Yancheng Liang, Simon Shaolei Du, Yejin Choi, Tim Althoff, Natasha Jaques
Conventional large language model (LLM) safety alignment relies on a reactive, disjoint loop: attackers exploit a static model, then defenders patch exposed vulnerabilities. This sequential setup leads to attackers overfitting obsolete exploits while defenders perpetually lag behind emerging threats. To address this, we introduce Self-RedTeam, the first fully online self-play multi-agent reinforcement learning (MARL) algorithm that continuously co-evolves attacker and defender for robust safety alignment. A single policy self-plays as both attacker and defender, generating adversarial prompts and defending against them, with a reward model adjudicating outcomes. Each role uses hidden chain-of-thought for strategic planning. Grounded in two-player zero-sum game theory, we establish a theoretical safety guarantee: if the game converges to Nash Equilibrium, the defender produces safe responses against any adversarial input. Empirically, Self-RedTeam generalizes across five models from the Llama and Qwen families, uncovering more diverse attacks (+17.80% SBERT) and improving safety of RLHF-trained models by up to 95% across 14 benchmarks. Our work motivates a shift from reactive patching to proactive co-evolution, enabling LLM safety self-improvement via online self-play MARL.
****
DDSVM: A Differentiable Framework for Deep Support Vector Machines with Iterative Geometry-Aware Optimization
Yirun Ding, Zhihui Lai
Modern deep networks optimize features via cross-entropy without explicit margin maximization, while classical Support Vector Machines maximize the margin on a

fixed feature space. Hybrid Deep-SVM approaches typically treat the deep feature extractor as a static input to an SVM head, so SVM geometry never flows back to shape representation learning. We propose the **Differentiable Deep Support Vector Machine (DDSVM)**, an iterative framework that alternates between re-fitting a linear SVM on L_2-normalized features and updating the backbone to pull each feature along the SVM-defined margin-widening direction, treating the decision boundary as a dynamic teacher for representation learning. Under spherical normalization the resulting feature gradient lies in the tangent space and optimization focuses exclusively on angular separability. DDSVM reduces top-1 error by **5.6--8.3\%** on image classification benchmarks under data scarcity.

(Doubly) Exponential Lower Bounds for Follow the Regularized Leader in Potential Games

Ioannis Anagnostides, Ioannis Panageas, Nikolas Patris, Tuomas Sandholm

Follow the regularized leader (FTRL) is the premier algorithm for online optimization---and potential games in particular---its behavior remained hitherto poorly understood. In this paper, we establish that FTRL can take exponential time to converge to a Nash equilibrium in two-player potential games for any (permutation-invariant) regularizer and potentially vanishing learning rate. By known equivalences, this translates to an exponential lower bound for certain mirror descent counterparts, most notably multiplicative weights update. On the positive side, we establish the potential property for FTRL and obtain an exponential upper bound $\exp(O_{\epsilon}(1/\epsilon^2))$ for any no-regret dynamics executed in a lazy, alternating fashion, matching our lower bound up to factors in the exponent. Finally, in multi-player potential games, we show that fictitious play---the extreme version of FTRL---can take doubly exponential time to reach a Nash equilibrium. This constitutes an exponentially stronger lower bound for the foundational learning algorithm in games.

Plug-and-Play Spiking Operators: Breaking the Nonlinearity Bottleneck in Spiking Transformers

Xinzhe Yuan, Xiang Peng, Bin Gu, Huan Xiong

ANN-to-SNN conversion offers a practical, training-free route to spiking large language models.

However, current pipelines primarily focus on spike-driven realizations for Transformer linear-algebra operations, while providing limited support for key nonlinear operators.

This gap limits compatibility with neuromorphic-style execution constraints, where such nonlinearities typically require division, exponentiation, or norm computations that are not naturally supported by standard leaky integrate-and-fire dynamics.

To solve this problem, we propose a plug-and-play framework that implements spike-friendly approximations for Transformer nonlinearities and integrates into existing ANN-to-SNN pipelines.

Our method decomposes these nonlinear computations into three recurring primitives---division, exponentiation, and ℓ_2 norms---and realizes them via population computation using LIF neuron groups, combined with lightweight bit-shift scaling to avoid floating-point arithmetic.

By composing these primitives as modular operator blocks, our framework supports common Transformer nonlinearities (e.g., Softmax, SiLU, and normalization) without any fine-tuning.

Experiments on a range of LLMs Transformers show that selectively replacing the targeted nonlinear operators incurs less than a 1% accuracy drop across all evaluated tasks.

****

Bottleneck-Guided Spectral Subgoals For Offline Goal-Conditioned RL

Hebin Liang, Yi Ma, Chenjun Xiao, Zibin Dong, Zilin Cao, Fei Ni, Yifu Yuan, Jianye HAO

Offline goal-conditioned RL (OGCRL) learns to reach arbitrary goals from the off

line dataset, but long-horizon performance hinges on crossing a handful of hard-to-cross bottlenecks. These bottlenecks not only dictate the feasible paths towa rd the goal but also act as critical keypoints, marking the transitions between adjacent regions and providing the agent with essential directional guidance. Pr ior hierarchical methods pick subgoals by time or short-horizon value heuristics , which do not localize the bottleneck, and therefore the agent loses the clear guidance that bottlenecks could provide about where to pass next. We instead mod el long-horizon planning as ``cross the next bottleneck'': we apply Laplacian sp ectral clustering to the offline dataset to expose bottlenecks, identify traject ories from the offline dataset that cross these boundaries, and use the correspo nding boundary-supported states as keypoint (KP) candidates.
The most representative KPs are then instantiated from these candidates, and a d irected KP reachability graph $\mathcal G_{\mathrm{KP}}$ is constructed based on the resulting KPs.
We then restrict high-level choices to these bottleneck states and use a pluggab le low-level controller to execute the short transitions between them.
We provide theory showing that under a standard metastable decomposition of the state space, routing through bottlenecks yields an (approximately) optimal one-s tep subgoal in terms of hitting-time, and that Laplacian spectra recover bottle necks with high overlap. Thus, Laplacian spectral clustering can discover near-o ptimal subgoals under these assumptions. Empirically, the same pattern holds: ac ross D4RL and OGBench, our method achieves state-of-the-art results on a broad s et of navigation and manipulation tasks and across diverse dataset regimes, for example, **96.5\%** on **AntMaze** and **84.7\%** on **Franka-Kitchen**.

From Internal Diagnosis to External Auditing: A VLM-Driven Paradigm for Data-Fre e Online Backdoor Defense
Binyan Xu, Fan Yang, Xilin Dai, Di Tang, Kehuan Zhang
Deep Neural Networks (DNNs) remain fundamentally vulnerable to backdoor attacks. Traditional data-free defenses largely operate under the paradigm of internal d iagnosis methods like model repairing or input robustness, yet these approaches are often fragile under advanced attacks as they remain entangled with the victi m model’s corrupted parameters. We propose a paradigm shift to data-free Externa l Semantic Auditing, using universal Vision-Language Models (VLMs) as independen t auditors to decouple defense from the compromised model. We introduce PRISM (P rototype Refinement & Inspection via Statistical Monitoring), which transforms g eneric VLMs into domain-adaptive gatekeepers purely via online test-time adaptat ion. PRISM bridges the domain gap through a Hybrid VLM Teacher that refines prot otypes from the test stream and an Adaptive Router that calibrates thresholds vi a statistical monitoring. Evaluation across 17 datasets and 11 attack types conf irms PRISM achieves state-of-the-art performance (suppressing Attack Success Rat e to < 1% on CIFAR-10), proving that robust defense is achievable without touchi ng the model weights or accessing a single training sample.

FIRE-Bench: Evaluating AI Agents on the Rediscovery of Scientific Insights
Zhen Wang, Fan Bai, Zhongyan Luo, Jinyan Su, Kaiser Sun, Xinle Yu, Jieyuan Liu, Kun Zhou, Claire Cardie, Mark Dredze, Zhiting Hu, Eric P. Xing
Autonomous AI agents powered by large language models (LLMs) are increasingly ca pable of running a full cycle of scientific research, yet we still lack reliable ways to verify that their discoveries are correct. Because novel findings deman d costly real-world validation, existing benchmarks fall back on LLM-as-judge sc oring of generated papers or single leaderboard metrics, both coarse proxies for scientific reasoning. We introduce FIRE-BENCH (Full-cycle Insight Rediscovery E valuation), which instead asks agents to rediscover established, verifiable find ings from recent, high-impact machine learning research. Given only a high-level research question from a published study, an agent must independently design ex periments, run them, and draw evidence-backed conclusions, scored against the st udy's documented findings. Across state-of-the-art agents with frontier backbone s such as gpt-5, even the strongest reaches limited rediscovery success (<50 F1) , with high run-to-run variance and recurring failures in experimental design, e

xecution, and evidence-based reasoning. Beyond diagnosing current systems, FIRE-BENCH shows that open-ended discovery can be evaluated rigorously and verifiably , laying a foundation for building reliable environments that improve agents.

Temporal-Aware Reasoning Optimization for Video Temporal Grounding
Minghang Zheng, Zihao Yin, Yi Yang, Yuxin Peng, Yang Liu
Multi-modal Large Language Models (MLLMs) have achieved remarkable progress in v ideo temporal grounding with reinforcement learning for generating reasoning pat hs. However, existing models often produce superficial reasoning, which offers l imited guidance for precise temporal localization. This limitation stems from (1) inefficient random exploration and (2) reward functions that focus solely on t he answer correctness while ignoring reasoning quality. To address these issues, we propose TaRO (Temporal-Aware Reasoning Optimization), a framework that expli citly enhances the model’s ability of thinking with time. First, we introduce a Constructive Reasoning Exploration that leverages pre-generated dense captions t o construct reasoning paths grounded in explicit visual cues and timestamps, ena bling efficient exploration of high-quality time-aware reasoning. Second, to eva luate reasoning quality, we design a Temporal-Sensitivity Reward. High-quality r easoning should be anchored to specific events and timestamps. If the event boun dary under thinking is disrupted, such reasoning should become invalid, leading to a drop in the logit of the reasoning path. We utilize this drop as a critique of reasoning quality. Finally, TaRO follows a progressive curriculum, which sta rts by utilizing this reward to select better constructed reasoning paths, and e volves to a free exploration phase where the model autonomously generates effect ive reasoning. Experiments demonstrate that TaRO achieves state-of-the-art perfo rmance on VTG benchmarks. Code is available at https://github.com/oceanflowlab/T aRO.

On the Theory of Continual Learning with Gradient Descent for Neural Networks
Hossein Taheri, Avishek Ghosh, Arya Mazumdar
Continual learning, the ability of a model to adapt to an ongoing sequence of ta sks without forgetting earlier ones, is a central goal of artificial intelligenc e. To better understand its underlying mechanisms, we study the limitations of c ontinual learning in a tractable yet representative setting. Specifically, we an alyze one-hidden-layer quadratic neural networks trained by gradient descent on a sequence of XOR-cluster datasets with Gaussian noise, where different tasks co rrespond to clusters with orthogonal means. Our analysis is based on a tight cha racterization of gradient descent dynamics for the training loss, which yields e xplicit bounds on the rate of train-time forgetting as functions of the number o f iterations, sample size, number of tasks, and hidden-layer width. We then leve rage an algorithmic stability framework to bound the generalization gap, leading to corresponding guarantees on test-time forgetting. Together, our results prov ide the first closed-form guarantees for forgetting in continual learning with neural networks and show how key problem parameters jointly govern forgetting dy namics. Numerical experiments corroborate our theoretical results.

Cascaded Flow Matching for Heterogeneous Tabular Data with Mixed-Type Features
Markus Mueller, Kathrin Gruber, Dennis Fok
Advances in generative modeling have recently been adapted to tabular data conta ining discrete and continuous features.
However, generating mixed-type features that combine discrete states with an oth erwise continuous distribution in a single feature remains challenging. We advan ce the state-of-the-art in diffusion models for tabular data with a cascaded app roach. We first generate a low-resolution version of a tabular data row, that is , the collection of the purely categorical features and a coarse categorical rep resentation of numerical features. Next, this information is leveraged in the hi gh-resolution flow matching model via a novel guided conditional probability pat h and data-dependent coupling. The low-resolution representation of numerical fe atures explicitly accounts for discrete outcomes, such as missing or inflated va lues, and therewith enables a more faithful generation of mixed-type features. W

e formally prove that this cascade tightens the transport cost bound. The result s indicate that our model generates significantly more realistic samples and cap tures distributional details more accurately, for example, the detection score i mproves by 51.9%. Code is available at https://github.com/muellermarkus/tabcasca de.

Push, Pop, Parallelize: Stack-Augmented Linear Attention via the Delta Rule
Anh T Nguyen, Saleh Momeni, Ashutosh Chaubey, Changnan Xiao, Bing Liu
Linear attention architectures based on the Delta rule, such as DeltaNet and RWK V-7, combine Transformer-level performance with RNN-like efficiency and provably solve regular language tasks. However, their fixed-size states struggle to capt ure the recursive, hierarchical structures intrinsic to natural languages. To br idge this gap, we introduce DeltaStack, which augments DeltaNet's associative me mory with a lightweight, differentiable stack. Unlike prior approaches that rely on sequential recurrence, DeltaStack formulates stack operations as linear delt a-rule updates, enabling a hardware-aware implementation fully parallelizable ov er sequence length. Theoretically, we prove DeltaStack extends DeltaNet's expres sivity to model both regular and hierarchical languages. Empirically, DeltaStack outperforms DeltaNet and Stack-Attention on formal language benchmarks and cons istently surpasses DeltaNet baselines in language modeling perplexity and zero-s hot performance across scales up to 760M parameters.

Our code is publicly available at https://github.com/teeann/DeltaStack.

Imagination Helps Visual Reasoning, But Not Yet in Latent Space
You Li, Chi Chen, Yanghao Li, Fanhu Zeng, Kaiyu Huang, Jinan Xu, Maosong Sun
Latent visual reasoning aims to mimic human's *imagination* process by meditatin g through hidden states of Multimodal Large Language Models.

While recognized as a promising paradigm for visual reasoning, the underlying mechanisms driving its effectiveness remain unclear.

Motivated to demystify the true source of its efficacy, we investigate the val idity of latent reasoning using Causal Mediation Analysis.

We model the process as a causal chain: the input as the treatment, the latent tokens as the mediator, and the final answer as the outcome.

Our findings uncover two critical disconnections:

(a) **Input-Latent Disconnect**: dramatic perturbations on the input result in negligible changes to the latent tokens, suggesting that latent tokens do not e ffectively attend to the input sequence.

(b) **Latent-Answer Disconnect**: perturbations on the latent tokens yield min imal impact on the final answer, indicating the limited causal effect latent tok ens imposing on the outcome.

Furthermore, extensive probing analysis reveals that latent tokens encode limi ted visual information and exhibit high similarity.

Consequently, we challenge the necessity of latent reasoning and propose a str aightforward alternative named *CapImagine*, which teaches the model to explicit ly *imagine* using text.

Experiments on vision-centric benchmarks show that *CapImagine* significantly outperforms complex latent-space baselines, highlighting the superior potential of visual reasoning through explicit imagination.

OGPO: Sample Efficient Full-Finetuning of Generative Control Policies
Sarvesh Patil, Mitsuhiko Nakamoto, Manan Agarwal, Shashwat Saxena, Jesse Zhang, Giri Anantharaman, Cleah Winston, Chaoyi Pan, Douglas Chen, Nai-Chieh Huang, Zey nep Temel, Oliver Kroemer, Sergey Levine, Abhishek Gupta, Hongkai Dai, Paarth Sh ah, Max Simchowitz
Generative control policies (GCPs), such as diffusion- and flow-based control po licies, have proved effective parameterizations for robot learning. This work in troduces Off-policy Generative Policy Optimization (**OGPO**), a sample-efficien t algorithm for finetuning GCPs that maintains off-policy critics to maximize da ta reuse and propagate policy gradients through the full generative process of t he policy via a modified PPO objective, using critics as the terminal reward. **

OGPO** achieves state-of-the-art performance on manipulation tasks spanning mult
i-task settings, high-precision insertion, and dexterous control. To our knowled
ge, it is also the only method that can *fine-tune poorly-initialized behavior c
loning policies to near full task-success with no expert data in the online repl
ay buffer*, and does so with *few task-specific hyperparameter tuning*. Through
extensive investigations, we demonstrate that **OGPO** drastically outperforms a
lternative methods on policy steering and learning residual corrections, and ide
ntify the key mechanisms behind its performance. We further introduce practical
stabilization tricks, including success-buffer regularization and two-sided cons
ervative advantages to mitigate critic over-exploitation across state- and pixel
-based settings. Beyond proposing **OGPO**, we conduct a systematic empirical st
udy of GCP finetuning, identifying the stabilizing mechanisms and failure modes
that govern successful off-policy full-policy improvement.

Use What You Know: Causal Foundation Models with Partial Graphs
Arik Reuter, Anish Dhir, Cristiana Diaconu, Jake Robertson, Ole Ossen, Frank Hut
ter, Adrian Weller, Mark van der Wilk, Bernhard Schölkopf
Estimating causal quantities traditionally relies on bespoke estimators tailored
 to specific assumptions.
Recently proposed Causal Foundation Models (CFMs) promise a more unified approac
h by amortising causal discovery and inference in a single step.
However, in their current state, they do not allow for the incorporation of any
domain knowledge, which can lead to suboptimal predictions.
We bridge this gap by introducing methods to condition CFMs on causal informatio
n, such as the causal graph or more readily available ancestral information.
When access to complete causal graph information is too strict a requirement, ou
r approach also effectively leverages partial causal information.
We systematically evaluate conditioning strategies and find that injecting learn
able biases into the attention mechanism is the most effective method to utilise
 full and partial causal information.
Our experiments show that this conditioning allows a general-purpose CFM to matc
h the performance of specialised models trained on specific causal structures.
Overall, our approach addresses a central hurdle on the path towards all-in-one
causal foundation models: the capability to answer causal queries in a data-driv
en manner while effectively leveraging any amount of domain expertise.

Hyperbolic Hierarchical Alignment for Video-Based Visible-Infrared Person Re-Ide
ntification
Shuang Li, Changjiang Kuang, Jiaxu Leng, Mingpi Tan, Zhanjie Wu, Shuanglin Yan,
Xinbo Gao
Video-based visible-infrared person re-identification (VVI-ReID) aims to learn r
obust video-level representations under modality discrepancy. However, existing
methods typically rely on Euclidean geometry, which is suboptimal for modeling t
he complex temporal dynamics within visible and infrared tracklets, as it inevit
ably distorts the intrinsic hierarchical structure inherent in diverse temporal
variations (e.g., occlusion, pose). In this paper, we propose Hyperbolic Hierarc
hical Alignment (HHA), which unifies spatio-temporal modeling and cross-modality
 alignment on the Poincaré ball. HHA employs a Hyperbolic Hierarchical Spatio-Te
mporal Aggregator (HHSA) to organize time-varying cues into low-distortion hiera
rchical representations via Hyperbolic Geometry Interaction (HGI) and Dual-Geome
try Fusion (DGF). Furthermore, we introduce Geometry-Aware Modality Alignment (G
MA), which integrates Hyperbolic Modality Alignment (HMA) to couple modality cen
troids for geometric consistency and Hyperbolic Prototype Alignment (HPA) to anc
hor both modalities to shared identity prototypes for robust discrimination. Exp
eriments on HITSZ-VCM and BUPTCampus demonstrate state-of-the-art performance. T
he code will be available at https://github.com/Visuang/HHA.

Imitation Learning for Multi-turn LM Agents via On-policy Expert Corrections
Niklas Lauffer, Xiang Deng, Srivatsa R Kundurthy, Brad Kenstler, Jeff Da
A popular paradigm for training LM agents relies on imitation learning, fine-tun

ing on expert trajectories. However, we show that the off-policy nature of imita tion learning for multi-turn LM agents suffers from the fundamental limitation k nown as covariate shift: as the student policy's behavior diverges from the expe rt's, it encounters states not present in the training data, reducing the effect iveness of fine-tuning. Taking inspiration from the classic DAgger algorithm, we propose a novel data generation methodology for addressing covariate shift for multi-turn LLM training. We introduce on-policy expert corrections (OECs), parti ally on-policy data generated by starting rollouts with a student model and then switching to an expert model part way through the trajectory. We explore the ef fectiveness of our data generation technique in the domain of software engineeri ng (SWE) tasks, a multi-turn setting where LLM agents must interact with a devel opment environment to fix software bugs. Our experiments compare OEC data agains t various other on-policy and imitation learning approaches on SWE agent problem s and train models using a common rejection sampling (i.e., using environment re ward) combined with supervised fine-tuning technique. Experiments find that OEC trajectories show a relative 14% and 13% improvement over traditional imitation learning in the 7b and 32b setting, respectively, on SWE-bench verified. Our res ults demonstrate the need for combining expert demonstrations with on-policy dat a for effective multi-turn LM agent training.

FAFO: Lossy KV Cache Compression for Lossless Inference Acceleration via Draftle ss Fumble Decoding
Hoang Anh Duy Le, Shaochen Zhong, Yifan Lu, Yingtong Dou, Jiayi Yuan, Yu-Neng Ch uang, Xiran Fan, Guanchu Wang, Yuzhong Chen, Xia Hu
Lossy KV cache compression is a well-explored subfield of machine learning eff iciency, with improved latency being one of its major gains. However, lossy comp ression techniques can fumble from time to time, exhibiting various, and often c atastrophic, failure patterns that are not only difficult to resolve but sometim es even hard to identify, making direct deployment of models with compressed KV cache a risky endeavor. In this work, we explore a way to preserve *lossless* ge neration quality while still benefiting from the acceleration provided by KV cac he compression. Specifically, we draw inspiration from the *n-gram candidate poo l decoding* paradigm where we purposely allow the model to Fumble Around with co mpressed KV cache to generate multiple lossy "n-gram guesses", while in parallel Find Out via lossless verification in the same forward pass. From a conceptual standpoint, our proposed framework is compatible with all typical static or dyna mic KV cache compression methods from the token dropping realm, thus opening up a new avenue for the stagnant n-gram decoding paradigm. Practically, we show tha t this framework presents many useful traits that similar draftless baselines (e .g., Self-Speculative Decoding) cannot achieve, such as requiring only one set o f KV cache and being far less sensitive to model, task, and input-length scenari os. Our comprehensive empirical results show FAFO provides 1.20-2.71× latency sp eedup over the original model, while consistently outperforming other lossless + draftless solutions.

Mosaic: Unlocking Over 30$\times$ Context Length for Diffusion LLMs Inference vi a Global Memory Planning and Dynamic Peak Taming
Liang Zheng, Bowen Shi, Yitao Hu, Jiawei Zhang, Ruofan Li, Guotao Yang, Zhixin Z hao, Zhengchao Wang, Sheng Chen, Wenxin Li, Dezhi Ran, Tao Xie, Keqiu Li
Diffusion-based large language models (dLLMs) have emerged as a promising altern ative to autoregressive models, leveraging simultaneous denoising to enable glob al planning and iterative refinement. These properties make dLLMs attractive for long-context generation. However, deploying dLLMs faces a prohibitive memory ba rrier, as existing inference systems are inefficient for the diffusion paradigm. We observe that current inference systems are misaligned with dLLMs. Unlike auto regressive models, whose memory footprint is dominated by the KV-Cache, dLLMs ar e bottlenecked by transient activations rematerialized per step. Moreover, gener ic memory reuse mechanisms lack the global visibility to handle dynamic memory p eaks of dLLMs, which alternate between logits and feed-forward networks.
To address these challenges, we present Mosaic, a memory-efficient inference sys

tem that shifts dLLM execution from local, static management to a global, dynami c paradigm. Mosaic integrates (i) a mask-only logits kernel eliminating redundan t activation materialization, (ii) a lazy chunking optimizer using online heuris tics to tame dynamic memory peaks, and (iii) a global memory manager leveraging virtual addressing to mitigate memory fragmentation.
Evaluations show that Mosaic reduces the memory peak-to-average ratio by 2.71$\t imes$ on average and increases the maximum inference sequence length on identica l hardware by 15.30--32.34$\times$. Crucially, Mosaic is training-free and pres erves exact model outputs, while reducing end-to-end latency by 2.5\%--55.4\%. O ur code is publicly available at https://github.com/flashserve/Mosaic.

Reasoning to Edit: Hypothetical Instruction-Based Image Editing with Visual Reas oning
Qingdong He, Xueqin Chen, Chaoyi Wang, Yanjie Pan, Xiaobin Hu, Zhenye Gan, Cheng jie Wang, Xiangtai Li, Jiangning Zhang, Yabiao Wang
Instruction-based image editing (IIE) has advanced rapidly with the success of d iffusion models. However, existing efforts primarily focus on simple and explici t instructions to execute editing operations such as adding, deleting, moving, o r swapping objects. They struggle to handle more complex implicit hypothetical i nstructions that require deeper reasoning to infer plausible visual changes and user intent. Additionally, current datasets provide limited support for training and evaluating reasoning-aware editing capabilities. Architecturally, these met hods also lack mechanisms for fine-grained detail extraction that support such r easoning. To address these limitations, we propose Reason50K, a large-scale data set specifically curated for training and evaluating hypothetical instruction–re asoning image editing, along with ReasonBrain, a novel framework designed to rea son over and execute implicit hypothetical instructions across diverse scenarios . Reason50K includes over 50K samples spanning four key reasoning scenarios: Phy sical, Temporal, Causal, and Story reasoning. ReasonBrain leverages Multimodal L arge Language Models (MLLMs) for editing guidance generation and a diffusion mod el for image synthesis, incorporating a Fine-grained Reasoning Cue Extraction (F RCE) module to capture detailed visual and textual semantics essential for suppo rting instruction reasoning. To mitigate the semantic loss, we further introduce a Cross-Modal Enhancer (CME) that enables rich interactions between the fine-gr ained cues and MLLM-derived features. Extensive experiments demonstrate that Rea sonBrain consistently outperforms state-of-the-art baselines on reasoning scenar ios while exhibiting strong zero-shot generalization to conventional IIE tasks. Our dataset and code will be released publicly.
****

TexEditor: Structure-Preserving Text-Driven Texture Editing
Bo Zhao, Yihang Liu, Chenfeng Zhang, Huan Yang, Kun Gai, Wei Ji
Text-guided texture editing aims to modify object appearance while preserving th e underlying geometric structure.
However, our empirical analysis reveals that even SOTA editing models frequently struggle to maintain structural consistency during texture editing, despite the intended changes being purely appearance-related. Motivated by this observation , we jointly enhance structure preservation from both data and training perspect ives, and build TexEditor, a dedicated texture editing model based on Qwen-Image -Edit-2509. Firstly, we construct BlenderTex, a high-quality SFT dataset generat ed with Blender, which provides strong structural priors for a cold start. Secon dly, we introduce StructureNFT, a RL–based approach that integrates structure-pr eserving losses to transfer the structural priors learned during SFT to real-wor ld scenes. Moreover, due to the limited realism and evaluation coverage of exist ing benchmarks, we introduce TexBench, a general-purpose real-world benchmark fo r text-guided texture editing. Extensive experiments on existing Blender-based t exture benchmarks and our TexBench show that TexEditor consistently outperforms strong baselines such as Nano Banana Pro. In addition, we assess TexEditor on th e general-purpose benchmark ImgEdit to validate its generalization.

Curated Synthetic Data Doesn’t Have to Collapse: A Theoretical Study of Generati

ve Retraining with Pluralistic Preferences
Ali Falahati, Mohammad Mohammadi Amiri, Kate Larson, Lukasz Golab
Recursive retraining of generative models poses a critical representation challe nge: when synthetic outputs are curated based on a fixed reward signal, the mode l tends to collapse onto a narrow set of outputs that over-optimize that objecti ve, causing diversity to vanish and failing to represent the full range of prefe rences. Prior work has suggested that such collapse is unavoidable without addin g real data into the mix. In this paper, we revisit that conclusion from an alig nment perspective and show that collapse can be mitigated through curation based on multiple reward functions. We formalize the dynamics of recursive training u nder heterogeneous preferences and prove that, under certain conditions, the mod el converges to a stable distribution that allocates probability mass across com peting high-reward regions. The limiting distribution preserves diversity and pr ovably satisfies a weighted Nash bargaining solution, offering a formal interpre tation of value aggregation in synthetic retraining loops.

When Softmax Fails at the Top: Extreme■Value Corrections for InfoNCE
Hasan Sabri Melihcan Erol, Suat Evren, Oktay Ozel, Alexander Morgan, Jongha Jon Ryu, Lizhong Zheng
InfoNCE is the standard contrastive learning objective, but its softmax form is not only a computational convenience: it also encodes a statistical assumption a bout how the top-scoring example is selected. Using extreme value theory, we sho w that this assumption is often misaligned with the normalized embedding setting used in modern contrastive learning. Motivated by this mismatch, we propose \te xtsc{WEINCE}, a simple modification of InfoNCE that uses anchor-wise online batc h statistics to blend the usual softmax logits with an endpoint shortfall correc tion, adding no trainable parameters. Across five vision benchmarks, \textsc{WEI NCE} yields consistent improvements in frozen-feature evaluation. These results show that a more faithful statistical treatment of hard negatives can improve co ntrastive objectives.\footnote{Code: \href{https://github.com/hsme98/weince}{git hub.com/hsme98/weince}.}

Robust Federated Learning Against Adaptive Compression
Wenjing Yan, Xiangyu Zhong, Ying-Jun Angela Zhang
This paper addresses the critical challenges of hyperparameter tuning and commun ication efficiency in federated learning (FL). Despite recent advancements in pa rameter-free FL algorithms such as PAdaMFed, significant communication overhead remains a major obstacle to their practical deployment. To tackle these challeng es, we propose a novel communication-efficient parameter-free FL algorithm ParFr eFL that halves the communication requirements of PAdaMFed while preserving its parameter-free property. Building on this foundation, we introduce a compressed variant, ComParFreFL, which unifies the momentum increment and error feedback in to a single parameter, effectively handling biased compression while maintaining the minimal communication cost. Notably, ComParFreFL also operates independent of the compression ratio, representing the first instance of such robustness in the compressed FL literature to our knowledge. Theoretically, our methods are pr oven to handle arbitrary data heterogeneity, partial client participation, and a chieve linear speedup with respect to both local updates and participating clien ts. Extensive empirical evaluations demonstrate that our approaches match or sli ghtly surpass the performance of carefully tuned alternatives while significantl y reducing communication overhead, making FL more accessible and deployable in d ynamic, resource-constrained environments.

Guided Star-Shaped Masked Diffusion
Viacheslav Meshchaninov, Egor Shibaev, Artem Makoian, Ivan Klimov, Nikita Balaga nsky, Daniil Gavrilov, Aibek Alanov, Dmitry Vetrov
The performance of pre-trained masked diffusion models is often constrained by t heir sampling procedure, which makes decisions irreversible and struggles in low -step generation regimes. We introduce a novel sampling algorithm that works wit h pre-trained models and, after a lightweight fine-tuning of a single layer, sig

nificantly improves sample quality and efficiency. Our method reformulates the g
eneration process using a star-shaped paradigm, which inherently allows for erro
r correction. To make this process effective, we augment it with a learnable rem
asking module that intelligently identifies and revises likely errors. This appr
oach yields a substantial quality boost, particularly when using a small number
of sampling steps. We extensively ablate key components of our approach and show
 its usability in different scenarios. In experiments on text, and code generati
on, our sampling algorithm outperforms or matches existing methods. Code is avai
lable at https://github.com/EgorShibaev/G-Star.

UniDrag: Unified Multi-Field Prediction and Robust Shape Optimization for Vehicl
e Aerodynamics
Ye Liu, Shouyi Liu, Ding Wang, Huiyu Yang, Ruizhe Deng, Qian Li, Yuxiao Hu, Jian
ghang gu, Yongzheng Liu, Quanshi Zhang, Shiyi Chen, Yuntian Chen
High-fidelity vehicle aerodynamics analysis is bottlenecked by costly CFD simula
tions. Neural surrogates accelerate prediction but lack inverse design capabilit
ies, while existing generative optimization methods suffer from unstable converg
ence and frequent engineering constraint violations. We present UniDrag, a unifi
ed framework bridging multi-field aerodynamic prediction with robust differentia
ble shape optimization. Given a vehicle geometry, UniDrag predicts surface press
ure, volume flow fields, drag coefficient C_d, and a streamwise build-up profi
le localizing drag contributions.
Our architecture combines enhanced Physics-Sliced Attention (ePSA), Gated Expert
 Routing, and Modality-Protected Learning to prevent negative transfer across ou
tput modalities. At deployment, the frozen surrogate enables gradient-based opti
mization via Free-Form Deformation with engineering constraints. We introduce Ex
pectation-over-Transformation to prevent adversarial exploitation of surrogate f
ragility.
We curate a large-scale dataset of 15,000 vehicle geometries spanning four body
types with GPU-accelerated LBM simulations. On this benchmark, UniDrag achieves
C_d prediction R^2 of 0.937 (+7.6\% over baselines) and 13.7\% mean CFD-veri
fied drag reduction with 100\% success rate and only 21.3~mm average displacemen
t (0.46\% vehicle length).

Quantitative Estimation of Target Task Performance from Unsupervised Pretext Tas
k in Semi/Self-Supervised Learning
Lin-Han Jia, Siyu Han, Wen-Chao Hu, Jie-Jing Shao, Wen-Da Wei, Zhi Zhou, Lan-Zhe
 Guo, Yu-Feng Li
The effectiveness of unlabeled data in Semi/Self-Supervised Learning (SSL) depen
ds on appropriate assumptions for specific scenarios, thereby enabling the selec
tion of beneficial unsupervised pretext tasks. However, existing research has pa
id limited attention to assumptions in SSL, resulting in practical situations wh
ere the compatibility between the unsupervised pretext tasks and the target scen
arios can only be assessed after training and validation.
This paper centers on the assumptions underlying unsupervised pretext tasks and
explores the feasibility of preemptively estimating the impact of unsupervised p
retext tasks at low cost.
Through rigorous derivation, we show that the impact of unsupervised pretext tas
ks on target performance depends on three factors: assumption learnability with
respect to the model, assumption reliability with respect to the data, and assum
ption completeness with respect to the target.
Building on this theory, we propose a low-cost estimation method that can quanti
tatively estimate the actual target performance. We build a benchmark of over on
e hundred pretext tasks and demonstrate that our estimated performance strongly
correlates with the actual performance obtained through large-scale training and
 validation.

Backjump-on-Graph: Empowering Large Language Models with Reinforced Retrospectiv
e Exploration for Agentic Knowledge Graph Reasoning
Yunqi Zhang, Shiqi Yan, Zhenzhao Yuan, Wenrui Liang, Yangming Liu, Zhixiao Qi, T

ianyi Zhang, Shijie Zhang, Wei-Qiang Zhang, Yongfeng Huang, Haixin Duan, Shuai C
hen, Yubo Chen
Grounding Large Language Models (LLMs) in Knowledge Graphs (KGs) has shown signi
ficant promise for complex Question Answering (QA) tasks.
Since LLMs' limited context window cannot accommodate the sheer volume of large-
scale KGs, existing work usually utilizes agents to reason on real-world KGs, wh
ich follows reasoning paths derived from the queries step by step.
However, the mismatch between query-derived paths and the KG's structure, stemmi
ng from users' lack of schema knowledge, usually leads the agents into dead ends
.
To address this problem, in this paper, we propose Backjump-on-Graph (BoG), a no
vel framework that empowers LLMs to retrospectively explore alternative reasonin
g paths at dead ends.
We first propose to formalize each reasoning step with four atomic operations to
 create a structural scaffold that allows LLMs to revert to historical status.
Next, we fine-tune the LLM with synthetic data containing the above atomic opera
tions to instill basic backjump abilities.
Finally, we leverage reinforcement learning and propose a hybrid reward function
, which penalizes redundant transitions and promotes correct answers, to optimiz
e the timing and landing nodes of backjumping.
Extensive experiments on several KGQA benchmark datasets demonstrate the effecti
veness of our BoG method.

Spectral Imbalance Causes Forgetting in Low-Rank Continual Adaptation
Hao Gu, Mao-Lin Luo, Zi-Hao Zhou, Han-Chen Zhang, Min-Ling Zhang, Tong Wei
Parameter-efficient continual learning aims to adapt pre-trained models to seque
ntial tasks without forgetting previously acquired knowledge. Most existing appr
oaches treat continual learning as avoiding interference with past updates, rath
er than considering what properties make the current task-specific update natura
lly preserve previously acquired knowledge.
From a knowledge-decomposition perspective, we observe that low-rank adaptations
 exhibit highly imbalanced singular value spectra: a few dominant components abs
orb most of the adaptation energy, thereby (i) more likely to disrupt previously
 acquired knowledge and (ii) making the update more vulnerable to interference f
rom subsequent tasks.
To enable explicit balance among components, we decouple the *magnitude* of the
task update from its *directional structure* and formulate it as a constrained o
ptimization problem on a restricted Stiefel manifold.
We address this problem using a projected first-order method compatible with sta
ndard deep-learning optimizers used in vision-language models.
Our method mitigates both backward and forward forgetting, consistently outperfo
rming continual learning baselines. Source code is available in supplementary ma
terial.

Torus Graphs for Large Scale Neural Phase Analysis
Jack Goffinet, Casey Hanks, David Carlson
Oscillatory neural signals such as electroencephalography (EEG) and local field
potentials (LFPs) show phase relationships that coordinate communication across
brain regions. Modern recordings capture hundreds of channels across many freque
ncy bins, yet standard phase analyses are restricted to only a few variables. Th
e Torus Graph (TG) model, an exponential-family distribution over phases whose u
nivariate and pairwise potentials generalize von Mises distributions, infers pri
ncipled structure among oscillations but models only static, undirected dependen
cies and is limited to $\sim \! 100$ variables because its score matching infere
nce scales as $\mathcal{O}(d^{6})$. We introduce a stochastic score matching pro
cedure that reduces the per-iteration cost to $\mathcal{O}(d^{2})$, enabling inf
erence on datasets with thousands of variables. This scalable foundation support
s analyses of 1,860 frequency-phase features from multi-electrode LFPs and enabl
es two extensions previously inaccessible to TGs or classical circular statistic
s: (i) a TG Hidden Markov Model capturing state-dependent phase-coupling changes

(e.g., spindle-related states during sleep) and (ii) an autoregressive TG inferring directional interactions via transfer-entropy estimation. Applied to LFP recordings, these models reveal state-dependent phase-interaction patterns between wakefulness and NREM sleep. Together, they enable systematic, large-scale mapping of dynamic and directional phase relationships across brain and cognitive states.

The Flexibility Trap: Rethinking the Value of Arbitrary Order in Diffusion Language Models

Zanlin Ni, Shenzhi Wang, Yang Yue, Tianyu Yu, Weilin Zhao, Yeguo Hua, Tianyi Chen, Jun Song, Cheng Yu, Bo Zheng, Gao Huang

Diffusion Large Language Models (dLLMs) break the rigid left-to-right constraint of traditional LLMs, enabling token generation in arbitrary orders. Intuitively, this flexibility implies a solution space that strictly supersets the fixed autoregressive trajectory, theoretically unlocking superior reasoning potential. However, in this paper, we find that for general reasoning tasks (e.g., mathematics and coding), arbitrary order generation may in fact limit the reasoning potential of dLLMs.

We observe that dLLMs tend to exploit this order flexibility to bypass high-uncertainty tokens that are crucial for exploration, which can lead to a premature collapse of solution coverage.

This observation motivates a rethink of RL approaches for dLLMs, where considerable complexities, such as handling combinatorial trajectories and intractable likelihoods, are often devoted to preserving this flexibility.

We show that effective reasoning can be elicited by simply forgoing arbitrary order and applying standard Group Relative Policy Optimization (GRPO) instead.

Our approach, JustGRPO, is minimalist yet surprisingly effective (e.g., 89.1\% accuracy on GSM8K) while fully retaining the parallel decoding ability of dLLMs.

Code: https://github.com/LeapLabTHU/JustGRPO.

The Relative Instability of Model Comparison with Cross-validation

Alexandre Bayle, Lucas Janson, Lester Mackey

Cross-validation (CV) is known to provide asymptotically exact tests and confidence intervals for model improvement but only when the model comparison is *relatively stable*. Surprisingly, we prove that even simple, individually stable models can generate relatively unstable comparisons, calling into question the validity of CV inference. Specifically, we show that the Lasso and its close cousin, soft-thresholding, generate relatively unstable comparisons and invalid CV inferences, even in the most favorable of learning settings and when both models are individually stable. These findings highlight the importance of verifying relative stability before deploying CV for model comparison.

ScaleSim: Serving Large-Scale Multi-Agent Simulation with Invocation Distance-Based Memory Management

Zaifeng Pan, Yipeng Shen, Zhengding Hu, Zhuang Wang, Aninda Manocha, Zheng Wang, Zhongkai Yu, Yue Guan, Yufei Ding

LLM-based multi-agent simulations are increasingly adopted across application domains, but remain difficult to scale due to GPU memory pressure. Each agent maintains private GPU-resident states, including models, prefix caches, and adapters, which quickly exhaust device memory as the agent count grows. We identify two key properties of these workloads: sparse agent activation and an estimable agent invocation order. Based on an analysis of representative workload classes, we introduce invocation distance, a unified abstraction that estimates the relative order in which agents will issue future LLM requests. Leveraging this abstraction, we present ScaleSim, a memory-efficient LLM serving system for large-scale multi-agent simulations. ScaleSim enables proactive prefetching and priority-based eviction, supports diverse agent-specific memory through a modular interface, and achieves up to 1.74$\times$ speedup over SGLang on simulation benchmarks. ScaleSim's source code is available at https://github.com/PanZaifeng/KVFlow.

LoPhyDA: Low-Rank Tensor and Physics Gradient Guided Diffusion for Atmospheric Data Assimilation
Danyang Peng, Yang Chen, Yunlong Zhou, Xiaotong Yuan
Data Assimilation (DA) aims to integrate observations with model forecasts to estimate the state of dynamical systems. Despite the widespread application of diffusion-based assimilation methods, they remain constrained by the high dimensionality of atmospheric states and the reliance on imperfect state-observation mappings. This leaves regions lacking observations spatially unconstrained, leading to severe error accumulation and physical inconsistency.. In this paper, we propose LoPhyDA, a diffusion assimilation algorithm dual-guided by low-rank tensor and physical gradients. By leveraging the low-rank property of meteorological field, we employ tensor completion to exploit spatial continuity and dynamic correlations, reconstructing a globally informative dense field from sparse observations to serve as a global prior. This approach mitigates the information deficit inherent in sparse settings. The framework further incorporates physical constraints into the iterative denoising process, utilizing Partial Differential Equation (PDE) residual gradients to rectify the generative trajectory in real-time. Experimental results demonstrate that LoPhyDA outperforms state-of-the-art generative assimilation models in global weather prediction. It achieves robust and physically consistent assimilation, significantly reducing error accumulation in regions lacking observations.
****
Compositional Behavioral Semantics for State Abstraction in Reinforcement Learning
Yivan Zhang, Ziyan Luo, Manuel Baltieri
State abstraction plays a key role in scaling reinforcement learning to complex but structured systems. In studying such systems, a wide range of behavioral structures have been studied in reinforcement learning, including value functions, invariants, bisimulation relations, and behavioral metrics. However, a general principle for determining what structures are provably preserved under state abstraction is still lacking. In this paper, we present a unified framework for defining and analyzing behavioral structures in reinforcement learning. Our framework provides a compositional way to specify behavioral semantics based on local, one-step descriptions of system dynamics. Using this framework, we establish results showing how behavioral structures can be safely transferred between abstract and concrete systems. We further show how to construct quantitative metrics from logical behavioral semantics with soundness guarantees. Together, these results provide a principled foundation for reasoning about behaviors under state abstraction in reinforcement learning and offer reusable definition and proof principles for a broad class of behavioral structures in reinforcement learning.
****
Scalable and General Whole-Body Control for Cross-Humanoid Locomotion
Yufei Xue, Yunfeng Lin, Wentao Dong, Yang Tang, Jingbo Wang, Jiangmiao Pang, Ming Zhou, Minghuan Liu, Weinan Zhang
Learning-based whole-body controllers have become a key driver for humanoid robots, yet most existing approaches require robot-specific training.
In this paper, we study the problem of cross-embodiment humanoid control and show that a single policy can robustly generalize across a wide range of humanoid robot designs with one-time training.
We introduce XHugWBC, a novel cross-embodiment training framework that enables generalist humanoid control through:
(1) physics-consistent morphological randomization,
(2) semantically aligned observation and action spaces across diverse humanoid robots, and
(3) effective policy architectures modeling morphological and dynamical properties.
XHugWBC is not tied to any specific robot. Instead, it internalizes a broad distribution of morphological and dynamical characteristics during training. By learning motion priors from diverse randomized embodiments, the policy acquires a strong structural bias that supports zero-shot transfer to previously unseen robot

s.
Experiments on twelve simulated humanoids and seven real-world robots demonstrate the strong generalization and robustness of the resulting universal controller.
****
INDUCTION: Finite-Structure Concept Synthesis in First-Order Logic
Serafim Batzoglou
Induction is the search for a general rule that explains observations. We study logical induction in finite relational worlds: each problem gives small structures over a fixed vocabulary, labels objects belonging to an unknown unary concept, and asks for one first-order formula $\phi(x)$ that accounts for those labels across worlds. Finite domains make formulas mechanically checkable by exact evaluation and SMT. We introduce INDUCTION, a benchmark for finite-structure concept synthesis with three regimes: FULLOBS (full observation), where all facts are observed; CI (contrastive induction), where YES/NO worlds require discriminative hypotheses; and EC (existential completion), where validity is defined by world-local completion of unknown facts. We evaluate frontier language models, include symbolic synthesis baselines, and score both validity and formula size. Prompted models show real but incomplete capability, with sharp difficulty gradients and hard structural families. Held-out evaluation shows that compact formulas generalize far better than bloated ones; parsimony separates concept recovery from finite-world fit.
****
Neural QAOA^2: Differentiable Joint Graph Partitioning and Parameter Initialization for Quantum Combinatorial Optimization
Zubin Zheng, Jiahao Wu, Shengcai Liu
The quantum approximate optimization algorithm (QAOA) holds promise for combinatorial optimization but is constrained by limited qubits. While divide-and-conquer frameworks like QAOA^2 address scalability by partitioning graphs into subgraphs, existing methods suffer from two fundamental limitations: i) misalignment between heuristic partitioning metrics and quantum optimization goals, and ii) topology-blind parameter initialization that leads to optimization cold starts. To bridge these gaps, we propose **Neural QAOA^2**, an end-to-end differentiable framework that jointly generates graph partitions and initial parameters. By integrating a generative evaluative network (GEN), our method utilizes a differentiable quantum evaluator as a high-fidelity performance surrogate to provide direct gradient guidance, enabling the joint generator to learn the intrinsic mapping from graph topology to high-quality partition and parameter configurations. Extensive experiments on 183 QUBO, Ising, and MaxCut instances (21 to 1000 variables) demonstrate that our gradient-driven approach broadly outperforms heuristic baselines, ranking first on 101 instances. It exhibits zero-shot generalization across out-of-distribution graph topologies and scales.
****
ResRL: Boosting LLM Reasoning via Negative Sample Projection Residual Reinforcement Learning
Zihan Lin, Xiaohan Wang, Jie Cao, Jiajun Chai, Li Wang, Xiaodong Lu, Wei Lin, Ran He, Guojun Yin
Reinforcement Learning with Verifiable Rewards (RLVR) enhances reasoning of Large Language Models (LLMs) but usually exhibits limited generation diversity due to the over-incentivization of positive rewards. Although methods like Negative Sample Reinforcement (NSR) mitigate this issue by upweighting penalty from negative samples, they may suppress the semantic distributions shared between positive and negative responses. To boost reasoning ability without losing diversity, this paper proposes negative sample projection Residual Reinforcement Learning (ResRL) that decouples similar semantic distributions among positive and negative responses. We theoretically link Lazy Likelihood Displacement (LLD) to negative-positive head-gradient interference and derive a single-forward proxy that upper-bounds representation alignment to guide conservative advantage reweighting. ResRL then projects negative-token hidden representations onto an SVD-based low-rank positive subspace and uses projection residuals to modulate negative gradie

nts, improving reasoning while preserving diversity and outperforming strong bas
elines on average across twelve benchmarks spanning Mathematics, Code, Agent Tas
ks, and Function Calling. Notably, ResRL surpasses NSR on mathematical reasoning
 by 9.4\% in Avg@16 and 7.0\% in Pass@128. Code is available at https://github.c
om/1229095296/ResRL.git.

Towards the Training of Deeper Predictive Coding Neural Networks
Chang Qi, Matteo Forasassi, Thomas Lukasiewicz, Tommaso Salvatori
Predictive coding networks are neural models that perform inference through an i
terative energy minimization process, whose operations are local in space and ti
me. While effective in shallow architectures, they suffer significant performanc
e degradation beyond five to seven layers. In this work, we show that this degra
dation is caused by exponentially imbalanced errors between layers during weight
 updates, and by predictions from the previous layers not being effective in gui
ding updates in deeper layers. Furthermore, when training models with skip conne
ctions, the energy propagated by the residuals reaches higher layers faster than
 that propagated by the main pathway, affecting test accuracy. We address the fi
rst issue by introducing a novel precision-weighted optimization of latent varia
bles that balances error distributions during the relaxation phase, the second i
ssue by proposing a novel weight update mechanism that reduces error accumulatio
n in deeper layers, and the third one by using auxiliary neurons that slow down
the propagation of the energy in the residual connections. Empirically, our met
hods achieve performance comparable to backpropagation on deep models such as Re
sNets, opening new possibilities for predictive coding in complex tasks.

Equivariant Covariance Tensors: Guaranteed SPD Uncertainty for Tensor-Valued Geo
metric Learning
Ruihan Liu, Yu Ji, Jianbo Yu, Shifu Yan, Qingchao Jiang
Tensor-valued prediction is fundamental to geometric deep learning, yet uncertai
nty quantification (UQ) for such outputs remains an open challenge. While E(3)-e
quivariant neural networks excel at point estimates, they lack rigorous confiden
ce measures. We focus on symmetric rank-2 tensor prediction, where the target ha
s six Kelvin-Mandel coordinates and full uncertainty is represented by a $6\time
s6$ covariance matrix. We introduce a framework for E(3)-equivariant UQ, modelin
g the full predictive distribution where both mean and covariance preserve rotat
ional symmetry. Our approach decomposes the covariance into irreducible represen
tations $\mathrm{Sym}^2(\rho_c) \cong 2\times(l=0) \oplus 2\times(l=2) \oplus 1\
times(l=4)$. By mapping from the flat Lie algebra $\mathfrak{sym}(6)$ to the cur
ved SPD manifold via matrix exponentiation, we strictly ensure positive-definite
 covariances while maintaining exact equivariance. Furthermore, we formulate a L
og-Euclidean Equivariant Scoring Objective (LE-ESO)---a robust surrogate loss ba
sed on the Multivariate Laplace distribution---providing robustness to heavy-tai
led errors and stable optimization. Validation on ModelNet40 inertia tensors and
 Materials Project dielectric tensors demonstrates that our method achieves comp
etitive performance and provides physically consistent, symmetry-preserving unce
rtainty estimates with useful risk and OOD sensitivity.

On the Computational Complexity of Performative Prediction
Ioannis Anagnostides, Rohan Chauhan, Ioannis Panageas, Tuomas Sandholm, Jingming
 Yan
Performative prediction captures the phenomenon where deploying a predictive mod
el shifts the underlying data distribution. While simple retraining dynamics are
 known to converge linearly when the performative effects are weak ($\rho < 1$),
 the complexity in the regime $\rho > 1$ was hitherto open. In this paper, we es
tablish a sharp phase transition: computing an ϵ-performatively stable
point is PPAD-complete---and thus polynomial-time equivalent to Nash equilibria
in general-sum games---even when $\rho = 1 + O(\epsilon)$. This intractability p
ersists even in the ostensibly simple setting with a quadratic loss function and
 linear distribution shifts. One of our key technical contributions is to extend
 this PPAD-hardness result to general convex domains, which is of broader intere

st in the complexity of variational inequalities. Finally, we address the specia
l case of strategic classification, showing that computing a strategic local opt
imum is PLS-hard.

Effective Distillation to Hybrid xLSTM Architectures
Lukas Hauzenberger, Niklas Schmidinger, Thomas Schmied, Anamaria-Roberta Hartl,
David Stap, Pieter-Jan Hoedt, Sebastian Böck, Günter Klambauer, Sepp Hochreiter
There have been numerous attempts to distill quadratic attention-based large lan
guage models (LLMs) into sub-quadratic linearized architectures.
However, despite extensive research, such distilled models often fail to match t
he performance of their teacher LLMs on various downstream tasks.
We set out the goal of *lossless distillation*, which we define in terms of tole
rance-corrected *Win-and-Tie rates* between student and teacher on sets of tasks
.
To this end, we introduce an effective distillation pipeline for xLSTM-based stu
dents.
We propose an additional merging stage, where individually linearized experts ar
e combined into a single model.
We show the effectiveness of this pipeline by distilling base and instruction-tu
ned models from the Llama, Qwen, and Olmo families.
In many settings, our xLSTM-based students recover most of the teacher's perform
ance, and even exceed it on some downstream tasks.
Our contributions are an important step towards more energy-efficient and cost-e
ffective replacements for transformer-based LLMs.

Relational In-Context Learning via Synthetic Pre-training with Structural Prior
Yanbo Wang, Jiaxuan You, Chuan Shi, Muhan Zhang
Relational Databases (RDBs) are the backbone of modern business, yet they lack f
oundation models comparable to those in text or vision. A key obstacle is that h
igh-quality RDBs are private, scarce, and structurally heterogeneous, making int
ernet-scale pre-training infeasible. To overcome this data scarcity, we introduc
e RDB-PFN, the first relational foundation model trained purely via synthetic da
ta. Inspired by Prior-Data Fitted Networks (PFNs), where synthetic data generate
d from Structural Causal Models (SCMs) enables reasoning on single tables, we de
sign a Relational Prior Generator to create an infinite stream of diverse RDBs f
rom scratch. Pre-training on over 2 million synthetic single-table and relationa
l tasks, RDB-PFN learns to adapt to any new database instantly via genuine in-co
ntext learning. Experiments show that RDB-PFN achieves strong few-shot performan
ce on 19 real-world relational prediction tasks, outperforming state-of-the-art
tabular foundation models evaluated on the same DFS-linearized inputs, while usi
ng a lightweight architecture and fast inference. The code is available at https
://github.com/MuLabPKU/RDBPFN.

Stable Asynchrony: Variance-Controlled Off-Policy RL for LLMs
Luke J. Huang, Zhuoyang Zhang, Qinghao Hu, Shang Yang, Song Han
Asynchronous reinforcement learning has become increasingly central to scaling L
LM post-training, delivering major throughput gains by decoupling rollout genera
tion from policy updates. However, widely used policy-gradient objectives such a
s REINFORCE and GRPO suffer under high asynchrony: stale rollouts produce heavy-
tailed importance weights, so a small number of trajectories dominate updates an
d the policy-gradient estimator becomes **markedly higher variance**. Through sy
stematic analysis on math, reasoning, and tool-use benchmarks, we establish that
 this increasing variance is reliably predicted by collapsing effective sample s
ize (ESS), which prior stabilization methods largely fail to address. Motivated
by this diagnosis, we introduce **V**ariance **C**ontrolled **P**olicy **O**ptim
ization (VCPO), a method that (i) dynamically scales the learning rate with ESS
to dampen unreliable updates and (ii) applies a closed-form minimum-variance bas
eline for off-policy settings, without a critic model and adding minimal overhea
d. Empirically, across math and general reasoning benchmarks, this enables robus
tly stable asynchronous training compared to previous stabilization and algorith

mic methods, even in highly off-policy regimes (128 steps off-policy). In a long-horizon, tool-use task, VCPO matches synchronous performance while delivering a 2.5× speedup in training time. Code is available at: https://github.com/mit-han-lab/vcpo

PLoRA: Efficient Concurrent LoRA Training for Large Language Models

Minghao Yan, Zhuang Wang, Zhen Jia, Shivaram Venkataraman, Yida Wang

Low-Rank Adaptation (LoRA) has gained popularity as a fine-tuning approach for Large Language Models (LLMs) due to its low resource requirements and good performance. While numerous studies have investigated improving LoRA serving efficiency by serving multiple LoRAs concurrently, existing methods assume that a wide range of LoRA adapters are available for serving. In our work, we conduct extensive empirical studies to show that current LoRA training paradigms do not efficiently utilize hardware resources and incur high overhead to obtain a performant LoRA adapter. Leveraging these insights, we propose PLoRA, which automatically orchestrates concurrent LoRA fine-tuning jobs under given hardware and model constraints and develops performant kernels to improve training efficiency. Across a range of LLMs and LoRA configurations, PLoRA improves training throughput by up to 12.8x and reduces the overall fine-tuning makespan by up to 7.52x compared to existing approaches.

Supervised Classification Heads as Semantic Prototypes: Unlocking Vision-Language Alignment via Weight Recycling

David Méndez, Roberto Confalonieri, Natalia Díaz-Rodríguez

Vision-Language Models (VLMs) excel at tasks like zero-shot classification and cross-modal retrieval by mapping images and text to a shared space, but this requires expensive end-to-end training with massive paired datasets. Current post-hoc alignment methods reduce computational costs by connecting pretrained encoders through lightweight mappings, yet still demand substantial paired data.

In this work, we investigate the potential of repurposing the classification heads of pretrained vision models as semantic prototypes. The recycling of these weights, typically discarded after pretraining, unlocks two distinct capabilities: it enables zero-shot alignment by using weights as semantic anchors, and serves as a robust data augmentation strategy by mixing these prototypes with real image-text pairs. We demonstrate that integrating our approach with several state-of-the-art post-hoc alignment techniques consistently boosts accuracy in cross-modal retrieval, zero- and few-shot classification tasks.

****

Adversarial Attack and Defense for Denoising Diffusion Sampling

Zhao-Rong Lai, Xiwen Yuan, Jian Weng

Denoising diffusion sampling (DDS) is an emerging approach for generating new samples that have the same distribution as some training samples. However, it is vulnerable to adversarial attacks by even a Gaussian perturbation. In this work, we propose a complete set of adversarial attack and defense methodology for DDS. In the attack side, we propose to inject a perturbation to the sampling stage, which significantly worsen the performance of sample generation. In the defense side, we propose a local variation based regularization model for the potential function minimization, which effectively tolerates the adversarial perturbations. Moreover, we develop a conjugate gradient algorithm to solve the defense model, which integrates with a recently-developed zeroth order rejection sampling method that saves computational cost. Experimental results show that the proposed attack significantly worsen the existing state-of-the-art methods, but can be defended by the proposed local variation regularization.

****

Proactive Defense Benchmark against Deepfake Generation

Joonhyuk Baek, Wonjune Seo, Jae-yun Kim, Saerom Park, Hoki Kim

Despite the proliferation of proactive defenses against deepfakes, the lack of a unified evaluation protocol precludes fair comparison and masks critical vulnerabilities. To bridge this gap, we present the first comprehensive benchmark that systematically assesses disruption, robustness, and transferability encompassin

g pixel, perceptual, and identity metrics. Our extensive analysis reveals that f idelity and identity metrics capture orthogonal performance axes, often leading to conflicting interpretations when relied upon individually. Furthermore, we id entify a fundamental trade-off where peak white-box performance signals overfitt ing, and we introduce a calibrated evaluation to correct generator-induced ident ity bias. By exposing these blind spots, we establish a rigorous standard to gui de the development of genuinely generalizable protections. Project page is avail able at: https://proactivedefensebenchmark.github.io/

SpatialReward: Bridging the Perception Gap in Online RL for Image Editing via Ex plicit Spatial Reasoning

Yancheng Long, Yankai Yang, Hongyang Wei, Wei Chen, Tianke Zhang, Haonan fan, Ch angyi Liu, Kaiyu Jiang, Jiankang Chen, Kaiyu Tang, Bin Wen, Fan Yang, Tingting G ao, Han Li, Shuo Yang

Online Reinforcement Learning (RL) offers a promising avenue for complex image e diting but is currently constrained by the scarcity of reliable and fine-grained reward signals. Existing evaluators frequently struggle with a critical percept ion gap we term "Attention Collapse," where models neglect cross-image compariso ns and fail to capture fine-grained details, resulting in inaccurate perception and miscalibrated scores. To address these limitations, we propose **SpatialRewa rd**, a reward model that enforces precise verification via explicit spatial rea soning. By anchoring reasoning to predicted edit regions, SpatialReward grounds semantic judgments in pixel-level evidence, significantly enhancing evaluative a ccuracy. Trained on a curated 260k spatial-aware dataset, our model achieves sta te-of-the-art performance on MMRB2 and EditReward-Bench, and outperforms proprie tary evaluators on our proposed **MultiEditReward-Bench**. Furthermore, SpatialR eward serves as a robust signal in online RL, boosting OmniGen2 by +0.90 on GEdi t-Bench—surpassing the leading discriminative model and doubling the gain of GPT -4.1 (+0.45). These results demonstrate that spatial reasoning is essential for unlocking effective alignment in image editing.

Walrus: A Cross-domain Foundation Model for Continuum Dynamics

Michael McCabe, Payel Mukhopadhyay, Tanya Marwah, Bruno Régaldo-Saint Blancard, François Rozet, Cristiana Diaconu, Lucas Thibaut Meyer, Kaze W. K. Wong, Mohamma d-Hadi Sotoudeh, Alberto Bietti, Irina Espejo Morales, Rio Alexa Fear, Siavash G olkar, Tom Hehir, Keiya Hirashima, Geraud Krawezik, Francois Lanusse, Rudy Morel , Ruben Ohana, Liam Holden Parker, Mariel Pettee, Jeff Shen, Kyunghyun Cho, Mile s Cranmer, Shirley Ho

Foundation models have transformed machine learning for language and vision, but achieving comparable impact in physical simulation remains a challenge. Data he terogeneity and unstable long-term dynamics inhibit learning from sufficiently d iverse dynamics, while varying resolutions and dimensionalities challenge effici ent training on modern hardware. Through empirical and theoretical analysis, we incorporate new approaches to mitigate these obstacles, including a harmonic-ana lysis–based stabilization method, load-balanced distributed 2D-3D training strat egies, and compute-adaptive tokenization. Using these tools, we develop Walrus, a transformer-based foundation model developed primarily for fluid-like continuu m dynamics. Walrus is pretrained on nineteen diverse scenarios spanning astrophy sics, geoscience, rheology, plasma physics, acoustics, and classical fluids. Exp eriments show that Walrus outperforms prior foundation models on both short- and long-term prediction horizons on downstream tasks and across the breadth of pre training data, while ablation studies confirm the value of our contributions to forecast stability, training throughput, and transfer performance over conventio nal approaches.

Quadratically Regularized Optimal Transport: Localization Bounds and Affine Case Analysis

Long Nguyen Chi, Nam Nguyen, Binh Nguyen

Quadratically regularization has emerged as a potential alternative to the popul ar entropic regularization in computational optimal transport, offering the theo

retical advantage of producing sparse couplings through its hinge density structure. Despite recent progress in one-dimensional setting and general upper bounds, fundamental questions about the localization rate of QOT optimizers around the Monge coupling have remained open. In this work, we establish a general lower bound showing that the support of the QOT optimizer cannot concentrate around the Monge graph faster than order $\varepsilon^{\frac{1}{d+2}}$ in the directed Hausdorff distance, matching the conjectured optimal exponent under standard regularity assumptions in Wiesel & Xu (2025). We also show that the QOT value gap controls the mean-squared deviation $\mathbb E_{\pi_\varepsilon}||y-T(x)||^2$ by the scale of $\varepsilon^{\frac{2}{d+2}}$. As a corollary, in the affine Brenier regime, which includes Gaussian-to-Gaussian transport, we derive a sharp pointwise tube bound of order $\varepsilon^{\frac{1}{d+2}}$ by reducing the problem to self-transport and applying recent self-transport sparsity results. Finally, we validate our theoretical bound with synthetic experiment in high dimensions setting.

****

ML-Agent: Reinforcing LLM Agents for Autonomous Machine Learning Engineering

Zexi Liu, Jingyi Chai, Xinyu Zhu, Shuo Tang, Rui Ye, Weiyu Ma, Bo Zhang, LEI BAI, Siheng Chen

The emergence of large language model (LLM)-based agents has significantly advanced the development of autonomous machine learning (ML) engineering. However, the dominant prompt-based paradigm exhibits limitations: smaller models lack the capacity to learn from execution trajectories for generalization, while large proprietary models incur high computational overhead, restricting accessibility and scalability. Focusing on this, for the first time, we explore the paradigm of learning-based agentic ML, where an LLM agent learns through interactive experimentation on ML tasks using online reinforcement learning (RL). To realize this, we propose a novel agentic ML training framework with three key components: (1) exploration-enriched fine-tuning, which enables LLM agents to generate diverse actions for enhanced RL exploration; (2) step-wise RL, which enables training on a single action step, accelerating experience collection and improving training efficiency; (3) an agentic ML-specific reward module, which unifies varied ML feedback signals into consistent rewards for RL optimization. Leveraging this framework, we train ML-Agent, driven by a 7B-sized Qwen-2.5 LLM for autonomous ML. Despite training on only 9 ML tasks, our 7B-sized ML-Agent achieves comparable performance to agents using much larger proprietary LLMs (e.g., GPT-5) but at significantly lower computational cost, demonstrating strong performance and cross-task generalization.

****

SAGE-NAS: Synergizing LLM-Based Semantic Agent with Graph-Based Evaluator for Neural Architecture Search

Kaiqi Lin, Jianping Luo

While LLM-driven Neural Architecture Search (NAS) leverages exceptional code generation and reasoning, it suffers from a critical "Semantic-Physical Misalignment": LLMs prioritize high-level semantic plausibility but are agnostic to intrinsic physical dynamics such as gradient flow, whereas Zero-Cost Proxies (ZCPs) capture these local sensitivities but lack global semantic planning. To bridge this gap, we propose SAGE-NAS, a closed-loop evolutionary framework that synergizes an LLM-Based Semantic Agent with a Graph-Based Evaluator. Specifically, SAGE-NAS coordinates an LLM-driven Semantic Agent to construct candidate architectures by dynamically scheduling complementary sub-policies that balance exploitation with exploration. Furthermore, the framework integrates a Dual-Modality Graph Evaluator that serves as a rapid performance predictor by fusing ZCP statistics with topological features, and a State-Aware Behavioral Atlas that guides sparsity-driven exploration to escape local optima. Experiments demonstrate that SAGE-NAS achieves state-of-the-art performance across multiple mainstream search spaces and downstream tasks, exhibiting a superior balance between search efficiency, model accuracy, and cross-task generalization capability.

Inference-time optimization for experiment-grounded protein ensemble generation

Sai Advaith Maddipatla, Anar Rzayev, Marco Pegoraro, Martin Pacesa, Paul Schanda, Ailie Marx, Sanketh Vedula, Alexander Bronstein
Protein function relies on dynamic conformational ensembles, yet current generative models like AlphaFold3 (AF3) often fail to produce ensembles that match experimental data. Recent experiment-guided generators attempt to address this by steering the reverse diffusion process. However, these methods are limited by fixed sampling horizons and sensitivity to initialization, often yielding thermodynamically implausible results.

We introduce a general inference-time optimization framework to solve these challenges. First, we optimize over latent representations to maximize ensemble log-likelihood, rather than perturbing structures post hoc. This approach eliminates dependence on diffusion length, removes initialization bias, and easily incorporates external constraints. Second, we present novel sampling schemes for drawing Boltzmann-weighted ensembles. By combining structural priors from AF3 with force-field–based priors, we sample from their product distribution while balancing experimental likelihoods.

Our results show that this framework consistently outperforms state-of-the-art guidance, improving diversity, physical energy, and agreement with data in X-ray crystallography and NMR, sometimes fitting the experimental data better than deposited PDB structures. Finally, inference-time optimization experiments maximizing iPTM scores reveal that perturbing MSA embeddings can artificially inflate model confidence. This exposes a vulnerability in current design metrics, whose mitigation could offer a pathway to reduce false discovery rates in binder engineering.
****
Compass-RoPE: Isotropic Rotary Position Embeddings for Vision Transformers
Chengxi Min, Wei Wang, Yao Zhao
Recent works introduce Rotary Position Embeddings (RoPE) into vision transformers (ViTs) to enhance their extrapolation capability, i.e., maintaining performance when inference is conducted on higher resolution images. RoPE encodes positions via rotating phases whose change is controlled by frequency components.
Strandard 2D RoPE does not generalize well to input resolution changes as it only applies axial frequencies separately along each individual axis. To solve this issue, Mix-RoPE combines xy■axis frequencies, such that it can model position relations in diagonal direction.
However, in practice, we observe that the learned 2D frequencies become anisotropic in their direction distributions due to the axial spectral bias in image features, limiting the extrapolation ability of ViTs.

Motivated by this observation, we propose Compass■RoPE. We replace the xy cartesian coordinates with a polar parameterization that explicitly decouples frequency scale and angle. By initializing the angle vectors uniformly over $[0,2\pi)$, it ensures the isotropic direction coverage. Besides, we further introduce discrete Fourier transform (DFT) mixing for the angle vectors, allowing each transformed individual angle vector element to nest multipule angles and thus to enrich angular expressiveness.
Extensive experiments on multi-resolution classification and dense prediction tasks show that our Compass-RoPE achieves more stable extrapolation performance under large-scale resolution changes.
****
Stabilizing Native Low-Rank LLM Pretraining
Paul Janson, Edouard Oyallon, Eugene Belilovsky
Foundation models have achieved remarkable success, yet their growing parameter counts pose significant computational and memory challenges. Low-rank factorization offers a promising route to reduce training and inference costs, but the community lacks a stable recipe for training models from scratch using exclusively low-rank weights while matching performance of the dense model.

We demonstrate that Large Language Models (LLMs) can be trained from scratch using exclusively low-rank factorized weights for all non-embedding matrices without auxiliary "full-rank" guidance required by prior methods. While native low-rank training often suffers from instability and loss spikes, we identify uncontrolled growth in the spectral norm (largest singular value) of the weight matrix update as the dominant factor. To address this, we introduce **Spectron: Spectr**al renormalization with orthogonalizati**on**, which dynamically bounds the resultant weight updates based on the current spectral norms of the factors. Our method enables stable, end-to-end factorized training with negligible overhead. Finally, we establish compute-optimal scaling laws for natively low-rank transformers, demonstrating predictable power-law behavior and improved inference efficiency relative to dense models.

Our code is available at https://github.com/Pauljanson002/spectron

NanoSpec: Accelerating Speculative Decoding using Minimalist In-Context Vocabularies
Zhiyang Chen, Daliang Xu, Yinyuan Zhang, Chenghua Wang, Mengwei Xu, Yun Ma
The massive vocabulary sizes of large language models, often exceeding 100k tokens, impose a computational bottleneck on the final linear projection layer during speculative decoding. Existing vocabulary pruning solutions rely on static or coarsely-grained sub-vocabularies that necessitate large active sizes ($\sim$30k) to maintain draft quality. We propose NanoSpec, a novel training-free approach that breaks this trade-off by dynamically constructing a minimalist, context-aware active vocabulary for each generation step. Leveraging the inherent temporal locality of language generation, NanoSpec achieves high coverage while slashing the average vocabulary size by over $40\times$ (to $<$3k tokens) without requiring any auxiliary trained parameters. To realize the theoretical benefits of such high sparsity on modern hardware, we introduce a system-algorithm co-design that overcomes the inefficiencies of sparse memory access through asynchronous gathering and GPU-resident state management. As a complementary plug-and-play module, NanoSpec cuts draft time by an average of 51.6\%, delivering a 1.17-$1.29\times$ end-to-end speedup over the state-of-the-art speculative decoding methods EAGLE-2 and EAGLE-3 across 7 tasks and outperforming complex training-based pruning baselines.
****
Semantic Editing with Coupled Stochastic Differential Equations
Jianxin Zhang, Clayton Scott
Editing the content of an image with a pretrained text-to-image model remains challenging. Existing methods often distort fine details or introduce unintended artifacts. We propose using coupled stochastic differential equations (coupled SDEs) to guide the sampling process of any pre-trained generative model that can be sampled by solving an SDE, including diffusion and rectified flow models. By driving both the source image and the edited image with the same correlated noise, our approach steers new samples toward the desired semantics while preserving visual similarity to the source. The method works out-of-the-box—without retraining or auxiliary networks—and achieves high prompt fidelity along with near-pixel-level consistency. These results position coupled SDEs as a simple yet powerful tool for controlled generative AI.

LEGO: An LLM-Enabled Hierarchical Optimizer for Tensor Computation Graphs with Structure-Aware Search and Compositional Synthesis
Ruiyuan Xu, Shuoming Zhang, Guangli Li, Qiuchu Yu, Rui Zhang, Yangyu Zhang, Hao Qian, Chunwei Xia, Jiacheng Zhao, Chenxi Wang, Xiaobing Feng, Jingling Xue, Huimin Cui
Automating end-to-end GPU kernel generation with Large Language Models (LLMs) faces a critical tension between global performance and exploration efficiency. We present LEGO, a hierarchical framework that resolves this trade-off via a parallel multi-agent search over a recursive AND-OR FusionTree. LEGO synergizes two c

omplementary flows: Top-Down Construction decomposes complex graphs into valid, context-isolated sub-problems to guarantee correctness and enable parallel exploration, while Bottom-Up Mutation speculatively fuses verified sub-plans to recover global locality for peak performance. This bi-directional mechanism effectively prunes the search space to avoid repetitive unguided sampling, while naturally parallelizing exploration and enabling the discovery of sophisticated fusion strategies. Evaluations demonstrate that LEGO achieves 2.18×–13.48× speedups over PyTorch Eager and, compared to monolithic baselines, reduces end-to-end exploration time by up to 2.47× and token consumption by up to 7×, across diverse end-to-end models.

Video2GUI: Synthesizing Large-Scale Interaction Trajectories for Generalized GUI Agent Pretraining

Weimin Xiong, Shuhao Gu, Bowen Ye, Zihao Yue, Lei Li, Feifan Song, Sujian Li, Hao Tian

Recent advances in multimodal large language models have driven growing interest in graphical user interface (GUI) agents, yet their generalization remains constrained by the scarcity of large-scale training data spanning diverse real-world applications. Existing datasets rely heavily on costly manual annotations and are typically confined to narrow domains.

To address this challenge, we propose Video2GUI, a fully automated framework that extracts grounded GUI interaction trajectories directly from unlabeled Internet videos. Video2GUI employs a coarse-to-fine filtering strategy to identify high-quality GUI tutorial videos and convert them into structured agent trajectories.

Applying this pipeline to 500 million video metadata entries, we construct WildGUI, a large-scale dataset containing 12 million interaction trajectories spanning over 1,500 applications and websites. Pre-training Qwen2.5-VL and Mimo-VL on WildGUI yields consistent improvements of 5–20\% across multiple GUI grounding and action benchmarks, matching or surpassing state-of-the-art performance.

We will release both the WildGUI dataset and the Video2GUI pipeline to support future research of GUI agents.

“very likely” Means “uncertain”? How LLMs Diverge from Humans in Linguistic Uncertainty Quantification

Jinhao Duan, Zicheng Liu, Zijie Liu, Kaidi Xu, Tianlong Chen

Humans express uncertainty verbally via markers (e.g., "possible", "likely"), yet most LLM uncertainty quantification (UQ) relies on costing likelihood- or consistency-based signals. From a cognitive perspective, accurate verbal uncertainty reflects metacognitive monitoring, representing knowledge boundaries ("knowing that you don't know") to support regulation and information seeking. In this paper, we investigate: How LLMs diverge from humans in verbal uncertainty quantification? Can verbal markers reliably quantify LLM uncertainty? We curate a corpus of human uncertainty markers from psychology and decision-science literature and benchmark LLMs against it. We observe that LLMs encode verbal uncertainty with numerical levels that differ substantially from those of humans. We then introduce VOCAL, a novel optimization-based algorithm that learns an optimal uncertainty profile over uncertainty markers directly from LLM outputs. By fitting a marker–uncertainty mapping to best explain empirical correctness, VOCALdiscovers how much probability mass each verbal marker should convey, rather than estimating uncertainty via repeated sampling. VOCAL enables a direct, marker-level comparison of confidence semantics between humans and LLMs, disentangling mismatch and revealing systematic confidence disparities in verbal expressions.

Self-evolving LLM agents with in-distribution Optimization

Yudi Zhang, Meng Fang, Zhenfang Chen, Mykola Pechenizkiy

Large Language Models (LLMs) have recently emerged as powerful controllers for interactive agents in complex environments, yet training them to perform reliable long-horizon decision making remains a fundamental challenge. A key difficulty lies in credit assignment: agents often receive delayed rewards only at the end

of episodes. In this paper, we propose Q-Evolve, a self-evolving framework for LLM agents that unifies automatic process-reward labeling and policy learning within a principled in-distribution reinforcement learning paradigm. In each evolving iteration, our method learns an in-distribution critic from a hybrid off-policy dataset that combines expert demonstrations with agent-generated trajectories, stabilizing Bellman backups in sparse-reward settings via a weighted Implicit Q-Learning objective. The learned value function is then used to derive step-wise process rewards through advantage estimation, enabling dense and reliable supervision without environment backtracking or human annotation. Leveraging these signals, we perform behavior-proximal policy optimization that evolves the agent over the data used for process reward labeling, allowing iterative self-improvement without exacerbating distribution shift.
We evaluate our method on AlfWorld, WebShop, and ScienceWorld, showing Q-Evolve outperforms strong baselines in sample efficiency, robustness, and overall task performance. Our results demonstrate that stable agent self-evolution is achievable through the co-evolution of process-level supervision and policy, both grounded within a shared in-distribution learning loop.

MEC: Machine-Learning-Assisted Generalized Entropy Calibration for Semi-Supervised Mean Estimation
Se Yoon Lee, Jae Kwang Kim
Obtaining high-quality labels is costly, whereas unlabeled covariates are often abundant, motivating semi-supervised inference methods with reliable uncertainty quantification. Prediction-powered inference (PPI) leverages a machine-learning predictor trained on a small labeled sample to improve efficiency, but it can lose efficiency under model misspecification and suffer from coverage distortions due to label reuse. We introduce Machine■Learning■Assisted Generalized Entropy Calibration (MEC), a cross■fitted, calibration■weighted variant of PPI. MEC improves efficiency by reweighting labeled samples to better align with the target population, using a principled calibration framework based on Bregman projections. This yields robustness to affine transformations of the predictor and relaxes requirements for validity by replacing conditions on raw prediction error with weaker projection■error conditions. As a result, MEC attains the semiparametric efficiency bound under weaker assumptions than existing PPI variants. Across simulations and a real■data application, MEC achieves near■nominal coverage and tighter confidence intervals than CF■PPI and vanilla PPI.

Mode Seeking meets Mean Seeking for Fast Long Video Generation
Shengqu Cai, Weili Nie, Chao Liu, Julius Berner, Lvmin Zhang, Nanye Ma, Hansheng Chen, Maneesh Agrawala, Leonidas Guibas, Gordon Wetzstein, Arash Vahdat
Scaling video generation from seconds to minutes faces a critical bottleneck: while short-video data is abundant and high-fidelity, coherent long-form data is scarce and limited to narrow domains.
While multi-resolution image training works because higher resolution is largely an interpolation of the same underlying patch distribution, training across video lengths is fundamentally different: a longer video is an extrapolation that must invent new events and causal structure beyond the short-clip horizon.
To address this, we propose a training paradigm where Mode Seeking meets Mean Seeking, decoupling local fidelity from long-term coherence from a unified representation via a Decoupled Diffusion Transformer.
Our approach utilizes a global Flow Matching head trained via supervised learning on long videos to capture narrative structure, while simultaneously employing a local Distribution Matching head that aligns sliding windows to a frozen short-video teacher via a mode-seeking reverse-KL divergence.
This strategy enables the synthesis of minute-scale videos that learns long-range coherence and motions from limited long videos via supervised flow matching, while inheriting local realism by aligning every sliding-window segment of the student to a frozen short-video teacher.

UniSVQ: 2-bit Unified Scalar-Vector Quantization

Haoyu Wang, Haiyan Zhao, Xingyu Yu, Zhangyang Yao, Xu Han, Zhiyuan Liu, Maosong Sun

Post-training quantization at the 2-bit level enables low-cost deployment and inference acceleration for large language models (LLMs). Scalar quantization (SQ) and vector quantization (VQ) are two primary quantization methods, however, the former suffers from significant performance degradation, and the latter incurs computational and storage overhead.

We propose UniSVQ, a unified 2-bit quantization framework that bridges scalar and vector quantization by parameterizing codewords as an affine transform of integer lattices.

This structure preserves compatibility with optimized integer kernels while retaining much of VQ's flexibility.

We further introduce a data-driven block-wise fine-tuning strategy to directly minimize quantization reconstruction error.

Extensive experiments across multiple LLM families and zero-shot benchmarks demonstrate that UniSVQ consistently outperforms state-of-the-art SQ methods and achieves performance comparable to advanced VQ methods, while providing higher inference throughput.

Large Language Model Agents Are Not Always Faithful Self-Evolvers

Weixiang Zhao, Yingshuo Wang, Yichen Zhang, Yang Deng, Yanyan Zhao, Wanxiang Che, Bing Qin, Ting Liu

Self-evolving large language model (LLM) agents continually improve by accumulating and reusing past experience, yet it remains unclear whether they faithfully rely on that experience to guide their behavior. We present the first systematic investigation of \emph{experience faithfulness}—the causal dependence of an agent's decisions on the experience it is given—in self-evolving LLM agents. Using controlled causal interventions on both raw and condensed forms of experience, we comprehensively evaluate four representative frameworks across 13 LLM backbones and 9 environments. Our analysis uncovers a striking asymmetry: while agents consistently depend on raw experience, they often disregard or misinterpret condensed experience, even when it is the only experience provided. This gap persists across single- and multi-agent configurations and across backbone scales. We trace its underlying causes to three factors: the semantic limitations of condensed content, internal processing biases that suppress experience, and task regimes where pretrained priors already suffice. These findings challenge prevailing assumptions about self-evolving methods and underscore the need for more faithful and reliable approaches to experience integration.

TABX: A High-Throughput Sandbox Battle Simulator for Multi-Agent Reinforcement Learning

Hayeong Lee, JunHyeok Oh, Byung-Jun Lee

The design of environments plays a critical role in shaping the development and evaluation of cooperative multi-agent reinforcement learning (MARL) algorithms. While existing benchmarks highlight critical challenges, they often lack the modularity required to design custom evaluation scenarios. We introduce the Totally Accelerated Battle Simulator in JAX (TABX), a high-throughput sandbox designed for reconfigurable multi-agent tasks. TABX provides granular control over environmental parameters, permitting a systematic investigation into emergent agent behaviors and algorithmic trade-offs across a diverse spectrum of task complexities. Leveraging JAX for hardware-accelerated execution on GPUs, TABX enables massive parallelization and significantly reduces computational overhead. By providing a fast, extensible, and easily customized framework, TABX facilitates the study of MARL agents in complex structured domains and serves as a scalable foundation for future research. Our code is available at: https://anonymous.4open.science/r/TABX-00CA.

Beyond Majority Voting: Self-Reflective Test-Time Reinforcement Learning for LLM Reasoning

Sitong Wu, Haoru Tan, Xichen Zhang, Bin Xia, Shaofeng Zhang, Xiaojuan Qi, Bei Yu

, Jiaya Jia
The core challenge of Test-Time Reinforcement Learning (TTRL) lies in estimating rewards without access to ground-truth supervision.
Existing TTRL methods predominantly rely on majority voting to generate pseudo-labels, under the assumption that the most frequent answer among sampled trajectories is correct.
However, we observe that this assumption frequently breaks down in complex reasoning tasks, where correct solutions often constitute a logical minority.
As a result, rare yet correct trajectories are systematically undervalued by majority-voting-based approaches.
To address this limitation, we propose Self-Reflective Test-Time Reinforcement Learning (SR-TTRL), a novel framework that leverages self-reflective verification to produce high-fidelity pseudo-labels.
Specifically, given multiple sampled trajectories for a problem, SR-TTRL first groups trajectories according to their final answers and selects one representative from each group to form a candidate pool.
Each candidate trajectory is then summarized to preserve its core reasoning steps while reducing verbosity.
Finally, the model performs self-reflection over the candidate pool, critically evaluating and selecting the most plausible trajectory as the pseudo-label.
Empirically, SR-TTRL achieves substantially higher pseudo-label fidelity and sample efficiency than prior majority-voting-based TTRL methods.
Extensive experiments across diverse benchmarks and model families demonstrate that SR-TTRL consistently outperforms majority-voting baselines and significantly improves generalization to novel problems.
For example, SR-TTRL improves the Pass@1 accuracy of Qwen3-8B on AIME24 from 29.1 to 55.8 (a gain of +26.7), exceeding standard TTRL by an additional +9.1.
The code will be released at: https://github.com/JIA-Lab-research/SR-TTRL.

Safety Generalization Under Distribution Shift in Safe Reinforcement Learning: A Diabetes Testbed
Minjae Kwon, Josephine Lamp, Lu Feng
Safe Reinforcement Learning (RL) algorithms are typically evaluated under fixed training conditions. We investigate whether training-time safety guarantees transfer to deployment under distribution shift, using diabetes management as a safety-critical testbed. We benchmark safe RL algorithms on a unified clinical simulator
and reveal a safety generalization gap: policies satisfying
constraints during training frequently violate safety requirements on unseen patients. We demonstrate that test-time shielding, which filters unsafe actions using learned dynamics models, effectively restores safety across algorithms and patient populations. Across eight safe RL algorithms, three diabetes types, and three age groups, shielding achieves Time-in-Range gains of 13--14\% for strong baselines such as PPO-Lag and CPO while reducing clinical risk index and glucose variability. Our simulator and benchmark provide a platform for studying safety under distribution shift in safety-critical control domains. Code is available at https://github.com/safe-autonomy-lab/GlucoSim and https://github.com/safe-autonomy-lab/GlucoAlg.

How does information access affect LLM monitors' ability to detect sabotage?
Rauno Arike, Raja Mehta Moreno, Rohan Subramani, Shubhorup Biswas, Francis Rhys Ward
Frontier language model agents can exhibit misaligned behaviors, including deception, exploiting reward hacks, and pursuing hidden objectives. To control such agents, we can use LLMs themselves to *monitor* for misbehavior. In this paper, we study how *information access* affects LLM monitor performance and find that contemporary systems often perform better with less information, a phenomenon we call the *less-is-more effect* for automated oversight. We demonstrate this phenomenon, and analyze the conditions under which it occurs, in three evaluation environments where agents must conduct sabotage while evading monitors. Leveraging

this effect, we introduce *extract-and-evaluate* (EaE) monitoring—a new hierarchical approach where one monitor isolates relevant excerpts from the monitored agent's trajectory and another monitor scores these excerpts. In BigCodeBench-Sabotage with a GPT-4.1-mini monitor, EaE improves sabotage detection rates by 16.8 percentage points over the next-best approach. In other settings, EaE either outperforms or is competitive with baselines. Additionally, we find that agents unaware of being monitored can be caught much more easily, that monitors scoring longer reasoning traces gain more from information filtering, and that monitor performance scales linearly with cost.

Navigating the Flatlands: Dual Adaptive Sharpness-Aware Minimization for Domain Generalization
Junwen He, Yang He, Lebing Zheng, Zirui Yin, Hong-Yu Zhang, Yulong Wang
Finding flat minima in the loss landscape is a key strategy for Domain Generalization (DG). However, its effectiveness is often limited by two crucial challenges. 1) Domain Shift: Existing methods like Sharpness-Aware Minimization (SAM) apply a uniform optimization strategy across all domains, overlooking the differences of the learning difficulties among multiple domains and thus performing poorly on challenging domains. 2) Anisotropic Sharpness: By perturbing parameters along a single gradient direction, SAM and its variants ignore multi-directional flatness, making the model converge to minima that remain sharp in other directions. The combined challenges make it more difficult for the model to find truly robust solutions in multi-domain scenarios. To overcome these limitations, we propose the Dual Adaptive Sharpness-Aware Minimization (DA-SAM), which comprises two key modules: Dynamic Adaptive Scaling (DAS) module and Adaptive Multi-Directional Flattening (AMDF) module. First, to tackle the domain shift problem, the DAS module computes the real-time loss on each domain to adaptively generate domain-specific scaling factors that guide the generation of perturbation directions. Second, the AMDF module calculates local flatness by generating multiple directions to simulate perturbations in the parameter space. Based on the learned local flatness metric, it dynamically adjusts the perturbation step size to guide the model parameters to be away from anisotropic sharp regions. Crucially, DAS provides domain-level guidance that makes AMDF’s multi-directional geometric exploration more targeted and effective. Extensive experiments on five DG benchmarks demonstrate the effectiveness of our DA-SAM algorithm.

ThunderAgent: A Fast, Simple, and Program-Aware Agentic Inference System
Hao Kang, Ziyang li, Weili Xu, Xinyu Yang, Yinfang Chen, Junxiong Wang, Beidi Chen, Tushar Krishna, Chenfeng Xu, Simran Arora
Large language models (LLMs) are now used to power complex multi-turn agentic workflows. Existing systems run agentic inference by loosely assembling isolated components: an LLM inference engine (e.g., vLLM) and a tool orchestrator (e.g., Kubernetes). Although agentic workflows involve multiple LLM and tool requests, these systems schedule and allocate resources separately on a per-request basis, without end-to-end knowledge of the workflow. This leads to sub-optimal management of KV cache and tool execution environments. To address the challenges, we propose **ThunderAgent**, a fast, simple, and program-aware agentic inference system. We first abstract agentic workflows as ***LLM Programs***, enabling a unified view of heterogeneous resources, including KV caches, system states, and external tool assets such as disk memory and network ports. Built upon this abstraction, ThunderAgent introduces a program-aware scheduler and a tool resource manager designed to maximize KV cache hit rates, mitigate memory imbalances, and enable asynchronous environment preparation. Evaluations across coding, routing, and scientific discovery agents demonstrate that ThunderAgent achieves **1.5-3.6×** throughput improvements in serving, **1.8-3.9×** in RL rollout, and up to **4.2×** disk memory savings compared to state-of-the-art inference systems. To facilitate reproducibility and support future development, we open-source the system implementations of ThunderAgent at: https://github.com/ThunderAgent-org/ThunderAgent

Certifying Graph Neural Networks Against Label and Structure Poisoning
Lukas Gosch, Xichuan Chen, Yan Scholten, Stephan Günnemann
Robust machine learning for graph-structured data has made significant progress against test-time attacks, yet certified robustness to poisoning – where adversaries manipulate the training data – remains largely underexplored. For image data, state-of-the-art poisoning certificates rely on partitioning-and-aggregation schemes. However, we show that these methods fail when applied in the graph domain due to the inherent label and structure sparsity found in common graph datasets, making effective graph-partitioning difficult. To address this challenge, we propose a novel semi-supervised learning framework called deep Self-Training Graph Partition Aggregation (ST-GPA), which enriches each graph partition with informative pseudo-labels and synthetic edges, enabling effective certification against node-label and graph-structure poisoning under sparse conditions. Our method is architecture-agnostic, scales to large numbers of partitions, and consistently and significantly improves robustness guarantees against both label and structure poisoning across multiple benchmarks, while maintaining strong clean accuracy. Overall, our results establish a promising direction for certifiably robust learning on graph-structured data against poisoning under sparse conditions.
****
Implicit Safety Alignment from Crowd Preferences
Qian Lin, Daniel S. Brown
Reinforcement Learning from Human Feedback (RLHF) can reveal implicit objectives such as safety considerations that go beyond task completion. In this work, we focus on the common safety criteria embedded in crowd preference datasets, where different users may express distinct preferences or objectives, yet follow similar safety principles. Our aim is to discover shared safety criteria from crowd preferences and then transfer them to downstream RL tasks to regularize agent behavior and enforce safety. We first show that direct reward combination—optimizing a preference-learned reward model together with downstream task rewards—has inherent limitations. Motivated by this, we propose Safe Crowd Preference-based RL, a hierarchical framework that extracts safety-aligned skills from crowd preferences and composes them via a high-level policy to safely solve downstream tasks. Experiments across safe RL environments and a preliminary LLM-style task with diverse user goals and shared safety constraints demonstrate that our approach substantially lowers safety costs without access to explicit safety rewards, while achieving task performance comparable to oracle methods trained with ground-truth safety signals.
****
FedHera: Towards Drift-Resilient Federated Fine-tuning with Heterogeneous Resources
Ke Xiao, Qiyuan Wang, Christos Anagnostopoulos, Zhuoran Tan, Wenhao Li
Driven by the imperative to leverage privacy-sensitive data scattered across decentralized devices, federated fine-tuning has emerged as a vital paradigm for adapting large language models without compromising data privacy. Yet, its practical efficacy is bottlenecked by severe client resource heterogeneity. Existing truncation-based methods typically couple the transmitted rank with the trainable rank, which (i) under-utilizes bandwidth on communication-rich but compute-limited clients and (ii) exacerbates truncation-induced gradient drift. To address this, we propose FedHera, a resource-decoupled framework that explicitly differentiates information reception from gradient optimization. FedHera employs a spectrum-preserving allocation strategy to maximize the transfer of global knowledge (via high-rank singular values) within bandwidth limits, irrespective of training constraints. Furthermore, we introduce a prefix-gating mechanism that utilizes the downloaded high-capacity basis as a frozen reference to guide local updates, thereby minimizing the optimization gap caused by aggressive truncation. Extensive experiments under different heterogeneous settings show that FedHera improves stability and accuracy over state-of-the-art baselines.

Frequency Matching in Spiking Neural Networks for mmWave Sensing
Zhenyu Liao, Di Yu, Changze Lv, Wentao Tong, Linshan Jiang, Sijie Ji, Xin Du, Ha

iliang Zhao, Xiaoqing Zheng, Shuiguang Deng
Millimeter-wave (mmWave) sensing enables privacy-preserving, always-on edge perc eption, but its measurements are often sparse, temporally irregular, and corrupt ed by high-frequency noise. Existing mmWave pipelines predominantly rely on arti ficial neural networks (ANNs), which achieve robustness through extensive prepro cessing or deep architectures, thereby limiting their efficiency on edge devices . In this work, we study spiking neural networks (SNNs) for mmWave sensing from a mechanism–data alignment perspective. By leveraging the low-pass filtering beh avior of leaky integrate-and-fire (LIF) dynamics, we analyze how their implicit temporal filtering interacts with the frequency structure of mmWave signals. Our analysis shows that when discriminative information resides in low-to-mid frequ encies, LIF dynamics can inherently suppress high-frequency noise, clarifying wh en and why SNNs outperform ANNs. Based on this insight, we derive a principled c riterion for configuring the membrane decay factor by matching the effective ban dwidth of LIF dynamics to the data’s discriminative spectral content. Experiment al results across four widely used mmWave datasets validate the proposed frequen cy-matching hypothesis, yielding an average test-accuracy improvement of 6.22% a nd a 3.64× reduction in theoretical energy consumption relative to ANN baselines , under a unified evaluation protocol.
****
Mean Flow Distillation: Robust and Stable Distillation for Flow Matching Models
An Zhao, Shengyuan Zhang, Zhongjian Sun, Yixiang Zhou, Zejian Li, Ling Yang, Tia nrun Chen, Lingyun Sun
Flow Matching models have demonstrated strong performance across a wide range of generative tasks.
However, their reliance on ODE-based iterative sampling incurs substantial compu tational overhead, which limits their applicability in real-time scenes.
While distillation is a promising solution, existing approaches largely borrow f rom diffusion-based score matching, often failing to exploit the intrinsic geome tric structure of flows and suffering from training instability, high variance, and degraded generation quality.
In this paper, we propose Mean Flow Distillation (MFD), a novel distillation fra mework tailored for flow matching models.
We theoretically demonstrate that MFD acts as a temporal low-pass filter, effect ively suppressing the high-frequency optimization noise inherent in variational score distillation (VSD) while ensuring global trajectory consistency. We furthe r prove the Mean Flow Matching Theorem, establishing that matching expected aver age velocities is sufficient for strict distribution alignment. Empirically, on challenging high-dimensional manifolds including 4D occupancy forecasting and te xt-to-image generation, MFD achieves state-of-the-art performance, enabling high -fidelity single-step generation.
****
Disentangling Geometry, Performance, and Training in Language Models
Atharva Kulkarni, Jacob Mitchell Springer, Arjun Subramonian, Swabha Swayamdipta
Geometric properties of Transformer weights, particularly the unembedding matrix , have been widely useful in language model interpretability research.
Yet, their utility for estimating downstream performance remains unclear.
In this work, we systematically investigate the relationship between model perfo rmance and the unembedding matrix geometry, particularly its effective rank.
Our experiments, involving a suite of 108 OLMo-style language models trained und er controlled variation, reveal several key findings.
While the best-performing models often exhibit a high effective rank, this trend is not universal across tasks and training setups.
Contrary to prior work, we find that low effective rank does not cause late-stag e performance degradation in small models, but instead co-occurs with it; we fin d adversarial cases where low-rank models do not exhibit saturation.
Moreover, we show that effective rank is strongly influenced by pre-training hyp erparameters, such as batch size and weight decay, which in-turn affect the mode l's performance.
Lastly, extending our analysis to other geometric metrics and final-layer repres

entation, we find that these metrics are largely aligned, but none can reliably predict downstream performance.
Overall, our findings suggest that the model's geometry, as captured by existing metrics, primarily reflects training choices rather than performance.
****
Budget-Constrained Step-Level Diffusion Caching
Mingkun Lei, Tong Zhao, Liangyu Yuan, Chi Zhang
Step-level caching accelerates diffusion models by exploiting temporal redundancy across denoising steps.
Existing methods make per-step cache decisions using threshold-based heuristics, without directly optimizing for final output quality.
As a result, their inference latency varies across inputs and is difficult to control at deployment.
In this work, we propose BudCache, which inverts this formulation: rather than letting per-step error thresholds dictate the runtime cost, we fix the compute budget in advance and search for the cache policy that best preserves the final output.
To tackle the combinatorial complexity of step selection, we combine Simulated Annealing with deterministic Hill Climbing. This offline search identifies high-quality cache policies within minutes and introduces no online search or thresholding overhead during inference.
When the compute budget is very tight, we further introduce cache-aware schedule alignment, which adapts the time discretization to the selected cache policy to reduce cache-induced trajectory mismatch.
Experiments on FLUX.1-dev and Wan2.1 show that BudCache achieves better generation quality than heuristic caching baselines under the same inference budgets.
****
A Control-Theoretic View of Mamba on Stability and Robustness
Liang Cao, Weide Liu, Zhuo Chen, Yan Qin
Selective State Space Models (SSMs) such as Mamba have emerged as efficient alternatives to Transformers, achieving linear complexity through input-dependent parameterization. However, this selectivity transforms the system from linear time-invariant (LTI) to linear parameter-varying (LPV), where individually stable matrices can produce unbounded trajectories under switching. Existing work focuses on empirical performance, leaving global stability, robustness bounds, and practical certification unresolved. This paper develops a control-theoretic framework providing the first comprehensive stability and robustness analysis for selective SSMs. We prove BIBO stability by viewing selective scans as continuous-time LTI sampling and establish two-term robustness bounds with linear growth in sequence length. For general LPV systems, we provide common quadratic Lyapunov function conditions and develop algorithms to extract certificate constants directly from trained weights. These results bridge control theory and SSM architectures, enabling formal guarantees for safety-critical deployment.
****
Understanding Generalization from Embedding Dimension and Distributional Convergence
Junjie Yu, Zhuoli Ouyang, Haotian Deng, Chen Wei, Wenxiao Ma, Jianyu Zhang, Zihan Deng, Quanying Liu
Deep neural networks often generalize well despite heavy over-parameterization, challenging classical parameter-based analyses.
We study generalization from a representation-centric perspective and analyze how the geometry of learned embeddings is associated with generalization performance for a fixed trained model.
We derive a post-hoc generalization bound that relates the gap between population risk and held-out empirical risk to two factors:
(i) the intrinsic dimension of the embedding, which determines the convergence rate of the empirical embedding distribution to its population counterpart in Wasserstein distance, and
(ii) the sensitivity of the downstream mapping from embeddings to predictions, characterized by Lipschitz constants.

Together, these provide a post-hoc explanation of generalization for trained models.
At the final embedding layer, architectural sensitivity disappears and the bound is dominated by embedding dimension, explaining its strong empirical correlation with generalization performance.
Experiments across architectures and datasets validate the theory and demonstrate the utility of embedding-based diagnostics.

Breaking the Reversal Curse in Autoregressive Language Models via Identity Bridge
Xutao Ma, Yixiao Huang, Hanlin Zhu, Somayeh Sojoudi
Autoregressive large language models (LLMs) have achieved remarkable success in many complex tasks, yet they can still fail in very simple logical reasoning such as the "reversal curse" --- when trained on forward knowledge data of the form "$A \rightarrow B$" (e.g., Alice's husband is Bob), the model is unable to deduce the reversal knowledge "$B \leftarrow A$" (e.g., Bob's wife is Alice) during test. Extensive prior research suggests that this failure is an inherent, fundamental limit of autoregressive causal LLMs, indicating that these models tend to memorize factual-level knowledge rather than capture higher-level rules. In this paper, we challenge this view by showing that this seemingly fundamental limit can be mitigated by slightly tweaking the training data with a simple regularization data recipe called the Identity Bridge of the form "$A \to A$" (e.g., The name of Alice is Alice). Theoretically, we prove that under this recipe, even a one-layer transformer can break the reversal curse by analyzing the implicit bias of gradient descent. Empirically, we show that a 1B pretrained language model finetuned with the proposed data recipe achieves a 50\% success rate on reversal tasks, in stark contrast to a near-zero success rate when trained solely on forward-knowledge data. Our work provides a novel theoretical foundation for the reversal curse and offers a principled, low-cost path to encouraging LLMs to learn higher-level rules from data.
****
Anchoring Self-Play for Code Repair
Caroline Choi, Zeyneb N. Kaya, Shirley Wu, Tengyu Ma, Tatsunori Hashimoto, Ludwig Schmidt
Code repair is an important capability for language models (LMs): given a buggy program and unit tests, an LM must produce a fixed program that passes the tests.
We aim to scale supervision for code repair by having an LM generate bug--fix tasks with unconstrained edits, using unit tests as the only verifier.
We propose generator-fixer self-play, in which a single model is trained with reinforcement learning to alternate between generating bugs and fixing them.
As the fixer improves, the generator adapts to produce increasingly difficult bugs, yielding an automatic curriculum.
However, because unit tests certify correctness but not realism, we find that the generator can drift from bugs encountered in practice, improving repair on self-generated bugs while degrading on real-world bugs.
We propose Anchored Self Play (ASP), which anchors self-play with a small reference set by (i) adding a code-embedding similarity reward to guide generation and (ii) mixing reference bugs into fixer training to prevent drift.
To reflect LM-assisted programming, where bugs come from humans, LMs, and human edits of LM code, we introduce BugSourceBench, a code repair benchmark spanning human-authored bugs, human-edited buggy LM code, and errors in LM-generated code.
Across bug sources, ASP achieves the best fix rates, improving average fix rate by $+25$% (relative) / $+7.2$ pp (absolute) over standard self-play, with gains on both LM-error bugs ($+100$% relative / $+11$ pp absolute) and human-authored bugs ($+7.1$% relative / $+3.4$ pp absolute).

(Be Cautious!) Bio-Foundation Models Are Not Yet Robust to Biologically Plausible Perturbations and ML Transformations

Jinhao Duan, Ruichen Zhang, Gengwei Zhang, Huaizhi Qu, Jie Peng, Sijia Liu, Tianlong Chen

Though biological foundation models (Bio-FMs) have delivered strong performance across biomedical tasks, their robustness to small-but-real perturbations is underexplored. In this work, we ask: Are Bio-FMs robust for real-world use? What perturbations compromise their reliability? Our pilot study suggests that due to subtle biological data curation issues and common machine-learning (ML) processing choices, Bio-FMs suffer from two complementary perturbation sources: biologically plausible perturbations (capturing experimental corruptions and curation artifacts) and ML-induced transformations (capturing preprocessing, data augmentation, and embedding choices). Guided by this taxonomy, we design perturbation suites that mimic corruptions frequently encountered in biological experiments, and we systematically probe how transformations in the ML pipeline reshape model behavior. By conducting 2,128 experiments over 11 state-of-the-art Bio-FMs on 7 bio-tasks, we show that most Bio-FMs are vulnerable to both biological perturbations and ML transformations, revealing underappreciated robustness gaps that can directly translate into deployment risk. Interestingly, we find that subtle biological perturbations, which are often imperceptible to current measurement tools, can induce severe discrepancies in Bio-FM outputs and lead to critical failures, yet cryo-EM models (e.g., CryoDRGN) exhibit a surprising level of robustness even under worst-case perturbations. Our study for the first time surfaces critical failure modes and provides a principled perspective for evaluating the robustness of Bio-FMs.

Pluralistic Leaderboards

Nika Haghtalab, Ariel D. Procaccia, Han Shao, Serena Lutong Wang, Kunhe Yang

Recent leaderboard-based evaluations of large language models aggregate user feedback by fitting a Bradley--Terry model to pairwise comparisons, producing a single global ranking based on a latent quality score. While appealing for its simplicity, this approach is incompatible with heterogeneous preferences: when LLMs are used across diverse tasks and use cases, users who favor fundamentally different model behaviors can be systematically misrepresented when collapsed into a single quality score. To address this issue, we study *pluralistic leaderboards* that aim to remain *stable* with respect to heterogeneous user populations. Drawing on ideas from social choice theory, we adapt the notion of *local stability*, which requires that no model outside the top-k positions is collectively preferred to the top-k set by more than $O(1/k)$ fraction of users. Building on techniques from the social choice literature, we design an alternative leaderboard mechanism that satisfies local stability while eliciting only $\widetilde{O}(k)$ pairwise comparisons per user, where k is the size of the prefix for which stability is guaranteed. Using data from LMArena, we show that standard Bradley--Terry aggregation can violate local stability in practice, whereas our method provides substantially stronger stability guarantees.

Federated Multi-view Clustering for Remote Sensing Data

Renxiang Guan, Xiang Yang, Hao Yu, Siwei Wang, Suyuan Liu, Wenjing Yang, Jun-Jie Huang, Ao Li, Xinwang Liu, Yuhua Tang

The rapid expansion of remote sensing technology has generated massive amounts of unlabeled multi-view data distributed across different institutions. Analyzing this data presents significant challenges, as centralized processing incurs prohibitive communication costs and raises data privacy concerns. To address these issues, this paper proposes a novel deep federated multi-view clustering (MVC) framework tailored for remote sensing data. Unlike existing methods that transmit sensitive data features, our approach shares only privatized prototypes masked with adaptive noise, ensuring both communication efficiency and privacy preservation. First, we employ superpixel segmentation to reduce the spatial dimensionality of remote sensing data, lowering computational burdens. Furthermore, to resolve the inconsistency of cluster assignments across different clients, we design a co-occurrence structural alignment module that synchronizes local models. Finally, we incorporate a wasserstein prototype contrastive learning mechanism, whi

ch models clusters as distributions rather than points, to enhance global consis tency and robustness against data heterogeneity. Extensive experiments on four p ublic datasets demonstrate that our framework achieves superior clustering perfo rmance and efficiency compared to state-of-the-art methods.

Balanced LoRA: Removing Parameter Invariance to Accelerate Convergence
Valérie Castin, Kimia Nadjahi, Pierre Ablin, Gabriel Peyré
Low-Rank Adaptation (LoRA) is the most widely adopted method for fine-tuning lar ge language models. Notably, LoRA is inherently overparameterized: multiple pair s of low-rank factors can yield the same adapted weight matrix. We show—both the oretically and empirically—that these pairs exhibit significantly different cond ition numbers. As a result, converging to different loss minimizers directly imp acts the convergence rate of LoRA.
Building on this observation, we introduce Balanced Low-Rank Adaptation (BaLoRA) , a variant of LoRA that projects iterates onto a balanced manifold. This manifo ld improves the conditioning of the loss landscape while preserving the adapted matrix. The projection step is computationally lightweight and integrates seamle ssly into existing fine-tuning pipelines.
Empirically, BaLoRA converges faster than standard LoRA and achieves superior pe rformance across a range of fine-tuning tasks.

A Causal Decomposition Approach for Fair Contextual Multi-Armed Bandits
Jiajun Chen, Jin Tian, Christopher John Quinn
Counterfactual reasoning is one of the fundamental facets of human cognition, in volved in various tasks such as explanation, credit assignment, blame, and respo nsibility. It describes the queries what would have happened had some interventi on been performed given that something else, corresponding to Layer 3 of the Pea rl Causal Hierarchy. In this project, we examine a specific type of counterfact ual quantities, called counterfactual direct (Ctf-DE), indirect (Ctf-IE), and sp urious (Ctf-SE) effects for quantifying fairness in a sequential decision-making framework. Building on these measures, we formulate an online causally-fair lea rning problem with multiple long-term constraints and study it in both non-param etric contextual bandits and parametric logistic bandits settings. We achieve su blinear regret and violations bounds for both bandits settings with roundwise co unterfactual fairness constraints (that are a priori unknown) without Slater's c ondition. For logistic bandits, our method achieves $\mathcal{O}(1)$ per-round t ime complexity using an online mirror descent estimator, yielding an efficient a lgorithm.

Dynamics Within Latent Chain-of-Thought: An Empirical Study of Causal Structure
Zirui Li, Xuefeng Bai, Kehai Chen, Yizhi LI, Jian Yang, Chenghua Lin, Min Zhang
Latent or continuous chain-of-thought methods replace explicit textual rationale s with a number of internal latent steps, but these intermediate computations ar e difficult to evaluate beyond correlation-based probes. In this paper, we view latent chain-of-thought as a manipulable causal process in representation space by modeling latent steps as variables in a structural causal model (SCM) and ana lyzing their effects through step-wise do-interventions.
We study two representative paradigms (i.e., Coconut and CODI) on both mathemati cal and general reasoning tasks to investigate three key questions: (1) which st eps are causally necessary for correctness and when answers become decodable ear ly;
(2) how influence propagates across steps and how this structure compares to exp licit CoT; and
(3) whether intermediate trajectories retain competing answer modes and how outp ut-level commitment differs from representational commitment across steps. We fi nd that latent-step budgets behave less like homogeneous extra depth and more li ke staged functionality with non-local routing, and we identify a persistent gap between early output bias and late representational commitment. These results m otivate mode-conditional and stability-aware analyses, together with correspondi ng training/decoding objectives, as more reliable tools for interpreting and imp

roving latent reasoning systems. Code is available at https://github.com/J1mL1/causal-latent-cot.

Flexibility-Aware Geometric Latent Diffusion for Full-Atom Peptide Design
Dongjiang Niu, Xiaofeng Wang, Zhiqiang Wei, Zhen Li
Although peptides are well suited for flexible and shallow binding interfaces, their intrinsic flexibility induces a strongly coupled sequence–structure relationship that current fixed-geometry latent models cannot simultaneously model with conformational diversity and physical feasibility, ultimately limiting design quality. To overcome this bottleneck, PepFGLD is proposed as a receptor-conditioned, flexibility-aware framework for full-atom peptide design. The framework is motivated by a systematic analysis of existing limitations: geometry shifts driven by interfacial flexibility are not well captured by standard equivariant encoders; the static combination of sequence information and 3D geometry cannot represent their dynamic interactions; and diffusion models without timely geometric feedback tend to drift away from physically reasonable energy landscapes. In PepFGLD, FlexEGNN is used to improve the sensitivity of geometric representations to local flexibility, a coherent and adaptable latent conformational manifold is formed through bidirectional sequence–structure interaction and nonlinear latent mapping, and a time-dependent energy-guided diffusion mechanism is incorporated to balance exploration and convergence during diffusion so that sampling trajectories are continuously guided toward physically feasible full-atom structures. PepFGLD yields improved binding affinity and design success across multiple peptide design tasks.

MultiHal: Multilingual Dataset for Knowledge-Graph Grounded Evaluation of LLM Hallucinations
Ernests Lavrinovics, Russa Biswas, Katja Hose, Johannes Bjerva
Large Language Models (LLMs) have inherent limitations of faithfulness and factuality, commonly referred to as hallucinations. Several benchmarks have been developed that provide a test bed for factuality evaluation within the context of English-centric datasets, while relying on supplementary informative context like web links or text passages but ignoring the available structured factual resources. To this end, Knowledge Graphs (KGs) have been identified as a useful aid for hallucination mitigation, as they provide a structured way to represent the facts about entities and their relations with minimal linguistic overhead. We bridge the lack of KG paths and multilinguality for factual language modeling within the existing hallucination evaluation benchmarks and propose a KG-based multilingual, multihop benchmark called MultiHal framed for generative text evaluation. As part of our data collection pipeline, we mined 140k KG-paths from open-domain KGs, from which we pruned noisy KG-paths, curating a high-quality subset of 25.9k. Our baseline evaluation shows an absolute scale improvement by approximately 0.12 to 0.36 points for the semantic similarity score, 0.16 to 0.36 for NLI entailment and 0.29 to 0.42 for hallucination detection in KG-RAG over vanilla QA across multiple languages and multiple models, demonstrating the potential of KG integration. We anticipate MultiHal will foster future research towards several graph-based hallucination mitigation and fact-checking tasks.

L2G-NET: Local to Global Spectral Graph Neural Networks via Cauchy Factorizations
Samuel Fernandez, Eduardo Pavez, Antonio Ortega
Despite their theoretical advantages, spectral methods based on the graph Fourier transform (GFT) are seldom used in graph neural networks (GNNs) due to the cost of computing the eigenbasis and the lack of vertex-domain locality in the resulting representations. As a result, most GNNs rely on local approximations such as polynomial Laplacian filters or message passing, which limit their ability to model long-range dependencies. In this paper, we introduce an exact factorization of the GFT into operators acting on subgraphs, which are then combined via a sequence of Cauchy matrices. Building on this factorization, we propose a new class of spectral GNNs, termed L2G-Net (Local to Global Net). Unlike existing spec

tral methods, which are either fully global (when using the GFT) or local (when using polynomial filters), L2G-Net operates by processing the spectral representations of subgraphs and then combining them via structured matrices. Our algorithm avoids full eigendecompositions, exploiting graph topology to construct the factorization with quadratic complexity in the number of nodes, scaled by the maximum cut size between subgraphs. Experiments stressing long-range dependencies on large graphs show that L2G-Net scales to regimes out of reach for the standard GFT, and is competitive with state-of-the-art methods with orders of magnitude fewer learnable parameters.

Can LLMs Reason Structurally? Benchmarking via the lens of Data Structures
Yu He, Yingxi Li, Colin White, Ellen Vitercik
Large language models (LLMs) are deployed on increasingly complex tasks that require multi-step decision-making. Understanding their algorithmic reasoning abilities is therefore crucial. However, we lack a diagnostic benchmark for evaluating these capabilities. We propose to use data structures as a principled lens: as fundamental building blocks of algorithms, they naturally probe structural reasoning—the ability to understand and manipulate relationships such as order, hierarchy, and connectivity that underpin algorithmic reasoning. We introduce DSR-Bench (Data Structure Reasoning Benchmark), spanning 20 data structures, 35 operations, and 4,140 problem instances. DSR-Bench features hierarchical task organization, fully automated generation and evaluation, and fine-grained diagnostics. Evaluating 13 state-of-the-art LLMs reveals critical limitations: the top-performing model achieves only 0.46/1 on challenging instances. Three auxiliary probes targeting more realistic usages expose further weaknesses: models perform poorly on spatial data and context-rich scenarios, and they struggle to reason over their own code.

Instruction Lens Score: Your Instruction Contributes a Powerful Object Hallucination Detector for Multimodal Large Language Models
Runhe Lai, Xinhua Lu, Yanqi Wu, Jinlun Ye, Weijiang Yu, Ruixuan Wang
Multimodal large language models (MLLMs) have achieved remarkable progress, yet the object hallucination remains a critical challenge for reliable deployment. In this paper, we present an in-depth analysis of instruction token embeddings and reveal that they implicitly encode visual information while effectively filtering erroneous information introduced by misleading visual embeddings. Building on this insight, we propose the Instruction Lens Score (InsLen), which combines a Calibrated Local Score with a Context Consistency Score that measures context consistency of the object tokens. The proposed approach serves as a plug-and-play object hallucination detector without relying on auxiliary models or additional training. Extensive experiments across multiple benchmarks and diverse MLLM architectures demonstrate that InsLen consistently outperforms existing hallucination detection methods, highlighting its effectiveness and robustness. The code will be publicly available.

Omitted Variable Bias in Language Models Under Distribution Shift
Victoria Lin, Louis-Philippe Morency, Eli Ben-Michael
Despite their impressive performance on a wide variety of tasks, modern language models remain susceptible to distribution shifts, exhibiting brittle behavior when evaluated on data that differs in distribution from their training data. In this paper, we describe how distribution shifts in language models can be separated into *observable* and *unobservable* components, and we discuss how established approaches for dealing with distribution shift address only the former. Importantly, we identify that the resulting *omitted variable bias* from unobserved variables can compromise both evaluation and optimization in language models. To address this challenge, we introduce a framework that maps the strength of the omitted variables to bounds on the *worst-case generalization performance* of language models under distribution shift. In empirical experiments, we show that using these bounds directly in language model evaluation and optimization provides more principled measures of out-of-distribution performance, improves true out

-of-distribution performance relative to standard distribution shift adjustment methods, and further enables inference about the strength of the omitted variables when target distribution labels are available.

A Bi-metric Framework for Efficient Nearest Neighbor Search
Haike Xu, Sandeep Silwal, Piotr Indyk
We propose a new ``bi-metric'' framework for designing nearest neighbor data structures. Our framework assumes two dissimilarity functions: a ground-truth metric that is accurate but expensive to compute, and a proxy metric that is cheaper but less accurate. In both theory and practice, we show how to construct data structures using only the proxy metric such that the query procedure achieves the accuracy of the expensive metric, while only using a limited number of calls to both metrics. Our theoretical results instantiate this framework for two popular nearest neighbor search algorithms: DiskANN and Cover Tree. In both cases we show that, as long as the proxy metric used to construct the data structure approximates the ground-truth metric up to a bounded factor, our data structure achieves arbitrarily good approximation guarantees with respect to the ground-truth metric. On the empirical side, we apply the framework to the text retrieval problem with two dissimilarity functions evaluated by ML models with vastly different computational costs. We observe that for almost all the large data sets in the BEIR benchmark, our approach achieves a considerably better accuracy-efficiency tradeoff than the alternatives, such as retrieve-then-rerank.

Zero-shot Active Mapping via Fused 360-BEV Representations and Vision–Language Models
Yuanze Wang, Dianxi Shi, Yuetian Wang, Shiming Song, Haikuo Peng, Chunping Qiu, Mengzhu Wang
Active mapping enables embodied agents to understand and interact in previously unseen environments. However, most methods struggle to achieve zero-shot generalization to large-scale scenes and lack support for language instructions. We propose a VLM-based active mapping method that achieves zero-shot mapping while facilitating language-driven human–agent interaction. First, we introduce a 360-BEV representation that integrates omnidirectional semantics with BEV-aligned geometric structure to enhance scene understanding. Second, we develop a candidate waypoint generation strategy that allows the VLM-driven agent to select informative 2D waypoints in image space and back-project them into executable metric actions in 3D space, enabling the VLM to plan in its strongest modality. Third, we design a VLM-based depth-first exploration agent that decomposes the scenes into explorable regions, selects informative waypoints within each region, and organizes them into a topological tree. The agent follows the depth-first exploration policy to achieve thorough coverage of large-scale scenes. Without task-specific training, our method outperforms the strongest baseline, improving coverage and AUC by approximately 13.25\% and 14.00\%, respectively, while enabling language-conditioned interaction.
****

Discovering Implicit Large Language Model Alignment Objectives
Edward Chen, Sanmi Koyejo, Carlos Guestrin
Large language model (LLM) alignment relies on complex reward signals that often obscure the specific behaviors being incentivized, creating critical risks of misalignment and reward hacking. Existing interpretation methods typically rely on pre-defined rubrics, risking the omission of "unknown unknowns", or fail to identify objectives that comprehensively cover and are causal to the model behavior on some dataset. To address these limitations, we introduce Obj-Disco, a framework that automatically decomposes an alignment reward signal into a sparse, weighted combination of human-interpretable natural language objectives. Our approach utilizes an iterative greedy algorithm to analyze behavioral changes across training checkpoints, identifying and validating candidate objectives that best explain the residual reward signal. Extensive evaluations across diverse tasks, model sizes, and alignment algorithms demonstrate the framework's robustness. Experiments with popular open-source reward models show that the framework consiste

ntly captures > 90\% of reward behavior, a finding further corroborated by human evaluation. Additionally, a case study on alignment with an open-source reward model reveals that Obj-Disco can successfully identify latent misaligned incentives that emerge alongside intended behaviors. Our work provides a crucial tool for uncovering the implicit objectives in LLM alignment, paving the way for more transparent and safer AI development.

Proact-VL: A Proactive VideoLLM for Real-Time AI Companions

Weicai Yan, Yuhong Dai, Qi Ran, Haodong Li, Wang Lin, Tao Jin, Xing Xie, Hao Liao, Jianxun Lian

Proactive and real-time interactive experiences are essential for human-like AI companions, yet face three key challenges: (1) achieving low-latency inference under continuous streaming inputs, (2) autonomously deciding when to respond, and (3) controlling both quality and quantity of generated content to meet real-time constraints. In this work, we instantiate AI companions through two gaming scenarios—commentator and guide—selected for their suitability for automatic evaluation. We introduce the Live Gaming Benchmark, a large-scale dataset with three representative scenarios: solo commentary, co-commentary, and user guidance, and present Proact-VL, a general framework that shapes multimodal language models into proactive, real-time interactive agents capable of human-like environment perception and interaction. Extensive experiments show Proact-VL achieves superior response latency and quality while maintaining strong video understanding capabilities, demonstrating its practicality for real-time interactive applications.

Learning Decentralized LLM Collaboration with Multi-Agent Actor Critic

Shuo Liu, Tianle Chen, Ryan Amiri, Christopher Amato

Recent work has explored optimizing LLM collaboration through Multi-Agent Reinforcement Learning (MARL). However, most MARL fine-tuning approaches rely on predefined execution protocols, which often require centralized execution. Decentralized LLM collaboration is more appealing in practice, as agents can run inference in parallel with flexible deployments. Also, current approaches use Monte Carlo methods for fine-tuning, which suffer from high variance and thus require more samples to train effectively. Actor-critic methods are prevalent in MARL for dealing with these issues; thus, we developed Multi-Agent Actor-Critic (MAAC) methods to optimize decentralized LLM collaboration. In this paper, we analyze when and why these MAAC methods are beneficial. We propose 2 MAAC approaches, **CoLLM-CC** with a **C**entralized **C**ritic and **CoLLM-DC** with **D**ecentralized **C**ritics. Our experiments across writing, coding, and game-playing domains show that Monte Carlo methods and CoLLM-DC can achieve performance comparable to CoLLM-CC in short-horizon and dense-reward settings. However, they both underperform CoLLM-CC on long-horizon or sparse-reward tasks, where Monte Carlo methods require substantially more samples and CoLLM-DC struggles to converge.

****

CMI-RewardBench: Evaluating Music Reward Models with Compositional Multimodal Instruction

Yinghao Ma, Haiwen Xia, Hewei Gao, Weixiong Chen, Ye Yuxin, Yuchen Yang, Sungkyun Chang, Mingshuo Ding, Yizhi LI, Ruibin Yuan, Simon Dixon, Emmanouil Benetos

While music generation models have evolved to handle complex multimodal inputs mixing text, lyrics, and reference audio, evaluation mechanisms have lagged behind, remaining fragmented and narrowly focused. In this paper, we bridge this critical gap by establishing a comprehensive ecosystem for Compositional Music Instruction (CMI) reward modeling, where the generated music may be conditioned on text descriptions, lyrics, and/or audio prompts. We first introduce CMIPref-Pseudo, a large-scale preference dataset comprising 110k pseudo-labeled samples, and CMI-Pref, a high-quality, human-annotated corpus tailored for fine-grained alignment tasks. To unify the evaluation landscape, we propose CMIRewardBench, a unified benchmark that evaluates music reward models on heterogeneous samples across musicality, text–music alignment, and compositional instruction alignment. Leveraging these resources, we develop CMI reward models (CMI-RMs), a parameter-efficient reward model family capable of processing heterogeneous inputs. We evaluate

their correlation with human judgments scores on Music Arena and CMI-Pref test set, as well as preference agreement on Music Arena and CMI-Pref. Additional analyses examine performance variation across factors such as annotators, annotation timing and confidence, music generation models, and audio length. Experiments demonstrate that CMI-RM not only correlates strongly with human judgments, but also enables effective inference-time scaling via topk filtering. Our work provides the necessary data, benchmarks, and models to advance aligned music generation.

****

FOAM: Blocked State Folding for Memory-Efficient LLM Training

Ziqing Wen, Jiahuan Wang, Ping Luo, Dongsheng Li, Tao Sun

Large language models (LLMs) have demonstrated remarkable performance due to their large parameter counts and extensive training data. However, their scale leads to significant memory bottlenecks during training, especially when using memory-intensive optimizers like Adam. Existing memory-efficient approaches often rely on techniques such as singular value decomposition (SVD), projections, or weight freezing, which can introduce substantial computational overhead, require additional memory for projections, or degrade model performance. In this paper, we propose Folded Optimizer with Approximate Moment (FOAM), a method that compresses optimizer states by computing block-wise gradient means and incorporates a residual correction to recover lost information. Theoretically, FOAM achieves convergence rates equivalent to vanilla Adam under standard non-convex optimization settings. Empirically, FOAM eliminates up to 90\% of the memory overhead of optimizer states and accelerates convergence. Furthermore, FOAM is compatible with other memory-efficient optimizers, delivering performance and throughput that match or surpass both full-rank and existing memory-efficient baselines.

QuantWear: Quantum-scale Wear Particle Detection for Jet Engine Diagnosis

Zheng Wang, Yanwen Wang, Tianyu Fang, Jiaxing Shen, Yisen Kang, Di Wu, Yuanqing Zheng

The quantity and 3-D shape of wear particles are essential indicators for assessing the health of jet engines, enabling early detection of potential damage and preventing accidents caused by catastrophic failures. However, capturing wear particles is difficult due to their minute sizes and ultra high-speed movement within intense jet flows. Existing technologies struggle with the extreme background noise and low resolution in such harsh environments. In this paper, we propose QuantWear, the first quantum sensing system designed to directly quantify and profile wear particles on the sub-millimeter scale. QuantWear innovatively tracks wear particles by monitoring the spectral signatures of Sodium (Na) and Potassium (K) atoms within jet flow, which naturally adhere to particle surfaces due to electrochemical reactions in high-temperature combustion. We construct a custom atomic detector that leverages quantum jump and Faraday rotation effects to isolate these specific atomic signals, effectively suppressing the broad-spectrum flame noise. Next, we apply a deep learning framework to effectively measure the quantity of wear particles in dynamic vaporous backgrounds. Finally, we generate a fully reconstructed 3-D model of the wear particles from multiple 2-D images. Extensive field tests and high-fidelity simulations demonstrate that QuantWear achieves an imaging Signal-to-Noise Ratio (SNR) of 22.5 dB and a 3-D reconstruction similarity exceeding 95%, significantly outperforming state-of-the-art technologies.

****

Bayesian Meta-Learning with Expert Feedback for Task-Shift Adaptation through Causal Embeddings

Lotta Mäkinen, Jorge Loria, Samuel Kaski

Meta-learning methods perform well on new within-distribution tasks but often fail when adapting to out-of-distribution target tasks, where transfer from source tasks can induce negative transfer. We propose a causally-aware Bayesian meta-learning method, by conditioning task-specific priors on precomputed latent causal task embeddings, enabling transfer based on mechanistic similarity rather than spurious correlations. Our approach explicitly considers realistic deployment s

ettings where access to target-task data is limited, and adaptation relies on no isy (expert-provided) pairwise judgments of causal similarity between source and target tasks. We provide a theoretical analysis showing that conditioning on ca usal embeddings controls prior mismatch and mitigates negative transfer under ta sk shift. Empirically, we demonstrate reductions in negative transfer and improv ed out-of-distribution adaptation in controlled simulations and a real-world cli nical prediction setting for cross-disease transfer, where causal embeddings ali gn with underlying clinical mechanisms; we include the judgments from a medical expert in the clinical prediction task and obtain improved performance in predic tions of unseen diseases.

Meta-learning Structure-Preserving Dynamics

Cheng Jing, Uvini Balasuriya Mudiyanselage, Woojin Cho, Minju Jo, Anthony Gruber , Kookjin Lee

Structure-preserving approaches to dynamics discovery have demonstrated great po tential for modeling physical systems due to their use of strong inductive biase s, which enforce key features such as conservation laws and dissipative behavior . However, these models are typically trained on a per-configuration basis, requ iring explicit knowledge of system parameters and costly retraining when these p arameters vary. While meta-learning provides a potential remedy, optimization-ba sed approaches can suffer from limited generalizability. Motivated by recent adv ances in modulation-based learning aimed at mitigating these drawbacks, we syste matically investigate the use of modulation techniques in learning conservative dynamical systems. We study a range of existing modulation strategies alongside newly proposed variants, integrating them into a Hamiltonian learning framework without requiring an explicit system parameterization. Through extensive experim ents on benchmark problems, we demonstrate that modulation-based meta-learning e nables accurate few-shot adaptation, achieving robust generalization across para meter space without compromising the conservation of key invariants responsible for the dynamics.

Latent Guided Sampling for Combinatorial Optimization

Sobihan Surendran, Adeline Fermanian, Sylvain Le Corff

Combinatorial Optimization problems are widespread in domains such as logistics, manufacturing, and drug discovery, yet their NP-hard nature makes them computat ionally challenging. Recent Neural Combinatorial Optimization (NCO) methods leve rage deep learning to learn policies for constructing solutions, trained via Sup ervised or Reinforcement Learning. While promising, these approaches often rely on task-specific augmentations, perform poorly on out-of-distribution instances, and lack robust inference mechanisms. Moreover, existing latent space models ei ther require labeled data or use an instance-independent latent distribution. In this work, we propose LGS-Net, a novel latent space model that conditions on pr oblem instances, and introduce an efficient inference method, Latent Guided Samp ling (LGS), based on Markov Chain Monte Carlo and Stochastic Approximation. We s how that the iterations of our method form a time-inhomogeneous Markov Chain and provide rigorous theoretical convergence guarantees. Empirical results on bench mark routing tasks show that our method achieves state-of-the-art performance am ong NCO baselines.

KnapSpec: Self-Speculative Decoding via Adaptive Layer Selection as a Knapsack P roblem

Seongjin Cha, Gyuwan Kim, Dongsu Han, Tao Yang, Insu Han

Self-speculative decoding (SSD) accelerates LLM inference by skipping layers to create an efficient draft model, yet existing methods often rely on static heuri stics that ignore the dynamic computational overhead of attention in long-contex t scenarios. We propose KnapSpec, a training-free framework that reformulates dr aft model selection as a knapsack problem to maximize tokens-per-time throughput . By decoupling Attention and MLP layers and modeling their hardware-specific la tencies as functions of context length, KnapSpec adaptively identifies optimal d raft configurations on the fly via a parallel dynamic programming algorithm. Fur

thermore, we provide the first rigorous theoretical analysis establishing cosine similarity between hidden states as a mathematically sound proxy for the token acceptance rate. This foundation allows our method to maintain high drafting faithfulness while navigating the shifting bottlenecks of real-world hardware. Our experiments on Qwen3 and Llama3 demonstrate that KnapSpec consistently outperforms state-of-the-art SSD baselines, achieving up to 1.47$\times$ wall-clock speedup across various benchmarks. Our plug-and-play approach ensures high-speed inference for long sequences without requiring additional training or compromising the target model's output distribution.

Budget-Efficient Attacks and Robustness Training for Cooperative MARL
junyong jiang, Xin Yuan, Longhe Lin, Songze Li, Lu Dong
Cooperative multi-agent reinforcement learning (CMARL) policies are vulnerable to
action hijacking even when only a few timesteps are compromised.
Recent adversarial attacks and adversarial training methods have been explored,
but under an explicit attack budget, existing attacks often fail to accurately
expose critical coordination weaknesses and incur substantial training cost.
We propose Budgeted Hierarchical Efficient Attack (BHEA), a budgeted
hierarchical adversarial attack that separates decisions on when and which agents
to hijack from action replacement, enabling more precise vulnerability discovery
under limited attack opportunities.
We further show that training cooperative policies against BHEA substantially
improves robustness to limited-step action hijacking while reducing training
overhead.
Experiments on the StarCraft Multi-Agent Challenge (SMAC) demonstrate stronger attacks
under the same attack budget and improved robustness. Code is available at https://anonymous.4open.science/r/BHEA-068D.

Learning Manifold and Itô Dynamics with Branched Neural Rough Differential Equations
Luke Thompson, Dai Shi, Lequan Lin, Junbin Gao, Andi Han
Neural rough differential equations (NRDEs) stay accurate under irregular sampling while taking far fewer integration steps than standard neural differential equations, summarising a finely sampled driver by its log-signature and advancing the hidden state over coarse intervals using the log-ODE method. This efficiency rests on the shuffle algebra, the algebraic counterpart of Stratonovich calculus. This reliance means NRDEs cannot expose the quadratic-variation terms Itô dynamics require, nor the ordered covariant derivatives that govern Itô flows on connection-equipped manifolds. Ameliorating this, we introduce Branched Neural Rough Differential Equations (B-NRDEs), a Hopf-algebraic framework that recasts the NRDE log-ODE step as geometric numerical integration on the state-space manifold, matching the driving algebra to the governing calculus: Grossman–Larson rooted trees for Euclidean Itô dynamics, Munthe–Kaas–Wright planar rooted trees for ordered covariant derivatives on manifolds, and the shuffle algebra in the classical Stratonovich case. This yields intrinsic coarse-step dynamics that exactly preserve manifold constraints. Finally, we introduce a branched signature-kernel objective to enable Itô-consistent law matching by making quadratic-variation terms visible during training. On rough Bergomi volatility, sim-to-real $\mathrm{SO}(3)$ forecasting, and SPD covariance dynamics, B-NRDEs offer a unified, effective approach to stochastic and manifold-valued dynamics beyond the Euclidean–Stratonovich setting.

FedCDWA: Decoupled Federated Prototype Distillation with Hierarchical Wasserstein Aggregation
Zhenshen Liu, Kai Fan, Wenjie Li, Kuan Zhang, HUI LI, Yintang Yang
Federated learning enables decentralized clients to collaboratively train models without sharing local data. However, heterogeneous client distributions often i

nduce client drift and hinder convergence. This paper proposes FedCDWA, a decoup
led hierarchical federated distillation framework. FedCDWA decouples client-side
 personalized distillation from server-side mutual distillation to mitigate dist
illation-induced optimization conflicts. It further adopts Hierarchical Wasserst
ein Aggregation to aggregate prototypes without restrictive parametric assumptio
ns while preserving intra-class structure and inter-class geometry. To achieve f
iner-grained feature alignment, Prototype–Variance Dual Alignment matches featur
e means and variances in the feature space. We prove convergence guarantees for
FedCDWA. Experiments on three datasets demonstrate that FedCDWA consistently imp
roves both global and personalized accuracy across heterogeneity levels, with sm
aller performance degradation under more severe heterogeneity.

Privasis: Synthesizing the Largest "Public" Private Dataset from Scratch

Hyunwoo Kim, Niloofar Mireshghallah, Michael Duan, Rui Xin, Shuyue Stella Li, Ja
ehun Jung, David Acuna, Qi Pang, Hanshen Xiao, G. Edward Suh, Sewoong Oh, Yulia
Tsvetkov, Pang Wei Koh, Yejin Choi

Research involving privacy-sensitive data has always been constrained by data sc
arcity, standing in sharp contrast to other areas that have benefited from data
scaling. To quench this thirst, we present Privasis (i.e., privacy oasis), the f
irst million-scale fully synthetic dataset entirely built from scratch—an expans
ive reservoir of texts with rich and diverse private information—designed to bro
aden and accelerate research in areas where processing sensitive social data is
inevitable. Compared to existing datasets, Privasis, comprising 1.4 million reco
rds, offers orders-of-magnitude larger scale with quality, and far greater diver
sity across various document types, including medical records, legal documents,
financial records, calendars, emails, meeting transcripts, and text-messages wit
h a total of 55.1 million annotated attributes such as ethnicity, date of birth,
 workplace, etc. We leverage Privasis to construct a parallel corpus for text sa
nitization with our pipeline that recursively decomposes texts and applies targe
ted sanitization. Our compact sanitization models ($\leq$
4B) trained on this dataset outperform state-of-the-art large language models, s
uch as GPT-5 and Qwen-3 235B.

EmWorld: Emotion World Model with Latent State Evolution for Scenario-Incrementa
l Dynamic Facial Expression Recognition

ke Wang, Yuanyuan Liu, Kejun Liu, Yuyang Xia, Chang Tang, Yibing Zhan, Zhe Chen

Dynamic Facial Expression Recognition (DFER) models the temporal evolution of fa
cial expressions in videos. In real-world scenarios, changing scenarios distort
expression trajectories, challenging existing methods. Most current approaches a
ddress this via passive feature alignment or domain-incremental learning but do
not explicitly model scenario evolution, limiting their ability to capture expre
ssion dynamics under scenario-incremental changes. To address this, we propose *
*EmWorld**, an emotion world model for DFER that explicitly models latent emotio
n state evolution under scenario variations. Specifically, **EmWorld** formulate
s scenario-incremental DFER as a progressive Bayesian inference problem over lat
ent world states with dual temporal scales. Slow-timescale component (**STS**) m
odels scenario evolution using stochastic evolutionary priors, capturing long-te
rm scenario effects and providing proactive guidance in new scenarios. Fast-time
scale component (**FTS**) models frame-level expression dynamics with temporally
 consistent latent transitions, decoupling expression dynamics from scenario inf
luences. By jointly inferring latent states at both timescales, EmWorld shifts D
FER from a passive feature discrimination to active probabilistic state inferenc
e under evolving scenarios. Experiments on FERV39k, DFEW, and MAFW demonstrate t
hat EmWorld consistently outperforms state-of-the-art methods, achieving up to 3
.84\% improvement while exhibiting strong cross-scenario stability and long-term
 robustness.

The Silent Thought: Modeling Internal Cognition in Full-Duplex Spoken Dialogue M
odels via Latent Reasoning

Donghang Wu, Tianyu Zhang, Yuxin Li, Hexin Liu, Chen Chen, Eng Siong Chng, Yoshu

a Bengio
During conversational interactions, humans subconsciously engage in concurrent thinking while listening to a speaker. Although this internal cognitive processing may not always manifest as explicit linguistic structures, it is instrumental in formulating high-quality responses. Inspired by this cognitive phenomenon, we propose a novel **F**ull-duplex **LA**tent and **I**nternal **R**easoning method named FLAIR that conducts *latent* thinking simultaneously with speech perception. Unlike conventional "thinking" mechanisms in NLP, which require post-hoc generation, our approach aligns seamlessly with spoken dialogue systems: during the user’s speaking phase, it recursively feeds the latent embedding output from the previous step into the next step, enabling continuous reasoning that strictly adheres to causality without introducing additional latency. To enable this latent reasoning, we design an Evidence Lower Bound-based objective that supports efficient supervised finetuning via teacher forcing, circumventing the need for explicit reasoning annotations. Experiments demonstrate the effectiveness of this think-while-listening design, which achieves competitive results on a range of speech benchmarks. Furthermore, FLAIR robustly handles conversational dynamics and attains competitive performance on full-duplex interaction metrics.

Enhancing Multi-Modal LLMs Reasoning via Difficulty-Aware Group Normalization
Jinghan Li, Junfeng Fang, Jinda Lu, Yuan Wang, Xiaoyan Guo, Tianyu Zhang, Xiang Wang, Xiangnan He
Reinforcement Learning with Verifiable Rewards (RLVR) and Group Relative Policy Optimization (GRPO) have significantly advanced the reasoning capabilities of large language models.
Extending these methods to multimodal settings, however, faces a critical challenge: the instability of std-based normalization, which is easily distorted by extreme samples with nearly positive or negative rewards.
Unlike pure-text LLMs, multimodal models are particularly sensitive to such distortions, as both perceptual and reasoning errors influence their responses.
To address this, we characterize each sample by its difficulty, defined through perceptual complexity (measured via visual entropy) and reasoning uncertainty (captured by model confidence).
Building on this characterization, we propose difficulty-aware group normalization (Durian), which re-groups samples by difficulty levels and shares the std within each group.
Our approach preserves GRPO's intra-group distinctions while eliminating sensitivity to extreme cases, yielding significant performance gains across multiple multimodal reasoning benchmarks.
****
Robust Self-reflective Hashing for Cross-modal Retrieval with Noisy Label
Hao Sun, Qibing Qin, Lei Huang
Cross-modal Hashing (CMH) typically assumes a perfectly complete data annotation, whereas noisy labels are unavoidable in practical scenarios.
■Existing CMH methods often overlook the uncertainty introduced by noise or semantic ambiguity, making models susceptible to overfitting noisy labels and yielding unreliable similarity judgments during inference.
■To address this issue, we propose a Robust Self-reflective Hashing (RSH) framework that prudently analyzes semantic discrepancies while accounting for uncertainty, thereby effectively mitigating interference from noisy labels.
■Specifically, the Double Feature Representation (DFR) method is introduced, employing semantic and uncertainty features to represent the semantic representation and fuzziness of samples.
■With a double feature, we propose a novel cross-modal similarity metric - the Self-reflective Similarity Metric (SSM), which judges sample similarity by integrating semantic discrepancy and fuzziness, enabling the model to adaptively weaken semantic discrepancy according to uncertainty level.
■The proposed method is plug-and-play, enabling seamless integration into diverse objective functions to enhance model robustness and reliability.
■Extensive experiments on benchmark datasets demonstrate that RSH outperforms ex

isting methods. Code is available at https://github.com/QinLab-WFU/RSH.

Offline Reinforcement Learning of High-Quality Behaviors Under Robust Style Alig nment
Mathieu Petitbois, Rémy Portelas, Sylvain Lamprier
We study offline reinforcement learning of style-conditioned policies using expl icit style supervision via subtrajectory labeling functions. In this setting, al igning style with high task performance is particularly challenging due to distr ibution shift and inherent conflicts between style and reward. Existing methods, despite introducing numerous definitions of style, often fail to reconcile thes e objectives effectively. To address these challenges, we propose a unified defi nition of behavior style and instantiate it into a practical framework. Building on this, we introduce Style-Conditioned Implicit Q-Learning (SCIQL), which leve rages offline goal-conditioned RL techniques, such as hindsight relabeling and v alue learning, and combine it with a new Gated Advantage Weighted Regression mec hanism to efficiently optimize task performance while preserving style alignment . Experiments demonstrate that SCIQL achieves superior performance on both objec tives compared to prior offline methods. Code, datasets and visuals are availabl e in: https://mathieu-petitbois.github.io/projects/sciql/.

CrossQ: Task-Aligned Cross-Token Conditional Quantization for Late Interaction R etrieval
Rohit Kumar Salla, Manoj Saravanan, Ramya Manasa Amancherla
Late-interaction retrievers like ColBERT achieve high quality but suffer from la rge multi-vector indices. Standard compression minimizes token reconstruction er ror, while ranking depends critically on preserving scores of sparse "winner" to kens. We introduce CrossQ, which adaptively improves effective token fidelity wi thin documents by conditioning token codes on lightweight document context compu ted at indexing time (but not stored). CrossQ is trained with ranking-aligned ob jectives that preserve candidate score distributions and protect hard-negative m argins. At 2 B/token, CrossQ improves MRR@10 by +0.010 over the strongest strict ly footprint-matched quantization baseline and by +0.012 over the strongest cand idate-matched system reference. On the nine-dataset BEIR subset reported in Appe ndix G.1, CrossQ improves average nDCG@10 by +0.009 at 4 B/token over the strong est candidate-matched system reference. At 4 B/token, CrossQ achieves
$64\times$ raw token-storage reduction, approximately
$61\times$ including metadata and approximately
$58\times$ under conservative padding/alignment accounting. At 8 B/token, CrossQ + light fine-tuning retains approximately 98% of full-precision ColBERT MRR@10, improving the footprint-quality tradeoff for memory-constrained late-interactio n retrieval.

Unified Multimodal Autoregressive Modeling with Shared Context—Visual Tokenizer is Key to Unification
Wujian Peng, Lingchen Meng, Yuxuan Cai, Xianwei Zhuang, Yuhuan Yang, Rongyao Fan g, Chenfei Wu, Junyang Lin, Zuxuan Wu, Shuai Bai
Unified Multimodal Modeling aims to integrate visual understanding and generatio n within a single system. However, existing approaches typically rely on two dis parate visual tokenizers, which splits the representation space and hinders trul y unified modeling. We propose UniAR, a unified autoregressive framework where a single discrete visual tokenizer serves as the key bridge between understanding and generation, enabling a shared context in which the model can directly inter pret its own generated visual tokens without additional re-encoding. UniAR adapt s a pretrained vision encoder with multi-level feature fusion and a lookup-free bitwise quantization scheme, preserving both high-level semantics and low-level details while scaling the effective visual vocabulary at minimal cost. Building on this, the unified autoregressive model adopts parallel-bitwise-prediction to jointly predict spatially grouped, multi-level visual codes, substantially reduc ing visual sequence length and accelerating generation. Finally, a diffusion-bas ed visual decoder operates on discrete visual tokens to decode high-fidelity ima

ges. Through large-scale pre-training, followed by supervised fine-tuning and re
inforcement learning, UniAR achieves state-of-the-art performance on image gener
ation and image editing while remaining competitive on multimodal understanding
benchmarks. The project homepage is at https://sharelab-sii.github.io/uniar-web.

Temporal Difference Learning for Diffusion Models
Qizhen Ying, Yangchen Pan, Victor Adrian Prisacariu, Junfeng Wen
Diffusion models are typically trained with objectives that focus on local denoi
sing targets at individual time steps (or adjacent pairs), which do not enforce
consistency between predictions along the denoising trajectory. This lack of cro
ss-time consistency can degrade performance, especially for few-step samplers. W
e introduce a temporal difference (TD) objective that penalizes inconsistency of
 the model’s \emph{multi-step} progress along the denoising path. By reformulati
ng the diffusion process as a Markov reward process and casting denoising as a p
olicy evaluation problem in reinforcement learning, we derive a unified TD appro
ach that applies to both discrete- and continuous-time diffusion formulations. W
e further propose a principled sample-based reweighting method that stabilizes t
raining. Empirically, we show that using our TD training can significantly impro
ve sample quality measured by FID, with stronger advantages when the number of s
ampling steps is small, highlighting its practical utility under low-computation
-budget scenarios. We provide ablation studies to justify our design choices, in
cluding pairwise loss reweighting, regularization weight, and one-step stride. O
verall, our TD approach can be a general drop-in that enforces cross-time consis
tency and improves generation quality across different diffusion generative mode
ls.

A Graph Foundation Model with Cross-Modal Alignment and Modality-Aware Expert F
usion for Multi-Modal Graphs
Dongxiao He, Ankang Yang, Jitao Zhao, Di Jin
Graph Foundation Models (GFMs) aim to learn universal patterns through large-sca
le pretraining on diverse graphs and generalize to open-world scenarios. While G
FMs have garnered significant attention, existing works primarily focus on sigle
-modal graphs. However, many real-world graphs are multimodal, consisting of str
uctures alongside diverse features derived from modalities such as text and imag
es. To date, exploration into Multimodal Graph Foundation Models (MGFMs) remains
 limited. Incorporating multimodal data provides a more comprehensive view, allo
wing models to learn richer semantics, thereby advancing GFMs. We are therefore
motivated to explore MGFMs, where the core challenge lies in synergistically enc
oding structures and multimodal features to achieve effective cross-modal alignm
ent and fusion. To this end, we propose a graph foundation model with Cross-moda
l Alignment and Modality-aware Expert fusion, CAME. Specifically, CAME first gen
erates graph embeddings for each individual modality. We then introduce a multim
odal multi-expert encoding mechanism, which includes a dimension-wise routing st
rategy to fuse multimodal information. Finally, we employ a cross-modal contrast
ive loss to train CAME, enabling the adaptive alignment and fusion across differ
ent modalities. Extensive experiments demonstrate the effectiveness of CAME acro
ss multiple tasks and diverse multimodal graph datasets.

Language Generation with Feedback: Queries and Mistakes
Steve Hanneke, Amin Karbasi, Anay Mehrotra, Grigoris Velegkas
We investigate language generation in the limit (Kleinberg & Mullainathan, 2024;
 Li et al., 2025) in variants where the generator receives some feedback based o
n its “actions.” We study two such variants. In the first, which is inspired by
Littlestone’s model of online learning, the generator observes whether it made a
 mistake at each iteration. In the second, introduced by Charikar & Pabbaraju (2
025a), the generator can query whether a string belongs to the target language.

Our main result is a characterization of collections that are generable with mis
take feedback. Using similar techniques, we also characterize when generation is
 possible in the query model with set-based generators; set-based generators hav

e been studied in several works (Charikar & Pabbaraju, 2025a; Kalavasis et al., 2025; Kleinberg & Wei, 2025a; Li et al., 2025). Beyond the characterizations themselves, we derive several implications. First, our results imply new closure properties for generation with mistake and query feedback. Second, our results show that, under feedback, generation is robust to noise: it remains possible with arbitrary contamination in the adversary’s examples and with finite contamination in the feedback. Third, our techniques also yield new sufficient and necessary conditions for generation without feedback among other implications.

OpenGPT-4o-Image: A Comprehensive Dataset for Advanced Image Generation and Editing
zhihong Chen, Xuehai Bai, Yang Shi, Chaoyou Fu, Huanyu Zhang, Haotian Wang, Xiaoyan Sun, Zhang Zhang, Liang Wang, Yuanxing Zhang, Pengfei Wan, YiFan Zhang
The performance of unified multimodal models for image generation and editing is fundamentally constrained by the quality and comprehensiveness of their training data. While existing datasets have covered basic tasks like style transfer and simple object manipulation, they often lack the systematic structure and challenging scenarios required for real-world applications. To address this bottleneck, we introduce OpenGPT-4o-Image, a large-scale dataset constructed using a novel methodology that combines hierarchical task taxonomy with automated data generation. Our taxonomy not only includes fundamental capabilities such as text rendering and style control but also introduces highly practical yet challenging categories like scientific imagery for physics/chemistry illustrations and complex instruction editing requiring simultaneous execution of multiple operations. Through an automated pipeline leveraging structured resource pools and GPT-4o, we generate 80k high-quality instruction-image pairs with controlled diversity, covering 11 major domains and 51 subtasks. Extensive experiments show that fine-tuning leading models on our dataset achieves significant performance gains across multiple benchmarks, with improvements of up to 18% on editing tasks UniWorld-V1 on ImgEdit-Bench and 13% on generation tasks Harmon on GenEval. Our work demonstrates that systematic data construction is key to advancing multimodal AI capabilities.

Video-SVD: Efficient Video Diffusion via Orthogonal Basis Composition
Zhang Wan, Yu Li, Tianze Huang, Haochen Li, Juan Cao, Sheng Tang
Video Diffusion Transformers (VDiTs) represent the state of the art in video generation but remain constrained by the quadratic complexity of dense self-attention. To address this attention bottleneck, we analyze the pre-softmax matrix ($QK^\top$) and reveal two key properties: (1) video attention exhibits an effective low-dimensional structure with rapid singular-value decay, and (2) real motion induces hybrid spatio-temporal patterns rather than rigid ``spatial vs. temporal'' layouts. Guided by these observations, we propose Video-SVD, a training-free and plug-and-play acceleration method that does not modify the original network parameters. Video-SVD learns checkpoint-adaptive orthogonal bases offline and, at inference time, replaces expensive dense attention computation with lightweight online subspace projection and basis composition. To preserve high fidelity, Video-SVD further employs layer-shared dual-stream residual modules to recover fine-grained content details and positional information. Across HunyuanVideo and Wan2.1 backbones, Video-SVD achieves significant end-to-end speedups while maintaining high visual quality, reaching 1.92$\times$ on HunyuanVideo, 1.75$\times$ on Wan2.1-1.3B, and 1.79$\times$ on Wan2.1-14B.

Doubly Robust Distributionally Robust Offline Contextual Pricing
Min Xu, Xinyi Yin, Yunfan Zhang, Yuxuan Han, Houcai Shen, Caihua Chen
Offline contextual pricing often relies on logged observational data, but faces challenges from distributional shifts between training and deployment environments. Distributionally robust optimization (DRO) provides a principled approach to off-policy evaluation and learning (OPE/L). However, existing methods are mostly limited to discrete actions. Recent work has explored DRO for continuous treatments using inverse propensity weighting (IPW), while such IPW-based estimators

can be sensitive to the convergence rate of propensity score estimates, particularly when estimated nonparametrically, which may lead to larger estimation errors and regret.
In this work, we develop a doubly robust (DR) framework for distributionally robust OPE/L in continuous pricing settings. For evaluation, we propose a localized DR estimator that addresses the computational challenges of worst-case expectations by fitting only a small number of regressions, comparable to standard non-robust DR, while achieving semiparametric efficiency under mild product rate conditions. For learning, we leverage the inherent smoothness of demand noise to handle pricing-specific discontinuities in revenue outcomes (e.g., threshold-based purchase decisions), establishing a finite-sample regret bound of $\tilde{\mathcal{O}}_p(T^{-s/(2s+1)})$ for smoothness orders $s=1,2$. This bound improves upon existing regret rates in existing DRO-based off-policy learning (OPL) for continuous treatments. Extensive experiments under various levels of distribution shift validate our proposed framework.

A Theory of How Pretraining Shapes Inductive Bias in Fine-Tuning
Nicolas Anguita, Francesco Locatello, Andrew M Saxe, Marco Mondelli, Flavia Mancini, Samuel Lippl, Clémentine Carla Juliette Dominé
Pretraining and fine-tuning are central stages in modern machine learning systems. In practice, feature learning plays an important role across both stages: deep neural networks learn a broad range of useful features during pretraining and further refine those features during fine-tuning. However, an end-to-end theoretical understanding of how choices of initialization impact the ability to reuse and refine features during fine-tuning has remained elusive. Here we develop an analytical theory of the pretraining–fine-tuning pipeline in diagonal linear networks, deriving exact expressions for the generalization error as a function of initialization parameters and task statistics. We find that different initialization choices place the network into four distinct fine-tuning regimes that are distinguished by their ability to support feature learning and reuse—and therefore by the task statistics for which they are beneficial. In particular, a smaller initialization scale in earlier layers enables the network to both reuse and refine its features, leading to superior generalization on fine-tuning tasks that rely on a subset of pretraining features. We demonstrate empirically that the same initialization parameters impact generalization in ResNets trained on CIFAR-100 and SVHN as well as Transformers trained on modular arithmetic tasks. Overall, our results demonstrate analytically how data and network initialization interact to shape fine-tuning generalization, highlighting an important role for the relative scale of initialization across different layers in enabling continued feature learning during fine-tuning.

Safeguarded Stochastic Polyak Step Sizes for Non-smooth Optimization: Robust Performance Without Small (Sub)Gradients
Dimitris Oikonomou, Nicolas Loizou
The stochastic Polyak step size (SPS) has proven to be a promising choice for stochastic gradient descent (SGD), delivering competitive performance relative to state-of-the-art methods on smooth convex and non-convex optimization problems, including deep neural network training. However, extensions of this approach to non-smooth settings remain in their early stages, often relying on interpolation assumptions or requiring knowledge of the optimal solution. In this work, we propose a novel SPS variant, Safeguarded SPS (SPS$_{safe}$), for the stochastic subgradient method, and provide rigorous convergence guarantees for non-smooth convex optimization with no need for strong assumptions. We further incorporate momentum into the update rule, yielding equally tight theoretical results. Comprehensive experiments on convex benchmarks and deep neural networks corroborate our theory: the proposed step size achieves competitive performance to existing adaptive baselines and exhibits stable behavior across a wide range of problem settings. Finally, in the context of deep neural network training, the gradient norms under our step size do not collapse to (near) zero, indicating robustness to vanishing gradients.

Exposing Hidden Biases in Text-to-Image Models via Automated Prompt Search
Manos Plitsis, Giorgos Bouritsas, Vassilis Katsouros, Yannis Panagakis
Text-to-image (TTI) diffusion models have achieved remarkable visual quality, yet they have been repeatedly shown to exhibit social biases across sensitive attributes such as gender, race and age. To mitigate these biases, existing approaches frequently depend on curated prompt datasets - either manually constructed or generated with large language models (LLMs) - as part of their training and/or evaluation procedures. Beside the curation cost, this also risks overlooking unanticipated, less obvious prompts that trigger biased generation, even in models that have undergone debiasing. In this work, we introduce Bias-Guided Prompt Search (BGPS), a framework that automatically generates prompts that aim to maximize the presence of biases in the resulting images. BGPS comprises two components: (1) an LLM instructed to produce attribute-neutral prompts and (2) attribute classifiers acting on the TTI's internal representations that steer the decoding process of the LLM toward regions of the prompt space that amplify the image attributes of interest. We conduct extensive experiments on Stable Diffusion 1.5 and a state-of-the-art debiased model and discover an array of subtle and previously undocumented biases that severely deteriorate fairness metrics. Crucially, the discovered prompts are interpretable, i.e they may be entered by a typical user, quantitatively improving the perplexity metric compared to a prominent hard prompt optimization counterpart. Our findings uncover TTI vulnerabilities, while BGPS expands the bias search space and can act as a new evaluation tool for bias mitigation.
****
Decision Transformers As Zero-Shot Learners via Text-Behavior Alignment
Xin Zhang, Jonathan Martinez, Yanhua Li, Yingxue Zhang
Offline meta-reinforcement learning (meta-RL) aims to train agents that can generalize to unseen tasks using pre-collected data from related tasks. Recent approaches leverage the scalability of transformer architectures to model behavior sequences and support task adaptation using target task demonstrations. However, such data is often unavailable in real-world settings, where the task objective may be known but cannot be easily demonstrated. In contrast, humans routinely interpret and perform new tasks based solely on natural language instructions. In this work, we explore the potential of using natural language task descriptions to enable zero-shot task adaptation in offline meta-RL without requiring any data from the target task. We propose the Text-Guided Decision Transformer (TG-DT), a framework that enables zero-shot generalization by grounding policy learning in natural language. TG-DT learns a shared embedding space between task descriptions and behavioral trajectories via a dual contrastive and matching-based objective, ensuring robust alignment. A transformer-based policy is then conditioned on these aligned representations to generate task-appropriate actions. At test time, TG-DT synthesizes policies for unseen tasks using only their text descriptions and can optionally leverage a description-guided data sharing strategy to enhance adaptation. Experiments on standard offline meta-RL benchmarks, including MuJoCo and Meta-World, demonstrate that TG-DT achieves strong generalization to unseen tasks.

GCIB: Graph Contrastive Information Bottleneck for Multi-Behavior Recommendation
Likang Wu, Zihao Chen, Jianxin Zhang, Sangqi Zhu, Yuanyuan Ge, Haipeng Yang, Lei Zhang
With the rapid emergence of multi-behavior learning in recommender systems, leveraging auxiliary user behaviors has proven effective for mitigating target-behavior data sparsity. Yet auxiliary behavior graphs frequently contain noisy or irrelevant interactions that do not align with the target task, impeding the learning of accurate user and item embeddings. Moreover, the scarcity of direct supervised from the target behavior complicates the extraction of informative collaborative signals. In this paper, we introduce GCIB Graph Contrastive Information Bottleneck, a novel framework that denoises auxiliary behavior information and enriches target behavior representations at both the structural and feature levels.

At the structural level, GCIB employs a Graph Information Bottleneck (GIB) objective to maximize mutual information between the denoised auxiliary graph and the target-behavior graph while minimizing mutual information with the original auxiliary graph. This formulation preserves task-relevant structural patterns and suppresses spurious interactions. At the feature level, we propose a cross-behavior Graph Contrastive Learning (GCL) scheme in which denoised auxiliary features and target-behavior features serve as complementary views for both users and items. By contrasting these views, GCIB enriches sparse target-behavior representations with semantics distilled from auxiliary behaviors. Extensive experiments on multiple real-world datasets demonstrate that GCIB outperforms state-of-the-art baselines, highlighting its ability to learn noise-resilient and target-aware representations for multi-behavior recommendation.

Understanding MARS: When Scaling Momentum Provably Helps
Egor Shulgin, Tamaz Gadaev, Sarit Khirirat, Peter Richtárik
MARS (Yuan et al., 2025) has recently emerged as a strong optimizer for large language model (LLM) training by scaling the correction term in momentum-based variance reduction (MVR). However, existing theory does not explain why this modification can improve convergence over the unscaled MVR choice $\gamma=1$. In this paper, we provide a theoretical explanation for this phenomenon. We introduce **γ-similarity**, a refined similarity condition that captures how the scaling coefficient interacts with the stochastic gradient-difference structure. This condition recovers standard similarity at $\gamma=1$ and smoothness at $\gamma=0$. Using γ-similarity, we derive convergence guarantees for fixed-γ MARS whose complexity depends explicitly on γ and the corresponding γ-similarity constant. The bound reveals why small values of γ can be beneficial: they may reduce the similarity term enough to outweigh the penalty from deviating from MVR. We prove that optimizing γ gives MARS a lower complexity guarantee than MVR. Experiments with MARS-AdamW on GPT-style LLM pretraining corroborate the theory, showing that properly chosen small values of γ improve token efficiency over $\gamma=1$ and AdamW under a fixed training protocol.

Stabilizing PPO via Latent-Space Regularization and KDE-Driven Exploration
Meiyu Du, Yuqing Gao, Wei Wang
Proximal Policy Optimization (PPO) is widely used in continuous-control tasks, yet its performance is often highly sensitive to training dynamics when neural networks approximate the policy and value functions. This paper introduces SPPO, a drop-in augmentation that preserves PPO’s clipped objective and network architecture while stabilizing actor-critic geometry via three mechanisms: (i) a CKA-based constraint on critic representations, (ii) a no-flip regularizer on actor updates, and (iii) KDE-driven advantage shaping. Theoretical analysis shows that these mechanisms tighten bounds on one-step bootstrapping error, improve expected directional alignment of action updates, and ensure non-decreasing occupancy mass over high-novelty regions. Experiments on standard continuous-control benchmarks demonstrate consistent gains over PPO and recent PPO stabilization methods. Ablation studies further quantify the contribution and complementary effects of each component. Additional training-dynamics analyses indicate that SPPO reduces instability and oscillations in both actor and critic updates, improving training stability and final performance.

SafeCompass: Dynamic Chain-of-Thought Steering via Inference-Time Safety Signals
Zeyang Zhang, HAOTIAN XU, Linbao Li, Qi Sun, Xuebo Liu, Yu Li, Cheng Zhuo
Large reasoning models (LRMs) achieve strong performance by explicitly generating chain-of-thought (CoT) reasoning, but this reasoning process can be manipulated by adversarial prompts.
Inference-time CoT interventions offer a simple and lightweight approach to improving safety, yet existing methods typically apply static heuristics that ignore the dynamic nature of reasoning, leading to an inherent trade-off between robustness and over-refusal.

This paper introduces *SafeCompass*, a plug-and-play framework for dynamically s teering chain-of-thought reasoning using inference-time safety signals extracted from internal states.
At different reasoning positions, *SafeCompass* derives a latent safety directio n through contrastive analysis of internal representations and uses this directi on to quantify the model’s current safety state.
These signals enable selective intervention, allowing the model’s reasoning traj ectory to be modified only when and where it becomes unsafe.
Extensive experiments demonstrate that *SafeCompass* significantly improves robu stness, reducing the average attack success rate up to $10\times$ compared to th e best baseline, while preserving general reasoning performance and minimizing o ver-refusal rates.

Learning Permutation Distributions via Reflected Diffusion on Ranks
Sizhuang He, Yangtian Zhang, Shiyang Zhang, David van Dijk
The finite symmetric group S_n provides a natural domain for permutations, yet learning probability distributions on S_n is challenging due to its factorial ly growing size and discrete, non-Euclidean structure. Recent permutation diffus ion methods define forward noising via shuffle-based random walks (e.g., riffle shuffles) and learn reverse transitions with Plackett–Luce (PL) variants, but th e resulting trajectories can be abrupt and increasingly hard to denoise as n g rows. We propose *Soft-Rank Diffusion*, a discrete diffusion framework that repl aces shuffle-based corruption with a structured soft-rank forward process: we li ft permutations to a continuous latent representation of order by relaxing discr ete ranks into soft ranks, yielding smoother and more tractable trajectories. Fo r the reverse process, we introduce *contextualized generalized Plackett–Luce (c GPL)* denoisers that generalize prior PL-style parameterizations and improve exp ressivity for sequential decision structures. Experiments on sorting and combina torial optimization benchmarks show that Soft-Rank Diffusion consistently outper forms prior diffusion baselines, with particularly strong gains in long-sequence and intrinsically sequential settings.
****

Explaining Data Mixing Scaling Laws
Rui Dai, SHURAN ZHENG
Recent research has established empirical scaling laws to predict model performa nce on multi-domain data mixtures. However, a theoretical understanding of these model loss behaviors remains absent. In this work, we propose a unified framewo rk to explain the underlying mechanics of data mixing. Our approach extends theo retical perspectives originally developed for standard neural scaling laws (e.g. , Kaplan and Chinchilla) to the multi-domain setting. Based on the distributiona l assumption that domains overlap on fundamental skills while diverging on speci alized skills, we identify two key factors that govern the domain losses of mode ls trained on different data mixtures: (1) Capacity Competition, where the allo cation of finite model capacity couples domain losses globally, and (2) Noise Re duction, where optimal weights shift toward harder-to-learn domains to minimize overall noise. Empirical evaluations show that our framework outperforms existin g baselines by fitting the loss landscape with a lower Mean Relative Error and i dentifying higher-performing training mixtures. Most importantly, our model succ essfully extrapolates across scales, predicting highly effective mixtures for la rge, unseen scales using parameters fitted on smaller ones. In addition, our mod el achieves these results using significantly fewer parameters compared to prev ious empirical laws.

DAG: A Dual Correlation Network for Time Series Forecasting with Exogenous Varia bles
Xiangfei Qiu, Yuhan Zhu, Zhengyu Li, Xingjian Wu, Bin Yang, Jilin Hu
Time series forecasting is essential in various domains. Compared to relying sol ely on endogenous variables (i.e., target variables), considering exogenous vari ables (i.e., covariates) provides additional predictive information and often le ads to more accurate predictions. However, existing methods for time series fore

casting with exogenous variables (TSF-X) have the following shortcomings: 1) they do not leverage future exogenous variables, 2) they fail to fully account for the correlation between endogenous and exogenous variables. In this study, to better leverage exogenous variables, especially future exogenous variables, we propose $\textbf{DAG}$, which $\textit{utilizes $\underline{D}$ual correl$\underline{A}$tion network along both the temporal and channel dimensions for time series forecasting with exo$\underline{G}$enous}$ variables. Specifically, we propose two core components: the Temporal Correlation Module and the Channel Correlation Module. Both modules consist of a correlation discovery submodule and a correlation injection submodule. The former is designed to capture the correlation effects of historical exogenous variables on future exogenous variables and on historical endogenous variables, respectively. The latter injects the discovered correlation relationships into the processes of forecasting future endogenous variables based on historical endogenous variables and future exogenous variables.

Credit-assigned Policy Gradient for Early Stage Retrieval in Two-stage Ranking
Haruka Kiyohara, Mihaela Curmei, Ariel Evnine, Shankar Kalyanaraman, Israel Nir, Ana-Roxana Pop, Nitzan Razin, Sarah Dean, Thorsten Joachims, Udi Weinsberg
Large-scale search, recommendation, and retrieval-augmented generation (RAG) systems typically employ a two-stage architecture: an early-stage ranker (ESR) generates a candidate set, which is subsequently re-ranked by a late-stage ranker (LSR). While there are many reinforcement learning (RL) methods for training the LSR, end-to-end training of the ESR has proven challenging. In particular, naive application of "vanilla" policy gradient (V-PG) is not scalable for candidate-set sizes relevant for practical use due to exploding variance. This issue arises because V-PG propagates the gradient to the joint probability of the candidate sets, ignoring the contribution of each specific item in the candidate set to the reward. To mitigate this issue, we propose a novel **"credit-assigned" policy gradient (CA-PG)**, which computes gradients with respect to the probability that the target item is chosen in any candidate set, i.e. marginalizing over all candidate sets that contain it. Our theoretical analysis reveals that CA-PG significantly reduces the variance of V-PG by marginalizing over the specific composition of the candidate set, while preserving the ability to learn the correct ranking of items under a reasonably aligned LSR policy. Experiments on both synthetic and real-world data demonstrate that CA-PG improves the convergence speed and training stability for ESRs utilizing the canonical Plackett-Luce model, especially when the candidate-set size is large.

Attention Sink Forges Native MoE in Attention Layers: Sink-Aware Training to Address Head Collapse
Zizhuo Fu, Wenxuan Zeng, Runsheng Wang, Meng Li
Large Language Models (LLMs) often assign disproportionate attention to the first token, a phenomenon known as the attention sink. Several recent approaches aim to address this issue, including Sink Attention in GPT-OSS and Gated Attention in Qwen3-Next. However, a comprehensive analysis of the relationship among these attention mechanisms is lacking. In this work, we provide both theoretical and empirical evidence demonstrating that the sink in Vanilla Attention and Sink Attention naturally construct a Mixture-of-Experts (MoE) mechanism within attention layers. This insight explains the head collapse phenomenon observed in prior work, where only a fixed subset of attention heads contributes to generation. To mitigate head collapse, we propose a sink-aware training algorithm with an auxiliary load balancing loss designed for attention layers. Extensive experiments show that our method achieves effective head load balancing and improves model performance across Vanilla Attention, Sink Attention, and Gated Attention. We hope this study offers a new perspective on attention mechanisms and encourages further exploration of the inherent MoE structure within attention layers.

A Direct Second-Order Method for Solving Two-Player Zero-Sum Games
David Yang, Yuan Gao, Tianyi Lin, Christian Kroer
We introduce, to our knowledge, the first direct second-order method for computi

ng Nash equilibria in two-player zero-sum games. To do so, we construct a Dougla s-Rachford-style splitting formulation, which we then solve with a semi-smooth N ewton (SSN) method. We show that our algorithm enjoys local superlinear converge nce. To augment the fast local behavior of our SSN method with global efficiency guarantees, we develop a hybrid method that combines our SSN method with the st ate-of-the-art first-order method for game solving, Predictive Regret Matching (PRM$^+$). Our hybrid algorithm leverages the global progress provided by PRM$^+$ while achieving a local superlinear convergence rate once it switches to SSN ne ar a Nash equilibrium. Numerical experiments on matrix games demonstrate order-o f-magnitude speedups over PRM$^+$ for high-precision solutions.

Unveiling the Role of Data Uncertainty in Tabular Deep Learning
Nikolay Kartashev, Ivan Rubachev, Artem Babenko
Recent advancements in tabular deep learning have demonstrated exceptional pract ical performance, yet the field often lacks a clear understanding of why these t echniques actually succeed. To address this gap, our paper highlights the import ance of the concept of data (aleatoric) uncertainty for explaining the effective ness of recent tabular DL methods. While data uncertainty leads to irreducible p rediction errors on test samples, it also introduces stochasticity into the trai ning signal that can impede effective learning. We demonstrate that tabular meth ods differ significantly in their ability to cope with this optimization challen ge. Specifically, we reveal that the success of many beneficial design choices i n tabular DL, such as numerical feature embeddings, advanced ensembling strategi es, retrieval-augmented models, and tabular Prior-Fitted Networks, can be partia lly attributed to their respective implicit mechanisms for performing well under high data uncertainty. By dissecting these varied mechanisms, we provide a unif ying understanding of recent performance improvements.
Furthermore, leveraging insights from this perspective, we design a novel, more effective numerical feature embedding method as an immediate practical outcome o f our analysis. Overall, our work paves the way toward a principled understandin g of the benefits introduced by modern tabular methods that results in the concr ete advancements of existing techniques and outlines future research directions for tabular DL.

Multimarginal flow matching with optimal transport potentials
Raghav Kansal, David Crair, Nghia D. Nguyen, Scott D Pope, Bradley R Parry
Flow matching (FM) has emerged as a powerful framework for learning dynamic tran sport maps between two empirical distributions.
However, less explored is the setting with intermediate observed marginals that can help constrain the flows between the endpoints.
This "multimarginal" regime is central to modeling temporal evolution in dynamic al systems in many scientific domains that can sample sequential distributions.
We tackle this problem with a novel approach that leverages the connection betwe en FM and dynamic optimal transport (OT),
softly steering the flow towards the intermediate marginals through potential te rms in the dynamic OT action.
By extending the conditional FM learning target to incorporate these potentials, we derive an efficient,
simulation-free algorithm for multimarginal FM that offers considerable flexibil ity in the spatiotemporal dynamics of the learned flows.
We demonstrate state-of-the-art performance and training efficiency of OT-potent ial FM (OTP-FM) on diverse single-cell RNA sequencing, oceanographic, and meteor ological datasets.

When Tabular Foundation Models Meet Strategic Tabular Data: A Prior Alignment Ap proach
Xinpeng Lv, Yunxin Mao, Renzhe Xu, Chunyuan Zheng, Yikai Chen, Haoxuan Li, Jinxu an Yang, Yuanlong Chen, Kun Kuang, Mingyang Geng, Shixuan Liu, Wanrong Huang, Sh aowu Yang, Wenjing Yang, Zhouchen Lin, Haotian Wang
Tabular foundation models based on pretrained prior-data fitted networks (PFNs)

have shown strong generalization on diverse tabular tasks, but they are typicall y designed for non-strategic settings where data distributions are independent o f deployed classifiers. In many real-world decision scenarios, however, individu als may strategically modify their features after deployment to obtain favorable outcomes, inducing a post-deployment distribution shift. This paper studies whe ther PFN-style tabular foundation models can generalize to such strategic tabula r data. We show that strategic manipulation creates a fundamental mismatch betwe en the non-strategic prior learned during pretraining and the post-manipulation strategic prior encountered at deployment, which leads to an irreducible structu ral prediction bias. To address this issue, we propose the Strategic Prior-data Fitted Network (SPN), an inference-time strategy-aware framework that adapts tab ular foundation models to strategic environments without retraining or architect ural modification. SPN constructs strategic in-context examples to approximate p ost-manipulation inputs and aligns PFN predictions with the induced strategic di stribution via in-context learning, with theoretical guarantees on bias reductio n. Experiments on real-world and synthetic tabular datasets show that SPN consis tently improves robustness and predictive performance under strategic manipulati on compared with both tabular foundation models and classical tabular methods.

Fine-Tuning Without Forgetting In-Context Learning: A Theoretical Analysis of Li near Attention Models

Chungpa Lee, Jy-yong Sohn, Kangwook Lee

Transformer-based large language models exhibit in-context learning, enabling ad aptation to downstream tasks via few-shot prompting with demonstrations. In prac tice, such models are often fine-tuned to improve zero-shot performance on downs tream tasks, allowing them to solve tasks without examples and thereby reducing inference costs. However, fine-tuning can degrade in-context learning, limiting the performance of fine-tuned models on tasks not seen during fine-tuning. Using linear attention models, we provide a theoretical analysis that characterizes h ow fine-tuning objectives modify attention parameters and identifies conditions under which this leads to degraded few-shot performance. We show that fine-tunin g all attention parameters can harm in-context learning, whereas restricting upd ates to the value matrix improves zero-shot performance while preserving in-cont ext learning. We further show that incorporating an auxiliary few-shot loss enha nces in-context learning primarily on the target task, at the expense of degrade d in-context learning ability on tasks not seen during fine-tuning. We provide e mpirical evidence from synthetic and real-world datasets consistent with the qua litative predictions of our theory.

Full-Spectrum Graph Neural Networks: Expressive and Scalable

Xiaohan Wang, Deyu Bo, Longlong Li, Kelin Xia

It is well established that spectral graph neural networks (GNNs) can universall y approximate node signals; however, their expressive power remains bounded by t he 1-dimensional Weisfeiler-Lehman test, which is mirrored in their lack of univ ersality for higher-order signals. To go beyond this bound, we propose the Full-Spectrum GNNs (FSpecGNNs), a second-order generalization of classical spectral G NNs. FSpecGNN advances spectral filtering from two perspectives: (1) it lifts si gnals from the node domain to the node-pair domain; and (2) it extends the univa riate spectral filter over eigenvalues to a bivariate filter over eigenvalue pai rs.

We show that classical spectral GNNs arise as a diagonal special case of FSpecGN Ns, and prove that FSpecGNNs can be at most as expressive as Local 2-GNN while u niversally approximating node-pair signals, the latter being particularly benefi cial for heterophilic graph learning. Moreover, FSpecGNNs admit scalable impleme ntations that avoid explicit node-pair-level computations; combined with a low-r ank approximation that reduces full-spectrum convolution to a combination of pol ynomial spectral filters, it enables learning on large graphs. Empirically, FSpe cGNNs validate the predicted expressivity on substructure-counting benchmarks an d delivers strong performance on heterophilic benchmarks. Our code is available at https://github.com/xwangxshi/FSpecGNN.

Trajectory-Stabilized Inference for Diffusion-Based Video Inpainting
Zhanhe Zhang, Jiahua Li, Xu Yang, Kun Wei, Cheng Deng
Video inpainting aims to restore missing regions while preserving spatial and te
mporal coherence. Diffusion-based methods achieve strong per-frame reconstructio
n, but their sampling implicitly generates temporally coupled latent trajectorie
s whose long-horizon stability is not explicitly modeled, leading to a trade-off
 between temporal consistency and structural detail. We revisit video inpainting
 from the perspective of temporal trajectory stability, viewing temporal inconsi
stency as instability along time-indexed denoising trajectories rather than an o
utput-level error. Based on this view, we propose an inference-time trajectory s
tabilization framework that monitors motion-aligned deviation and triggers risk-
aware correction only when instability accumulates. It combines sparsely sampled
 trajectory anchors as stability references with neighborhood-consistent propaga
tion to regulate trajectory evolution while preserving local generative freedom.
 Implemented as a lightweight control layer in the sampling loop, it selectively
 contracts unstable trajectories toward motion-consistent manifolds instead of e
nforcing uniform temporal constraints. Experiments show consistent improvements
in temporal coherence and structural fidelity.

Embedding Hybrid Systems into Continuous Latent Vector Fields
Sangli Teng, Hang Liu, Koushil Sreenath
This work proves that an n-dimensional hybrid system can be embedded into an $
m$-dimensional Euclidean space equipped with a continuous vector field on its em
bedded image whenever $m>2n$. This result suggests that an *intrinsically* disco
ntinuous hybrid system generically admits a continuous *extrinsic* representatio
n that is well-posed for differentiable optimization.
Building on this existence theorem, we show that a latent Neural ODE with consis
tency loss in both the latent and state space can accurately recover the flow of
 hybrid systems. Extensive experiments suggest the proposed method outperforms t
he existing method in learning hybrid systems with varying geometries from only
time series data.

VSCD: Video-based Scene Change Detection in Unaligned Scenes
Jiae Yoon, Ue-Hwan Kim
Detecting what has changed in an environment is essential for long-term autonomy
, yet most change detection settings assume fixed viewpoints, mild misalignment,
 or only a few changed objects. We introduce Video-based Scene Change Detection
(VSCD), which predicts a pixel-wise change mask for each query frame, given a re
ference and a query RGB video of the same indoor space recorded at different tim
es under unconstrained camera motion. The two videos are not temporally synchron
ized, and many object instances may appear or disappear. To study this setting,
we build a large-scale benchmark with over 1.1 million frames annotated with pix
el-accurate change masks, together with a real-world test set for evaluating tra
nsfer beyond simulation. We propose a query-centric multi-reference model that l
earns temporal matching implicitly from change-mask supervision, aligns candidat
e reference features to the query via local patch correspondence, and fuses per-
candidate change features using frame-level and patch-level confidence before de
coding a high-resolution mask once per frame. Our approach achieves state-of-the
-art performance against strong image- and video-based baselines, and we validat
e its real-world impact by deploying it on a mobile robot for two downstream app
lications—visual surveillance and object incremental learning.

AIR: Post-training Data Selection for Reasoning via Attention Head Influence
Jinrui Liu, Kai Hua, Xuanguang Pan, Ge Zhang, Yong Wang, Shuai Ma, Chongyang Tao
LLMs achieve remarkable multi-step reasoning capabilities, yet effectively trans
ferring these skills via post-training distillation remains challenging. Existin
g data selection methods, ranging from manual curation to heuristics based on le
ngth, entropy, or overall loss, fail to capture the causal importance of individ
ual reasoning steps, limiting distillation efficiency. To address this, we propo

se Attention Influence for Reasoning (AIR), a principled, unsupervised and train ing-free framework that leverages mechanistic insights of the retrieval head to select high-value post-training data. AIR first identifies reasoning-critical at tention heads of an off-the-shelf model, then constructs a weakened reference mo del with disabled head influence, and finally quantifies the resulting loss dive rgence as the Attention Influence Score. This score enables fine-grained assessm ent at both the step and sample levels, supporting step-level weighted fine-tuni ng and global sample selection. Experiments across multiple reasoning benchmarks show that AIR consistently improves reasoning accuracy, surpassing heuristic ba selines and effectively isolating the most critical steps and samples. Our work establishes a mechanism-driven, data-efficient approach for reasoning distillati on in LLMs.

Think Twice Before You Act: Protecting LLM Agents Against Tool Description Poiso ning via Isolated Planning
Shanghao Shi, Xiao Wang, Chaoyu Zhang, Hao Li, Wenjing Lou, Thomas Hou, Yevgeniy Vorobeychik, Chongjie Zhang, Ning Zhang
The integration of external tools has substantially expanded the capabilities of large language model (LLM) agents, but it also introduces new attack surfaces b eyond prompt injection. In particular, cross-tool description poisoning can mani pulate planner-visible tool metadata to steer an agent’s trajectory, even if the poisoned tool itself is never chosen. To understand the effectiveness of existi ng defenses against this emerging threat, we first evaluate several prompt-injec tion defenses and find that they transfer poorly to cross-tool description poiso ning. A key observation is that poisoned descriptions persist in the planning co ntext across steps, enabling continuous influence over subsequent tool choices. Building on this insight, we propose Tool-Guard, a novel system-level defense ba sed on a new concept called *isolated planning*, in which tool invocations that are detected as misaligned or suspicious cause the corresponding tool to be plac ed in a quarantined list (the *influenced list*), breaking further influence fro m poisoned descriptions. With this influence isolated, the tool can continue to be used to support the task, enabling a robust defense that preserves legitimate tool utility. Experiments on the AgentDojo and ASB benchmarks show that Tool-Gu ard substantially reduces attack success while maintaining high task utility. Ou r code is available at https://github.com/shishishi123/Tool-Guard.

Reinforcement Learning with Action-Triggered Observations
Alexander Ryabchenko, Wenlong Mou
We introduce Action-Triggered Sporadically Traceable Markov Decision Processes (ATST-MDPs), a reinforcement learning framework for partial observability in whic h full state observations occur stochastically at each step, with probability de termined by the chosen action. We derive Bellman equations tailored to this sett ing and establish the existence of an optimal policy. Exploiting the fact that s poradic observations reveal the full state, we provide an equivalent formulation in which agents commit to action-sequences between consecutive observations. Un

der the linear MDP assumption, we show that the value function over such action-sequences admits a linear representation in a finite-dimensional feature map, enabling standard regression-based methods. As an application, we derive ATST-LSVI-UCB, an optimistic algorithm achieving regret $\widetilde{O}(\sqrt{Kd^3(1-\gamma)^{-3}})$ for episodic learning with geometrically distributed horizons, where K is the number of episodes, d the feature dimension, and γ the discount factor (episode continuation probability), matching the known rate for linear MDPs with full observability.

Flow Equivariant World Models: Structured Memory for Dynamic Environments

Hansen Lillemark, Benhao Huang, Fangneng Zhan, Yilun Du, T. Anderson Keller

Embodied systems experience the world as 'a symphony of flows': a combination of many continuous streams of sensory input coupled to self-motion, interwoven with the dynamics of external objects. These sensory streams and the underlying dynamics of the world obey smooth, time-parameterized symmetries which existing world models ignore. Without a memory that respects this structure, partial observability presents a major obstacle to existing methods: each observation reveals only a fraction of the world, while unobserved regions continue to evolve. In this work, we introduce Flow Equivariant World Modeling, a framework that leverages time-parameterized symmetries within a latent memory for stable and accurate dynamics prediction over long horizons. The latent memory shifts and transforms equivariantly with self-motion and inferred external object motion, keeping information about out-of-view regions aligned as time progresses. We demonstrate the advantage of this framework over state-of-the-art diffusion, memory-augmented, and recurrent world model architectures on 2D and 3D partially observed video world modeling benchmarks.

More broadly, our results suggest that predictive representations become more powerful when they are organized in line with the temporal and dynamical structure of the world they model. Project page: https://flowequivariantworldmodels.github.io/

Turning Drift into Constraint: Robust Reasoning Alignment in Non-Stationary Multi-Stream Environments

Xiaoyu Yang, En Yu, Wei Duan, Jie Lu

This paper identifies a critical yet underexplored challenge in reasoning alignment from multiple multi-modal large language models (MLLMs): In non-stationary environments, the diverse reasoning distributions of source models often evolve unpredictably, transmitting systematic biases and drift to the target model. To address this, we formulate multi-source reasoning alignment as a constraint satisfaction problem under concept drift theory. We propose Autonomous Preference Optimization (APO), a novel framework that treats inter-model divergences not as noise, but as dynamic negative constraints. APO operates via a two-stage protocol: first, supervised bootstrapping projects the target model into the capability union of source models; second, constraint-aware optimization synthesizes a consistent consensus manifold by explicitly suppressing drifting trajectories via a multi-negative Plackett-Luce objective. Extensive experiments on chest X-ray interpretation demonstrate that our 7B model achieves superior robustness, outperforming even proprietary source models in average accuracy. Furthermore, we release CXR-MAX, a large-scale benchmark comprising 170,982 reasoning trajectories from seven large-scale MLLMs to facilitate research on reasoning alignment under drift. Code and data are available at: https://github.com/XiaoyuYoung/APO.

Towards High-Fidelity CAD Generation via LLM-Driven Program Generation and Text-Based B-Rep Primitive Grounding

Jiahao Li, Qingwang Zhang, Qiuyu Chen, Guozhan Qiu, Yunzhong Lou, Xiangdong Zhou

The field of Computer-Aided Design (CAD) generation has made significant progress in recent years.

Existing methods typically fall into two separate categories: parametric CAD modeling and direct boundary representation (B-Rep) synthesis.

In modern feature-based CAD systems, parametric modeling and B-Rep are inherentl

y intertwined, as advanced parametric operations (e.g., *fillet* and *chamfer*) require explicit selection of B-Rep geometric primitives, and the B-Rep itself is derived from parametric operations.
Consequently, this paradigm gap remains a critical factor limiting AI-driven CAD modeling for complex industrial product design.
This paper presents *FutureCAD*, a novel text-to-CAD framework that leverages large language models (LLMs) and a B-Rep grounding transformer (*BRepGround*) for high-fidelity CAD generation.
Our method generates executable CadQuery scripts, and introduces a text-based query mechanism that enables the LLM to specify geometric selections via natural language, which *BRepGround* then grounds to the target primitives.
To train our framework, we construct a new dataset comprising real-world CAD models.
For the LLM, we apply supervised fine-tuning (SFT) to establish fundamental CAD generation capabilities, followed by reinforcement learning (RL) to improve generalization.
Experiments show that *FutureCAD* achieves state-of-the-art CAD generation performance.
Code and dataset are available at https://github.com/JohanStackk/FutureCAD.

Transformers Can Learn Posterior Predictive Distributions In-Context
Gyeonghun Kang, Changwoo J. Lee, Xiang Cheng
Prior-data fitted networks (PFNs) have recently emerged as a powerful approach for Bayesian prediction tasks, approximating the posterior predictive distribution (PPD) through in-context learning. Despite their strong empirical performance and ability to go beyond point predictions, theoretical understandings of the algorithmic capability of transformers to learn distributions in context are still lacking. Focusing on Gaussian process regression problems, we show by construction that transformers can implement a gradient descent algorithm targeting the posterior predictive mean and variance, followed by nonlinear mappings that yield binned probabilities of PPD. We study the error bounds of the approximated PPD in terms of attention depth and bin resolution. Based on these results, we further demonstrate the key role of normalization and the choice of attention depth in enabling the extrapolation abilities of transformers beyond the pretraining sample size range. We conduct simulations that corroborate our findings, providing insight into the expressivity of PFNs targeting PPDs and how architectural choices may influence generalization capabilities.
****

LLM Self-Recognition: Steering and Retrieving Activation Signatures
Thibaud Ardoin, Jonas Schäfer, Gerhard Wunder
Recent advances in interpretability suggest that large language models (LLMs) implicitly encode signals in their generated text that enable self-recognition of their outputs. We demonstrate that this capability is reliable, even in low-entropy scenarios, and that it can be amplified through targeted intervention. By steering the internal residual stream during generation with a random sparse vector, we create a detectable fingerprint that enables attribution of a given text to a specific LLM. This signal is recoverable from the activations of an LLM used as a detector, achieving over 98% accuracy across multiple detection settings while preserving the quality of generated text. As AI-generated content proliferates, this approach offers a practical alternative to traditional detectors, by leveraging the model's natural representation structure for attribution rather than embedding a signal externally. Our contributions include: (i) establishing reliable self-recognition capabilities in LLMs, (ii) a simple steering mechanism enabling multi-LLM identification with no quality degradation, (iii) demonstrating that activation spaces contain exploitable structure for encoding signals without semantic interference.

Grounding LLMs in Scientific Discovery via Embodied Actions
Bo Zhang, Jinfeng Zhou, Yuxuan Chen, Jianing Yin, Minlie Huang, Hongning Wang
Large Language Models (LLMs) have shown significant potential in scientific disc

overy but struggle to bridge the gap between theoretical reasoning and verifiable physical simulation. Existing solutions operate in a passive "execute-then-response" loop and thus lack runtime perception, obscuring agents to transient anomalies (e.g., numerical instability or diverging oscillations). To address this limitation, we propose EmbodiedAct, a framework that transforms established scientific software into active embodied agents by grounding LLMs in embodied actions with a tight perception-execution loop. We instantiate EmbodiedAct within MATLAB and evaluate it on complex engineering design and scientific modeling tasks. Extensive experiments show that EmbodiedAct significantly outperforms existing baselines, achieving SOTA performance by ensuring satisfactory reliability and stability in long-horizon simulations and enhanced accuracy in scientific modeling.
****
Causal Identification from Counterfactual Data: Completeness and Bounding Results
Arvind Raghavan
Previous work establishing completeness results for *counterfactual identification* has been limited to the setting where the input data belongs to observational and interventional distributions (Layers 1 and 2 of Pearl's Causal Hierarchy), since it was generally presumed impossible to obtain data from counterfactual distributions, belonging to Layer 3. However, recent work (Raghavan & Bareinboim, 2025) has formally characterized a family of counterfactual distributions which can be directly estimated via experimental methods - a notion they call *counterfactual realizabilty*. This leaves open the question of what *additional* Layer 3 quantities now become identifiable, given this new access to (some) Layer 3 data. We develop the **ctfIDu+** algorithm for identifying a counterfactual query from an arbitrary set of Layer 3 data, and prove that it is complete for this task. Using this, we establish the theoretical limit of which counterfactuals can be identified from physically realizable data, thus implying the *fundamental limit to exact causal inference in the non-parametric setting*. Finally, we derive novel analytic bounds for important non-identifiable quantities given realizable counterfactual data, that are provably tighter than the previously established benchmark. We corroborate using simulations that even if a quantity is non-identifiable, counterfactual data can be used to further tighten bounds for its range.
****
A Recursive Decomposition Framework for Causal Structure Learning in the Presence of Latent Variables
Zheng Li, Feng Xie, Shenglan Nie, Xichen Guo, Ruxin Wang, Hao Zhang
Constraint-based causal discovery is widely used for learning causal structures, but heavy reliance on conditional independence (CI) testing makes it computationally expensive in high-dimensional settings.
To mitigate this limitation, many divide-and-conquer frameworks have been proposed, but most assume causal sufficiency, i.e., no latent variables.
In this paper, we show that divide-and-conquer strategies can be theoretically generalized beyond causal sufficiency to settings with latent variables.
Specifically, we propose a recursive decomposition framework, termed DiCoLa, that enables divide-and-conquer causal discovery in the presence of latent variables. It recursively decomposes the global learning task into smaller subproblems and integrates their solutions through a principled reconstruction step to recover the global structure.
We theoretically establish the soundness and completeness of the proposed framework. Extensive experiments on synthetic data demonstrate that our approach significantly improves computational efficiency across a range of causal discovery algorithms, while experiments on a real-world dataset further illustrate its practical effectiveness.
****
LIFT: A Novel Framework for Enhancing Long-Context Understanding of LLMs via Long Input Fine-Tuning
Yansheng Mao, Yufei Xu, Jiaqi Li, Fanxu Meng, Haotong Yang, Zilong Zheng, Xiyuan Wang, Muhan Zhang

Long-context understanding remains challenging for LLMs due to limited context windows. This paper introduces **Long Input Fine-Tuning (LIFT)**, a framework that improves the long-context performance of arbitrary short-context LLMs by dynamically adapting their parameters to each long input. Instead of endlessly extending context windows to fit longer inputs **in context**, LIFT stores and absorbs the input **in parameters**. By fine-tuning long inputs into parameters, LIFT enables short-context LLMs to answer questions even when required information is absent from the inference context, avoiding the quadratic input-length complexity of standard long-context models. Rather than simple continued pretraining on new long contexts, LIFT uses carefully designed LLM-generated synthetic tasks to enhance comprehension beyond memorization. To offset fine-tuning overhead, we design a highly optimized pipeline that reduces Time to First Token (TTFT) to under 10 seconds for 8k context. We further analyze LIFT's strengths and limitations, discuss large-scale deployment feasibility, and highlight future research directions. Implementation is open-sourced at https://github.com/MuLabPKU/LIFT.

When to Think, When to Speak: Learning Disclosure Policies for LLM Reasoning
Jiaqi Wei, Xuehang Guo, Pengfei Yu, Xiang Zhang, Wanli Ouyang, Siqi Sun, Qingyun Wang, Chenyu You
In single-stream autoregressive interfaces, the same tokens both update the model state and constitute an irreversible public commitment.
This coupling creates a \emph{silence tax}: additional deliberation postpones the first \emph{task-relevant} content, while naive early streaming risks premature commitments that bias subsequent generations.
We introduce \textbf{\emph{Side-by-Side (SxS)}} Interleaved Reasoning, which makes \emph{disclosure timing} a controllable decision within standard autoregressive generation.
SxS interleaves partial disclosures with continued private reasoning in the same context, but releases content only when it is \emph{supported} by the reasoning so far.
To learn such pacing without incentivizing filler, we construct entailment-aligned interleaved trajectories by matching answer prefixes to supporting reasoning prefixes, then train with SFT to acquire the dual-action semantics and RL to recover reasoning performance under the new format.
Across two Qwen3 architectures/scales (MoE \textbf{Qwen3-30B-A3B}, dense \textbf{Qwen3-4B}) and both in-domain (AIME25) and out-of-domain (GPQA-Diamond) benchmarks, SxS improves accuracy--\emph{content-latency} Pareto trade-offs under token-level proxies (e.g., inter-update waiting).
****

Search-R2: Enhancing Search-Integrated Reasoning via Actor-Refiner Collaboration
Bowei He, Minda Hu, Zenan Xu, Hongru WANG, Licheng Zong, Yankai Chen, Chen Ma, Xue Liu, Pluto Zhou, Irwin King
Search-integrated reasoning enables language agents to transcend static parametric knowledge by actively querying external sources. However, training these agents via reinforcement learning is hindered by the *multi-scale credit assignment* problem: existing methods typically rely on sparse, trajectory-level rewards that fail to distinguish between high-quality reasoning and fortuitous guesses, leading to redundant or misleading search behaviors. To address this, we propose Search-R2, a novel Actor–Refiner collaboration framework that enhances reasoning through targeted intervention, with both components jointly optimized during training. Our approach decomposes the generation process into an Actor, which produces initial reasoning trajectories, and a Meta-Refiner, which selectively diagnoses and repairs flawed steps via a ``cut-and-regenerate'' mechanism. To provide fine-grained supervision, we introduce a hybrid reward design that couples outcome correctness with a dense process reward quantifying the information density of retrieved evidence. Theoretically, we formalize the Actor–Refiner interaction as a smoothed mixture policy, proving that selective correction yields strict performance gains over strong baselines. Extensive experiments across various general and multi-hop QA datasets demonstrate that Search-R2 consistently outperform

s strong RAG and RL-based baselines across model scales, achieving superior reas
oning accuracy with minimal overhead.

Talk, Judge, Cooperate: Gossip-Driven Indirect Reciprocity in Self-Interested LL
M Agents
Shuhui Zhu, Yue Lin, Shriya Kaistha, Wenhao Li, Baoxiang Wang, Hongyuan Zha, Gil
lian K Hadfield, Pascal Poupart
Indirect reciprocity, which means helping those who have helped others, is diffi
cult to sustain among decentralized, self-interested LLM agents without reliable
 reputation systems. We address this challenge with the Agentic LInguistic Gossi
p Network (ALIGN), an automated framework that enables decentralized agents to f
orm reputations, evaluate trustworthiness, and coordinate social norms by strate
gically sharing open-ended gossip with hierarchical tones. We demonstrate that A
LIGN consistently improves indirect reciprocity and resists malicious entrants b
y identifying and ostracizing defectors. Notably, we find that stronger
reasoning capabilities in LLMs lead to more incentive-aligned cooperation,
whereas chat models often over-cooperate even when strategically
suboptimal. These results suggest that leveraging LLM reasoning through decentra
lized
gossip is a promising path for maintaining social welfare in agentic ecosystems.
Our code is available at \url{https://github.com/shuhui-zhu/ALIGN}.

Singularity-aware Optimization via Randomized Geometric Probing: Towards Stable
Non-smooth Optimization
Ruoran Xu, Borong She, Xiaobo Jin, Qiufeng Wang
Deep learning optimization relies heavily on the assumption of smooth loss lands
capes, a condition systematically violated by modern architectures due to non-sm
ooth components like ReLU activations and quantization operators. In such non-sm
ooth regimes, adaptive optimizers such as Adam suffer from **gradient chattering
**—violent oscillations caused by conflicting signals within the Clarke subdiffe
rential—leading to poor convergence and suboptimal generalization. To address th
is, we introduce **Singularity-aware Adam (S-Adam)**, a novel optimizer that sta
bilizes training by dynamically modulating step sizes based on local geometric i
nstability. Our key contribution is the **Local Geometric Instability (LGI)** me
tric, a computationally efficient estimator of the Clarke subdifferential diamet
er derived from the variance of randomized directional derivatives. S-Adam incor
porates an adaptive damping mechanism $\exp(-\lambda \rho_t)$ that decelerates u
pdates in high-instability regions while preserving fast convergence in smooth b
asins. We provide a rigorous convergence analysis using differential inclusions,
 proving that S-Adam converges almost surely to (δ, ϵ)-Clarke stat
ionary points at the optimal $\mathcal{O}(1/\sqrt{T})$ rate. Empirical evaluatio
ns on Quantization-Aware Training (QAT) and high-noise small-batch learning demo
nstrate that S-Adam consistently outperforms AdamW and Prox-SGD, achieving accur
acy gains of up to +6% on CIFAR-100 and +3% on TinyImageNet while effectively mi
tigating gradient oscillations.

CARE: Adaptive Calibration for Reliable Recommendations
Nitin Bisht, Huan Huo, Xiuwen Gong, Guandong Xu
Modern recommender systems are typically trained offline and deployed with param
eters held fixed between periodic refreshes, yet user behavior can evolve substa
ntially during deployment. This can cause ranking utility to degrade over time a
nd makes it difficult to provide formal guarantees about recommendation quality.
 We propose **CARE**, an adaptive calibration framework that wraps an arbitrary
backbone recommender and outputs variable-size recommendation sets with finite-s
ample performance guarantees over interaction streams. CARE combines (i) a loss-
based monitoring module that localizes behavioral changes and triggers threshold
 recalibration, and (ii) an online aggregation rule that promotes compact recomm
endation sets by dynamically reweighting candidate set predictors. We provide th
eoretical results establishing finite-sample guarantees for utility-based risk c
ontrol and bounds on the expected set size relative to the best constituent pred

ictor. Experiments across multiple datasets and backbone models demonstrate that CARE improves robustness and maintains compact recommendation sets while preserving the desired statistical guarantees. The code and implementation are available in https://github.com/kalpiree/CARE.

A Narrowing Geometry in Contaminated Reasoning
Jiakuan Xie, Pengfei Cao, Kang Liu, Jun Zhao
Despite the advancing reasoning capabilities of large language models (LLMs), many reasoning evaluations are increasingly compromised by data contamination, which induces unreliable **contaminated reasoning** on leaked inputs.
While this phenomenon is widely observed, its underlying mechanism remains poorly understood, hindering the ability to distinguish generalization from memorization and to develop effective solutions.
In this work, we first identify a distinctive signal of contaminated reasoning, namely the mutual information decay between representations and gradients.
Our mechanistic analysis reveals that contaminated models exhibit pronounced eigenspectrum concentration in their representations, leading to a low-dimensional computation regime.
Under leaked inputs, this mechanism weakens the linear coupling between representations and gradients, manifested as a structural decay of the singular values in the whitened space.
We show that this narrowing geometry mathematically implies a reduction in mutual information, and further demonstrate the practical utility of our analysis by successfully restoring the reasoning behavior of contaminated models, achieving up to an 11.03% absolute improvement in average consistency with the base model over the strongest baseline. Our code is available at https://github.com/jiakuan929/ContamReasoning.

CyberGym-E2E: Scalable Real-World Benchmark for AI Agents' End-to-End Cybersecurity Capabilities
Tianneng Shi, Robin Rheem, Dongwei Jiang, Mona Wang, Francisco De La Riega, Zhun Wang, Jingzhi Jiang, Alexander Cheung, Sean Tai, Jonah Cha, Jianhong Tu, Gabriel Han, Chenguang Wang, Jingxuan He, Wenbo Guo, Dawn Song
AI has the potential to transform cybersecurity by enabling systems that can autonomously detect, analyze, and remediate software vulnerabilities. However, existing cybersecurity evaluations of AI systems are limited in scale or scope, and fail to capture the end-to-end lifecycle of real-world software vulnerability discovery and remediation. To address this gap, we propose CyberGym-E2E, a large-scale and realistic end-to-end cybersecurity benchmark that comprehensively evaluates AI agents' abilities across the full lifecycle of vulnerability discovery, PoC generation, and patch generation. CyberGym-E2E is comprehensive and scalable, as we build an automated, agent-enhanced pipeline for transforming open-source vulnerability data into realistic evaluation environments. Currently, the benchmark consists of 920 real-world vulnerabilities across 139 different open-source projects.

The Decrypto Benchmark for Multi-Agent Reasoning and Theory of Mind
Andrei Lupu, Timon Willi, Jakob Nicolaus Foerster
As Large Language Models (LLMs) gain agentic abilities, they will have to navigate complex multi-agent scenarios, interacting with human users and other agents in cooperative and competitive settings. This will require new reasoning skills, a crucial one being theory of mind (ToM), or the ability to reason about the ``mental'' states of other agents. However, ToM and other multi-agent abilities in LLMs are poorly understood, since existing benchmarks suffer from narrow scope, data leakage, saturation, and lack of interactivity. We thus propose Decrypto, a game-based benchmark for multi-agent reasoning and ToM drawing inspiration from cognitive science, computational pragmatics and multi-agent reinforcement learning. It is designed to be as easy as possible in all other dimensions, eliminating confounding factors common in other benchmarks. To our knowledge, it is also the first platform that isolates ToM evaluation in an interactive setting.

We validate the benchmark design through comprehensive empirical evaluations of frontier LLMs, robustness studies, and human-AI cross-play experiments. We find that LLMs lag behind humans and simple word-embedding baselines on key game metrics. We then create variants of two classic cognitive science experiments within Decrypto to evaluate three distinct ToM abilities. Surprisingly, our results show that state-of-the-art reasoning models are significantly worse at those tasks than their older counterparts. This demonstrates that Decrypto addresses a crucial gap in current reasoning and ToM evaluations, and paves the path towards better artificial agents. Code at https://github.com/facebookresearch/decrypto.

Concept Heterogeneity-aware Representation Steering
Laziz Abdullaev, Noelle Y. L. Wong, Ryan Lee T. Z., Shiqi Jiang, Minh-Khoi Nguyen-Nhat, Tan Minh Nguyen
Representation steering offers a lightweight mechanism for controlling the behavior of large language models (LLMs) by intervening on internal activations at inference time. Most existing methods rely on a single global steering direction, typically obtained via difference-in-means over contrastive datasets. This approach implicitly assumes that the target concept is homogeneously represented across the embedding space. In practice, however, LLM representations can be highly non-homogeneous, exhibiting clustered, context-dependent structure, which renders global steering directions brittle. In this work, we view representation steering through the lens of optimal transport (OT), noting that standard difference-in-means steering implicitly corresponds to the OT map between two identical distributions with differing first moments, yielding a global translation. To relax this restrictive assumption, we theoretically model source and target representations as Gaussian mixture models and formulate steering as a discrete OT problem between semantic latent clusters. From the resulting transport plan, we derive an explicit, input-dependent steering map via barycentric projection, producing a smooth, kernel-weighted combination of cluster-level shifts. We term this method Concept Heterogeneity-aware Representation Steering (CHaRS). Through numerous experimental settings, we show that CHaRS yields more effective behavioral control than global steering. The code is publicly available at https://github.com/lazizcodes/CHaRS.

STAR: Rethinking MoE Routing as Structure-Aware Subspace Learning
Sumin Park, Noseong Park
Mixture-of-Experts (MoE) scales model capacity efficiently by selectively routing inputs to a specialized subset of experts. However, input-expert specialization, the core motivation of MoE, critically depends on whether the router is actually aware of input structure. In practice, MoE routing is typically implemented as a shallow linear projection with limited awareness of input representation, which often leads to unstable routing. We propose STAR, a Structure Aware Routing that rethinks MoE routing as a subspace learning problem by augmenting standard learnable routing with an evolving principal subspace that tracks dominant input structure via Generalized Hebbian Algorithm (GHA). By aligning routing decisions directly with input structure, STAR enables stable expert specialization. We evaluate STAR on controlled synthetic setup and large-scale language and vision tasks, where it consistently improves routing quality and downstream performance over strong MoE baselines. Moreover, optional test-time subspace updates further enhance routing robustness and generalization under input distribution shifts. Code is available at \url{https://github.com/psmiz/STAR}.

Rethinking Calibration for Early-Exit Neural Networks
Piotr Kubaty, Filip Szatkowski, Grzegorz Choczy■ski, Eric Nalisnick, Bartosz Wójcik
Early-exit neural networks (EENNs) accelerate inference by allowing intermediate classifiers to stop computation once predictions are confident enough.
Most methods rely on confidence thresholds for exiting, and consequently, improving classifier calibration is widely assumed to improve performance.
In this work, we challenge this assumption and show that calibration alone is no

t sufficient for EENNs to exploit adaptive computation. To address this insuffic iency, we introduce Early-Exit Failure Prediction (EEFP), which accounts for bot h prediction correctness and the cost of further computation. We also propose a lightweight, EEFP-motivated procedure to improve the intermediate classifiers, w hich can directly replace calibration in EENNs.
Extensive experiments demonstrate that our approach achieves superior cost-accur acy trade-offs compared to calibration, and EEFP more reliably reflects overall EENN performance.
Our code is available at [https://github.com/gmum/rethinking-calibration-for-een ns](https://github.com/gmum/rethinking-calibration-for-eenns).

AnalogVerifier: A Neuro-Symbolic Framework for Analog Circuit Verification
Yanfang Liu, Mingjun Wang, Peng XU, Rongliang Fu, Bei Yu, Tsung-Yi Ho
Analog circuits constitute the indispensable interface between physical reality and digital computation, underpinning safety-critical systems from autonomous dr iving to medical implants. Consequently, verification correctness is paramount; yet, it remains the critical bottleneck in hardware design, consuming over 50\% of engineering cycles due to a heavy reliance on the manual interpretation of un structured, heterogeneous specifications. While Large Language Models (LLMs) off er automation potential, their probabilistic, autoregressive nature is structura lly misaligned with the strict determinism required for analog verification, str uggling with semantic dispersion, latent causal dependencies, and numerical prec ision. To bridge this gap, we introduce AnalogVerifier, a neuro-symbolic framewo rk that automates end-to-end testbench generation by decoupling semantic transla tion from logical enforcement. It comprises four parts: (1) Context-Aware Task Serialization transforms complex specifications into atomic tasks via an agentic workflow; (2) Graph-Symbolic Scheduling satisfies analog design constraints thr ough Port Dependency Graphs (PDG) for correct-by-construction sequencing; (3) Nu merical-Symbolic Grounding mitigates numerical hallucination by delegating thres hold derivation to a deterministic symbolic oracle; (4) Closed-Loop Repair enabl es correctness and completeness of the generated testbenches by simulation feedb ack. Evaluation on five industrial analog circuits demonstrates that AnalogVerif ier achieves 82.3\%--100\% functional pass rate, establishing a new paradigm for reliable, automated analog verification.

Open-o3-Video: Grounded Video Reasoning with Explicit Spatio-Temporal Evidence
Jiahao Meng, Xiangtai Li, Haochen Wang, Tan Yue, Tao Zhang, Lingdong Kong, Yunha i Tong, Anran Wang, Zhiyang Teng, Yujing Wang, Zhuochen Wang
Most video reasoning models only generate textual reasoning traces without indic ating when and where key evidence appears. Recent models such as OpenAI-o3 have sparked wide interest in evidence-centered reasoning for images, yet extending t his ability to videos is more challenging due to the need for joint temporal tra cking and spatial localization across dynamic scenes. We introduce Open-o3-Video , a non-agent framework that integrates explicit spatio-temporal evidence into v ideo reasoning by highlighting key timestamps, objects, and bounding boxes, maki ng the reasoning process traceable and verifiable. To enable this capability, we first construct high-quality datasets STGR that provide unified spatio-temporal supervision, which is absent in existing resources. We further adopt a cold-sta rt reinforcement learning strategy with specially designed rewards that jointly encourage answer accuracy, temporal alignment, and spatial precision. On the V-S TAR benchmark, Open-o3-Video achieves state-of-the-art performance, improving mA M by 14.4% and mLGM by 24.2% over the Qwen2.5-VL baseline, and shows consistent gains across a range of video understanding benchmarks. Beyond accuracy, the gro unded reasoning traces produced by Open-o3-Video support confidence-aware test-t ime scaling, improving answer reliability. The code, model and datasets are publ icly available at https://marinero4972.github.io/projects/Open-o3-Video/.

Return-to-Go Is More Than a Number: Q-Guided Alignment for Return-Conditioned Su pervised Learning
Yuxiao Yang, Weitong Zhang

Conditioned Sequence Models (CSMs) learn policies by treating return-to-go (RTG) as a control signal.
However, existing CSMs often treat the RTGs as simple numerical inputs rather than aligning them with the performance of their policies.
In this paper, we propose Q-ALIGN DT, a framework that enforces this alignment by ensuring the Q-value of the output policy is consistent with the input RTG.
By leveraging a Q function to provide dense guidance to CSMs and further fine-tuning it using an *RTG-perturbation* technique with the CSM, our method ensures that higher RTGs are consistently mapped to trajectories with higher expected returns.
Theoretically, we show that Q-ALIGN DT can efficiently learn the desired policy and output a near-optimal one when the RTG is sufficiently high.
Empirically, we demonstrate through extensive experiments that Q-ALIGN DT achieves superior controllability and performance across the D4RL benchmark. Remarkably, our model effectively learns a structured family of policies that maintains precise alignment and generalizes to tasks like velocity-tracking where prior methods fail.

AliMark: Enhancing Robustness of Sentence-Level Watermarking Against Text Paraphrasing
Yuexin Li, Wenjie Qu, Linyu Wu, Yulin Chen, Yufei He, Tri Cao, Bryan Hooi, Jiaheng Zhang
Existing sentence-level watermarking methods enhance robustness to paraphrasing by anchoring watermarks in sentence semantics. However, their prefix-based designs remain vulnerable to structural perturbations, such as sentence splitting and merging, which commonly arise under strong paraphrasers like DIPPER and GPT-3.5. To mitigate this issue, we propose AliMark, a framework that reformulates sentence-level watermarking as a bit sequence encoding and alignment problem between a potentially watermarked text and a secret bit sequence. Notably, our approach adopts a two-stage detection strategy: we generate multiple restructured text variants and adaptively align their extracted bit sequences with the secret bit sequence to minimize alignment cost. This multi-candidate alignment design naturally improves robustness to sentence merges and splits. Extensive experiments demonstrate that AliMark substantially outperforms state-of-the-art baselines under diverse paraphrasing attacks. Our code is available at https://github.com/imethanlee/AliMark.

DiffThinker: Towards Generative Multimodal Reasoning with Diffusion Models
Zefeng He, Xiaoye Qu, Yafu Li, Tong Zhu, Qipeng Guo, Muxin Fu, Siyuan Huang, Yu Cheng
While recent Multimodal Large Language Models (MLLMs) have attained significant strides in multimodal reasoning, their reasoning processes remain predominantly text-centric and fail to visualize and track intermediate visual states during the reasoning process, leading to suboptimal performance in complex long-horizon, vision-centric tasks.
Moving beyond the constraints of text-centric reasoning, we establish Generative Multimodal Reasoning as a novel paradigm and introduce DiffThinker, a diffusion-based reasoning framework.
Conceptually, DiffThinker reformulates multimodal reasoning as a native generative image-to-image task, where the iterative denoising trajectory naturally serves as a visual reasoning path. This enables the model to track the evolution of visual information throughout the reasoning process.
We perform a systematic comparison between DiffThinker and MLLMs, providing the first in-depth investigation into the intrinsic characteristics of this paradigm, revealing four core properties: efficiency, controllability, native parallelism, and collaboration. Extensive experiments across
seven tasks demonstrate that DiffThinker significantly outperforms leading closed-source models, including GPT-5 (+314.2%) and Gemini-3-Flash (+111.6%), as well as the fine-tuned Qwen3-VL-32B baseline (+39.0%), highlighting Generative Multimodal Reasoning as a promising approach for vision-centric reasoning.

Reference-Free Meta-Learning for Generalized Implicit Neural Representation in Efficient MRI Reconstruction
Haonan Zhang, Qing Wu, Xuanyu Tian, Bowen Li, Yuyao Zhang, Hongjiang Wei
Implicit Neural Representation (INR) has emerged as a powerful paradigm for continuous MRI reconstruction. However, standard self-supervised INR requires time-consuming optimization from scratch for each scan, hindering clinical deployment. This work presents IPOD, a Reference-Free Meta-Learning framework designed to learn generalized parameter initializations for INR directly from undersampled data. Distinct from conventional meta-learning that relies on fully-sampled ground truth, IPOD operates in an inverse-problem-driven manner, leveraging diverse reconstruction tasks with varying sampling patterns to capture a robust prior. Furthermore, we introduce an adaptive meta-update strategy modulated by task-specific performance to ensure optimal parameter distribution for diverse anatomical structures. Extensive experiments demonstrate that IPOD provides a superior initialization that enables rapid adaptation and achieves high-fidelity reconstruction across various imaging protocols, significantly outperforming existing INR baselines. By eliminating the dependence on reference images, IPOD offers a scalable and efficient solution for a wide range of imaging inverse problems. Code and data available at: https://github.com/zhn00310/RFML4MRI

Protein Fold Classification at Scale: Benchmarking and Pretraining
Dexiong Chen, Andrei Manolache, Mathias Niepert, Karsten Borgwardt
Classifying protein topology is essential for deciphering biological function, but progress is held back by the lack of large-scale benchmarks that avoid duplicates and by models that do not scale well. We introduce TEDBench, a large-scale, non-redundant benchmark for protein fold classification constructed from the Encyclopedia of Domains (TED) and Foldseek-clustered AlphaFold structures. We show that on TEDBench, current protein representation learning methods either require very large models or fail to deliver strong performance.
To address this challenge, we propose Masked Invariant Autoencoders (MiAE), a self-supervised framework for protein structure representation learning. MiAE uses an extremely high masking ratio of up to 90% with an $\mathrm{SE(3)}$-invariant encoder and a lightweight decoder that reconstructs backbone coordinates from the latent representation and mask tokens. MiAE scales well and outperforms supervised counterparts and state-of-the-art baselines on TEDBench, establishing a strong recipe for protein fold classification. To test transfer beyond AlphaFold structures, we further benchmark on a curated dataset from experimental structures of CATH v4.4. TEDBench is available at https://github.com/BorgwardtLab/TEDBench.
****
Look on Demand: A Cognitive Scheduling Framework for Visual Evidence Acquisition in Multimodal Reasoning
Yang Zhang, Xiaoshuai Sun, Rui Zhao, Wujin Sun, Yidong Chen, Jiayi Ji, Qian Chen, Rongrong Ji
Existing multimodal reasoning approaches predominantly follow two paradigms: converting visual inputs into text prior to reasoning, or performing end-to-end reasoning within a unified vision–language representation space. Despite their empirical progress, both paradigms suffer from fundamental structural limitations. The former relies on static visual-to-text conversion, which tends to compress and lose fine-grained visual details. The latter is prone to linguistic dominance induced by joint optimization and attention mechanisms, leading to systematically weakened faithfulness to visual evidence during reasoning. In this work, we argue that a central challenge is how and when visual evidence is introduced into the reasoning process. Motivated by this insight, we propose CSMR, a multimodal reasoning framework in which a language model controls the reasoning process by deciding when to invoke an independent visual perception module to acquire task-relevant visual evidence. Experiments across multiple multimodal reasoning benchmarks show that CSMR consistently outperforms representative baseline methods in accuracy under a

zero-shot setting. Further experimental analysis confirms that these advantages primarily arise from the proposed cognitive scheduling mechanism.
****
Set-Preserving Calibration from Conformal P-Values to E-Values
Nabil Alami, Jad Zakharia, Souhaib Ben Taieb
Standard conformal prediction (CP) procedures are typically formulated in terms of p-values, but reliance on p-values alone limits flexibility, for example, when combining dependent evidence across models or data splits. Recent work has explored e-value formulations for conformal inference, yet a direct connection between p- and e-value formulations in CP has been missing, especially regarding their statistical efficiency. We first identify limitations of classical p-to-e calibrators in the CP setting, showing that they are not set-preserving and can lead to overly conservative prediction sets. To address this, we propose a novel P2E calibrator that converts conformal p-values into e-values without altering the prediction set induced by the original conformal p-value. We establish both theoretically and empirically that our calibrator can yield significant efficiency gains over existing p-to-e calibrators. This e-value formulation enables principled use of recent advances in e-value merging and randomization, where we demonstrate its impact in two applications: cross-conformal prediction (CCP), whose variants typically provide only approximate $1-2\alpha$ coverage, and conformal aggregation (CA). In both cases, our e-value-based methods satisfy the desired $1-\alpha$ coverage guarantee while improving efficiency over standard baselines. More broadly, our approach expands the flexibility of CP and opens new directions for efficient, distribution-free uncertainty quantification.
****
Old Habits Die Hard: How Conversational History Geometrically Traps LLMs
Adi Simhi, Fazl Barez, Martin Tutek, Yonatan Belinkov, Shay B Cohen
How does the conversational past of large language models (LLMs) influence their future performance? Recent work suggests that LLMs are affected by their conversational history in unexpected ways. For instance, hallucinations in prior interactions may influence subsequent model responses. In this work, we introduce History Echoes, a framework that investigates how conversational history biases subsequent generations. The framework explores this bias from two perspectives: probabilistically, we model conversations as Markov chains to quantify state consistency; geometrically, we measure the consistency of consecutive hidden representations. Across three model families and six datasets spanning diverse phenomena, our analysis reveals a strong correlation between the two perspectives. By bridging these perspectives, we demonstrate that behavioral persistence manifests as a geometric trap, where gaps in the latent space confine the model's trajectory.

$\texttt{MetaDistill}$: Unlocking the Performance Ceiling for Pretrained Optimizers
Muqi Han, Ruoqi Xing, Kai Wu, Xiaoyu Zhang, Handing Wang, Zilong Wang
Meta Black-Box Optimization (MetaBBO) has emerged as a promising paradigm by employing meta learning to automatically optimize the configurations of low-level black-box optimizers. Despite its potential, the generalization of MetaBBO remains significantly constrained when facing unseen, complex objective landscapes. We identify that this bottleneck stems from a restricted performance upper bound inherent in current training mechanisms: by learning from scratch in a self-supervised or unsupervised manner, low-level learnable optimizers are never exposed to advanced, high-quality optimization behaviors, forcing them to converge on suboptimal strategies. In this paper, we propose \texttt{MetaDistill}, a general MetaBBO training framework designed to lift the strategy ceiling through pretraining and test-time fine-tuning. In the pretraining stage, we represent high-quality strategies from classical algorithms as expert optimization trajectories and utilize them for diversity-preserving distillation, enabling the learnable optimizer to internalize advanced optimization behaviors. In the optional fine-tuning stage, we perform self-supervised fine-tuning as a warm-start procedure to further refine the distilled knowledge on unseen tasks. We evaluate our \texttt{MetaD

istill} framework on the BBOB test suite and three control tasks. The results de
monstrate that \texttt{MetaDistill} significantly improves the generalization ab
ility of various learnable optimizers compared to their original training paradi
gms. Our code is available at \href{https://github.com/Roki-Xing/MetaDistill}{he
re}.

Score Correction for Generative Models with Probabilistic Constraints
Shishang Wu, Bingjing Tang, Vinayak Rao
We introduce DualScore, a framework for correcting score functions so that scor
e-based generative models satisfy probabilistic constraints. These constraints a
re specified through the marginal distribution of a stochastic transformation of
 the modeled variable. We formulate this as a constrained KL-minimization proble
m, and optimize its dual, parameterizing the infinite-dimensional dual variable
with a neural network. This yields an additive correction to the original score
function that can be used directly for sampling via stochastic gradient Langevin
 dynamics or reverse diffusion sampling, without modifying the base model. We ev
aluate DualScore on synthetic tasks and two real-world applications: regularized
 nonparametric maximum likelihood estimation and the incorporation of class-leve
l constraints such as fairness into pretrained image diffusion models.
****

In-Context Learning as Rate–Distortion Optimization
Jiayu Zhang, Changbang Li, Canran Xiao
In-context learning (ICL) is a practical way to adapt large models, yet under st
rict context limits, it remains unclear how to spend scarce tokens without being
 misled by noisy, redundant, or conflicting demonstrations. We address this gap
by targeting token-budgeted context construction: how to select and compress dem
onstrations so the prompt carries maximal task-relevant signal with minimal pred
ictive distortion. We propose RDCO, a deterministic, training-free optimizer tha
t scores demonstrations by marginal task information per token, penalizes redund
ancy and prefix-conditioned conflicts, and finally compacts the selected context
 under a bounded predictive-divergence constraint to control drift. Across a 10-
dataset ICL suite spanning classification and structured generation, RDCO achiev
es the best average performance (63.26 Acc. on classification and 60.26 EM on ge
neration), improving over the strongest classification and generation baselines
by 2.20 and 2.26 points, respectively, and improving the 10-task overall average
 by 4.94 points under the same budget. Our results suggest that viewing prompts
as finite-capacity messages yields a principled and effective path to more relia
ble and token-efficient ICL.

A Fully First-Order Layer for Differentiable Optimization
Zihao Zhao, Kai-Chia Mo, Shing-Hei Ho, Brandon Amos, Kai Wang
Differentiable optimization studies how to embed a mathematical program as a dif
ferentiable layer in machine learning pipelines. However, existing approaches ty
pically rely on implicit differentiation, involving expensive Hessian computatio
n while differentiating through optimality conditions. To address this challenge
, we formulate the differentiable optimization problem as a bilevel optimization
 instance.
We construct a new active-set Lagrangian as a proxy to compute an ϵ-app
roximate hypergradient using only near-constant $O(\log (1/\epsilon))$ first-ord
er information. We also show that applying this efficient hypergradient oracle t
o constrained bilevel optimization improves the overall gradient complexity to $
\tilde{O}(\delta^{-1}\epsilon^{-3})$ to reach a (δ, ϵ)-Goldstein s
tationary point. We implement our method `FFOLayer`, as a drop-in Python library
 compatible with existing differentiable optimization solvers. Our algorithm sho
ws significantly faster computation with similar convergence compared to other e
xisting solvers. The source code is available at [https://github.com/GT-KOALA/FF
OLayer](https://github.com/GT-KOALA/FFOLayer).

The Theory and Practice of MAP Inference over Non-Convex Constraints
Leander Kurscheidt, Gabriele Masina, Roberto Sebastiani, Antonio Vergari

In many safety-critical settings, probabilistic ML systems have to make predictions subject to algebraic constraints, e.g., predicting the most likely trajectory that does not cross obstacles. These real-world constraints are rarely convex, nor the densities considered are (log-)concave.
This makes computing this constrained maximum a posteriori (MAP) prediction in an efficient and reliable way extremely challenging. In this paper, we first investigate under which conditions we can perform constrained MAP inference over continuous variables exactly and efficiently and devise a scalable message-passing algorithm for this tractable fragment. Then, we devise a general constrained MAP strategy that interleaves partitioning the domain into convex feasible regions with numerical constrained optimization. We evaluate both methods on synthetic and real-world benchmarks, showing our structure aware approach outperforms constraint-agnostic baselines.
****
NBCG: Nash-Bargained Causal Game for Long-Tailed Multi-Label NLP
Jing Yang, Jusheng Zhang, Keze Wang
Long-tailed multi-label text classification is often treated as a data scarcity problem, addressed by re-sampling or fixed re-weighting.
We argue that a central failure mode is \textit{dominant coalition capture}: frequent labels, amplified by spurious co-occurrences, form dominant coalitions that dominate shared representations and gradient allocation during optimization.
As a result, rare labels are learned via superficial shortcuts, yielding brittle generalization under distribution shifts.
We propose \textbf{NBCG}, a Nash-Bargained Causal Game that reformulates multi-label learning as a cooperative bargaining process among label coalitions.
NBCG first leverages Neural Structural Equation Models to learn a directed dependency structure, inducing causally coherent coalitions---rather than random partitions---and coalition-specific communication masks.
We then optimize a Nash bargaining objective over coalition utilities relative to an adaptive disagreement point, which serves as a principled credit-allocation mechanism: it adaptively prioritizes under-served coalitions while maintaining a Pareto-efficient trade-off among all players.
****
Global Credit Assignment via Dynamical Criticality
Wentao Wang, Keren Gao, Guozhang Chen
Efficiently training recurrent neural networks on long sequences remains an open challenge. The standard global paradigm, backpropagation through time (BPTT), suffers from vanishing and exploding gradients and memory costs that scale linearly with sequence length. Conversely, biologically inspired local learning rules are memory-efficient but typically introduce severe bias. To bridge this gap, we introduce Criticality-driven Online Local Alignment (COLA). By leveraging the long-range spatiotemporal correlations inherent to the critical regime, COLA enables a strictly local learning rule to approximate global error propagation, thereby combining online efficiency with gradient descent precision. Theoretically, for a recurrent neural network with H hidden units, COLA requires only an $O(H)$ auxiliary state and constant activation memory, completely independent of sequence length. Empirically, COLA is competitive with BPTT on standard benchmarks and demonstrates superior robustness on stability-sensitive tasks. Finally, we conduct a rigorous analysis of the approximation error to provide a theoretical foundation for reliable online learning. Code is available at \url{https://github.com/Criticality-Cognitive-Computation-Lab/COLA}
****
Stability and Generalization of Nonconvex Optimization with Heavy-Tailed Noise
Hongxu Chen, Ke Wei, Xiaoming Yuan, Luo Luo
The empirical evidence indicates that stochastic optimization with heavy-tailed gradient noise is more appropriate to characterize the training of machine learning models than that with standard bounded gradient variance noise. Most existing works on this phenomenon focus on the convergence of optimization errors, while the analysis for generalization bounds under the heavy-tailed gradient noise remains limited. In this paper, we develop a general framework for establishing

generalization bounds under heavy-tailed noise. Specifically, we introduce a tru
ncation argument to achieve the generalization error bound based on the algorith
mic stability under the assumption of bounded pth centered moment with $p\in(1
,2]$. Building on this framework, we further provide the stability and generaliz
ation analysis for several popular stochastic algorithms under heavy-tailed nois
e, including clipped and normalized stochastic gradient descent, as well as thei
r mini-batch and momentum variants.

HaloProbe: Bayesian Detection and Mitigation of Object Hallucinations in Vision-Language Models

Reihaneh Zohrabi, Hosein Hasani, Akshita Gupta, Mahdieh Soleymani Baghshah, Anna Rohrbach, Marcus Rohrbach

Large vision-language models can produce object hallucinations in image descript
ions, highlighting the need for effective detection and mitigation strategies. P
rior work commonly relies on the model's attention weights on visual tokens as a
 detection signal. We reveal that coarse-grained attention-based analysis is unr
eliable due to hidden confounders, specifically token position and object repeti
tion in a description. This leads to Simpson’s paradox: the attention trends rev
erse or disappear when statistics are aggregated. Based on this observation, we
 introduce HaloProbe, a Bayesian framework that factorizes external description s
tatistics and internal decoding signals to estimate token-level hallucination pr
obabilities.

HaloProbe uses balanced training to encourage learning from internal evidence an
d combines it with a learned prior over external features to recover the true po
sterior. While intervention-based mitigation methods often degrade utility or fl
uency by modifying models' internals, we use HaloProbe as an external scoring si
gnal for non-invasive mitigation. Our experiments
show that HaloProbe-guided decoding reduces hallucinations more effectively than
 state-of-the-art intervention-based methods while preserving caption utility an
d linguistic fluency.

Scam2Prompt: A Scalable Framework for Auditing Malicious Scam Endpoints in Production LLMs

Zhiyang Chen, Tara Saba, Xun Deng, Xujie Si, Fan Long

The insatiable demand for web-scale training data has exposed LLMs to a subtle b
ut consequential threat: the absorption of malicious scam content into model wei
ghts and its subsequent reproduction during inference. In November 2024, this ri
sk materialized when a developer reportedly lost 2,500 USD after ChatGPT generat
ed an otherwise routine cryptocurrency trading script containing a live phishing
 URL. To systematically investigate this problem, we introduce Scam2Prompt, an a
utomated auditing framework that crawls known scam websites, infers their functi
onal intent, and synthesizes innocuous developer-style prompts — the kind of leg
itimate coding requests a programmer might naturally submit — to evaluate whethe
r LLMs reproduce the underlying scam endpoints. Importantly, our approach requir
es neither jailbreaking nor adversarial prompting; all 1,377 prompts in our benc
hmark, Innoc2Scam-bench, which is automatically constructed by Scam2Prompt, were
 human-validated as benign coding tasks. Evaluation of seven production LLMs rel
eased in 2025 on Innoc2Scam-bench shows that the vulnerability proves both persi
stent and severe: malicious code generation rates range from 12.9% to 47.3% acro
ss the evaluated models, and no tested model proves immune. State-of-the-art gua
rdrails and RAG-based agents offer only limited protection, underscoring an urge
nt need for explicit URL validation in LLM-assisted software development pipelin
es.

Plug-and-Play Diffusion Meets ADMM: Dual-Variable Coupling for Robust Medical Image Reconstruction

Chenhe Du, Xuanyu Tian, Qing Wu, Muyu Liu, Jingyi Yu, Hongjiang Wei, Yuyao Zhang

Plug-and-Play diffusion prior (PnPDP) frameworks have emerged as a powerful para
digm for solving imaging inverse problems by treating pretrained generative mode
ls as modular priors. However, we identify a critical flaw in prevailing PnP sol

vers (e.g., based on HQS or Proximal Gradient): they function as *memoryless operators*, updating estimates solely based on instantaneous gradients. This lack of historical tracking inevitably leads to non-vanishing *steady-state bias*, where the reconstruction fails to strictly satisfy physical measurements under heavy corruption. To resolve this, we propose **Dual-Coupled PnP Diffusion (DC-PnPDP)**, which restores the classical *dual variable* to provide integral feedback, progressively enforce agreement between the data-consistency and prior. However, this rigorous geometric coupling introduces a secondary challenge: the accumulated dual residuals exhibit spectrally colored, structured artifacts that violate the Additive White Gaussian Noise (AWGN) assumption of diffusion priors, causing severe hallucinations. To bridge this gap, we introduce **Spectral Homogenization (SH)**, a frequency-domain adaptation mechanism that modulates these structured residuals into statistically compliant *pseudo-AWGN* inputs. This effectively aligns the solver's rigorous optimization trajectory with the denoiser's valid statistical manifold. Extensive experiments on CT and MRI reconstruction demonstrate that our approach resolves the bias-hallucination trade-off, achieving state-of-the-art fidelity with significantly accelerated convergence. The code is available at https://github.com/duchenhe/DC-PnPDP.

scChord: A Probabilistic Manifold Rectification Framework for RNA-to-Protein Translation

Jiawei Zhang, Kangjun Jin, Shuai Xiao, Jiachen Yang

Measuring single-cell protein abundance is essential for resolving biological mechanisms and disease progression with high resolution. However, due to the high costs and antibody throughput limitations of current proteomics, inferring protein levels from readily available RNA data has become a critical computational necessity. Existing regression and generative methods face a fundamental geometric bottleneck: enforcing deterministic constraints on noisy, heteroscedastic data collapses intrinsic uncertainty into a rough latent manifold, which destabilizes the learning process. To overcome this, we present scChord, a noise-decoupled conditional flow matching framework built on Probabilistic Manifold Rectification. Our approach utilizes a probabilistic decoder to disentangle technical noise and over-dispersion from the raw counts, absorbing them into distributional parameters. This allows the rectified latent manifold to focus more on biological signals, serving as a robust geometric regularizer for learning efficient transport trajectories. Extensive experiments on multiple multi-omics benchmarks demonstrate that scChord not only achieves state-of-the-art inference accuracy but also faithfully reconstructs high-fidelity biological heterogeneity and complex protein distributions.

AutoWebWorld: Synthesizing Infinite Verifiable Web Environments via Finite State Machines

Yifan Wu, Yiran Peng, Yiyu Chen, Jianhao Ruan, Zijie Zhuang, Cheng Yang, Jiayi Zhang, Man CHEN, Yenchi Tseng, Zhaoyang Yu, Liang Chen, Yuyao Zhai, Bang Liu, Chenglin Wu, Yuyu Luo

The performance of autonomous Web GUI agents heavily relies on the quality and quantity of their training data. However, a fundamental bottleneck persists: collecting interaction trajectories from real-world websites is expensive and difficult to verify. The underlying state transitions are hidden, leading to reliance on inconsistent and costly external verifiers (e.g., human or LLM judges) to evaluate step-level correctness. To address this, we propose AutoWebWorld, a novel framework for synthesizing controllable and verifiable web environments by modeling them as Finite State Machines (FSMs) and use coding agents to translate FSMs into interactive websites. Unlike real websites, where state transitions are implicit, AutoWebWorld explicitly defines all states, actions, and transition rules. This enables programmatic verification: action correctness is checked against predefined rules, and task success is confirmed by reaching a goal state in the FSM graph. AutoWebWorld enables a fully automated search-and-verify pipeline, generating over 11,663 verified trajectories from 29 diverse web environments at only \$0.04 per trajectory. Training on this synthetic data significantly boosts

real-world performance. Our 7B Web GUI agent achieves state-of-the-art on WebVoyager, outperforming all baselines within 15 steps. Furthermore, we observe a clear scaling law: as the synthetic data volume increases, performance on WebVoyager and Online-Mind2Web consistently improves.

Demystifying Scientific Problem-Solving in LLMs by Probing Knowledge and Reasoning
Alan Li, Yixin Liu, Arpan Sarkar, Doug Downey, Arman Cohan
Scientific problem solving poses unique challenges for LLMs, requiring both deep domain knowledge and the ability to apply such knowledge through complex reasoning. While automated scientific reasoners hold great promise for assisting human scientists, there is currently no widely adopted holistic benchmark for evaluating scientific reasoning, and few approaches systematically disentangle the distinct roles of knowledge and reasoning in these tasks.

To address these gaps, we introduce **SciReas**, a diverse suite of existing benchmarks for scientific reasoning tasks, and **SciReas-Pro**, a selective subset that requires more complex reasoning. Our holistic evaluation surfaces insights about scientific reasoning performance that remain hidden when relying on individual benchmarks alone. We then propose **KRUX**, a probing framework for studying the distinct roles of reasoning and knowledge in scientific tasks.

Combining the two, we conduct an in-depth analysis that yields several key findings:

(1) Retrieving task-relevant knowledge from model parameters is a critical bottleneck for LLMs in scientific reasoning;

(2) Reasoning models consistently benefit from external knowledge added in-context on top of the reasoning enhancement;

(3) Enhancing verbalized reasoning improves LLMs' ability to surface task-relevant knowledge.

Autoregressive Image Generation with Masked Bit Modeling
Qihang Yu, Qihao Liu, Ju He, Xinyang Zhang, Yang Liu, Liang-Chieh Chen, Xi Chen
This paper challenges the dominance of continuous pipelines in visual generation. We systematically investigate the performance gap between discrete and continuous methods. Contrary to the belief that discrete tokenizers are intrinsically inferior, we demonstrate that the disparity arises primarily from the total number of bits allocated in the latent space (i.e., the compression ratio). We show that scaling up the codebook size effectively bridges this gap, allowing discrete tokenizers to match or surpass their continuous counterparts. However, existing discrete generation methods struggle to capitalize on this insight, suffering from performance degradation or prohibitive training costs with scaled codebook. To address this, we propose masked **B**it **A**uto**R**egressive modeling (**BAR**), a scalable framework that supports arbitrary codebook sizes. By equipping an autoregressive transformer with a masked bit modeling head, BAR predicts discrete tokens through progressively generating their constituent bits. BAR achieves a new state-of-the-art gFID of **0.99** on ImageNet-256, outperforming leading methods across both continuous and discrete paradigms, while significantly reducing sampling costs and converging faster than prior continuous approaches. Project page is available at https://bar-gen.github.io

DSENet: A Novel Dual-Stream Enhancement Network for Multi-Scale Non-Stationary Time Series Forecasting
Yuhan Wang, Yuanyuan Zou, Jie Cheng, Bin Dai, Jinhong Guo
Accurately capturing local variations in long series has always been
one of the most challenging problems in time-series forecasting
especially in medical signals, where local variations often indicate pathologica

l events. Our study reveals a previously overlooked key bottleneck in this field : traditional global and local branches learn similar representations, leading t o strong feature coupling and reduced sensitivity to local variations. To addres s this challenge, we propose the novel Dual-Stream Enhancement Mechanism, which structurally enlarges the difference between global and local patterns, enabling weak interactions between the two. Based on this idea, we introduce a new basel ine model for blood glucose prediction: Dual-Stream Enhancement Network (DSENet) , which fundamentally alleviates the problem of excessively strong coupling betw een global and local features. Experimental results show that our model achieves SOTA performance on multiple public datasets. Moreover, benefiting from extreme ly low computational cost, our model demonstrates strong application potential a nd can serve as a baseline model in multiple domains in the future.

Mirror Descent Under Generalized Smoothness

Dingzhi Yu, Wei Jiang, Hongyi Tao, Yuanyu Wan, Lijun Zhang

Smoothness is crucial for attaining fast rates in first-order optimization. Howe ver, many optimization problems in modern machine learning involve non-smooth ob jectives. Recent studies relax the smoothness assumption by allowing the Lipschi tz constant of the gradient to grow with respect to the gradient norm, which acc ommodates a broad range of objectives in practice. Despite this progress, existi ng generalizations of smoothness are restricted to Euclidean geometry with $\ell _2$-norm and only have theoretical guarantees for optimization in the Euclidean space. In this paper, we address this limitation by introducing a new $\ell*$-sm oothness concept that measures the norm of Hessians in terms of a general norm a nd its dual, and establish convergence for mirror-descent-type algorithms, match ing the rates under the classic smoothness. Notably, we propose a generalized se lf-bounding property that facilitates bounding the gradients via controlling sub optimality gaps, serving as a principal component for convergence analysis. Beyo nd deterministic optimization, we establish sharp convergence for stochastic mir ror descent, matching state-of-the-art under classic smoothness. Our theory also extends to non-convex and composite optimization, which may shed light on pract ical usages of mirror descent, including pre-training and post-training of LLMs.

Layer-wise Gradient Disentanglement: Decoupling Semantics and Preferences in Dir ect Preference Optimization

Mengyang Li, Shuang Liu, Zhong Zhang

Direct Preference Optimization (DPO) has become the dominant approach for aligni ng large language models with human preferences. However, standard DPO treats al l preference pairs uniformly, overlooking the heterogeneous nature of the learni ng problem: some samples demand sophisticated semantic understanding of the prom pt, while others require nuanced discrimination between similar responses. We ar gue that these two objectives should be disentangled during training. Through gr adient analysis, we identify a layer-wise localization phenomenon where semantic complexity predominantly drives lower-layer updates while preference uncertaint y modulates upper layers. Building on this insight, we propose Gradient-Guided D isentangled DPO (GDO-DPO), a curriculum framework that independently regulates l earning pace along each dimension based on layer-specific gradient stability. Ex periments on UltraFeedback and HH-RLHF demonstrate consistent improvements, with GDO-DPO outperforming DPO by 4.1\% on AlpacaEval 2.0 and showing particularly s trong gains on reasoning-intensive tasks.

Hierarchical Decision Making with Structured Policies: A Principled Design via I nverse Optimization

Yuexuan Wang, Jingyuan Zhou, Kaidi Yang

Hierarchical decision-making frameworks are pivotal for addressing complex contr ol tasks, enabling agents to decompose intricate problems into manageable subgo als. Despite their promise, existing hierarchical policies face critical limitat ions: (i) reinforcement learning (RL)-based methods struggle to guarantee strict constraint satisfaction, and (ii) optimal control (OC)-based approaches often r ely on myopic and computationally prohibitive formulations. To reconcile these t

rade-offs, hierarchical RL-OC architectures have emerged as a promising paradigm . However, the formulation of the lower-level optimization within these framewor ks remains underexplored, often relying on heuristic or myopic objectives. In th is work, we propose a principled framework that systematically integrates upper- level goal abstraction with structured lower-level decision making. We adopt an inverse optimization approach to inform the structure of the lower-level problem from expert demonstrations, ensuring that the objective of the lower-level poli cy remains aligned with the overall long-term task goal. To validate the approac h, our framework is evaluated on distinct decision making tasks: network-based r esource allocation and continuous collision avoidance. Empirical results demonst rate that our method consistently outperforms strong baselines based on end-to-e nd RL, learning-augmented optimal control, and existing hierarchical RL approach es in both efficiency and decision quality.

Best-of-Both-Worlds for Heavy-Tailed Markov Decision Processes

Yu Chen, Yuhao Liu, Jiatai Huang, Yihan Du, Longbo Huang

We investigate episodic Markov Decision Processes with heavy-tailed losses (HTMD Ps). Existing approaches for HTMDPs are conservative in stochastic environments and lack adaptivity in adversarial regimes. In this work, we propose algorithms HT-FTRL-OM and HT-FTRL-UOB for HTMDPs that achieve Best-of-Both-Worlds (BoBW) gu arantees: instance-independent regret in adversarial environments and logarithmi c instance-dependent regret in self-bounding (including the stochastic case) env ironments. For the known transition setting, HT-FTRL-OM applies the Follow-The-R egularized-Leader (FTRL) framework over occupancy measures with novel skipping l oss estimators, achieving a $\widetilde{\mathcal{O}}(T^{1/\alpha})$ regret bound in adversarial regimes and a $\mathcal{O}(\log T)$ regret in stochastic regimes . Building upon this framework, we develop a novel algorithm HT-FTRL-UOB to tack le the more challenging unknown-transition setting. Under a mild truncative nonn egativity condition on the loss distributions, this algorithm employs a pessimis tic skipping loss estimator and achieves a $\widetilde{\mathcal{O}}(T^{1/\alpha} + \sqrt{T})$ regret in adversarial regimes and a $\mathcal{O}(\log^2(T))$ regre t in stochastic regimes. Our analysis overcomes key barriers through several tec hnical insights, including a local control mechanism for heavy-tailed shifted lo sses, a new suboptimal-mass propagation principle, and a novel regret decomposit ion that isolates transition uncertainty from heavy-tailed estimation errors and skipping bias.

Learning Multi-Scale Hypergraph for High-Order Brain Connectivity Analysis

Jaeyoon Sim, Soojin Hwang, Seunghun Baek, Guorong Wu, Won Hwa Kim

Understanding complex interactions between brain regions is critical for early n eurodegenerative disease classification such as Alzheimer’s Disease (AD) and Par kinson’s Disease (PD). While graph-based models are widely used to analyze brain networks, most existing approaches primarily focus on pairwise interactions bet ween directly connected nodes, limiting their ability to capture higher-order de pendencies across multiple regions. Although hypergraph-based methods have been proposed to model higher-order relations, many rely on predefined hyperedges or restrict learning to hyperedge weights, reducing flexibility and limiting their capacity to capture multi-resolution structural patterns. In this regard, we int roduce an adaptive multi-scale hyperedge learning framework, i.e., MuHL, which c onstructs hierarchical node features and dynamically learns high-order interacti on through continuous hyper-edge construction over multi-resolution graph signal s. Extensive experiments on multiple brain network benchmarks demonstrate that M uHL consistently improves disease classification performance across different st ages, and further identifies key regions of interest (ROIs) and their group-wise interactions from the learned hyperedges that are associated with disease progr ession, highlighting its potential as a powerful tool for brain network analysis with neurodegenerative disorders.

When Embedding-Based Defenses Fail: Rethinking Safety in LLM-Based Multi-Agent S ystems

Lingxi Zhang, Guangtao Zheng, Hanjie Chen
Large language model (LLM)-powered multi-agent systems (MAS) enable agents to co
mmunicate and share information, achieving strong performance on complex tasks.
However, this communication also creates an attack surface where malicious agent
s can propagate misinformation and manipulate group decisions, undermining MAS s
afety. Existing embedding-based defenses aim to detect and prune suspicious agen
ts, but their effectiveness depends on a clear separation between the text embed
dings of malicious and benign messages.
Attackers can circumvent such defenses by crafting messages whose embeddings lie
 close to benign ones.
We analyze this failure mode theoretically and validate it empirically with thre
e attacks, Slow Drift, Benign Wrapper, and Chaos Seeding. Our analysis further r
eveals a fundamental limitation of embedding-based defenses: because they rely s
olely on the text embeddings, they ignore token-level confidence signals such as
 logits, which can remain informative when embeddings are not distinguishable un
der attack.
We propose using confidence scores to prune or down-weight messages during MAS c
ommunication. Experiments show improved robustness across models, datasets, and
communication topologies. Moreover, we find that the effectiveness of confidence
 signals decays over communication rounds, highlighting the importance of early
intervention.

DPO Unchained: Your Training Algorithm is Secretly Disentangled in Human Choice
Theory (and Its Loss' Convexity is Dispensable)
Wenxuan Zhou, Shujian Zhang, brice magdalou, John Wheatley Lambert, Ehsan Amid,
Richard Nock, Andrew Hard
Normative theories allow one to elicit key parts of a ML algorithm from first pr
inciples, which is crucial at a time of championed scrutiny for ML work. Direct
Preference Optimization (DPO) cleverly bypasses reward modeling by making an exp
licit link with a specific normative model of human choice. Our paper elevates t
his connection to the full generality of DPO's normative framework. Getting ther
e requires reworking social choice theory's textbook path for a better RLHF/ML f
it. It elevates the connection to a remarkably broad viewpoint on preference opt
imization, considering the current panorama of DPO follow-ups. It also unveils u
nexpected riches for ML, chief among which the support for *non-convex* losses,
the fact that *any* compliant ML analytical choice can be embedded with *any* hu
man choice model, and a normative framework's umbrella wide enough to safeguard
DPO's *extensions* (margins, length correction, ...). A *toy* experiment ``far a
way'' from the DPO crowd is given.

Scheduling Thoughts: Learning the Order of Thought in Diffusion Language Models
Jiawei Xu, Minghui Liu, Aakriti Agrawal, Yifan Chen, Furong Huang
Masked diffusion language models decode by iteratively unmasking tokens, where t
he unmasking order defines an ``order of thought''
that strongly influences generation quality yet is typically chosen heuristicall
y.
We derive a tractable upper bound on the sequential decoding mismatch, measured
by the Kullback–Leibler divergence and expressed in terms of the model’s pathwis
e log-likelihood, with tightness under sufficient model expressivity.
This bound induces a dense self-aware reward for a target sequence x and unmas
king order σ,
over ordered paths,
casting order selection as a principled policy optimization problem with a froze
n denoiser.
We instantiate this idea as **Self-Aware Scheduling (SAS)**, which learns a ligh
tweight order policy using Group Relative Policy Optimization and applies seamle
ssly to both sequential and semi-autoregressive decoding.
On Sudoku with 1B MDM, SAS improves puzzle accuracy from 82.0% (best heuristi
c schedule) to 91.8%, and reaches 97.9% with second-stage fine-tuning alon
g learned trajectories.

On LLaDA-8B, SAS improves pass@1 on GSM8K from 64% to 76% (full diffusion) and on MBPP from 39.5% to 41%, while consistently matching or exceeding heuristic schedules across generation lengths and block sizes.

Evolving Quantitative Reasoning through Self-Play in Digital Twin Markets
Tianmi Ma, Wenxin Huang, Jiawei Du, Lin Li, Xian Zhong, Joey Tianyi Zhou
Large language models (LLMs) demonstrate strong capabilities in high-level semantic reasoning and strategic planning, making them appealing for complex decision-making tasks; however, their quantitative reasoning remains unreliable despite recent progress in tool-augmented and structured inference. To address this limitation, we decouple reasoning from computation by assigning LLMs to planning, analysis, and result interpretation, while delegating numerical computation and statistical inference to specialized external tools. Rather than being hard-coded, these tools are constructed in a constrained and structured manner during planning as explicit intermediate reasoning artifacts, enabling adaptive and scenario-dependent quantitative reasoning. LLMs iteratively analyze tool outputs under diverse market conditions and leverage performance-based feedback to refine subsequent tool selection and construction, thereby forming a bounded self-evolving loop. We instantiate this process through self-play in a controllable digital twin market, DecoupledMarket, where LLM agents continuously test, compare, and adapt their strategies. By coupling high-level planning with robust quantitative execution, the proposed framework enhances the quantitative reliability of LLM-driven decision-making. All code and data are available at https://github.com/MTMQuantAI/Agent-Trading-Arena.git.

Difference-Aware Decision Learning for Multimodal Image Fusion
Hao Pan, Jian Dai, Yuan Sun, Zhenwen Ren, Xingfeng Li
Multimodal image fusion aims to integrate complementary information from different modalities, but cross-modal discrepancies and local conflicts often make modality allocation uncertain, causing information loss or artifact propagation.
We address this problem by formulating fusion as an observation-conditioned probabilistic decision-learning problem, where local modality contribution is explicitly modeled as a decision variable. Based on this view, we propose a dIfference-aware Decision-lEArning muLtimodal image fusion paradigm (IDEAL). IDEAL uses cross-modal differences as decision triggers and constructs spatial and spectral decision conditions from multi-scale difference attention, power-spectrum energy, complementary spectra, and spectral-entropy reliability. These conditions are mapped to interpretable contribution policies through a symmetric Beta prior, while uncertainty modulation pulls unreliable decisions toward conservative mixing when evidence is insufficient. Extensive experiments on multiple fusion tasks demonstrate stable and competitive performance against state-of-the-art methods. Code is available at: https://github.com/Pon915/IDEAL-main.

Robust Vision-Language Models via Manifold-Adversarial Adapters
Hao Li, Zeyu Xiao, Junhao Zhou, Peng Liu, Yang Zhao, Wei Jia
Vision-language models (VLMs) have progressed rapidly with large-scale high-quality data and adaptation strategies, yet remain brittle under real-world corruptions, where both visual recognition and language-grounded reasoning degrade. Beyond cascaded image restoration, a natural alternative is parameter-efficient adaptation that aligns corrupted features with clean references; however, Euclidean alignment alone is not semantics-preserving and can even harm downstream reasoning. We attribute this to a semantic misalignment gap, where features become geometrically closer while drifting off the in-distribution support on which multimodal reasoning is calibrated. To address this, we propose Manifold-Adversarial Adapters (MAA), parameter-efficient layer-wise modules for a frozen vision encoder that explicitly steer corrupted features back onto the clean in-distribution manifold rather than merely shrinking feature-space distance. MAA combines paired feature self-distillation with a token-level adversarial manifold constraint to prevent off-manifold semantic shortcuts. At inference, only the adapters are retained, enabling single-stage robustness with negligible overhead and avoiding th

e latency and semantic drift of restoration pipelines. Across benchmarks and cor
ruption settings, MAA consistently improves performance over strong baselines.
****

GeoMoLa: Geometry-Aware Motion Latents for Learning Robust Manipulation Policies
Yunchao Zhang, Yijia Weng, Ruizhe Liu, Ming Hu, Leonidas Guibas, Yanchao Yang
Learning motion latents for robotic manipulation heavily relies on extracting mo
tion patterns from visual sequences, yet effective action abstractions require u
nderstanding three-dimensional geometric transformations. Here, we introduce Geo
MoLa (Geometry-Aware Motion Latents), which learns discrete motion latent codes
by predicting how point clouds evolve during manipulation rather than reconstruc
ting visual observations. This four-dimensional objective – spatial geometry cha
nging through time – forces latent representations to encode actual physical mot
ion rather than appearance patterns. GeoMoLa achieves state-of-the-art performan
ce using only single-view RGB-D input, while existing methods require multi-view
 reconstruction, succeeding across diverse manipulation benchmarks. Our ablation
s reveal that geometric prediction is the key to driving performance, quantitati
vely validating that manipulation depends on spatial understanding. Furthermore,
 the learned codes exhibit effective motion abstraction: applying them to novel
scenes produces physically consistent transformations regardless of visual conte
xt. Our real-world experiments also confirm this robustness capability, achievin
g robust manipulation with minimal demonstrations in cluttered environments wher
e geometric reasoning determines success. Thus, we demonstrate that effective mo
tion latents for robot control can better emerge from understanding motion throu
gh its three-dimensional effects rather than pixel-level patterns.

Entropy-Aware Dynamic KV Cache Sparsification for Autoregressive Image Generati
on and Editing
Tong Tong, Ling Xing, Linjie Li, Rui Yan, Zhengyuan Yang, Lijuan Wang, Alex Jinp
eng Wang
Autoregressive (AR) image generation has recently gained momentum as a scalable
alternative to diffusion models, benefiting from unified next-token prediction p
aradigm and strong instruction following ability. However, AR visual generation
must decode excessively long sequences of visual tokens, making inference heavil
y bottlenecked by the memory footprint and latency of the self-attention KV cach
e. While KV cache compression is well studied in Large Language Model, its count
erparts in AR image generation remain underexplored. The reason is fundamental:
visual tokens are highly redundant, and their spatial information density is hig
hly non-uniform. In this work, we introduce SparseAR, a training-free, entropy-a
ware sparse attention method that is specifically designed for AR image generati
on and editing. Our key insight is that information-rich regions exhibit higher
entropy and require broader attention, while redundant regions show lower entrop
y and allow aggressive sparsification. Based on this insight, we dynamically ide
ntify information-rich regions during decoding and adaptively adjust attention s
parsity to reduce KV-cache overhead. SparseAR is plug-and-play and can be readil
y applied to mainstream AR models. Extensive experiments on four representative
AR models across multiple benchmarks demonstrate that SparseAR significantly im
proves inference efficiency while maintaining, and often even improving, generat
ion and editing quality.

Towards Execution-Grounded Automated AI Research
Chenglei Si, Zitong Yang, Yejin Choi, Emmanuel Candes, Diyi Yang, Tatsunori Hash
imoto
Automated AI research holds great potential to accelerate scientific discovery.
However, current LLMs often generate plausible-looking but ineffective ideas.
Execution grounding may help, but it is unclear whether automated execution is f
easible and whether LLMs can learn from the execution feedback.
To investigate these, we first build an automated executor to implement ideas an
d launch large-scale parallel GPU experiments to verify their effectiveness.
We then convert two realistic research problems -- LLM pre-training and post-tra
ining -- into execution environments and demonstrate that our automated executor

can implement a large fraction of the ideas sampled from frontier LLMs.
We analyze two methods to learn from the execution feedback: evolutionary search and reinforcement learning.
Execution-guided evolutionary search is sample-efficient: it finds a method that significantly outperforms the GRPO baseline
on post-training, and finds a pre-training recipe that outperforms the nanoGPT baseline
on pre-training, all within just ten search epochs.
Frontier LLMs often generate meaningful algorithmic ideas during search, but they tend to saturate early and only occasionally exhibit scaling trends.
Reinforcement learning from execution reward, on the other hand, suffers from mode collapse.
It successfully improves the average reward of the ideator model but not the upper-bound, due to models converging on simple ideas.
We thoroughly analyze the executed ideas and training dynamics to facilitate future efforts.
****

Breaking the Capacity Bottleneck in Model-Heterogeneous Federated Learning via Gradual Model Restoration
Chengjie Ma, Seungeun Oh, Jihong Park, Seong-Lyun Kim
Federated learning (FL) enables distributed model training, yet in heterogeneous deployments, Bandwidth-Constrained Clients (BCCs) often contribute inefficiently due to limited uplink bandwidth. In model-heterogeneous FL with fixed small sub-models, BCCs with sub-models may improve quickly in early rounds but become under-parameterized later, resulting in slow convergence and poor generalization.
To address this challenge, we propose **FedGMR**, a federated learning framework centered around **Gradual Model Restoration (GMR)**, where GMR progressively increases each client’s sub-model density during training, allowing BCCs to remain effective contributors throughout optimization. To make GMR practical under real-world heterogeneity, FedGMR is realized as an end-to-end workflow with asynchronous coordination and stable, mask-aware aggregation. We further establish convergence guarantees, showing that the aggregation error scales with the **average** sub-model density across clients and rounds, and that GMR provably narrows the gap toward full-model FL. Extensive experiments on FEMNIST, CIFAR-10, ImageNet-100, and StackOverflow demonstrate that FedGMR improves both convergence speed and final accuracy, especially under severe heterogeneity and non-IID data distributions.
Code is available at https://github.com/machengjie321/ICML2026-FedGMR.

Learning Stochastic Bridges for Video Object Removal via Video-to-Video Translation
Zijie Lou, Xiangwei Feng, Jiaxin Wang, Jiangtao Yao, Fei Che, Tianbao Liu, WU CHENGJING, Xiaochao Qu, Luoqi Liu, Ting Liu
Existing video object removal methods predominantly rely on diffusion models following a noise-to-data paradigm, where generation starts from uninformative Gaussian noise. This approach discards the rich structural and contextual priors present in the original input video. Consequently, such methods often lack sufficient guidance, leading to incomplete object erasure or the synthesis of implausible content that conflicts with the scene's physical logic. In this paper, we reformulate video object removal as a video-to-video translation task via a stochastic bridge model. Unlike noise-initialized methods, our framework establishes a direct stochastic path from the source video (with objects) to the target video (objects removed). This bridge formulation effectively leverages the input video as a strong structural prior, guiding the model to perform precise removal while ensuring that the filled regions are logically consistent with the surrounding environment. To address the trade-off where strong bridge priors hinder the removal of large objects, we propose a novel adaptive mask modulation strategy. This mechanism dynamically modulates input embeddings based on mask characteristics, balancing background fidelity with generative flexibility. Extensive experiments demonstrate that our approach significantly outperforms existing methods in bo

th visual quality and temporal consistency. The project page is https://bridgere
moval.github.io/.

SphericalDreamer: Generating Navigable Immersive 3D Worlds with Panorama Fusion
Antoine Schnepf, Karim Kassab, Flavian Vasile, Andrew I. Comport
The generation of immersive and navigable 3D environments is increasingly preval
ent with the growing adoption of virtual reality and 3D content.
However, recent methods face a fundamental limitation: they cannot produce 3D wo
rlds that simultaneously (i) are navigable over long-range spatial extents and (
ii) cover the complete omnidirectional field of view (360° horizontally a
nd 180° vertically).
To address this challenge, we introduce SphericalDreamer, a method for generatin
g fully immersive and long-range 3D outdoor environments from textual prompts.
Our approach is built on the generation of multiple panoramic images, which are
subsequently lifted into 3D and fused together while maintaining visual and geom
etric consistency.
SphericalDreamer produces highly detailed, fully immersive 3D environments, whil
e substantially improving scale and navigability compared to prior approaches.

BYORn: Bootstrap Your Own Responses to Defend Large Vision-Language Models Again
st Backdoor Attacks
Ivan Sabolic, Marin Orši■, Josip Šari■, Sven Loncaric
Supervised fine-tuning is the predominant approach for adapting autoregressive v
ision–language models to downstream tasks. Recent work has shown that this parad
igm is highly vulnerable to backdoor attacks, and that existing defenses are ine
ffective in open-ended generation settings. In response, we propose BYORn, a bac
kdoor-robust fine-tuning framework motivated by the observation that poisoned ta
rget responses are often semantically implausible given the corresponding image–
text inputs and a pretrained model. BYORn identifies such misaligned responses a
nd dynamically replaces them with alternative responses generated by the model,
thereby breaking the correlation between triggers and target outputs. The result
ing objective gradient corresponds to the gradient of the empirical estimate of
the population risk upper bound over the clean data distribution. Empirically, B
YORn consistently improves robustness to backdoor attacks while preserving clean
-task performance, establishing a new trade-off frontier between generalization
and attack success rate. Finally, we demonstrate that BYORn remains effective ag
ainst adaptive attacks specifically designed to circumvent the proposed defense.

Reconstructing Template-Memorized Images from Natural Prompts
Sol Yarkoni, Mahmood Sharif, Roi Livni
Recent advances in generative models, such as diffusion models, have raised conc
erns related to privacy, copyright infringement, and data curation. Prior work h
as shown that training data can be reconstructed from such models, but existing
attacks typically rely on substantial computational resources, access to the tra
ining set, or carefully engineered prompts.

In this work, we present a low-resource reconstruction attack that operates thro
ugh seemingly benign prompts and requires little to no access to the training da
ta. Our attack targets **template-memorized images (TMI)**, where recurring layo
uts and visual structures are memorized during training. We show that such memor
ization manifests under potentially realistic usage. This raises a possibility o
f unintentional reconstruction by naive users that don't carry explicit adversar
ial intent. For example, we observe that a simple prompt such as "blue Unisex T-
Shirt" can reproduce visual content depicting a real individual. Beyond extracti
on, we observe novel phenomena occurring in TMI (e.g., interpolation), raising q
uestions about the novelty of generated content and the effectiveness of establi
shed methods for detecting memorized content.

Our code is available at \url{https://github.com/TheSolY/lr-tmi}.

Temporal Weighted Encoding: Towards Maximal-Capacity Spike Coding for ANN–SNN Co
nversion
Yiwen Gu, Junchuan Gu, Haibin Shen, Kejie Huang
Spiking Neural Networks (SNNs) emulate the spiking behavior of biological neuron
s
and are promising for energy-efficient neuromorphic computing.
A widely used strategy to train SNNs is to convert pretrained Artificial Neural
Networks (ANNs),
where the accuracy and efficiency are determined by the spike encoding scheme.
Traditional methods based on spike count or timing severely underutilize the ava
ilable encoding space,
leading to large accuracy degradation under low-timestep constraints. More expre
ssive alternatives
involve complex dynamics, which hinder scalability and practical deployment.
To address these challenges, we propose Temporal Weighted Encoding (TWE).
Spikes are implicitly assigned exponentially decaying weights through a recursiv
e integration, drawing an analogy
to a temporal bit sequence. We systematically analyze the temporal mismatch caus
ed by this weight pattern
and propose temporal relaxation and threshold relaxation to resolve this issue,
enabling fast and
accurate activation encoding. Extensive experiments demonstrate that TWE achieve
s negligible conversion
loss with significantly fewer timesteps, offering a scalable and efficient solut
ion for SNN deployment.

Continual Learning through Control Minimization
Sander de Haan, Yassine Taoudi-Benchekroun, Pau Vilimelis Aceituno, Benjamin F G
rewe
Catastrophic forgetting remains a fundamental challenge for neural networks when
 tasks are trained sequentially. In this work, we reformulate continual learning
 as a control problem where learning and preservation signals compete within neu
ral activity dynamics. We convert regularization penalties into preservation sig
nals that protect prior-task representations. Learning then proceeds by minimizi
ng the control effort required to integrate new tasks while competing with the p
reservation of prior tasks. At equilibrium, the neural activities produce weight
 updates that implicitly encode the full prior-task curvature, a property we ter
m the *continual-natural gradient*, requiring no explicit curvature storage. Exp
eriments confirm that our learning framework recovers true prior-task curvature
and enables task discrimination, outperforming existing methods on standard benc
hmarks without replay.

Is Spurious Correlation Removal Always Learnable?
Yibo Zhou, Bo Li, Hai-Miao Hu, Hanzi Wang, Xiaokang Zhang, Ruifan Zhang
Invariant learning can fail even when the invariant structure is statistically i
dentifiable. We show a conditional computational barrier: under a black-box samp
lable supervised sparse recovery primitive motivated by average-case sparse-reco
very reductions, there exist \emph{samplable} multi-environment instances with a
 one-dimensional predictive invariant subspace ($k=1$) that are learnable with p
olynomial samples by exhaustive search, while any polynomial-time constant-accur
acy recovery algorithm would contradict the primitive. We further quantify envir
onment diversity by a separation parameter γ, which controls identifiabil
ity and the curvature of invariance objectives. Under sufficient diversity and l
ocal Gaussian regularity, the minimax risk is $\mathbb{E}[dist(\hat{V},V_{\mathr
m{inv}})^2]=\Theta(k(d-k)/(n|\mathcal{E}|))$, and under label-induced shifts a p
hase transition occurs at $n^*\propto k(d-k)/(|\mathcal{E}|\gamma^2)$ with refin
ed estimation error scaling proportional to $1/\gamma^2$. Synthetic and real dat
asets illustrate the predicted gaps and transitions and motivate simple diversit
y diagnostics.

Memory-Efficient LLM Training with Dynamic Sparsity: From Stability to Practical Scaling
Qiao Xiao, Boqian Wu, Patrik Okanovic, Tomasz Sternal, Maurice van Keulen, Elena Mocanu, Mykola Pechenizkiy, Decebal Constantin Mocanu, Torsten Hoefler
Dynamic Sparse Training (DST) offers a promising paradigm for improving the training and inference efficiency of deep neural networks; however, we find that in large language model training, DST can suffer from optimization instability, manifested as loss spikes after topology updates. In this work, we show that the naive use of standard Adam-based optimizers leads to a cold-start issue for newly regrown parameters, resulting in excessively large updates and disrupted training dynamics. To address this issue, we propose Sparse Memory-Efficient Training (SMET), which stabilizes DST with optimizer warm-up and improves training progress through density-aware learning-rate scaling. SMET further reduces memory consumption by storing gradients and optimizer states only for active parameters. We provide a theoretical analysis of the update behaviors under SMET, showing improved optimization stability. Extensive experiments demonstrate that SMET enables stable, scalable, and memory-efficient sparse pre-training of LLMs, paving the way for sparse training as a practical alternative to dense training. Our code is publicly available at: https://github.com/QiaoXiao7282/SMET.

Tempora: Characterising the Time-Contingent Utility of Online Test-Time Adaptation
Sudarshan Sreeram, Young D. Kwon, Cecilia Mascolo
Test-time adaptation (TTA) offers a compelling remedy for machine learning (ML) models that degrade under domain shifts, improving generalisation *on-the-fly* with only unlabelled samples. This flexibility suits real deployments, yet conventional evaluations unrealistically assume unbounded processing time, overlooking the accuracy-latency trade-off. As ML increasingly underpins latency-sensitive and user-facing use-cases, temporal pressure constrains the viability of adaptable inference; predictions arriving too late to act on are futile. We introduce *Tempora*, a framework for evaluating TTA under this pressure. It consists of temporal scenarios that model deployment constraints, evaluation protocols that operationalise measurement, and time-contingent utility metrics that quantify the accuracy-latency trade-off. We instantiate the framework with three such metrics: (1) *discrete* utility for asynchronous streams with hard deadlines, (2) *continuous* utility for interactive settings where value decays with latency, and (3) *amortised* utility for budget-constrained deployments. By applying Tempora to 11 TTA methods, we find that *rank instability* persists across 750+ temporal evaluations spanning diverse datasets, models, and hardware platforms; *i.e.,* conventional rankings do not predict rankings under temporal pressure. The highest-utility method varies with the shift and temporal pressure, with no clear winner. By enabling systematic evaluation across diverse temporal constraints for the first time, Tempora reveals when and why rankings change, offering practitioners a lens for method selection and researchers a target for deployable adaptation. Code: https://github.com/sudotensor/tempora.

Semi-Supervised Noise Adaptation: Transferring Knowledge from Noise Domain
Yuan Yao, Jin Song, Huixia Li, Tongtong Yuan, Jiaqi Wu, Yu Zhang
Transfer learning aims to facilitate the learning of a target domain by transferring knowledge from a source domain. The source domain typically contains semantically meaningful samples (*e.g.*, images) to facilitate effective knowledge transfer. However, a recent study observes that the noise domain constructed from simple distributions (*e.g.*, Gaussian distributions) can serve as a surrogate source domain in the semi-supervised setting, where only a small proportion of target samples are labeled while most remain unlabeled. Based on this surprising observation, we formulate a novel problem termed *Semi-Supervised Noise Adaptation* (SSNA), which aims to leverage a synthetic noise domain to improve the generalization of the target domain. To address this problem, we first establish a generalization bound characterizing the effect of the noise domain on generalization, based on which we propose a Noise Adaptation Framework (NAF). Extensive experi

ments demonstrate that NAF effectively leverages the noise domain to tighten the generalization bound of the target domain, leading to improved performance. The codes are available at https://github.com/AIResearch-Group/SSNA.

Finding the Minimal Parameter Budget for Implicit Reasoning: A Data Complexity Driven Scaling Law for Language Models
Xinyi Wang, Shawn Tan, Shenbo Xu, Mingyu Jin, William Yang Wang, Rameswar Panda, Yikang Shen
Reasoning is a core capability of language models (LMs), yet it remains unclear how much model capacity is necessary to support reasoning during pretraining. In this work, we study the minimal parameter budget required for implicit reasoning, defined as the ability to infer new facts from learned knowledge without explicit chain-of-thought supervision. To isolate this phenomenon, we pretrain LMs from scratch in a controlled synthetic environment that mimics the structure and distribution of real-world knowledge graphs, and evaluate their ability to complete missing edges via multi-hop inference.
From both a theoretical and an empirical perspective, we identify a scaling law linking this optimal parameter budget to a graph search entropy measure.
Across a wide range of model sizes, training steps, and graph complexities, we show that an optimally sized language model can reliably reason over approximately 0.008 bits of information per parameter at most.
Our results characterize the minimal sufficient capacity for implicit reasoning during pretraining. Our findings provide principled guidance for matching model size to data complexity and offer new insights into the scaling behavior of reasoning in large language models.
****
Probabilistic Robustness Certificates against Adversarial Attacks
Sara Taheri, Majid Zamani
The growing use of machine learning in safety-critical settings heightens vulnerability to *adversarial attacks*. Existing defense mechanisms typically either lack formal guarantees or depend on restrictive assumptions about the model family, the threat model, or the poisoning budget, and many only offer point-wise certification. Importantly, they often overlook the inherent stochasticity of modern training pipelines, which undermines their practical reliability. We introduce a probabilistic framework that views gradient-based training as a *discrete-time stochastic dynamical system* and formulates poisoning robustness as a safety verification task. Leveraging *barrier certificates* (BCs), we derive sufficient conditions to probabilistically certify a robust radius against worst-case ${\ell}_p$-bounded poisoning, guaranteeing that the final model parameters remain within a safe set. For tractable computation, we represent BCs with neural networks and obtain *probably approximately correct* (PAC) guarantees through a *scenario convex problem*. Our method identifies the largest certified radius for which the trained model is probabilistically accurate with a specified confidence level. Experiments on MNIST, SVHN, and CIFAR-10 show that our framework offers formal robustness guarantees under stochastic training, while being model-agnostic and not requiring prior knowledge of the attack strategy.

RoboTwin 2.0: A Scalable Data Generator and Benchmark with Strong Domain Randomization for Robust Bimanual Robotic Manipulation
Tianxing Chen, Zanxin Chen, Baijun Chen, Zijian Cai, Yibin Liu, Zixuan Li, Qiwei Liang, Xianliang Lin, Yiheng Ge, Zhenyu Gu, Weiliang Deng, Yubin Guo, Tian Nian, Xuanbing Xie, Qiangyu Chen, Kailun Su, Tianling Xu, Guodong Liu, Mengkang Hu, Huan-ang Gao, Kaixuan Wang, Zhixuan Liang, Yusen Qin, Xiaokang Yang, Ping Luo, Yao Mu
Simulation-based data synthesis has emerged as a powerful paradigm for enhancing real-world robotic manipulation. However, existing synthetic datasets remain insufficient for robust bimanual manipulation due to two key challenges: (1) the lack of an autonomous self-correcting mechanism to resolve execution failures in complex coordination tasks, and (2) the scarcity of diverse visual and spatial variations required to bridge the sim-to-real gap. To this end, we present RoboTw

in 2.0, a scalable simulation framework that enables closed-loop, automated, large-scale generation of diverse and realistic data, along with unified evaluation protocols for dual-arm manipulation. Built upon RoboTwin-OD, a foundational library of 731 instances across 147 categories with rich semantic annotations, our framework integrates Multimodal Large Language Models (MLLMs) with simulation-in-the-loop verification. This integration forms an automated feedback mechanism that significantly boosts the success rate of expert task program generation. To enhance robust sim-to-real transfer, RoboTwin 2.0 incorporates structured domain randomization along five axes: clutter, lighting, background, tabletop height and language instructions, thereby maximizing data diversity. We instantiate this framework across 50 dual-arm tasks spanning five robot embodiments. Empirical evaluations demonstrate that Vision-Language-Action (VLA) models pre-trained on our synthetic data achieve a 3.6x improvement in few-shot real-world transfer (over a 10-demo baseline) and a 2.2x gain in zero-shot generalization. We release the data generator, benchmark, pre-collected dataset, and code to support scalable research in robust bimanual manipulation.

BRIDGE: Triangular Fixed-Point Refinement for Long-Horizon Persona Consistency

Yinghui Jiang, Bocheng Xu, Jianye Xie, Haotong Sun

Long-horizon dialogue agents suffer from latent state drift: what an agent says, what it internally represents, and what it stores in memory can diverge silently across turns. This creates asymmetric rupture risk—many locally coherent exchanges undone by a single high-cost contradiction. We propose BRIDGE (Behavioral Reasoning through Integrated Dynamic Gated Evolution), which performs triangular fixed-point refinement to explicitly couple Observable ($\mathcal{O}$), Latent ($\mathcal{L}$), and Memory ($\mathcal{M}$) before decoding each response. We prove that under mild conditions, the refinement operator converges to a unique fixed point, providing a theoretical guarantee that the agent's internal state remains self-consistent before each response. Empirically, BRIDGE achieves the highest scores on both PersonaGym (4.59 avg., surpassing Claude-3.7-Sonnet) and CoSER (59.5% avg., +3.1 over Claude-3.7-Sonnet), with gains concentrated on persona-specific metrics (+8.0 Character Fidelity over Qwen2.5-32B-Instruct)—while updating only 0.85% trainable parameters of the frozen backbone. We also provide a Lyapunov-style uniform drift bound for tiered memory updates, grounding bounded persona evolution in long-horizon interaction.

Rethinking the Flow-based Gradual Domain Adaptation: A Semi-Dual Optimal Transport Perspective

Zhichao Chen, Zhan Zhuang, Yunfei Teng, Hao Wang, Fangyikang Wang, Zhengnan Li, Tianqiao Liu, Haoxuan Li, Zhouchen Lin

Gradual domain adaptation (GDA) aims to mitigate domain shift by progressively adapting models from the source domain to the target domain via intermediate domains. However, real intermediate domains are often unavailable or ineffective, necessitating the synthesis of intermediate samples. Flow-based models have recently been used for this purpose by interpolating between source and target distributions. Notably, their training typically relies on sample-based log-likelihood estimation, which can discard useful information and thus degrade GDA performance. The key to addressing this limitation is constructing the intermediate domains via samples directly. To this end, we propose an $\underline{\text{E}}$ntropy-regularized $\underline{\text{S}}$emi-dual $\underline{\text{U}}$nbalanced $\underline{\text{O}}$ptimal $\underline{\text{T}}$ransport (E-SUOT) framework to construct intermediate domains. Specifically, we reformulate flow-based GDA as a Lagrangian dual problem and derive an equivalent semi-dual objective that circumvents the need for likelihood estimation. However, the dual problem leads to an unstable min–max training procedure. To alleviate this issue, we further introduce the entropy regularization to convert it into a more stable sequential optimization procedure. Based on this, we propose a novel GDA training framework and provide theoretical analysis in terms of stability and generalization. Finally, extensive experiments are conducted to demonstrate the efficacy of the E-SUOT framework.

FlowNar: Scalable Streaming Narration for Long-Form Videos
Zeyun Zhong, Manuel Martin, Chengzhi Wu, David Schneider, Frederik Diederichs, Juergen Gall, Jürgen Beyerer
Recent Large Multimodal Models (LMMs), primarily designed for offline settings, are ill-suited for the dynamic requirements of streaming video. While recent online adaptations improve real-time processing, they still face critical scalability challenges, with resource demands typically growing at least linearly with video duration. To overcome this bottleneck, we propose FlowNar, a novel framework for scalable streaming video narration. The core of FlowNar is a dynamic context management strategy for historical visual context removal, combined with our CLAM (Cross Linear Attentive Memory) module for streaming visual history retention, ensuring bounded visual memory usage and computational complexity, crucial for efficient streaming. We also introduce a realistic self-conditioned evaluation protocol and complementary evaluation metrics to assess streaming narration models under deployment-like conditions. Experiments on the Ego4D, EgoExo4D, and EpicKitchens100 datasets demonstrate that FlowNar substantially improves narration quality over strong baselines while being highly efficient, supporting processing of 10$\times$ longer videos and achieving 3$\times$ higher throughput (FPS). The code is available at https://github.com/zeyun-zhong/FlowNar.
****
Local Constrained Bayesian Optimization
Jingzhe Jing, Zheyi Fan, Szu Hui Ng, Qingpei Hu
Bayesian optimization (BO) for high-dimensional constrained problems remains a significant challenge due to the curse of dimensionality. We propose **L**ocal **C**onstrained **B**ayesian **O**ptimization (LCBO), a novel framework tailored for such settings. Unlike trust-region methods that are prone to premature shrinking when confronting tight or complex constraints, LCBO leverages the differentiable landscape of constraint-penalized surrogates to alternate between rapid local descent and uncertainty-driven exploration. Theoretically, we prove that LCBO achieves a convergence rate for the Karush-Kuhn-Tucker (KKT) residual that depends polynomially on the dimension d for common kernels under mild assumptions, offering a rigorous alternative to global BO where regret bounds typically scale exponentially. Extensive evaluations on high-dimensional benchmarks (up to 100D) demonstrate that LCBO consistently outperforms state-of-the-art baselines.

Towards Uniformity and Alignment for Multimodal Representation Learning
Wenzhe Yin, Pan Zhou, Zehao Xiao, Jie Liu, Shujian Yu, Jan-Jakob Sonke, Stratis Gavves
Multimodal representation learning aims to construct a shared embedding space in which heterogeneous modalities are semantically aligned. Despite strong empirical results, InfoNCE-based objectives introduce inherent conflicts that yield distribution gaps across modalities. In this work, we identify two conflicts in the multimodal regime, both exacerbated as the number of modalities increases: (i) an alignment–uniformity conflict, whereby the repulsion of uniformity undermines pairwise alignment, and (ii) an intra-alignment conflict, where aligning multiple modalities induces competing alignment directions. To address these issues, we propose a principled decoupling of alignment and uniformity for multimodal representations, providing a conflict-free recipe for multimodal learning that simultaneously supports discriminative and generative use cases without task-specific modules. We then provide a theoretical guarantee that our method acts as an efficient proxy for a global Hölder divergence over multiple modality distributions, and thus reduces the distribution gap among modalities. Extensive experiments on retrieval and UnCLIP-style generation demonstrate consistent gains.

Plug-and-Play Benchmarking of Reinforcement Learning Algorithms for Large-Scale Flow Control
Jannis Becktepe, Aleksandra Franz, Nils Thuerey, Sebastian Peitz
Reinforcement learning (RL) has shown promising results in active flow control (AFC), yet progress in the field remains difficult to assess as existing studies

rely on heterogeneous observation and actuation schemes, numerical setups, and evaluation protocols. Current AFC benchmarks attempt to address these issues but heavily rely on external computational fluid dynamics (CFD) solvers, are not fully differentiable, and provide limited 3D and multi-agent support. To overcome these limitations, we introduce FluidGym, the first standalone, fully differentiable benchmark suite for RL in AFC. Built entirely in PyTorch on top of the GPU-accelerated PICT solver, FluidGym runs in a single Python stack, requires no external CFD software, and provides standardized evaluation protocols. We present baseline results with PPO, SAC, DPC, and TD-MPC, and release all environments, datasets, and trained models as public resources. FluidGym enables systematic comparison of control methods, establishes a scalable foundation for future research in learning-based flow control, and is available at github.com/safe-autonomous-systems/fluidgym.

MORALISE: A Structured Benchmark for Moral Alignment in Visual Language Models

Xiao Lin, Zhining Liu, Ze Yang, Gaotang Li, Ruizhong Qiu, Shuke Wang, Hui Liu, Haotian Li, Yuchen Yan, Sumit Keswani, Vishwa Pardeshi, Huijun Zhao, Wei Fan, Hanghang Tong

Recently, vision-language models have demonstrated increasing influence in morally sensitive domains such as autonomous driving and medical analysis, owing to their powerful multimodal reasoning capabilities. As these models are deployed in high-stakes real-world applications, it is of paramount importance to ensure that their outputs align with human moral values and remain within moral boundaries. However, existing work on moral alignment either focuses solely on textual modalities or relies heavily on AI-generated images, leading to distributional biases and reduced realism. To overcome these limitations, we introduce MORALISE, a comprehensive benchmark for evaluating the \underline{mor}al \underline{al}ignment of v\underline{is}ion-languag\underline{e} models (VLMs) using diverse, expert-verified real-world data. We begin by proposing a comprehensive taxonomy of 13 moral topics grounded in Turiel's Domain Theory, spanning the personal, interpersonal, and societal moral domains encountered in everyday life. Built on this framework, we manually curate 2,481 high-quality image-text pairs, each annotated with two fine-grained labels: (1) \textit{topic annotation}, identifying the violated moral topic(s), and (2) \textit{modality annotation}, indicating whether the violation arises from the image or the text. For evaluation, we encompass two tasks, \textit{moral judgment} and \textit{moral norm attribution}, to assess models' awareness of moral violations and their reasoning ability on morally salient content. Extensive experiments on 19 popular open- and closed-source VLMs show that MORALISE poses a significant challenge, revealing persistent moral limitations in current state-of-the-art models.

From Kepler to Newton: Inductive Biases Guide Learned World Models in Transformers

Ziming Liu, Surya Ganguli, Andreas S. Tolias

Vafa et al. recently showed that a transformer fails to acquire an internal Newtonian world model when trained on synthetic planetary-motion data. How can we fix this problem? We find that inductive biases are key to learning the veridical world model: (1) **Spatial smoothness** is required for any world model to be learned. However, naive tokenization may disrupt smoothness since two close points in physical space may be far apart in token embedding space without sufficient training or data. We fix this by formulating the prediction problem as regression instead of classification. (2) **Spatial stability** makes the prediction robust to noise, which is not guaranteed by default, but can be taught via correcting in-context noise perturbations. (3) With both spatial smoothness and stability built in, further imposing **temporal locality** induces a Newtonian world model, while the lack of this knowledge induces a Keplerian world model -- fitting elliptical parameters instead of computing gravitational forces. Our results suggest that even simple general inductive biases are powerful enough to induce correct and specific world models. The inductive biases do not need to know that much about the underlying law to be learned, but without them, it is impossible to

learn.

Easier to Judge than to Find: Predicting In-Context Learning Success for Demonstration Selection
Haochun Wang, Chaofen Yang, Jiatong Liu, Jingbo Wang, Zewen Qiang, Sendong Zhao, Bing Qin, Ting Liu
In-context learning (ICL) is highly sensitive to which demonstrations appear in the prompt, but selecting them is expensive because candidate contexts must be validated with repeated LLM calls. We argue that demonstration selection is \emph{easier to judge than to find}: predicting whether a specific query--context pair (q,D) will succeed is cheaper and more general than searching for an optimal $D^\star$. Based on this insight, we propose DiSP, a sample-and-judge framework that stratifies queries by difficulty. DiSP runs random demonstration trials to estimate each training query's success rate, trains a lightweight router to predict difficulty from the query, and trains level-specific judges to score sampled contexts. At inference, DiSP performs stop-on-acceptance judging under an explicit budget and typically makes a single LLM call, emitting diagnostic risk tags when no suitable context is found. Across five classification datasets with Llama 3–8B and Qwen 2.5–7B, DiSP achieves the best average accuracy, improving over strong learned selection baselines by up to 3.4%, while achieving up to 23× end-to-end wall-clock speedup.
****
RAPNet: Accelerating Algebraic Multigrid with Learned Sparse Corrections
Yali Fink, Ido Ben-Yair, Lars Ruthotto, Eran Treister
The scalable solution of large sparse linear systems is a bottleneck in scientific computing and graph analysis. While algebraic multigrid (AMG) offers optimal linear scaling, its performance is severely constrained by the trade-off between the sparsity and convergence quality of coarse-grid operators. Classical AMG heuristics struggle to balance these objectives, often sacrificing stability or performance for sparsity. We propose RAPNet, a graph neural network (GNN) framework that resolves this trade-off by learning to generate sparse, robust coarse operators directly from the sparse algebraic system. Key to our approach is a level-wise training strategy that enables learning from small subgraphs and generalization to million-node domains, bypassing the bottlenecks of prior neural AMG attempts. RAPNet executes exclusively during the solver setup phase, ensuring that the solve phase retains its favorable computational properties. We show that our method outperforms classical non-Galerkin baselines on diverse PDE discretizations and graph Laplacians, making it particularly effective for multi-query tasks such as eigenproblems, time-dependent simulations, and inverse or design problems.
****
ReflFlow: Learning Geometry-Guided Ray Tracing for Dynamic Specular Reconstruction
Jiachen Tao, Junyi Wu, Haoxuan Wang, Zongxin Yang, Dawen Cai, Yan Yan
We present ReflFlow, a novel framework for high-fidelity rendering of dynamic specular scenes by addressing two key challenges: precise reflection direction estimation and physically accurate modeling. To achieve this, we propose a Residual Material-Augmented 2D Gaussian Splatting representation that models dynamic geometry and material properties, allowing accurate reflection ray computation. Furthermore, we introduce a Dynamic Environment Gaussian and a hybrid rendering pipeline that decomposes rendering into diffuse and specular components, enabling physically informed specular synthesis via rasterization and ray tracing. Finally, we devise a coarse-to-fine training strategy to improve optimization stability and promote physically meaningful decomposition. Extensive experiments on dynamic scene benchmarks demonstrate that ReflFlow outperforms prior methods quantitatively and qualitatively, producing sharper and more realistic specular reflections in complex dynamic environments.
****
Sharp Inequalities between Total Variation and Hellinger Distances for Gaussian Mixtures

Joonhyuk Jung, Chao Gao
We study the relation between the total variation (TV) and Hellinger distances between two Gaussian location mixtures. Our first result establishes a general upper bound: for any two mixing distributions supported on a compact set, the Hellinger distance between the two mixtures is controlled by the TV distance raised to a power $1-o(1)$, where the $o(1)$ term is of order $1/\log\log(1/\mathrm{TV})$. We also construct two sequences of mixing distributions that demonstrate the sharpness of this bound. Taken together, our results resolve an open problem raised in Jia et al. (2023) and thus lead to an entropic characterization of learning Gaussian mixtures in total variation. Our inequality also yields optimal robust estimation of Gaussian mixtures in Hellinger distance, which has a direct implication for bounding the minimax regret of empirical Bayes under Huber contamination.
****

A Flat Vocabulary or a Rich Hierarchy? Re-introducing Intrinsic Structure Transforms the Autoregressive Image Generation
Landis He, Shikang Zheng
Autoregressive (AR) models have shown great promise in image generation, yet they face a fundamental inefficiency stemming from their core component: a vast, unstructured vocabulary of visual tokens. By treating tokens as a flat set, standard models overlook the manifold structure where geometric proximity reflects semantic similarity. This oversight unnecessarily complicates the prediction task, hindering training efficiency and limiting generation quality. To resolve this, we propose Manifold-Aligned Semantic Clustering (MASC), a principled framework that constructs a hierarchical semantic tree directly from the codebook's intrinsic geometry. Utilizing a geometry-aware distance metric and density-driven agglomerative construction, MASC faithfully models the token embedding manifold. By transforming the flat, high-dimensional prediction into a structured hierarchical task, MASC introduces a powerful inductive bias that simplifies learning. Designed as a plug-and-play module, MASC accelerates training by up to 71\% and significantly boosts generation quality, improving LlamaGen-XL's FID from 2.87 to 2.49. Crucially, MASC further serves as a convergence enabler for complex architectures. These results establish that structuring the prediction space is as vital as architectural innovation, elevating existing AR frameworks to state-of-the-art performance.

Systematic Failures in Collective Reasoning under Distributed Information in Multi-Agent LLMs
Yuxuan Li, Aoi Naito, Hirokazu Shirado
Multi-agent systems built on large language models (LLMs) are expected to enhance decision-making by pooling distributed information, yet systematically evaluating this capability has remained challenging. We introduce HiddenBench, a 65-task benchmark grounded in the Hidden Profile paradigm, which isolates collective reasoning under distributed information from individual reasoning ability. Evaluating 15 frontier LLMs, we find that multi-agent LLMs achieve only 30.1% accuracy under distributed information, compared to 80.7% accuracy for single agents given complete information. We trace this gap to a systematic failure mode: agents cannot recognize or act under latent information asymmetry—they fail to reason about what others might know but have not yet expressed, leading to premature convergence on shared evidence while critical distributed facts remain unexplored. These failures persist across prompting strategies, communication depths, and group sizes—and worsen as groups scale. While some models (e.g., Gemini-2.5-Flash/Pro) outperform others, neither model scale nor individual reasoning accuracy reliably predicts collective performance. We further show that this bottleneck is actionable: a lightweight structured communication protocol substantially improves collective reasoning across model families. Our results identify failures in collective information exploration in decision-making as a key limitation of multi-agent LLMs, and provide a theory-grounded, reproducible framework for diagnosing collective reasoning failures.

Neural Attention Search Linear: Towards Adaptive Token-Level Hybrid Attention Models

Difan Deng, Andreas Bentzen Winje, Lukas Fehring, Marius Lindauer

The quadratic computational complexity of softmax transformers has become a bottleneck in long-context scenarios. In contrast, linear attention model families provide a promising direction towards a more efficient sequential model. These linear attention models compress past KV values into a single hidden state, thereby efficiently reducing complexity during both training and inference. However, their expressivity remains limited by the size of their hidden state. Previous work proposed interleaving softmax and linear attention layers to reduce computational complexity while preserving expressivity. Nevertheless, the efficiency of these models remains bottlenecked by their softmax attention layers. In this paper, we propose Neural Attention Search Linear (NAtS-L), a framework that applies both linear attention and softmax attention operations within the same layer on different tokens. NAtS-L automatically determines whether a token can be handled by a linear attention model, i.e., tokens that have only short-term impact and can be encoded into fixed-size hidden states, or require softmax attention, i.e., tokens that contain information related to long-term retrieval and need to be preserved for future queries. By searching for optimal Gated DeltaNet and softmax attention combinations across tokens, we show that NAtS-L provides a strong yet efficient token-level hybrid architecture.

Normality Calibration in Semi-supervised Graph Anomaly Detection

Guolei Zeng, Hezhe Qiao, Guoguo Ai, Jinsong Guo, Guansong Pang

Semi-supervised graph anomaly detection (GAD), which assumes a subset of labeled normal nodes for training, is widely studied. However, existing methods learn normality only from these labeled nodes, often overfitting their patterns and causing high detection errors, such as many false positives. To overcome this limitation, we propose $GraphNC$, a graph normality calibration framework that leverages both labeled and unlabeled data to calibrate the normality from a teacher (a pre-trained semi-supervised GAD model) jointly in anomaly score and representation spaces. GraphNC includes two main components, anomaly score distribution alignment ($ScoreDA$) and perturbation-based normality regularization ($NormReg$). ScoreDA optimizes our model’s anomaly scores by aligning them with the teacher’s score distribution. Because the teacher provides accurate scores for most normal nodes and some anomalies, this alignment pulls the scores of the two classes toward opposite ends, making them more separable. To reduce the impact of inaccurate teacher scores, NormReg regularizes normality in the representation space, making normal node representations more compact via a perturbation-guided consistency loss applied only to the labeled nodes. Comprehensive experiments on six benchmarks demonstrate that GraphNC (1) consistently and substantially enhances the performance of teacher models from different GAD methods (2) achieves new state-of-the-art performance. Our code is available at https://github.com/mala-lab/GraphNC.

GenAlign: Towards Unified Alignment Framework of MLLMs via Generative Reward Model

Jingyu Zhang, Kun Yang, Ming Wen, Jiawei Zhao, Yuxuan Liu, Zhuoer Xu, shiwen cui

Aligning Multimodal Large Language Models (MLLMs) with human preferences remains a fundamental challenge. While Generative Reward Models (GRMs) offer a promising reasoning-based alternative to scalar models, they are often hindered by severe position bias and prohibitively high computational overhead. To address these limitations, we propose GenAlign, a unified framework that synergizes robust generative reward modeling with efficient MLLM alignment. First, we introduce a rubric-based GRM that explicitly models the preference judgment process. By employing reinforcement learning with verifiable rewards and an online position debiasing mechanism, our model produces interpretable reasoning critiques and robust preference predictions. Second, we propose a policy optimization strategy utilizing advantage-smoothed dynamic reference anchoring. This approach reduces computational complexity while mitigating gradient instability caused by variance colla

pse. Extensive experiments demonstrate that GenAlign achieves state-of-the-art p
reference prediction accuracy on multimodal reward modeling benchmarks. Moreover
, it consistently improves the performance of three MLLMs across seven diverse e
valuation benchmarks, particularly making significant progress in safety and hal
lucination.

Co-Evolving Latent Action World Models
Yucen Wang, Fengming Zhang, De-Chuan Zhan, Li Zhao, Kaixin Wang, Jiang Bian
Adapting pre-trained video generation models into controllable world models via
latent actions is a promising step towards creating generalist world models. The
 dominant paradigm adopts a two-stage approach that trains latent action model (
LAM) and the world model separately, resulting in redundant training and limitin
g their potential for co-adaptation. A conceptually simple and appealing idea is
 to directly replace the forward dynamic model in LAM with a powerful world mode
l and training them jointly, but it is non-trivial and prone to representational
 collapse. In this work, we propose CoLA-World, which for the first time success
fully realizes this synergistic paradigm, resolving the core challenge in joint
learning through a critical warm-up phase that effectively aligns the representa
tions of the from-scratch LAM with the pre-trained world model. This unlocks a c
o-evolution cycle: the world model acts as a knowledgeable tutor, providing grad
ients to shape a high-quality LAM, while the LAM offers a more precise and adapt
able control interface to the world model. Empirically, CoLA-World matches or ou
tperforms prior two-stage methods in both video simulation quality and downstrea
m visual planning, establishing a robust and efficient new paradigm for the fiel
d.

Does Reasoning Improve Seeing? Understanding When Vision-Language Models Benefit
 from Thinking
Jing Bi, Luchuan Song, Dingxin Zhang, Pinxin Liu, Guangyu Sun, Lianggong Bruce W
en, Weidong Cai, Chen Chen, Chenliang Xu
Vision-language models (VLMs) now support both direct Instruct and explicit-reas
oning Thinking modes, yet practitioners still lack principled ways to decide whe
n reasoning actually improves performance, or how much computation to spend at t
est time, so we investigate whether VLMs encode meta-cognitive signals for adapt
ive inference.
We derive oracle labels for two properties: (1) reasoning helpfulness, namely wh
ether explicit reasoning improves accuracy, and (2) desired generation length, t
he minimal token budget needed for a correct answer. Probing final-layer represe
ntations in InternVL and Qwen3-VL models, we find Thinking models encode these s
ignals more linearly than Instruct models, suggesting that reasoning-oriented tr
aining enhances meta-cognitive structure.
Head-wise attribution reveals two circuits: length-control heads in lower layers
 and reasoning/difficulty heads in higher layers. Causal interventions confirm t
hese roles across benchmarks: scaling length heads controls output length with m
inimal accuracy loss, while scaling reasoning heads enables a perception-reasoni
ng trade-off, improving accuracy by up to 5.3\%.
Our results demonstrate that reasoning-tuned VLMs develop localized, manipulable
 circuits for meta-cognitive control, enabling test-time steering of computation
 and reasoning without retraining.

Geometry-Guided Generative Representation for Functional Brain Graphs
Subati Abulikemu, Tiago Azevedo, Michail Mamalakis, John Suckling
In network neuroscience, functional brain systems are often characterized using
separate yet related graph-theoretic or spectral descriptors, overlooking how th
ese properties covary and partially overlap across individuals and conditions. W
e anticipate that dense, weighted functional connectivity graphs lie on a low-di
mensional latent geometry along which both topological and spectral structures v
ary smoothly at the population level. Although graph-based deep learning offers
a powerful framework for modeling these brain connectomes, supervised approaches
 are constrained by the limited availability of labeled data. Existing unsupervi

sed graph representation methods also typically focus on node-level embeddings, which are limited in capturing compact graph-level representations that preserve information from dense functional connectomes. To address these gaps, we learn compact brain graph representations using a graph transformer autoencoder, where domain-specific, aligned functional gradient geometry provides an inductive bias to guide learning. Despite being trained in a fully unsupervised manner, our approach meaningfully separates cognitive states and enables decoding of visual stimuli, with performance further improved by incorporating neural dynamics. In parallel, to enable generation of synthetic brain graphs, we fit a diffusion model to the learned latent representation and decode samples back to dense connectomes.

Scalable RF Simulation in Generative 4D Worlds

Zhiwei Zheng, Dongyin Hu, Mingmin Zhao

Radio Frequency (RF) sensing has emerged as a powerful, privacy-preserving alternative to vision-based methods for various perception tasks. However, building high-quality RF datasets in dynamic and diverse environments remains a major challenge. To address this, we introduce WaveVerse, a prompt-based, scalable framework that simulates realistic RF signals from generated indoor scenes with human motions guided by spatial paths, enabling diverse and feasible behaviors without manual trajectory design. WaveVerse features a language-guided 4D world generator and a physics-based signal simulator that enables realistic simulation of RF signals in diverse environments. It employs a phase-coherent ray tracer that preserves both spatial and temporal phase consistency. The simulated signals show high fidelity on phase-sensitive benchmarks, and closely align with both real-world collected measurements and simulations from a proprietary electromagnetic solver. When used for data augmentation, WaveVerse consistently improves performance in downstream tasks like RF imaging and human activity recognition, with gains that grow with the amount of simulated data and surpass existing methods. Code and additional materials are available on the webpage.

Inconsistency-Aware Minimization: Improving Generalization with Unlabeled Data

Hee-Sung Kim, Hyeonseong Kim, Sungyoon Lee

Estimating the generalization gap and developing optimization methods that improve generalization are crucial for deep learning models, for both theoretical understanding and practical applications.

Leveraging unlabeled data for these purposes offers significant advantages in real-world scenarios.

This paper introduces a novel generalization measure, $\textit{local inconsistency}$, derived from an information-geometric perspective on the parameter space of neural networks. A key feature of local inconsistency is that it can be computed without explicit labels.

We establish theoretical underpinnings by connecting local inconsistency to the Fisher information matrix and the loss Hessian.

Empirically, we demonstrate that local inconsistency correlates with the generalization gap.

Based on these findings, we propose Inconsistency-Aware Minimization (IAM), which incorporates local inconsistency into the training objective.

We demonstrate that in standard supervised learning settings, IAM enhances generalization, achieving performance comparable to that of existing methods such as Sharpness-Aware Minimization.

Furthermore, IAM exhibits efficacy in semi- and self-supervised learning scenarios, where the local inconsistency is computed from unlabeled data.

Scaling Transformers for End-to-End Discrete Audio Tokenization

Yitian Gong, Kuangwei Chen, Zhaoye Fei, Xiaogui Yang, Ke Chen, Yang Wang, Kexin Huang, Mingshu Chen, Ruixiao Li, Qinyuan Cheng, Shimin Li, Xipeng Qiu

Discrete audio tokenizers are fundamental to empowering large language models with native audio processing and generation capabilities. Despite recent progress, existing approaches often rely on pretrained encoders, semantic distillation, o

r heterogeneous CNN-based architectures. These designs introduce fixed inductive biases that limit reconstruction fidelity and hinder effective scaling. In this paper, we argue that discrete audio tokenization should be learned fully end-to-end using a homogeneous and scalable architecture.
Based on this perspective, we propose $\textbf{TAC}$, a Transformer-based audio tokenizer that jointly optimizes the encoder, quantizer, and decoder from scratch for high-fidelity reconstruction of general audio.
We show that a simple, fully end-to-end learned tokenizer built from homogeneous, causal Transformer blocks scales gracefully and supports high-fidelity reconstruction across diverse audio domains. Across speech, sound, and music, the proposed tokenizer consistently outperforms prior codecs over a wide range of bitrates, while exhibiting predictable improvements with increased scale. Notably, leveraging TAC’s discrete tokens, we develop the first purely autoregressive TTS model that surpasses prior non-autoregressive and cascaded systems. Furthermore, TAC enables competitive ASR performance without auxiliary encoders. Our findings position TAC as a unified, scalable interface for the next generation of native audio foundation models.

EvoMAS: Evolutionary Generation of Multi-Agent Systems
Yuntong Hu, Yuting Zhang, Matthew Trager, Yi Zhang, Shuo Yang, Wei Xia, Stefano Soatto
Large language model (LLM)-based multi-agent systems (MAS) show strong promise for complex reasoning, planning, and tool-augmented tasks, but designing effective MAS architectures remains labor-intensive, brittle, and hard to generalize. Existing automatic MAS generation methods either rely on code generation, which often leads to executability and robustness failures, or impose rigid architectural templates that limit expressiveness and adaptability. We propose Evolutionary Generation of Multi-Agent Systems (EvoMAS), which formulates MAS generation as structured configuration generation. EvoMAS performs evolutionary generation in configuration space. Specifically, EvoMAS selects initial configurations from a pool, applies feedback-conditioned mutation and crossover guided by execution traces, and iteratively refines both the candidate pool and an experience memory. We evaluate EvoMAS on diverse benchmarks, including BBEH, SWE-Bench, and WorkBench, covering reasoning, software engineering, and tool-use tasks. EvoMAS consistently improves task performance over both human-designed MAS and prior automatic MAS generation methods, while producing generated systems with higher executability and runtime robustness. EvoMAS outperforms the agent evolution method EvoAgent by +10.5 points on BBEH reasoning and +7.1 points on WorkBench. With Claude-4.5-Sonnet, EvoMAS also reaches 79.1% on SWE-Bench-Verified, matching the top of the leaderboard. Code is available at https://github.com/amazon-science/EvoMAS

Training-Free Bayesian Filtering with Generative Emulators
Thomas Savary, François Rozet, Gilles Louppe
Bayesian filtering is a well-known problem that aims to estimate plausible states of a dynamical system from observations. Among existing approaches to solve this problem, particle filters are theoretically exact for non-linear dynamics and observations, but suffer from poor scalability in high dimensions. In this work, we show that diffusion-based emulators of dynamical systems can be used to implement, without additional training, an optimal variant of particle filters that has remained largely unexplored due to implementation challenges with classical numerical solvers. Experiments on nonlinear chaotic systems, including atmospheric dynamics, demonstrate that the proposed approach successfully scales particle filtering to high-dimensional settings.

Geometry-Guided Modeling of Foundation Features Enables Generalizable Object Shape Deformation Learning
Yiyao Ma, Kai Chen, Zhongxiang Zhou, Zhuheng Song, Dongsheng Xie, Zelong Tan, Rong Xiong, Qi Dou
Monocular 3D shape recovery is fundamental to geometric understanding, yet achieving robust generalization across arbitrary viewpoints and unseen object categor

ies remains a significant challenge. In this paper, we present a generalizable d
eformation learning framework that reconstructs 3D objects by explicitly deformi
ng a category-level shape template to match the target observation. To address c
omplex shape variations between the template and the target, we introduce a geom
etry-guided feature modeling mechanism. This process first enriches foundation f
eatures with template topology to yield a geometry-aware representation, which i
s then explicitly correlated with the target observation to guide precise deform
ation. Furthermore, to bridge the disparity between the fixed template and arbit
rary target views, we propose a view-adaptive feature aggregation module. This m
odule leverages multi-view template features and their corresponding camera pose
s to enrich the canonical template representation, ensuring robust feature align
ment regardless of the target's perspective. Extensive experiments demonstrate
that our approach significantly outperforms state-of-the-art methods in handling
 large shape variations and diverse viewpoints, exhibiting strong generalization
 to novel categories and effectively supporting downstream real-world dexterous
robotic manipulation tasks. Project homepage: https://GODeform.github.io/

MASPO: Joint Prompt Optimization for LLM-based Multi-Agent Systems
Zhexuan Wang, Xuebo Liu, Li Wang, Zifei Shan, Yutong Wang, Zhenxi Song, Min Zhan
g
Large language model (LLM)-based Multi-agent systems (MAS) have shown promise in
 tackling complex collaborative tasks, where agents are typically orchestrated v
ia role-specific prompts. While the quality of these prompts is pivotal, jointly
 optimizing them across interacting agents remains a non-trivial challenge, prim
arily due to the misalignment between local agent objectives and holistic system
 goals. To address this, we introduce MASPO, a novel framework designed to autom
atically and iteratively refine prompts across the entire system. A core innovat
ion of MASPO is its joint evaluation mechanism, which assesses prompts not merel
y by their local validity, but by their capacity to facilitate downstream succes
s for successor agents. This effectively bridges the gap between local interacti
ons and global outcomes without relying on ground-truth labels. Furthermore, MAS
PO employs a data-driven evolutionary beam search to efficiently navigate the hi
gh-dimensional prompt space. Extensive empirical evaluations across 6 diverse ta
sks demonstrate that MASPO consistently outperforms state-of-the-art prompt opti
mization methods, achieving an average accuracy improvement of 2.9. We release o
ur code at https://github.com/wangzx1219/MASPO.

Many Needles in a Haystack: Active Hit Discovery for Perturbation Experiments
Andrea Rubbi, Arpit Merchant, Samuel Ogden, Amir Akbarnejad, Pietro Lio, Sattar
Vakili, Mohammad Lotfollahi
High-throughput gene perturbation experiments can test several genetic intervent
ions in parallel, yet experimental budgets remain limited. A central goal is hit
 discovery: identifying as many perturbations as possible whose phenotypic effec
t exceeds a predefined threshold. Pure exploration strategies are statistically
inefficient, wasting budget on low-value regions. Bayesian optimization methods
offer a principled alternative but target a single global optimum, over-exploiti
ng dominant modes while neglecting other high-value regions. We formalize hit di
scovery as a sequential experimental design problem and propose Probability-of-H
it, an acquisition function that directly targets threshold exceedance by rankin
g candidates according to their posterior probability of being a hit. We prove a
symptotic optimality of this approach and demonstrate strong empirical performan
ce on both synthetic benchmarks and real biological immunology datasets, includi
ng upto 6.4\% improvement over baselines on the Schmidt IL-2 dataset.
****

Alterbute: Editing Intrinsic Attributes of Objects in Images
Tal Reiss, Daniel Winter, Matan Yaakov Cohen, Alex Rav-Acha, Yael Pritch, Ariel
Shamir, Yedid Hoshen
We introduce Alterbute, a diffusion-based method for editing an object's intrins
ic attributes in an image. We allow changing color, texture, material, and even
the shape of an object, while preserving its perceived identity and scene contex

t. Existing approaches either rely on unsupervised priors that often fail to pre serve identity or use overly restrictive supervision that prevents meaningful in trinsic variations. Our method relies on: (i) a relaxed training objective that allows the model to change both intrinsic and extrinsic attributes conditioned o n an identity reference image, a textual prompt describing the target intrinsic attributes, and a background image and object mask defining the extrinsic contex t. At inference, we restrict extrinsic changes by reusing the original backgroun d and object mask, thereby ensuring that only the desired intrinsic attributes a re altered; (ii) Visual Named Entities (VNEs) - fine-grained visual identity cat egories (e.g., "Porsche 911 Carrera") that group objects sharing identity-defin ing features while allowing variation in intrinsic attributes. We use a vision-l anguage model to automatically extract VNE labels and intrinsic attribute descri ptions from a large public image dataset, enabling scalable, identity-preserving supervision. Alterbute outperforms existing methods on identity-preserving obje ct intrinsic attribute editing.

Multi-Head Attention as a Source of Catastrophic Forgetting in MoE Transformers
Anrui Chen, Ruijun Huang, Xin Zhang, Fang Dong, Hengjie Cao, Zhendong Huang, Yif eng Yang, Mengyi Chen, Jixian Zhou, Mingzhi Dong, Yujiang Wang, Jinlong Hou, Qin Lv, Robert P. Dick, Yuan Cheng, Tun Lu, Fan Yang, Li Shang
Mixture-of-Experts (MoE) architectures are appealing for continual learning beca use sparse routing should localize updates and reduce interference, yet MoE Tran sformers still forget substantially even with sparse, well-balanced expert utili zation. We attribute this gap to a pre-routing bottleneck: multi-head attention concatenates head-specific signals into a single post-attention router input, fo rcing routing to act on co-occurring feature compositions rather than separable head channels. We show that this router input simultaneously encodes multiple se parately decodable semantic and structural factors with uneven head support, and that different feature compositions induce weakly aligned parameter-gradient di rections; as a result, routing maps many distinct compositions to the same route . We quantify this collision effect via a route-wise effective composition numbe r N_{eff} and find that higher N_{eff} is associated with larger old-task loss increases after continual training. Motivated by these find ings, we propose MH-MoE, which performs head-wise routing over sub-representatio ns to increase routing granularity and reduce composition collisions. On TRACE a cross multiple backbones, MH-MoE consistently improves the retention--accuracy t rade-off over LoRA-MoE variants.

Towards a Unified Generative Model for Scarce Time Series with Domain Experts
Zihao Yao, Qi Zheng, Jiankai Zuo, Yaying Zhang
Synthesizing realistic time series with generative models has wide-ranging appli cations in real-world scenarios. Despite recent progress, most existing methods are trained under the assumption of abundant training data, which substantially limits their effectiveness in data-scarce settings. In this paper, we propose Ti meMoDE, a novel framework that integrates Diffusion Transformers with Mixture-of -Experts to exploit both domain adaptability and diffusion-stage awareness for t ime series generation under data scarcity. It is pre-trained on a large-scale co llection of multi-domain datasets to extract domain-agnostic temporal representa tions and domain-specific information benefiting generalization during fine-tuni ng. We propose Domain Prompts to condition expert assignment for indistinguishab le noised tokens, mitigating the limitations of capturing inter-dataset relation ships. Moreover, we incorporate diffusion timestep signals to equip the experts with awareness of time series degradation variations, facilitating adaptive cali brate to stage-dependent denoising requirements. Extensive experiments demonstra te that TimeMoDE outperforms existing methods under diverse low-data settings. I t establishes an innovative paradigm for advanced time series few-shot generatio n.

AdaSCALE: Adaptive Scaling for OOD Detection
Sudarshan Regmi

The ability of the deep learning model to recognize when a sample falls outside its learned distribution is critical for safe and reliable deployment. Recent state-of-the-art out-of-distribution (OOD) detection methods leverage activation shaping to improve the separation between in-distribution (ID) and OOD inputs. These approaches resort to sample-specific scaling but apply a static percentile threshold across all samples regardless of their nature, resulting in suboptimal ID-OOD separability. In this work, we propose \textbf{AdaSCALE}, an adaptive scaling procedure that dynamically adjusts the percentile threshold based on a sample's estimated OODness. This estimation leverages our key observation: OOD samples exhibit significantly more pronounced activation shifts at high-magnitude activations under minor perturbation compared to ID samples. AdaSCALE enables stronger scaling for likely ID samples and weaker scaling for likely OOD samples, yielding highly separable energy scores. Our approach achieves state-of-the-art OOD detection performance, outperforming the latest rival OptFS by $\textbf{14.94}$% in near-OOD and $\textbf{21.28}$% in far-OOD datasets in average FPR@95 metric on the ImageNet-1k benchmark across eight diverse architectures.

Branch Scaling Manifests as Implicit Architectural Regularization for Improving Generalization in Overparameterized ResNets
Zixiong Yu, Guhan Chen, Jianfa Lai, Bohan Li, Songtao Tian
Scaling factors in residual branches have emerged as a prevalent method for boosting neural network performance, especially in normalization-free architectures. While prior work has primarily examined scaling effects from an optimization perspective, this paper investigates their role in residual architectures through the lens of generalization theory. Specifically, we establish that wide residual networks (ResNets) with constant scaling factors become asymptotically unlearnable as depth increases. In contrast, when the scaling factor exhibits rapid depth-wise decay combined with early stopping, over-parameterized ResNets achieve minimax-optimal generalization rates.
To establish this, we demonstrate that the generalization capability of wide ResNets can be approximated by the kernel regression associated with a specific kernel. Our theoretical findings are validated through experiments on synthetic data and real-world classification tasks, including MNIST and CIFAR-100.

Beyond Procedure: Substantive Fairness in Conformal Prediction
Pengqi Liu, Zijun Yu, Mouloud Belbahri, Arthur Charpentier, Masoud Asgharian, Jesse C. Cresswell
Conformal prediction (CP) offers distribution-free uncertainty quantification for machine learning models, yet its interplay with fairness in downstream decision-making remains underexplored. Moving beyond CP as a standalone operation (procedural fairness), we analyze the holistic decision-making pipeline to evaluate substantive fairness—the equity of downstream outcomes. Theoretically, we derive an upper bound that decomposes prediction-set size disparity into interpretable components, clarifying how label-clustered CP helps control method-driven contributions to unfairness. To facilitate scalable empirical analysis, we introduce an LLM-in-the-loop evaluator that approximates human assessment of substantive fairness across diverse modalities. Our experiments show that label-clustered CP often provides a favorable balance between utility and substantive fairness, while reducing set-size disparities in line with our theory. Finally, we empirically show that equalized set sizes, rather than coverage, strongly correlate with improved substantive fairness, enabling practitioners to design more fair CP systems. Our code is available at https://github.com/layer6ai-labs/llm-in-the-loop-conformal-fairness.

Doc-to-LoRA: Learning to Instantly Internalize Contexts
Rujikorn Charakorn, Edoardo Cetin, Shinnosuke Uesaka, Robert Tjarko Lange
Long input sequences are central to in-context learning, document understanding, and multi-step reasoning in Large Language Models (LLMs).
However, the quadratic attention cost of Transformers makes inference memory-intensive and slow.

While context distillation (CD) can transfer information into model parameters, per-prompt distillation is impractical due to training costs and latency. To address these limitations, we propose Doc-to-LoRA (D2L), a lightweight hypernetwork that meta-learns to perform approximate CD within a single forward pass. Given an unseen prompt, D2L generates a LoRA adapter for a target LLM, enabling subsequent queries to be answered without re-consuming the original context, reducing latency and KV-cache memory consumption during target LLM inference. On a long-context needle-in-a-haystack task, D2L successfully learns to map contexts into adapters that store the needle information, achieving near-perfect zero-shot accuracy at sequence lengths exceeding the target LLM's native context window by more than 4x. On real-world QA datasets with limited compute, D2L outperforms standard CD while significantly reducing peak memory consumption and update latency. We envision that D2L can facilitate rapid adaptation of LLMs, opening up the possibility of frequent knowledge updates and personalized chat behavior. Code and checkpoints are available at https://github.com/SakanaAI/doc-to-lora.

Tight Margin-Based Generalization Bounds for Voting Classifiers over Finite Hypothesis Sets

Kasper Green Larsen, Natascha Schalburg

We prove the first margin-based generalization bound for voting classifiers, that is asymptotically tight in the tradeoff between the size of the hypothesis set, the margin, the fraction of training points with the given margin, the number of training samples and the failure probability.

****

CLINIC: Towards High-quality Graph Out-Of-Distribution Detection

Yifan Wang, Haodong Zhang, Changhu Wang, Tao Ren, Dongjie Wang, Wei Ju, Chong Chen, Xian-Sheng Hua, Xiao Luo

This paper studies the problem of graph out-of-distribution (OOD) detection, which aims to identify anomaly graphs out of a graph dataset. Prior efforts usually focus on the utilization of topological structures with unsupervised graph learning to foster typical pattern recognition, which overlooks the semantic structure preserved in contextually affine neighborhoods. Towards this end, we propose a novel approach named Contextual Affinity Exploration with Twin Concordance (CLINIC) for graph OOD detection. The core of CLINIC is to explore and exploit the contextual affinity of the graph data samples for discriminative graph representations. In particular, our CLINIC first builds a contextual affinity graph to depict the semantic structure in the hidden space. More importantly, we introduce high-order affinity to enhance geometric understanding of the structure by utilizing a meta-graph neural network. To enhance representation discriminability with high robustness, we introduce twin concordance learning, which not only minimizes the difference of affinity distributions across different views, but also encourages the consistency between contextually affinitive neighbors. Finally, we introduce a compression strategy to expand the decision boundary for enhanced separation between in-distribution and out-of-distribution graphs. Extensive experimental results demonstrate the superiority of our CLINIC across ten real datasets in comparison to various baselines.

Probabilistic Performance Guarantees for Multi-Task Reinforcement Learning

Yannik Schnitzer, Mathias Jackermeier, Alessandro Abate, David Parker

Multi-task reinforcement learning trains generalist policies that can execute multiple tasks. While recent years have seen significant progress, existing approaches rarely provide formal performance guarantees, which are indispensable when deploying policies in safety-critical settings. We present an approach for computing high-confidence guarantees on the performance of a multi-task policy on tasks not seen during training. Concretely, we introduce a new generalisation bound that composes (i) per-task lower confidence bounds from finitely many rollouts with (ii) task-level generalisation from finitely many sampled tasks, yielding a high-confidence guarantee for new tasks drawn from the same arbitrary and unknown distribution. Across state-of-the-art multi-task RL methods, we show that the

guarantees are theoretically sound and informative at realistic sample sizes.
****
Med-Scout: Curing MLLMs' Geometric Blindness in Medical Perception via Geometry-Aware RL Post-Training
Anglin Liu, Ruichao Chen, Yi Lu, Hongxia Xu, Jintai Chen
Despite recent Multimodal Large Language Models (MLLMs)' linguistic prowess in medical diagnosis, we find even state-of-the-art MLLMs suffer from a critical perceptual deficit: **geometric blindness**. This failure to ground outputs in objective geometric constraints leads to plausible yet factually incorrect hallucinations, rooted in training paradigms that prioritize linguistic fluency over geometric fidelity. This paper introduces Med-Scout, a novel framework that "cures" this blindness via Reinforcement Learning (RL) that leverages the intrinsic geometric logic latent within unlabeled medical images. Instead of relying on costly expert annotations, Med-Scout derives verifiable supervision signals through three strategic proxy tasks inspired by the systematic reading and reasoning patterns of clinicians: Hierarchical Scale Localization, Topological Jigsaw Reconstruction, and Anomaly Consistency Detection. To rigorously quantify this deficit, we present Med-Scout-Bench, a new benchmark specifically designed to evaluate geometric perception. Extensive evaluations show that Med-Scout significantly mitigates geometric blindness, outperforming leading proprietary and open-source MLLMs by over **40%** on our benchmark. Furthermore, this enhanced geometric perception generalizes to broader medical understanding, achieving superior results on radiological and comprehensive medical VQA tasks. The project page is: https://github.com/HKUSTGZ-ML4Health-Lab/Med-Scout.
****
What Does Vision Tool-Use Reinforcement Learning Really Learn? Disentangling Tool-Induced and Intrinsic Effects for Crop-and-Zoom
Yan Ma, Weiyu Zhang, Tianle Li, Du Linge, Xuyang Shen, Pengfei Liu
Vision tool-use reinforcement learning (RL) can equip vision--language models with visual operators such as crop-and-zoom and achieves strong performance gains, yet it remains unclear whether these gains are driven by improvements in tool use or evolving intrinsic capabilities. We introduce \textbf{MED} (Measure--Explain--Diagnose), a coarse-to-fine framework that disentangles intrinsic capability changes from tool-induced effects, decomposes the tool-induced performance difference into gain and harm terms, and probes the mechanisms driving their evolution. Across checkpoint-level analyses on two VLMs with different tool priors and six benchmarks, we find that improvements are dominated by intrinsic learning, while tool-use RL mainly reduces tool-induced harm (e.g., fewer call-induced errors and weaker tool schema interference) and yields limited progress in tool-based correction of intrinsic failures.Overall, current vision tool-use RL learns to coexist safely with tools rather than master them.
****
Unsafer in Many Turns: Benchmarking and Defending Multi-Turn Safety Risks in Tool-Using Agents
Xu Li, Simon Yu, Minzhou Pan, Yiyou Sun, Bo Li, Dawn Song, Xue Lin, Weiyan Shi
LLM-based agents are becoming increasingly capable, yet their safety lags behind. This creates a gap between what agents can do and should do. This gap widens as agents engage in multi-turn interactions and employ diverse tools, introducing new risks overlooked by existing benchmarks. To systematically scale safety testing in multi-turn, tool-realistic settings, we propose a principled taxonomy that transforms single-turn harmful tasks into multi-turn attack sequences. Using this taxonomy, we construct MT-AgentRisk (Multi-Turn Agent Risk Benchmark), the first benchmark to evaluate tool-using agent safety under multi-turn, harmful-distribution settings. Our experiments reveal substantial safety degradation: the Attack Success Rate (ASR) increases by 16\% on average across open and closed models in multi-turn settings. To close this gap, we propose ToolShield, a training-free, tool-agnostic, self-exploration defense: when encountering a new tool, the agent autonomously generates test cases, executes them to observe downstream effects, and distills safety experiences for deployment. Experiments show that ToolShield effectively reduces ASR by 30\% on average in multi-turn interactions.

****
Inducing Overthink: Hierarchical Genetic Algorithm-based DoS Attack on Black-Box Large Language Reasoning Models
Shuqiang Wang, Wei Cao, Jiaqi Weng, Jialing Tao, Licheng Pan, Hui Xue, Zhixuan Chu
Large Reasoning Models (LRMs) are increasingly integrated into systems requiring reliable multi-step inference, yet this growing dependence exposes new vulnerabilities related to computational availability. In particular, LRMs exhibit a tendency to “overthink’’—producing excessively long and redundant reasoning traces—when confronted with incomplete or logically inconsistent inputs. This behavior significantly increases inference latency and energy consumption, forming a potential vector for denial-of-service (DoS) style resource exhaustion.
In this work, we investigate this attack surface and propose an automated black-box framework that induces overthinking in LRMs by systematically perturbing the logical structure of input problems. Our method employs a hierarchical genetic algorithm (HGA) operating on structured problem decompositions, and optimizes a composite fitness function designed to maximize both response length and reflective overthinking markers.
Across four state-of-the-art reasoning models, the proposed method substantially amplifies output length, achieving up to a 26.1× increase on the MATH benchmark and consistently outperforming benign and manually crafted missing-premise baselines. We further demonstrate strong transferability, showing that adversarial inputs evolved using a small proxy model retain high effectiveness against large commercial LRMs. These findings highlight overthinking as a shared and exploitable vulnerability in modern reasoning systems, underscoring the need for more robust defenses.
****
RSF-GLLM: Bridging the Semantic Gap in Multi-Hop Knowledge Graph QA via Recurrent Soft-Flow and Decoupled LLM Generation
Sambaran Bandyopadhyay, Ananth Muppidi
Multi-hop Question Answering over Knowledge Graphs faces a critical challenge: traditional retrieve-then-read pipelines break differentiability, preventing the retriever from learning to bridge the semantic gap where intermediate nodes lack lexical overlap with the query. To address this, we propose RSF-GLLM, a framework decoupling differentiable graph reasoning from answer generation. Our Recurrent Soft-Flow (RSF) module employs a GRU-guided query updater to propagate continuous relevance scores, utilizing a dynamic gating mechanism to traverse semantically dissimilar bridge nodes via structural cues. We introduce flow sparsity regularization to theoretically guarantee convergence from soft probabilities to discrete reasoning paths. These paths are extracted and textualized to fine-tune a Large Language Model (LLM), ensuring generation is grounded in factual topology. Experiments on WebQSP and CWQ demonstrate that RSF-GLLM achieves competitive performance with superior inference efficiency compared to LLM based computationally expensive approaches.
****
Innovation: An Almost Characterization of Hallucination
Nishant P. Das, Piyush Srivastava
Hallucination is a central limitation of large language models (LLMs), and substantial effort has been devoted to understanding and mitigating it. Towards this, Kalai and Vempala (STOC 2024) introduced a probabilistic framework formalizing calibration and hallucination, and showed that, with high probability, calibrated LLMs hallucinate roughly at the rate of the "missing mass", a measure of how incomplete the training data is relative to its source. This raises two fundamental questions: (i) what property of a calibrated LLM makes hallucinations unavoidable? and (ii) can hallucinations be avoided by giving up calibration? We answer these questions by introducing a simpler property we call *innovation* that measures the tendency of a model to produce outputs outside the training data. We show that innovation is implied by the condition for hallucination identified by Kalai and Vempala, and,

further, that it is an almost characterization of hallucination: hallucination implies innovation, and conversely, innovation implies hallucination with high probability. We also provide lower bounds on the hallucination rate based on the "innovation rate", and by relating innovation rate back to missing mass, we obtain new hallucination rate lower bounds based on missing mass that extend the results of Kalai and Vempala.

The Pareto-optimal Trade-off between Regret and Statistical Inference in Linear Stochastic Bandits under Safety Constraints

Yuming Shao, Zhixuan Fang

Linear bandits traditionally prioritize regret minimization, often overlooking statistical inference of the underlying parameter as a critical objective. In high-stakes settings such as healthcare, precise parameter estimation is indispensable, as it provides fundamental insights into system mechanisms and ensures robust decision-making under covariate shift. We investigate the tripartite balance between regret, inference, and safety, deriving a fundamental minimax lower bound that characterizes the Pareto-optimal frontier of these competing goals. We then propose SERMiSC, a novel algorithm that achieves the optimal trade-off by matching this lower bound while maintaining a near-constant $\tilde{O}(1)$ safety risk. Empirical results demonstrate that SERMiSC effectively navigates the Pareto frontier and outperforms various baselines, thereby validating our theoretical analysis.

Stronger Benchmarks for Prediction as a Service with Constraints

Yahav Bechavod, Jiuyao Lu, Aaron Roth

We study a learner who sequentially makes and broadcasts predictions of some underlying adversarially varying state. Many downstream decision makers with different goals and different long-term constraints consume these decisions to choose actions. In this setting we give the first algorithm that obtains simultaneous *dynamic regret* guarantees for all of the decision makers --- where regret for each agent is measured against a potentially changing sequence of actions across rounds of interaction, while also ensuring vanishing constraint violation for each agent. We can promise these dynamic regret bounds not just marginally, but simultaneously on many different intersecting subsequences, which lets decision makers compete with strategies that adapt with both long-term drift and short-term variation. Our results do not require the decision makers to maintain any state, but just to react myopically to our predictions.

AdaS: Adaptive Gradient Descent for Spiking Transformers

Zijian Zhou, Honglin Cao, Ammar Belatreche, Wenjie Wei, Yimeng Shan, Yu Liang, Yu Yang, Shuai Wang, Yalan Ye, Malu Zhang, Yang Yang, Haizhou Li

Transformer-based Spiking Neural Networks (SNNs) combine Transformer performance with SNN energy efficiency through an event-driven self-attention mechanism. However, Spiking Transformers still lag behind their Artificial Neural Network (ANN) counterparts. Most existing studies address this issue through new architectural designs, yet few have explored optimization algorithms tailored to Spiking Transformers.

We substantiate the excessive noise problem in Spiking Transformer training by quantitatively defining parameter-update noise and, based on this definition, providing theoretical analysis and experimental validation.

To address this problem, we propose AdaS, an adaptive gradient descent method for Spiking Transformers. AdaS reduces excessive noise by adaptively incorporating a gradient update component into adaptive optimization. Instead of simply removing noise, AdaS maintains it at an appropriate level to preserve its generalization benefits, thereby improving the performance of Spiking Transformers.

We conduct extensive experiments on various Spiking Transformer architectures and datasets from both computer vision and natural language processing. The results demonstrate that the proposed AdaS consistently enhances performance across different Spiking Transformers, validating its effectiveness and generalizability.

This work is among the first systematic studies of optimizer design specifically for Spiking Transformers, offering a practical tool to narrow the accuracy gap with ANNs while preserving the energy advantages of spike-based computation. Code is available at https://github.com/CayleyZ/AdaS.

Revisiting Efficiency–Accuracy Scaling in Mixture-of-Experts Architectures
Venmugil Elango, Nidhi Bhatia, Roger Waleffe, Rasoul Shafipour, Tomer Asida, Abhinav Khattar, Nave Assaf, Maximilian Golub, Joseph Guman, Tiyasa Mitra, Ritchie Zhao, Ritika Borkar, Ran Zilberstein, Mostofa Patwary, Mohammad Shoeybi, Bita Darvish Rouhani
Mixture-of-Experts (MoEs) have become a central component of many state-of-the-art open-source and proprietary large language models. Despite their widespread adoption, it remains unclear how close existing MoE architectures are to optimal for inference cost, as measured by accuracy per floating-point operation and per parameter. In this work, we revisit MoE design from a hardware-software co-design perspective, grounded in empirical and theoretical considerations. We characterize key performance bottlenecks across diverse deployment regimes, spanning offline high-throughput execution and online, latency-critical inference. Guided by these insights, we introduce **LatentMoE**, a new model architecture resulting from systematic design exploration and optimized for maximal accuracy per unit of compute. Empirical design space exploration at scales of up to 95B parameters and over a 1T-token training horizon, together with supporting theoretical analysis, shows that LatentMoE consistently outperforms standard MoE architectures in terms of accuracy per FLOP and per parameter. Given its strong performance, the LatentMoE architecture has been adopted by the flagship Nemotron-3 Super and Ultra models and scaled to substantially larger regimes, including longer token horizons and larger model sizes, as reported in (NVIDIA et al., 2025, arXiv:2512.20856).

A Random Matrix Perspective on the Consistency of Diffusion Models
Binxu Wang, Jacob A Zavatone-Veth, Cengiz Pehlevan
Diffusion models trained on different, non-overlapping subsets of a dataset often produce strikingly similar outputs when given the same noise seed. We trace this consistency to a simple linear effect: the shared Gaussian statistics across splits already predict much of the generated images. To formalize this, we develop a random matrix theory (RMT) framework that quantifies how finite datasets shape the expectation and variance of the learned denoiser and sampling map in the linear setting. For expectations, sampling variability acts as a renormalization of the noise level through a self-consistent relation $\sigma^2\to\kappa(\sigma^2)$, explaining why limited data overshrink low-variance directions and pull samples toward the dataset mean. For fluctuations, our variance formulas reveal three key factors behind cross-split disagreement: \textit{anisotropy} across eigenmodes, \textit{inhomogeneity} across inputs, and overall scaling with dataset size. Extending deterministic-equivalence tools to fractional matrix powers further allows us to analyze entire sampling trajectories. The theory sharply predicts the behavior of linear diffusion models, and we validate its predictions on U Net and DiT architectures in their non-memorization regime, identifying where and how samples deviates across training data split. This provides a principled baseline for reproducibility in diffusion training, linking spectral properties of data to the stability of generative outputs.

Image-to-Brain Signal Generation for Visual Prosthesis with CLIP Guided Multimodal Diffusion Models
Ganxi Xu, Zhao-Rong Lai, Yuting Tang, Yonghao Song, Guoxu Zhou, Boyu Wang, Jian Zhu, Jinyi Long
Visual prostheses hold great promise for restoring vision in blind individuals. While researchers have successfully utilized M/EEG signals to evoke visual perceptions during the brain decoding stage of visual prostheses, the complementary process of converting images into M/EEG signals in the brain encoding stage remains largely unexplored, hindering the formation of a complete functional pipeline

. In this work, we present a novel image-to-brain signal framework that generate
s M/EEG from images by leveraging the diffusion transformer architecture enhance
d with cross-attention mechanisms. Specifically, we employ a diffusion transform
er (DiT) architecture based on denoising diffusion implicit models (DDIM) to ach
ieve brain signal generation. To realize the goal of image-to-brain signal conve
rsion, we use cross-attention mechanisms to align brain signal embeddings with C
LIP image embeddings. Moreover, we leverage large language models (LLMs) to gene
rate image captions, and concatenate the resulting CLIP text embeddings with CLI
P image embeddings to form unified embeddings for cross-attention alignment, ena
bling our model to capture core semantic information. Furthermore, we introduce
a learnable spatio-temporal position encoding that combines brain region embeddi
ngs with temporal embeddings to capture both spatial and temporal characteristic
s of brain signals. We evaluate the framework on two multimodal benchmark datase
ts (THINGS-EEG2 and THINGS-MEG) and demonstrate that it generates biologically p
lausible brain signals.

Anytime Safe PAC Efficient Reasoning
Chengyao Yu, Hao Zeng, Youxin Zhu, Jianguo Huang, Huajun Zeng, Bingyi Jing
Large Reasoning Models (LRMs) have demonstrated remarkable performance on comple
x tasks but suffer from high computational costs and latency. While selective th
inking strategies improve efficiency by routing easy queries to non-thinking mod
els, existing approaches often incur uncontrollable errors, especially in online
 settings where the performance loss of a non-thinking model is only partially o
bserved and data are non-stationary. To address this, we propose *Betting Probab
ly Approximately Correct* (B-PAC) *reasoning*, a principled method that enables
anytime safe and efficient online reasoning under partial feedback. Specifically
, we utilize inverse propensity scoring estimators to construct test supermartin
gales for candidate thresholds, and then dynamically adjust the routing threshol
d based on the accumulated statistical evidence of safety. Theoretically, we est
ablish the anytime-valid performance loss control and the efficiency of B-PAC re
asoning. Extensive experiments demonstrate that B-PAC reasoning significantly re
duces computational overhead, decreasing thinking model usage by up to 81.01\%,
while controlling the performance loss below the user-specified level.

Structure-Centric Graph Foundation Model via Geometric Bases
Xiaodong He, Haolan He, Ruiyi Fang, Ming Sun, zhao kang
Graph foundation models (GFMs) seek transferable representations across graph do
mains but are limited by structural heterogeneity and incompatible node feature
spaces. We propose Structure-Centric Graph Foundation Models (SCGFM), which trea
t graph topology as the primary source of transferable knowledge. Modeling graph
s as metric measure spaces, SCGFM introduces learnable geometric bases that defi
ne a shared structural coordinate system. Graphs are aligned to these bases via
Gromov–Wasserstein distances, yielding structure-aligned latent representations
that accommodate heterogeneous graph topologies. To address feature incompatibil
ity, SCGFM employs a structure-aware feature re-encoding mechanism that unifies
node representations without assuming a fixed feature dimensionality or requirin
g dataset-specific preprocessing. Experiments on graph- and node-level tasks dem
onstrate strong in-domain and cross-domain generalization, outperforming existin
g GFM approaches.

Beyond Gemini-3-Pro: Revisiting LLM Routing and Aggregation at Scale
Shengji Tang, Weihao Lin, Peng Ye, Jingqi Ye, Hao Li, Yiqun Zhang, Xiaosong Wang
, Bo Zhang, Shuyue Hu, Tao Chen, LEI BAI, Wanli Ouyang
Large Language Models (LLMs) have rapidly advanced, with Gemini-3-Pro setting a
new performance milestone. In this work, we explore collective intelligence as a
n alternative to monolithic scaling, and demonstrate that open-source LLMs' coll
aboration can surpass Gemini-3-Pro. We first revisit LLM routing and aggregation
 at scale and identify three key bottlenecks: (1) current train-free routers are
 limited by a query-based paradigm focusing solely on textual similarity; (2) re
cent aggregation methods remain largely static, failing to select appropriate ag

gregators for different tasks; (3) the complementarity of routing and aggregatio n remains underutilized. To address these problems, we introduce JiSi, a novel f ramework designed to release the full potential of LLMs' collaboration through t hree innovations: (1) Query-Response Mixed Routing capturing both semantic infor mation and problem difficulty; (2) Support-Set-based Aggregator Selection jointl y evaluating the aggregation and domain capacity of aggregators; (3) Adaptive Ro uting-Aggregation Switch dynamically leveraging the advantages of routing and ag gregation. Comprehensive experiments on nine benchmarks demonstrate that JiSi ca n surpass Gemini-3-Pro with only 47% costs by orchestrating ten open-source LLMs , while outperforming mainstream baselines. It suggests that collective intellig ence represents a novel path towards Artificial General Intelligence (AGI).

Identifying Learnwares via Reduced Neural Conditional Mean Embedding
Zi-Yu Mao, Ming Li
The learnware paradigm aims to establish a market of learnwares, each of which i s a well-trained model combined with a specification that describes its function ality without leaking data privacy. The market enables users to efficiently reus e relevant models based on specifications on their own tasks instead of training models from scratch. Recent works have attempted to generate specifications usi ng Reduced Kernel Mean Embedding (RKME), which maps input distributions into Rep roducing Kernel Hilbert Space (RKHS) while ignoring the output space, causing mo dels trained on similar input spaces to yield similar specifications, even when their functionalities differ. Many labeled-RKME improvements attempt to address this by indirectly modeling the input-output conditional distributions, but they remain limited to classification tasks and lack clear theoretical explanations. In this work, we propose Reduced Neural Conditional Mean Embedding (RNCME), a n ovel specification generation method that directly models input-output condition al distributions via Conditional Mean Embedding (CME). Our RNCME method has a cl ear theoretical understanding based on CME and is applicable to both regression and classification tasks. Empirical experiments demonstrate the effectiveness an d efficiency of our RNCME method.

Fine-Tune Once, Reuse Across Models: Bayesian Task-Update Factors and Approximat ions
Siyang Guo, Junbo Wang, Zibin Zheng
As pre-trained models evolve rapidly, transferring fine-tuning knowledge to upda ted models without retraining has become a critical challenge. Most existing met hods reuse parameter updates, yet the same dataset can induce substantially diff erent updates across base models due to mismatched local loss landscapes, making such transfer unstable. We instead adopt a Bayesian-updating perspective: a bas e model defines a prior, while fine-tuning contributes a task-update factor that is prior-agnostic, thereby making it feasible to reuse the update across base m odels. Specifically, we formalize a reusable task-update factor by requiring *in variance across base models* and *a fixed-dimensional parameterization*. Our mai n theoretical result shows that such reusable factors exist when the variational family is a half-space, and it is already maximal among convex families. In par ticular, an ideal regime arises when the priors and their Bayesian posteriors re main within a shared exponential family, as it always admits a reusable update f actor. Building on this existence, we propose ***B**ayesian Task Update **Transf er*** (*BTransfer*), which extracts a reusable task-update factor from a single fine-tuning run and applies it to a new prior. For deep networks, we implement * BTransfer* with a ``lift–transfer–return'' pipeline: 1) lift model parameters to distributions; 2) transfer the extracted task-update factor in the exponential family distributions; and 3) return the updated posterior distribution to parame ter space. Extensive experiments demonstrate that our approach effectively reuse s fine-tuning knowledge across models without post-training.

FlexiFlow: decomposable flow matching for generation of flexible molecular ensem ble
Riccardo Tedoldi, Ola Engkvist, Patrick Bryant, Hossein Azizpour, Jon Paul Janet

, Alessandro Tibo
Sampling useful three-dimensional molecular structures along with their most favorable conformations is a key challenge in drug discovery. Current state-of-the-art 3D de-novo molecular design generative models are limited to generating a single conformation. However, the conformational landscape of a molecule determines its observable properties and how tightly it is able to bind to a given protein target. By generating a representative set of low-energy conformers, we can more directly assess these properties and potentially improve the ability to generate molecules with desired thermodynamic observables. Towards this aim, we propose \textit{FlexiFlow}, a novel architecture that extends flow-matching models, allowing for the joint sampling of molecules along with multiple conformations while preserving both equivariance and permutation invariance. We demonstrate the effectiveness of our approach on the QM9 and GEOM Drugs datasets, achieving state-of-the-art results in 3D molecular generation producing valid, unique, and novel molecules with high fidelity to the training data distribution. Moreover, we show that our model can generate unstrained conformational ensembles capturing the conformational diversity and providing similar coverage to state-of-the-art physics-based methods at a fraction of the inference time. Finally, FlexiFlow can be successfully transferred to the protein-conditioned ligand generation task, even when the dataset contains only static pockets without accompanying conformations.

LIVE: Long-horizon Interactive Video World Modeling
Junchao Huang, Ziyang Ye, Xinting Hu, Tianyu He, Guiyu Zhang, Shaoshuai Shi, Jiang Bian, Li Jiang
Autoregressive video world models predict future visual observations conditioned on actions. While effective over short horizons, these models often struggle with long-horizon generation, as small prediction errors accumulate over time. Prior methods alleviate this by introducing pre-trained teacher models and sequence-level distribution matching, which incur additional computational cost and fail to prevent error propagation beyond the training horizon. In this work, we propose LIVE, a Long-horizon Interactive Video world modEl that enforces bounded error accumulation via a novel cycle-consistency objective, thereby eliminating the need for teacher-based distillation. Specifically, LIVE first performs a forward rollout from ground-truth frames and then applies a reverse generation process to reconstruct the initial state. The diffusion loss is subsequently computed on the reconstructed terminal state, providing an explicit constraint on long-horizon error propagation. Moreover, we provide a unified view that encompasses different approaches and introduce progressive training curriculum to stabilize training. Experiments demonstrate that LIVE achieves state-of-the-art performance on long-horizon benchmarks, generating stable, high-quality videos far beyond training rollout lengths.

From Outcomes to Actions: Leveraging Hindsight for Long-Horizon Language Agent Training
Zishang Jiang, tingyun li, Jinyi Han, Xinyi Wang, Sihang Jiang, Yizhou Ying, Xiaojun Meng, Jiansheng Wei, Jiaqing Liang, Yanghua Xiao
Reinforcement learning (RL) has become a widely adopted technique for improving large language models (LLMs) on complex tasks. Despite this progress, existing RL methods still face challenges in training agents with longer-horizon interactions. One major bottleneck is distinguishing the contribution of different actions in long-horizon interaction, leading to high optimization variance. To address this, we introduce a novel policy gradient method, Hindsight Policy Optimization (HPO), that projects both the current policy distribution and the hindsight distribution into an intent space and extracts low-variance learning signals from the Wasserstein distance between them. We theoretically and empirically show that aggregating semantically similar states and actions in the intent space yields a bounded-variance estimator and improves policy performance stably. Our code is available online.

Recovering Policy-Induced Errors: Benchmarking and Trajectory Synthesis for Robust GUI Agents
Tianpeng Bu, Xin Liu, Qihua Chen, Hao Jiang, Shurui Li, hongtao duan, Lu Jiang, lulu hu, Bin Yang, Minying Zhang
While GUI agents have advanced rapidly, they often lack the robustness to recover from their own errors, hindering real-world deployment. To bridge this gap at both the evaluation and data levels, we introduce GUI-RobustEval and propose Robustness-driven Trajectory Synthesis. GUI-RobustEval contains 1,216 executable test cases that systematically measure error recovery capabilities across a broad and realistic spectrum of error modes. At the data level, RoTS is a scalable synthesis framework that creates 800k high-quality data via a tree-based pipeline that proactively discovers diverse error modes and synthesizes corresponding recovery steps. Our two models, RoTS-7B and RoTS-32B, fine-tuned on our dataset, both demonstrate significant gains on GUI-RobustEval and traditional GUI benchmarks. Notably, RoTS-32B achieves state-of-the-art performance on OSWorld, with a 47.4% success rate and a 33.8% All-Pass@4 score, suggesting that improved long-horizon error recovery ability contributes to both robustness and overall performance. Our code is available at https://github.com/AlibabaResearch/RoTS

MAnchors: Memorization-Based Acceleration of Anchors via Rule Reuse and Transformation
Haonan Yu, Junhao Liu, Xin Zhang
Anchors is a popular local model-agnostic explanation technique whose applicability is limited by its computational inefficiency. To address this limitation, we propose a memorization-based framework that accelerates Anchors while preserving explanation fidelity and understandability. Our approach leverages the iterative nature of Anchors' algorithm which gradually refines an explanation until it is precise enough for a given input by storing and reusing intermediate results obtained during prior explanations. Specifically, we maintain a memory of low-precision, high-coverage rules and introduce a rule transformation framework to adapt them to new inputs: the horizontal transformation adapts a retrieved explanation to the current input by replacing features, and the vertical transformation refines the general explanation until it is precise enough for the input. We evaluate our method across tabular, text, and image datasets, demonstrating that it significantly reduces explanation generation time while maintaining fidelity and understandability, thereby enabling the practical adoption of Anchors in time-sensitive applications.

Speedup Patch: Learning a Plug-and-Play Policy to Accelerate Embodied Manipulation
Zhichao Wu, Junyin Ye, Zhilong Zhang, Yihao Sun, Haoxin Lin, Jiaheng Luo, Haoxiang Ren, Lei Yuan, Yang Yu
While current embodied policies exhibit remarkable manipulation skills, their execution remains unsatisfactorily slow as they inherit the tardy pacing of human demonstrations. Existing acceleration methods typically require policy retraining or costly online interactions, limiting their scalability for large-scale foundation models. In this paper, we propose **S**peed**u**p **P**atch (**SuP**), a lightweight, policy-agnostic framework that enables **plug-and-play acceleration** using solely offline data. SuP introduces an external scheduler that adaptively downsamples action chunks provided by embodied policies to eliminate redundancies. Specifically, we formalize the optimization of our scheduler as a Constrained Markov Decision Process (CMDP) aimed at maximizing efficiency without compromising task performance. Since direct success evaluation is infeasible in offline settings, SuP introduces **World Model based state deviation** as a surrogate metric to enforce safety constraints. By leveraging a learned world model as a virtual evaluator to predict counterfactual trajectories, the scheduler can be optimized via offline reinforcement learning. Empirical results on simulation benchmarks (Libero, Bigym) and real-world tasks validate that SuP achieves an overall $1.8\times$ execution speedup for diverse policies while maintaining their original success rates.

mmBERT: A Modern Multilingual Encoder with Annealed Language Learning
Marc Marone, Orion Weller, William Fleshman, Eugene Yang, Dawn Lawrie, Benjamin Van Durme
Encoder-only language models are frequently used for a variety of language tasks, including classification and retrieval.
However, there has been a lack of recent research efforts for encoder models, especially with respect to multilingual models. We introduce mmBERT, an encoder-only language model pretrained on 3T tokens of multilingual text in over 1800 languages.
To build mmBERT we introduce several novel elements to massively multilingual encoder training, including phased data curation and scheduled language inclusion.
We add over 1700 low-resource languages to the data mix only during the decay phase, showing that it boosts performance dramatically and maximizes the gains from the relatively small amount of training data without excessive repetition.
The model uses recent advances in architecture and training schemes to be faster and more multilingual than other models and we release weights, data, and code.
We show that mmBERT significantly outperforms the previous generation, on various tasks, for both high and low-resource languages.

Robust Signal Enhancement via Fractional Detail Views and Knowledge Guided Multi-view Fusion
Zikun Jin, Yuhua Qian, Xinyan Liang, Jiaqian Zhang, Haijun Geng
Robust signal enhancement at low SNR is fundamentally challenging because noise becomes strongly entangled with the signal and corrupts local time–frequency (TF) evidence.
In this regime, fixed resolution short time Fourier transform (STFT) enhancement with purely data driven convolutional biases can become overconfident in unreliable TF regions, causing unstable suppression or residual artifacts.
We propose FracKGMF, which couples Fractional Distance Decay Convolution (FracConv) with Knowledge Guided Multi-view Fusion (KGMF) for expressive TF modeling and reliability aware decisions under heavy corruption.
FracConv introduces a lightweight fractional distance decay family that reshapes local interactions into long tailed receptive patterns, enabling aggregation of weak but globally consistent cues when per-bin observations are ambiguous.
KGMF uses a wiener inspired reliability prior to calibrate multi-view fusion and reduce excessive suppression in uncertain regions.
Experiments on speech and EM benchmarks show consistent improvements over state-of-the-art baselines, with particularly large gains under extremely low SNR, including a 33 dB average improvement on EM signals at -20 dB.
****
Solving the Offline and Online Min-Max Problem of Non-smooth Submodular-Concave Functions: A Zeroth-Order Approach
Amir Ali Farzin, Yuen-Man Pun, Philipp Braun, Tyler Summers, Iman Shames
We consider max-min and min-max problems with objective functions that are possibly non-smooth, submodular with respect to the minimiser and concave with respect to the maximiser. We investigate the performance of a zeroth-order method applied to this problem. The method is based on the subgradient of the Lovász extension of the objective function with respect to the minimiser and based on Gaussian smoothing to estimate the smoothed function gradient with respect to the maximiser. In expectation sense, we prove the convergence of the algorithm to an ϵ-saddle point in the offline case. Moreover, we show that, in the expectation sense, in the online setting, the algorithm achieves $O(\sqrt{N\bar{P}_N})$ online duality gap, where N is the number of iterations and $\bar{P}_N$ is the path length of the sequence of optimal decisions. The complexity analysis and hyperparameter selection are presented for all the cases. The theoretical results are illustrated via numerical examples.
****
Empty Shelves or Lost Keys? Recall Is the Bottleneck for Parametric Factuality
Nitay Calderon, Eyal Ben-David, Zorik Gekhman, Eran Ofek, Gal Yona

Standard factuality evaluations of LLMs treat all errors alike, obscuring whether failures arise from missing knowledge (empty shelves) or from limited access to encoded facts (lost keys). We propose a behavioral framework that profiles factual knowledge at the level of facts rather than questions, characterizing each fact by whether it is encoded, and then by how accessible it is: cannot be recalled, can be directly recalled, or can only be recalled with inference-time computation (thinking). To support such profiling, we introduce WikiProfile, a new benchmark constructed via an automated pipeline with a prompted LLM grounded in web search. Across 4 million responses from 13 LLMs, we find that encoding is nearly saturated in frontier models on our benchmark, with GPT-5 and Gemini-3 encoding 95--98\% of facts. However, recall remains a major bottleneck: many errors previously attributed to missing knowledge instead stem from failures to access it. These failures are systematic and disproportionately affect long-tail facts and reverse questions. Finally, we show that thinking improves recall and can recover a substantial fraction of failures, indicating that future gains may rely less on scaling and more on methods that improve how models utilize what they already encode.
****

SGERA: Stein-Guided ECG-Report Alignment for ECG Representation Learning
Jian Chen, Yipeng Du, Wenhao Yuan, Shuai Wang, Jinfeng Xu, Zewei Liu, Running Zhao, Edith Cheuk-Han Ngai
Electrocardiogram (ECG) representation learning via ECG-report alignment is often hindered by the inherent structural and statistical divergence between signals and natural language. Existing methods struggle to bridge this gap with simple contrastive objectives, but struggle with distribution dependencies between heterogeneous features. To address this, we propose **SGERA** (**S**tein-**G**uided **E**CG-**R**eport **A**lignment), which leverages the unique properties of Stein kernels to provide a more rigorous geometric alignment in the latent space: **instance-level** alignment via a Stein-RBF kernel enforces pairwise consistency between ECG and report embeddings and **distribution-level** alignment via a Stein-Score kernel captures higher-order interactions for global alignment. Furthermore, we introduce an ECG-Report matching task with a Hard Sample Mining strategy to refine discriminative boundaries. Experiments across three public datasets demonstrate that SGERA significantly outperforms state-of-the-art SSL methods in zero-shot classification, linear probing, and transfer learning, proving the superiority of Stein-guided alignment in handling complex medical modalities. Code is available at supplementary materials.
****

Emergent Alignment via Competition
Natalie Collina, Surbhi Goel, Aaron Roth, Emily Ryu, Mirah Shi
Aligning AI systems with human values remains a fundamental challenge, but does our inability to create perfectly aligned models preclude obtaining the benefits of alignment? We study a strategic setting where a human user interacts with multiple differently misaligned AI agents, none of which are individually well-aligned. Our key insight is that when the user's utility lies approximately within the convex hull of the agents' utilities, a condition that becomes easier to satisfy as model diversity increases, strategic competition can yield outcomes comparable to interacting with a perfectly aligned model.

We model this as a multi-leader Stackelberg game, extending Bayesian persuasion to multi-round conversations between differently informed parties, and prove three results: (1) when perfect alignment would allow the user to learn her Bayes-optimal action, she can also do so in all equilibria under the convex hull condition; (2) under weaker assumptions requiring only approximate utility learning, a non-strategic user employing quantal response achieves near-optimal utility in all equilibria; and (3) when the user selects the best single AI after an evaluation period, equilibrium guarantees remain near-optimal without further distributional assumptions.

We complement the theory with two forms of empirical evidence: First, we perform

simulations of the best-AI selection game using best response dynamics, which show that competition among individually misaligned agents reliably improves user utility when the approximate convex hull assumption is satisfied, but does not always when it fails. Second, we show that synthetically generated AI utility functions (produced via perturbations of the same prompt to evaluate instances on a movie recommendation (MovieLens) and ethical judgement (ETHICS) dataset) quickly produce a convex hull that contains a good approximation of a given utility function even when none of the individual LLM utility functions is well aligned. We show that this phenomenon extends to human and LLM responses on real-world polling data (OpinionQA): a convex hull of LLM opinions can approximate human opinions more accurately than any individual LLM across a wide range of survey questions.

TurboGS: Accelerating 3D Gaussian Splatting via Error-Guided Sparse Pixel Sampling and Optimization

Zheng Dong, Daifei Qiu, Pinxuan Dai, Ke Xu, Jiamin Xu, Lili He, Rynson W. H. Lau, Weiwei Xu

Consumer-level applications require fast optimization of 3D Gaussian Splatting (3DGS) with high-fidelity novel view rendering. However, existing 3DGS acceleration approaches still incur substantial computation on redundant pixels while sacrificing fine details. In this paper, we present TurboGS, an error-guided training framework that accelerates 3DGS by concentrating optimization on perceptually informative pixels. TurboGS is built upon four core components: (1) a tile-wise sparse pixel sampling, which, driven by multi-view reconstruction errors during training, prioritizes challenging regions and skips well-reconstructed ones to avoid redundant gradient computation; (2) a tile-wise structure-aware loss with sparse Normalized Cross-Correlation, which provides sparse yet effective supervision to preserve fine details and stabilize training; (3) an error-driven Gaussian density control strategy, which dynamically allocates model capacity and removes redundant primitives; and (4) a tailored hybrid optimizer that couples Hessian-informed updates with Adam moment damping to stabilize and improve convergence under sparse supervision. Experiments on standard benchmarks demonstrate that TurboGS can deliver on par or superior rendering quality within 100 seconds (up to 10x training speedup over vanilla 3DGS).

The Efficiency Gap in Byte Modeling

Celine Lee, Jing Nathan Yan, Chen Liang, Jiaxin Shi, Yin Zhang, Jeremiah Zhe Liu, Pengcheng Yin, Fernando Pereira, Ed H. Chi, Derek Zhiyuan Cheng, Alexander M Rush, Ruoxi Wang

Modern language models have historically relied on two dominant design choices: subword tokenization and autoregressive (AR) ordering.
These design decisions bake in priors that dictate a model's learning.
Recently, two alternative paradigms have challenged this: byte-level modeling, which bypasses static statistically-derived token vocabularies, and masked diffusion modeling (MDM), which conducts parallel, non-sequential generation.
Their intersection represents a fully end-to-end modality-agnostic generative prototype; however,
removing these structural priors incurs a significant computational cost. In this work, we investigate this cost through a compute-matched scaling study. Our results reveal that the performance penalty of byte modeling is not uniform; across scale, the scaling overhead of byte modeling is worse for MDM than for AR.
We hypothesize that this disparity stems from context fragility: while AR's stable causal history allows models to naturally rediscover subword patterns, the MDM objective destroys the local contiguity required to efficiently resolve semantics from raw bytes. Our findings from controlled permutation experiments suggest that future modality-agnostic designs must incorporate alternative structural biases to maintain viable scaling trajectories in the byte regime.

Harnessing Spectrum Video for Subject-Level Few-Shot and Cross-Montage EEG Generalization

Wei Wang, Fang He, Yifan Li, Wanying Qu, Yawei Li, Quanying Liu, Yanwei Fu
Existing EEG models are limited by electrode heterogeneity and rigid "channel-first" architectures that treat sensors as independent features. We propose Brain Signal Rendering (BSR), which reinterprets EEG as a physical projection of neural activity and transforms raw signals into structured spatiotemporal tensors (termed Spectrum Videos), enabling the transfer of rich priors from video foundation models. By utilizing VideoMAE for self-supervised pre-training, BSR learns robust, layout-agnostic spatiotemporal representations that preserve neural topology. We further employ subject-level few-shot learning and introduce cross-montage fine-tuning to rigorously evaluate generalization across subjects and electrode configurations. Experiments show that VideoMAE model integrated with the BSR framework significantly outperforms state-of-the-art spectrum based methods, providing a scalable and data-efficient foundation for generalizable EEG modeling. Our code is available at https://github.com/yanweifu-sii/BSR-VideoMAE.

Fine-to-Coarse Fairness-Informed Multi-View Clustering
Shengju Yu, Suyuan Liu, Wenhao SHAO, Siwei Wang, Dayu Hu, Yiu-ming Cheung
In multi-view clustering (MVC), conventional anchor learning based models implicitly assume a uniform distribution of anchors across clusters, which could lead to inferior representation, especially when clusters vary significantly in size, as larger clusters require more anchors so as to adequately capture their intrinsic structural complexity. To alleviate this, we design a method termed FCFMVC that explicitly encourages proportional anchor allocation. To be specific, we transfer anchor allocation to discrete sample-cluster learning via bipartite graph bridge, and then backpropagate cluster state consisting of size and dispersion degree to guide anchor assignment. This allows the model to integrate cluster cardinality awareness and structural compactness directly into anchor distribution. On the other hand, we regard anchors as pseudo-samples, introduce an anchor-cluster indicator matrix on each view, and directly constrain the number of anchors assigned to each cluster within a tolerance margin. These two paths are further coupled through anchor-sample label alignment, and collaboratively facilitate anchor generation from fine-grained (anchor-level) to coarse-grained (cluster-level) structures. Besides, the entire optimization operation with linear time and space cost makes FCFMVC well-scalable to large-scale tasks. Experiments on datasets with diverse scales confirm the effectiveness of our FCFMVC.

Efficient Public Verification of Private ML via Regularization
Zoë Ruha Bell, Anvith Thudi, Olive Franzese, Nicolas Papernot, Shafi Goldwasser
Training with differential privacy (DP) guarantees dataset members that they cannot be identified by users of the released model. However, those data providers, and, in general, the public, lack methods to efficiently verify that models trained on their data satisfy DP guarantees. The amount of compute needed to verify DP guarantees for current algorithms scales with the amount of computation required to train the model. In this paper we design the first DP algorithm with near optimal privacy-utility trade-offs but whose DP guarantees can be verified cheaper than training. We focus on DP stochastic convex optimization (DP-SCO), where optimal privacy-utility trade-offs are known. Here we show we can obtain tight privacy-utility trade-offs by privately minimizing a series of regularized objectives and only using the standard DP composition bound. Crucially, this method can be verified with much less compute than training. This leads to the first known DP-SCO algorithm with near optimal privacy-utility whose DP verification scales better than training cost, significantly reducing verification costs on large datasets.

Discriminative Mixture-of-Experts on Graphs with Reliable Expert Fusion
Haoyue Deng, Menghui Wang, Yunlong Zhou, Ziwei Zhang, Ran Zhang, Chunming Hu, Xiao Wang
Graph Mixture-of-Experts (Graph-MoE) offers a way to scale GNNs via adaptive capacity allocation, with the goal of allowing different experts to capture diverse

graph patterns. Its effectiveness heavily depends on the coordination between routing decisions and expert specialization. However, through extensive empirical study, we identify two critical phenomena. First, discrimination loss occurs on both the expert and routing sides, where GNN experts become highly homogenized and the router collapses to a small subset of experts, failing to reflect diverse graph semantics. Second, routing uncertainty is prevalent, as existing routers produce uncertain expert assignments for most nodes, and such uncertainty exhibits a strong negative correlation with model performance.
To address these issues, we propose C^{2}GMoE, a novel Graph-MoE framework featuring Contrastive routing and Confidence-aware fusion. We introduce a group-wise contrastive routing strategy that provides explicit guidance for routing optimization by aligning node-level routing decisions with semantic clusters while satisfying load-balancing constraints. Moreover, through a theoretical analysis of generalization error, we develop a confidence-aware fusion mechanism that adaptively reweights expert predictions according to their confidence. Extensive experiments across multiple benchmarks demonstrate the effectiveness of our proposed C^{2}GMoE.

D²Evo: Dual Difficulty-Aware Self-Evolution for Data-Efficient Reinforcement Learning
Ru Zhang, Renda Li, Ziyu Ma, Weijie Qiu, Chongyang Tao, Yong Wang, Xiangxiang Chu
Reinforcement learning (RL) has demonstrated potential for enhancing reasoning in large language models (LLMs). However, effective RL training, which requires medium-difficulty training samples, faces two fundamental challenges: Effective Data Scarcity and Dynamic Difficulty Shifts, where medium-difficulty samples are scarce and become trivial as models improve. Existing methods mitigate this scarcity to some extent by generating training samples. However, these approaches suffer from anchor-free generation, ignoring co-evolution, and difficulty mismatch. To address these issues, we propose D²Evo, a Dual Difficulty-aware self-Evolution RL framework. In each iteration, our method mines medium-difficulty anchors based on the current Solver's capability, trains the Questioner to generate diverse questions at appropriate difficulty levels, and jointly optimizes both components to enable progressive reasoning gains. Extensive experiments demonstrate that D²Evo outperforms existing methods on mathematical reasoning benchmarks with fewer than 2K real mathematical samples, and exhibits strong generalization on general reasoning benchmarks.
****

Diffusion Language Model Parallel Decoding via Product-of-Experts Bridge
Juntong Shi, Brian L. Trippe, Jure Leskovec, Stefano Ermon, Minkai Xu
Diffusion language models (DLMs) offer substantial speed advantages through parallel decoding, but the lack of token dependencies limits generation quality compared to autoregressive (AR) models. Recent progress attempts to bridge the gap via importance sampling, with DLM being the proposal and AR being the target. However, due to the huge gap between their distributions, the sampling requires a large number of particles and is thus expensive to compute. In this paper, we introduce PoE-Bridge, a novel decoding framework that drastically improves generation speed and accuracy by introducing an intermediate distribution to bridge the gap. The distribution is constructed as a Product-of-Experts (PoE) of the DLM proposal and the AR target. With the intermediate distribution, we first use the DLM to draft multiple continuations in parallel, then apply rejection sampling to verify the drafted tokens and move the resulting candidates toward the PoE. We then use importance sampling to further correct the PoE-aligned candidates toward the AR target. We further propose several improved techniques, including mixed-temperature sampling for enhanced diversity and elastic rejection windows for reducing wasted verification. Empirically, PoE-Bridge achieves significantly improved accuracy with $5\times$ speedup over the standard DLM decoding approach, and recovers at least 95% of the target AR model's performance, efficiently advancing most of the quality gap on challenging mathematical reasoning and coding tasks. Our code is available at [https://github.com/juntongshi48/poe-bridge](https:

//github.com/juntongshi48/poe-bridge).

Multi-view Consistent Latent Action Learning for World Modeling and Control
Shenghua Wan, Xiaohai Hu, Xunlan Zhou, Lei Yuan, Le Gan, De-Chuan Zhan
The scalability of world models is currently bottlenecked by the scarcity of act ion annotations. While self-supervised latent action learning offers a potential solution, existing single-view paradigms—relying on information bottlenecks or Vector Quantization (VQ)—often conflate superficial 2D pixel displacements with the underlying physical-spatial dynamics of an action. Consequently, these metho ds remain highly susceptible to view-dependent noise, such as camera shake. We i ntroduce **MuCoLA** (**Mu**lti-view **Co**nsistent **L**atent **A**ction learnin g), a framework that learns robust, view-invariant action representations by enf orcing semantic consistency across synchronized video streams. MuCoLA utilizes a Student-Teacher network with DINO-style self-distillation to align action distr ibutions across viewpoints, effectively filtering high-frequency visual noise wh ile preserving motion semantics. Theoretical analysis reveals that our multi-vie w objective functions as a spectral filter, isolating agent dynamics from enviro nmental nuisances. Empirically, MuCoLA significantly outperforms baselines in ac tion regression, video reconstruction, and downstream visual control tasks. Furt hermore, we demonstrate that MuCoLA exhibits favorable scaling properties with r espect to model capacity and data volume, paving the way for large-scale action- free world modeling.

One Batch Is Enough: A Unified Dataset Condensation Framework for General Time S eries Analysis
Wei Shao, Ziquan Fang, Zheqi Lu, Yongfeng Su, Yuzhu Wang, Yunjun Gao
Time-series analysis is critical in real-world applications, yet the explosion o f time-series data imposes severe burdens on storage and computational resources . Recently, dataset condensation has emerged as a promising data-centric solutio n by synthesizing compact yet informative datasets to replace large-scale raw da ta. However, existing methods are largely vision-centric, failing to capture uni que temporal properties of time series, or task-specific, tightly coupling the c ondensed data to a particular downstream objective. As a result, these approache s suffer from feature mismatch and fail to generalize across diverse time-series tasks. To bridge this gap, we propose UniTSC, the first unified dataset condens ation framework for general time-series analysis. UniTSC employs a multi-view hy brid encoder to capture task-invariant representations across temporal, spectral , and topological perspectives. Building upon this representation, we design a t ri-space alignment paradigm that jointly aligns optimization trajectories, power spectral densities, and multivariate dependency structures, enabling comprehens ive information preservation under extreme compression. Extensive experiments sh ow that UniTSC retains up to 97.9\% of downstream performance using as little as 0.01\% of the original training data, within our experimental settings tied to standard sequence lengths, revealing that a single batch-equivalent budget ($\te xtless$ 128 samples) is sufficient to capture the essential dynamics of complex time-series data.

A Generalist Pair-wise Progress Critic Model for Vision-Language-Action Robots
Qi Zhang, Shaopeng Zhai, Shengzhe Zhang, Litao Liu, Tianyi Zhang, Fuxian Huang, Ming Zhou
Recent advances in Vision-Language-Action (VLA) models have significantly improv ed robotic perception and manipulation capabilities, but still struggling to ada pt in dynamic, open-ended real-world environments due to a lack of reliable task progress feedback and improvement mechanisms. To address these challenges, we p ropose a generalist Vision Language Action-Critic model, VLAC, which can integra te both human and robot data, and unify action policy and task progress critic w ithin a single autoregressive architecture. Specifically, we propose a scalable and generalizable pair-wise progress understanding approach that can predict the delta of task progress between two steps in a trajectory and generate correct a ctions to complete the task. Then, we trained the model on large-scale, multi-so

urce human, robot, and general vision-language data for a generalist. Furthermor e, we deploy reinforcement learning where VLAC can autonomously evaluate task pr ogress to provide intrinsic rewards. Extensive evaluations demonstrate that our model generalizes effectively across diverse tasks and environments, leveraging its pair-wise progress understanding to provide reliable dense rewards, robust a ction generation, and significant improvements in real-world reinforcement learn ing. Our codes are available at \url{https://github.com/InternRobotics/VLAC}.

Solving Spatial-Spectral Fusion with Latent Spectral Operators
Wei Li, Jieyuan Pei, Junnan Xu, Xuanfeng Ding, Junwei Zhu, wanjun chen, Jianwei Zheng
Existing deep spatial–spectral fusion (SSF) methods typically learn the fusion m apping in the coordinate domain using convolutions and attentions, making it har d to scale across varying spatial resolutions and offering limited control over the frequency content of the reconstructions, which may further lead to severe s pectral distortion.
In this work, we propose Latent Spectral Operators (LSO), a SSF framework that l earns fusion mappings between spectral functions through a structured operator p arameterization.
Specifically, LSO first applies a cross-attention projection, where learned late nt tokens serve as spectral prompts, to compress high-dimensional observations i nto a compact latent representation, and then adopts a hierarchical, patch-based architecture to integrate rich multi-scale cues.
Furthermore, to parameterize the latent fusion operator in a controllable manner , a Trigonometric Basis Solver is elaborated, which represents the mapping using a trigonometric basis expansion.
This formulation naturally supports multi-frequency modeling, with a capacity-st ability trade-off governed by the number of basis functions.
Extensive experiments on the CAVE and Harvard benchmarks demonstrate that LSO ac hieves consistent state-of-the-art performance and exhibits strong transferabili ty across different spatial scales.

Beyond Independence: Learning Correlated Views for Variational Incomplete Multi-View Clustering
Zheming Xu, Aiyue Tang, Shidi Chen, Xuechao Zou, Congyan Lang, Rogelio A. Mancis idor, Michael Kampffmeyer
Incomplete multi-view clustering (IMVC) aims to uncover shared cluster structure s from data with partially observed views. Although recent imputation-free metho ds based on variational inference demonstrate robustness to missing views, they commonly rely on a conditional independence assumption across views, which fails to capture the inherently structured and potentially correlated nature of multi -view data. In this paper, we propose a variational framework that explicitly go es beyond this assumption by introducing a learnable cross-view correlation stru cture. Specifically, we explicitly model and learn correlations between views by utilizing the covariance structure of posterior estimation errors. To facilitat e robust and efficient learning, the correlation matrix is parameterized through a normalized Cholesky decomposition, ensuring positive definiteness and enablin g the entire model to be trained jointly through a unified variational objective . Extensive experiments on multiple IMVC benchmarks demonstrate that our method consistently outperforms state-of-the-art approaches across a wide range of miss ing-view settings. These results highlight the effectiveness of adaptive correla tion modeling in variational IMVC, demonstrating the need to go beyond the indep endence assumption in IMVC.

Deep Reinforcement Learning Finds Bayes-Nash Equilibrium in Competitive Newsvend or Problems
Kassian Köck, Fabian Raoul Pieroth, Martin Bichler
We investigate learning dynamics in competitive newsvendor games, a class of con tinuous-action games with strategic substitutes. Despite established equilibrium properties, convergence of independent learning algorithms in repeated general-

sum play remains uncertain. We analyze structural properties under complete and incomplete information, deriving closed-form equilibria for a symmetric complete-information benchmark with perfect substitution. Our main theoretical contribution proves strict monotonicity in both complete-information and Bayesian models with private costs, ensuring equilibrium uniqueness and ruling out unstable dynamics. This provides convergence guarantees for variational-inequality-based algorithms. Numerical experiments using deep reinforcement learning agents with Proximal Policy Optimization empirically demonstrate convergence to Nash and Bayesian Nash equilibria, verified by equilibrium checks. These results establish a foundation for applying deep reinforcement learning in competitive inventory management.

Brep2Shape: Boundary and Shape Representation Alignment via Self-supervised Transformers

Yuanxu Sun, Yuezhou Ma, Haixu Wu, Guanyang Zeng, Muye Chen, Jianmin Wang, Mingsheng Long

Boundary representation (B-rep) is the industry standard for computer-aided design (CAD). While deep learning shows promise in processing B-rep models, existing methods suffer from a representation gap: continuous approaches offer analytical precision but are visually abstract, whereas discrete methods provide intuitive clarity at the expense of geometric precision. To bridge this gap, we introduce Brep2Shape, a novel self-supervised pre-training framework designed to align abstract boundary representations with intuitive shape representations. Our framework employs a geometry-aware task where the model learns to predict dense spatial points from parametric Bézier control points, enabling the network to better understand physical manifolds derived from abstract coefficients. To enhance this alignment, we propose a dual transformer backbone with parallel streams that independently encode surface and curve tokens to capture their distinct geometric properties. Additionally, the topology attention is integrated to model the inherent interdependencies between surfaces and curves, thereby maintaining topological consistency. Experimental results demonstrate that Brep2Shape offers significant scalability, achieving state-of-the-art accuracy and faster convergence across various downstream tasks. Code is available at this repository: https://github.com/thuml/Brep2Shape.

Coupled Cluster con MoLe: Molecular Orbital Learning for Neural Wavefunctions

Luca Thiede, Abdulrahman Aldossary, Andreas Burger, Jorge A. Campos-Gonzalez-Angulo, Alex Zook, Melisa Alkan, KOHEI NAKAJI, Taylor Lee Patti, Jérôme Florian Gonthier, Mohammad Ghazi Vakili, Alan Aspuru-Guzik

Density functional theory (DFT) is the most widely used method for calculating molecular properties; however, its accuracy is often insufficient for quantitative predictions. Coupled cluster (CC) theory is the most successful method for achieving accuracy beyond DFT and predicting properties that closely align with experiment. It is known as the ``gold standard'' of quantum chemistry. Unfortunately, the high computational cost of CC limits its widespread applicability. In this work, we present the Molecular Orbital Learning Model (MoLe), an equivariant machine learning model that directly predicts CC's core mathematical objects, the excitation amplitudes, from the mean-field Hartree-Fock molecular orbitals as inputs. We test various aspects of our model and demonstrate its very high data efficiency and remarkable out-of-distribution generalization to larger molecules and off-equilibrium geometries, despite being trained only on small equilibrium geometries. Finally, we also examine its ability to reduce the number of cycles required to converge CC calculations. MoLe can set the foundations for high-accuracy wavefunction-based ML architectures to accelerate molecular design and complement force-field approaches.

Turbo4DGen: Ultra-Fast Acceleration for 4D Generation

Yuanbin Man, Ying Huang, Zhile Ren, Miao Yin

4D generation, or dynamic 3D content generation, integrates spatial, temporal, and view dimensions to model realistic dynamic scenes, playing a foundational rol

e in advancing world models and physical AI. However, maintaining long-chain consistency across both frames and viewpoints through the unique spatio-camera-motion (SCM) attention mechanism introduces substantial computational and memory overhead, often leading to out-of-memory (OOM) failures and prohibitive generation times. To address these challenges, we propose Turbo4DGen, an ultra-fast acceleration framework for diffusion-based multi-view 4D content generation. Turbo4DGen introduces a spatiotemporal cache mechanism that persistently reuses intermediate attention across denoising steps, combined with dynamically semantic-aware attention pruning and an adaptive SCM chain bypass scheduler, to drastically reduce redundant SCM attention computation. Our experimental results show that Turbo4DGen achieves an average 9.7$\times$ speedup without quality degradation on the ObjaverseDy and Consistent4D datasets. To the best of our knowledge, Turbo4DGen is the first dedicated acceleration framework for 4D generation.

Active Learning with Low-Rank Structure for Data Selection
Vincent Cohen-Addad, Sasidhar Kunapuli, Vahab Mirrokni, Mahdi Nikdan, David Woodruff, Samson Zhou
In the data selection problem, the objective is to choose a small, representative subset of data that can be used to efficiently train a machine learning model. Sener and Savarese [ICLR 2018] showed that, given an embedding representation of the data and suitable geometric assumptions, heuristics based on k-center clustering can be used to perform data selection. This perspective was further explored by Axiotis et. al. [ICML 2024], who proposed a data selection approach based on k-means clustering and sensitivity sampling. However, these methods rely on the assumption that the dataset exhibits intrinsic geometric structure that can be effectively captured by clustering, whereas many modern datasets instead possess global algebraic structure that is better exploited by low-rank approximation or principal component analysis.

In this paper, we introduce a new data selection framework based on low-rank approximation and residual-based sampling, formulated through the lens of row subset selection and loss-preserving coreset construction. Given an embedding representation of the data satisfying mild regularity conditions, which can be interpreted as algebraic or angular notions of Lipschitz continuity, we show that it is possible to select a weighted subset of $\tilde{O}\left(k + \frac{1}{\varepsilon^2}\right)$ data points whose average loss approximates the average loss over the full dataset within a $(1+\varepsilon)$ relative error, up to an additive $\varepsilon \Phi_k$ term, where Φ_k denotes the optimal rank-k approximation cost of the embedding matrix. We complement these theoretical guarantees with empirical evaluations, demonstrating that on a range of real-world datasets, our data selection approach achieves improved performance over prior strategies based on uniform sampling or clustering-based sensitivity sampling.
****
The Deterministic Horizon: When Extended Reasoning Fails and Tool Delegation Becomes Necessary
Dongxin Guo, Jikun Wu, SM Yiu
Extended chain-of-thought reasoning can degrade performance on deterministic state-tracking tasks, not due to preference biases, but limits rooted in the information-theoretic capacity of decoder-only attention. We establish: (1) an Attention Bottleneck Theorem with a complementary achievability construction, bounding state-tracking capacity as $O(H \cdot \log(L/H) \cdot \sqrt{d_h})$; (2) a context-dependent error model yielding super-exponential accuracy decay; (3) the State-Space Jaccard metric distinguishing capability from preference failures; (4) a Deterministic Horizon $d^* \in [19, 31]$ beyond which tool delegation becomes necessary. Across 12 models and 8 task domains (including SWE-Bench, WebArena, and SQL-Multi), tool-integrated reasoning consistently outperforms neural chain-of-thought; on the primary model suite it reaches 86–94% accuracy versus 24–42% for neural chain-of-thought. Fine-tuning on optimal-length traces yields $<$5% improvement, confirming an architectural ceiling, and high cross-model correlation ($r = 0.81$–0.91) indicates these failures are architectural rather than traini

ng-specific. Our results provide principled guidance for when pure neural reasoning should yield to hybrid approaches in agentic systems.

Evolution Strategies at Scale: LLM Fine-Tuning Beyond Reinforcement Learning
Xin Qiu, Yulu Gan, Conor F. Hayes, Qiyao Liang, Yinggan XU, Roberto Dailey, Elliot Meyerson, Babak Hodjat, Risto Miikkulainen
Fine-tuning large language models (LLMs) for downstream tasks is an essential stage of modern AI deployment. Reinforcement learning (RL) has emerged as the dominant fine-tuning paradigm, underpinning many state-of-the-art LLMs. In contrast, evolution strategies (ES) has largely been overlooked due to the widespread belief that it does not scale to modern model sizes. This paper overturns this assumption by demonstrating the first successful application of ES to full-parameter fine-tuning of LLMs at the billion-parameter scale, without dimensionality reduction. ES can indeed search over extremely high-dimensional parameter spaces and outperform established RL implementations across multiple axes, including improved tolerance to long-horizon and delayed rewards, robustness across diverse base LLMs, reduced susceptibility to reward hacking, and improved training stability. These findings suggest that ES is not merely a viable alternative to RL, but a fundamentally different and powerful backpropagation-free post-training paradigm that opens a new direction for LLM fine-tuning beyond current RL-based approaches.

Step-Level Sparse Autoencoder for Reasoning Process Interpretation
Xuan Yang, Jiayu Liu, Yuhang Lai, Hao Xu, Zhenya Huang, Ning Miao
Large Language Models (LLMs) have achieved strong complex reasoning capabilities through Chain-of-Thought (CoT) reasoning. However, their reasoning patterns remain too complicated to analyze. While Sparse Autoencoders (SAEs) have emerged as a powerful tool for interpretability, existing approaches predominantly operate at the token level, creating a granularity mismatch when capturing more critical step-level information, such as reasoning direction and semantic transitions. In this work, we propose step-level sparse autoencoder (SSAE), which serves as an analytical tool to disentangle different aspects of LLMs' reasoning steps into sparse features. Specifically, by precisely controlling the sparsity of a step feature conditioned on its context, we form an information bottleneck in step reconstruction, which splits incremental information from background information and disentangles it into several sparsely activated dimensions. Experiments on multiple base models and reasoning tasks show the effectiveness of the extracted features. By linear probing, we can easily predict surface-level information, such as generation length and first token distribution, as well as more complicated properties, such as the correctness and logicality of the step. These observations indicate that LLMs should already at least partly know about these properties during generation, which provides the foundation for the self-verification ability of LLMs. Our code is available at https://github.com/Miaow-Lab/SSAE.

UniRTL: Unifying Code and Graph for Robust RTL Representation Learning
Yi Liu, Hongji Zhang, Lei Chen, Mingxuan Yuan, Qiang Xu
Developing effective representations for register transfer level (RTL) designs is crucial for accelerating the hardware design workflow. Existing approaches, however, typically rely on a single data modality, either the RTL code or its associated graph-based representation, limiting the expressiveness and generalization ability of the learned representations. For RTL, the control data flow graph (CDFG) offers a comprehensive structural representation that preserves complete information, while the code modality explicitly encodes semantic and functional information. We argue that integrating these complementary modalities is essential for a thorough understanding of RTL designs. To this end, we propose UniRTL, a multimodal pretraining framework that learns unified RTL representations by jointly leveraging code and CDFG. UniRTL achieves fine-grained alignment between code and graph through mutual masked modeling and employs a hierarchical training strategy that incorporates a pretrained graph-aware tokenizer and staged alignment of text (*i.e.*, functional summary) and code prior to graph integration. We

evaluate UniRTL on two downstream tasks, performance prediction and code retriev
al, under multiple settings. Experimental results show that UniRTL consistently
outperforms prior methods, establishing it as a more robust and powerful foundat
ion for advancing hardware design automation.

Equalized Generative Treatment: Matching f-divergences for Fairness in Generativ
e Models
Alexandre Verine, Rafael Pinot, Florian Le Bronnec
Fairness is a crucial concern for generative models, which not only reflect but
can also amplify societal and cultural biases. Existing fairness notions for gen
erative models are largely adapted from classification and focus on balancing th
e probability of generating samples from each sensitive group. We show that such
 criteria are brittle, as they can be met even when different sensitive groups a
re modeled with widely varying quality. To address this limitation, we introduce
 a new fairness definition for generative models, termed as \emph{equalized gene
rative treatment} (EGT), which requires comparable generation quality across all
 sensitive groups, with quality measured via a reference f-divergence. We furt
her analyze the trade-offs induced by EGT, demonstrating that enforcing fairness
 constraints necessarily couples the overall model quality to that of the most c
hallenging group to approximate. This indicates that a simple yet efficient min–
max fine-tuning method should be able to balance f-divergences across sensitiv
e groups to satisfy EGT. We validate this theoretical insight through a set of e
xperiments on both image and text generation tasks. We demonstrate that min-max
methods consistently achieve fairer outcomes compared to other approaches from t
he literature, while maintaining competitive overall performance for both tasks.
****
Hierarchical Policy Learning via Spectral Decomposition
Shuxin Cao, Liquan Wang, Walker Byrnes, Yiye Chen, Yilun Du, Animesh Garg
In this paper, we identify a semantic decomposition in robot action sequences, s
eparating task-level motion intent from execution-level refinements.
By analyzing actions in the spectral domain using the discrete cosine transform
(DCT), we observe that low-frequency components capture global motion trajectori
es, while high-frequency components encode precise timing, alignment, and contac
t behaviors.
Motivated by this structure, we propose Causal Spectral Policy (CSP), which mode
ls action generation as a causal coarse-to-fine process: coarse motion is predic
ted from observation and language, and fine corrections are generated conditiona
lly on the realized trajectory.
Across simulation and real-world evaluations, CSP consistently outperforms stron
g baselines on precision-sensitive manipulation tasks.
Additionally, we propose human-inspired teleoperation noise injection as a data
augmentation method under which our approach demonstrates strong robustness to n
oisy demonstrations
****
DRL-STAF: A Deep Reinforcement Learning Framework for State-Aware Forecasting of
 Complex Multivariate Hidden Markov Processes
Manrui Jiang, Jingru Huang, Yong Chen, Chen Zhang
Forecasting multivariate hidden Markov processes is challenging due to nonlinear
 and nonstationary observations, latent state transitions, and cross-sequence de
pendencies. While deep learning methods achieve strong predictive accuracy, they
 typically lack explicit state modeling, whereas Hidden Markov Models (HMMs) pro
vide interpretable latent states but struggle with complex nonlinear emissions a
nd scalability. To address these limitations, we propose DRL-STAF, a **D**eep **
R**einforcement **L**earning based **ST**ate-**A**ware **F**orecasting framework
 that jointly predicts next-step observations and estimates the corresponding hi
dden states for complex multivariate hidden Markov processes. Specifically, DRL-
STAF models complex nonlinear emissions using deep neural networks and estimates
 discrete hidden states using reinforcement learning, reducing the reliance on p
redefined transition structures and enabling flexible adaptation to diverse temp
oral dynamics. In particular, DRL-STAF mitigates the state-space explosion encou

ntered by typical multivariate HMM-based methods. Extensive experiments demonstrate that DRL-STAF outperforms HMM variants, standalone deep learning models, and existing DL-HMM hybrids in most cases, while also providing reliable hidden-state estimates.
****

Towards Diffeomorphism-Equivariant Neural Networks via Canonicalization
Josephine Elisabeth Oettinger, Zakhar Shumaylov, Johannes Bostelmann, Jan Lellmann, Carola-Bibiane Schönlieb
Incorporating group symmetries via equivariance into neural networks has emerged as a robust approach for improving efficiency and overcoming the data requirements of modern deep learning. While most existing approaches, such as group convolutions and averaging-based methods, focus on compact, finite, or low-dimensional groups with linear actions, this work explores how equivariance can be extended to infinite-dimensional groups. We propose a strategy designed to induce diffeomorphism equivariance in pre-trained neural networks via energy-based canonicalization. Formulating equivariance as an optimization problem allows us to access the rich toolbox of already established differentiable image registration methods. Empirical results on segmentation and classification tasks confirm that our approach achieves approximate equivariance and generalizes to unseen transformations without relying on extensive data augmentation or retraining.

Generalizing Multi-Scale Time-Series Modeling with a Single Operator
Cheonwoo Lee, Dooho Lee, Doyun Choi, Jaemin Yoo
Multi-scale modeling has emerged as an effective design principle for time-series forecasting by capturing temporal dynamics at multiple resolutions. As no principled foundation has been established in the literature, we unify existing scaling methods into a scaling operator family, revealing a fundamental limitation of existing approaches: reliance on fixed and discrete scaling. To address this limitation, we propose SiGMA (Single Generalized Multi-scale Architecture), which enables distance-aware scaling via the learnable discrete Gaussian (LDG) kernel grounded in scale-space theory. We evaluate SiGMA comprehensively on long- and short-term forecasting benchmarks against state-of-the-art multi-scale baselines. SiGMA outperforms all competitors on both tasks, especially achieving the best performance in 13 out of 16 long-term evaluation settings. Beyond accuracy, SiGMA significantly improves training speed by up to 5.3 times and reduces memory consumption by up to 3.8 times over the strongest competitors. Code is available at https://github.com/cheonwoolee/SiGMA.

AReaL-DTA: Dynamic Tree Attention for Efficient Reinforcement Learning of Large Language Models
Jiarui Zhang, Yuchen Yang, Ran Yan, Zhiyu Mei, Liyuan Zhang, Daifeng Li, Wei Fu, Jiaxuan Gao, Shusheng Xu, Yi Wu, Binhang Yuan
Reinforcement learning (RL)-based post-training for large language models (LLMs) is computationally expensive, as it generates many rollout sequences that frequently share long token prefixes. Existing RL frameworks usually process these sequences independently during policy training, i.e., repeatedly recomputing identical prefixes in both the forward and backward passes of policy gradient computation, leading to substantial inefficiencies in computation resources and memory usage. Although prefix sharing naturally induces a tree structure over rollouts, packed tree-mask approaches scale poorly in RL settings. In this paper, we introduce AReaL-DTA, which efficiently exploits prefix sharing in RL training. AReaL-DTA employs a depth-first search (DFS)-based execution strategy that dynamically traverses the rollout prefix tree during both forward and backward computation, materializing only a single root-to-leaf path at a time. To further improve scalability, AReaL-DTA incorporates a load-balanced distributed batching mechanism that dynamically constructs and processes prefix trees across multiple GPUs. On τ^2-bench, AReaL-DTA improves training throughput by up to $8.31\times$ over dense training and up to $1.70\times$ over sparse training. Our code is available at https://github.com/areal-project/AReaL/tree/feat/dta.

PRISM: Distribution-free Adaptive Computation of Matrix Functions for Accelerating Neural Network Training
Shenghao Yang, Zhichao Wang, Oleg Balabanov, N. Benjamin Erichson, Michael W. Mahoney
Matrix functions such as square root, inverse roots, and orthogonalization play a central role in preconditioned gradient methods for neural network training. This has motivated the development of iterative algorithms that avoid explicit eigendecompositions and rely primarily on matrix multiplications, making them well suited for modern GPU accelerators. We present PRISM (Polynomial-fitting and Randomized Iterative Sketching for Matrix functions computation), a general framework for accelerating iterative algorithms for computing matrix functions. PRISM combines adaptive polynomial approximation with randomized sketching: at each iteration, it fits a polynomial surrogate to the current spectrum via a sketched least-squares problem, adapting to the instance at hand with minimal overhead. We apply PRISM to accelerate Newton–Schulz-like iterations for matrix square roots and orthogonalization, which are core primitives in machine learning. Unlike prior methods, PRISM requires no explicit spectral bounds or singular value estimates; it adapts automatically to the evolving spectrum. Empirically, PRISM accelerates training when integrated into Shampoo and Muon optimizers.

Noisy-Space Policy Gradient for Diffusion Policies in Offline Reinforcement Learning
Mahmoud Selim, Cristina Cipriani, Karl Henrik Johansson
Diffusion policies offer a powerful and expressive parameterization for continuous control. Yet, their integration with reinforcement learning remains conceptually and algorithmically challenging. In this work, we address this gap by introducing a noisy-space action-value (Q-)function that assigns values to diffusion latents through the distribution of executed actions induced by the denoising process. We show that this construction admits a precise semantic interpretation and derive a noisy-space policy gradient (NSPG) that optimizes noisy latents using only clean action space value estimates. Building on this result, we formulate a KL-regularized policy improvement over noisy latents and show that the resulting objective admits a diffusion-compatible regression form, avoiding backpropagation through the denoising process. Empirical results on state-based D4RL benchmarks and vision-based OGBench tasks demonstrate that the proposed noisy-space objective provides a principled and effective basis for training diffusion policies in offline reinforcement learning. Project webpage: https://mahmoud-selim.github.io/NSPG/

Towards Efficient Large Language Reasoning Models via Extreme-Ratio Chain-of-Thought Compression
Yuntian Tang, Bohan Jia, Wenxuan Huang, Lianyue Zhang, Jiao Xie, Wenxi Li, Wei Li, Jie Hu, Xinghao Chen, Rongrong Ji, Shaohui Lin
Chain-of-Thought (CoT) reasoning successfully enhances the reasoning capabilities of Large Language Models (LLMs), yet it incurs substantial computational overhead for inference. Existing CoT compression methods often suffer from a critical loss of logical fidelity at high compression ratios, resulting in significant performance degradation. To achieve high-fidelity, fast reasoning, we propose a novel EXTreme-RAtio Chain-of-Thought Compression framework, termed Extra-CoT, which aggressively reduces the token budget while preserving answer accuracy. To generate reliable, high-fidelity supervision, we first train a dedicated semantically-preserved compressor on mathematical CoT data with fine-grained annotations. An LLM is then fine-tuned on these compressed pairs via a mixed-ratio supervised fine-tuning (SFT), teaching it to follow a spectrum of compression budgets and providing a stable initialization for reinforcement learning (RL). We further propose Constrained and Hierarchical Ratio Policy Optimization (CHRPO) to explicitly incentivize question-solving ability under lower budgets by a hierarchical reward. Experiments on three mathematical reasoning benchmarks show the superiority of Extra-CoT. For example, on MATH-500 using Qwen3-1.7B, Extra-CoT achieves over 73\% token reduction with an accuracy improvement of 0.6\%, significantly ou

tperforming state-of-the-art (SOTA) methods. Our source codes are released in th
e Supplementaries.

Mosaic: Runtime-Efficient Multi-Agent Embodied Planning

Kunjal Panchal, Saayan Mitra, Sunav Choudhary, Victor Bursztyn, Somdeb Sarkhel,
Hui Guan

LLM-based multi-agent embodied planning remains impractical due to prohibitively
 high execution latency. We identify failed actions as the dominant bottleneck,
stemming from two core challenges: inaccurate state tracking under partial obser
vability and inefficient coordination that produces redundant or conflicting act
ions. We introduce Mosaic, a runtime-efficient multi-agent planning framework th
at addresses both challenges. Mosaic maintains accurate yet lightweight state tr
acking through agent-centric semantic memory that stores objects in relative coo
rdinates, enabling geometric transformations and coordination. It ensures effici
ent coordination through Integer Linear Programming that allocates actions at ev
ery planning step, enforcing physical feasibility and inter-agent coordination c
onstraints. Across AI2-THOR and search-and-rescue benchmarks, Mosaic achieves 27
–32% faster execution, 30–33% fewer LLM calls, 25–31% fewer steps, and 4–10% poi
nts higher success rates. These results demonstrate that efficient memory and co
nstraint-guided coordination are critical for scalable, low-latency multi-agent
planning.

Agentic Model Predictive Questioning Control in Visual Design

Kuang-Da Wang, Zhao Wang, Wei-Yao Wang, Yotaro Shimose, Jaechang Kim, Shingo Tak
amatsu

Recent Large Language Model based approaches for clarifying visual design largel
y focus on selecting questions that better uncover user intent, but often overlo
oks the cognitive burden imposed on users, i.e., the effort required to interpre
t and answer these questions, which is crucial for effective human-agent interac
tion. In this paper, we propose Agentic Model Predictive Questioning Control (A-
MPQC), a test-time framework that reduces proxy-estimated user interaction burde
n while improving visual design alignment by formulating multi-round clarificati
on as trajectory optimization with receding-horizon replanning to revise its que
stioning strategy. In addition, we introduce lookahead question plans to reduce
ambiguity early, and a lightweight respond-or-reject surrogate reward to steer q
uestions toward lower user-burden formats (e.g., yes/no). Experiments on webpage
 and ad banner generation benchmarks show that A-MPQC not only generates designs
 better aligned with user intent, but also achieves lower user-interaction cost
across diverse interaction baselines, including fixed-format strategies (e.g., m
ultiple-choice and open-ended) and a retrieval-augmented baseline, without retra
ining. This paper sets a new perspective that explicitly formulates and optimize
s the human cognitive burden jointly with final design alignment, opening new op
portunities to advance human-agent interaction.

Rapid Poison: Practical Poisoning Attacks Against the Rapid Response Framework

David Huang, Jaewon Chang, Avidan Shah, Prateek Mittal, Chawin Sitawarin

The Rapid Response (RR) framework (Peng et al., 2024), deployed in production sy
stems including Anthropic’s ASL-3 safeguards (Anthropic, 2025), dynamically adap
ts jailbreak detection classifiers by generating synthetic training data from em
erging attacks. We reveal that prompt injection can infiltrate this pipeline to
deliver poisoned samples into the classifier’s training set, enabling two attack
 objectives: (I) targeted poisoning attacks that create false positives on harml
ess samples by categorizing them as a jailbreak, with a specific desired feature
 (e.g., certain formatting, subject, or keyword), (II) concept-based backdoor at
tacks that induce false negatives on jailbreak inputs, generalizing even to jail
breaks from attack strategies the defender explicitly trained against, when the
backdoor trigger is present. Importantly, our threat model restricts adversaries
 to modify- ing only jailbreak samples (not benign data or labels), a constraint
 unexplored by prior work that makes the second objective particularly challeng-
 ing. We address this with Omission Attack, which exploits a new phenomenon: whe

n training on concept-absent unsafe samples, the classifier mis- associates that concept’s presence with the safe label. Both attacks flip nearly all target labels with only 1% poisoning rate. Code: https://github.com/DH-davidhuang/rapid-poison

Wasserstein Geometry-Aware Adaptive Control via Meta-Learning

Xingyu Yang, Hanzhang Qu, Ye Cao, Jianfu Cao

Adaptive control of nonlinear systems under unknown disturbances requires learning algorithms aligned with the downstream control objective. While control-oriented meta-learning addresses the mismatch between regression-based identification and tracking performance, existing methods rely on Euclidean or static algebraic geometries that fail to capture the distributional structure of system uncertainties. We propose a framework that lifts adaptation into Wasserstein space, measuring parameter estimation errors as the optimal transport cost between estimated and true system behaviors. By constructing a Wasserstein Bregman divergence over representative task distributions, we use meta-learning to jointly optimize nonlinear feature representations, control gains, and transport geometry. This adaptation law learns an adaptation geometry that captures structural properties of the underlying physical system, implementing a physically grounded, data-driven attention mechanism. Closed-loop tracking simulations demonstrate that our controller achieves optimal performance on both fully-actuated and underactuated nonlinear planar rotorcraft, maintaining robustness under significant distributional shifts between training and testing conditions.

TSP with Predictions: Heatmap to Tour with Provable Guarantees

Marek Elias, Fabrizio Grandoni, Adam Polak, Eleonora Vercesi

The Traveling Salesperson Problem (TSP) has long served as a benchmark for evaluating the strength of optimization techniques in the classical theory of algorithms. In recent efforts to apply ML to algorithmic problems, TSP has also become a natural testbed for the development of ML-based techniques. A common approach is to train a neural network to output a heatmap estimating the likelihood of each edge to be part of the optimal tour; however, converting such a heatmap into an actual tour remains a non-trivial and often computationally intensive step. In this work, we propose algorithms for transforming heatmaps into tours with theoretical guarantees linking the achieved approximation ratio to the quality of the provided heatmap. In the spirit of *algorithms with predictions*, our results can be described as $(1+2\eta/OPT)$-approximation algorithms, where η denotes the L1 distance between the prediction (heatmap) and an optimal solution (tour). Since the previous works lack such explicit guarantees, we compare our approach against them experimentally.

Structure Enables Effective Self-Localization of Errors in LLMs

Ankur Samanta, Akshayaa Magesh, Ayush Jain, Kavosh Asadi, Youliang Yu, Daniel Jiang, Boris Vidolov, Kaveh Hassani, Paul Sajda, Jalaj Bhandari, Yonathan Efroni

Self-correction in language models remains elusive. In this work, we explore whether language models can explicitly localize errors in incorrect reasoning, as a path toward building AI systems that can effectively correct themselves. We introduce a prompting method that structures reasoning as discrete, semantically coherent thought steps, and show that models can localize errors more reliably within this structure than in conventional, unstructured chain-of-thought reasoning. Motivated by how the human brain monitors errors at discrete decision points and resamples alternatives, we introduce Iterative Correction Sampling of Thoughts (Thought-ICS), a self-correction framework. Thought-ICS iteratively prompts the model to generate reasoning one discrete and complete thought at a time—where each thought represents a deliberate decision by the model—creating natural boundaries for precise error localization. Upon verification, the model localizes the first erroneous step, and the system backtracks to generate alternative reasoning from the last correct point. When asked to correct reasoning verified as incorrect by an oracle, Thought-ICS achieves 20-40% self-correction lift. In a completely autonomous setting without external verification, it outperforms contempo

rary self-correction baselines.

The Art of Interrogation: Consistency Amplifies Factuality in Spatial Reasoning
Théo Uscidda, Marta Tintore Gazulla, Maks Ovsjanikov, Federico Tombari, Leonidas Guibas
Current Large Reasoning Models (LRMs) exhibit remarkable general capabilities but significantly underperform in spatial reasoning tasks. Existing approaches treat this gap as a knowledge deficit, relying on supervised fine-tuning (SFT) to ingest labeled data from external vision sources or synthetic engines. In contrast, we argue that for many tasks, spatial capabilities are already present in pre-trained LRMs but require alignment through principles of internal logical coherence. In this work, we propose a self-supervised reinforcement learning (RL) framework that targets the internal Chain-of-Thought (CoT) process without requiring ground-truth annotations. By formalizing the notion of consistency verifiers—reward functions that check for geometric and semantic consistency under transformations like flipping or swapping the order of objects in the question—and optimizing them via our new OT-GRPO strategy, a minimal-consistency matching variant of group relative policy optimization, we demonstrate that models can self-correct their spatial logic. Our results show that this label-free consistency training approaches the accuracy of models trained with ground-truth supervision and achieves similar generalization across diverse tasks and domains.
****
Streaming Sliced Optimal Transport
Khai Nguyen
Sliced optimal transport (SOT), or sliced Wasserstein (SW) distance, is widely recognized for its statistical and computational scalability. In this work, we further enhance computational scalability by proposing the first method for estimating SW from sample streams, called streaming sliced Wasserstein (Stream-SW). To define Stream-SW, we first introduce a streaming estimator of the one-dimensional Wasserstein distance (1DW). Since the 1DW has a closed-form expression, given by the integral of the absolute difference between the quantile functions of the compared distributions, we leverage quantile approximation techniques for sample streams to define a streaming 1DW estimator. By applying the streaming 1DW to all projections, we obtain Stream-SW. The key advantage of Stream-SW is its low memory complexity while providing theoretical guarantees on the approximation error. We demonstrate that Stream-SW achieves a more accurate approximation of SW than random subsampling, with lower memory consumption, when comparing Gaussian distributions and mixtures of Gaussians from streaming samples. Additionally, we conduct experiments on point cloud classification, point cloud gradient flows, and streaming change point detection to further highlight the favorable performance of the proposed Stream-SW.

No Need to Train Your RDB Foundation Model
Linjie Xu, Yanlin Zhang, Quan Gan, Minjie Wang, David Wipf
Relational databases (RDBs) contain vast amounts of heterogeneous tabular information that can be exploited for predictive modeling purposes. But since the space of potential targets is vast across enterprise settings, how can we avoid retraining a new model each time we wish to predict a new quantity of interest? Foundation models based on in-context learning (ICL) offer a convenient option, but so far are largely restricted to single-table operability. In generalizing to multiple interrelated tables, it is essential to compress variably-sized RDB neighborhoods into fixed-length ICL samples for consumption by the decoder. However, the details here are critical: unlike existing supervised learning RDB pipelines, we provide theoretical and empirical evidence that ICL-specific compression should be constrained within high-dimensional RDB columns where all entities share units and roles, not across columns where the relevance of heterogeneous data types cannot be determined without extensive label information. Conditioned on this restriction, we then demonstrate that encoder expressiveness is actually not compromised by excluding trainable parameters. Hence we arrive at a principled family of RDB encoders that can be seamlessly paired with already-existing

single-table ICL foundation models, whereby no training or fine-tuning is required. From a practical standpoint, we develop scalable SQL primitives to implement the encoder stage, resulting in the easy-to-use open-source RDBLearn foundation model capable of robust performance on unseen datasets out of the box.

Towards One-to-Many Temporal Grounding
Qi Xu, Tan Yue, Shihao Chen, Jiahao Meng, Anran Wang, Shunping Ji, Hao Fei, Xiangtai Li
Temporal Grounding (TG) aims to localize video segments corresponding to a textual query. Prior research predominantly focuses on single-segment retrieval. Real-world scenarios, however, often require localizing multiple disjoint segments for a single query—a setting we term **One-to-Many Temporal Grounding (OMTG)**. Previous state-of-the-art MLLMs, optimized for one-to-one settings, struggle in this context, often yielding near-zero scores due to a lack of event cardinality perception. To bridge this gap, we present a systematic solution with three key contributions. First, we establish the first comprehensive OMTG benchmark, introducing Count Accuracy (C-Acc) and Effective Temporal F1 (EtF1) as evaluation metrics. Second, we curate a high-quality OMTG dataset comprising 56k samples through a sophisticated construction pipeline. Third, we develop novel temporal and caption reward functions specifically designed for OMTG. In particular, the caption reward leverages Chain-of-Thought reasoning over dense video captions to explicitly guide policy optimization toward both preciseness and completeness. Extensive experiments show our model achieves a new state-of-the-art EtF1 of 43.65\% on OMTG Bench, outperforming Gemini 2.5 Pro and Seed-1.8 by 15.85\% and 15.61\%, respectively.

Budget-Feasible Mechanisms for Submodular Welfare Maximization in Procurement Auctions
Shuang Cui, He Huang, Yu-e Sun, Chen Xue
Budget-feasible procurement auctions play a pivotal role in various AI-driven marketplaces, such as data acquisition and crowdsourcing, where a buyer with a limited budget seeks to procure services from strategic sellers with private costs. While numerous budget-feasible mechanisms have been proposed for the classic objective of maximizing the buyer's valuation, the more challenging and economically significant objective of social welfare maximization has only recently been studied, and existing approaches still sacrifice budget feasibility, thereby limiting their practical applicability. In this paper, we bridge this gap by proposing BFM-SWM, the first budget-feasible mechanism with provable approximation guarantees for submodular welfare maximization in procurement auctions. Our mechanism satisfies standard economic properties, including truthfulness, individual rationality, and non-negative auctioneer surplus. As a by-product, we develop BFM-VM, a variant tailored for valuation maximization, which achieves a deterministic approximation ratio of $1/(12+4\sqrt{3})$ for general submodular functions, substantially improving upon the best-known deterministic ratio of $1/64$ established by [Balkanski et al., SODA 2022], while reducing the running time from $\mathcal{O}(n^2\log n)$ to $\mathcal{O}(n\log n)$. Extensive experiments demonstrate the efficiency and effectiveness of our mechanisms.

Demystifying Entropy Control in LLM RL Training: Theoretical Analysis and Dynamic Scheduling
Jingchu Gai, Guanning Zeng, Huaqing Zhang, Han Zhong, Yige Hong, Andrej Risteski, Aditi Raghunathan
This paper investigates a pivotal yet debated component of reinforcement learning (RL) for training large language models (LLMs): controlling entropy (increasing or decreasing it) during RL fine-tuning. The existing literature presents a dichotomy: some studies posit that increasing entropy facilitates exploration, whereas others argue that decreasing entropy enhances performance. To reconcile these conflicting observations, we provide a theoretical framework showing that the effect of entropy is governed by \emph{Entropy Discrepancy}, the distributional divergence between positive and negative samples. Guided by this insight, we de

rive a principled dynamic scheduling method that adaptively modulates the entrop
y coefficient, effectively switching between entropy maximization and minimizati
on as training evolves. Extensive experiments confirm the correlation between En
tropy Discrepancy and the efficacy of entropy control. Furthermore, our adaptive
 method yields substantial improvements, boosting Pass@K by 6.7\% on AIME24 and
17.52\% on puzzle tasks compared to vanilla RL, while consistently outperforming
 recent state-of-the-art reasoning methods.
****
The Optimal Token Baseline: Variance Reduction for Long-Horizon LLM-RL
Yingru Li, Jiawei Xu, Ziniu Li, Jiacai Liu, Wei Liu, Yuxuan Tong, Longtao Zheng,
 Zhenghai Xue, Yaxiang Zhang, Tianle Cai, Ge Zhang, Qian Liu, Baoxiang Wang
Reinforcement Learning (RL) for Large Language Models (LLMs) often suffers from
training collapse in long-horizon tasks due to exploding gradient variance. To m
itigate this, a baseline is commonly introduced for advantage computation; howev
er, traditional value models remain difficult to optimize, and standard group-ba
sed baselines overlook sequence heterogeneity. Although classic optimal baseline
 theory can achieve global variance reduction, it neglects token heterogeneity a
nd requires prohibitive gradient-based computation. In this work, we derive the
Optimal Token Baseline (OTB) from first principles, proving that gradient update
s should be weighted inversely to their cumulative gradient norm. To ensure effi
ciency, we propose the Logit-Gradient Proxy that approximates the gradient norm
using only forward-pass probabilities. Our method achieves training stability an
d matches the performance of large group sizes ($N=32$) with only $N=4$, reducin
g token consumption by over 65\% across single-turn and tool-integrated reasonin
g tasks.
****
DR^{2}Seg: Decomposed Two-Stage Rollouts for Efficient Reasoning Segmentation in
 Multimodal Large Language Models
Yulin He, Wei Chen, jian zhikang, Tianhang Guo, Wenjuan Zhou, Minglong Li, Shaow
u Yang, Wenjing Yang
Reasoning segmentation is an emerging vision-language task that requires reasoni
ng over intricate text queries to precisely segment objects. However, existing m
ethods typically suffer from overthinking, generating verbose reasoning chains t
hat interfere with object localization in multimodal large language models (MLLM
s). To address this issue, we propose DR^{2}Seg, a self-rewarding framework that
 improves both reasoning efficiency and segmentation accuracy without requiring
extra thinking supervision. DR^{2}Seg employs a two-stage rollout strategy that
decomposes reasoning segmentation into multimodal reasoning and referring segmen
tation. In the first stage, the model generates a self-contained description tha
t explicitly specifies the target object. In the second stage, this description
replaces the original complex query to verify its self-containment. Based on thi
s design, two self-rewards are introduced to mitigate overthinking and the assoc
iated attention dispersion. Extensive experiments conducted on 3B and 7B variant
s of Qwen2.5-VL, as well as on both SAM2 and SAM3, demonstrate that DR^{2}Seg co
nsistently improves reasoning efficiency and overall segmentation accuracy. The
source code can be found at https://github.com/harrylin-hyl/DR2Seg.

Finite-time Convergence Analysis of Actor-Critic with Evolving Reward
Rui Hu, Yu Chen, Longbo Huang
Many popular practical reinforcement learning (RL) algorithms employ evolving re
ward functions—through techniques such as reward shaping, entropy regularization
, or curriculum learning—yet their theoretical foundations remain underdeveloped
. This paper provides the first finite-time convergence analysis of a single-tim
escale actor-critic algorithm in the presence of an evolving reward function und
er Markovian sampling. We consider a setting where the reward parameters may cha
nge at each time step, affecting both policy optimization and value estimation.
Under standard assumptions, we derive non-asymptotic bounds for both actor and c
ritic errors. Our result shows that an $O(1/\sqrt{T})$ convergence rate is achie
vable, matching the best-known rate for static rewards, provided the reward para
meters evolve slowly enough. This rate is preserved when the reward is updated v

ia a gradient-based rule with bounded gradient and on the same timescale as the actor and critic, offering a theoretical foundation for many popular RL techniques. As a secondary contribution, we introduce a novel analysis of distribution mismatch under Markovian sampling, improving the best-known rate by a factor of $\log^2T$ in the static-reward case.
****

GradMem: Learning to Write Context into Memory with Test-Time Gradient Descent
Yuri Kuratov, Matvey Kairov, Aydar Bulatov, Ivan Rodkin, Mikhail Burtsev
Many large language model applications require conditioning on long contexts.
Transformers typically support this by storing a large per-layer KV-cache of past activations, which incurs substantial memory overhead.
A desirable alternative is compressive memory: read a context once, store it in a compact state, and answer many queries from that state.
We study this in a context removal setting, where the model must generate an answer without access to the original context at inference time.
We introduce GradMem, which writes context into memory via per-sample test-time optimization.
Given a context, GradMem performs a few steps of gradient descent on a small set of prefix memory tokens while keeping model weights frozen.
GradMem explicitly optimizes a model-level self-supervised context reconstruction loss, resulting in a loss-driven write operation with iterative error correction, unlike forward-only methods.
On associative key--value retrieval, GradMem outperforms forward-only memory writers with the same memory size, and additional gradient steps scale capacity much more effectively than repeated forward writes.
We further show that GradMem transfers beyond synthetic benchmarks: with pretrained language models, it attains competitive results on natural language tasks including bAbI and SQuAD variants, relying only on information encoded in memory.

LASER: Learning Active Sensing for Continuum Field Reconstruction
Huayu Deng, Jinghui Zhong, Xiangming Zhu, Yunbo Wang, Xiaokang Yang
High-fidelity measurements of continuum physical fields are essential for scientific discovery and engineering design but remain challenging under sparse and constrained sensing. Conventional reconstruction methods typically rely on fixed sensor layouts, which cannot adapt to evolving physical states. We propose LASER, a unified, closed-loop framework that formulates active sensing as a Partially Observable Markov Decision Process (POMDP). At its core, LASER employs a continuum field latent world model that captures the underlying physical dynamics and provides intrinsic reward feedback. This enables a reinforcement learning policy to simulate ''what-if'' sensing scenarios within a latent imagination space. By conditioning sensor movements on predicted latent states, LASER navigates toward potentially high-information regions beyond current observations. Our experiments demonstrate that LASER consistently outperforms static and offline-optimized strategies, achieving high-fidelity reconstruction under sparsity across diverse continuum fields.

SPADA: A Verifiable Test-Driven Agent for Controllable Parametric CAD Assembly Generation
Keyou Zheng, Xuyang Su, Jiewu Leng
Parametric CAD is widely used in mechanical and product engineering, but current generative models still have difficulty producing assemblies that are both editable at the parameter level and consistent with inter-part constraints.
Methods that generate meshes or history-free B-rep can represent multi-part shape, but they often lack the program structure and constraint logic needed for reliable downstream edits; in contrast, code-based CAD generation offers direct parametric control, yet most published settings and evaluations focus on single-part solids rather than constrained assemblies.
We introduce SPADA (Self-testing Parametric Assembly Design Agent), a test-driven agent that synthesizes assembly code together with deterministic verification tests, and uses these tests as an executable contract for controllable generatio

n.
SPADA runs an iterative compile-test-repair loop with multimodal feedback, checking both specification logic and physical feasibility through programmatic constraints.
To support evaluation, we release SPADA-Bench-Verified, a human-validated benchmark of real-world code-centric assemblies paired with deterministic tests and engineering-style constraints.
Experiments show that SPADA could produces complex assemblies while maintaining geometric fidelity, supporting test-driven agents as a concrete path toward reliable, controllable CAD generation.

Locally Coherent Parallel Decoding in Diffusion Language Models
Michael Hersche, Nicolas Menet, Ronan Tanios, Abbas Rahimi
Diffusion language models (DLMs) have emerged as a promising alternative to autoregressive (AR) models, offering sub-linear generation latency and bidirectional capabilities that are particularly appealing for code generation and editing. Achieving sub-linear latency in discrete DLMs requires predicting multiple tokens in parallel. However, standard DLMs sample tokens independently from conditional marginal distributions, failing to capture the joint dependencies among concurrently generated tokens. As a result, they often lead to syntactic inconsistencies and break multi-token structures. In this work, we introduce CoDiLA (Coherent Diffusion with Local Autoregression), a method that reconciles parallel sampling with local dependency modeling. Rather than forcing the DLM to resolve fine-grained syntax, CoDiLA delegates local decoding to a small, auxiliary AR model operating on the diffusion latents. This design allows for parallel generation while ensuring sequential validity within a block and maintaining core DLM capabilities, including bidirectional modeling across blocks. We demonstrate that using a highly compact auxiliary AR model (e.g., 0.6B parameters) effectively eliminates coherence artifacts, establishing a new Pareto frontier for accuracy and speed in code generation benchmarks.
****

Stochastic Lifting for Generating Trajectories of Stochastic Physical Systems
Jules Berman, Tobias Blickhan, Benjamin Peherstorfer
Many stochastic physical systems evolve smoothly over time in the sense that the distribution of states changes regularly with time. The precise transition from current to next state is often modeled as the interplay of a smooth map and an explicit source of randomness. Stochastic Lifting leverages this premise by attaching an independent, high-dimensional random label to each state transition in the training data and fitting a transition map from the current state and label to the next state using a standard regression loss. The labels act as auxiliary coordinates that let the model represent multiple plausible outcomes for similar current states, avoiding collapse to a mean prediction in the finite-sample size regime. At inference, drawing fresh labels and rolling the map forward generates diverse trajectories with a single network evaluation per time step, with the smoothness bias of the learned map supporting accurate sampling in practice.

T-GINEE: A Tensor-Based Multi-Graph Representation Learning
Maolin Wang, ZiTing Mai, Xuhui Chen, Zhiqi Li, Tianshuo Wei, Yutian Xiao, Wenlin Zhang, Wanyu Wang, Ruocheng Guo, Haoxuan Li, Zenglin Xu, Xiangyu Zhao
While traditional network analysis focuses on single-layer networks, real-world systems often form multilayer networks with multiple relationship types. However, existing methods typically fail to capture complex inter-layer dependencies by treating layers independently or aggregating them. To address this, we propose T-GINEE (Tensor-Based Generalized Multilayer-graph Estimating Equation), a statistical regularization framework combining tensor-based generalized estimating equations with task-specific loss to model cross-network correlations explicitly. Key innovations include: (1) CP tensor decomposition capturing structural dependencies via shared latent factors; (2) a generalized estimating equation framework modeling inter-layer correlations through working covariance matrices; and (3) a flexible link function accommodating characteristics like sparsity. Our theor

etical analysis establishes consistency and asymptotic normality under mild cond
itions. Extensive experiments on synthetic and real-world datasets validate T-GI
NEE’s effectiveness for multilayer network analysis. Our code is available in th
e \textbf{supplementary materials} to ensure reproducibility.

ReJump: A Tree-Jump Representation for Analyzing and Improving LLM Reasoning
Yuchen Zeng, Shuibai Zhang, Wonjun Kang, Shutong Wu, Lynnix Zou, Ying Fan, Heeju
 Kim, Ziqian Lin, Jungtaek Kim, Hyung Il Koo, Dimitris Papailiopoulos, Kangwook
Lee
Large Reasoning Models (LRMs) are Large Language Models (LLMs) explicitly traine
d to generate long-form Chain-of-Thoughts (CoTs), achieving impressive success o
n challenging tasks like math and programming. However, their underlying reasoni
ng "algorithms" remain poorly understood. To investigate this, we propose *ReJum
p*, which represents a reasoning trace as a visitation order over nodes in a tre
e of intermediate problem-solving steps. Transitions between nodes, which we ter
m *jumps*, include adjacent moves that capture behaviors such as calculation, an
d non-adjacent moves that capture behaviors such as backtracking and verificatio
n. ReJump enables analyzing LLM reasoning with diverse metrics that quantify exp
loration, exploitation, overthinking, forgetting, and verification. Using our pr
oposed LLM agent to extract reasoning traces into ReJump format, we evaluate sta
te-of-the-art LRMs on two tasks and find that models with similar accuracy can e
xhibit distinct reasoning behaviors, while different tasks favor different reaso
ning styles (e.g., varying balance between exploration and exploitation). To fur
ther understand how learning strategies shape reasoning, we use ReJump to compar
e distilled LRMs with their teachers, compare CoT-prompted LLMs with LRMs, and e
xamine how reinforcement learning affects reasoning behavior. Finally, we show t
hat ReJump can improve reasoning quality at test time through strategies such as
 ReJump-guided Best-of-N selection and prompt selection. Our code is available a
t https://github.com/UW-Madison-Lee-Lab/ReJump.
****
Functional Cache Grafting: Robust and Rapid Code-Policy Synthesis for Embodied A
gents
Saehun Chun, Wonje Choi, Sera Choi, Sanghyun Ahn, Honguk Woo
Code-writing large language models (CodeLLMs) generate executable code policies
for embodied agents by translating natural language goals and environmental cons
traints into structured control programs. However, policy generation in open-dom
ain embodied environments suffers from two fundamental limitations:
(i) delayed decoding caused by repetitive prefill computation over long prompts,
 and
(ii) limited robustness due to fully generative decoding, which often produces A
PI mismatches, missing safety guards, and unstable control logic. To address the
se limitations, we present FCGraft, a Functional Cache Grafting framework.
FCGraft maintains a library of function-level validated code skeletons and their
 associated prompt-level Transformer key–value (KV) caches, and synthesizes new
policies by retrieving relevant functions and grafting their KV caches when a ne
w task is provided. Given retrieved function caches, FCGraft performs cache graf
ting via stitching, which composes cached function segments into a composite pol
icy, and patching, which locally adapts only the necessary code regions to satis
fy task-specific parameters and constraints with minimal additional decoding. By
 eliminating redundant prefill computation, this approach reduces generation lat
ency, while reusing validated control structures improves robustness over prompt
-level caching methods RAGCache, achieving $18.31\$% higher task success rate an
d $2.3\times$ faster policy synthesis.
****
Capacity-Agnostic Parameter Isolation for Continual Graph Learning
Ye Xiao, Ruikun Li, Zhenyu Yang, Andrey Vasnev, Junbin Gao
Existing parameter isolation-based continual learning methods employ diverse des
igns to accommodate more tasks within limited model capacity, but often incur in
creasing computational overhead as model capacity expands for growing task strea
ms. To address this efficiency bottleneck, we propose CAGNN, a graph continual l

earning framework with a biological neuron-inspired architecture that features capacity-agnostic efficiency. CAGNN leverages graph contextual information to construct task-specific subnetworks and decouples them during training and inference, reducing full-network propagation overhead while enabling knowledge transfer across tasks. Extensive experiments demonstrate CAGNN's superior effectiveness and computational efficiency over state-of-the-art methods.

SpecMD: A Comprehensive Study On Speculative Expert Prefetching
Duc N.M Hoang, Mohammad Samragh, AJAY KUMAR JAISWAL, Minsik Cho
Mixture-of-Experts (MoE) models enable sparse expert activation, meaning that only a subset of the model’s parameters is used during each inference. However, to translate this sparsity into practical performance, an expert caching mechanism is required.
Previous works have proposed hardware-centric caching policies, but how these various caching policies interact with each other and different hardware specification remains poorly understood. To address this gap, we develop \textbf{SpecMD}, a standardized framework for benchmarking ad-hoc cache policies on various hardware configurations. Using SpecMD, we perform an exhaustive benchmarking of several MoE caching strategies, reproducing and extending prior approaches in controlled settings with realistic constraints. Our experiments reveal that MoE expert access is not consistent with temporal locality assumptions (e.g LRU, LFU). Motivated by this observation, we propose \textbf{Least-Stale}, a novel eviction policy that exploits MoE's predictable expert access patterns to reduce collision misses by up to $85\times$ over LRU. With such gains, we achieve over 88% hit rates with up to 34.7% Time-to-first-token (TTFT) reduction on OLMoE at only 5% or $0.6GB$ of VRAM cache capacity.

Toward Culturally Aligned LLMs through Ontology-Guided Multi-Agent Reasoning
Wonduk Seo, Wonseok Choi, Junseo Koh, JuHyeon Lee, Hyunjin An, Minhyeong Yu, Jian Park, Qingshan Zhou, Seunghyun lee, Yi Bu
Large Language Models (LLMs) increasingly support culturally sensitive decision making, yet often exhibit misalignment due to skewed pretraining data and the absence of structured value representations. Existing methods can steer outputs, but often lack demographic grounding and treat values as independent, unstructured signals, reducing consistency and interpretability. We propose OG-MAR, an Ontology-Guided Multi-Agent Reasoning framework. OG-MAR summarizes respondent-specific values from the World Values Survey (WVS) and constructs a global cultural ontology by eliciting relations over a fixed taxonomy via competency questions. At inference time, it retrieves ontology-consistent relations and demographically similar profiles to instantiate multiple value-persona agents, whose outputs are synthesized by a judgment agent that enforces ontology consistency and demographic proximity. Experiments on regional social-survey benchmarks across four LLM backbones show that OG-MAR improves cultural alignment and robustness over competitive baselines, while producing more transparent reasoning traces.

Return of Frustratingly Easy Unsupervised Video Domain Adaptation
Pengfei Wei, Yiqun Sun, zhiqiang xu, Yiping Ke, Lawrence B. Hsieh
Unsupervised video domain adaptation (UVDA) is a practical but under-explored problem.
In this paper, we propose a frustratingly easy UVDA method, called \emph{MetaTrans}.
Specifically, \emph{MetaTrans} adopts a concise learning objective that contains only two fundamental loss terms.
Despite the simplicity of the learning objective, \emph{MetaTrans} embodies an advanced UVDA idea, that is, handling the spatial and temporal divergence of cross-domain videos separately, through a subtle model architecture design.
By implementing a temporal-static subtraction module, \emph{MetaTrans} effectively removes spatial and temporal divergence.
Extensive empirical evaluations, particularly on various cross-domain action recognition tasks, show substantial absolute adaptation performance enhancement and

significantly superior relative performance gain compared with state-of-the-art UVDA baselines.
****
On Path to Multimodal Historical Reasoning: HistBench and HistAgent
Jiahao Qiu, Fulian Xiao, Yimin Wang, Yuchen Mao, Yijia Chen, Xinzhe Juan, Siran Wang, Xuan Qi, Tongcheng Zhang, Zixin Yao, Jiacheng Guo, Yifu Lu, Charles Argon, Jundi Cui, Daixin Chen, Junran Zhou, Shuyao Zhou, Zhanpeng Zhou, Ling Yang, Shilong Liu, Hongru WANG, Kaixuan Huang, xun jiang, Xi Gao, Mengdi Wang
Recent advances in large language models (LLMs) have led to remarkable progress across various domains, yet their capabilities in the humanities, particularly history, remain underexplored. Historical reasoning poses unique challenges for LLMs, involving multimodal source interpretation, temporal inference, and cross-linguistic analysis. Existing general-purpose agents perform well on many current benchmarks but lack the domain expertise needed to address complex historical questions.
To address this gap, we introduce HistBench, a new benchmark of 414 high-quality and carefully-reviewed questions stratified by difficulty and designed to evaluate LLM's capacity for historical reasoning. The tasks span a wide range of historical problems—from factual retrieval based on primary sources to interpretive analysis of manuscripts and images, to interdisciplinary challenges involving archaeology, linguistics, or cultural history. Furthermore, the benchmark dataset spans 29 ancient and modern languages and covers a wide range of historical periods and world regions. Finding the poor performance of LLMs and other agents on HistBench, we further present HistAgent, a history-specific agent equipped with carefully designed tools for OCR, translation, archival search, and image understanding in history. On HistBench, HistAgent based on GPT-4o achieves an accuracy of 28.50\% pass@1 and 36.47\% pass@2, significantly outperforming LLMs with online search and generalist agents, including GPT-4o (18.60\%), DeepSeek-R1 (14.98\%), Grok 3 (17.63\%) and Open Deep Research by smolagents (19.57\% pass@1 and 25.12\% pass@2). These results highlight the limitations of existing LLMs and generalist agents and demonstrate the advantages of HistAgent for historical reasoning. Notably, HistAgent also achieves 60.00\% pass@1 accuracy on the GAIA benchmark, showing that domain-specific customization doesn't hinder HistAgent's competitive performance on real-world general tasks. Code is available at https://github.com/CharlesQ9/HistAgent.

Beyond Theorem Proving: Formulation, Framework and Benchmark for Formal Problem-Solving
Qi Liu, Xinhao Zheng, Renqiu Xia, Xingzhi Qi, Qinxiang Cao, Junchi Yan
Large language models (LLMs) have achieved remarkable progress in mathematical reasoning, yet persistently suffer from hallucinations and erroneous logic. While formal theorem proving (FTP) shows promise in process-level reliability, it is limited to _verification_ (checking known propositions). This leaves constructive problem-solving (finding unknown terms that satisfy specific conditions) underexplored and disconnected from process-level verifiability.
To bridge this gap, we introduce **FPS** (_**F**ormal **P**roblem-**S**olving_), a principled framework to encompass the end-to-end problem-solving process in Lean 4. In FPS, the answer is an unknown metavariable coupled with a proof obligation, forcing it to be mathematically derived and verified. We further present **D-FPS** (_**D**eductive **FPS**_), which structures solving into forward derivation and backward verification, aligning more closely with human reasoning steps.
Three benchmarks of over 1,000 problems are constructed for evaluation: **FormalMath500**, **MiniF2F-Solving**, and **PutnamBench-Solving**. We further propose **RPE** (_**R**estricted **P**ropositional **E**quivalence_), a symbolic metric that evaluates semantic correctness beyond brittle string matching. Extensive experiments with state-of-the-art provers reveal that solving is significantly harder than proving, highlighting the ``alignment tax'' required to transition from loose validity checking to constructive, human-aligned reasoning.
Code and data are available at [https://github.com/Purewhite2019/formal_problem_

solving_main](https://github.com/Purewhite2019/formal_problem_solving_main).

AgentSteerTTS: A Multi-Agent Closed-Loop Framework for Composite-Instruction Tex
t-to-Speech
Bin Kang, Shaoguo Wen, Yang Fan, Shunlong Wu, Junjie Wang, Yulin Li, Junzhi Zhao
, Junle Wang, Zhuotao Tian
While existing text-to-speech (TTS) models exhibit high expressiveness, fine-gra
ined control over composite instructions remains challenging due to the structur
al mismatch between discrete textual intents and continuous acoustic realization
s. Inspired by human cognitive decoupling, we introduce AgentSteerTTS, a multi-a
gent closed-loop framework designed for intent-faithful expressive control of co
mposite instructions. First, in our framework, an adversarial disentanglement mo
dule mitigates speaker-emotion leakage through gradient reversal and cross-covar
iance regularization. Next, a Dual-Stream Anchoring Controller grounds abstract
intents using a large-scale acoustic prototype library: a Retrieval Agent select
s expressive anchors, while a Synthesis Agent fuses them into continuous control
 vectors via gated attention. Finally, a Fast–Slow Feedback Agent refines output
 intensity through latent gradient correction and resolves semantic–acoustic mis
matches using high-level perceptual critique. Experiments on a composite-instruc
tion benchmark and public test sets show that AgentSteerTTS yields consistent an
d significant improvements to the baselines, demonstrating the effectiveness of
the proposed method. Our code and models will be released.

VIBE: Disentangling Social Dynamics via Kinematics-Informed Variational Inferenc
e for Behavioral Emotion
Abhishek Pratap Singh, Vaibhav Pratap Singh, Deepak Kumar, Balasubramanian Raman
Group Emotion Recognition (GER) is crucial for understanding social dynamics, ra
nging from interpreting intimate conversations to evaluating crowd behavior in l
arge-scale surveillance scenarios. While current AI models can analyze these sce
nes, they often act as black boxes that take shortcuts. Instead of focusing on h
ow people are actually behaving, these models often get distracted by the backgr
ound environment, leading to inaccurate results. To bridge this gap, we introduc
e VIBE (Variational Inference for Behavioral Emotion), a kinematics-aware framew
ork that integrates audio, video, and text modalities through causal structuring
. Unlike standard models that simply mix data together, VIBE utilizes mathematic
al constraints to filter out background noise and isolate the genuine emotions o
f the people involved. This purified representation enables our model to focus e
xclusively on the sociological mechanics of the crowd, dynamically modulating ne
ural attention based on raw physical synchrony. Simultaneously, we align visual
dynamics with human interpretability by projecting latent representations into a
 semantically structured space informed by textual descriptions. Comprehensive e
xperiments demonstrate that VIBE consistently outperforms state-of-the-art metho
ds. Code is available at GitHub.

Identifiable Smooth Conjugacy Learning via Adversarial Orthogonality
In Huh, Changwook Jeong, Muhammad Alam
Data-driven dynamical system models often fail to recover the long-term structur
e of the underlying system, as their behavior is weakly constrained off the data
 manifold. Conjugacy-based approaches address this limitation by learning a diff
eomorphism that pushes forward a source vector field to match observed dynamics,
 inheriting qualitative topology from the source. However, such methods typicall
y presuppose that the chosen source system is topologically compatible with the
target data. When this assumption is violated, the conjugacy problem becomes ill
-posed, and arbitrary corrections can be traded off against diffeomorphic variat
ion, leading to non-identifiability. We propose a framework that relaxes this as
sumed prior by jointly learning the diffeomorphic conjugacy together with contro
lled adjustments to the source dynamics via low-dimensional context modulation.
Inspired by versal unfolding theory, we enforce the modulation space to be ortho
gonal to the worst-case orbit-tangent directions, obtained by adversarially sear
ching over a class of parameterized diffeomorphisms. This promotes an identifiab

le decomposition of dynamical variation into diffeomorphic and intrinsic, topolo gy-changing components, enabling interpretable corrections that recover the cano nical structure such as normal forms and symmetries.

Multi-Label Learning with Contrastive Cluster Self-Supervision for 3D Hierarchic al Semantic Segmentation

Shuyu Cao, Chongshou Li, Jie Xu, Tianrui Li, Na Zhao

3D hierarchical semantic segmentation (3DHS) is crucial for embodied intelligenc e that demands the coarse-to-fine grained and multi-hierarchy understanding of 3 D scenes. 3DHS tasks can be addressed by multi-label learning, but facing two is sues: I) learning multiple labels for each point with a shared model can lead to multi-hierarchy conflicts in cross-hierarchy optimization, and II) the class im balance issue is inevitable across multiple hierarchies of 3D scenes, making the model easily be dominated by major classes. To address these issues, we propose a novel multi-label learning with contrastive cluster self-supervision framewor k for 3DHS. Specifically, we propose a late-decoupled multi-label learning 3DHS network which employs decoupled decoders with the coarse-to-fine hierarchical co nsistency guidance. This late-decoupled model architecture can mitigate the unde rfitting and overfitting conflicts among multiple hierarchies and also constrain the class imbalance problem within each individual hierarchy. Moreover, we intr oduce a 3DHS-oriented contrastive cluster self-supervision learning method, whic h learns cluster-wise point cloud features with contrastive loss and produces se lf-supervised information to enhance the class-imbalance segmentation. Extensive experiments on multiple datasets and backbones demonstrate that our approach pr omotes the multi-hierarchy balance and mitigates the class imbalance issue in 3D HS tasks.

OmniVideo-R1: Reinforcing Audio-visual Reasoning with Query Intention and Modali ty Attention

Zhangquan Chen, Jiale Tao, Ruihuang Li, Yihao Hu, Ruitao Chen, Zhantao Yang, Xin lei Yu, Haodong Jing, Manyuan Zhang, Shuai Shao, Biao Wang, Qinglin Lu, Ruqi Hua ng

While humans perceive the world through diverse modalities that operate synergis tically to support a holistic understanding of their surroundings, existing omni video models still face substantial challenges on audio-visual understanding tas ks. In this paper, we propose OmniVideo-R1, a novel reinforced framework that im proves mixed-modality reasoning. OmniVideo-R1 empowers models to "think with om nimodal cues" by two key strategies: (1) query■intensive grounding based on self ■supervised learning paradigms; and (2) modality■attentive fusion built upon con trastive learning paradigms. Extensive experiments on multiple benchmarks demons trate that OmniVideo-R1 consistently outperforms strong baselines, highlighting its effectiveness and robust generalization capabilities.

SymSpectra: Symmetric Information Bottleneck Framework for Molecular Structure R ecognition under Imbalanced Settings

Xiaohan Qin, Wenjie Du, Yang Wang

Identifying molecular structures from spectral data is essential for early-stage chemical analysis, yet it remains a difficult task due to severe functional gro up imbalance and complex inter-group dependencies, which often cause existing me thods to overfit frequent groups while underperforming on rare ones. To address these issues, we present **SymSpectra**, a **Sym**metric Conditional Information Bottleneck (SCIB) framework designed to seamlessly integrate multi-modal **Spec tra** features. Our model employs the SCIB framework to fuse multi-modal spectro scopic data into a unified representation, effectively preserving discriminative signals while mitigating redundancy. To enhance robustness against data imbalan ce, we incorporate conditional mutual information into the training objective, i ncreasing the model’s sensitivity to rare functional groups and challenging mole cular cases. Additionally, a specialized module captures the dependencies among functional groups, improving both prediction accuracy and chemically meaningful interpretability. Experiments on multimodal spectral datasets show that SymSpect

ra outperforms state-of-the-art methods, achieving an F1-score of 0.970 in substructure classification and demonstrating strong robustness under various imbalance settings.

On the Relationship Between Activation Outliers and Feature Death in Sparse Autoencoders
Elana Simon, Etowah Adams, James Zou
Sparse autoencoders (SAEs) decompose neural network activations into interpretable features, but many learned features never activate, a problem called feature death that wastes dictionary capacity and can reintroduce superposition. Death rates vary dramatically between models: near-zero on GPT-2, over 70\% on AlphaFold3 with identical configurations. We find that dimension-level activation outliers (dimensions whose mean magnitude is large relative to per-token variation) cause this by shifting pre-activations at initialization based on each feature's alignment with the activation mean. Features anti-aligned with the mean receive permanently negative pre-activations and never fire. We formalize outlier severity as $\gamma = \|\boldsymbol{\mu}\|/\|\boldsymbol{\sigma}\|$; it predicts initial death rates (Spearman $\rho = 0.89$ for dead-by-TopK, 0.82 for dead-by-ReLU) across 454 model-layer combinations spanning language, vision, protein, and genomic models. Dead features can revive during training, but recovery requires the SAE bias to learn the activation mean, a process that is prohibitively slow at high γ. Mean-centering (subtracting the activation mean) sidesteps this and eliminates outlier-induced death across all tested models, confirming the mechanism and providing a principled basis for when and why this preprocessing step is necessary.
****

Axiomatic Atlas: A Prescriptive Framework for Neural Architecture Design
Minghao Guo, Wojciech Matusik
Neural architecture design lacks first principles: innovations are discovered empirically and justified post-hoc, with no systematic way to diagnose *why* an architecture fails or derive *what* repair will succeed.
We introduce the *Axiomatic Atlas*, encoding requirements as composable axioms over graph connectivity, operator contracts, numerical stability, and information preservation.
Given an operator library and wiring conventions, the Atlas constructs certificates lower-bounding output variation via min-cut analysis and diagnoses failures by locating axiom violations.
Crucially, the framework is prescriptive: each violation implies a targeted repair, reducing architecture design to constraint satisfaction.
We prove variation bounds under exact and finite-precision arithmetic, enabling modular verification across transformers, MoEs, SSMs, and GNNs.
Four Atlas-derived interventions validate the approach: +46 percentage points on GNN bottlenecks, $3\times$ robustness to MoE quantization, 83\% gap closure with adaptive expert budgets, and 0\%$\to$100\% retrieval via orthogonal keys---each against matched negative controls.

SorryDB: Can AI Provers Complete Real-World Lean Theorems?
Austin Letson, Leopoldo Sarra, Auguste Poiroux, Oliver Dressler, Paul Lezeau, Dhyan Aranha, Frederick Pu, Aaron Hill, Miguel Corredera Hidalgo, Julian Berman, George Tsoukalas, Lenny Taelman
We present SorryDB, a dynamically-updating benchmark of open Lean tasks drawn from 78 real world formalization projects on GitHub. Unlike existing static benchmarks, often composed of competition problems, hillclimbing the SorryDB benchmark will yield tools that are aligned to the community needs, more usable by mathematicians, and more capable of understanding complex dependencies. Moreover, by providing a continuously updated stream of tasks, SorryDB mitigates test-set contamination and offers a robust metric for an agent's ability to contribute to novel formal mathematics projects. We evaluate a collection of approaches, including generalist large language models, agentic approaches, and specialized symbolic provers, over a selected snapshot of 1000 tasks from SorryDB. We show that cur

rent approaches are complementary: even though an agentic approach based on Gemi ni Flash is the most performant, it is not strictly better than other off-the-sh elf large-language models, specialized provers, or even a curated list of tactic s.

Towards A Generative Protein Evolution Machine with DPLM-Evo
Xinyou Wang, Liang Hong, Jiasheng Ye, Zaixiang Zheng, Shujian Huang, Quanquan Gu
Proteins are shaped by gradual evolution under biophysical and functional constr aints. Protein language models learn rich evolutionary constraints from large-sc ale sequences, and discrete diffusion-based protein language models (e.g., DPLMs) are promising for both understanding and generation. However, existing DPLMs t ypically rely on masked diffusion that contradicts a simple biological intuition : proteins evolve through accumulated edits, not by emerging from masks. Consequ ently, these frameworks lack explicit pretraining objectives for substitution an d insertion/deletion (indel) operations, limiting both optimization-style post-e diting and flexible guided generation. To address these limitations, we present DPLM-Evo, an evolutionary discrete diffusion framework that explicitly predicts substitution, insertion, and deletion operations during denoising. DPLM-Evo deco uples an upsampled-length latent alignment space from the variable-length observ ed sequence space, which makes indel-aware generation tractable. To better align substitutions with real evolution, we further introduce a contextualized evolut ionary noising kernel that produces biologically informed, context-dependent mut ation patterns. Across tasks, DPLM-Evo improves sequence understanding and achie ves state-of-the-art mutation effect prediction performance on ProteinGym in the single-sequence setting. It also enables variable-length simulated evolution, a nd post-editing/optimization of existing proteins via explicit edit trajectories .

Anchor-guided Hypergraph Condensation with Dual-level Discrimination
Fan Li, Xiaoyang Wang, Chen Chen, Wenjie Zhang
The increasing prevalence of large-scale hypergraphs poses significant computati onal challenges for hypergraph neural network (HNN) training. To address this, h ypergraph condensation (HGC) distills large real hypergraphs into compact yet in formative synthetic ones, beyond graph condensation (GC) methods limited to pair wise relations.
However, existing HGC methods rely on decoupled training architectures, where st ructure generators are pre-trained on the original hypergraph but not jointly op timized with condensed features during refinement, resulting in misaligned struc tures that degrade downstream utility. Moreover, trajectory-based optimization i ncurs substantial computational overhead in refinement, limiting condensation ef ficiency.
To tackle these issues, we propose \textbf{A}nchor-guided \textbf{H}yper\textbf{ G}raph \textbf{C}ondensation with \textbf{D}ual-level \textbf{D}iscrimination (\ textbf{AHGCDD}), which consists of three key components: (1) a node initializati on module based on Heat Kernel PageRank (HKPR) to encode structural knowledge in to feature semantics; (2) an anchor-guided hyperedge synthesis strategy for join t optimization of condensed features and structure; (3) a theoretically grounded dual-level discrimination objective for utility-preserving condensation without redundant HNN training. Extensive experiments demonstrate the superior effectiv eness and efficiency of AHGCDD.

Best of Both Worlds: Multimodal Reasoning and Generation via Unified Discrete Fl ow Matching
Onkar Kishor Susladkar, Tushar Prakash, Gayatri Deshmukh, Kiet A. Nguyen, Jiaxun Zhang, Adheesh Sunil Juvekar, Tianshu Bao, Lin Chai, Sparsh Mittal, Inderjit S Dhillon, Ismini Lourentzou
We propose UniDFlow, a unified discrete flow-matching framework for multimodal u nderstanding, generation, and editing. It decouples understanding and generation via task-specific low-rank adapters, avoiding objective interference and repres entation entanglement, while a novel reference-based multimodal preference align

ment optimizes relative outcomes under identical conditioning, improving faithfu lness and controllability without large-scale retraining. UniDFlow achieves SOTA performance across eight benchmarks and exhibits strong zero-shot generalizatio n to tasks including inpainting, in-context image generation, reference-based ed iting, and compositional generation, despite no explicit task-specific training.
****

MAC-NeRF: Motion-Aware Curriculum Learning for Dynamic LiDAR NeRFs
Shangshu Yu, Xiaotian Sun, Wen Li, Rui She, Hanyun Wang, Sheng Ao, Chenglu Wen, Cheng Wang
While LiDAR NeRFs excel in static environments, synthesizing dynamic scenes rema ins challenging as moving objects break multi-view consistency, causing conflict ing supervision and ghosting artifacts across frames.
Existing methods typically suffer from optimization difficulty from the start, s truggling to disentangle valid geometry from motion noise when initial motion pr iors are unreliable.
To address this, we propose MAC-NeRF, a novel LiDAR NeRF framework enhanced by m otion-aware curriculum learning for high-fidelity dynamic scene synthesis.
First, we propose Rectified Temporal Consistency to resolve motion-induced super vision conflicts.
By filtering out erroneous supervision via forward-backward geometric verificati on, it creates a curriculum that prioritizes trustworthy temporal correspondence s before handling challenging motions.
Second, we propose Confidence-Modulated Frequency Regularization (CMFR) to elimi nate geometric ambiguity.
It adaptively modulates the frequency regularization bandwidth, progressively tr ansitioning from strict low-frequency constraints for artifact suppression to fu ll-spectrum modeling for fine-grained detail preservation.
Extensive experiments on KITTI-360 and nuScenes demonstrate that MAC-NeRF signif icantly outperforms state-of-the-art methods in rendering quality.

Privately Fine-Tuned LLMs Preserve Temporal Dynamics in Tabular Data
Lucas Rosenblatt, Peihan Liu, Ryan McKenna, Natalia Ponomareva
Research on differentially private synthetic tabular data has largely focused on independent and identically distributed rows where each record corresponds to a unique individual. This perspective neglects the temporal complexity in longitu dinal datasets, such as electronic health records, where a user contributes an e ntire (sub) table of sequential events. While practitioners might attempt to mod el such data by flattening user histories into high-dimensional vectors for use with standard marginal-based mechanisms, we demonstrate that this strategy is in sufficient. Flattening fails to preserve temporal coherence even when it maintai ns valid marginal distributions. We introduce PATH, a novel generative framework that treats the full table as the unit of synthesis and leverages the autoregre ssive capabilities of privately fine-tuned large language models. Extensive eval uations show that PATH effectively captures long-range dependencies that traditi onal methods miss. Empirically, our method reduces the distributional distance t o real trajectories by over 60% and reduces state transition errors by nearly 50 % compared to leading marginal mechanisms while achieving similar marginal fidel ity.

Geometrically Constrained Stenosis Editing in Coronary Angiography via Entropic Optimal Transport
Jialin Li, Zhuo Zhang, Cao Yue, Guipeng Lan, Jiabao Wen, Shuai Xiao, Jiachen Yan g
The scarcity of high-quality imaging data for coronary angiography (CAG) stenosi s limits the clinical translation of automated stenosis detection. Synthetic ste nosis data provides a practical avenue to augment training sets, improving data quality, diversity, and distributional coverage, and enhancing detection precisi on and generalization. However, diffusion-based editing commonly relies on soft guidance in a noise-initialized reverse process, offering limited pixel-level pr ecision and structure preservation. We propose the **OT-Bridge Editor**, which r

eframes localized editing as a constrained entropic optimal transport (OT) probl em and leverages geometric information to steer the generation path, enabling st ronger geometric control. Extensive experiments show that our synthesized angiog rams consistently improve downstream stenosis detection, yielding substantial re lative gains of 27.8% on the public ARCADE benchmark and 23.0% on our multi-cent er dataset, supported by consistent qualitative results.

Names Don’t Matter: Symbol-Invariant Transformer for Open-Vocabulary Learning
■lker I■■k, Wenchao Li
Current neural architectures lack a principled way to handle interchangeable tok ens, i.e., symbols that are semantically equivalent yet distinguishable, such as bound variables. As a result, models trained on fixed vocabularies often strugg le to generalize to unseen symbols, even when the underlying semantics remain un changed. We propose a novel Transformer-based mechanism that is provably invaria nt to the renaming of interchangeable tokens. Our approach employs parallel embe dding streams to isolate the contribution of each interchangeable token in the i nput, combined with an aggregated attention mechanism that enables structured in formation sharing across streams. Experimental results confirm the theoretical g uarantees of our method and demonstrate substantial performance gains on open-vo cabulary tasks that require generalization to novel symbols. LieWarper: Geometry-Aware Motion Transfer via Lie Algebra
Linsong Shan, Laurence Tianruo Yang, Zecan Yang, Fukai Guo, Honglu Zhao, Yixuan Geng
Video motion transfer aims to synthesize novel content videos that strictly foll ow the motion trajectories of a reference video. However, existing methods typic ally operate in Euclidean space, treating motion as unconstrained pixel displace ments or linear phase shifts. This simplification frequently causes severe shear ing artifacts and perspective collapse under complex camera and object motions. In this work, we present LieWarper, a geometry-aware motion transfer framework t hat reconceptualizes motion as coordinate evolution on a manifold rather than me re pixel displacement. Specifically, we derive an analytic solver on the $\text{ Sim}(2)$ manifold to extract global evolution parameters from noisy optical flow . We then introduce a flow-guided phase modulation mechanism, enabling non-rigid dynamics to undergo coordinate transformation along the evolution path. This ap proach achieves accurate trajectory transfer while maintaining global geometric integrity. Extensive experiments show that LieWarper significantly outperforms s tate-of-the-art training-free baselines in both motion fidelity and geometric st ability, while maintaining high generation quality.

SPHERE: Mitigating the Loss of Spectral Plasticity in Mixture-of-Experts for Dee p Reinforcement Learning
Lirui Luo, Guoxi Zhang, Hongming Xu, Cong Fang, Qing Li
In DRL, an agent is trained from a stream of experience. In a continual learning setting, such agents can suffer from \emph{plasticity loss}: their ability to l earn new skills from new experiences diminishes over training. Recently, Mixture -of-Experts (MoE) networks have been reported to enable scaling laws and facilit ate the learning of diverse skills. However, in continual reinforcement learning settings, their performance can degenerate as learning proceeds, indicating a l oss of plasticity. To address this, building on Neural Tangent Kernel (NTK) theo ry, we formalize the plasticity loss in MoE policies as a loss of \emph{spectral plasticity}. We then derive a tractable proxy for spectral plasticity, one expr essible in terms of individual expert feature matrices. Leveraging this proxy, w e introduce \emph{SPHERE}, a practical Parseval penalty tailored for MoE-based p olicies that alleviates the loss of spectral plasticity. On MetaWorld and Humano idBench, SPHERE improves average success under continual RL by 133\% and 50\% ov er an unregularized MoE baseline, while maintaining higher spectral plasticity t hroughout training.

Anytime Detection of Strategic Deviations in Multi-Agent Systems
Etienne Gauthier, Francis Bach, Michael I. Jordan
In many multi-agent systems, agents interact repeatedly and are expected to sett le into stable, rational behavior over time. Yet in practice, behavior often dri fts, and detecting such deviations in real time remains an open challenge. We in troduce a sequential testing framework that monitors whether observed play is co nsistent with a benchmark of strategic behavior, without assuming a fixed sample size. Our approach builds on the e-value framework for safe anytime-valid infer ence: by "betting" against the benchmark, we construct a test supermartingale th at accumulates evidence whenever observed payoffs systematically violate the exp ected conditions. For repeated normal-form games, we take equilibrium as the ben chmark, yielding a statistically sound, interpretable measure of departure from equilibrium that can be monitored online; our framework unifies the treatment of Nash, correlated, and coarse correlated equilibria, offering finite-time guaran tees and a detailed analysis of detection times. We also leverage Benjamini-Hoch berg-type procedures to increase detection power in large games while rigorously controlling the false discovery rate. Finally, we extend our method to stochast ic games, verifying online whether observed trajectories adhere to a specified t arget policy, such as a computed equilibrium, broadening the framework's applica bility to dynamic, state-dependent settings.

The Hidden Cost of Structured Generation in LLMs: Draft-Conditioned Constrained Decoding
Avinash Reddy, Thayne T. Walker, Jaime S. Ide, Amrit Singh Bedi
Large language models (LLMs) are increasingly used to generate executable output s, JSON objects, and API calls, where a single syntax error can make the output unusable. Constrained decoding enforces validity token-by-token via masking and renormalization, but it can distort generation when the model assigns low probab ility mass to valid continuations, pushing decoding toward locally valid yet sem antically incorrect trajectories. We propose \emph{Draft-Conditioned Constrained Decoding (DCCD)}, a simple two-step, training-free inference procedure that dec ouples semantic planning from structural enforcement: an unconstrained draft is generated first, and constrained decoding is then applied, conditioned on this d raft, to guarantee validity. We analyze DCCD through a KL-projection view, showi ng that draft conditioning increases feasible mass and reduces the cumulative “p rojection tax” induced by hard constraints, with an optional best-of-K draft s election. Across structured reasoning benchmarks, DCCD improves strict structure d accuracy by up to +24 percentage points over standard constrained decoding (e. g., 15.2\% to 39.0\% on GSM8K with a 1B model), and enables smaller model pairs to match or exceed much larger constrained baselines, yielding substantial gains in parameter efficiency.
****
Is Code Better Than Language for Algorithmic Reasoning?
Terry Tong, Yu Feng, Surbhi Goel, Dan Roth
For tool-augmented language models, comparing natural-language reasoning with co de-execution pipelines is difficult because the comparison changes both the inte rmediate representation and the execution mechanism. We separate these factors w ith an intermediate intervention: the model expresses its reasoning as executabl e code, and the language model simulates that code in context to produce an answ er. On a 40-task verifiable algorithmic benchmark, deterministic code execution outperforms natural-language reasoning by +31.6pp. We observe that the intermedi ate intervention is not meaningfully different from natural-language reasoning (+0.15pp). These results suggest that, in our evaluated setting, changing the int ermediate representation alone does not explain the tool-use advantage, providin g evidence for the performance gains requiring reliable external execution. We formalize this intuition with a simple statistical decision-theoretic model that characterizes when execution dominates end-to-end risk in our disentangled trac e-generation/execution regime. We validate our theory using a reconstruction int ervention that leverages a proxy language model to infer natural-language reason ing traces from code representations, recovering performance comparable to the o

riginal natural-language reasoning pipeline. All experiments are at https://github.com/TerryTong-Git/ToolProj.
****
A Task-centric Theory for Iterative Self-Improvement with Easy-to-Hard Curricula
Chenruo Liu, Yijun Dong, Yiqiu Shen, Qi Lei
Iterative self-improvement fine-tunes an autoregressive large language model (LLM) on reward-verified outputs generated by the LLM itself.
In contrast to the empirical success of self-improvement, the theoretical foundation of this generative, iterative procedure in a practical, finite-sample setting remains limited.
We make progress toward this goal by modeling each round of self-improvement as maximum-likelihood fine-tuning on a reward-filtered distribution and deriving finite-sample guarantees for the expected reward.
Our analysis reveals an explicit feedback loop where better models accept more data per iteration, supporting sustained self-improvement while explaining eventual saturation of such improvement.
Adopting a task-centric view by considering reasoning tasks with multiple difficulty levels, we further prove quantifiable conditions on model initialization, task difficulty, and sample budget where easy-to-hard curricula provably achieve better guarantees than training on fixed mixtures of tasks.
Our analyses are validated through Monte-Carlo simulations and experiments spanning a synthetic graph-based reasoning task and multiple standard mathematical reasoning benchmarks.

ProSAR: Prototype-Guided Semantic Augmentation and Refinement for Time Series Contrastive Learning
Caiyi Yang, Chenglin Li, Hao Zhang, Weijia Lu, ZHIFEI YANG, Wenrui Dai, xiaodong Zhang, Xiaofeng Ma, Can Zhang, Junni Zou, Hongkai Xiong
Contrastive learning has advanced the representation learning across domains, yet its success relies on data augmentations that preserve semantic contents while providing the view diversities. Multivariate time series, however, are inherently noisy, non-stationary, and lack such intuitive semantic cues. Consequently, standard heuristic augmentations that ignore semantic parts may risk destroying critical temporal dependencies. Though some recent approaches attempt to isolate informative components, they typically rely on an implicit neural mechanism to infer semantics, thus limiting the interpretability and controllability.
To address this, we propose ProSAR, an information-theoretic framework that leverages the explicit prototype alignment to guide semantic augmentations, and establish a feedback loop between the augmentation, contrastive learning, and prototype updates.
Specifically, grounded in our proposed Prototype-Conditioned Information Bottleneck principle, we leverage the time-domain prototypes as explicit anchors to localize semantic segments, and develop a time–frequency augmentation strategy that retains prototype-consistent information while discarding noise. To promote semantically consistent prototypes for a reliable view generation, we design a dual-prototype loop where the augmented views are encoded into representations and then the learned representations are clustered to update latent prototypes, whose decoded feedback refines the time-domain prototypes for the next round of augmentation.
Experiments on diverse time-series benchmarks demonstrate that ProSAR outperforms the other contrastive learning methods on downstream forecasting and classification tasks.

Learning Cardiac Latent Representations in Vectorcardiogram Space
Bosong Huang, Panzhen Zhao, Zengxiang Li, Patricia Lee, Wei Jin, Alan Wee-Chung Liew, Ming Jin, Shirui Pan
Electrocardiography (ECG) is a cornerstone of cardiac assessment, making the learning of informative ECG representations fundamental to tasks ranging from disease diagnosis to clinical report generation.
However, existing methods operate almost exclusively in the observable ECG signa

l space.
In practice, the standard twelve-lead ECG represents multiple projections of the same underlying cardiac electrical activity from different spatial orientations. Therefore, representation learning in the ECG space inevitably introduces substantial redundancy, which may lead to spurious correlations and increased risk of overfitting.
To address this and motivated by the Frank vectorcardiogram (VCG) model, we propose learning a unified latent representation of cardiac electrical activity directly in the VCG space.
We introduce LVCG, the first general self-supervised representation learning framework designed to operate in this physically grounded latent space.
By learning view-invariant latent VCG representations rather than lead-specific artifacts, VCG minimizes redundancy and improves generalization.
LVCG generally outperforms ECG-space baselines across tasks, demonstrating enhanced robustness and generalization, especially in domain shift settings. Our code has been made available at https://github.com/BosonHwang/LVCG.

Noise as a Natural Regularizer in Markov Decision Processes: Connecting Environmental Stochasticity and Policy Simplicity
Harry Chen, Yiyang Sun, Michal Moshkovitz, Zachery Boner, Lesia Semenova, Cynthia Rudin, Ronald Parr
The planning horizon in a Markov Decision Process (MDP) determines how far into the future an agent reasons. In practice, shorter horizons are commonly associated with policies that exhibit simpler or more interpretable decision-making behavior. In this paper, we establish a formal connection between environmental stochasticity and planning horizon in MDPs. We show that for broad classes of transition noise, solving a noisy MDP can be formally related to solving a noise-free MDP with a shorter effective discount factor, leading to identical optimal policies in some cases and near-optimal ones in others. We further characterize settings in which this correspondence breaks down, clarifying when horizon-based interpretations of noise are not valid. These results, which are supported by both theory and experiments, also give some insight into the common practice of using smaller discount factors for reinforcement learning than those that can be justified by standard modeling interpretations.

From Absolute to Relative: Rethinking Reward Shaping in Group-Based Reinforcement Learning
Wenzhe Niu, Wei He, Zongxia Xie, Jinpeng Ou, Huichuan Fan, Yuchen Ge, Yanru Sun, Ziyin Wang, Yizhao Sun, Chengshun Shi, Jiuchong Gao, Jinghua Hao, Renqing He
Reinforcement learning has become a cornerstone for enhancing the reasoning capabilities of Large Language Models, where group-based approaches such as GRPO have emerged as efficient paradigms that optimize policies by leveraging intra-group performance differences. However, these methods typically rely on absolute numerical rewards, introducing intrinsic limitations. In verifiable tasks, identical group evaluations often result in sparse supervision, while in open-ended scenarios, the score range instability of reward models undermines advantage estimation based on group means. To address these limitations, we propose **Reinforcement Learning with Relative Rewards (RLRR)**, a framework that shifts reward shaping from absolute scoring to relative ranking. Complementing this framework, we introduce the **Ranking Reward Model**, a listwise preference model tailored for group-based optimization to directly generate relative rankings. By transforming raw evaluations into robust relative signals, RLRR effectively mitigates signal sparsity and reward instability. Experimental results demonstrate that RLRR yields consistent performance improvements over standard group-based baselines across reasoning benchmarks and open-ended generation tasks.

Scene Graph Thinking: Reinforcing Structured Visual Reasoning for Multimodal Large Language Models
Zhiwei Yang, Yuanchen Wu, NAN ZHANG, Yucong Meng, Ke Yan, Shouhong Ding
Multimodal Large Language Models (MLLMs) have demonstrated strong perception and

reasoning capabilities. However, most existing models focus on isolated objects and neglect structured relationships for efficient target navigation, limiting their performance on visually intensive tasks. To address this challenge, we introduce Scene Graph Thinking (SaGe), a novel paradigm that enables fine-grained and structured visual reasoning through explicit scene-graph representations. Specifically, we first introduce an automated data engine that converts flat image–text corpora into structured scene graphs, where hierarchical entities constitute the nodes and diverse visual relations define the edges. Building upon this, we construct 120K high-quality training data by sampling reasoning traces from scene graphs. Then two-stage graph-aligned post-training paradigms are introduced, where supervised fine-tuning internalizes MLLMs with structured reasoning, and subsequent reinforcement fine-tuning proposes node-as-proxy graph rewards to consolidate efficient graph exploration. With curated data and graph-aligned training, our approach achieves significant improvements across eight multimodal benchmarks, demonstrating strong effectiveness on fine-grained perception and reasoning tasks.

CONTINUUM: Restoring the Contiguous Tensor Abstraction Efficiently for Dynamic AI Workloads via Hardware Virtualization

Yangyu Zhang, Shuoming Zhang, Chunwei Xia, Shuaijiang Li, Zhicheng Li, Ruiyuan Xu, Zheming Yang, Lei Chen, YUAN WEN, Guangli Li, Xiaobing Feng, Huimin Cui, Jiacheng Zhao

Emerging LLM workloads demand extreme memory agility. However, state-of-the-art inference systems such as vLLM rely on software-defined paging, which sacrifices the contiguous tensor abstraction. This rigid interface exposes fragmentation complexity to developers, imposing a severe engineering burden that stifles algorithmic innovation. We introduce CONTINUUM, a tensor memory virtualization subsystem implemented as a PyTorch extension. By bypassing serialized OS bottlenecks through a lightweight GPU driver extension, CONTINUUM significantly reduces mapping costs by orders of magnitude, from milliseconds to microseconds. Built atop this low-latency API, CONTINUUM provides Elastic Tensor, a set of flexible tensor operations that natively support complex memory dynamics and zero-copy topological aliasing. Evaluations demonstrate that CONTINUUM achieves significantly higher throughput across diverse dynamic scenarios, effectively lowering the barrier to implementing next-generation LLM applications.

StyleDistillation: A New Insight of Image Style Enables Personalized Aesthetic Manipulation

Yuxin Wang, Xiaoyu Geng, Yuke Li, Zheng Wang

Text-guided stylized image generation has yielded promising advances by leveraging the powerful capabilities of text-to-image diffusion models. However, the inherent coupling of style and content information within the reference image presents a significant challenge. To address this, we propose StyleDistillation, a novel approach grounded in two key observations about the CLIP embedding space from a style perspective. By leveraging a lightweight StyleDistiller module, combined with carefully designed optimization objectives based on geometric and semantic priors, we can extract fine-grained style representation from the reference image. Additionally, we introduce a Prompt Alignment Enhancement mechanism during inference, which significantly improves the control that text prompts exert over the generated images. Extensive experiments demonstrate that our method achieves outstanding performance in both style reproduction and prompt alignment. Furthermore, StyleDistillation supports various personalized operations, including style editing and style fusion, highlighting its substantial potential for diverse applications.

CAOS: Conformal Aggregation of One-Shot Predictors

Maja Waldron

One-shot prediction enables rapid adaptation of pretrained foundation models to new tasks using only one labeled example, but lacks principled uncertainty quantification. While conformal prediction provides finite-sample coverage guarantees

, standard split conformal methods are inefficient in the one-shot setting due t
o data splitting and reliance on a single predictor. We propose Conformal Aggreg
ation of One-Shot Predictors (CAOS), a conformal framework that adaptively aggre
gates multiple one-shot predictors and uses a leave-one-out calibration scheme t
o fully exploit scarce labeled data. Despite violating classical exchangeability
 assumptions, we prove that CAOS achieves valid marginal coverage using a monoto
nicity-based argument. Experiments on one-shot facial landmarking and RAFT text
classification tasks show that CAOS produces substantially smaller prediction se
ts than split conformal baselines while maintaining reliable coverage.

From Flat Facts to Sharp Hallucinations: Detecting Stubborn Errors via Gradient
Sensitivity

Liew Yee Zhing, Andrew Huey Ping Tan, Anwar P.P. Abdul Majeed

Traditional hallucination detection fails on "Stubborn Hallucinations" — errors
where LLMs are confidently wrong. We propose a geometric solution: Embedding-Per
turbed Gradient Sensitivity (EPGS). We hypothesize that while robust facts resid
e in flat minima, stubborn hallucinations sit in sharp minima, supported by brit
tle memorization. EPGS detects this sharpness by perturbing input embeddings wit
h Gaussian noise and measuring the resulting spike in gradient magnitude. This a
cts as an efficient proxy for the Hessian spectrum, differentiating stable knowl
edge from unstable memorization. Our experiments show that EPGS significantly ou
tperforms entropy-based and representation-based baselines, providing a robust s
ignal for detecting high-confidence factual errors.

PointDiT: Pixel-Space Diffusion for Monocular Geometry Estimation

Haofei Xu, Rundi Wu, Philipp Henzler, Nikolai Kalischek, Michael Oechsle, Fabian
 Manhardt, Marc Pollefeys, Andreas Geiger, Federico Tombari, Michael Niemeyer

State-of-the-art single-image 3D reconstruction methods often rely on complex hy
brid architectures and loss functions (e.g., MoGe), or necessitate compressing g
eometry into latent spaces (e.g., GeometryCrafter) to leverage pre-trained laten
t diffusion models. In this work, we demonstrate that such architectural overhea
d and intricate loss formulations are unnecessary. We introduce a minimalist pix
el-space Diffusion Transformer built on a plain ViT, which operates directly on
raw 3D point map patches and is conditioned on image tokens from a pre-trained D
INOv3. Unlike existing latent diffusion-based approaches, we train our diffusion
 backbone entirely from scratch, eliminating the need for point map tokenizers.
We show that this streamlined approach yields results superior to complex latent
-based diffusion models while remaining significantly simpler than hybrid altern
atives. Notably, our model produces sharper geometric structures and achieves si
gnificantly better results on highly ambiguous regions, such as transparent obje
cts.

Temporal-aware Flow Matching for Video Generation with Temporally Coherent Motio
n

Zirui Pan, Xin Wang, Yipeng Zhang, Yuwei Zhou, Wenwu Zhu

Despite rapid advances in text-to-video generation, state-of-the-art generative
models still suffer from producing temporally incoherent and unrealistic motion
for videos. The key weakness of existing works is that they commonly treat video
s as frame sequences and directly adopt Flow Matching (FM) objectives, which are
 originally designed for images. This practice fails to explicitly model motion
priors or temporal dependencies, resulting in suboptimal dynamics that may appea
r incoherent and unrealistic. To solve this problem, we propose Temporal-aware F
low Matching (TFM), a novel training paradigm that embeds inter-frame constraint
s into the flow objective, leading to temporally coherent motion modeling in vid
eo generation. More specifically, the proposed TFM enforces temporal correlation
s across frames while retaining the desirable properties of FM, and further intr
oduces a residual-type loss that aligns naturally with this new flow. We theoret
ically prove that models trained with TFM are able to exhibit remarkably enhance
d temporal perception ability. Notably, TFM imposes no additional cost during in
ference and is applicable to any model using FM. Extensive experiments demonstra

te that our TFM can significantly improve motion realism across diverse motion t
ypes. Generated videos are presented at https://pzrain.github.io/tfm.

AIR: Improving Agent Safety through Incident Response
Zibo Xiao, Jun Sun, Junjie Chen
Large Language Model (LLM) agents are increasingly deployed in practice across a
 wide range of autonomous applications. Yet current safety mechanisms for LLM ag
ents focus almost exclusively on preventing failures in advance, providing limit
ed capabilities for responding to, containing, or recovering from incidents afte
r they inevitably arise. In this work, we introduce AIR, the first incident res
ponse framework for LLM agent systems. AIR defines a domain-specific language fo
r managing the incident response lifecycle autonomously in LLM agent systems, an
d integrates it into the agent's execution loop to (1) detect incidents via sema
ntic checks grounded in the current environment state and recent context, (2) gu
ide the agent to execute containment and recovery actions via its tools, and (3)
 synthesize guardrail rules during eradication to block similar incidents in fut
ure executions. We evaluate AIR on three representative agent types. Results sho
w that AIR achieves detection, remediation, and eradication success rates all ex
ceeding 90%. Extensive experiments further confirm the necessity of AIR's key de
sign components, show the timeliness and moderate overhead of AIR, and demonstra
te that LLM-generated rules can approach the effectiveness of developer-authored
 rules across domains. These results show that incident response is both feasibl
e and essential as a first-class mechanism for improving agent safety.

Adalina: Adaptive Linear Approximation for the Shapley Value and Beyond
Weida Li, Yaoliang Yu, Bryan Kian Hsiang Low
The Shapley value, and its broader family of semi-values, has received much atte
ntion in various attribution problems. A fundamental and long-standing challenge
 is their efficient approximation, since exact computation generally requires an
 exponential number of utility queries in the number of players n. To meet the
 challenges of large-scale applications, we explore the limits of efficiently ap
proximating semi-values under a $\Theta(n)$ space constraint. Building upon a ve
ctor concentration inequality, we establish a theoretical framework that enables
 sharper query complexities for existing unbiased randomized algorithms. Within
this framework, we systematically develop a linear-space algorithm that requires
 $O(\frac{n}{\epsilon^{2}}\log\frac{1}{\delta})$ utility queries to ensure $P(\\
|\hat{\boldsymbol\phi}-\boldsymbol\phi\\|\geq\epsilon)\leq \delta$ for all commo
nly used semi-values. In particular, our framework naturally bridges OFA, unbias
ed kernelSHAP, SHAP-IQ and the regression-adjusted approach, and definitively ch
aracterizes when paired sampling is beneficial. Moreover, our algorithm allows e
xplicit minimization of the mean squared error $\mathbb{E}[\\|\hat{\boldsymbol\p
hi}-\boldsymbol\phi\\|^{2}]$ for each specific utility function. Accordingly, we
 introduce the first adaptive, linear-time, linear-space randomized algorithm, A
dalina, that theoretically achieves improved mean squared error. All of our theo
retical findings are experimentally validated. Our code is available at https://
github.com/watml/adalina.

DiffuMamba: High-Throughput Diffusion LMs with Mamba Backbone
Vaibhav Singh, Oleksiy Ostapenko, Pierre-Andre Noel, Eugene Belilovsky, Torsten
Scholak
Diffusion language models (DLMs) have emerged as a promising alternative to auto
regressive (AR) generation, yet their reliance on Transformer backbones limits i
nference efficiency due to quadratic attention or KV-cache overhead. We introduc
e DiffuMamba, a masked diffusion language model built on a bidirectional Mamba b
ackbone that combines the diffusion objective with linear-time sequence modeling
, and DiffuMamba-H, a hybrid variant with interleaved attention. Across scales u
p to 1.3B parameters, our models match Transformer-based diffusion in downstream
 performance while achieving up to 8.2× and 4.3× higher inference throughput, re
spectively, on long sequences. We further present a systematic analysis of infer
ence efficiency across modern DLM variants, combining asymptotic complexity with

empirical measurements. Notably, cache-efficient block diffusion with Mamba mixers emerges as the only strategy that scales linearly with sequence length and achieves the strongest performance across all baselines, suggesting a promising direction for future diffusion-based generation systems.
****

RedVisor: Reasoning-Aware Prompt Injection Defense via Zero-Copy KV Cache Reuse
Mingrui Liu, Sixiao Zhang, Cheng Long, Kwok-Yan Lam
Large Language Models (LLMs) are increasingly vulnerable to *Prompt Injection (PI)* attacks, where adversarial instructions hidden within retrieved contexts hijack the model's execution flow. Current defenses typically face a critical trade-off: *prevention-based* fine-tuning often degrades general utility via the "alignment tax", while *detection-based* filtering incurs prohibitive latency and memory costs. To bridge this gap, we propose **RedVisor**, a unified framework that synthesizes the explainability of detection systems with the seamless integration of prevention strategies. To the best of our knowledge, RedVisor is the first approach to leverage fine-grained reasoning paths to simultaneously *detect* attacks and *guide* the model's safe response. We implement this via a lightweight, removable adapter positioned atop the frozen backbone. This adapter serves a dual function: it first generates an explainable analysis that precisely localizes the injection and articulates the threat, which then explicitly conditions the model to reject the malicious command. Uniquely, the adapter is active only during this reasoning phase and is effectively muted during the subsequent response generation. This architecture yields two distinct advantages: (1) it mathematically preserves the backbone's original utility on benign inputs; and (2) it enables a novel **KV Cache Reuse** strategy, eliminating the redundant prefill computation inherent to decoupled pipelines. We further pioneer the integration of this defense into the vLLM serving engine with custom kernels. Experiments demonstrate that RedVisor outperforms state-of-the-art defenses in detection accuracy and throughput while incurring negligible utility loss.

Supervised Guidance Training for Infinite-Dimensional Diffusion Models
Elizabeth Louise Baker, Alexander Denker, Jes Frellsen
Score-based diffusion models have recently been extended to infinite-dimensional function spaces, with uses such as inverse problems arising from partial differential equations. In the Bayesian formulation of inverse problems, the aim is to sample from a posterior distribution over functions obtained by conditioning a prior on noisy observations. While diffusion models provide expressive priors in function space, the theory of conditioning them to sample from the posterior remains open. We address this, assuming that either the prior lies in the Cameron-Martin space, or is absolutely continuous with respect to a Gaussian measure. We prove that the models can be conditioned using an infinite-dimensional extension of Doob's h-transform, and that the conditional score decomposes into an unconditional score and a guidance term. As the guidance term is intractable, we propose a simulation-free score matching objective (called *Supervised Guidance Training*) enabling efficient and stable posterior sampling. We illustrate the theory with numerical examples on Bayesian inverse problems in function spaces. In summary, our work offers the first function-space method for fine-tuning trained diffusion models to accurately sample from a posterior.

AgentExpt: Automating AI Experiment Design with LLM-based Resource Retrieval Agent
Yu Li, Lehui Li, Lin Chen, Qingmin Liao, Fengli Xu, Yong Li
In modern AI research, baseline and dataset selection is a high-stakes decision in experimental design.
It operationalizes a research idea into a concrete evaluation protocol and largely determines the validity and comparability of empirical conclusions.
However, making appropriate choices is increasingly difficult as baselines and datasets proliferate, while suitability is inherently context-dependent and rarely captured by baseline and dataset metadata.
To address these challenges, we present \textbf{AgentExpt}, a comprehensive fram

ework for baseline and dataset recommendation.
We first curate a large-scale, high-quality knowledge base that links 108{,}825 accepted papers to their used baselines and datasets.
Based on this resource, we design a \textit{collective perception-enhanced retriever} that represents each baseline or dataset by integrating first-person self-descriptions with third-person citation contexts, thereby effectively positioning them within the scholarly network.
We further design a \textit{reasoning-augmented reranker} that encodes baseline-dataset interaction chains as a reasoning prior to fine-tune an LLM, producing refined rankings with interpretable justifications.
Experiments show that our framework outperforms the strongest baseline, with average gains of +5.85\% in Recall@20 and +7.90\% in HitRate@10, and ablation studies confirm the effectiveness of our designed components.
Overall, AgentExpt advances the efficient and reliable automation of experimental design.
Our code is available at \url{https://anonymous.4open.science/r/Agentexpt-DD3E}.

BPDQ: Bit-Plane Decomposition Quantization on a Variable Grid for Large Language Models
Junyu Chen, Jungang Li, Jing Xiong, Wenjie Wang, Qingyao Yang, He Xiao, Zhen Li, Taiqiang Wu, Mengzhao Chen, Zhen Peng, Chaofan Tao, Long Shi, Hongxia Yang, Ngai Wong
Large language model inference is often bounded by memory footprint and bandwidth in resource-constrained deployments, making quantization fundamental to efficient serving.
While post-training quantization (PTQ) maintains high fidelity at 4-bit, it deteriorates at 2-3 bits.
In essence, existing methods enforce a shape-invariant quantization grid (e.g., the fixed uniform intervals of UINT2) for each group, severely restricting the feasible set for error minimization.
To address this, we propose Bit-Plane Decomposition Quantization (BPDQ), which constructs a variable quantization grid via bit-planes and scalar coefficients, and iteratively refines them using second-order information while progressively compensating for quantization errors to minimize output discrepancy.
In the 2-bit regime, BPDQ enables serving Qwen2.5-72B on a single RTX 3090 with 83.85\% GSM8K accuracy (vs. 90.83\% at 16-bit).
Moreover, we theoretically show that the variable grid expands the feasible set, and that the quantization process consistently aligns with the optimization objective in Hessian-induced geometry.
The code is available at github.com/KingdalfGoodman/BPDQ.
****

FiRE: Fine-grained Ranking Evaluation for Machine Translation
Wenyang Gao, Yinghao Yang, Xi Jin, Jing Li, Yue Zhang
Developing reliable machine translation (MT) systems hinges on our ability to distinguish superior translations from inferior ones. However, existing evaluation paradigms, whether limited to coarse overall rankings or misaligned with human preferences, fail to deliver interpretable, fine■grained feedback in reference■free settings. We present a Fine-Grained Ranking Evaluation method (FiRE) that leverages off■the■shelf large language models to perform criterion■driven pairwise comparison across three complementary dimensions: faithfulness, fluency, and consistency of style, instead of producing a single holistic judgment. To enable rigorous meta■evaluation of evaluation paradigms in the absence of any suitable testbed, we construct the first human■annotated, reference■free benchmark for fine-grained ranking evaluation, achieving substantial inter■annotator agreement. Through meta■evaluation on this benchmark and existing MQM datasets, FiRE demonstrably outperforms regression■based and error■analysis metrics in aligning with human comparative judgments, while providing more informative insights into translation quality. Finally, our examination of LLM evaluator biases (position and self-enhancement) and their handling of tied cases offers guidance for more nuanced MT evaluation. Code and benchmark resources are available at https://github.c

om/wygao8/FiRE-MT.

Powerful and Theoretically Guaranteed Independence Testing on Heterogeneous Federated Clients

Yixin Ren, Hongquan Liu, Juncai Zhang, Yewei Xia, Zichuan Lin, Deheng Ye, Hao Zhang, Jihong Guan, Shuigeng Zhou

In this paper, we present a novel federated independence testing (FedIT) method that addresses both theoretical and practical challenges arising from client heterogeneity. We begin by revisiting existing federated independence testing methods and showing why they fail to provide valid guarantees or maintain statistical power under data distributional shift across clients. Building on this analysis, we develop a copula-based marginal alignment technique together with a stacking-based aggregation strategy that amplifies intra-client dependence while mitigating inter-client variation, resulting in a theoretically sound and powerful global test. For practicality, we further accelerate the aggregation step and incorporate a privacy-preserving mechanism. On the theoretical side, we prove both the correctness of our method and the validity of the test. Empirically, we conduct extensive experiments on both synthetic and real-world datasets, which demonstrate the superiority of our solution over existing methods.
****

CoIRL-AD: Collaborative-Competitive Imitation-Reinforcement Learning in Latent World Models for Autonomous Driving

Xiaoji Zheng, Ziyuan Yang, Yanhao Chen, Yuhang Peng, Yuanrong Tang, Gengyuan Liu, Bokui Chen, Jiangtao Gong

End-to-end autonomous driving models trained with imitation learning (IL) often generalize poorly, particularly in long-tail scenarios where expert demonstrations are sparse. Reinforcement learning (RL) can provide complementary task-level supervision, but applying RL to real-world autonomous driving is challenging in offline settings without interactive simulators, where datasets are dominated by expert actions and provide limited behavioral diversity. We propose CoIRL-AD, a competitive dual-policy framework that integrates IL and RL under a unified offline training regime. CoIRL-AD decouples imitation and reward optimization into separate actors to alleviate objective conflicts, uses imagined future rollouts for long-horizon reward estimation, and introduces a competition mechanism that selectively transfers beneficial behaviors while keeping RL anchored to expert-like driving. Experiments on the nuScenes benchmark show that CoIRL-AD consistently improves robustness over strong IL-based baselines, with especially large gains in cross-city generalization and long-tail scenarios. Code is available at: https://github.com/SEU-zxj/CoIRL-AD.

Learning Multi-Agent Coordination via Sheaf-ADMM

Jeffrey Seely, Bart■omiej Cupia■, Llion Jones

We present a differentiable optimization framework for multi-agent coordination. An input is decomposed into overlapping local views, each processed by an agent that solves a convex subproblem parameterized by a neural encoder. Agents coordinate through the Alternating Direction Method of Multipliers (ADMM) with inter-agent constraints specified by a cellular sheaf. The sheaf specifies which aspects of neighboring solutions must agree, allowing for heterogeneous notions of global consensus. Backpropagating through the unrolled optimization jointly trains all components of the multi-agent system. We evaluate on maze pathfinding, image classification, and Sudoku, where agents with individually insufficient local views learn to coordinate to produce correct global outputs. On MNIST, the local-view decomposition yields improved robustness to distribution shifts relative to a standard CNN. On Sudoku, the optimization-derived structure yields markedly higher solve rates than parameter-matched MPNN baselines. Finally, the ADMM structure exposes distinct primal, consensus, and dual state variables, opening the coordination dynamics to direct analysis and intervention—a property unavailable in standard message-passing architectures.
****

Deep Networks Learn Deep Hierarchical Models

Amit Daniely
We consider supervised learning with n labels and show that layerwise SGD on r esidual networks can efficiently learn a class of hierarchical models. This mode l class assumes the existence of an (unknown) label hierarchy $L_1 \subseteq L_2 \subseteq \dots \subseteq L_r = [n]$, where labels in L_1 are simple function s of the input, while for $i > 1$, labels in L_i are simple functions of simpl er labels.

Our class surpasses models that were previously shown to be learnable by deep le arning algorithms, in the sense that it reaches the depth limit of efficient lea rnability. That is, there are models in this class that require polynomial depth to express, whereas previous models can be computed by log-depth circuits.

Furthermore, we suggest that learnability of such hierarchical models might even tually form a basis for understanding deep learning.
Beyond their natural fit for domains where deep learning excels, we argue that t he mere existence of human ``teachers" supports the hypothesis that hierarchical structures are inherently available. By providing granular labels, teachers eff ectively reveal ``hints'' or ``snippets'' of the internal algorithms used by the brain. We formalize this intuition, showing that in a simplified model where a teacher is partially aware of their internal logic, a hierarchical structure eme rges that facilitates efficient learnability.

Scalable Simulation-Based Model Inference with Test-Time Complexity Control
Manuel Gloeckler, J.P. Manzano-Patrón, Stamatios Sotiropoulos, Cornelius Schröde r, Jakob H. Macke
Simulation plays a central role in scientific discovery. In many applications, t he bottleneck is no longer running a simulator—it is choosing among large famili es of plausible simulators, each corresponding to different forward models/hypot heses consistent with observations. Over large model families, classical Bayesia n workflows for model-selection are impractical. Furthermore, amortized model-se lection methods typically hard-code a fixed model prior—or complexity penalty—at training time, requiring users to commit to a particular parsimony assumption b efore seeing the data. We introduce PRISM, a simulation-based encoder-decoder th at infers a joint posterior over both discrete model structures and associated c ontinuous parameters, while enabling test-time control of model complexity via a tunable model prior that the network is conditioned on. We show that PRISM scal es to families with combinatorially many (up to billions of) model instantiation s on a synthetic symbolic regression task. As a scientific application, we evalu ate PRISM on biophysical modeling for diffusion MRI data, showing the ability to perform model selection across several multi-compartment models, on both synthe tic and in-vivo neuroimaging data.
****
Gauge-Equivariant Graph Networks via Self-Interference Cancellation
Yoonhyuk Choi, Jiho Choi, Jiwoo Kang
Graph neural networks often degrade on heterophilous graphs because repeated nei ghbor aggregation can reinforce self-aligned low-frequency components while supp ressing phase-inconsistent signals. We propose GESC, a complex-valued graph netw ork that augments attention-based message passing with gauge-consistent U(1) tra nsport and projection-based self-interference cancellation. For each transported neighbor message, GESC removes the component parallel to the target representat ion before computing attention and applies a sign-aware gate based on gauge-inva riant complex alignment. We prove gauge equivariance of the hidden update and de rive coefficient-frozen stability bounds showing that SIC contracts self-paralle l message components. On nine benchmarks, GESC ranks first on seven datasets and remains within the top three on the other two. These results suggest that expli cit self-parallel cancellation is an effective mechanism for improving message p assing under heterophily. Our code is available at https://github.com/ChoiYoonHy uk/GESC.

Deep neural networks divide and conquer dihedral multiplication
Sihui Wei, Gavin McCracken, Gabriela Moisescu-Pareja, Harley Wiltzer, Doina Precup, Irina Rish, Jonathan Love
We find multilayer perceptrons and transformers both universally learn an instantiation of the same divide-and-conquer algorithm that requires only a logarithmic number of neural representations to solve dihedral multiplication. Clustering neurons based on similar activation behaviour reveals remarkably clear structure: each neural representation corresponds to a Cayley graph. To our knowledge, this is the first work that fully characterizes and describes all neural representations that are learnable on a dataset, while prior work on group multiplications studied neuron-level behavior, or preliminarily investigated cluster behavior. Thus, we can understand the algorithm networks universally learn at three levels of abstraction: 1) Neurons activate on coset or approximate coset structure of the dihedral group. 2) Groups of neurons together form neural representations that act to divide the dataset into different subproblems, being Cayley graphs, where the equivalence class of the answer is computed. 3) The global algorithm then linearly combines each neural representation (subproblem) together at the logits. This work provides the community with a deep case study and a well-understood toy model for interpretability, and makes progress toward proving the conjecture that networks trained via stochastic gradient methods divide and conquer all group multiplication tasks.
****
DTop-p MoE: Sparsity-Controlled Dynamic Top-p MoE for Foundation Model Pre-training
Can Jin, Hongwu Peng, Mingcan Xiang, Qixin Zhang, Xiangchi Yuan, Amit Hasan, Ohi Dibua, Yifan Gong, Yan Kang, Dimitris N. Metaxas
Sparse Mixture-of-Experts architectures are essential for scaling model capacity efficiently, yet the standard Top-k routing imposes a rigid sparsity pattern that ignores the intrinsic variance in token difficulty and layer-specific computational needs. Top-p routing is more adaptive because it selects experts until their cumulative routing probability reaches a threshold, allowing confident tokens to use fewer experts and ambiguous tokens to recruit more. However, we demonstrate that existing naive Top-p implementations with fixed global probability thresholds provide only marginal gains over Top-k, suffer from hyperparameter sensitivity, and result in uncontrolled computational costs. In this paper, we propose **DTop-p**, a sparsity-controllable dynamic routing mechanism that learns the Top-p probability threshold with a Proportional-Integral controller and uses dynamic routing normalization to support layer-wise expert selection under a global sparsity constraint. Extensive experiments on Large Language Models and Diffusion Transformers demonstrate that **DTop-p** consistently outperforms both Top-k and fixed Top-p baselines while matching the average FLOPs of Top-k MoE. Our analysis confirms that **DTop-p** exhibits strong scaling properties across expert granularity, total expert capacity, model size, and dataset size, offering a robust and efficient MoE framework for foundation model pre-training.
****
Open-World LLM Logical Reasoning
Ye Mo, Chuan Zhou, Fengxiang Cheng, Jialin Yu, Liangming Pan, Fenrong Liu, Sheng Zhou, Haoxuan Li, Zhouchen Lin, Philip Torr
Large Language Models (LLMs) achieve remarkable performance but struggle with complex logical reasoning, particularly in real-world settings.
Existing research is largely confined to the closed-world assumption, which posits that all premises required for reasoning are explicitly provided.
However, real-world tasks frequently exhibit open-world characteristics, where the provided information is insufficient to infer a conclusion due to missing premises or implicit commonsense knowledge.
To address this, we propose OpenIKLR, an Open-world Incomplete-Knowledge-aware Logical Reasoning framework that integrates symbolic logic solvers with LLMs.
OpenIKLR first translates natural language into symbolic representations to pinpoint reasoning gaps via a logical solver.

It then iteratively generates a minimal set of necessary missing premises using LLMs.
To ensure these added premises are both logically sound and factually accurate, we introduce a dual-verification: logic verification via the solver and fact ver ification via the LLMs.
Experiments show that OpenIKLR consistently outperforms existing logical reasoni ng and RAG baselines across multiple backbones and real-world datasets.
The code is available at https://github.com/OpenIKLR/OpenIKLR.
****

Are First-Order Diffusion Samplers Really Slower? A Fast Forward-Value Approach
Yuchen Jiao, Na Li, Changxiao Cai, Gen Li
Higher-order ODE solvers have become a standard tool for accelerating diffusion probabilistic model (DPM) sampling, motivating the widespread view that first-or der methods are inherently slower and that increasing discretization order is th e primary path to faster generation. This paper challenges this belief and revis its acceleration from a complementary angle: beyond solver order, the placement of DPM evaluations along the reverse-time dynamics can substantially affect samp ling accuracy in the low-neural function evaluation (NFE) regime. We propose a n ovel training-free, first-order sampler named Forward DPMSolver (F-DPMSolver), w hose leading discretization error has the opposite sign to that of DDIM. Algorit hmically, the method approximates the forward-value evaluation via a cheap one-s tep lookahead predictor. We provide theoretical guarantees showing that the resu lting sampler provably approximates the ideal forward-value trajectory while ret aining first-order convergence. Empirically, across standard image generation be nchmarks, the proposed sampler consistently improves sample quality under the sa me NFE budget and can be competitive with, and sometimes outperform, state-of-th e-art higher-order samplers. Overall, the results suggest that the placement of DPM evaluations provides an additional and largely independent design angle for accelerating diffusion sampling. Our code is available at https://github.com/Na-Li66/F-DPMSolver.

An Approximation Algorithm for Graph Label Selection
Josia John, Simon Meierhans, Maximilian Probst Gutenberg
In the graph label selection problem, one is given an n-vertex graph and a bud get k, and seeks to select k vertices whose labels enable accurate predictio n of the labels on the remaining vertices. This problem formalizes distilling a small representative set from the whole graph.
We present the first $\tilde{O}(\log^{1.5} n)$-approximation algorithm for graph label selection under the standard budget constraint. Prior work either relies on resource augmentation, allowing substantially more than k labeled vertices, or consists primarily of heuristics without provable guarantees.
Finally, we demonstrate that practical heuristic variants of our algorithm scale to significantly larger graphs than previous methods, while essentially retaini ng their quality.

R2R2: Robust Representation for Intensive Experience Reuse via Redundancy Reduct ion in Self-Predictive Learning
Sanghyeob Song, Donghyeok Lee, Jinsik Kim, Sungroh Yoon
For reinforcement learning in data-scarce domains like real-world robotics, inte nsive data reuse enhances efficiency but induces overfitting. While prior works focus on critic bias, representation-level instability in Self-Predictive Learni ng (SPL) under high Update-to-Data (UTD) regimes remains underexplored. To bridg e this gap, we propose Robust Representation via Redundancy Reduction (R2R2), a regularization method within SPL. We theoretically identify that standard zero-c entering conflicts with SPL's spectral properties and design a non-centered obje ctive accordingly. We verify R2R2 on SPL-native algorithms like TD7. Furthermore , to demonstrate its orthogonality to prior advancements, we extend the state-of -the-art SimbaV2, which originally lacks SPL, by integrating a tailored SPL modu le, termed SimbaV2-SPL. Experiments across 11 continuous control tasks confirm t hat R2R2 effectively mitigates overfitting; specifically, at a UTD ratio of 20,

it improves TD7 by $\sim$22\% and provides additional gains on top of SimbaV2-SP L, which itself establishes a new state-of-the-art. The code can be found at [th is link](https://github.com/songsang7/R2R2).
****
WAVE: Window-Aware Vocabulary-Efficient Early-Exit for Training-Free LLM Acceler ation
Seonggeun Kim, Gilha lee, Hyun Kim
Large language models (LLMs) incur substantial inference latency due to autoregr essive decoding, in which each token requires a full forward pass through all tr ansformer layers. Early-exit methods that terminate computation at intermediate layers offer a promising remedy, yet existing approaches suffer from fundamental limitations. Confidence-based methods rely on evaluating the full LM head at ev ery layer, introducing considerable overhead that can negate the expected speedu p. Schedule-based methods avoid this cost through predetermined exit schedules, but their monotonically decreasing layer allocation collapses to shallow layers, thereby constraining the maximum generation length. Learned exit predictors fur ther require costly task-specific training and are vulnerable to distribution sh ifts in unseen domains. We propose Window-Aware Vocabulary-Efficient Early-Exit (WAVE), a training-free framework that addresses these challenges through two ke y innovations. First, exit window scheduling identifies an optimal layer range f or early-exit decisions via offline calibration, preventing premature convergenc e to shallow layers while substantially reducing the number of exit checks. Seco nd, a proxy LM head constructs a lightweight vocabulary subset at the window’s s tarting layer, reducing per-layer exit overhead by 87\% relative to full LM head . WAVE requires no gradient-based training and enables immediate deployment with only a brief calibration phase. Experiments on Llama-2 7B demonstrate up to 1.4 $\times$ average speedup while preserving output quality, with full compatibilit y with W4A16 quantization, establishing WAVE as a practical early-exit framework for accelerating LLMs inference without retraining.

Steer Where It Matters: Token-Level Visual-Sensitivity Steering for LVLMs Halluc ination Mitigation
Ruipeng Zhang, Zhihao Li, C.L.Philip Chen, Tong Zhang
Large vision language models (LVLMs) have made rapid advancements and are deploy ed across various applications, yet hallucinations remain a major challenge. Act ivation steering is appealing due to its minimal training overhead and controlla bility at inference time. However we found that during autoregressive decoding, visual conditioning affects token prediction sparsely and locally across decodin g steps, and many existing methods that average image-versus-no-image difference s over the entire sequence dilute these critical signals, yielding low signal-to -noise ratio steering directions. Additionally, many existing methods apply a fi xed steering strength, which misallocates the intervention budget, over-perturbs non-critical tokens, and can cause instability. To address these limitations, w e propose Token-Level Visual-Sensitivity Steering (TLVS) for hallucination mitig ation. Our approach first extract token-level steering vectors and refines them, and then applies fine-grained, visual-sensitivity–adaptive steering only where it matters. This lightweight, plug-and-play mechanism requires only minimal trai ning for calibration and can be applied across diverse vision-language models. I t modulates the steering strength at each decoding step, selectively suppressing hallucination-prone spans while preserving evidence-grounded content. We evalua te TLVS on several benchmarks, including POPE, AMBER, CHAIR (COCO), MMHal and Ha llusionBench, demonstrating consistent improvements over previous steering metho ds.

Efficient Stochastic Optimisation via Sequential Monte Carlo
James Cuin, Davide Carbone, Yanbo Tang, O. Deniz Akyildiz
The problem of optimising functions with intractable gradients frequently arises in machine learning and statistics, ranging from maximum marginal likelihood es timation procedures to fine-tuning of generative models. Stochastic approximatio n methods for this class of problems typically require inner sampling loops to o

btain (biased) stochastic gradient estimates, which rapidly becomes computationa lly expensive. In this work, we develop sequential Monte Carlo (SMC) samplers fo r optimisation of functions with intractable gradients. Our approach replaces ex pensive inner sampling methods with efficient SMC approximations, which can resu lt in significant computational gains. We establish convergence results for the basic recursions defined by our methodology which SMC samplers approximate. We d emonstrate the effectiveness of our approach on the reward-tuning of energy-base d models within various settings.

Learning Randomized Reductions
Ferhat Erata, Orr Paradise, Thanos Typaldos, Timos Antonopoulos, ThanhVu Nguyen, Shafi Goldwasser, Ruzica Piskac
Randomized self-reductions (RSRs) express $f(x)$ using f evaluated at random c orrelated points, enabling self-correcting programs, instance-hiding protocols, and applications in complexity theory and cryptography. Yet discovering RSRs has required manual expert derivation for over 40 years, limiting their practical u se.
We present Bitween for automated RSR learning. First, we formalize RSR learning with sample complexity analysis under correlated sampling. Second, we develop Va nilla Bitween, which integrates multiple backends (linear regression, genetic pr ogramming, symbolic regression, and mixed-integer programming). The linear regre ssion backend outperforms the others, discovering RSRs for 43 of 80 functions (5 4%) in RSR-Bench, our benchmark suite, including the first known reduction for s igmoid. Third, we introduce Agentic Bitween, a neuro-symbolic approach where LLM agents propose novel query functions beyond the fixed set ($x+r$, $x-r$, $x \cd ot r$, x, r) in prior work. Agentic Bitween discovers RSRs for 64 of 80 func tions (80%), outperforming pure neural baselines in both RSR discovery and verif ication accuracy.

This State Looks Like That: Self-Interpretable Reinforcement Learning Agents usi ng Prototype Soft Actor-Critic
Andrea Marzo, Alessio Ragno, Roberto Capobianco
Reinforcement learning (RL) has achieved remarkable success across complex decis ion-making tasks, especially with the advent of deep neural networks. However, t he resulting models are often opaque, making their deployment in safety-critical domains challenging. Explainable AI aims to address this issue, but most specif ic efforts for deep RL remain limited either to post-hoc explanation methods or to imitation learning and distillation procedures. These latter approaches rely on pre-trained black-box agents and are typically restricted to environments wit h discrete action spaces, limiting their scalability and interpretability. In th is paper, we introduce ProtoSAC, a novel deep RL architecture that integrates a prototype-based actor into the Soft Actor-Critic (SAC) algorithm, enabling intri nsic interpretability in continuous action spaces. Our method learns a set of pr ototypes that represent interpretable state clusters, each associated with a Gau ssian action distribution. Actions are generated as a similarity-weighted mixtur e over these prototypes, providing more inspectable and decomposable decision-ma king without sacrificing performance compared to standard SAC. We evaluate Proto SAC on continuous control environments and show that it matches the performance of the original SAC while offering enhanced interpretability.

Safe Autoregressive Image Generation with Iterative Self-Improving Codebooks
Yunqi Xue, Zhijiang Li, Philip Torr, Jindong Gu
Unlike diffusion-based models that operate in continuous latent spaces, autoregr essive unified multimodal models produce images by sequentially predicting discr etized visual tokens. These tokens are derived from a codebook that maps embeddi ngs to quantized visual patterns. The language-like architecture enables unified multimodal models to effectively capture text conditional information for gener ation, making them promising for text-to-image tasks. This also raises an intere sting question: *how safe are the images generated in such an autoregressive way ?* In this work, we propose iterative self-improving codebooks for safe autoregr

essive generation. We leverage the understanding and judgment capabilities of th
e unified multimodal model itself to identify unsafe generated images without hu
man annotation. Subsequently, the inherent representations in the codebook are f
ixed to eliminate harmful mappings. Our method comprises two steps: first, we us
e the unified model to identify unsafe generations and construct corresponding h
armful and safe image-text pairs. These pairs are used to construct the Harmful
Space and guide updates to the codebook, thereby eliminating harmful outputs. Se
cond, we perform adaptive fine-tuning on the codebook within the harmless space
using safe image-text pairs to ensure the quality of generated images. These two
 steps are repeated until no further improvement is observed, producing a safety
-enhanced model codebook. Without additional external feedback, the safety of mo
dels is improved iteratively.

Why Agentic Theorem Prover Works: A Statistical Provability Theory of Mathematic
al Reasoning Models

Sho Sonoda, Shunta Akiyama, Yuya Uezato

Agentic theorem provers combine a reasoning model, retrieval, search, and a proo
f assistant verifier, yet it remains unclear which components actually improve f
inite-budget proof success and why they help on real mathematical workloads. We
study this question through **statistical provability**: the probability of reac
hing a verified proof within a budget on a specified stream of theorem instances
. We model formal proof search as a finite-horizon reachability MDP with determi
nistic verifier dynamics, and show that under a faithful state abstraction the o
ptimal success probability coincides with ordinary syntactic provability. We the
n analyze a simple but practically important pipeline: depth-wise offline action
-value regression followed by greedy test-time proving. Our main theorem bounds
the provability gap between the learned prover and the optimal prover by an occu
pancy-weighted sum of uniform action-value errors; in the common uniform-error r
eading, the leading complexity multiplier is the learned prover's average trunca
ted proof length. The error decomposes into approximation error, geometric cover
age of the training distribution, and Monte Carlo label noise, and improves to a
 fast rate under an action-gap margin condition. The result gives a component-se
nsitive account of why verifier feedback, retrieval, representation geometry, an
d proof-shortening mechanisms help on biased theorem workloads, without contradi
cting classical worst-case hardness.

GaussTrace: Provenance Analysis of 3D Gaussian Splatting Models with Evidence-ba
sed LLM Reasoning

Haoliang Han, Ziyuan Luo, Renjie Wan

3D Gaussian Splatting (3DGS) is a powerful technique for creating high-fidelity
3D assets. However, the widespread sharing and iterative modification of 3DGS mo
dels across digital platforms create pressing challenges for intellectual proper
ty protection and forensic traceability. To address this, we propose GaussTrace,
 a novel framework for constructing directed provenance graphs for 3DGS models.
GaussTrace formulates provenance analysis as an evidence-based reasoning problem
. It builds upon attribute-wise statistical profiling of 3DGS parameters to capt
ure intrinsic properties. Moreover, we introduce hypothesis-driven editing simul
ations of common operations to provide auxiliary evidence for plausible transfor
mation pathways. These statistical and simulated cues jointly enable a Large Lan
guage Model (LLM) to perform structured Chain-of-Thought (CoT) reasoning, yieldi
ng directional provenance inferences and explainable edge reasons. Experimental
results demonstrate that GaussTrace effectively constructs evolutionary relation
ships among diverse 3DGS models, delivering accurate, interpretable, and robust
provenance graphs without requiring model training or access to editing historie
s. Project page: https://haolianghan.github.io/GaussTrace.

Corrected Samplers for Discrete Flow Models

Zhengyan Wan, Yidong Ouyang, Liyan Xie, Hongyuan Zha, Fang Fang, Guang Cheng

Discrete flow models (DFMs) have been proposed to learn the data distribution on
 finite state space, offering a flexible framework as an alternative to discrete

diffusion models. A line of recent work has studied samplers for discrete diffu
sion models, such as tau-leaping and Euler solver. However, these samplers requi
re a large number of iterations to control discretization error, since the trans
ition rates are frozen in time and evaluated at the initial state within each ti
me interval. Moreover, theoretical results for these samplers often require bou
ndedness conditions of the transition rate or they focus on a specific type of s
ource distributions. To address those limitations, we establish non-asymptotic d
iscretization error bounds for those samplers without any restriction on transit
ion rates and source distributions, under the framework of discrete flow models.
 Furthermore, by analyzing a one-step lower bound of the Euler sampler, we propo
se two corrected samplers: \textit{time-corrected sampler} and \textit{location-
corrected sampler}, which can reduce the discretization error of tau-leaping and
 Euler solver with almost no additional computational cost. We rigorously show t
hat the location-corrected sampler has a lower complexity than existing parallel
 samplers. We validate the effectiveness of the proposed method by achieving bet
ter generation quality with reduced inference time on simulations and text-to-im
age generation tasks. Code can be found in \url{https://github.com/WanZhengyan/C
orrected-Samplers-for-Discrete-Flow-Models}.

Ski Rental with Distributional Predictions of Unknown Quality
Qiming Cui, Michael Dinitz
We revisit the central online problem of *ski rental* in the "algorithms with pr
edictions" framework from the point of view of *distributional* predictions. If
 we are given as a prediction a *distribution* $\hat p$ over the ski days, and t
he true number of ski days comes from some (unknown) distribution p, then we s
how as our main result that there is an algorithm with expected cost at most $OP
T + O\left(\min \left(\max(\eta,1) \cdot \sqrt{b},\ b \log b \right) \right)$,
where OPT is the expected cost of the optimal policy for the true distribution
 p, b is the cost of buying, and η is the Earth Mover's (Wasserstein-1)
 distance between p and $\hat p$. An implication of this bound is that our al
gorithm has *consistency* $O(\sqrt{b})$ (additive loss when the prediction error
 is 0) and *robustness* $O(b \log b)$ (additive loss when the prediction error
 is arbitrarily large). Moreover, we do not need to assume that we know (or hav
e any bound on) the prediction error η, in contrast with previous work in r
obust optimization which assumes that we know this error. We also complement thi
s upper bound with a variety of lower bounds showing that it is essentially tigh
t: not only can the consistency/robustness tradeoff not be improved, but our par
ticular loss function cannot be meaningfully improved.

Efficient Parallel Samplers for Recurrent-Depth Models and Their Connection to D
iffusion Language Models
Jonas Geiping, Xinyu Yang, Guinan Su
Language models with recurrent depth, also referred to as universal or looped wh
en considering transformers, are defined by the capacity to increase their compu
tation through the repetition of layers. Recent efforts in pretraining have demo
nstrated that these architectures can scale to modern language modeling tasks wh
ile exhibiting advantages in reasoning tasks.
  In this work, we examine the relationship between recurrent-depth models and d
iffusion language models. Building on their similarities, we develop a new diffu
sion forcing sampler for these models to accelerate generation. The sampler adva
nces by decoding new tokens at every forward pass of the model, while the latent
 states of these tokens can be further refined in parallel through recurrence. T
heoretically, under a fixed wall-clock budget, generation with our sampler is st
rictly more expressive than baseline autoregressive generation as it preserves t
he same recurrent depth while updating a strictly wider front of token positions
 in parallel, enabling more computation at equal serial depth.
  Moreover, this sampler, based on principles from diffusion literature, can be
directly applied to existing 3.5B recurrent-depth transformers without any tunin
g, leading to up to a 5x speedup.

Breaking the Scale Barrier: One-Shot Knowledge Transfer via Frequency Transform
Jianlu Shen, Fu Feng, Yucheng Xie, Jiaqi Lv, Xin Geng
Transferring knowledge by fine-tuning large-scale pre-trained networks has becom e a standard paradigm for downstream tasks, yet the knowledge of a pre-trained m odel is tightly coupled with monolithic architecture, which restricts flexible r euse across models of varying scales.
In response to this challenge, recent approaches typically resort to either para meter selection, which fails to capture the interdependent structure of this kno wledge, or parameter prediction using generative models that depend on impractic al access to large network collections.
In this paper, we identify the low-frequency components of model weights as the concrete carrier of foundational, task-agnostic knowledge—its "learngene"—and va lidate this by demonstrating its efficient inheritance by downstream models and tasks.
Based on this insight, we propose FRONT (FRequency dOmain kNowledge Transfer), a novel framework that uses the Discrete Cosine Transform (DCT) to isolate the lo w-frequency "learngene".
This learngene can be seamlessly adapted to initialize models of arbitrary size via simple truncation or padding, a process that is entirely training-free.
For enhanced performance, we propose an optional low-cost refinement process tha t introduces a spectral regularizer to further improve the learngene's transfera bility.
Extensive experiments demonstrate that FRONT achieves the state-of-the-art perfo rmance, accelerates convergence by up to $15\times$ in vision tasks, and reduces training FLOPs by an average of 40.5\% in language tasks. Code is available at https://github.com/LUcy0505/FRONT.

BOCLOAK: Optimal Transport-Guided Adversarial Attacks on Graph Neural Network-Ba sed Bot Detection
Kunal Mukherjee, Zulfikar Alom, Tran Gia Bao Ngo, Cuneyt Gurcan Akcora, Murat Ka ntarcioglu
The rise of bot accounts on social media poses significant risks to public disco urse. To address this threat, modern bot detectors increasingly rely on Graph Ne ural Networks (GNNs). However, the effectiveness of these GNN-based detectors in real-world settings remains poorly understood. In practice, attackers continuou sly adapt their strategies and must operate under domain-specific
and temporal constraints, which can fundamentally limit the applicability of exi sting attack methods. As a result, there is a critical need for robust GNN-based bot detection methods under realistic, constraint-aware attack scenarios. We in troduce BOCLOAK to systematically evaluate the robustness of GNN-based bot detec tion via both edge editing and node injection adversarial attacks under realisti c constraints. BOCLOAK constructs a probability measure over spatio-temporal nei ghbor features and learns an optimal transport (OT)
geometry that separates human and bot behaviors. It then decodes transport plans into sparse, plausible edge edits that evade detection while obeying real-world constraints. We evaluate BOCLOAK across three social bot datasets, five state-o f-the-art bot detectors, three adversarial defenses, and compare it against four leading graph adversarial attack baselines. BOCLOAK achieves up to 80.13% highe r attack success rates while using 99.80% less GPU memory under real-world const raints. BOCLOAK shows that OT provides a lightweight, principled framework for b ridging adversarial attacks and real-world bot detection.

PGD-NO: A Neural Operator with Precomputed Geometry Decomposition for 3D Million -Scale Physics Simulations
Weiheng Zhong, Jing Bi, Victor Oancea, Hadi Meidani
While neural PDE solvers have demonstrated significant potential for acceleratin g engineering simulations, existing architectures remain constrained by high mem ory consumption and the "single-node bottleneck," where the maximum processable mesh resolution is strictly limited by the VRAM of a single compute unit. To add ress these challenges, we propose PGD-NO, a neural operator with Precomputed Geo

metry Decomposition, that relocates the computational overhead of geometric enco ding to a deterministic pre-computation phase. By utilizing an iterative geometr y decomposition algorithm to extract "geometry tokens," our model decouples feat ure extraction from solution querying. This architecture enables linear memory s calability, allowing high-fidelity learning on meshes exceeding 10 million nodes —a scale where existing architectures typically encounter memory exhaustion. PGD -NO demonstrates competitive predictive accuracy across diverse industrial bench marks and provides intrinsic interpretability through attention mechanisms. By e ffectively overcoming traditional mesh-size constraints, PGD-NO offers a robust and efficient solution for the next generation of large-scale, high-fidelity ind ustrial design applications.

Watermarking LLM Agent Trajectories

Wenlong Meng, Chen GONG, Terry Yue Zhuo, Fan Zhang, Kecen Li, Zheng Liu, Zhou Ya ng, Chengkun Wei, Wenzhi CHEN

LLM agents rely heavily on high-quality trajectory data to guide their problem-s olving behaviors, yet producing such data requires substantial task design, high -capacity model generation, and manual filtering. Despite the high cost of creat ing these datasets, existing literature has overlooked copyright protection for LLM agent trajectories. This gap leaves creators vulnerable to data theft and ma kes it difficult to trace misuse or enforce ownership rights. This paper introdu ces ActHook, the first watermarking method tailored for agent trajectory dataset s. Inspired by hook mechanisms in software engineering, ActHook embeds *hook act ions* that are activated by a secret input key and do not alter the original tas k outcome. Like software execution, LLM agents operate sequentially, allowing ho ok actions to be inserted at decision points without disrupting task flow. When the activation key is present, an LLM agent trained on watermarked trajectories can produce these hook actions at a significantly higher rate, enabling reliable black-box detection. Experiments on mathematical reasoning, web searching, and software engineering agents show that ActHook achieves an average detection AUC of 94.3 on Qwen-2.5-Coder-7B while incurring negligible performance degradation.

Hidden in Plain Tokens: Simply Robust, Gradient-Free Watermark for Synthetic Aud io

Georgios Milis, Yubin Qin, Yihan Wu, Heng Huang

As policy catches up with the capabilities of generative AI, watermarking is cen tral to content provenance efforts. Inference-time watermarks for autoregressive models are unfit for continuous modalities due to discretization inconsistencie s. Existing methods overcome this by finetuning the modality tokenizers, nullify ing the watermark's training-free advantage. In this work, motivated by the voca bulary redundancy of discretization, we propose an elegant solution for powerful and robust watermarking of synthetic audio. We theoretically analyze the impact of token errors on watermark detection, and effectively mitigate them using a r educed vocabulary obtained via community detection. Thorough experiments showcas e that our gradient-free method can boost detectability by several orders of mag nitude, while also achieving built-in robustness to audio modifications. Broadly , we discover a new state-of-the-art for token-level watermarks in multimedia, w hich simply arises from the nature of discrete representation learning.

MoDA: Modulation Adapter for Fine-Grained Visual Understanding in Instructional MLLMs

Wayner Barrios, Andrés Villa, Juan C Leon Alcazar, SouYoung Jin, Bernard Ghanem

Multimodal Large Language Models (MLLMs) have achieved remarkable success in ins truction-following tasks by integrating pretrained visual encoders with large la nguage models (LLMs). However, existing approaches often struggle with fine-grai ned visual grounding due to semantic entanglement in visual patch representation s, where individual patches blend multiple distinct visual elements, making it d ifficult for models to focus on instruction-relevant details. To address this ch allenge, we propose MoDA (Modulation Adapter), a lightweight module that enhance s visual grounding through instruction-guided channel-wise modulation. Unlike to

ken-level methods such as Q-Former that perform additive feature selection, MoDA operates at the channel level through multiplicative modulation on already-aligned features, enabling fine-grained control over which embedding dimensions are relevant for each instruction. Following the standard LLaVA training protocol, MoDA applies cross-attention between language instructions and pre-aligned visual features, generating dynamic modulation masks without architectural modifications or additional supervision. We evaluate MoDA across 12 benchmarks spanning visual question answering, vision-centric reasoning, and hallucination detection, including recent 2024 benchmarks (MMVP, CV-Bench, MMStar, RealWorldQA), on three distinct MLLM architectures: LLaVA-1.5, LLaVA-MoRE (2025), and Qwen3-VL (2025). MoDA delivers consistent gains across all three families, with +12.0 points on MMVP for the LLaVA-1.5 family and +4.8 points on ScienceQA for the LLaVA-MoRE family, and +4.9 ScienceQA, +4.1 RealWorldQA, and +3.8 GQA on Qwen3-VL, confirming that the gains generalize beyond CLIP-based encoders with minimal overhead (<1% FLOPs). Code is available at https://github.com/waybarrios/MoDA.

Hi-Time: Hierarchical Latent Prediction for Multivariate Time Series Classification
Kun Zeng, Binquan Wu, Qianli Ma
Integrating Large Language Models (LLMs) into time series tasks has yielded impressive performance. While some works aim to enhance accuracy by explicitly designing step-by-step reasoning into prompts, such explicit Chain-of-Thought (CoT) approaches are difficult to generalize to time series. This is because it is difficult to clearly define the reasoning trajectories of time series. In addition, the high heterogeneity across time series often requires specialized prompt designs, limiting the model's scalability. To address these challenges, we propose **Hi-Time**, a **hi**erarchical latent prediction framework based on temporal semantic codes for multivariate **time** series classification. This framework automatically constructs scenario-specific coarse-to-fine prediction trajectories based on the characteristics of time series, thereby providing structured supervision for the LLM. Specifically, Hi-Time first performs temporal representation pre-training with a multi-view temporal representation fusion to acquire high-quality temporal embeddings. We then discretize these temporal embeddings into hierarchical temporal semantic codes that form the coarse-to-fine prediction trajectory. Finally, the LLM predicts temporal semantic codes in a stepwise manner and then infers the final label, thereby establishing a coarse-to-fine decision process. Experiments on ten public multivariate time series datasets demonstrate that Hi-Time effectively adapts to diverse datasets and outperforms state-of-the-art methods. Our code is available at <https://github.com/qianlima-lab/Hi-Time>.

Reasoning LLM Improves Speaker Recognition in Long-form TV Dramas
Yuxuan Li, Lingxi Xie, Xinyue Huo, Jihao Qiu, Jiacheng Shao, Pengfei Chen, Jiannan Ge, Kaiwen Duan, Qi Tian
Long-form TV dramas present a formidable challenge for comprehensive video understanding, where deciphering complex storyline often relies on **speaker recognition**, the task of accurately attributing each spoken utterance to its respective character. In this paper, we advance this field through two primary contributions. (1) We introduce **DramaSR-532K**, a large-scale benchmark comprising 532K annotated dialogue lines across more than 900 unique characters, necessitating the integration of auditory, linguistic, and visual cues for speaker recognition. (2) We propose **DramaSR-LRM**, a robust approach built upon a large reasoning model (LRM). DramaSR-LRM is designed to autonomously aggregate contextual evidence via multimodal tool-use, synthesizing diverse inputs to achieve high-fidelity attribution. Experimental results demonstrate that DramaSR-LRM significantly outperforms existing baselines, particularly on short utterances where acoustic biometrics are inherently unreliable. *All the data and code will be made publicly available.*
****
Gram2Token: Enabling Run-time GPU-Native Grammar-Constrained Decoding for LLMs
Hantao Hua, Jiming Su, Hao Tang, Yiping Yao, Feng Zhu

Grammar-constrained decoding enables large language models (LLMs) to reliably ge
nerate structured outputs such as JSON, SQL, and domain-specific programs. Exist
ing systems often enforce constraints by executing byte-level parser logic insid
e the token-level decoding loop, introducing CPU-side control flow and CPU--GPU
synchronization that become bottlenecks under continuous batching. We propose Gr
am2Token, a GPU-native framework that preprocesses deterministic byte-level gram
mar execution into token-level transitions before inference. Gram2Token aligns t
okenizer byte sequences with grammar transitions through a trie and groups token
s with identical transition outcomes across preprocessed grammar states. These c
ategories yield compact validity masks and transition tables, reducing run-time
enforcement to category lookup, masking, and state update rather than parser-sty
le byte traversal. Across four model families under schema-diverse continuous ba
tching, Gram2Token achieves a geometric-mean throughput improvement of 1.38$\tim
es$ over the strongest baseline, with a maximum speedup of 1.85$\times$, at the
cost of additional preprocessing and time-to-first-token overhead. Break-even an
d grammar-complexity analyses show that this overhead is amortized by grammar re
use, longer outputs, and larger batches. These results show that token-level gra
mmar preprocessing is an effective design point for high-throughput structured L
LM serving. Code is available at https://github.com/Paradozile/Gram2Token.

TimeMRA: LLM-Empowered Time Series Forecasting via Multi-Scale Retrieval-Augment
ed Representations
Zongjiang Shang, Chengxi Jin, Binqing Wu, Dongliang Cui, Yue Yu, Haobang Sun, Ch
uanlin Xu, Ling Chen
Time series forecasting plays a pivotal role in data-driven decision-making acro
ss various time series domains. Recently, leveraging their ability to extract se
mantically rich representations, Large Language Models (LLMs) have achieved prom
ising results in time series forecasting. However, existing LLM-based methods st
ruggle to obtain multi-scale retrieval-augmented representations due to entangle
d multi-scale representations and redundant multi-scale interference. To address
 this, we propose TimeMRA, an LLM-empowered Time series forecasting framework vi
a Multi-Scale Retrieval-Augmented representations. Specifically, a scale-aware p
rompt generation (SAPG) module is designed to decompose time series into multipl
e scales and generate augmented multi-scale representations. Then, a cross-scale
 disentanglement constraint (CSDC) mechanism with a router network is designed t
o obtain the disentangled multi-scale semantic representations while mitigating
interference from irrelevant scales. Finally, a cross-modality retrieval module
is designed to obtain multi-scale retrieval-augmented representations for time s
eries forecasting. Experiments on 10 real-world datasets demonstrate that TimeMR
A achieves state-of-the-art (SOTA) performance.

Inference of Online Newton Methods with Nesterov's Accelerated Sketching
Haoxuan Wang, Xinchen Du, Sen Na
Reliable decision-making with streaming data requires principled uncertainty qua
ntification of online methods. While first-order methods enable efficient iterat
e updates, their inference procedures still require updating proper (covariance)
 matrices, incurring $O(d^2)$ time and memory complexity, and are sensitive to i
ll-conditioning and noise heterogeneity of the problem. This costly inference ta
sk offers an opportunity for more robust second-order methods, which are, howeve
r, bottlenecked by solving Newton systems with $O(d^3)$ complexity. In this pape
r, we address this gap by studying an online Newton method with Hessian averagin
g, where the Newton direction at each step is approximately computed using a *sk
etch-and-project solver with Nesterov's acceleration*, matching $O(d^2)$ complex
ity of first-order methods. For the proposed method, we quantify its uncertainty
 arising from both random data and randomized computation. Under standard smooth
ness and moment conditions, we establish global almost-sure convergence, prove a
symptotic normality of the last iterate with a limiting covariance characterized
 by a Lyapunov equation, and develop a fully online covariance estimator with no
n-asymptotic convergence guarantees. We also connect the resulting uncertainty q
uantification to that of exact and sketched Newton methods without Nesterov's ac

celeration. Extensive experiments on regression models demonstrate the superiority of the proposed method for online inference.

CRPO: Character-centric Group Relative Policy Optimization for Role-aware Reasoning in Role-playing Agents
Yihong Tang, Kehai Chen, Liang Yue, Benyou Wang, Min Zhang
Recent advancements in Reinforcement Learning (RL), particularly Group Relative Policy Optimization (GRPO), have significantly enhanced the reasoning capabilities of Large Language Models. However, applying these problem-centric optimization methods to role-playing agents often leads to a loss of character fidelity and style collapse, as they prioritize context-specific utility over persona alignment. To address this, we propose Character-Centric Group Relative Policy Optimization (CRPO), a framework designed to realign RL objectives with the role-playing task. CRPO improves character distinctiveness through three mechanisms: decoupling task logic from stylistic rewards to resolve gradient conflicts, dynamically adapting optimization constraints based on character complexity, and utilizing generic responses as negative baselines to prevent the model from reverting to a common distribution. Extensive experiments demonstrate that CRPO outperforms existing methods in consistency, emotion and others.
****

FRACTAL: State Space Model with Fractional Recurrent Architecture for Computational Temporal Analysis of Long Sequences
Mengqi Li, Wensheng Lin, Jinshuai Yang, Lixin Li
Effective sequence modeling fundamentally requires balancing the retention of unbounded history with the high-resolution detection of abrupt short-term variations common in real-world phenomena. However, existing state space models (SSMs) relying on high-order polynomial projection operators (HiPPO) face a critical trade-off where uniform measures dilute recent information to maintain timescale invariance, while exponential measures sacrifice global context to capture local dynamics. This paper proposes a Fractional Recurrent Architecture for Computational Temporal Analysis of Long sequences (FRACTAL), a novel architecture integrating fractional measure theory into recursive memory updates to address this limitation. By deriving projection operators with analytically characterized spectral properties and a tunable singularity index, the proposed method amplifies sensitivity to recent signal perturbations while preserving the spectral structure that encodes scale-invariant memory dynamics. This theoretical innovation is instantiated within a simplified diagonalized state space framework by modulating input projection initialization to enable simultaneous capture of multi-scale temporal features. FRACTAL achieves an average score of 87.11\% on the Long Range Arena benchmark, including 61.85\% on the ListOps task, outperforming the S5 model.
****

Contrastive Symbolic Regression: Aligned Representations, Adaptive Prediction, and Diverse Ensembles
Hengzhe Zhang, Qi Chen, Bing Xue, Wolfgang Banzhaf, Mengjie Zhang
Existing symbolic regression approaches primarily focus on learning explicit input-output mappings, often neglecting relational structures among data instances. This paper introduces Contrastive Symbolic Regression (CSR), a feature-construction-based symbolic regression approach that integrates evolutionary feature construction with contrastive learning to shape a representation space where geometric proximity reflects similarity in the target space. CSR employs a contrastive objective that optimizes a linear transformation of constructed features, with a closed-form solution for aligning the feature space with the target space. The constructed features are applied to K-nearest neighbor regression, where we propose an efficient leave-one-out cross-validation (LOOCV) method that addresses standard LOOCV's computational expense and adaptively selects the neighborhood size, along with a linear-rank weighted K-nearest neighbor variant for faithful assessment of representation quality during evolution. A determinantal point process-based ensemble selection mechanism further enhances robustness by jointly considering model quality and diversity. Extensive experiments on 58 real-world reg

ression datasets demonstrate that CSR consistently surpasses both traditional sy
mbolic regression and modern machine learning counterparts, highlighting CSR as
a promising direction for interpretable and effective regression modeling.

Advancing LLM Reasoning with Natural Language and Numerical Feedback
Xiaoying Zhang, Yipeng Zhang, Hao Sun, Kaituo Feng, Chaochao Lu, Chao Yang, Hele
n M. Meng
Recent advances in reinforcement learning (RL) using numerical rewards have sign
ificantly enhanced the complex reasoning capabilities of large language models (
LLMs). However, we identify three fundamental limitations of purely numerical fe
edback: performance plateaus, ineffective spontaneous self-reflection, and persi
stent failures. We show that plateaued RL models can successfully refine failed
solutions when given natural language critiques. Motivated by this, we propose C
ritique-GRPO, an online RL framework that integrates both natural language and n
umerical feedback for policy optimization. This approach enables LLMs to learn s
imultaneously from initial responses and critique-guided refinements, effectivel
y internalizing the exploration benefits of both stages. Extensive experiments s
how that Critique-GRPO outperforms all compared supervised and RL-based fine-tun
ing methods, achieving average Pass@1 improvements of approximately +15.0-21.6%
on various Qwen models and +7.3% on Llama-3.2-3B-Instruct across eight challengi
ng reasoning tasks. Notably, Critique-GRPO facilitates effective self-improvemen
t through self-critiquing, achieving substantial gains over GRPO, e.g., a +16.7%
 Pass@1 improvement on AIME 2024. The code and models are released at: https://g
ithub.com/zhangxy-2019/critique-GRPO

Scalable and Stable Estimation of Amari α-Divergence using Random Fourier
 Features
Jiaolong Wang, Fode Zhang, Lingrui Wang
Reliable estimation of Amari α-divergences underpins variational inferenc
e, yet unconstrained neural critics are notoriously prone to instability. We pro
pose a scalable estimator by constraining the critic to a Reproducing Kernel Hil
bert Space (RKHS) ball and approximating the kernel via band-limited Random Four
ier Features (RFF). This formulation yields a linear-time objective amenable to
mini-batch stochastic optimization while avoiding the cubic complexity of Gram-m
atrix methods. We present a unified analysis based on a four-term error decompos
ition—comprising RKHS approximation, feature discretization, statistical deviati
on, and optimization residual.
Under a spectral source condition, we derive non-asymptotic bounds establishing
that the RKHS approximation bias scales as $\mathcal{O}(R^{-\gamma})$, the RFF d
iscretization error as $\mathcal{O}(R D^{-1/2})$, and the statistical error as $
\mathcal{O}(R n^{-1/2})$.
We further show that statistical non-degeneracy induces intrinsic local curvatur
e, enabling our proposed Armijo-SGD to achieve local linear convergence. Empiric
al evaluations demonstrate that the RFF-RKHS estimator outperforms varying-repre
sentation baselines in stability, and applying this spectral regularization to G
AN critics significantly enhances the capture of high-frequency data components.

DiScoFormer: Plug-In Density and Score Estimation with Transformers
Vasily Ilin, Peter Sushko, Ranjay Krishna
Estimating probability density and its score from samples remains a core problem
 in generative modeling, Bayesian inference, and kinetic theory. Existing method
s are bifurcated: classical kernel density estimators (KDE) generalize across di
stributions but suffer from the curse of dimensionality, while modern neural sco
re models achieve high precision but require retraining for every target distrib
ution. We introduce DiScoFormer (Density and Score Transformer), a ``train-once,
 infer-anywhere" equivariant Transformer that maps i.i.d. samples to both densit
y values and score vectors, generalizing across distributions and sample sizes.
Analytically, we prove that self-attention can recover normalized KDE, establish
ing it as a functional generalization of kernel methods; empirically, individual
 attention heads learn multi-scale, kernel-like behaviors. The model converges f

aster and achieves higher precision than KDE for density estimation, and provide s a high-fidelity plug-in score oracle for score-debiased KDE, Fisher informatio n computation, and Fokker-Planck-type PDEs.

Dimension-Independent Convergence of Underdamped Langevin Monte Carlo in KL Dive rgence
Shiyuan Zhang, Qiwei Di, Xuheng Li, Quanquan Gu
Underdamped Langevin dynamics (ULD) is a widely-used sampler for Gibbs distribut ions $\pi\propto e^{-V}$, and is often empirically effective in high dimensions. However, existing non-asymptotic convergence guarantees for discretized ULD typ ically scale polynomially with the ambient dimension d, leading to vacuous bou nds when d is large. The main known dimension-free result concerns the randomi zed midpoint discretization in Wasserstein-2 distance (Liu et al., 2023), while dimension-independent guarantees for ULD discretizations in KL divergence have r emained open. We close this gap by proving the first dimension-free KL divergenc e bounds for discretized ULD. Our analysis refines the KL local error framework (Altschuler et al., 2025) to a dimension-free setting and yields bounds that dep end on $\mathrm{tr}(\mathbf{H})$, where $\mathbf{H}$ upper bounds the Hessian of V, rather than on d. As a consequence, we obtain improved iteration complex ity for underdamped Langevin Monte Carlo relative to overdamped Langevin methods in regimes where $\mathrm{tr}(\mathbf{H})\ll d$.

Terminal Dimension Reduction for Time Series with Applications
Alexander Munteanu, Matteo Russo, David Saulpic, Chris Schwiegelshohn
Terminal embeddings have emerged as a powerful tool for dimension reduction. Giv en a set of points $P\subset \mathbb{R}^d$, a terminal embedding is a mapping $f :\mathbb{R}^d\rightarrow \mathbb{R}^t$ that preserves the pairwise distance betw een any pair of points $p\in P$ and $q\in \mathbb{R}^d$ up to small distortion u nder this mapping. Terminal embeddings have been particularly fruitful for const ructing k-means and k-median coresets, where the objective is to find a typi cally weighted subset Ω of P such that for any candidate solution, the cost of the clustering objective on Ω approximates the cost of the cluste ring objective on P up to small distortion. Unfortunately, these techniques ha ve not been extended to more complicated structures such as clustering time-seri es data under common straight-line interpolation between measurements. The main issue is that terminal embeddings, arguably the central technique in this line o f research, cannot be linear and are thus not immediately suitable to preserve l inear structures. In this work, we develop a generalization of terminal embeddin gs to affine line-segments that overcomes this issue. We showcase their applicab ility by using our lines-preserving terminal embeddings to obtain the first dime nsion-free coresets for clustering time-series under the Fréchet distance. The u nderlying dimension reduction uses Johnson-Lindenstrauss embeddings, and our exp eriments indicate that they compare favorably against PCA for real-world time-se ries.

Lions and Muons: Optimization via Stochastic Frank-Wolfe under Heavy-Tailed Nois es
Maria-Eleni Sfyraki, Jun-Kun Wang
Stochastic Frank-Wolfe is a classical optimization method for solving constraine d optimization problems. On the other hand, recent optimizers such as Lion and M uon have gained quite significant popularity in deep learning. In this work, bui lding on recent initiatives, we provide a unifying perspective by interpreting t hese seemingly disparate methods through the lens of Stochastic Frank-Wolfe. Spe cifically, we show that Lion and Muon with weight decay can be viewed as special instances of a Stochastic Frank-Wolfe, and we establish their convergence guara ntees in terms of the Frank-Wolfe gap, a standard stationarity measure in non-co nvex optimization for Frank-Wolfe methods. We further find that convergence to t his gap implies convergence to a KKT point of the original problem under a norm constraint for Lion and Muon. Moreover, motivated by recent empirical findings t hat stochastic gradients in modern machine learning tasks often exhibit heavy-ta

iled distributions, we extend Stochastic Frank-Wolfe to settings with heavy-tail ed noise by developing two robust variants with strong theoretical guarantees th at hold for general compact convex sets without the need for a large batch size, filling the gap in the literature on Stochastic Frank-Wolfe for non-convex opti mization. Our contributions in the later part of this work, in turn, yield new v ariants of Lion and Muon, that better accommodate heavy-tailed gradient noise, t hereby enhancing their practical scope.

Convergence Rate Analysis of the AdamW-Style Shampoo: Unifying One-Sided and Two -Sided Preconditioning
Huan Li, Yiming Dong, Zhouchen Lin
This paper studies the AdamW-style Shampoo optimizer, an effective implementatio n of the classical Shampoo that notably won the external tuning track of the Alg oPerf neural network training algorithm competition. Our analysis unifies one-si ded and two-sided preconditioning and establishes the convergence rate $\frac{1} {K}\sum_{k=1}^KE[|||\nabla f(X_k)|||]\leq O(\frac{\sqrt{m+n}C}{K^{1/4}})$ measur ed by nuclear norm (denoted as $|||\cdot|||$ to display correctly in OpenReview) , where K represents the iteration number, (m,n) denotes the size of matrix parameters, and C matches the constant in the optimal convergence rate of SGD. Theoretically, we have $||\nabla f(X)||\leq|||\nabla f(X)|||\leq\sqrt{\min(m,n) }||\nabla f(X)||$ (denote $||\cdot||$ as the Frobenius norm to display correctly in OpenReview), supporting that our convergence rate can be considered to be an alogous to the optimal $\frac{1}{K}\sum_{k=1}^K E[||\nabla f(X_k)||]\leq O(\frac {C}{K^{1/4}})$ convergence rate of SGD in the ideal case of $|||\nabla f(X)|||= \Theta(\sqrt{\min(m,n)})||\nabla f(X)||$ and balanced m and n.

dLLM-Cache: Accelerating Diffusion Large Language Models with Adaptive Caching
Zhiyuan Liu, Yicun Yang, Yaojie Zhang, Junjie Chen, Chang Zou, Qingyan Wei, Shao bo Wang, Yichen Zhu, Linfeng Zhang
Autoregressive Models (ARMs) have long dominated the landscape of Large Language Models. Recently, a new paradigm has emerged in the form of diffusion-based Lar ge Language Models (dLLMs), which generate text by iteratively denoising masked segments. This approach has shown significant advantages and potential. However, dLLMs suffer from high inference latency. Traditional ARM acceleration techniqu es, such as Key-Value caching, are incompatible with dLLMs due to their bidirect ional attention mechanism. To address this specific challenge, our work begins w ith a key observation that dLLM inference involves a static prompt and a partial ly dynamic response, where most tokens remain stable across adjacent denoising s teps. Based on this, we propose dLLM-Cache, a training-free adaptive caching fra mework that combines long-interval prompt caching with partial response updates guided by feature similarity. This design enables efficient reuse of intermediat e computations without compromising model performance. Extensive experiments on representative dLLMs, including LLaDA 8B and Dream 7B, show that dLLM-Cache achi eves up to *9.1*$\times$ FLOPs reduction on LongBench-HotpotQA while maintaining competitive output quality. Notably, our method brings dLLM inference latency c lose to that of ARMs under many settings. *The code for this work is publicly av ailable at: https://github.com/maomaocun/dLLM-cache*.

No Data? No Problem: Robust Vision-Tabular Learning with Missing Values
Marta Hasny, Laura Alexandra Daza, Keno Bressem, Maxime Di Folco, Julia Schnabel
Large-scale medical biobanks provide imaging data complemented by extensive tabu lar information, such as clinical measurements or demographics. However, this ab undance of tabular attributes does not reflect real-world datasets, where only a subset of attributes may be available. This discrepancy calls for methods that remain robust to missing values at inference. To address this challenge, we prop ose RoVTL (Robust Vision-Tabular Learning), a framework designed to handle any l evel of tabular data availability, from 0% to 100%. RoVTL comprises two key stag es: contrastive pretraining, where we introduce tabular attribute missingness as data augmentation to promote robustness, and downstream task tuning, where tabu lar missingness is complemented by a novel Tabular More vs. Fewer loss that rank

s performance based on the amount of available tabular data. Combined with gated
-cross attention fusion module,
our tuning approach enables consistent performance across all tabular data compl
eteness scenarios. We evaluate RoVTL on cardiac MRI scans from the UK Biobank, d
emonstrating superior robustness to missing tabular data compared to prior metho
ds. Furthermore, RoVTL successfully generalizes to an external cardiac MRI datas
et for multimodal disease classification, and extends to the natural images doma
in, achieving robust performance on a car advertisements dataset. The model weig
hts and code are available at https://github.com/marteczkah/RoVTL.

Deep Forcing: Training-Free Long Video Generation with Deep Sink and Participati
ve Compression
Jung Yi, Wooseok Jang, Paul Hyunbin Cho, Jisu Nam, Heeji Yoon, Seungryong Kim
Recent advances in autoregressive video diffusion have enabled real-time frame s
treaming, however, existing methods still suffer from visual error accumulation
including visual fidelity and motion degradation over long-horizon. To address t
hese challenges, we introduce Deep Forcing, a training-free extension of autoreg
ressive video diffusion models that stabilizes long video generation through two
 complementary mechanisms. Deep Sink preserves approximately half of the sliding
 context window as persistent sink tokens and realigns their temporal RoPE phase
s to the current timeline, thereby maintaining global context during extended ro
llouts. Participative Compression performs importance-aware KV cache pruning, re
taining only tokens that actively participate in recent attention while removing
 redundant or degraded history, effectively mitigating error accumulation under
out-of-distribution lengths. Together, these components enable over 12× length e
xtrapolation (e.g., 5s-trained → 60s+) without sacrificing inference speed, whil
e improving visual fidelity and motion dynamics compared to prior methods. Our r
esults demonstrate that Deep Forcing can achieve performance comparable to state
-of-the-art training-based methods trained specifically for long video generatio
n.

ChaosNexus: A Foundation Model for ODE-based Chaotic System Forecasting with Hie
rarchical Multi-scale Awareness
Chang Liu, Bohao Zhao, Jingtao Ding, Yong Li
Foundation models show great promise in achieving zero-shot or few-shot forecast
ing for ODE-based chaotic systems via large-scale pretraining. However, existing
 architectures often fail to capture the multi-scale temporal structures and dis
tinct spectral characteristics of chaotic dynamics. To address this, we introduc
e ChaosNexus, a foundation model for chaotic system forecasting underpinned by t
he proposed ScaleFormer architecture. By processing temporal contexts across hie
rarchically varying patch sizes, ChaosNexus effectively captures long-range depe
ndencies and preserves high-frequency fluctuations. To address heterogeneity acr
oss distinct systems, we integrate Mixture-of-Experts (MoE) layers into each Sca
leFormer block and explicitly condition the final forecasts on a learned frequen
cy fingerprint, providing the model with a global spectral view of the system. E
xtensive evaluations on over 9,000 synthetic systems demonstrate that ChaosNexus
 achieves superior fidelity in long-term attractor statistics while maintaining
competitive point-wise accuracy. Furthermore, in real-world applications, it ach
ieves a remarkable zero-shot mean error below 1°C for 5-day station-based weathe
r forecasting. Code is available at https://github.com/tsinghua-fib-lab/ChaosNex
us.

SPEED: Sharpened-Teacher Distillation for Parallel Decoding of Diffusion Languag
e Models
Qiuhong Shen, Xingyi Yang, Xinyin Ma, Gongfan Fang, Xinchao Wang
Diffusion-based large language models generate text by gradually filling in mask
ed tokens, yet they remain slow because they usually decode only a few tokens pe
r step. Parallel decoding, which unmasks multiple tokens simultaneously, promise
s acceleration but often degrades quality when too many tokens are predicted at
once. We identify the root cause: when decoding is viewed as iterative token gro

uping, overly permissive grouping places interdependent tokens in the same step, violates the conditional independence assumption, and amplifies reliance on noisy context even when the top prediction is already correct. We introduce SPEED, a framework that enlarges safe parallel groups through complementary training and inference designs. At training time, a sharpened teacher distillation objective selectively aligns the student to teacher-correct positions using a temperature-scaled KL term together with a masked language modeling loss, producing a student that assigns more probability mass to correct token identities and elevates more positions above the decoding threshold. At inference time, Slow-Fast Decoding partitions tokens by sensitivity to revealed context using token-wise Jensen-Shannon Divergence computed with and without access to the preceding block, decoding low-sensitivity tokens jointly in parallel while deferring high-sensitivity tokens until sufficient context resolves them. Through extensive experiments, our framework attains up to 12.2$\times$ speedup on LLaDA-8B-Instruct and 6.7$\times$ on Dream-7B-Instruct with accuracy close to greedy decoding across standard reasoning and code benchmarks.

Benign Overfitting in Adversarial Training for Vision Transformers
Jiaming Zhang, Meng Ding, Shaopeng Fu, Jingfeng Zhang, Di Wang
Despite the remarkable success of Vision Transformers (ViTs) across a wide range of vision tasks, recent studies have revealed that they remain vulnerable to adversarial examples, much like Convolutional Neural Networks (CNNs). A common empirical defense strategy is adversarial training, yet the theoretical underpinnings of its robustness in ViTs remain largely unexplored. In this work, we present the first theoretical analysis of adversarial training under simplified ViT architectures. We show that, when trained under a signal-to-noise ratio that satisfies a certain condition and within a moderate perturbation budget, adversarial training enables ViTs to achieve nearly zero robust training loss and robust generalization error under certain regimes. Remarkably, this leads to strong generalization even in the presence of overfitting, a phenomenon known as benign overfitting, previously only observed in CNNs (with adversarial training). Experiments on both synthetic and real-world datasets further validate our theoretical findings.

Many Experiments, Few Repetitions, Unpaired Data, and Sparse Effects: Is Causal Inference Possible?
Felix Schur, Niklas Pfister, Peng Ding, Sach Mukherjee, Jonas Peters
In many applications, practical constraints prevent measuring covariates and outcomes on the same units, resulting in unpaired data. We study the problem of estimating causal effects under hidden confounding in the following unpaired data setting: we observe some covariates X and an outcome Y under different experimental conditions (environments) but do not observe them jointly -- we either observe X or Y. Under appropriate regularity conditions, the problem can be cast as an instrumental variable (IV) regression with the environment acting as a (possibly high-dimensional) instrument. When there are many environments but only a few observations per environment, standard two-sample IV estimators fail to be consistent. We propose a GMM-type estimator based on cross-fold sample splitting of the instrument–covariate sample that also applies in standard IV settings. We prove that it is consistent as the number of environments grows but the sample size per environment remains constant. We further extend the method to sparse causal effects via ℓ_1-regularized estimation and post-selection refitting.

Theoretical Challenges in Learning for Branch-and-Cut
Hongyu Cheng, Amitabh Basu
Machine learning is increasingly used to guide branch-and-cut (B&C) for mixed-integer linear programming by learning score-based policies for selecting branching variables and cutting planes. Many approaches train on local signals from look ahead heuristics such as strong branching, and linear programming (LP) bound improvement for cut selection. Training and evaluation of the learned models often

focus on local score accuracy. We show that such local score-based methods can l
ead to search trees exponentially larger than optimal tree sizes, by identifying
 two sources of this gap. The first is that these widely used expert signals can
 be misaligned with overall tree size. LP bound improvement can select a root cu
t set that yields an exponentially larger strong branching tree than selecting c
uts by a simple proxy score, and strong branching itself can be exponentially su
boptimal (Dey et al., 2024). The second is that small discrepancies can be ampli
fied by the branch-and-bound recursion. An arbitrarily small perturbation of the
 right-hand sides in a root cut set can change the minimum tree size from a sing
le node to exponentially many. For branching, arbitrarily small score discrepanc
ies, and differences only in tie-breaking, can produce trees of exponentially di
fferent sizes, and even a small number of decision differences along a trajector
y can incur exponential growth. These results show that branch-and-cut policies
trained and learned using local expert scores do not guarantee small trees, thus
 motivating the study of data-driven methods that produce policies better aligne
d with tree size rather than only accuracy on expert scores.

LSGQuant: Layer-Sensitivity Guided Quantization for One-Step Diffusion Real-Worl
d Video Super-Resolution
Tianxing Wu, Zheng Chen, Cirou Xu, Bowen Chai, Yong Guo, Yutong Liu, Linghe Kong
, Yulun Zhang
One-step diffusion models have demonstrated a promising capability and fast infe
rence in video super-resolution (VSR) for real-world applications. Nevertheless,
 the substantial model size and high computational cost of Diffusion Transformer
s (DiTs) limit downstream applications. While low-bit quantization is a common a
pproach for model compression, the effectiveness of quantized models is challeng
ed by the high dynamic range of input latent and diverse layer behaviors. To add
ress these challenges, we introduce LSGQuant, a layer-sensitivity-guided quantiz
ation approach for one-step diffusion-based real-world VSR. Our method incorpora
tes a Dynamic Range Adaptive Quantizer (DRAQ) to fit video token activations. Fu
rthermore, we estimate layer sensitivity and implement a Variance-Oriented Layer
 Training Strategy (VOLTS) by analyzing layer-wise statistics in calibration. We
 also introduce Quantization-Aware Optimization (QAO) to jointly refine the quan
tized branch and a retained high-precision branch. Extensive experiments demonst
rate that our method has nearly the performance of the original model with full-
precision and significantly exceeds existing quantization techniques. All models
 and code are available at https://github.com/zhengchen1999/LSGQuant.

Error Amplification Limits ANN-to-SNN Conversion in Continuous Control
Zijie Xu, Zihan Huang, Yiting Dong, Kang Chen, Wenxuan Liu, Zhaofei Yu
Spiking Neural Networks (SNNs) can achieve competitive performance by converting
 already existing well-trained Artificial Neural Networks (ANNs), avoiding furth
er costly training. This property is particularly attractive in Reinforcement Le
arning (RL), where training through environment interaction is expensive and pot
entially unsafe. However, existing conversion methods perform poorly in continuo
us control, where suitable baselines are largely absent. We identify error ampli
fication as the key cause: small action approximation errors become temporally c
orrelated across decision steps, inducing cumulative state distribution shift an
d severe performance degradation. To address this issue, we propose Cross-Step R
esidual Potential Initialization (CRPI), a lightweight gradient-free mechanism t
hat carries over residual membrane potentials across decision steps to suppress
temporally correlated errors. Experiments on continuous control benchmarks with
both vector and visual observations demonstrate that CRPI can be integrated into
 existing conversion pipelines and substantially recovers lost performance. Our
results highlight continuous control as a critical and challenging benchmark for
 ANN-to-SNN conversion, where small errors can be strongly amplified and impact
performance. Code is available at https://github.com/xuzijie32/ANN2SNN-CRPI.

MemPot: Defend Against Memory Extraction Attack with Optimized Honeypots
Yuhao Wang, Shengfang Zhai, Guanghao Jin, Yinpeng Dong, Linyi Yang, Jiaheng Zhan

g
Large Language Model (LLM)-based agents employ external and internal memory systems to handle complex, goal-oriented tasks, yet this exposes them to severe extraction attacks, and corresponding defenses are currently lacking.
In this paper, we propose *MemPot*, the first theoretically verified defense framework against memory extraction attacks by injecting optimized honeypots into the memory.
Through a two-stage optimization process, *MemPot* generates trap documents that maximize the retrieval probability for attackers while remaining inconspicuous to benign users.
We model the detection process as Wald’s Sequential Probability Ratio Test (SPRT) and theoretically prove that *MemPot* achieves a lower average number of sampling rounds compared to optimal static detectors.
Empirically, *MemPot* significantly outperforms state-of-the-art baselines, achieving a 50% improvement in detection AUROC and an 80% increase in True Positive Rate under low False Positive Rate constraints.
Furthermore, our experiments confirm that *MemPot* incurs zero online inference latency and preserves the agent's utility on standard tasks, verifying its superiority in safety, harmlessness and efficiency.

Enhancing Protein-Protein Interaction Prediction with Hierarchical Motif-based Multimodal Protein Embedding
Zaifei YANG, Samuel Ping-Man Choi, James Kwok
Protein-protein interactions (PPIs) are essential for many biological processes. However, existing PPI prediction approaches suffer from two major limitations: they overlook the hierarchical organization of proteins, particularly meso-scale motifs that critically regulate PPIs, and fail to effectively integrate sequence, structure, and function modalities. To address these limitations, we propose MMM-PPI, a Hierarchical Motif-based Multi-Modal protein Encoder for PPI Prediction that constructs PPI embeddings in a bottom-up multi-modal manner across three scales. At the micro-scale, we encode three modal residue features; at the meso-scale, a novel multimodal motif encoder aggregates residues into spatially-informed motif embeddings; at the macro-scale, a multimodal protein encoder integrates motifs into protein embeddings by jointly modeling motif importance and inter-modal correlations. The pre-trained encoder can be used off-the-shelf for large-scale PPI prediction. Extensive experiments on multiple PPI datasets show that MMM-PPI outperforms state-of-the-art multi-label PPI prediction models, particularly under challenging data partitions and limited data scenarios. Codes are in https://github.com/yzf-code/MMM-PPI.
****
Multi-Way Representation Alignment
Akshit Achara, Tatiana Gaintseva, Matéo Mahaut, Pritish Chakraborty, Viktor Stenby Johansson, Melih Barsbey, Emanuele Rodolà, Donato Crisostomi
The Platonic Representation Hypothesis suggests that independently trained neural networks converge to increasingly similar latent spaces. However, current strategies for mapping these representations are inherently pairwise, scaling quadratically with the number of models and failing to yield a consistent global reference. In this paper, we study the alignment of $M \ge 3$ models. We first adapt Generalized Procrustes Analysis (GPA) to construct a shared orthogonal universe that preserves the internal geometry essential for tasks like model stitching. We then show that strict isometric alignment is suboptimal for retrieval, where agreement-maximizing methods like Canonical Correlation Analysis (CCA) typically prevail. To bridge this gap, we finally propose Geometry-Corrected Procrustes Alignment (GCPA), which establishes a robust GPA-based universe followed by a post-hoc correction for directional mismatch. Extensive experiments demonstrate that GCPA consistently improves any-to-any retrieval while retaining a practical shared reference space.
****
Imposing Boundary Conditions on Neural Operators via Learned Function Extensions
Sepehr Mousavi, Siddhartha Mishra, Laura De Lorenzis

Neural operators have emerged as powerful surrogates for the solution of partial differential equations (PDEs), yet their ability to handle general, highly variable boundary conditions (BCs) remains limited. Existing approaches often fail when the solution operator exhibits strong sensitivity to boundary forcings. We propose a general framework for conditioning neural operators on complex non-homogeneous BCs through function extensions. Our key idea is to map boundary data to latent pseudo-extensions defined over the entire spatial domain, enabling any standard operator learning architecture to consume boundary information. The resulting operator, coupled with an arbitrary domain-to-domain neural operator, can learn rich dependencies on complex BCs and input domain functions at the same time. To benchmark this setting, we construct 18 challenging datasets spanning Poisson, linear elasticity, and hyperelasticity problems, with highly variable, mixed-type, component-wise, and multi-segment BCs on diverse geometries. Our approach achieves state-of-the-art accuracy, outperforming baselines by large margins, while requiring no hyperparameter tuning across datasets. Overall, our results demonstrate that learning boundary-to-domain extensions is an effective and practical strategy for imposing complex BCs in existing neural operator frameworks, enabling accurate and robust scientific machine learning models for a broader range of PDE-governed problems.

Equivariant Latent Alignment via Flow Matching under Group Symmetries
Sunghyun Kim, Jaehoon Hahm, Jeongwoo Shin, Joonseok Lee
Geometry-aware generative models and novel view synthesis approaches have shown strong potential in visual fidelity and consistency. In parallel, equivariant representation learning has emerged as a powerful framework for constructing latent spaces where analytically known group transformations could act directly, capturing geometric structure in data and enhancing both interpretability and generalization in novel view synthesis. However, we identify that existing approaches often suffer from latent misalignment, a discrepancy between the intended group action and the actually required transformations in the latent space. Consequently, the learned latents often fail to consistently preserve the equivariant relations imposed by the underlying group symmetry. To address this, we propose Residual Latent Flow, a flow-based framework that corrects the misaligned latents, thereby improving compliance with the underlying equivariance relation. Our comprehensive experiments show that our method significantly reduces latent misalignment and improves novel view synthesis quality, under rotation groups SO(n).
****

Evaluating Robustness of Reasoning Models on Parameterized Logical Problems
Naïm Es-sebbani, Esteban Marquer, Yakoub Salhi, Zied Bouraoui
Logic provides a controlled testbed for evaluating LLM-based reasoners, yet standard SAT-style benchmarks often conflate surface difficulty (length, wording, clause order) with the structural phenomena that actually determine satisfiability. We introduce a diagnostic benchmark for 2-SAT built from parameterized families of structured 2-CNF formulas, where satisfiability is characterized by the implication graph and can be tuned along interpretable axes. Our generators isolate distinct competencies and failure modes: (i) contradiction-cycle UNSAT cores with controllable size and imbalance, (ii) SAT instances with a prescribed fraction of free variables to control solution multiplicity, (iii) planted backbones that modulate propagation, (iv) late bridge clauses that couple otherwise monotone regions to probe sensitivity to ordering and revision, and (v) symmetry/duplication variants that test abstraction under renaming and redundant structure. We evaluate LLM-based reasoners on decision accuracy and assignment validity, and quantify robustness under semantics-preserving perturbations such as clause reordering, filler clauses, and variable renaming. Across models, we observe sharp performance transitions under targeted structural interventions even when surface statistics are held fixed, revealing brittleness regimes that are invisible to aggregate SAT accuracy.
****

RAMAC: Multimodal Risk-Aware Offline Reinforcement Learning and the Role of Behavior Regularization

Kai Fukazawa, Kunal Mundada, Iman Soltani
In safety-critical domains where online data collection is infeasible, offline r
einforcement learning (RL) is attractive only if policies achieve high returns w
ithout catastrophic lower-tail risk. Prior work on risk-averse offline RL achiev
es safety at the cost of value- or model-based pessimism, and restricted policy
classes that limit policy expressiveness, whereas diffusion/flow-based expressiv
e generative policies have largely been used in risk-neutral settings.
We introduce **Risk-Aware Multimodal Actor-Critic (RAMAC)**, a simple, modular,
model-free framework that couples an expressive generative actor (e.g., diffusio
n/flow) with a distributional critic and optimizes a composite objective that co
mbines Conditional Value-at-Risk (CVaR) with behavioral cloning (BC), enabling r
isk-sensitive learning in complex multimodal scenarios. Since out-of-distributio
n (OOD) actions are a major driver of catastrophic failures in offline RL, we fu
rther provide an objective-level analysis showing that controlling behavior dive
rgence via BC suppresses OOD actions and stabilizes CVaR. Instantiating RAMAC wi
th a diffusion actor, we illustrate these insights on a 2-D risky bandit and eva
luate on Stochastic-D4RL, observing consistent gains in CVaR$_{0.1}$ while maint
aining strong returns.
****

Mind the Gap: Catching Hallucinations via Evidence Drop on the Reasoning Manifol
d
Qunjie Chen, Yufei Chen, Xiaodong Yue, Linye Li
Large Language Models (LLMs) show strong reasoning abilities, yet their reliabil
ity is hindered by hallucinations, where fluent reasoning becomes factually or l
ogically incorrect.
Most existing uncertainty-based detectors rely on sequence-level averaging, whic
h ignores the step-wise dynamics of reasoning and often misclassifies hard-but-c
orrect or easy-but-wrong samples.
We propose a dynamic perspective that models reasoning as a trajectory on a late
nt Evidence Manifold, where each step is supported by local evidence.
Hallucinations are characterized as Evidence Drops, i.e., sudden declines in loc
al evidence support that indicate topological deviations from this manifold.
Based on this insight, we design a training-free and model-agnostic detector tha
t identifies hallucinations via the worst-case Evidence Drop and enables step-le
vel error localization.
Experiments on GSM8K, MATH, and ProcessBench show consistent improvements over s
equence-level uncertainty baselines in selective accuracy and risk–coverage trad
e-offs.

Variational Learning of Disentangled Representations
Yuli Slavutsky, Ozgur Beker, David Blei, Bianca Dumitrascu
Disentangled representations separate factors that are shared across conditions
from those that are condition-specific. Such separation is needed for generaliza
tion to new domains, treatments, patients, or species. A dominant line of work p
ursues this goal through variational formulations. While these approaches achiev
e partial disentanglement, they often exhibit three common limitations: they eit
her do not remove all condition-specific information from the shared representat
ion, allow the shared representation to become uninformative, or impose independ
ence assumptions that do not reflect the underlying generative process. In this
work, we introduce DisCoVR, a variational framework that addresses these limitat
ions. Its objective is aligned with the probabilistic structure of the data-gene
rating process, and includes an adversarial term that prevents condition-specifi
c information from being encoded in the shared representation. DisCoVR reconstru
cts the data from both shared and condition-specific representations, ensuring t
hat each remains informative, and uses a structured prior that further reinforce
s the informativeness of both representations. We show that across synthetic, im
age, and single-cell RNA-sequencing datasets, DisCoVR achieves stronger disentan
glement compared to previous approaches.

CAMEL: Confidence-Gated Reflection for Reward Modeling

Zirui Zhu, Hailun Xu, Yang Luo, Yong Liu, Kanchan Sarkar, Kun Xu, Yang You
Reward models play a fundamental role in aligning large language models with hum an preferences. Existing methods predominantly follow two paradigms: scalar disc riminative preference models, which are efficient but lack interpretability, and generative judging models, which offer richer reasoning at the cost of higher c omputational overhead.
We observe that the log-probability margin between verdict tokens strongly corre lates with prediction correctness, providing a reliable proxy for instance diffi culty without additional inference cost.
Building on this insight, we propose CAMEL, a confidence-gated reflection framew ork that performs a lightweight single-token preference decision first and selec tively invokes reflection only for low-confidence instances. To induce effective self-correction, we train the model via reinforcement learning with counterfact ual prefix augmentation, which exposes the model to diverse initial verdicts and encourages genuine revision.
Empirically, CAMEL achieves state-of-the-art performance on three widely used re ward-model benchmarks with 82.9% average accuracy, surpassing the best prior mod el by 3.2% and outperforming 70B-parameter models using only 14B parameters, whi le establishing a strictly better accuracy-efficiency Pareto frontier.
****
Modeling Long-Tail Relations in the Operating Room via In-Context Multimodal Lea rning
Boqiang Xu, Wei Zhang, Ding Ma, Jian Liang, Zhenan Sun, Zhen Lei
Operating room (OR) scene graph generation (SGG) enables holistic modeling of OR domains by encoding interactions among medical staff, tools, and equipment as t riplet-based structured scene graphs. Although existing OR SGG methods demonstra te satisfactory overall performance, they exhibit substantially lower accuracy o n long-tail categories compared to head categories in OR data. We introduce SGG-ICL, a novel framework that represents the first attempt to address the long-tai l problem in OR SGG by leveraging in-context learning (ICL). SGG-ICL first ident ifies long-tail samples via an Adaptive Router module and selectively applies IC L only to these samples. This selective routing strategy enhances performance on long-tail categories without degrading head-category accuracy. Subsequently, SG G-ICL constructs a candidate pool through multimodal retrieval and then employs a trained MLLM Reranker to re-rank the candidates, selecting the most similar ex amples to the test sample for ICL. The reranker is supervised by IoU scores deri ved from annotated SGG triplets and exploits rich multimodal information to esti mate pairwise sample similarity. Experimental results show that SGG-ICL improves accuracy on long-tail categories by 6.9%, while also achieving a 2.6% improveme nt in overall accuracy.
****
Hide and Seek in Embedding Space: Geometry-based Steganography and Detection in Large Language Models
Charles Westphal, Keivan Navaie, Fernando Rosas
Fine-tuned LLMs can covertly encode prompt secrets into outputs via steganograph ic channels. Prior work demonstrated this threat but relied on trivially recover able encodings. We formalize payload recoverability via classifier accuracy and show previous schemes achieve 100\% recoverability. In response, we introduce l ow-recoverability steganography, replacing arbitrary mappings with embedding-spa ce-derived ones. For Llama-8B (LoRA) and Ministral-8B (LoRA) trained on TrojanSt ego prompts, exact secret recovery rises from 17$\rightarrow$30\% (+78\%) and 24 $\rightarrow$43\% (+80\%) respectively, while on Llama-70B (LoRA) trained on Wik i prompts, it climbs from 9$\rightarrow$19\% (+123\%), all while reducing payloa d recoverability. We then discuss detection. We argue that detecting fine-tuning -based steganographic attacks requires approaches beyond traditional steganalysi s. Standard approaches measure distributional shift, which is an expected side-e ffect of fine-tuning. Instead, we propose a mechanistic interpretability approac h: linear probes trained on later-layer activations detect the secret with up to 33\% higher accuracy in fine-tuned models compared to base models, even for low -recoverability schemes. This suggests that malicious fine-tuning leaves actiona

ble internal signatures amenable to interpretability-based defenses.

Explainable Federated Learning via Global–Local Attribution Alignment
Dawood Wasif, Terrence J Moore, Chang-Tien Lu, Jin-Hee Cho
Federated learning enables on-device training without centralizing data, yet existing systems still struggle to provide explanations that are both locally faithful and globally consistent under strict privacy and bandwidth constraints. Prior approaches either keep explanations siloed across clients, transmit heavy or sensitive artifacts, or replace expressive task models with interpretable surrogates that sacrifice accuracy. We propose xFedAlign, a model-agnostic framework that decouples task optimization in parameter space from explanation coordination in a compact group space. Each client distills a lightweight surrogate to produce private, per-class top-k attribution artifacts, which are robustly aggregated by the server into a Global Explanation Prior that softly aligns client explanations without constraining task learning. Across image, text, and tabular benchmarks with IID and non-IID partitions, xFedAlign matches FedAvg accuracy while consistently reducing explanation drift and improving deletion and insertion AUC relative to Local-XAI, FedAttr-Agg, and Fed-XAI, with only a few kilobytes of additional communication per round. Privacy and robustness evaluations further demonstrate reduced membership inference advantage and increased resistance to attribution poisoning, enabling consistent and trustworthy explanations in federated learning.
****
PRISM: Demystifying Retention and Interaction in Mid-Training
Bharat Runwal, Ashish Sunil Agrawal, Anurag Roy, Rameswar Panda
Mid-training is increasingly used to improve the reasoning capabilities of large language models (LLMs), yet its design choices and interaction with evaluation and reinforcement learning (RL) remain poorly understood. Prior work often focuses on narrow domain gains, overlooking retention of general abilities, long-context performance, and RL compatibility. We present $\textbf{PRISM}$ (Demystifying Retention and Interaction in Mid-Training), a holistic empirical study that analyzes mid-training design choices, what to evaluate, and how domain mixtures and training stages interact across model families. Experiments on Granite-3.3 8B, LLaMA-3.1 8B, and Mistral-7B/24B base models show that a relatively small, high-quality mid-training phase of $\textbf{$\sim$27B}$ tokens acts as a critical stabilizing stage for reasoning. Across models, PRISM yields consistent gains of $\textbf{$\sim$6–10}$ points on coding benchmarks and $\textbf{$\sim$17–30}$ points on mathematical reasoning benchmarks while preserving general performance. RL applied on top of PRISM-mid-trained models produces stable, monotonic improvements, adding a further $\textbf{$\sim$3–8}$ points across coding and math tasks such as LiveCodeBench, Codeforces, AIME and MATH500, and $\textbf{$\sim$17–20}$ points on science (GPQA-Diamond), whereas RL applied directly to base models is substantially less effective. Our results demonstrate that retention-aware mid-training is a necessary intermediate step for reliable reasoning enhancement and RL scaling, and provide practical guidance for designing robust mid-training pipelines for modern LLMs.

Sharper Generalization Guarantees for Asynchronous SGD: Beyond Lipschitzness, Smoothness and Data Homogeneity
Xie Yufeng, Yunwen Lei
Asynchronous stochastic gradient descent (ASGD) is widely adopted in distributed and federated learning. In this paper, we develop a sharp generalization analysis for ASGD by leveraging the concept of on-average model stability. For convex and smooth objectives, we establish stability and excess risk bounds under minimal assumptions, removing Lipschitz continuity, bounded noise, bounded parameter or data domains, while allowing randomly partitioned data and arbitrary delays. Our bounds are optimistic and explicitly characterize the impact of worker participation, recovering the minimax-optimal rate $O(1/\sqrt{mn})$ in balanced regimes where mn denotes the sample size and implying fast rates under low-noise conditions. We further extend the analysis to non-smooth objectives with Hölder-co

ntinuous gradients and to heterogeneous data settings via random ASGD, obtaining non-vacuous excess risk guarantees in both settings. Experimental results support our theoretical findings.

Finding Most Influential Sets

Lucas Darius Konrad, Nikolas Kuschnig

Identifying _most influential sets_ (MIS) – size-k subsets whose removal maximally changes a target estimand – is typically infeasible because it requires searching over n choose k subsets.

For estimands with linear-fractional leave-set-out effects, we show that MIS selection reduces to a one-parameter sequence of top-k problems. Dinkelbach's method yields an algorithm with $\mathcal{O}(n)$ cost per iteration and finite termination.

For fixed residualized inputs, the algorithm returns a globally optimal set for the univariate ratio objective, including the oracle-residualized partial linear model. With estimated nuisance functions, uniform denominator and generated-score stability imply approximation to the first-order oracle orthogonal-score objective; exact set recovery follows under a separation condition.

Simulations and applications show that the method recovers exact MIS that were previously computationally inaccessible.

SCOPE: Selective Conformal Optimized Pairwise LLM Judging

Sher Badshah, Ali Emami, Hassan Sajjad

Large language models (LLMs) are increasingly used as scalable judges in pairwise evaluation, but they remain prone to miscalibration and biases. We propose SCOPE (Selective Conformal Optimized Pairwise Evaluation), a framework that calibrates an acceptance threshold so that, under exchangeability, the error rate among non-abstained judgments is at most a user-specified level α. To supply SCOPE with a bias-neutral uncertainty signal, we introduce Bidirectional Preference Entropy (BPE), which queries the judge under both response positions and converts the order-averaged preference probability into an entropy-based score. Across various pairwise judging benchmarks, BPE outperforms standard confidence proxies in calibration and discrimination, while SCOPE consistently satisfies the target risk bound (empirical FDR ≈ 0.097--0.099 at $\alpha=0.10$) and retains substantial coverage. Compared to vanilla baselines, SCOPE accepts up to $2.4\times$ more judgments under the same risk constraint, demonstrating that BPE enables reliable and high-coverage LLM-based evaluation.

A Regret Minimization Framework on Preference Learning in Large Language Models

Suhwan Kim, Taehyun Cho, Geon-Hyeong Kim, Yu Jin Kim, Youngsoo Jang, Moontae Lee, Jungwoo Lee

Reinforcement learning with verifiable rewards (RLVR) has enabled progress on reasoning-intensive tasks by relying on task-specific verifiers that provide automated correctness signals. However, many realistic language tasks are difficult to equip with reliable verifiers, motivating a growing reliance on reinforcement learning from human feedback (RLHF).

In this setting, we argue that a closer examination of how human feedback should be interpreted is essential.

We introduce Regret-based Preference Optimization (RePO), which reframes RLHF through *regret minimization* rather than reward maximization.

Human preferences are often shaped by *prospective* anticipation of outcomes and *counterfactual* comparisons to alternative behaviors, rather than by immediate, outcome-independent utility.

RePO captures this structure by modeling preferences as behavior-conditioned assessments of relative suboptimality.

Within a KL-regularized reinforcement learning framework, RePO admits a closed-form policy update compatible with direct preference optimization.

Experiments on mathematical reasoning benchmarks and human-annotated preference datasets demonstrate consistent performance gains, indicating that regret-based preference learning is an effective and human-aligned approach for training larg

e language models.

A Geometry-Based View of Mahalanobis OOD Detection
Denis Janiak, Jakub Binkowski, Tomasz Jan Kajdanowicz
Out-of-distribution (OOD) detection is critical for reliable deployment of visio n models, and Mahalanobis-based detectors remain strong baselines. However, thei r performance varies widely across modern pretrained representations, making it unclear which feature-space properties determine success or failure. Across dive rse foundation-model backbones and Mahalanobis variants, we show that performanc e is highly representation-dependent and can shift substantially with pretrainin g data and fine-tuning. We link this variability to in-distribution geometry and identify a two-term ID summary that consistently tracks Mahalanobis OOD behavio r across detectors: within-class spectral structure and local intrinsic dimensio nality. Finally, we introduce radially scaled ℓ_2 normalization, $\phi_\bet a(z)=z/\|z\|^\beta$, a direction-preserving transformation that changes feature radii and exposes a different ID geometry to the same quadratic detector. Select ing β from ID-only geometry signals generally outperforms fixed normalizat ion baselines.

Harnessing Reasoning Trajectories for Hallucination Detection via Answer-agreeme nt Representation Shaping
Jianxiong Zhang, Bing Guo, Yuming Jiang, Haobo Wang, Bo An, Xuefeng Du
Large reasoning models (LRMs) often generate long, seemingly coherent reasoning traces yet still produce incorrect answers, making hallucination detection chall enging. Although trajectories contain useful signals, directly using trace text or vanilla hidden states for detection is brittle: traces vary in form and detec tors can overfit to superficial patterns rather than answer validity. We introdu ce Answer-agreement Representation Shaping (ARS), which learns detection-friendl y trace-conditioned representations by explicitly encoding answer stability. ARS generates counterfactual answers through small latent interventions, specifical ly, perturbing the trace-boundary embedding, and labels each perturbation by whe ther the resulting answer agrees with the original. It then learns representatio ns that bring answer-agreeing states together and separate answer-disagreeing on es, exposing latent instability indicative of hallucination risk. The shaped emb eddings are plug-and-play with existing embedding-based detectors and require no human annotations during training. Experiments demonstrate that ARS consistentl y improves detection and achieves substantial gains over strong baselines.

Reusing Trajectories in Policy Gradients Enables Fast Convergence
Alessandro Montenegro, Federico Mansutti, Marco Mussi, Matteo Papini, Alberto Ma ria Metelli
Policy gradient (PG) methods are a class of effective *reinforcement learning* algorithms, particularly when dealing with continuous control problems. They re ly on fresh *on-policy* data, making them sample-inefficient and requiring $\mat hcal{O}(\epsilon^{-2})$ trajectories to reach an ϵ-approximate stationa ry point. A common strategy to improve efficiency is to *reuse* information from past iterations, such as previous *gradients* or *trajectories*, leading to *of f-policy* PG methods. While gradient reuse has received substantial attention, l eading to improved rates up to $\mathcal{O}(\epsilon^{-3/2})$, the reuse of past trajectories, although intuitive, remains largely unexplored from a theoretical perspective.
In this work, we provide the first rigorous theoretical evidence that reusing pa st off-policy trajectories can significantly accelerate PG convergence. We propo se RT-PG (Reusing Trajectories - Policy Gradient), a novel algorithm that levera ges a *power mean*-corrected multiple importance weighting estimator to effectiv ely combine on-policy and off-policy data coming from the most recent ω i terations. Through a novel analysis, we prove that RT-PG achieves a sample compl exity of $\widetilde{\mathcal{O}}(\epsilon^{-2}\omega^{-1})$.
When reusing *all* available past trajectories, this leads to a rate of $\wideti lde{\mathcal{O}}(\epsilon^{-1})$, the best known

one in the literature for PG methods. We further validate our approach empirical
ly, demonstrating its effectiveness against baselines with state-of-the-art rate
s.

Stable Deep Reinforcement Learning via Isotropic Gaussian Representations
Ali Saheb Pasand, Johan Obando-Ceron, Aaron Courville, Pouya Bashivan, Pablo Sam
uel Castro
Deep reinforcement learning systems often suffer from unstable training dynamics
 due to non-stationarity, where learning objectives and data distributions evolv
e over time. We show that under non-stationary targets, isotropic Gaussian embed
dings are provably advantageous. In particular, they induce stable tracking of t
ime-varying targets for linear readouts, achieve maximal entropy under a fixed v
ariance budget, and encourage a balanced use of all representational dimensions-
-all of which enable agents to be more adaptive and stable. Building on this ins
ight, we propose the use of Sketched Isotropic Gaussian Regularization for shapi
ng representations toward an isotropic Gaussian distribution during training. We
 demonstrate empirically, over a variety of domains, that this simple and comput
ationally inexpensive method improves performance under non-stationarity while r
educing representation collapse, neuron dormancy, and training instability.

Weaving Graph over Tokens: Contextualizing Structured Sequences for LLMs
Jiaxuan Chen, Zixing Zhang, Ruijun Mao, Wei Sun, Zhicheng Liang, Yuhang Zhang, Y
axi Liu, Fangxin Wang
Generative Graph Language Models (GLMs) must reconcile topology with causal
  language modeling. Linearization obscures multi-hop connectivity, while
  encoder-based methods bottleneck token-level reasoning during generation.
  Viewing context modeling as a form of message passing, we
  introduce **Weaver**, an encoder-free framework that extends the attention mec
hanism of decoder-only LLMs to enable graph reasoning. Weaver
  maps graph distances into rotary positional embeddings so that structurally
  connected nodes become proximate in attention space, propagating information
  over graph topology as if it were sequential context. To achieve this, we
  combine: 1) a masking mechanism for causal tokens with graph structures; 2) a
  unified geometric encoding that couples sequential position and graph distance
  in joint rotary embeddings (Graph-over-Tokens RoPE); and 3) a design principle
  to prioritize local information to resolve positional ambiguity under graph
  symmetries. On zero-shot benchmarks, Weaver achieves state-of-the-art performa
nce among generative GLMs, with gains of up to 30\% over prior generative method
s on
heterophilic graphs, while matching specialized discriminative models on
citation networks---all within a unified decoder-only framework.

Mantis: Lightweight Foundation Model for Time Series Classification
Vasilii Feofanov, Songkang Wen, Shifeng Xie, Simon Roschmann, Marius Alonso, Hon
gbo Guo, Romain Ilbert, Malik Tiomoko, Quentin Bouniot, Zeynep Akata, Lujia Pan,
 Jianfeng Zhang, Ievgen Redko
While foundation models have revolutionized various domains, their application t
o time series classification remains rather under-explored, with existing litera
ture predominantly focused on forecasting. To bridge this gap, we introduce \tex
tbf{Mantis}, a transformer-based foundation model pre-trained exclusively on syn
thetic data via self-supervised contrastive learning. We demonstrate that effect
ive tokenization is critical to unlocking the full potential of transformers, pr
oposing a novel token generator unit. Furthermore, we introduce an enhanced test
-time methodology that bridges the performance gap between Mantis and strong spe
cialized approaches by leveraging intermediate-layer representations, self-ensem
bling, and cross-model embedding fusion. Extensive experiments demonstrate that
Mantis establishes a new state-of-the-art, outperforming existing foundation mod
els across four diverse dataset collections covering various application domains
.

Interpretability Driven Evolutionary Approach for the Design of Biological Sequences
Akash Pandey, Wei Chen, Sinan Keten
Designing biological sequences such as proteins and DNA for desired properties is challenging due to vast search spaces and limited wet lab evaluation budgets. Current evolutionary approaches ignore sequential dependencies and rely on random mutations, which scale poorly for long sequences. In contrast, reinforcement learning (RL) and generative models explicitly model sequence structure but require large datasets to guide generation toward the target properties. These limitations suggest the need for a method that combines the sample efficiency of evolutionary approaches with the ability to exploit sequential structure. In this work, we propose a novel evolutionary approach, $\texttt{IDEAS}$, in which mutations are guided by an explainable model. The model identifies critical motifs in high-fitness sequences and uses them to mutate non-critical positions. Across eight continuous-property datasets, seven baselines, and three evaluation budgets, $\texttt{IDEAS}$ achieves a 19% acceleration in design while maintaining a favorable position on the Pareto curve balancing acceleration, diversity, and novelty.
****
FreeText: Training-Free Text Rendering via Attention Localization and Spectral Glyph Injection
RuiQiang Zhang, Hengyi Wang, Chang Liu, Guanjie Wang, Zehua Ma, Weiming Zhang
Large-scale text-to-image (T2I) diffusion models excel at open-domain synthesis but still struggle with precise text rendering, especially for multi-line layouts, dense typography, and long-tailed scripts such as Chinese. Prior solutions typically necessitate costly retraining or impose rigid external layout constraints, often compromising aesthetic quality and flexibility. We propose **FreeText**, a training-free, plug-and-play framework that improves text rendering by leveraging intrinsic mechanisms of *Diffusion Transformer (DiT)* models. **FreeText** decomposes the problem into *where to write* and *what to write*. For the former, we localize writing regions by extracting token-wise spatial attribution from image-to-text attention, using sink-like tokens as stable spatial anchors and topology-aware refinement to produce high-confidence masks. For the latter, we introduce Spectral-Modulated Glyph Injection (SGMI), which injects a noise-aligned glyph prior with frequency-domain band-pass modulation to strengthen glyph structure and mitigate semantic leakage (rendering the concept instead of the word). Extensive experiments on Qwen-Image, FLUX.1-dev, and SD3 variants across longText-Benchmark, CVTG, and our CLT-Bench show consistent gains in text readability while maintaining semantic alignment and aesthetic quality, with modest inference overhead.
****
Reinforcement Learning for Reachability: Guaranteeing Asymptotic Optimality
Amogh Palasamudram, Jakub Svoboda, Suguman Bansal, Krishnendu Chatterjee
Reinforcement learning (RL) for reachability specifications is fundamental in sequential decision-making, yet theoretical guarantees remain less explored. A recent work achieves asymptotic convergence to optimal policies. However, this approach provides limited insight into convergence dynamics. In this work, we present an alternative approach that provides deeper theoretical insights into convergence. Our approach builds on PAC learning with assumptions. PAC learning guarantees near-optimal policies with high confidence in finite time but requires knowing internal MDP parameters like minimum transition probability. We argue that while these parameters are unknown in RL, they can be iteratively refined and estimated with increasing accuracy. By iteratively satisfying PAC conditions, we show that exact optimality can be achieved in the limit. Empirical evaluations on standard benchmarks validate our theoretical insights into convergence dynamics.
****
SpaCeFormer: Fast Proposal-Free Open-Vocabulary 3D Instance Segmentation
Chris Choy, Junha Lee, Chunghyun Park, Minsu Cho, Jan Kautz
Open-vocabulary 3D instance segmentation is a core capability for robotics and AR/VR, but prior methods trade one bottleneck for another: multi-stage 2D+3D pipelines aggregate foundation-model outputs at hundreds of seconds per scene, while

pseudo-labeled end-to-end approaches rely on fragmented masks and external region proposals. We present SpaCeFormer, a proposal-free space-curve transformer that runs in 0.12–0.30 seconds per scene across standard benchmarks, 2–3 orders of magnitude faster than multi-stage 2D+3D pipelines. We pair it with SpaCeFormer-3M, the largest open-vocabulary 3D instance segmentation dataset (3.0M multi-view-consistent captions over 604K instances from 7.4K scenes) built through multi-view mask clustering and multi-view VLM captioning; it reaches **21× higher mask recall** than prior single-view pipelines (54.3% vs 2.5% at IoU>0.5). SpaCeFormer combines spatial window attention with Morton-curve serialization for spatially coherent features, and uses a RoPE-enhanced decoder to predict instance masks directly from learned queries without external proposals. On ScanNet200 we achieve 11.1 zero-shot mAP, a 2.8× improvement over the prior best proposal-free method; on ScanNet++ and Replica, we reach 22.9 and 24.1 mAP, surpassing all prior methods including those using multi-view 2D inputs.

Probing the Knowledge Boundary: An Interactive Agentic Framework for Deep Knowledge Extraction

Yuheng Yang, Siqi Zhu, Tao Feng, Ge Liu, Jiaxuan You

Large Language Models (LLMs) can be seen as compressed knowledge bases, but it remains unclear what knowledge they truly contain and how far their knowledge boundary extends. Existing benchmarks are mostly static and provide limited support for systematic knowledge probing. In this paper, we propose an interactive agentic framework to systematically extract and quantify the knowledge of LLMs. Our method includes four adaptive exploration policies to probe knowledge at different granularity. To ensure the quality of extracted knowledge, we introduce a three-stage knowledge processing pipeline that combines vector-based filtering to remove strict duplicates, LLM-based adjudication to resolve ambiguous semantic overlap, and domain relevance auditing to retain valid knowledge units. Through extensive experiments, we find that Recursive Taxonomy is the most effective exploration strategy. We also observe a clear knowledge scaling law, where larger models consistently recover more knowledge. In addition, we identify a Pass@1 versus Pass@k trade-off: domain-specialized models achieve higher initial accuracy but experience rapid degradation, while general-purpose models maintain stable performance over extended extraction. Finally, our results show that differences in training data composition lead to distinct and measurable knowledge profiles across model families, reflecting how pretraining shapes each model's parametric knowledge.

****

Sparse Autoencoders are Topic Models

Leander Girrbach, Zeynep Akata

Sparse autoencoders (SAEs) are used to analyze embeddings, but their role and practical value are debated. We propose a new perspective on SAEs by demonstrating that they can be naturally understood as topic models. We propose a continuous topic model (CTM) inspired by Latent Dirichlet Allocation (LDA) for embedding spaces and derive the SAE objective as a maximum a posteriori estimator under this model. This view implies SAE features are thematic components rather than steerable directions. To confirm our theoretical findings, we introduce SAE-TM, a topic modeling framework that: (1) trains an SAE to learn reusable topic atoms, (2) interprets them as word distributions on downstream data, and (3) merges them into any number of topics without retraining. SAE-TM yields more coherent topics than strong baselines on text and image datasets while maintaining diversity. Finally, we analyze thematic structure in image datasets and trace topic changes over time in Japanese woodblock prints. Our work positions SAEs as effective tools for large-scale thematic analysis across modalities. Code is available at https://github.com/ExplainableML/SAE-TM.

NeurIPS: Neuro-anatomical Inductive Priors for Sphere-based Brain Decoding

Sijin Yu, Zijiao Chen, Zhenyu Yang, Zihao Tan, Jiakun Xu, Zhongliang Liu, shengxian chen, WENXUAN WU, Xiangmin Xu, Xin Zhang

Current fMRI decoders face a performance-fidelity trade-off where efficient ID e

ncoders outperform geometrically faithful surface-based models. We argue this is partly driven by inefficient surface tokenization and the failure to use anatomy as a predictive signal. We present **NeurIPS**, a framework that improves surface-based decoding by reframing anatomical variation from a nuisance to a powerful inductive prior. NeurIPS unites two innovations: a **Selective ROI Spherical Tokenizer (SRST)** for efficient geometric encoding, and a **Structure-Guided Mixture of Experts (SG-MoE)** that explicitly models individual anatomy using cortical features. On the Natural Scenes Dataset, NeurIPS establishes a new state-of-the-art for surface decoders and achieves performance comparable to strong 1D baselines. This is achieved with unprecedented efficiency, as the model converges dramatically faster (**10 vs. 600 epochs**). This efficiency enables rapid adaptation to new subjects using only **20\%** of data and ensures robust scalability as the training cohort is expanded. Ablations provide causal evidence that these gains are driven by the model's use of cortical features, not by memorizing subject IDs. By leveraging anatomical priors, NeurIPS provides a principled and scalable path toward robust, generalizable brain decoding.

LakeQA: An Exploratory QA Benchmark over a Million-Scale Data Lake

Haonan Wang, Jiaxiang Liu, Yurong Liu, Austin Senna Wijaya, Tianle Zhou, Eden Wu, Yijia Chen, Wanting You, Reya Vir, Daniela Pinto Veizaga, Grace Fan, Yusen Zhang, Juliana Freire, Eugene Wu

Recent large language models (LLMs) have shown rapid progress on reading-based question answering (QA), where the evidence is explicitly provided or trivially retrievable. In contrast, real-world questions are often not paired with accurate evidence documents. The useful evidence resides in a massive collection of data lakes, necessitating searching as a prerequisite for answering. However, there is a lack of a comprehensive benchmark that requires searching and reasoning over a large collection of data lakes. To this end, we introduce LakeQA, a comprehensive benchmark for search-centric question answering over data lakes that jointly emphasizes \emph{searching} and \emph{reasoning} capabilities. LakeQA is built on a heterogeneous collection of ~9.5 TB text resources from Wikipedia and open-source government data, spanning structured and unstructured data. To ensure the quality of LakeQA's tasks, each sample is annotated by at least one Ph.D level expert. Each task requires long-horizon multi-hop reasoning with implicit intermediate steps: agents need to discover the correct document(s) and then compose evidence across sources to produce the answer. Intensive experiment results on seven frontier LLMs have demonstrated that LakeQA is challenging. For instance, GPT-5.2 only obtains an exact matching score of 14.73% on LakeQA. Overall LakeQA provides a realistic testbed for developing LLM agents that can both \emph{find} and \emph{analyze} data in modern data lakes.

Trees to Flows and Back: Unifying Decision Trees and Diffusion Models

Sai Niranjan Ramachandran, Suvrit Sra

Decision trees and diffusion models are ostensibly disparate model classes, one discrete and hierarchical, the other continuous and dynamic. This work unifies the two by establishing a crisp mathematical correspondence between hierarchical decision trees and diffusion processes in appropriate limiting regimes. Our unification reveals a shared optimization principle: \emph{Global Trajectory Score Matching (GTSM)}, for which gradient boosting (in an idealized version) is asymptotically optimal. We underscore the conceptual value of our work through two key practical instantiations: treeflow, which achieves competitive
generation quality on tabular data with higher fidelity and a 2× computational speedup, and dsmtree, a novel distillation method that transfers hierarchical decision logic into neural networks, matching teacher performance within 2\% on many benchmarks.

****

The Stability of Singular Distribution: A Spectral Perspective on the Two-Phase Dynamics of Language Model Pre-training

Hongtao Zhang, WenJie Zhou, Chenxi Jia, Wei Chen, Xueqi Cheng

Large language model pre-training typically exhibits a two-phase trajectory: a f

ast initial loss drop followed by a prolonged slow improvement. We identify an u
nderlying spectral phenomenon, Stability of Singular Distribution (SoSD), where
the trace-normalized singular value spectrum stabilizes early, even as parameter
 matrices continue to evolve. We demonstrate that synchronization between SoSD a
nd the slow-descent regime is widely observed across diverse architectures (GPT-
2, LLaMA) and settings, including various schedules (Step-wise, WSD, Cosine Deca
y), weight decays, and optimizers (AdamW, Muon). By analyzing a simplified Trans
former, we prove that growing weight norms inevitably precipitate an early SoSD
threshold, after which the rate of loss decrease becomes theoretically bounded b
y the variation in the singular distribution. We further interpret strategies li
ke WSD and Muon through their ability to modulate the SoSD scale, offering a spe
ctral lens for understanding efficient pre-training dynamics.
****

Bridge Matching Sampler: Scalable Sampling via Generalized Fixed-Point Diffusion
 Matching

Denis Blessing, Lorenz Richter, Julius Berner, Egor Malitskiy, Gerhard Neumann

Sampling from unnormalized densities using diffusion models has emerged as a pow
erful paradigm. However, while recent approaches that use least-squares `matchin
g' objectives have improved scalability, they often necessitate significant trad
e-offs, such as restricting prior distributions or relying on unstable optimizat
ion schemes. By generalizing these methods as special forms of fixed-point itera
tions rooted in Nelson's relation, we develop a new method that addresses these
limitations. Our approach enables learning a stochastic transport map between ar
bitrary prior and target distributions with a single, scalable, and stable objec
tive. Furthermore, we introduce a damped variant of this iteration that incorpor
ates a regularization term to mitigate mode collapse. Empirically, we demonstrat
e that our method enables sampling at unprecedented scales while preserving mode
 diversity, achieving state-of-the-art results on complex synthetic densities an
d high-dimensional molecular benchmarks.

Unifying Value Alignment and Assignment in Cross-Domain Offline Reinforcement Le
arning with Heterogeneous Datasets

Zhongjian Qiao, Jiafei Lyu, Chenjia Bai, Peisong Wang, Siyang Gao, Shuang Qiu

Cross-domain offline reinforcement learning (RL) aims to learn a policy in the t
arget domain with a limited target domain dataset and a source domain dataset th
at exhibits a dynamics shift. Training directly on the original source dataset t
ypically leads to performance collapse. Recent studies perform data filtering fr
om the perspective of dynamics alignment or value alignment to enable efficient
policy transfer. However, these studies are typically validated on single-domain
 or single-behavior-policy source datasets. In this work, we explore a more gene
ral heterogeneous cross-domain offline RL setting, where the source datasets may
 be collected from multiple source domains by diverse behavior policies. We firs
t uncover a critical yet overlooked issue in this setting: value misassignment.
Empirically and theoretically, we demonstrate that value misassignment can under
mine value alignment, mislead data filtering toward selecting suboptimal samples
, and loosen the suboptimality gap, thereby degrading the agent’s performance. T
o address this issue, we propose V2A, which integrates dynamics alignment, value
 alignment, and value assignment. V2A first employs temporally-consistent modali
ty representation learning to extract dynamics modalities from the source datase
t, followed by modality-aware advantage learning to rectify value alignment. Fin
ally, it adopts a data filtering paradigm to selectively share source data for p
olicy learning. Empirical results show that V2A significantly outperforms strong
 baseline methods under general heterogeneous cross-domain offline RL settings.

Entangled No More: Multi-Domain Decoupling for Robust Dynamic Graph Neural Netwo
rks

Youda Mo, Chaobo He, Junwei Cheng, Peng Mei, Quanlong Guan

Dynamic graphs are pervasive in real-world systems, but their tightly entangled
spatiotemporal evolution causes significant modeling challenges. Existing Dynami
c Graph Neural Networks (DGNNs) lack a principled framework for systematically d

ecoupling this multi-domain entanglement, raising two key problems: (i) represen tation drift caused by structural incompleteness, and (ii) signal distortion amp lified by noise perturbation. These problems can accumulate over time, forming t emporal redundancy that weakens robustness of DGNNs.
In view of these, we propose DeR-Mamba(Decoupling for Robust Mamba), a multi-dom ain decoupling framework for robust DGNNs.
To address (i), we develop the Multi-Particle Kernel Kalman observation field (M P-K^{2}alman), which achieves spatial decoupling by sampling latent evolution p aths in kernel subspaces and performing Kalman-style updates to estimate structu ral states.
To address (ii), we design the Adversarial-aware Frequency Decoupling Module (AF DM), which performs frequency-domain decoupling and dynamic cross-frequency modu lation to purify spectral signals. Finally, a self-consistent dynamic graph stat e-space system performs temporal decoupling to control redundancy, suppressing r esidual disturbances through discretized cross-time modeling and selective snaps hot scanning. Extensive experiments on benchmark datasets with adversarial attac ks validate its superior robustness.

The Surprising Difficulty of Search in Model-Based Reinforcement Learning
Wei-Di Chang, Mikael Henaff, Brandon Amos, Gregory Dudek, Scott Fujimoto
This paper investigates search in model-based reinforcement learning (RL). Conve ntional wisdom holds that long-term predictions and compounding errors are the p rimary obstacles for model-based RL. We challenge this view, showing that search is not a drop-in replacement for a learned policy. Surprisingly, we find that s earch can harm performance even when the model is highly accurate. Instead, we s how that mitigating overestimation bias matters more than improving model or val ue function accuracy. Building on this insight, we identify that taking the mini mum over an ensemble of value functions effectively addresses this bias and enab les effective search, achieving state-of-the-art performance across multiple pop ular benchmark domains. Code can be found at https://github.com/facebookresearch /MRSQ.

CrispEdit: Low-Curvature Projections for Scalable Non-Destructive LLM Editing
Zarif Ikram, Arad Firouzkouhi, Stephen Tu, Mahdi Soltanolkotabi, Paria Rashidine jad
A central challenge in large language model (LLM) editing is capability preserva tion: methods that successfully change targeted behavior can quietly game the ed iting proxy and corrupt general capabilities, producing degenerate behaviors rem iniscent of proxy/reward hacking. We present CrispEdit, a scalable and principl ed second-order editing algorithm that treats capability preservation as an expl icit constraint, unifying and generalizing several existing editing approaches. CrispEdit formulates editing as constrained optimization and enforces the constr aint by projecting edit updates onto the low-curvature subspace of the capabilit y-loss landscape. At the crux of CrispEdit is expressing capability constraint via Bregman divergence, whose quadratic form yields the Gauss–Newton Hessian exa ctly and even when the base model is not trained to convergence. We make this se cond-order procedure efficient at the LLM scale using Kronecker-factored approxi mate curvature (K-FAC) and a novel matrix-free projector that exploits Kronecker structure to avoid constructing massive projection matrices. Across standard mo del-editing benchmarks and safety unlearning tasks, CrispEdit achieves high edit success while keeping capability degradation below 1% on average across dataset s, significantly improving over prior editors.

Fixed Aggregation Features Can Rival GNNs
Celia Rubio-Madrigal, Rebekka Burkholz
Graph neural networks (GNNs) are widely believed to excel at node representation learning through trainable neighborhood aggregations. We challenge this view by introducing Fixed Aggregation Features (FAFs), a training-free approach that tr ansforms graph learning tasks into tabular problems. This simple shift enables t he use of well-established tabular methods, offering strong interpretability and

the flexibility to deploy diverse classifiers. Across 14 benchmarks, well-tuned multilayer perceptrons trained on FAFs rival or outperform state-of-the-art GNNs and graph transformers on 12 tasks—often using only mean aggregation. The only exceptions are the Roman Empire and Minesweeper datasets, which typically require unusually deep GNNs. To explain the theoretical possibility of non-trainable aggregations, we connect our findings to Kolmogorov–Arnold representations and discuss when mean aggregation can be sufficient. In conclusion, our results call for (i) richer benchmarks benefiting from learning diverse neighborhood aggregations, (ii) strong tabular baselines as standard, and (iii) employing and advancing tabular models for graph data to gain new insights into related tasks.

Scaling Unsupervised Multi-Source Federated Domain Adaptation through Group-Wise Discrepancy Minimization
Larissa Reichart, Cem Ata Baykara, Ali Burak Ünal, Harlin Lee, Mete Akgün
Unsupervised multi-source domain adaptation (UMDA) leverages labeled data from multiple source domains to generalize to an unlabeled target. While federated UMDA addresses privacy by avoiding raw data sharing, existing methods scale poorly as the number of sources increases, often suffering from high computational overhead or training instability. We propose GALA, a scalable and robust federated UMDA framework designed for high-diversity settings. GALA achieves scalability by coupling a novel inter-group discrepancy minimization objective that approximates pairwise alignment with linear complexity alongside a temperature-controlled, centroid-based weighting strategy for dynamic source prioritization. These components enable stable, parallelizable training across many heterogeneous sources, addressing a critical scalability bottleneck that remains largely unaddressed in current literature. To evaluate performance in high-diversity scenarios, we introduce Digit-18, a new benchmark comprising 18 datasets with varied synthetic and real-world domain shifts. Extensive experiments demonstrate that GALA achieves state-of-the-art results on standard benchmarks and significantly outperforms prior methods in large-scale settings where others either fail to converge or become computationally infeasible.

Good SFT Optimizes for SFT, Better SFT Prepares for Reinforcement Learning
Dylan Zhang, Yufeng Xu, Haojin Wang, Qingzhi Chen, Hao Peng
Post-training of reasoning LLMs is a holistic process that typically consists of an offline SFT stage followed by an online reinforcement learning (RL) stage. However, SFT is often optimized in isolation to maximize SFT performance alone. We show that,
after identical RL training, models initialized from stronger SFT checkpoints can significantly underperform those initialized from weaker ones.
We propose PEAR ($\textbf{P}$olicy $\textbf{E}$valuation–inspired $\textbf{A}$lgorithm for Offline Learning Loss $\textbf{R}$eweighting), an SFT-stage method that corrects this mismatch and better prepares the model for RL.
PEAR uses importance sampling to reweight the SFT loss, with three variants operating at the token, block, and sequence levels.
It can be used to augment standard SFT objectives
and incurs little additional training overhead once probabilities for the offline data are collected.

We conduct controlled experiments on verifiable reasoning games and mathematical reasoning tasks on Qwen2.5/3 and DeepSeek-distilled models. PEAR consistently improves post-RL performance over canonical SFT, with pass@8 gains up to a 14.6% on AIME-2025.
Our results suggest that PEAR is an effective step toward more holistic LLM post-training by designing and evaluating SFT with downstream RL in mind rather than in isolation.

Protein Language Model Embeddings Improve Generalization of Implicit Transfer Operators
Panagiotis Antoniadis, Beatrice Pavesi, Simon Olsson, Ole Winther

Molecular dynamics (MD) is a central computational tool in physics, chemistry, a
nd biology, enabling quantitative prediction of experimental observables as expe
ctations over high-dimensional molecular distributions such as Boltzmann distrib
utions and transition densities. However, conventional MD is fundamentally limit
ed by the high computational cost required to generate independent samples. Gene
rative molecular dynamics (GenMD) has recently emerged as an alternative, learni
ng surrogates of molecular distributions either from data or through interaction
 with energy models. While these methods enable efficient sampling, their transf
erability across molecular systems is often limited. In this work, we show that
 incorporating auxiliary sources of information can improve the data efficiency
and generalization of transferable implicit transfer operators (TITO) for molecu
lar dynamics. We find that coarse-grained TITO models are substantially more dat
a-efficient than Boltzmann Emulators, and that incorporating protein language mo
del (pLM) embeddings further improves out-of-distribution generalization. Our ap
proach, PLaTITO, achieves state-of-the-art performance on equilibrium sampling b
enchmarks for out-of-distribution protein systems, including fast-folding protei
ns. We further study the impact of additional conditioning signals such as struc
tural embeddings, temperature, and large-language-model-derived embeddings on mo
del performance.

Dissecting Post-Training: Uncovering the Complementary Roles of SFT and RL for D
ocument Parsing
Jun-Peng Jiang, An-Yang Ji, Shiyin Lu, Guodong Zheng, Weihong Zhang, Qing-Guo Ch
en, Weihua Luo, Kaifu Zhang, Long Chen, De-Chuan Zhan, Han-Jia Ye
Document parsing, the task of extracting diverse content from PDFs while preserv
ing their structural integrity, has been significantly advanced by Multimodal La
rge Language Models (MLLMs). These models have achieved remarkable success, larg
ely driven by extensive post-training on massive datasets. This paper therefore
undertakes a deep analysis of the two dominant adaptation strategies, Supervised
 Fine-Tuning (SFT) and Reinforcement Learning (RL), prompted by a puzzling obser
vation on the PDF-to-Markdown task: SFT makes a negligible impact, especially on
 parsing complex tables and formulas, while RL achieves substantial overall gain
s. To unravel the reasons, our systematic investigation reveals a clear and comp
lementary division of labor: SFT primarily operates as a structure learner, bias
ed towards mastering the low-entropy syntax of document layouts. While it learns
 the format of a table, it struggles to ensure the fidelity of its high-entropy
cell content. Conversely, RL excels as a content refiner by optimizing a holisti
c reward that reflects final accuracy. We further ground this phenomenon in the
distinct theoretical nature of their respective objective functions. Based on th
ese findings, we introduce a unified strategy that explicitly harnesses their in
dividual strengths while mitigating their weaknesses. This work shows that a dee
p understanding of post-training methods is key to unlocking performance beyond
what data scaling alone can achieve.

On the Expressive Power of Permutation-Equivariant Weight-Space Networks
Adir Dayan, Yam Eitan, Haggai Maron
Weight-space learning studies neural architectures that operate directly on the
parameters of other neural networks. Motivated by the growing availability of pr
etrained models, recent work has demonstrated the effectiveness of weight-space
networks across a wide range of tasks.
SOTA weight-space networks rely on permutation-equivariant designs to improve ge
neralization. However, this may negatively affect expressive power, warranting t
heoretical investigation.
Importantly, unlike other structured domains, weight-space learning targets maps
 operating on both weight and function spaces, making expressivity analysis part
icularly subtle.
While a few prior works provide partial expressivity results, a comprehensive ch
aracterization is still missing. In this work, we address this gap by developing
 a systematic theory for expressivity of weight-space networks.
We first prove that all prominent permutation-equivariant networks are equivalen

t in expressive power. We then establish universality in both weight- and functi on-space settings under mild, natural assumptions on the input weights, and char acterize the edge-case regimes where universality no longer holds.
Guided by our theoretical results, we show that slight modifications to existing weight-space models yield a 34\% improvement over prior SOTA, demonstrating the practical relevance of our framework.

Insertion Based Sequence Generation with Learnable Order Dynamics
Dhruvesh Patel, Benjamin Rozonoyer, Gaurav Pandey, Tahira Naseem, Ramón Fernande z Astudillo, Andrew McCallum
Existing insertion-based masked diffusion models that generate sequences by inte rleaving token insertion with unmasking use fixed schedules that are not depende nt on the data. For structured sequences like graphs and molecules, learning dat a-dependent generation orders can improve generation quality by reducing uncerta inty over the action space. We propose LoFlexMDM, an insertion-based masked diff usion model with learnable order dynamics that learns data-dependent insertion a nd unmasking rates. We generalize the discrete flow matching framework to work w ith variable-length sequences, propose a tractable schedule parameterization and a training objective for joint training of the generator and the target order d ynamics. On De Novo and fragment-constrained molecule generation, LoFlexMDM impr oves sample quality over FlexMDM by up to 17.5% and 6.7%, respectively. These re sults show that learning the target generation order can improve insertion-based diffusion models without giving up tractable training. We open source the code at https://github.com/dhruvdcoder/LoFlexMDM.

Rational Neural Networks have Expressivity Advantages
Maosen Tang, Alex Townsend
We study neural networks with trainable low-degree rational activation functions and show that they are more expressive and parameter-efficient than modern piec ewise-linear and smooth activations such as ELU, LeakyReLU, LogSigmoid, PReLU, R eLU, SELU, CELU, Sigmoid, SiLU, Mish, Softplus, Tanh, Softmin, Softmax, and LogS oftmax. For an error target of $\varepsilon>0$, we establish approximation-theor etic separations: Any network built from standard fixed activations can be unifo rmly approximated on compact domains by a rational-activation network with only $\mathrm{poly}(\log\log(1/\varepsilon))$ overhead in size, while the converse pr ovably requires $\Omega(\log(1/\varepsilon))$ parameters in the worst case. This exponential gap persists at the level of full networks and extends to gated act ivations and transformer-style nonlinearities. In practice, rational activations integrate seamlessly into standard architectures and training pipelines, allowi ng rationals to match or outperform fixed activations under identical architectu res and optimizers.

Factored Value Functions for Graph-Based Multi-Agent Reinforcement Learning
Ahmed Rashwan, Keith Briggs, Chris Budd, Lisa Maria Kreusser
Credit assignment is a core challenge in multi-agent reinforcement learning (MAR L), especially in large-scale systems with structured, local interactions.
Graph-based Markov decision processes (GMDPs) capture such settings via an influ ence graph, but standard critics are poorly aligned with this structure: global value functions provide weak per-agent learning signals, while existing local co nstructions can be difficult to estimate and ill-behaved in infinite-horizon set tings.
We introduce the Diffusion Value Function (DVF), a factored value function for G MDPs that assigns to each agent a value component by diffusing rewards over the influence graph with temporal discounting and spatial attenuation.
We show that DVF is well-defined, admits a Bellman fixed point, and decomposes t he global discounted value via an averaging property.
DVF can be used as a drop-in critic in standard RL algorithms and estimated scal ably with graph neural networks.
Building on DVF, we propose Diffusion A2C (DA2C) and a sparse message-passing ac tor, Learned DropEdge GNN (LD-GNN), for learning decentralised algorithms under

communication costs.
Across the firefighting benchmark and three distributed computation tasks (vecto r graph colouring and two transmit power optimisation problems), DA2C consistent ly outperforms local and global critic baselines, improving average reward by up to 11%.

From Player to Master: Enhancing Test-Time Learning of LLM Agents via Reinforcem ent Learning over Memory
Yishuo Cai, Xingyu Guo, Xuancheng Huang, Jinhua Du, can huang, Wenxuan Huang, We nhan Ma, Yuyang Hu, Aohan Zeng, Jie Tang, Xu Sun
Large language model (LLM) agents are increasingly deployed in long-running sett ings where improving through experience at test time becomes important. A common approach is to update an explicit memory after each interaction to guide future decisions. However, most existing methods rely on hand-designed prompting rules , making it difficult to align memory updates with downstream objectives over mu lti-step horizons consistently. We propose MemoPilot, a plug-in memory copilot that explicitly trains the memory update process to improve a frozen LLM's perfo rmance across sequential interactions. We formulate memory updating as a multi-t urn decision problem and optimize it end-to-end with multi-turn GRPO. Our traini ng recipe introduces (i) a turn-wise reward signal and (ii) a context-independen t, turn-level advantage estimation across rollouts, enabling finer-grained credi t assignment and more stable training in multi-turn settings. We evaluate MemoPi lot on two testbeds: multi-round Rock-Paper-Scissors (RPS) and Limit Texas Hold' em (LHE). Across both environments, MemoPilot substantially improves test-time l earning of a frozen player over strong baselines, ranking first in Elo ratings o n both games (1762 on LHE and 1590 on RPS) and outperforming all baseline memory methods and proprietary models, including Deepseek-V3.2. Our code is publicly a vailable.

Global Geometry Is Not Enough for Vision Representations
Jiwan Chung, Seon Joo Kim
A common assumption in representation learning is that globally well-distributed embeddings support robust and generalizable representations. This focus has sha ped both training objectives and evaluation protocols, implicitly treating globa l geometry as a proxy for representational competence. While global geometry eff ectively encodes which elements are present, it is often insensitive to how they are composed. We investigate this limitation by testing the ability of geometri c metrics to predict compositional binding across 21 vision encoders. We find th at standard geometry-based statistics exhibit near-zero correlation with composi tional binding. In contrast, functional sensitivity, as measured by the input-ou tput Jacobian, reliably tracks this capability. We further provide an analytic a ccount showing that this disparity arises from objective design, as existing los ses explicitly constrain embedding geometry but leave the local input-output map ping unconstrained. These results suggest that global embedding geometry capture s only a partial view of representational competence and establish functional se nsitivity as a critical complementary axis for modeling composite structure.
****
Semi-Supervised Learning with Noisy Proxy Covariates: Generalization Bounds and Distribution Regression
Kwangho Kim, Jisu Kim
In many modern machine learning pipelines, abundant pretrained representations s erve as noisy proxy covariates, while task-specific labels remain scarce. We stu dy semi-supervised regression in this setting, and propose a simple two stage es timator that learns kernel eigenfeatures from all proxy covariates and fits a ri dge predictor on labeled data. We derive finite sample bounds showing that fast labeled sample rates are recovered when proxy perturbation is controlled and unl abeled proxy covariates are sufficiently abundant. We also show that distributio n regression is a direct special case, with analogous guarantees when the finite bag size is large enough. Experiments show consistent gains over supervised and semi-supervised baselines, especially in low label regimes.

PyHealth 2.0: A Comprehensive Open-Source Toolkit for Accessible and Reproducible Clinical Deep Learning
John Wu, Yongda Fan, Zhenbang Wu, Paul Landes, Eric Schrock, Sayeed Sajjad Razin, Arjun Chatterjee, Naveen Baskaran, Joshua Steier, Andrea Fitzpatrick, Bilal Arif, Rian Atri, Jathurshan Pradeepkumar, Siddhartha Laghuvarapu, Junyi Gao, Adam Richard Cross, Jimeng Sun
Difficulty replicating baselines, high computational costs, and required domain expertise create persistent barriers to clinical AI research. To address these challenges, we introduce PyHealth 2.0, an enhanced clinical deep learning toolkit that enables predictive modeling in as few as 7 lines of code. PyHealth 2.0 offers three key contributions: (1) a comprehensive toolkit addressing reproducibility and compatibility challenges by unifying 15+ datasets, 20+ clinical tasks, 25+ models, 5+ interpretability methods, and uncertainty quantification including conformal prediction within a single framework that supports diverse clinical data modalities—signals, imaging, and electronic health records—with translation of 5+ medical coding standards; (2) accessibility-focused design accommodating multimodal data and diverse computational resources with up to 39× faster processing and 20× lower memory usage, enabling work from 16GB laptops to production systems; and (3) an active open-source community of 400+ members lowering domain expertise barriers through extensive documentation, reproducible research contributions, and collaborations with academic health systems and industry partners, including multi-language support via RHealth. PyHealth 2.0 establishes an open-source foundation and community advancing accessible, reproducible healthcare AI.

Don't Ignore the Tail: Decoupled Distillation Produces Top Maths Students on an Academic Budget
Sayantan Dasgupta, Trevor Cohn, Timothy Baldwin
The core learning signal used in language model distillation is the standard Kullback-Leibler (KL) divergence between the student and teacher distributions. Traditional KL divergence tends to be dominated by the teacher’s highest-probability modes, thereby diminishing the influence of less-probable yet potentially informative components of the output distribution. We propose a new tail-aware divergence that decouples the contribution of the teacher model's top-K predicted probabilities from that of lower-probability predictions, while maintaining the same computational profile as the KL Divergence. Our decoupled approach reduces the impact of teacher modes and, consequently, increases the contribution of the distribution's tail. Experimental results demonstrate that our modified distillation method yields competitive performance in both pre-training and supervised distillation for mathematical reasoning of decoder models across various datasets. Furthermore, the distillation process is efficient and can be performed on modest academic budgets for large datasets, drastically reducing the computational costs typically associated with large-scale distillation.
****
Constrained Adaptive Rejection Sampling
Pawe■ Parys, Sairam Vaidya, Taylor Berg-Kirkpatrick, Loris D'Antoni
Language Models (LMs) are increasingly used in applications where generated outputs must satisfy strict semantic or syntactic constraints. Existing approaches to constrained generation fall along a spectrum: greedy constrained decoding methods enforce validity during decoding but distort the LM’s distribution, while rejection sampling (RS) preserves fidelity but wastes computation by discarding invalid outputs. Both extremes are problematic in domains such as program fuzzing, where both *validity* and *diversity* of samples are essential. We present *Constrained Adaptive Rejection Sampling* (CARS), an approach that strictly improves the sample-efficiency of RS without distributional distortion. CARS begins with unconstrained LM sampling and adaptively rules out constraint-violating continuations by recording them in a trie and subtracting their probability mass from future draws. This adaptive pruning ensures that prefixes proven invalid are never revisited, acceptance rates improve monotonically, and the resulting samples exactly follow the constrained distribution. In experiments on a variety of domai

ns---e.g., program fuzzing and molecular generation---CARS consistently achieves higher efficiency---measured in the number of LM forward passes per valid sample---while also producing stronger sample diversity than both Greedy Constrained Decoding (GCD) and methods that approximate the LM's distribution.

Test-time Generalization for Physics through Neural Operator Splitting

Louis Serrano, Jiequn Han, Edouard Oyallon, Shirley Ho, Rudy Morel

Neural operators have shown promise in learning solution maps of partial differential equations (PDEs), but they often struggle to generalize when test inputs lie outside the training distribution, such as novel initial conditions, unseen PDE coefficients or unseen physics.

Prior works address this limitation with large scale multi physics pretraining followed by fine tuning, but this still requires examples from the new dynamics, falling short of true zero shot generalization. In this work, we propose a method to enhance generalization at test-time, i.e, without modifying pretrained weights. Building on DISCO, which provides a dictionary of neural operators trained across different dynamics, we introduce a neural operator splitting strategy that, at test time, searches over compositions of training operators to approximate unseen dynamics. On challenging out-of-distribution tasks including parameter extrapolation and novel combinations of physics phenomena, our approach achieves state-of-the-art zero shot generalization results, while being able to recover the underlying PDE parameters. These results underscore test-time computation as a key avenue for building flexible, compositional, and generalizable neural operators.

D^3: Dynamic Directional Graph-Constrained Data Scheduling for LLM Training

Yuanjian Xu, Jianing Hao, Guang Zhang, Zhong Li

Training data plays a central role in large language models (LLMs) optimization, motivating extensive research on data scheduling strategies.

Most existing approaches concentrate on adjusting the overall data distribution but neglect the underlying interactions between samples during training.

However, we argue that such interactions cannot be overlooked, as real-world data samples frequently exhibit directional influences on each other, making the training order crucial.

Intuitively, we can prioritize train-units with greater influence to improves learning efficiency.

In this work, we propose D^3, a **D**ynamic, **D**irectional graph-constrained **D**ata scheduling framework. D^3 formulates the complex interactions among train-units as a dynamic influence graph, where edges represent loss-based dependencies. It then solves a constrained optimization problem over this graph to derive the training order, which ensures that the data sequence respects the evolving information flow throughout training.

Our approach is theoretically motivated and yields consistent improvements over existing data scheduling methods across both pre-training and post-training phases. Furthermore, for scalability, D^3 also employs an efficient approximation algorithm that keeps the additional computational overhead within a manageable range. For future research, the code is available at https://github.com/xuyj233/D3.

Iterated Population Based Training with Task-Agnostic Restarts

Alexander Chebykin, Tanja Alderliesten, Peter Bosman

Hyperparameter Optimization (HPO) can lift the burden of tuning hyperparameters (HPs) of neural networks. HPO algorithms from the Population Based Training (PBT) family are efficient thanks to dynamically adjusting HPs every few steps of the weight optimization. Recent results indicate that the number of steps between HP updates is an important meta-HP of all PBT variants that can substantially affect their performance. Yet, no method or intuition is available for efficiently setting its value. We introduce Iterated Population Based Training (IPBT), a novel PBT variant that automatically adjusts this HP via restarts that reuse weight information in a task-agnostic way and leverage time-varying Bayesian optimiza

tion to reinitialize HPs.
Evaluation on 8 image classification and reinforcement learning tasks shows that , on average, our algorithm matches or outperforms 5 previous PBT variants and o ther HPO algorithms (random search, ASHA, SMAC3), without requiring a budget inc rease or any changes to its HPs. The source code is available online.

Beyond Next-Token Alignment: Distilling Multimodal Large Language Models via Tok en Interactions
Lin Chen, Xiaoke Zhao, Kun Ding, Weiwei Feng, Changtao Miao, Zili Wang, Wenxuan Guo, Ying Wang, Kaiyuan Zheng, Bo Zhang, Zhe Li, Shiming Xiang
Multimodal Large Language Models (MLLMs) demonstrate impressive cross-modal capa bilities, yet their substantial size poses significant deployment challenges. Kn owledge distillation (KD) is a promising solution for compressing these models, but existing methods primarily rely on static next-token alignment, neglecting t he dynamic token interactions, which embed essential capabilities for multimodal understanding and generation. To this end, we introduce **Align-TI**, a novel K D framework designed from the perspective of **T**oken **I**nteractions. Our app roach is motivated by the insight that MLLMs rely on two primary interactions: v ision-instruction token interactions to extract relevant visual information, and intra-response token interactions for coherent generation. Accordingly, Align-T I introduces two components: IVA enables the student model to imitate the teache r's instruction-relevant visual information extract capability by aligning on sa lient visual regions. TPA captures the teacher's dynamic generative logic by ali gning the sequential token-to-token transition probabilities. Extensive experime nts demonstrate Align-TI's superiority. Notably, our approach achieves 2.6% rela tive improvement over Vanilla KD, and our distilled Align-TI-2B even outperforms LLaVA-1.5-7B (a much larger MLLM) by 7.0%, establishing a new state-of-the-art distillation framework for training parameter-efficient MLLMs.
****
LAST: Bridging Vision-Language and Action Manifolds via Gromov-Wasserstein Align ment
Huaihai Lyu, Chaofan Chen, Yuheng Ji, Xiansheng Chen, Pengwei Wang, Shanghang Zh ang, Changsheng Xu
We formulate the learning of generalist Vision-Language-Action (VLA) models as a Gromov-Wasserstein alignment problem, aiming to map semantically similar VL emb eddings to physically similar motion primitives. However, solving this is challe nging due to the mathematical heterogeneity between the domains: the semantic sp ace of vision-language is topologically linear and isotropic, while the physical manifold of robotic action is non-Euclidean and anisotropic. As a result, direc t regression approaches fail due to the disjoint metric structures of these doma ins, making standard distance minimization ill-posed.

To resolve this incompatibility, we introduce LAST (Lie-algebraic Action Space T okenizer). LAST reconstructs the action space to establish a more consistent met ric alignment between the VL and Action modalities. Specifically, LAST bridges t he heterogeneity via two stages: (1) *Global Topological Linearization*, which l inearizes the action manifold through Lie-algebraic mapping, converting trajecto ries into a fixed-length, physically additive representation; and (2) *Local Met ric Discretization*, where the representation is discretized hierarchically into schemas and whitened residuals, establishing a mathematical isomorphism with th e isotropic Euclidean metric. By addressing the structural mismatch globally and locally, LAST enables VLA models with enhanced convergence and generalizability .

E2Former-V2: On-the-Fly Equivariant Attention with Linear Activation Memory
Lin Huang, Chengxiang Huang, Ziang Wang, Yiyue Du, Chu Wang, Haocheng Lu, Yunyan g Li, Xiaoli LIU, Arthur JIANG, Jia Zhang
Equivariant Graph Neural Networks (EGNNs) have become a widely used approach for modeling 3D atomistic systems. However, mainstream architectures face critical efficiency bottlenecks due to the explicit construction of geometric features or

 dense tensor products on \textit{every} edge. To overcome this, we introduce \t
extbf{E2Former-V2}, an efficient architecture that integrates algebraic sparsity
 with hardware-aware execution.
We introduce \textbf{Equivariant Axis-Aligned Sparsification (EAAS)}, which leve
rages an $\mathrm{SO}(3)\!\rightarrow\!\mathrm{SO}(2)$ change of basis to conver
t dense Wigner-$6j$ tensor contractions into sparse, parity-based re-indexing op
erations.
Building on this representation, we propose \textbf{On-the-Fly Equivariant Atten
tion}, a fully node-centric mechanism implemented via a fused Triton kernel.
By eliminating materialized edge tensors and maximizing SRAM utilization, our ke
rnel achieves up to \textbf{20$\times$ higher TFLOPS} than standard implementati
ons.
Experiments on SPICE and OMol25 show that E2Former-V2 preserves predictive accur
acy while substantially accelerating inference, demonstrating the practical feas
ibility of large equivariant transformers on commodity GPUs. Our released code c
an be found at \url{https://github.com/IQuestLab/UBio-MolFM/tree/main}

Towards One-for-All Anomaly Detection for Tabular Data
Shiyuan Li, Yixin Liu, Yu Zheng, Xiaofeng Cao, Shirui Pan, Heng Tao Shen
Tabular anomaly detection (TAD) aims to identify samples that deviate from the m
ajority in tabular data and is critical in many real-world applications. However
, existing methods follow a ``one model for one dataset (OFO)'' paradigm, which
relies on dataset-specific training and thus incurs high computational cost and
yields limited generalization to unseen domains. To address these limitations, w
e propose OFA-TAD, a generalist one-for-all (OFA) TAD framework that only requir
es one-time training on multiple source datasets and can generalize to unseen da
tasets from diverse domains on-the-fly. To realize one-for-all tabular anomaly d
etection, OFA-TAD extracts neighbor-distance patterns as transferable cues, and
introduces multi-view neighbor-distance representations from multiple transforma
tion-induced metric spaces to mitigate the transformation sensitivity of distanc
e profiles. To adaptively combine multi-view distance evidence, a Mixture-of-Exp
erts (MoE) scoring network is employed for view-specific anomaly scoring and ent
ropy-regularized gated fusion, with a multi-strategy anomaly synthesis mechanism
 to support training under the one-class constraint. Extensive experiments on 34
 datasets from 14 domains demonstrate that OFA-TAD achieves superior anomaly det
ection performance and strong cross-domain generalizability under the strict OFA
 setting. The source code is available at https://github.com/Shiy-Li/OFA-TAD.

Knothe-Rosenblatt Quantile Regression for Risk-sensitive Multi-objective Reinfor
cement Learning
Gwangpyo Yoo, Woo Kyung Kim, Honguk Woo
In this work, we extend distributional reinforcement learning (RL) to develop a
risk-sensitive multi-objective RL framework, with applications to domains such a
s finance and robotics. We achieve this by adopting vector-risk measures and app
roximating them via Knothe-Rosenblatt (KR) quantile regression. This approach di
rectly extends the IQN framework to the multi-objective setting, aligns with the
 axiomatic definition of vector-risk measures, and guarantees that critics conve
rge under the distributional Bellman operator. To mitigate the artificial orderi
ng imposed by the KR map, we employ a transformer architecture without positiona
l encoding, and introduce MO-TQC for training stability. We demonstrate improved
 performance on MO-Gymnasium benchmarks and use our framework to study risk-sens
itive policies in multi-objective tasks.
****

Transport Clustering: Solving Low-Rank Optimal Transport via Clustering
Henri Schmidt, Peter Halmos, Benjamin Raphael
Optimal transport (OT) finds a least-cost transport plan between two probability
 distributions. Unlike standard OT, which infers unstructured pointwise mappings
, low-rank optimal transport explicitly constrains the rank of the transport pla
n to infer latent structure. This improves statistical robustness, yields sharpe
r parametric rates for estimating Wasserstein distances, and generalizes K-mea

ns to co-clustering. However, these advantages come at the cost of a non-convex and NP-hard optimization problem. We introduce Transport Clustering, an algorithm to compute a low-rank OT plan that reduces low-rank OT to a clustering problem on correspondences obtained from a full-rank transport registration step. We prove that this reduction yields polynomial-time, constant-factor approximation algorithms for low-rank OT: specifically, a $(1+\gamma)$ approximation for negative-type metrics, a $(1+\gamma+\sqrt{2\gamma}\,)$ approximation for kernel costs, and a $(1+\gamma+\rho)$ approximation for general metrics satisfying the triangle inequality. Here, $\gamma \in [0,1]$ is the cost
ratio of the optimal full-rank to low-rank solutions, and $\rho\in[0,1]$ is an asymmetry coefficient on the cluster variances. Numerically, Transport Clustering outperforms existing solvers on synthetic benchmarks and large-scale datasets.
****

Expectation Consistency Loss: Rethink Confidence Calibration under Covariate Shift

Jinzong Dong, Zhaohui Jiang, Bo Yang

Confidence calibration for classification models is vital in safety-critical decision-making scenarios and has received extensive attention. General confidence calibration methods assume training and test data are independent and identically distributed ($i.i.d.$), limiting their effectiveness under covariate shifts. Previous calibration methods under covariate shift struggle with class-wise or canonical calibrations and often rely on unstable importance weighting when density ratios are large or unbounded. Given the above limitations, this paper rethinks confidence calibration under covariate shifts. First, we derive a necessary and sufficient condition for confidence calibration under covariate shifts, named Expectation consistency condition, which reveals covariate shifts do not necessarily lead to uncalibrated confidence and provides a weaker condition for confidence calibration than global covariate distribution alignment. Then, utilizing Expectation consistency condition, this paper proposes an unsupervised domain adaptation loss to calibrate confidence of the target domain, named Expectation consistency loss (ECL), which is compatible with canonical calibration, class-wise calibration, and top-label calibration. Third, we prove that computing ECL loss has the same sample complexity as Expected Calibration Error (ECE) and provide a theoretically grounded mini-batch trainable scheme for ECL loss. Finally, we validate the effectiveness of our method on both simulated and real-world covariate shift datasets.

How to Guide Your Flow: Few-Step Alignment via Flow Map Reward Guidance

Jerry Yuyang Huang, Justin Lin, Sheel Shah, Kartik Nair, Nicholas Matthew Boffi

In generative modeling, we often wish to produce samples that maximize a user-specified reward such as aesthetic quality or alignment with human preferences, a problem known as guidance. Despite their widespread use, existing guidance methods either require expensive multi-particle, many-step schemes or rely on poorly understood approximations. We reformulate guidance as a deterministic optimal control problem, yielding a hierarchy of algorithms that subsumes existing approaches at the coarsest level. We show that the flow map, an object of significant recent interest for its role in fast inference, arises naturally in the optimal solution. Based on this observation, we propose Flow Map Reward Guidance (FMRG): a training-free, single-trajectory framework that uses the flow map to both integrate and guide the flow. At text-to-image scale, FMRG matches or surpasses baselines across inverse problems and reward-guided generation with as few as 3 NFEs, giving at least an order-of-magnitude speedup in comparison to prior state of the art.

DDP-WM: Disentangled Dynamics Prediction for Efficient World Models

Shicheng Yin, Kaixuan Yin, Weixing Chen, Yang Liu, Guanbin Li, Liang Lin

World models are essential for autonomous robotic planning. However, the substantial computational overhead of existing dense Transformer-based models significantly hinders real-time deployment. To address this efficiency-performance bottleneck, we introduce DDP-WM, a novel world model centered on the principle of Dise

ntangled Dynamics Prediction (DDP). We hypothesize that latent state evolution i
n observed scenes is heterogeneous and can be decomposed into sparse primary dyn
amics driven by physical interactions and secondary context-driven background up
dates. DDP-WM realizes this decomposition through an architecture that integrate
s efficient historical processing with dynamic localization to isolate primary d
ynamics. By employing a cross-attention mechanism for background updates, the fr
amework optimizes resource allocation and provides a smooth optimization landsca
pe for planners. Extensive experiments demonstrate that DDP-WM achieves superior
 efficiency and performance across diverse tasks, including navigation, precise
tabletop manipulation, and complex deformable or multi-body interactions. Specif
ically, on the challenging Push-T task, DDP-WM achieves an approximately 9 times
 inference speedup and improves the MPC success rate from 90% to 98% compared to
 state-of-the-art dense models.

Taming the Recent-Data Bias: Towards Robust Time Series Forecasting with Global
Context

Longlong Xu, Zeyan Li, Xiao He, Zhaoyang Yu, Changhua Pei, Zhe Xie, Zijun Dou, T
ieying Zhang, Dan Pei

Time series forecasting plays a vital role in numerous domains. However, real-wo
rld time series are frequently contaminated by noise, missing values, and anomal
ies, posing significant challenges to reliable forecasting. In this work, we fir
st systematically investigate a fundamental limitation prevalent in existing for
ecasting methods: an excessive reliance on the most recent observations---termed
 "recent-data bias". This bias renders forecasts highly vulnerable to perturbati
ons in recent data, severely undermining prediction reliability. To address this
 issue, we propose TameR, a novel approach for robust time series forecasting th
at effectively mitigates recent-data bias via enhancing the utilization of globa
l context. Specifically, it employs a basis-aligned randomized sampling strategy
 to reduce dependence on any specific recent data. Furthermore, TameR incorporat
es a learnable periodicity extraction module coupled with a two-stage learning p
rotocol to robustly separate periodic patterns from the sampled residual compone
nts. Comprehensive experiments demonstrate that TameR significantly outperforms
state-of-the-art methods in robustness against diverse perturbation scenarios, w
hile achieving comparable accuracy on clean data. Code is available at https://g
ithub.com/NetManAIOps/TameR.

SARL: Structure-Aligned Reinforcement Learning for Bridging the Perception-Actio
n Gap in Airspace

Binhao Gu, jinjun cai, Weihuang Zheng, Jiaxing Li, Youyong Kong, Hui Ding

Multi-Agent Reinforcement Learning (MARL) has been widely applied to automated a
ircraft conflict resolution due to its strong capability for cooperative control
 and distributed decision-making. However, existing approaches typically assume
a fixed number of aircraft and neglect the unique characteristics of air traffic
 control instructions. This structural misalignment between model architectures
and domain requirements leads to severe deficiencies in perception scalability a
nd action stability across scenarios of varying scales. To address these challen
ges, we propose Structural-Aligned Reinforcement Learning (SARL), which aims to
bridge the gap between perception and action. First, the Physics-Encoded Relatio
nal Graph (PERG) effectively resolves the fixed input dimensionality issue by in
corporating physical inductive biases into a graph attention mechanism. Second,
we design the Sparse Cognitive Mixture-of-Experts (SC-MoE) to enhance decision s
tability. In addition, we introduce a Kinematic Kafety Shield (KSS) based on avi
ation rules, which not only improves inference-time safety but also effectively
guides the model to generate semantically meaningful actions that comply with av
iation standards. Simulation experiment results demonstrate that SARL significan
tly outperforms existing reinforcement learning baselines across diverse scenari
os in terms of both success rate and operational efficiency.

Provably Learning Attention with Queries

Satwik Bhattamishra, Kulin Shah, Michael Hahn, Varun Kanade

We study the problem of learning Transformer-based sequence models with black-box access to their outputs. In this setting, a learner may adaptively query the oracle with any sequence of vectors and observe the output of the target function. We begin with studying the learnability of the simplest formulation, that is, learning a single-head attention-based regressor with queries. We show that for a model with width d, there is an elementary algorithm to learn the parameters of single-head attention with $O(d^2)$ queries. Further, we show that if there exists an algorithm to learn ReLU feedforward networks (FFNs), then the single-head algorithm can be easily adapted to learn one-layer Transformers with single-head attention. Next, we show that, in the common regime where the head dimension $r \ll d$, single-head attention-based models can be learned with $O(rd)$ queries via compressed sensing arguments. We also study robustness to noisy oracle access, proving that under mild norm and margin conditions, the parameters can be estimated to ε accuracy with a polynomial number of queries even when outputs are only provided up to additive tolerance. Finally, we consider the learnability of multi-head attention and show that they are not identifiable from queries, and hence, learnability in the same sense is not feasible without additional assumptions. We discuss potential approaches to learn multi-head attention-based models under certain structural assumptions.

DeepSight: Long-Horizon World Modeling via Latent States Prediction for End-to-End Autonomous Driving

Lingjun Zhang, Changjie Wu, Linzhe Shi, Jiangyang Li, Jiaxin Liu, Lei Yang, Hang Zhang, Mu Xu, Hong Wang

End-to-end autonomous driving systems are increasingly integrating Vision-Language Model (VLM) architectures, incorporating text reasoning or visual reasoning to enhance the robustness and accuracy of driving decisions.

However, the reasoning mechanisms employed in most methods are direct adaptations from general domains, lacking in-depth exploration tailored to autonomous driving scenarios, particularly within visual reasoning modules. In this paper, we propose a driving world model that performs parallel prediction of latent semantic features for consecutive future frames in the bird’s-eye-view (BEV) space, thereby enabling long-horizon modeling of future world states. We also introduce an efficient and adaptive text reasoning mechanism that utilizes additional social knowledge and reasoning capabilities to further improve driving performance in challenging long-tail scenarios. We present a novel, efficient, and effective approach that achieves state-of-the-art (SOTA) results on the closed-loop Bench2drive benchmark. Codes are available at: https://github.com/hotdogcheesewhite/DeepSight.

Where Detectors Fail: Probing Generative Space for Generalizable AI-Generated Image Detection

Zijie Cao, Weijie Tu, Yao Xiao, Weijian Deng, Weiyan Chen, Liang Lin, Pengxu Wei

Detecting AI-generated images (AIGI) remains challenging because detectors often fail to generalize to unseen generators. Although existing methods are trained on large datasets, their performance still degrades when generation settings change, indicating that data scale alone is insufficient and that limited coverage of generative variations during training is a key factor. Studies on generative model editing show that small changes in internal representations can produce diverse and meaningful image variations, many of which are not explored under standard sampling. Leveraging this insight, we propose PROBE (Probing Robustness via Boundary Exploration), a framework that improves detector generalization by actively exploring challenging regions of the generative process. Instead of treating the generator as a fixed data source, PROBE uses the detector as a critic to steer the generator through manifold-level modifications, producing realistic samples that are difficult to classify. These samples expose failure cases that are uncommon under standard data sampling strategies and are used to refine the detector. Experimental results across multiple benchmarks indicate that PROBE enhances generalization to unseen generators, resulting in more generalizable AIGI detection performance.

****
Sponge Tool Attack: Stealthy Denial-of-Efficiency against Tool-Augmented Agentic Reasoning
Qi Li, Xinchao Wang
Enabling large language models (LLMs) to solve complex reasoning tasks is a key step toward artificial general intelligence. Recent work augments LLMs with external tools to enable agentic reasoning, achieving high utility and efficiency in a plug-and-play manner. However, the inherent vulnerabilities of such methods to malicious manipulation of the tool-calling process remain largely unexplored. In this work, we identify a tool-specific attack surface and propose Sponge Tool Attack (STA), which disrupts agentic reasoning solely by rewriting the input prompt under a strict query-only access assumption. Without any modification on the underlying model or the external tools, STA converts originally concise and efficient reasoning trajectories into unnecessarily verbose and convoluted ones before arriving at the final answer. This results in substantial computational overhead while remaining stealthy by preserving the original task semantics and user intent. To achieve this, we design STA as an iterative, multi-agent collaborative framework with explicit rewritten policy control, and generates benign-looking prompt rewrites from the original one with high semantic fidelity. Extensive experiments across 6 models (including both open-source models and closed-source APIs), 12 tools, 4 agentic frameworks, and 13 datasets spanning 5 domains validate the effectiveness of STA.
****
STRIDE: Post-Training LLMs to Reason and Refine Bio-Sequences via Edit Trajectories
Daiheng Zhang, Shiyang Zhang, Sizhuang He, Yangtian Zhang, Syed A Rizvi, David van Dijk
Discrete biological sequence optimization often requires goal-directed, parser-valid edits to an existing protein or molecule. Diffusion models support iterative refinement but do not
  expose a controllable discrete-edit interface, while autoregressive LLMs can be myopic when planning constrained edits over multiple steps. We introduce *STRIDE* (Sequence Trajectory
  Refinement via Iterative Discrete Editing), a post-training framework that trains an LLM to emit executable INSERT/DELETE/REPLACE trajectories for variable-length refinement. *STRIDE*
  first learns Levenshtein-aligned shortest-edit demonstrations, then uses supervised fine-tuning and group-based policy optimization to align trajectories with task rewards while
  preserving coherent editing. On an oracle-based full-action protein stress test, *STRIDE* raises success over Vanilla SFT from 42% to 89% and novelty among unique improvements from 47%
  to 97%. On instruction-conditioned molecular editing, the GSPO-aligned variant improves strict success, controllability, and SMILES validity over the SFT-only *STRIDE* model (code:
  https://github.com/daiheng-zhang/STRIDE).
****
Generalized Correctness Models: Learning Calibrated and Cross-Model Correctness Predictors from Historical Patterns
Hanqi Xiao, Vaidehi Patil, Hyunji Lee, Elias Stengel-Eskin, Mohit Bansal
Generating accurate and calibrated confidence estimates is critical for deploying LLMs in high-stakes or user-facing applications, and remains an open challenge. Prior research has often framed confidence as a problem of eliciting a model's "self-knowledge", i.e., the ability of an LLM to judge whether its own answers are correct; this approach implicitly assumes that there is some privileged information about the answer's correctness that is accessible to the model itself. However, we find that whether trained or training-free, an LLM attempting to predict the correctness of its own outputs generally performs no better than an unrelated LLM attempting the same task. Moreover, we hypothesize that a key factor in predicting model correctness, i.e., building a "Correctness Model" (CM), is ex

posure to a target model’s historical predictions. We use multiple methods to in ject this historical correctness information, including training an LLM to predi ct the confidences of many other LLMs, i.e., creating a Generalized Correctness Model (GCM). We use GCMs and CMs as a lens for studying the source of correctnes s prediction ability and its generalization, studying the importance of answer p hrasing, world-knowledge, performance history, in-context examples, and post-hoc calibration for correctness prediction. We evaluate GCMs based on Qwen3-8B acro ss 5 model families and the MMLU, TriviaQA, and Spider datasets, as well as on a downstream selective prediction task, finding that reliable LLM confidence esti mation is a cross-model skill learned by encoding correctness history rather tha n a model-specific skill reliant on introspection. Code: https://github.com/The-Inscrutable-X/CalibratedModelAgnosticCorrectness.

CoGeoAD: Hierarchical Color-Geometric Fusion with Multi-View Attention for Zero-Shot 3D Anomaly Detection

Ke Xu, Xinle Wang, Yanning Hou, Xueliang Ma, Juan Xie, Jianfeng Qiu

Zero-shot 3D anomaly detection is essential for industrial quality inspection, w here labeled anomaly samples are scarce. Meanwhile, existing methods lack an eff ective mechanism to fuse complementary 2D color images with 3D geometric structu res, limiting their ability to detect both surface and structural defects in a u nified framework. To address these issues, we propose CoGeoAD, a unified CLIP-ba sed framework that fuses color and geometric features by constructing pixel-alig ned paired multi-view images. The framework introduces a Data-Driven Multi-View Attention (MVA) mechanism to adaptively aggregate 3D features and a Multi-Stage Color-Geometric Fusion (MS-CGF) module to hierarchically integrate multi-level f eatures from both modalities. Extensive experiments on the MVTec3D-AD and Eyecan dies benchmarks demonstrate that CoGeoAD achieves state-of-the-art performance, effectively capturing both structural and textural anomalies in complex industri al scenarios.

Truthfulness Does Not Scale Like Reasoning: Why Polling Fails as a Proxy Verifie r

Yegor Denisov-Blanch, Joshua Kazdan, Jessica Chudnovsky, Rylan Schaeffer, Sheng Guan, Soji Adeshina, Sanmi Koyejo

Pass@k and other methods of scaling inference compute can improve language mod el performance in domains with external verifiers, including mathematics and cod e, where incorrect candidates can be filtered reliably. This raises a natural qu estion: can we similarly scale compute to elicit gains in truthfulness for domai ns without convenient verification? We show that across five benchmarks and mode ls, surprisingly, it cannot. Even at $25\times$ the inference cost of naive samp ling, polling-style aggregation yields no consistent accuracy gains over single-sample baselines and often amplifies correlated errors. We find that under uncer tainty, models are better at predicting what other models will say within model ensembles than at identifying what is true, revealing a separation between socia l prediction and truth verification. Across models and benchmarks, aggregation fails to provide a robust truth signal because language model errors are strongl y correlated. The source of correlation goes beyond any individual benchmark: w e show that even when conditioned on out of distribution random strings and aske d to produce pseudo-random outputs, different models produce correlated outputs. Confidence-based weighting provides no benefit because self-reported confidence fails to reliably distinguish correct from incorrect answers.

These results delineate a boundary for inference-time scaling: in verified domai ns, additional samples provide more candidates for a verifier to filter; in unve rified domains, additional samples merely reinforce correlated errors.

Differentiable Weightless Controllers: Learning Logic Circuits for Continuous Co ntrol

Fabian Kresse, Christoph H. Lampert

Controlling autonomous systems under real-world conditions often requires polici es that can be evaluated with low latency and minimal energy consumption. Unfort

unately, these conditions are at odds with the use of high-precision deep neural networks as controllers. In this work, we introduce Differentiable Weightless Controllers (DWCs), a symbolic-differentiable architecture that learns flexible, non-linear, yet highly efficient control policies. DWCs can be trained end-to-end via gradient-based techniques, yet compile directly into FPGA-compatible circuits with few- or even single-clock-cycle latency and nanojoule-level energy cost per action. Across five MuJoCo benchmarks, including high-dimensional Humanoid, DWCs achieve returns competitive with standard deep policies (full-precision or quantized neural networks). Furthermore, DWCs exhibit structurally sparse and interpretable connectivity patterns, enabling direct inspection of which input values influence control decisions.

Floating-Point Networks with Automatic Differentiation Can Represent Almost All Floating-Point Functions and Their Gradients
Sejun Park, Yeachan Park, Geonho Hwang
Theoretical studies show that for any differentiable function on a compact domain, there exists a neural network that approximates both the function values and gradients. However, such a result cannot be used in practice since it assumes real parameters and exact internal operations. In contrast, real implementations only use a finite subset of reals and machine operations with round-off errors. In this work, we investigate whether a similar result holds for neural networks under floating-point arithmetic, when the gradient with respect to the input is computed by the automatic differentiation algorithm $D^\mathtt{AD}$. We first show that given a floating-point function ϕ (e.g., a loss function), arbitrary function values and gradients can be represented by a floating-point network f and $D^\mathtt{AD}(\phi\circ f)$, respectively. We further extend this result: given $\phi_1,\dots,\phi_n$, $D^\mathtt{AD}(\phi_i\circ f)$ can simultaneously represent arbitrary gradients while f represents the target values, under mild conditions. Our results hold for practical activation functions, e.g., ReLU, ELU, GELU, Swish, Sigmoid, and tanh.

NeurOCNN: A Neural-Operator-Based Model for Physiological Time Series
Daya Kumar, Uday Devulapalli, Aarat Satsangi, Apurva Narayan
Neural operators have become a central tool in scientific machine learning for learning discretization-consistent solution operators, achieving strong results on partial differential equation (PDE) benchmarks. Physiological time series, however, are highly nonstationary and dominated by localized transient events, properties that can challenge both PDE-oriented neural operators and conventional deep models. We propose NeurOCNN, a neural-operator-based model for physiological signals that learns a robust function-to-label mapping. NeurOCNN integrates continuous-time, spline-parameterized convolutions to capture localized morphology with Fourier projection pooling for variable-to-fixed dimensional mapping, thereby enabling robust, discretization-invariant inference under zero-shot sampling-rate shifts. Empirically, NeurOCNN outperforms standard neural-operator baselines, achieves performance comparable to state-of-the-art methods, and maintains stable accuracy across multiple previously unseen evaluation sampling rates. The code is available at https://github.com/Idsl-group/NeurOCNN.

Finite and Corruption-Robust Regret Bounds in Online Inverse Linear Optimization under M-Convex Action Sets
Taihei Oki, Shinsaku Sakaue
We study online inverse linear optimization, also known as contextual recommendation, where a *learner* sequentially infers an *agent*'s hidden objective vector from observed optimal actions over feasible sets that change over time. The learner aims to recommend actions that perform well under the agent's true objective, and the performance is measured by the *regret*, defined as the cumulative gap between the agent's optimal values and those achieved by the learner's recommended actions. Prior work has established a regret bound of $O(d\log T)$, as well as a finite but exponentially large bound of $\exp(O(d\log d))$, where d is the dimension of the optimization problem and T is the time horizon, while a re

gret lower bound of $\Omega(d)$ is known (Gollapudi et al. 2021; Sakaue et al. 2025). Whether a finite regret bound polynomial in d is achievable or not has remained an open question. We partially resolve this by showing that when the feasible sets are *M-convex*—a broad class that includes matroids—a finite regret bound of $O(d\log d)$ is possible. We achieve this by combining a structural characterization of optimal solutions on M-convex sets with a geometric volume argument. Moreover, we extend our approach to adversarially corrupted feedback in up to C rounds. We obtain a regret bound of $O((C+1)d\log d)$ without prior knowledge of C, by monitoring directed graphs induced by the observed feedback to detect corruptions adaptively.

****

Seeing to Generalize: How Visual Data Corrects Binding Shortcuts

Nicolás Buzeta, Felipe del Rio, Cristian Hinostroza, Denis Parra, Hans Lobel, Rodrigo Toro Icarte

Vision Language Models (VLMs) are designed to extend Large Language Models (LLMs) with visual capabilities, yet in this work we observe a surprising phenomenon: VLMs can outperform their underlying LLMs on purely text-only tasks, particularly in long-context information retrieval. To investigate this effect, we build a controlled synthetic retrieval task and find that a transformer trained only on text achieves perfect in-distribution accuracy but fails to generalize out-of-distribution (OOD), while subsequent training on an image-tokenized version of the same task nearly doubles text-only OOD performance. Mechanistic interpretability reveals that visual training changes the model’s internal binding strategy: text-only training encourages positional shortcuts, whereas image-based training disrupts them through spatial translation invariance and other encoder-level inductive biases, forcing the model to adopt a more robust symbolic binding mechanism that persists even after text-only examples are reintroduced.

We further characterize how binding strategies vary across training regimes and visual encoders, and show that analogous shifts occur during pre-trained LLM-to-VLM transitions. Our findings suggest that cross■modal training can enhance reasoning and generalization even for tasks grounded in a single modality.

****

Concept Concentration for Faithful Representation Intervention

Hongzheng Yang, Yongqiang Chen, Zeyu Qin, Tongliang Liu, Chaowei Xiao, Kun Zhang, Bo Han

Representation intervention aims to locate and modify the representations that encode the underlying concepts in Large Language Models (LLMs) to elicit the aligned and expected behaviors. Despite the empirical success, it has never been examined whether one could locate the faithful concepts for intervention. In this work, we explore the question in safety alignment. If the interventions are faithful, the intervened LLMs should erase the harmful concepts and be robust to both in-distribution adversarial prompts and the \textit{out-of-distribution} (OOD) jailbreaks. While it is feasible to erase harmful concepts without degrading the benign utility of LLMs in linear settings, we show that it is \textit{infeasible} in the general non-linear setting. To tackle the issue, we propose \texttt{Concept Concentration} (\texttt{COCA}). \texttt{COCA} refactors the training data with an explicit reasoning process, which first identifies the potential unsafe concepts and then decides the responses. Essentially, \texttt{COCA} simplifies the decision boundary between harmful and benign representations, enabling more effective linear erasure. Extensive experiments with multiple representation intervention methods and model architectures demonstrate that \texttt{COCA} significantly reduces both in-distribution and OOD jailbreak success rates, and meanwhile maintaining strong performance on regular tasks such as math and code generation. Our code is publicly available at: \url{https://github.com/tmlr-group/COCA}.

TimeLAVA: Learning-Agnostic Valuation for Time Series Data

Wenqin Liu, Weizhi Quan, Aoqi Zuo, Erdun Gao, Vu Nguyen, Dino Sejdinovic, Howard Bondell, Mingming Gong

Data valuation quantifies the intrinsic quality of individual samples to enable principled data curation, quality control, and robust learning. For time series

in critical domains such as healthcare, finance, and industrial monitoring, effe
ctive valuation methods are essential yet fundamentally lacking. Existing approa
ches are either model-dependent, limiting their generalizability, or designed fo
r i.i.d. data and thus fail to capture temporal dependencies, multi-scale patter
ns, and non-stationary dynamics inherent to sequential data. We introduce TimeLA
VA, a learning-agnostic framework that values temporal segments by their margina
l contribution to minimizing distributional discrepancy between evaluated and re
ference data. At its core is a novel Selective Wavelet-based Wasserstein ($\math
cal{W}_\text{SW}$) discrepancy combining multi-scale wavelet transforms for temp
oral localization with unbalanced optimal transport for robustness to distributi
onal shifts. Segment values are efficiently computed via sensitivity analysis wi
thout requiring model training and aggregated into point-wise scores. We provide
 theoretical guarantees linking valuation to model-agnostic generalization and p
rove bounded sensitivity to outlier contamination. Extensive experiments across
anomaly detection, data pruning, and label noise detection demonstrate that Time
LAVA produces significantly more informative value scores than existing methods
on diverse real-world datasets.

Attention Hijacking: Backdooring Text Dataset Distillation via Semantic Anchors
Hang Ren, Xin Wang, Tong Yue, Wen Chen, Junqing Le
Dataset Distillation has emerged as a promising technique for compressing large-
scale datasets into compact synthetic sets while preserving model performance. H
owever, the security implications of this paradigm, particularly within the Tran
sformer-based text classification domain, remain underexplored. In this paper, w
e identify "Distilled Attention Labels" as a pivotal yet overlooked vulnerabilit
y. We propose Attention Hijacking (AH), a stealthy backdoor attack that manipula
tes the bi-level optimization process to explicitly hijack the attention mechani
sm of target models via synthetic data. Distinct from traditional poisoning that
 often compromises clean accuracy, AH achieves stealthiness without utility degr
adation. To explain this, we formulate the "Semantic Anchoring Hypothesis", char
acterizing the interaction between trigger semantics and attack mechanisms. We d
emonstrate that AH functions as a semantic-adaptive mechanism: when triggers ali
gn with domain-specific semantic anchors (e.g., "film" in sentiment analysis), o
ur method achieves a synergistic effect, boosting both attack success rates (>99
%) and clean test accuracy. Conversely, for functional or noise triggers, AH enf
orces attention segregation to prevent utility collapse, maintaining exceptional
 robustness where baseline attacks fail. Extensive experiments across multiple d
atasets and varying model scales—ranging from BERT-Tiny to BERT-Base—validate th
e scalability and dominance of AH. Our findings reveal that attention-based dist
illation is a double-edged sword, underscoring the urgent need for robust defens
es in the era of data-efficient learning.

FedTreeLoRA: Reconciling Statistical and Functional Heterogeneity in Federated L
oRA Fine-Tuning
Jieming Bian, Lei Wang, Letian Zhang, Jie Xu
Federated Learning (FL) with Low-Rank Adaptation (LoRA) has become a standard fo
r privacy-preserving LLM fine-tuning. However, existing personalized methods pre
dominantly operated under a restrictive Flat-Model Assumption: they addressed cl
ient-side *statistical heterogeneity* but treated the model as a monolithic bloc
k, ignoring the *functional heterogeneity* across LLM layers. We argue that thes
e two statistical (horizontal) and functional (vertical) dimensions, are *orthog
onal in source yet coupled in interaction*, implying that the optimal depth of p
arameter sharing is functionally dependent on client similarity. To address this
, we propose **FedTreeLoRA**, a framework employing tree-structured aggregation
for fine-grained, layer-wise alignment. By dynamically constructing an aggregati
on hierarchy, FedTreeLoRA allows clients to share broad consensus on shallow ’tr
unks‘ while progressively specializing on deep ‘branches'. Experiments on NLU an
d NLG benchmarks demonstrate that FedTreeLoRA significantly outperforms state-of
-the-art methods by effectively reconciling generalization and personalization.

Spectral-Progressive Thought Flow for Lightweight Multimodal Reasoning
Yixian Shen, Zhiheng Yang, Qi Bi, Changshuo Wang, Shuai Wang, JIA-HONG HUANG, George Floros, Prayag Tiwari, Anuj Pathania
Multimodal reasoning often relies on long chains of intermediate textual and visual thoughts, where accumulating visual tokens and dense cross-modal attention incur substantial computation and memory overhead.
To address this challenge, we propose Spectral-Progressive Thought Flow (*SpecFlow*), a *novel* lightweight multimodal reasoning framework that represents intermediate visual thoughts in a fixed-size discrete cosine space.
By exploiting strong energy compaction, *SpecFlow* preserves global layout and relational structure while introducing high-frequency details only when increased spatial precision is required.
To align visual state evolution with linguistic intent, classifier-free guidance enables autoregressive textual thoughts to steer flow-based updates of the visual workspace without expanding the context.
As a result,*SpecFlow* maintains a bounded visual workspace whose updates depend only on the current visual state and accumulated textual trace, enabling long-horizon inference with stable latency and memory usage independent of reasoning depth.
Empirical results show that *SpecFlow* achieves competitive or superior reasoning performance while reducing computation and memory costs by up to *$2.1\times$*.
****
Generalization of Gibbs and Langevin Monte Carlo Algorithms in the Interpolation Regime
Andreas Maurer, Erfan Mirzaei, Massimiliano Pontil
This paper provides data-dependent bounds on the expected error of the Gibbs algorithm in the overparameterized interpolation regime, where low training errors are also obtained for impossible data, such as random labels in classification. The results show that generalization in the low-temperature regime is already signaled by small training errors in the noisier high-temperature regime. The bounds are stable under approximation with Langevin Monte Carlo algorithms. The analysis motivates the design of an algorithm to compute bounds, which on the MNIST, CIFAR-10 and SVHN datasets yield nontrivial, close predictions on the test error for true labeled data, while maintaining a correct upper bound on the test error for random labels.
****
Narrowing the ANN–SNN Gap for Continuous 1D Temporal Signal Classification with Multi-Scale Temporal Encoding and Sparsity-Regularized Transform Encoding
Qi Sun, Yulei Huang, Zhen Cao, Biao Hou
Spiking neural networks (SNNs) promise energy-efficient inference, yet on static vision benchmarks, they often trail matched ANNs under short simulation horizons. Under a matched-backbone and matched-budget protocol without extra tricks, we find that this ANN-SNN accuracy gap is consistently smaller on representative continuous 1D temporal signal classification benchmarks than on image benchmarks. We attribute this to a mechanism-level mismatch: leaky integration naturally implements causal evidence accumulation over time for native temporal signals, while static images typically require amplitude-to-spike encoding, whose finite-window estimation error becomes non-negligible at short horizons. Guided by this view, we propose a plug-and-play framework that combines Multi-Scale Temporal Encoding (MTE) and Sparsity-Regularized Transform Encoding (STE). MTE replaces naive repetition with multi-scale streams and allocates scale-aligned multi-bit integer spikes to increase per-step information density, and STE replaces a controllable fraction of LIF units with a transform-encoding neuron trained using auxiliary reconstruction and sparsity regularization, with a synthesis branch used only during training. Across diverse 1D datasets and backbone families, MTE$\times$STE consistently improves the accuracy-efficiency trade-off over standard SNN baselines and matches or occasionally surpasses ANN counterparts.

LMCleaner: Efficient and Certified Online Unlearning via Influence Propagation T

runcation
Jie Xu, Zihan Wu, Wenbo Pan, Jiao Yin, Yong-Feng Ge, Hua Wang, Cong Wang, Xiaohua Jia
Existing machine unlearning methods primarily focus on removing data influence after training completes, which is effective for many scenarios, but a complementary capability is needed when removal requests arise during ongoing training. We propose LMCleaner, an efficient and certified *online* unlearning framework that can process unlearning requests at any training step without waiting for training completion. Our key insight is that influence propagation can be decomposed into a trust region where linear approximation is accurate, and a residual that concentrates in a low-dimensional subspace and can be efficiently masked by calibrated noise. Building on this insight, we design an influence propagation truncation mechanism that treats mini-batch influence as atomic units, computes influence within a truncation window for efficient removal, and injects subspace-aware noise for certified privacy. Our theoretical analysis proves that the truncation residual decays exponentially with window size and that the unlearned model is (ε, δ)-indistinguishable from retraining. Experiments demonstrate that LMCleaner achieves over $100\times$ computational savings compared to baselines while maintaining model utility and defending against membership inference attacks.
****
Dismantling Pathological Shortcuts: A Causal Framework for Faithful LVLM Decoding
Liu Yu, Can Chen, PING KUANG, Zhikun Feng, Fan Zhou, Gillian Dobbie
Large Vision-Language Models (LVLMs) exhibit sophisticated reasoning but remain susceptible to object hallucination. Deviating from the prevailing *attention intensity assumption*, we reveal a deeper dynamic structural misalignment: hallucination is triggered at decision-critical steps where specific attention heads, acting as risky mediators, decouple from visual evidence to lock onto language priors. This establishes a pathological shortcut that bypasses visual grounding. To dismantle this, we propose **Fox** (*F*aithfulness and *O*bservational-flow via e*X*pression-rectification), a training-free inference-time framework. **Fox** diagnoses structural misalignment using a visual attention entropy probe to localize risky mediators unsupervisedly. We then execute a targeted causal intervention via numerical logit saturation to physically sever the shortcut path. Finally, a conflict-gated cooperative decoding strategy reconciles interventional faithfulness with observational fluency. Extensive experiments demonstrate that **Fox** achieves SOTA performance, outperforming SID by 29.1% while preserving linguistic richness. Code is available at <https://github.com/Cc2021start/Fox>.
****
One Intervention per Component is Enough: Towards Identifiability in Linear Stochastic Dynamics from Steady State
Saber Salehkaleybar
We study the problem of recovering the parameters of a multivariate Ornstein–Uhlenbeck (OU) process from steady-state observational and interventional data. In many applications, such as large-scale gene perturbation experiments, only stationary “snapshot” measurements are available, making standard stochastic differential equation estimation methods that rely on time-series trajectories inapplicable. We first establish an identifiability result: one intervention per strongly connected component (SCC) of the drift graph suffices to recover all OU process parameters generically up to a global scaling factor. This holds provided that the SCC condensation graph is connected with a single root and certain spectral nondegeneracy assumptions hold. We propose a recursive learning algorithm that orders SCCs topologically and, for each component, isolates its marginal dynamics and solves a linear system derived from the steady-state moment equations, leveraging parameters recovered for upstream components. Building on this theoretical foundation, we propose a regularized least-squares estimator that jointly minimizes residuals of the steady-state mean and covariance equations across observational and interventional data. Experiments on synthetic and real datasets demonstrate the effectiveness of our method in recovering parameters and predicting u

nseen interventions.

HiCI: Hierarchical Construction–Integration for Long-Context Attention
Xiangyu Zeng, Qi Xu, Yunke Wang, Chang Xu
Long-context language modeling is commonly framed as a scalability challenge of token-level attention, yet local-to-global information structuring remains largely implicit in existing approaches. Drawing on cognitive theories of discourse comprehension, we propose HiCI (Hierarchical Construction--Integration), a hierarchical attention module that constructs segment-level representations, integrates them into a shared global context, and broadcasts both to condition segment-level attention. We validate HiCI through parameter-efficient adaptation of LLaMA-2 (7B and 13B) and Qwen3-8B with only $\sim$4--5\% additional parameters, extending context to 100K/64K tokens for LLaMA-2-7B/13B and to 48K tokens for Qwen3-8B. Across language modeling, retrieval, and instruction-following benchmarks, HiCI yields consistent improvements over strong baselines, including matching proprietary models on topic retrieval and surpassing GPT-3.5-Turbo-16K on code comprehension. These results demonstrate the effectiveness of explicit hierarchical structuring as an inductive bias for long-context modeling.

Navigating Massive Visual Context in Retrieval-Augmented Generation via Multimodal Memory Graph
Qiuchen Wang, Shihang Wang, Yu Zeng, Qiang Zhang, Fanrui Zhang, Zhuoning Guo, Bosi Zhang, Wenxuan Huang, Lin Chen, Zehui Chen, Pengjun Xie, Ruixue Ding
Effectively retrieving, reasoning, and understanding multimodal information remains a critical challenge for agentic systems. Traditional Retrieval-augmented Generation (RAG) methods rely on linear interaction histories, which struggle to handle long-context tasks, especially those involving information-sparse yet token-heavy visual data in iterative reasoning scenarios. To bridge this gap, we introduce VimRAG, a framework tailored for multimodal Retrieval-augmented Reasoning across text, images, and videos. Inspired by our systematic study, we model the reasoning process as a dynamic directed acyclic graph that structures the agent states and retrieved multimodal evidence. Building upon this structured memory, we introduce a Graph-Modulated Visual Memory Encoding mechanism, with which the significance of memory nodes is evaluated via their topological position, allowing the model to dynamically allocate high-resolution tokens to pivotal evidence while compressing or discarding trivial clues. To implement this paradigm, we propose a Graph-Guided Policy Optimization strategy. This strategy disentangles step-wise validity from trajectory-level rewards by pruning memory nodes associated with redundant actions, thereby facilitating fine-grained credit assignment. Extensive experiments demonstrate that VimRAG consistently achieves state-of-the-art performance on diverse multimodal RAG benchmarks.

Asymmetric Perturbation in Solving Bilinear Saddle-Point Optimization
Kenshi Abe, Mitsuki Sakamoto, Kaito Ariu, Atsushi Iwasaki
This paper proposes asymmetric perturbation, where only one player's payoff function is perturbed, for solving bilinear saddle-point optimization problems, commonly arising in minimax problems, game theory, and constrained optimization.
Symmetric perturbation is known to require decreasing its strength to ensure convergence to a solution, i.e., an equilibrium in the original game, resulting in a slower rate.
First, with asymmetric perturbation, we show that, for a sufficiently small perturbation strength, the equilibrium strategy of the asymmetrically perturbed game coincides with an equilibrium strategy of the original unperturbed game.
Second, building on this coincidence, we construct a learning algorithm with a linear last-iterate convergence rate.
Third, motivated by the fact that the coincidence relies on the perturbation strength being sufficiently small, we also provide a parameter-free variant, retaining the linear rate.
Finally, we empirically demonstrate fast convergence toward equilibria in both normal-form and extensive-form games.

SPARD: Defending Harmful Fine-Tuning Attack via Safety Projection with Relevance–Diversity Data Selection
Shuhao Chen, Weisen Jiang, Yeqi Gong, Shengda Luo, Chengxiang Zhuo, Zang Li, James Kwok, Yu Zhang
Fine-tuning large language models often undermines their safety alignment, a problem further amplified by harmful fine-tuning attacks in which adversarial data removes safeguards and induces unsafe behaviors. We propose SPARD, a defense framework that integrates Safety-Projected Alternating optimization with Relevance-Diversity aware data selection. SPARD employs SPAG, which optimizes alternatively between utility updates and explicit safety projections with a set of safe data to enforce safety constraints. To curate safe data, we introduce a Relevance–Diversity Determinantal Point Process to select compact safe data, balancing task relevance and safety coverage. Experiments on GSM8K and OpenBookQA under four harmful fine-tuning attacks demonstrate that SPARD consistently achieves the lowest average attack success rates, substantially outperforming state-of-the-art defense methods, while maintaining high task accuracy. Code is available at https://github.com/shuhao02/SPARD.
****
ReViT: Rotational-equivariant Vision Transformers for Neural PDE Solvers
Hao Wei, Björn List, Nils Thuerey
Physics obeys strict symmetries like rotational equivariance. However, the standard Transformer architectures widely used in physics foundation models do not enforce these constraints by construction. We introduce ReViT, a rotationally equivariant Vision Transformer framework for neural PDE solvers operating on grid-based physical fields that achieves exact equivariance for the discrete groups C_4 (2D) and the chiral octahedral group O (3D), with bounded approximate $\mathrm{SO}(d)$ equivariance for continuous rotations. ReViT maps scalar and vector inputs into locally invariant representations derived from physics-based canonical bases, enabling the use of standard self-attention without symmetry violations. Built on a hierarchical Swin-style backbone with a precomputed reference basis pyramid, ReViT preserves equivariance across multi-scale operations.
We evaluate ReViT on a wide range of 2D and 3D PDE benchmarks, such as Magnetohydrodynamics and Turbulent Channel Flows, demonstrating significant gains over state-of-the-art baselines. ReViT exhibits strong generalization, and reduces MSE by up to 65\% compared with the best-performing alternatives.
****
InstEmb: Instruction-Following Embeddings through Glimpses of the Future
Tianhao Gao, Jun Fang, Xiaohui Zhang, Zhiyuan Liu, Chao Liu, Pengzhang Liu, Qixia Jiang
Recent advances have empowered large language models (LLMs) with remarkable fine-grained instruction-following capabilities in text generation tasks. However, embedding methods typically rely solely on the hidden state of the input's last token, limiting their ability to capture complete semantic signals distributed across the full output tokens. Moreover, existing discrete-to-continuous re-encoding approaches introduce semantic discontinuity. To address these limitations, we propose $\textbf{InstEmb}$, a novel instruction following embedding framework.
InstEmb jointly optimizes two key aspects: (1) Input-Intrinsic semantic information, achieved by employing contrastive learning focused on the representation of the last input token, and (2) Output-Aware semantic information, captured through representation self-distillation leveraging learnable look-ahead tokens without introducing additional decoding latency. Additionally, we introduce $\textbf{Dual-Anchor Alignment Pooling (DAAP)}$, explicitly aligned with our dual training objectives. Extensive experiments demonstrate that InstEmb achieves state-of-the-art performance across multiple instruction following benchmarks without benchmark-specific supervised data.
****
SubspacePath Pruner: Inference-time Pruning via Probe-based Representation–Parameter Coupling
Gong Zhiren, Yikun Hou, Fan Wu, CHE WANG, Fuyao Zhang, Tiantong Wu, Yurong Hao,

Jiaming Zhang, Yiyang Duan, Tiantong Wang, Fei Huang, Chau Yuen, Wei Yang Bryan Lim

Large-scale dedicated application of LLMs in diverse scenarios increasingly demands specialized model inference behavior under strict constraints of accuracy, latency, and memory. However, the heterogeneous and long-tailed nature of real-world specialized scenarios makes it difficult to obtain training data and optimize models.

We study a practical inference-time specialization setting: given an LLM base, we compile a reusable, budget-bounded pathway/subnetwork within a specific scenario.

Our approach is motivated by an empirical coupling phenomenon: input scenario sets aligned with similar representation subspaces (e.g., domain) in embedding space tend to activate a consistent and sparse set of internal reasoning pathways in model parameter space.

To build the bridge between them, we propose probe-based SubspacePath Pruner with two core components:

(1) Domain-Basis Synthesis (DBS) constructs a quasi-orthogonal basis of domain axes in embedding space, serving as a stable coordinate system.

(2) Probe-based Scenario Pruning (PSP) uses efficient layer-wise linear probes to estimate axis alignment and compute budgeted head-wise pathways for a specific scenario.

Experiments on LLaMA-2-13B show 29.3 average Recall on cross-domain tests (vs. 24.7 dense) and 21.6 on cross-dataset tests (vs. 25.5 dense) with 1.27x speedup at ~30% pruning ratio.

Anti-Aliasing Matters: A Dynamic Network for Time Series Forecasting

Heng Zhou, Xin Sun, Chao Li

Real-world time series inherently exhibit complex temporal patterns. Within chaotic systems, significant mixing and entanglement occur between different time-varying modes. Given that time series exhibit distinctly different patterns at various sampling scales, downsampling to extract multiscale features is a common approach. However, conventional downsampling causes high-frequency components in the original signal, those exceeding the new Nyquist frequency, to undergo spectral folding. This erroneously introduces spurious low-frequency patterns, perceived as low-frequency noise, thereby leading to the ***aliasing problem***. To address this problem, we propose a Decomposition-Prevention-Fusion architecture framework called **DMANet**, which introduces the **D**ynamic **M**ultiscale **A**nti-Aliasing **Net**work. Specifically, DMANet comprises two key components: Multiscale Convolutional Downsampling, designed to capture temporal dependencies and inter-channel interactions, and an Anti-Aliasing Operation, which includes Pre-Sampling Anti-Aliasing Filtering and Post-Sampling Interpolation. These designs guarantee the fidelity of multiscale features before and after downsampling. We show that by mitigating the risk of aliasing, our proposed simple convolutional downsampling architecture achieves performance competitive with common baselines. Our codes are available at https://github.com/HenryZhou2024/DMANet.

A Conflict-aware Evidential Framework for Reliable Sleep Stage Classification

Yunzhi Tian, Dekui Wang, Qirong Bu, Wei Zhou, Xingxing Hao, Jun Feng

Multi-view learning has been widely applied for sleep stage classification using multi-modal data. However, existing methods typically assume that different modalities are well-aligned, which is often unattainable in real-world scenarios, thereby compromising the reliability of the staging results. In this paper, we propose ConfSleepNet, a conflict-aware evidential framework that dynamically resolves inter-view conflicts. The framework consists of multi-view evidence extraction and conflict-aware aggregation. In the first phase, it learns category-related evidence from different modalities, which represents the degree of support for individual sleep stages. Considering the inherent characteristics of varying modalities, we propose hybrid category structures for different modalities to promote more reasonable evidence learning. In the second phase, view-specific opinions, including prediction results and uncertainty, are constructed from the learn

ed evidence. Notably, we propose a novel conflict-aware aggregation method that integrates these view-specific opinions into a reliable joint decision. This mechanism can effectively resolve conflicts among opinions and synthesize them into a reliable joint decision. Both theoretical analysis and experimental results demonstrate the effectiveness of ConfSleepNet in sleep staging tasks. The code is available at https://github.com/By4te/ConfSleepNet_ICML2026/.

Representational Curvature Modulates Behavioral Uncertainty in Large Language Models

Jack G. King, Evelina Fedorenko, Eghbal A. Hosseini

Temporal straightening describes how, across layers in autoregressive LLMs, the trajectory traced by the token representations of an input sequence becomes straighter, potentially enabling next-token prediction by linear extrapolation. However, a direct link between this trajectory and token-level behavior has been missing. We provide such a link by relating contextual curvature—a geometric measure of how sharply the representational trajectory bends over recent context—to next-token entropy. Across two models (GPT-2 XL and Pythia-2.8B), contextual curvature is correlated with entropy, and this relationship emerges during training. Perturbation experiments reveal selective dependence: manipulating curvature through trajectory-aligned interventions reliably modulates entropy, while geometrically misaligned perturbations have no effect. Finally, regularizing representations to be straighter during training modestly reduces token-level entropy without degrading validation loss. These results identify trajectory curvature as a task-aligned representational feature that influences behavioral uncertainty in LLMs.

Squeezing More from the Stream : Learning Representation Online for Streaming Reinforcement Learning

Nilaksh, Antoine Clavaud, Mathieu Reymond, Francois Rivest, Sarath Chandar

In streaming Reinforcement Learning (RL), transitions are observed and discarded immediately after a single update. While this minimizes resource usage for on-device applications, it makes agents notoriously sample-inefficient, since value-based losses alone struggle to extract meaningful representations from transient data. We propose extending Self-Predictive Representations (SPR) to the streaming pipeline to maximize the utility of every observed frame. However, due to the highly correlated samples induced by the streaming regime, naively applying this auxiliary loss results in training instabilities. Thus, we introduce orthogonal gradient updates relative to the momentum target and resolve gradient conflicts arising from streaming-specific optimizers. Validated across the Atari, MinAtar, and Octax suites, our approach systematically outperforms existing streaming baselines. Latent-space analysis, including t-SNE visualizations and effective-rank measurements, confirms that our method learns significantly richer representations, bridging the performance gap caused by the absence of a replay buffer, while remaining efficient enough to train on just a few CPU cores.

RobuQ: Pushing DiTs to W1.58A2 via Robust Activation Quantization

Kaicheng Yang, Xun Zhang, Haotong Qin, Yucheng Lin, Kaisen Yang, Xianglong Yan, Yulun Zhang

Diffusion Transformers (DiTs) have emerged as a powerful backbone for image generation, offering superior scalability over U-Nets. However, their practical deployment is hindered by significant computational costs. While Quantization-Aware Training (QAT) shows promise, its application to DiTs is challenged by the high sensitivity and complex distributions of activations. Identifying activation quantization as the primary bottleneck for low-bit settings, we propose **RobuQ**, a systematic QAT framework. We first establish a strong ternary weight (W1.58A4) baseline. Building on this, we introduce **RobustQuantizer**, which utilizes the Hadamard transform to convert unknown per-token distributions into normal distributions. Furthermore, we propose **AMPN**, the first **A**ctivation-only **M**ixed-**P**recision **N**etwork pipeline, applying ternary weights globally while allocating layer-specific activation precisions to eliminate information bottle

necks. Extensive experiments demonstrate that **RobuQ** achieves state-of-the-art performance on **ImageNet-1K**, representing the first stable image generation with activations quantized to an average of 2 bits. Code is available at https://github.com/racoonykc/RobuQ.

Granularity-Aware Adaptive Classifier Expansion via Zero-Shot Learning

Xiangyu Wang, Yanze Gao, Changxin Rong, Lyuzhou Chen, Xiren Zhou, Huanhuan Chen

Zero-shot classifier expansion aims to recognize unseen classes by learning a shared mechanism to map semantics of all classes to classifier weights without access to images. However, existing methods rely on a shared mapping, which is difficult to classify in scenarios containing a mixture of distinct and similar classes, especially with the continuous expansion of classes. Since this mapping prioritizes general attributes for distinct classes while neglecting subtle attributes for similar ones, this granularity mismatch, compounded by sensitivity to noise, induces optimization interference where gradients from distinct classes dominate the learning process. To overcome this limitation, a granularity-aware adaptive framework with interventions is introduced to balance them. Specifically, this method first generates multi-source semantics by intervening on non-causal noise, then discovers latent class structure to separate distinct classes, and finally refine similar classes to synthesize weights with invariance to non-causal noise. The effectiveness is demonstrated through theoretical and empirical analysis in multiple aspects.

One LR Doesn’t Fit All: Heavy-Tail Guided Layerwise Learning Rates for LLMs

Di He, Songjun Tu, Keyu Wang, Lu Yin, Shiwei Liu

Learning rate configuration is a fundamental aspect of modern deep learning. The prevailing practice of applying a uniform learning rate across all layers overlooks the structural heterogeneity of Transformers, potentially limiting their effectiveness as the backbone of Large Language Models (LLMs). In this paper, we introduce Layerwise Learning Rate (LLR), an adaptive scheme that assigns distinct learning rates to individual Transformer layers. Our method is grounded in Heavy-Tailed Self-Regularization (HT-SR) theory, which characterizes the empirical spectral density (ESD) of weight correlation matrices to quantify heavy-tailedness. Layers with weaker heavy-tailedness are assigned larger learning rates to accelerate their training, while layers with stronger heavy-tailedness receive smaller learning rates. By tailoring learning rates in this manner, LLR promotes balanced training across layers, leading to faster convergence and improved generalization.

Extensive experiments across architectures (from LLaMa to GPT-nano), optimizers (AdamW and Muon), and parameter scales (60M–3B, up to 100B tokens) demonstrate that LLR achieves up to 1.5× training speedup and outperforms baselines, notably raising average zero-shot accuracy from 47.09% to 49.02% for 1B models and from 48.58% to 50.61% for 3B models. A key advantage of LLR is its low tuning overhead: it transfers nearly optimal LR settings directly from the uniform baseline. Code is available at https://github.com/hed-ucas/Layer-wise-Learning-Rate.

Next-Token Prediction and Regret Minimization

Mehryar Mohri, Clayton Sanford, Jon Schneider, Kiran Vodrahalli, Yifan Wu

We study the robustification of next-token prediction models in adversarial online decision-making environments. Suppose a next-token predictor is trained on a distribution over sequences of opponent actions, and a decision maker acts by approximately best responding to the model’s predictions. If this induced decision-making algorithm achieves low adversarial regret, we call such distributions low-regret distributions. For models with unbounded context, we show that every distribution is exponentially close in total variation distance to a low-regret distribution. Thus, sublinear regret can always be achieved while changing the original next-token prediction distribution by only a negligible amount. By contrast, for models with bounded context windows, as in standard transformer architectures, we prove an impossibility result: some distributions are $\Theta(1)$-far from every low-regret distribution. We complement these results with two positive

findings. First, allowing a modest increase in context length restores robustification with near-optimal regret guarantees. Second, the unbounded-context robustification procedure can be implemented by adding a constant number of layers to a standard transformer architecture. Finally, we provide empirical evidence that small transformer models can be efficiently trained to represent these robustified low-regret distributions.

How Hard Can It Be? Hardness-Aware Multi-Objective Unlearning
Jiangwei Chen, Xinyuan Niu, Rachael Hwee Ling Sim, Zhengyuan Liu, Nancy F. Chen, Bryan Kian Hsiang Low
Machine unlearning aims to remove the influence of specific forget training data due to privacy, copyright or bias concerns while maintaining the model performance on the remaining retain data.
Existing unlearning algorithms, such as optimizing a weighted combination of losses, have tried to achieve these objectives of improving forget quality and maintaining retain utility.
However, they do not guarantee that these objectives can be improved by a specified extent for all forget and retain data.
In this work, we address this limitation with a novel and theoretically-grounded approach from a constrained optimization perspective.
Firstly, we identify that the *hardness* of reconciling both objectives can be quantified by the similarity between the forget data and the retain data.
Next, we derive an unlearning algorithm (HAMU) with the overall goal of guaranteeing a specified improvement in forget quality while minimizing the retain utility cost/degradation by updating the model weights based on our hardness measure.

Our hardness measure also informs users when retain utility degradation is unavoidable,
i.e., both objectives cannot be improved simultaneously, and stopping should be considered.
Our algorithm is applicable to non-convex models and is easily parallelizable, making it readily deployable in real-world scenarios.
We empirically demonstrate HAMU's superior performance over baselines on both image and text datasets using large models.
Our code is available at https://github.com/aoi3142/HAMU.

Overcoming PINNs Failure Modes In High Dimension With Low-Rank Fourier Sum
Natan Kaminsky, Daniel Freedman, Kira Radinsky
Physics-informed neural networks (PINNs) can be unreliable on PDEs with oscillatory, multiscale, stiff, or long-time solutions, and these difficulties worsen in high dimensions where collocation-based training yields large numerical integration error and high-variance gradients. We propose Low-Rank Fourier Sums (LoRFS), representing the solution as a low-rank sum of separable Fourier expansions (products of one-dimensional Fourier series across coordinates). This makes high-frequency structure explicit and enables closed-form evaluation of common physics-based objectives and their gradients (e.g., L^2 residual and variational losses), replacing sampling-based collocation estimates with analytic loss evaluation and eliminating sampling noise. We further provide theoretical results that clarify why LoRFS is particularly well suited to high-dimensional regimes. Across canonical PINN failure-mode benchmarks and their high-dimensional extensions, LoRFS consistently outperforms strong PINN baselines and remains stable in regimes where competing methods degrade.
****
GOTabPFN: From Feature Ordering to Compact Tokenization for Tabular Foundation Models on High-Dimensional Data
Al Zadid Sultan Bin Habib, Md Younus Ahamed, Prashnna Kumar Gyawali, Gianfranco Doretto, Donald Adjeroh
We investigate how to make small tabular foundation models effective for High-Dimensional, Low-Sample Size (HDLSS) tabular prediction without retraining large backbones. We introduce Graph-guided Ordering with Local Refinement (GO-LR), show

its equivalence to weighted Minimum Linear Arrangement, and interpret the practical solver as a TSP-path-style surrogate. We propose GOTabPFN,which builds on GO-LR, and a Neuro-Inspired Subunit Compression (NSC) unit to pool locally adjacent ordered features into meta-features, yielding a compact representation that makes TabPFN-style prediction practical in HDLSS regimes. Across tabular benchmarks, GOTabPFN improves stability and accuracy under tight token budgets.

Transporting Task Vectors across Different Architectures without Training
Filippo Rinaldi, Aniello Panariello, Giacomo Salici, Angelo Porrello, Simone Calderara

Adapting large pre-trained models to downstream tasks often produces task-specific parameter updates that are expensive to relearn for every model variant. While recent work has shown that such updates can be transferred between models with identical architectures, transferring them across models of different widths remains unexplored. In this work, we introduce Theseus, a training-free method for transporting task updates across heterogeneous-width models. Rather than matching parameters, we characterize a task update by the functional effect it induces on intermediate representations. We formalize task-vector transport as a functional matching problem on observed activations and show that, after aligning representation spaces via orthogonal Procrustes analysis, it admits a stable closed-form solution that preserves the geometry of the update. We evaluate Theseus on vision and language models across different widths, showing consistent improvements over baselines without additional training or backpropagation. Our results show that task updates can be meaningfully transferred across architectures when task identity is defined functionally rather than parametrically. Code is available at https://github.com/apanariello4/merge-and-rebase.

Pseudo-Mallows for Efficient Probabilistic Preference Learning
Sylvia Qinghua Liu, Valeria Vitelli, Carlo Mannino, Arnoldo Frigessi, Ida Scheel

We propose the Pseudo-Mallows distribution over the set of all permutations of n items, to approximate the posterior distribution of the Bayesian Mallows model. The Bayesian Mallows model has been successfully used for recommender systems to learn personal preferences from highly incomplete users data. However current inference algorithms do not scale, preventing its use in real-time applications. The Pseudo-Mallows distribution is a product of univariate discrete Mallows-like distributions, where the quality of the approximation depends on the order of the n items in the factorization sequence. In a variational setting, we optimize the variational order parameter by minimising a marginalized KL-divergence, conjecturing a certain form of the optimal variational order that depends on the data, and proposing an approximation algorithm for this discrete optimization. Empirical evidence and some theory support our conjecture. We demonstrate on clicking data that variational inference via the Pseudo-Mallows distribution allows much faster probabilistic preference learning compared to alternative MCMC-based options.

ManifoldKV: Training-Free KV Cache Compression via Euclidean Outlier Detection
Debajyoti Datta, Trishala Neeraj, Bibek Paudel, Vyom Sharma, Subhabrata Mukherjee

Long-context inference is constrained by KV-cache memory, which grows linearly with sequence length; KV-cache compression therefore hinges on reliably selecting which past tokens to retain. Most geometry-based eviction methods score keys by cosine similarity to a global centroid, but cosine is scale-invariant and can discard magnitude cues that distinguish semantically salient tokens. We propose ManifoldKV, a training-free scorer that ranks tokens by Euclidean distance to the key centroid, capturing both angular and radial deviations. On the RULER benchmark, ManifoldKV achieves **95.7%** accuracy at 4K–16K contexts with 20% compression, matching the best geometric baseline overall while *decisively* outperforming it in two regimes where magnitude information is critical. First, on multi-key retrieval, ManifoldKV reduces directional collisions, achieving **92.4%** vs KeyDiff's 77.0% (+15.4 points) on 3-key NIAH at 50% compression. Second, to addre

ss dilution and performance collapse of global centroids at 64K context, we introduce WindowedManifoldKV, which restores accuracy to 84.3% at 25% compression, a 49-point recovery over global L2 and +3.2 points over KeyDiff. Beyond RULER, we validate on real-world benchmarks: on LongBench, ManifoldKV outperforms KeyDiff by +2.80 points on Qwen3-8B (winning 12 of 14 tasks) and +0.49 on Phi-4; on HELMET, ManifoldKV achieves +6.5 EM on RAG and WindowedManifoldKV reaches +42 points on multi-key recall at 131K; and on InfiniteBench at 100K+ context, WindowedManifoldKV wins by +7.16 on Phi-4. Cross-architecture evaluation across six models reveals that the optimal distance metric depends on key-norm geometry, providing the first systematic guidelines for metric selection in geometric KV cache compression. The method requires only 3 lines of code and works across diverse architectures without tuning.
****

Beyond Static Endpoints: Tool Programs as an Interface for Flexible Agentic Web Services
Mugeng Liu, Shuoqi Li, Yixuan Zhang, Yun Ma
In the agentic web era, LLM-based agents increasingly invoke web services as tools, yet most interfaces remain static endpoints that poorly express long-horizon workflows with loops, conditionals, joins, and retries. We present ToolPro, which represents an agent's tool intent as an executable tool program that compactly encodes multi-step service interactions with explicit effect types. ToolPro combines constraint-guided program construction, effect-aware replay for exactly-once state-modifying calls, and a profile-driven policy that decides when program execution outperforms stepwise calling. We instantiate ToolPro over MCP-style services with WebAssembly sandboxing and evaluate it on diverse workflows of real-world applications. ToolPro reduces end-to-end latency by up to 53.4% and client-side traffic by up to 96.1%, with larger gains under higher network latency and workflow complexity.

Bring My Cup! Personalizing Vision-Language-Action Models with Visual Attentive Prompting
Sangoh Lee, Sangwoo Mo, Wook-Shin Han
While Vision-Language-Action (VLA) models generalize well to generic instructions, they struggle with personalized commands such as "bring *my* cup," where the robot must act on one specific instance among visually similar objects. We study this setting of manipulating personal objects, in which a VLA must identify and control a user-specific object unseen during training using only a few reference images. To address this challenge, we propose **Visual Attentive Prompting (VAP)**, a simple-yet-effective training-free perceptual adapter that equips frozen VLAs with top-down selective attention. VAP treats the reference images as a non-parametric visual memory, grounds the personal object in the scene through open-vocabulary detection and embedding-based matching, and then injects this grounding as a visual prompt by highlighting the object and rewriting the instruction. We construct two simulation benchmarks, Personalized-SIMPLER and Personalized-VLABench, and a real-world tabletop benchmark to evaluate personalized manipulation across multiple robots and tasks. Experiments show that VAP consistently outperforms generic policies and token-learning baselines in both success rate and correct-object manipulation, helping to bridge the gap between semantic understanding and instance-level control.

Overclocking Electrostatic Generative Models
Daniil Shlenskii, Alexander Korotin
Electrostatic generative models such as PFGM++ have recently emerged as a powerful framework, achieving competitive performance in image synthesis. PFGM++ operates in an extended data space with auxiliary dimensionality D, recovering the diffusion model framework as $D\to\infty$, while yielding superior empirical results for finite D.
Like diffusion models, PFGM++ relies on expensive ODE simulations to generate samples, making it computationally costly. To address this, we propose Inverse Poisson Flow Matching (IPFM), a principled distillation framework that accelerates

electrostatic generative models across all values of D.
Our IPFM reformulates distillation as an inverse problem: learning a generator w hose induced electrostatic field matches that of the teacher. We derive a tracta ble training objective for this problem and show that, as $D\to\infty$, our IPFM closely recovers Score Identity Distillation (SiD), a recent method for distill ing diffusion models.
Empirically, our IPFM produces distilled generators that achieve near-teacher or even superior sample quality using only a few function evaluations.
Moreover, we find that one-step generator distillation converges faster at finit e D than in the $D\to\infty$ diffusion limit, aligning with prior evidence tha t finite-D PFGM++ models offer more favorable optimization and sampling behavi or.

Search Space Synthesis for Parametric Functions
Felix Laarmann, Andreas Pauly, Sebastian Buschjäger, Andrea Bommert, Jakob Rehof
We present a general framework for synthesizing search spaces of parametric func tions, along with strategies for traversing these spaces to find optima. We form alize an algebraic theory for the categorical model of parametric functions in f inite combinatory logic with predicates (FCLP). Based on a component-oriented sy nthesis framework for FCLP we automate composition from given components and sea rch for parametric functions. Components are language-agnostic and may be instan tiated as any implementation of parametric functions, e.g., as PyTorch modules.
A proof-of-concept implementation demonstrates how to represent more specific co ncepts, such as neural architecture search and hyperparameter optimization, with in the framework.
****

PS-PPO : Prefix-Sampling PPO for Critic-Free RLHF
Doo Hwan Hwang, Kee-Eung Kim
Reinforcement Learning from Human Feedback (RLHF) for Large Language Models incr easingly relies on critic-free methods as a practical alternative to actor--crit ic training. Despite their simplicity, existing critic-free approaches propagate a trajectory-level learning signal uniformly across all tokens in a trajectory. This requires full-trajectory policy updates for every rollout, leading to subs tantial optimization cost for long reasoning traces, even though intermediate pr efixes often contain enough information to largely determine the final outcome.
We propose Prefix-Sampling Proximal Policy Optimization (PS-PPO), a compute-effi cient critic-free method for RLHF that exploits this temporal redundancy. PS-PPO introduces a prompt-conditioned cutoff distribution and samples a cutoff timest ep for each trajectory. During the update pass, PS-PPO backpropagates only throu gh the sampled prefix of each trajectory and applies an importance-weighting cor rection so that the resulting truncated gradient estimator remains unbiased with respect to the full-trajectory objective.
Experiments on mathematical reasoning and RLHF benchmarks show that PS-PPO achie ves large reductions in training compute and peak GPU memory, while maintaining accuracy comparable to strong critic-free baselines.

Transformers learn factored representations
Adam Shai, Loren Amdahl-Culleton, Casper L. Christensen, Henry R Bigelow, Fernan do Rosas, Alexander Boyd, Eric A. Alt, Kyle J Ray, Paul M. Riechers
Transformers pretrained via next token prediction learn to factor their world in to parts, representing these factors in orthogonal subspaces of the residual str eam. We formalize two representational hypotheses: (1) a representation in the p roduct space of all factors, whose dimension grows exponentially with the number of parts, or (2) a factored representation in orthogonal subspaces, whose dimen sion grows linearly. Both track context-induced uncertainty over the latent part s, but the factored representation sacrifices fidelity when factors are not cond itionally independent. We derive precise predictions about the geometric structu re of activations for each, including the number of subspaces, their dimensional ity, and the arrangement of context embeddings within them. We test between thes e hypotheses on transformers trained on synthetic processes with known latent st

ructure. When factors are conditionally independent, models learn factored repre
sentations; when noise or dependencies break this structure, models gradually ex
pand their effective dimensionality over training to recover fidelity. This prov
ides a principled explanation for why transformers decompose the world into part
s, and suggests that interpretable low dimensional structure may persist even in
 models trained on complex data.
****
DLLMQuant: A Post-Training Quantization Framework Tailored for Diffusion-Based L
arge Language Models
Chen Xu, Zhixuan Chen, Dawei Yang
Diffusion-based large language models (DLLMs) have shown promise for non-autoreg
ressive text generation, but their deployment is constrained by large model size
s and heavy computational costs. Post-training quantization (PTQ), a widely used
 method for compressing and accelerating Large Language Models (LLMs), suffers f
rom severe accuracy degradation and reduced generalization performance when dire
ctly applied to DLLMs (e.g., AWQ suffers a 16% accuracy drop on LLADA under W4A4
). This paper explores how the unique mechanisms of Dynamic Language Models (DLL
Ms) conflict with quantization, identifying three core issues: 1) During the ite
rative generation process of DLLMs, dynamic masking ratios are inherently involv
ed, leading to notable differences in token distributions across decoding steps.
 Unfortunately, these distinct distributions are not sufficiently captured by cu
rrent PTQ calibration approaches; 2) Quantization errors propogate and accumalte
 progressively during iterations in DLLMs, leading to a gradual decline in the p
erformance of quantized models as decoding steps advance; 3) The stability of un
masked tokens, combined with the probabilistic nature of masked tokens, gives ri
se to an overall feature distribution that is uncoordinated and unsuitable for P
TQ. To address these issues, we propose DLLMQuant, a PTQ framework tailored for
DLLMs, which incorporates three novel techniques: 1) Temporal-Mask Adaptive Samp
ling (TMAS), a calibration method that accounts for both time and mask factors,
with the capacity to capture distributions across timesteps. 2) Interaction-Awar
e Activation Quantization (IA-AQ), which utilizes bidirectional attention scores
 to identify important tokens, and prioritizes these tokens when minimizing quan
tization error. 3) Certainty-Guided Quantization (CGQ) incorporates mask status
and token scores as core weighting criteria for error compensation, enabling PTQ
 to better align with the unique weight distribution of DLLMs. Experiments show
that DLLMQuant achieves significant performance gains (e.g., over 10-point accur
acy improvement on GSM8K for LLADA under 4-bit quantization) while enhancing eff
iciency.

Factor-Wise Homogeneity of Slot-Attention for Continual Object-Centric Learning
Ilmin Kang, Hoyong Kim, Seungju Bang, Minwoo Kang, Kangil Kim
While Object-Centric Learning has shown great promise in modular perception, its
 extension to Continual Learning remains underexplored.
In this work, we observe that Slot Attention exhibits a distinctive behavior:
it organizes latent representations into small and separated regions, each of wh
ich preserves identical factor states, crucially emerging not only in the curren
t task but also across sequential tasks with novel factors. This *inter-task sep
aration* offers significant advantages in continual learning, which typically su
ffers from severe object-wise forgetting.
We refer to this phenomenon as *Factor-Wise Homogeneity*, and show that this int
rinsic inter-task separation is crucial, serving as a key mechanism to prevent c
atastrophic forgetting in Continual Object-Centric Learning.
However, despite its strong robustness, factor-wise homogeneity alone is insuffi
cient due to the bottleneck in exploiting this separation at the decoder.
To overcome this limitation and demonstrate the significance of our findings, we
 show that a minimal strategy *Decoder-only Post-Replay*, which freezes the fact
or-wise homogeneous representations and employs decoder-only fine-tuning, is suf
ficient.
This work serves as a fundamental basis for understanding and leveraging the int
rinsic dynamics of Slot Attention, offering essential insights for advancing obj

ect-centric systems.

Privacy-Aware Video Anomaly Detection through Orthogonal Subspace Projection
Lei Wang, Wenxiang Diao, Andrew Busch, Jun Zhou, Yongsheng Gao
Video anomaly detection (VAD) systems often prioritize accuracy while overlookin g privacy concerns, limiting their suitability for real-world deployment. We pro pose the Orthogonal Projection Layer (OPL), a lightweight module that removes ta sk-irrelevant variations to produce representations focused on anomaly-relevant cues. To address privacy risks in human-centered scenarios, we introduce Guided OPL (G-OPL), which suppresses facial attributes using weak supervision from face -presence signals while preserving non-identifying features such as pose and mot ion. A cosine alignment objective enforces consistent capture and removal of fac ial information without identity labels or adversarial training. We further pres ent a privacy-aware evaluation framework that jointly assesses detection perform ance and privacy preservation, and enables analysis of how sensitive information is filtered. Experiments show that embedding privacy constraints into model des ign reduces sensitive information while maintaining or improving detection accur acy, supporting projection-based architectures as a principled approach for priv acy-aware VAD.

miniF2F-Dafny: LLM-Guided Mathematical Theorem Proving via Auto-Active Verificat ion
Mantas Baksys, Stefan Zetzsche, Olivier Bouissou, Sean B. Holden
LLMs excel at reasoning, but validating their steps remains challenging. Formal verification offers a solution through mechanically checkable proofs. Interactiv e theorem provers (ITPs) dominate mathematical reasoning but require detailed lo w-level proof steps, while auto-active verifiers offer automation but focus on s oftware verification. Recent work has begun bridging this divide by evaluating L LMs for software verification in ITPs, but the complementary direction—LLMs for mathematical theorem proving in auto-active verifiers—remains unexplored. We pre sent miniF2F-Dafny, the first translation of the widely-used mathematical benchm ark miniF2F to an auto-active verifier: Dafny. We find that Dafny's automation a lone solves 39-44% of problems with empty proofs, whereas many require substanti al proof guidance in ITPs. We evaluate 8 off-the-shelf LLMs on proof generation, with the best model (Claude Opus 4.6) achieving 62.7% cumulative pass@4 on the full test set, improving over the 38.9% empty-proof baseline by 23.8 percentage points. These results show that auto-active verification offers a complementary empirical setting for AI-assisted mathematical reasoning, where LLMs provide hig h-level guidance while SMT automation handles low-level details. Our benchmark a nd evaluation infrastructure are publicly available on GitHub.

Can Adaptive Gradient Methods Converge under Heavy-Tailed Noise? A Case Study of AdaGrad
Zijian Liu
Many tasks in modern machine learning are observed to involve heavy-tailed gradi ent noise during the optimization process. To manage this realistic and challeng ing setting, new mechanisms, such as gradient clipping and gradient normalizatio n, have been introduced to ensure the convergence of first-order algorithms. How ever, adaptive gradient methods, a famous class of modern optimizers that includ es popular $\mathtt{Adam}$ and $\mathtt{AdamW}$, often perform well even without any extra operations mentioned above. It is therefore natural to ask whether ad aptive gradient methods can converge under heavy-tailed noise without any algori thmic changes. In this work, we take the first step toward answering this questi on by investigating a special case, $\mathtt{AdaGrad}$, the origin of adaptive g radient methods. We provide the first provable convergence rate for $\mathtt{Ada Grad}$ in non-convex optimization when the tail index p satisfies $4/3<p\leq2$. Notably, this result is achieved without requiring any prior knowledge of p and is hence adaptive to the tail index. In addition, we develop an algorithm-de pendent lower bound, suggesting that the existing minimax rate for heavy-tailed optimization is not attainable by $\mathtt{AdaGrad}$. Lastly, we consider $\math

tt{AdaGrad}\text{-}\mathtt{Norm}$, a popular variant of $\mathtt{AdaGrad}$ in th
eoretical studies, and show an improved rate that holds for any $1<p\leq2$ under
 an extra mild assumption.

Stationary MMD Points
Zonghao Chen, Toni Karvonen, Heishiro Kanagawa, Francois-Xavier Briol, Chris J.
Oates
Approximation of a target probability distribution using a finite set of points
 is a problem of fundamental importance in numerical integration. Several authors
 have proposed to select points by minimising a maximum mean discrepancy (MMD),
but the non-convexity of this objective typically precludes global minimisation.
 Instead, we consider the concept of \emph{stationary points of the MMD} which,
in contrast to points globally minimising the MMD, can be accurately computed. O
ur main contributions are two-fold and theoretical in nature.
We first prove the (perhaps surprising) result that, for integrands in the assoc
iated reproducing kernel Hilbert space, the numerical integration error of stati
onary MMD points vanishes \emph{faster} than the MMD. Motivated by this \emph{su
per-convergence} property, we consider MMD gradient flows as a practical strateg
y for computing stationary points of the MMD. We then prove that MMD gradient fl
ow can indeed compute stationary MMD points, based on a refined convergence anal
ysis that establishes a novel non-asymptotic finite-particle error bound.

Bimodal masked language modeling for bulk RNA-seq and DNA methylation representa
tion learning
Maxence Gélard, Hakim Benkirane, Thomas Pierrot, Guillaume Richard, Paul-Henry C
ournède
Oncologists are increasingly relying on multiple modalities to model the complex
ity of diseases. Within this landscape, transcriptomic and epigenetic data have
 proven to be particularly instrumental and play an increasingly vital role in cl
inical applications. However, their integration into multimodal models remains a
 challenge, especially considering their high dimensionality. In this work, we p
resent a novel bimodal model that jointly learns representations of bulk RNA-seq
 and DNA methylation leveraging self-supervision from masked language modeling.
We implement an architecture that reduces the memory footprint usually attribute
d to purely transformer-based models when dealing with long sequences. We demons
trate that the obtained bimodal embeddings can be used to fine-tune cancer-type
classification and survival models that achieve state-of-the-art performance com
pared to unimodal models. Furthermore, we introduce a robust learning framework
that maintains downstream task performance despite missing modalities, enhancing
 the model’s applicability in real-world clinical settings.
****

Decomposition-Based Modular Conformal Prediction for Two-Stage Modeling
William Zhang, Saurabh Amin, Georgia Perakis
Conformal prediction offers finite-sample coverage guarantees under minimal assu
mptions. However, existing methods treat the entire modeling process as a black
box, overlooking opportunities to exploit and understand modular
structure. We introduce a conformal prediction framework for two-stage sequentia
l models, where an upstream predictor generates intermediate representations for
 a downstream model. By decomposing the overall prediction residual into stage-s
pecific components, our method enables practitioners to attribute uncertainty to
 specific pipeline stages. We develop a risk-controlled parameter selection proc
edure using family-wise error rate (FWER) control to calibrate stage-wise scalin
g parameters, and introduce an adaptive extension for non-stationary settings. E
xperiments on synthetic distribution shifts, as well as real-world supply chain
and stock market data, demonstrate that our approach improves coverage under str
uctural, stage-wise shifts compared to standard conformal methods, while identif
ying stage-wise error contribution. This framework offers diagnostic advantages
and robust coverage that standard conformal methods lack.

Memory-Distilled Selection for Noise-Robust Anomaly Detection

Sirojbek Safarov, Jaewoo Park, Yoon Gyo Jung, Kuan-Chuan Peng, Wonchul Kim, Seongdeok Bang, Octavia Camps

Anomaly detection (AD) under data contamination is critical for deploying unsupervised defect detection in industrial environments, where curating perfectly clean training sets is impractical. However, existing methods are sensitive to contamination, suffering significant performance degradation as the noise ratio increases. In this paper, we propose Memory-Distilled Selection (MeDS), a training algorithm based on data selection. MeDS constructs an ensemble of partial memories via random subsampling, where the resulting sparsity acts as a low-pass filter that captures nominal patterns across a wide range of noise ratios, enabling coarse-level identification of contaminated samples. The aggregated distances to the bootstrapped memories are then distilled into a reconstruction score network, which is subsequently fine-tuned on clean data filtered using scores from the distilled model, enabling fine-grained localization of anomalies. MeDS is robust across a wide range of noise ratios without requiring noise-ratio-specific hyperparameter tuning, achieving 99.16\% image-level AUROC on MVTecAD at a 40\% noise ratio, and attaining state-of-the-art performance on both VisA and Real-IAD under noisy settings. We thoroughly verify the efficacy of MeDS on industrial AD benchmarks under noisy data scenarios, accompanied by in-depth empirical analyses.

Dissecting Multimodal In-Context Learning: Modality Asymmetries and Circuit Dynamics in modern Transformers

Yiran Huang, Karsten Roth, Quentin Bouniot, Wenjia Xu, Zeynep Akata

Transformer-based multimodal large language models often exhibit in-context learning (ICL) capabilities. Motivated by this phenomenon, we ask: how do transformers learn to associate information across modalities from in-context examples? We investigate this through controlled experiments on small transformers trained on synthetic classification tasks, enabling precise manipulation of data statistics and model architecture. We begin by revisiting core principles of unimodal ICL in modern transformers. While several prior findings replicate, we find that Rotary Position Embeddings (RoPE) can delay the onset of ICL circuits. Extending to the multimodal setting reveals a fundamental learning asymmetry: when pretrained on high-diversity data from a primary modality, surprisingly low data complexity in the secondary modality suffices for multimodal ICL to emerge. Mechanistic analysis shows that both settings rely on an induction-style mechanism that copies labels from matching in-context exemplars; multimodal training refines and extends these circuits across modalities. Our findings provide a mechanistic foundation for understanding multimodal ICL in modern transformers and introduce a controlled testbed for future investigation. Code is available at: https://github.com/YiranHuangIrene/multimodal-icl

RoboFlow4D: A Lightweight Flow World Model Toward Real-Time Flow-Guided Robotic Manipulation

Sixu Lin, Junliang Chen, Huaiyuan Xu, Zhuohao Li, Guangming Wang, Yixiong Jing, Sheng Xu, Runyi Zhao, Brian Sheil, Lap-Pui Chau, Guiliang Liu

Planning and acting in 3D environments is a fundamental capability for robotic manipulation in the real world.

Although prior work has explored predictive flow planners to guide 3D manipulation, existing approaches often rely on modular pipelines stacking multiple submodels, resulting in high computational overhead and limited real-time performance. To address these challenges, we introduce RoboFlow4D, a lightweight flow world model that unifies perception and planning by estimating temporal motion in physical 3D space. As an end-to-end framework, RoboFlow4D directly predicts multi-frame 3D flows from visual observations and textual instructions, providing explicit flow-based planning to guide action generation. This design allows seamless integration with general action policies, forming an efficient observation–planning–execution closed loop. Through slow–fast collaboration between flow prediction and action control, RoboFlow4D enables real-time and resource-efficient manipulation. Extensive experiments in both simulation and real-world settings demonstrate that RoboFlow4D consistently improves manipulation success rates and comput

ational efficiency, advancing flow-guided planning for embodied intelligence. Our project page is available at RoboFlow4D.

Why Dedicated Critics: Eliminating Target Drift in Multi-Constraint RL
Yue Yang, Chenghao Huang, Hao Wang
Lagrangian-based methodologies are one of the fundamental paradigms of safe reinforcement learning (RL) for constrained Markov decision processes, particularly when dealing with multi-constraint cases. While the specific details of the methodologies may differ, with some using a single estimator for the overall mixed penalty term of the constraints and others using separate estimators for the constraints, the fundamental question of the theoretical validity of the methodologies has remained largely unexplored. The present paper performs the first theoretical analysis of the methodologies and proves that the use of the mixed critic structure leads to the presence of a bias due to the target drift of the Lagrange multipliers. On the other hand, the use of the dedicated critic structure, where separate critics are used for the reward function and the constraint functions, does not suffer from this bias. The theoretical analysis is supported with experiments on a realistic power system environment with multiple constraints, where the dedicated critic structure succeeds in satisfying the constraints, whereas the mixed critic structure fails.
****
cuRegOT: A GPU-Accelerated Solver for Entropic-Regularized Optimal Transport
Yixuan Qiu
Optimal transport (OT) has emerged as a fundamental tool in modern machine learning, yet its computational cost remains a significant bottleneck for large-scale applications. While harnessing the massive parallelism of modern GPU hardware is critical for efficiency, the de facto standard Sinkhorn algorithm, despite its ease of parallelization, often suffers from slow convergence in challenging problems. More recently, the sparse-plus-low-rank quasi-Newton method offers a balance between convergence rate and per-iteration complexity; however, its efficiency on GPUs is severely hindered by the serial nature of sparse matrix symbolic analysis and irregular memory access patterns. To bridge this gap, we present cuRegOT, a high-performance GPU solver tailored for entropic-regularized OT. We introduce a suite of algorithmic and architectural optimizations, including an amortized symbolic analysis strategy to mitigate CPU bottlenecks, an asynchronous Sinkhorn iterates generation mechanism, and a fused kernel for bandwidth-efficient gradient evaluation. These strategies are backed by rigorous theoretical guarantees ensuring algorithmic convergence. Extensive numerical experiments demonstrate that cuRegOT achieves significant speedups over state-of-the-art GPU-based solvers across a variety of benchmark tasks.

Hista and Numca: Estimate State Value Effectively for Large Language Model Reinforcement Learning
Zizhe Chen, Jiqian Dong, Yizhou Tian, Garry YANG, Yongqiang Chen, Zhitang Chen, James Cheng
Reinforcement learning (RL) refines large language models (LLMs) by directly optimizing model behavior through reward signals. While accurate state value estimation is critical for stable training in classical RL, it remains an underexplored challenge in LLM post■training. In this work, we introduce the State Value Estimation Benchmark (SVEB) to assess state estimation within existing RL frameworks and show that critics in standard approaches like PPO collapse to a coarse group■average baseline. To address this, we propose two techniques: \textit{Numca}, which leverages numerical spans as gradable milestones for state value estimation, and \textit{Hista}, a framework that uses LLM's hidden states as representation to weighted average disjoint rollouts and their return. Extensive experiments demonstrate that both methods yield more accurate state value estimates and enhance training performance across different RL algorithms and model sizes without incurring significant computational overhead. Code available at \url{https://github.com/VOXXXX1874/Hista}.

Landmark-Guided Policy Optimization for Multi-Objective Language Model Selection
Marcio Monteiro, Weichen Li, Puyu Wang, Marius Kloft, Sophie Fellenz
Selecting a pretrained large language model (LLM) to fine-tune for a task-specif ic dataset can be time-consuming and costly. With several candidate models avail able to choose from, varying in size, architecture, and pretraining data, findin g the best model for a specific task often involves extensive trial and error. I n addition, the "best" model may not necessarily be the one with the lowest test loss, as practical considerations such as deployment costs, inference throughpu t, and limited search budgets might also play crucial roles. To address this, we introduce LAMPS (LAnguage Model Pareto Selection), a novel and open-source mult i-objective AutoML framework that meta-learns a resource allocation policy to ef ficiently identify (or approximate) the Pareto front of candidate LLMs for a tas k-specific dataset. It is based on two key ideas: (1) landmark fine-tuning, whic h generates early performance indicators of the candidate models, and (2) meta-l earning via reinforcement learning, which learns an effective selection policy f rom historical performance data (a meta-dataset). Our results show that, on held -out datasets, LAMPS reduces search time by an average of 73% compared to exhaus tive search, while still covering more than 99% of the optimal target space hype rvolume.

From Volume to Value: Preference-Aligned Memory Construction for On-Device RAG
Changmin Lee, Jaemin Kim, Taesik Gong
With the rapid emergence of personal AI agents based on Large Language Models (L LMs), implementing them on-device has become essential for privacy and responsiv eness.
To handle the inherently personal and context-dependent nature of real-world req uests, such agents must ground their generation in device-resident personal cont ext.
However, under tight memory budgets, the core bottleneck is *what to store* so t hat retrieval remains aligned with the user.
We propose EPIC (Efficient Preference-aligned Index Construction), which focuses on user preferences as a compact and stable form of personal context and integr ates them throughout the RAG pipeline.
EPIC selectively retains preference-relevant information from raw data and align s retrieval toward preference-aligned contexts.
Across four benchmarks covering conversations, debates, explanations, and recomm endations, EPIC reduces indexing memory by 2,404$\times$, improves preference-fo llowing accuracy by 18.79\%p, and achieves 32.17$\times$ lower retrieval latency over the best-performing baseline.
In on-device experiments, EPIC maintains under 1 MB memory and achieves 5.21 to 29.35 ms/query latency across three platforms, while supporting streaming update s under preference drift.
Our code and data are available at https://github.com/UbiquitousAILab/EPIC.

Weak Diffusion Priors Can Still Achieve Strong Inverse-Problem Performance
Jing Jia, Wei Yuan, Sifan Liu, Liyue Shen, Guanyang Wang
Can a diffusion model trained on bedrooms recover human faces? Diffusion models are widely used as priors for inverse problems, but standard approaches usually assume a high-fidelity model trained on data that closely match the unknown sign al. In practice, one often must use a mismatched or low-fidelity diffusion prior . Surprisingly, these weak priors often perform nearly as well as full-strength, in-domain baselines. We study when and why inverse solvers are robust to weak d iffusion priors. Through extensive experiments, we find that weak priors succeed when measurements are highly informative (e.g., many observed pixels), and we i dentify regimes where they fail. To explain this behavior, we combine Bayesian-c onsistency theory with local-correlation analysis: the theory gives conditions u nder which high-dimensional measurements make the posterior concentrate near the true signal, while the correlation analysis shows that weak and stronger natura l-image priors can share similar local spatial structure. These results provide a principled justification on when weak diffusion priors can be used reliably. C

ode is available at https://github.com/jjia131/weak-diffusion-priors-inverse-problem.

Learning to Rank by Directly Optimizing Full-Order Probabilities
Yongxiang Tang, Chao Wang, Jincheng Lu, Yanhua Cheng, Xialong Liu, Peng Jiang
Learning to rank can be cast as a probabilistic modeling problem over permutations, where the goal is to estimate the likelihood of an observed total ordering of items. This formulation naturally involves full-order probabilities of the form $\mathbb{P}(z_1 \leq \cdots \leq z_n)$, whose exact computation and optimization are intractable due to the factorial growth of the permutation space with respect to the list size. In this work, we introduce the *Full-Order Bound* (FOB), a tractable lower bound on the probability of an observed ordering, constructed from a subset of ordering constraints that factorizes across items while preserving full-order structure and order-reversal invariance. Under log-concave latent densities, the bound induces a convex inner tightening problem over latent cut points, which we solve efficiently during training using a *safe-region gradient ascent* (SRGA) procedure. Experiments on synthetic ranking tasks and large-scale learning-to-rank benchmarks show that FOB improves full-list ordering metrics and remains competitive on NDCG, while an optional metric-aligned variant recovers NDCG gains. Our code is available at https://github.com/tyxaaron/FOB.
****
Online Robust Reinforcement Learning with General Function Approximation
Debamita Ghosh, George K. Atia, Yue Wang
Reinforcement learning (RL) in real-world tasks often suffers from the performance degradation due to the distribution shift between training and deployment environments. Distributionally Robust RL (DR-RL) addresses this issue by optimizing the worst-case performance over an uncertainty set of transition dynamics, providing an optimized baseline performance upon deployment. However, existing methods typically require strong data access assumptions (e.g., a generative model or comprehensive offline datasets) and mostly focus on tabular settings. In this paper, we introduce a purely online DR-RL algorithm with general function approximation that learns a robust policy directly from interaction, without any prior knowledge or pre-collected data. Our method uses a dual-based fitted robust Bellman update to jointly learn the value function and the robust backup operator. We establish the first regret guarantee for online DR-RL in terms of an intrinsic complexity measure—the robust Bellman–Eluder (BE) dimension, for general ϕ-divergence uncertainty sets. Our regret bound is sublinear and independent of $|\mathcal{S}|$ and $|\mathcal{A}|$, and recovers sharp rates in structured regimes, providing a scalable method for practical DR-RL.
****
A model of errors in transformers
Suvrat Raju, Praneeth Netrapalli
We study the error rate of LLMs on tasks like arithmetic that require a deterministic output, and repetitive processing of tokens drawn from a small set of alternatives. We argue that incorrect predictions arise when small errors in the attention mechanism accumulate to cross a threshold, and use this insight to derive a quantitative two-parameter relationship between the accuracy and the complexity of the task. The two parameters vary with the prompt and the model; they can be interpreted in terms of an elementary noise rate, and the number of plausible erroneous tokens that can be predicted. Our analysis is inspired by an "effective field theory'' perspective: the LLM's many raw parameters can be reorganized into just two parameters that govern the error rate. We perform extensive empirical tests, using Gemini 2.5 Flash, Gemini 2.5 Pro and DeepSeek R1, and find excellent agreement between the predicted and observed accuracy for a variety of tasks, although we also identify deviations in some cases. Our model provides an alternative to suggestions that errors made by LLMs on long repetitive tasks indicate the "collapse of reasoning'', or an inability to express "compositional'' functions. Finally, we show how to construct prompts to reduce the error rate.

GraphFLEx: Unsupervised Structure Learning $\underline{\text{F}}$ramework for $\underline{\text{L}}$arge $\underline{\text{Ex}}$panding $\underline{\text{Graph}}$s

Mohit Kataria, Nikita Malik, Jayadeva Jayadeva, Sandeep Kumar

Graph structure learning is a core problem in graph-based machine learning, essential for uncovering latent relationships and ensuring model interpretability. However, most existing approaches are ill-suited for large-scale and dynamically evolving graphs, as they often require complete re-learning of the structure upon the arrival of new nodes and incur substantial computational and memory costs. In this work, we propose GraphFLEx—a unified and scalable framework for Graph Structure Learning in Large and Expanding Graphs. GraphFLEx mitigates the scalability bottlenecks by restricting edge formation to structurally relevant subsets of nodes identified through a combination of clustering and coarsening techniques. This dramatically reduces the search space and enables efficient, incremental graph updates. The framework supports 48 flexible configurations by integrating diverse choices of learning paradigms, coarsening strategies, and clustering methods, making it adaptable to a wide range of graph settings and learning objectives. Extensive experiments across 26 diverse datasets and graph neural network architectures demonstrate that GraphFLEx achieves state-of-the-art performance with significantly improved scalability. Our implementation is publicly available here: https://anonymous.4open.science/r/Scaling_Graph_Learning-CB67/README.md.

Unveiling And Addressing Dimensional Collapse In Vector Quantization Models Via Codebook Regularization

Fang Zhang, Yongxin Zhu, Yihao Liu, Bin Fu, Linli Xu

While recent advancements in Vector Quantization (VQ) models have successfully achieved complete codebook utilization, a critical bottleneck remains largely unexplored: the effective dimensionality of the codebook embedding space. We observe that discrete codebook representations tend to degenerate into low-dimensional subspaces, characterized by significantly lower effective rank than continuous representations during quantization. Through comprehensive spectral analysis, we identify that this dimensional collapse stems from the suppression of low-variance components inherent to the vector quantization process, thereby severely limiting the expressive capacity of VQ models. To mitigate this fundamental issue, we propose a simple yet effective codebook regularization strategy designed to restore low-variance components, effectively bridging the spectral gap between discrete codebook spaces and continuous representations. Extensive experiments demonstrate that this regularization objective is compatible with diverse VQ training paradigms, yielding significant improvements in reconstruction fidelity and downstream performance in autoregressive image generative models.

Correcting Split Selection in Online Decision Trees via Anytime-Valid Inference

Salim I. Amoukou, Saumitra Mishra, Manuela Veloso

Bagging-based ensembles, most notably Adaptive Random Forests, are among the strongest performers for learning from data streams. A common denominator across these methods is their reliance on Hoeffding Trees as base learners, which grow decision trees incrementally by testing whether a candidate split is significantly better than its alternatives using concentration inequalities. Despite their empirical success, existing Hoeffding Trees variants lack valid statistical guarantees. Current analyses rely on fixed-sample concentration bounds, while split decisions are made using data-dependent stopping rules, which invalidates their guarantees and can drive the probabilty of incorrect splits to one. We introduce a principled alternative based on \emph{anytime-valid inference}. Our method provides: (i) anytime-valid control of false splits under arbitrary data streams, including non-stationary settings; (ii) finite commitment time under a predictive advantage; and (iii) under stationary i.i.d.\ data, risk is monotone decreasing and strictly improves at every split. Empirically, we evaluate both standalone trees and their use within Adaptive Random Forests on non-stationary streams. Our method improves performance while producing substantially smaller trees.

RefineEvo: Planning-Guided Heuristic Evolution with Bidirectional Experience
Yang Wu, Junran Pan, Yifan Zhang, Ning Xu, Fanshuo Zeng, Jian Cheng
Automatic Heuristic Design (AHD) has emerged as a transformative approach for so lving combinatorial optimization problems. While recent Large Language Model (LL M)-based methods have shown promise, they predominantly rely on fixed evolutiona ry operators and struggle to effectively accumulate and reuse historical search experience. This paper proposes RefineEvo, a novel evolutionary framework that t ransforms AHD from a static trial-and-error process into a planning-guided, expe rience-driven system. RefineEvo introduces a Planner to dynamically schedule evo lutionary operators and trigger refinement based on the current search state, an d a Reflector to distill valuable lessons into a Bidirectional Experience Pool c ontaining both positive insights and negative pitfalls. This synergistic framewo rk enables the system to adapt its search tools to the evolving complexity of th e problem and leverage trajectory-aware, situation-conditioned insights to guide generation. Experiments on several classic combinatorial optimization benchmark s demonstrate that RefineEvo consistently outperforms strong baselines. In parti cular, RefineEvo delivers superior solution quality while improving token effici ency, enabling more efficient and autonomous heuristic design.

Endogenous Resistance to Activation Steering in Language Models
Alex McKenzie, Keenan Pepper, Stijn Servaes, Martin Leitgab, Murat Cubuktepe, Mi chael Vaiana, Diogo S de Lucena, Judd Rosenblatt, Michael S. A. Graziano
Large language models can resist task-misaligned activation steering during infe rence, sometimes recovering mid-generation to produce improved responses even wh en steering remains active. We term this Endogenous Steering Resistance (ESR). U sing sparse autoencoder (SAE) latents to steer model activations, we find that L lama-3.3-70B shows substantial ESR, while smaller models from the Llama-3 and Ge mma-2 families exhibit the phenomenon less frequently. We identify 26 ``off-topi c detector'' latents that predict ESR episodes in Llama-3.3-70B. Zero-ablating t hese latents reduces the multi-attempt rate by 25\%, providing causal evidence f or dedicated internal consistency-checking circuits. We demonstrate that ESR can be deliberately enhanced through both prompting and training: meta-prompts inst ructing the model to self-monitor increase the multi-attempt rate by 5$\times$ f or Llama-3.3-70B, and fine-tuning on self-correction examples successfully induc es ESR-like behavior in smaller models. These findings have dual implications: E SR could protect against adversarial manipulation but might also interfere with beneficial safety interventions that rely on activation steering. Understanding and controlling these resistance mechanisms is important for developing transpar ent and controllable AI systems.
****
StormInsight: Hierarchical Environmental Forcing and Vertical Coupling for Weath er System Evolution
Jun CHEN, Yan Fang, Minghui Qiu, Yueran Qiu, Lin CHEN, SHUXIN ZHONG, Yu ZHANG, K aishun Wu
Nowcasting forms the first line of defense against rapidly evolving weather haza rds, where even minutes of delay can lead to severe societal impacts. However, e xisting systems predominantly extrapolate 2D radar reflectivity, which struggles under rapid intensification regimes. We introduce StormInsight, a multi-scale m odeling framework that enables coherent reconstruction of the three-dimensional evolution of convective systems while explicitly conditioning on the ambient env ironment. StormInsight integrates multi-source observations—including radar, sat ellite, and station—with reanalysis fields through two components: (i) Storm Evo lution Encoder that explicitly disentangles convective system state form vertica l thermodynamic coupling and large-scale environmental forcing; (ii) Convective System Decoder that predicts future echos by adaptively aggregating cross-layer interactions conditioned on evolving environmental conditions. To support compre hensive evaluation, we build a new benchmark StormBench that integrates observat ional and reanalysis data across regions. On this benchmark, StormInsight consis tently achieves the best performance, reducing MAE by 12.4% and improving the mC SI by 34.0%.

****
LassoFlexNet: a Flexible Neural Architecture for Tabular Data
Kry Yik-Chau Lui, Cheng Chi, Kishore Basu, Yanshuai Cao
Despite their dominance in vision and language, deep neural networks often underperform relative to tree-based models on tabular data.
To bridge this gap, we incorporate five key inductive biases into deep tabular learning: robustness to irrelevant features, axis alignment,
localized irregularities, feature heterogeneity, and training stability. We propose *LassoFlexNet*,
an architecture that evaluates the linear and nonlinear marginal contribution of each input via Per-Feature Embeddings,
and sparsely selects relevant variables using a Tied Group Lasso mechanism.
Because these components introduce optimization challenges that destabilize standard proximal methods,
we analyze stochastic hierarchical proximal dynamics and develop a *Sequential Hierarchical Proximal Adaptive Gradient optimizer with exponential moving averages (EMA)*
designed to stabilize training in practice. Across 52 datasets from three benchmarks, LassoFlexNet matches or outperforms leading tree-based models,
achieving up to a 10\% relative gain, while maintaining Lasso-like interpretability. We substantiate these empirical results with ablation studies and theoretical proofs
confirming the architecture's enhanced expressivity and structural breaking of undesired rotational invariance.
****
Scaling Law for Quantization-Aware Training
Mengzhao Chen, Chaoyi Zhang, Jing Liu, Yutao Zeng, Zeyue Xue, Zhiheng Liu, Yunshui Li, Jin Ma, Jie Huang, zhou Xun, Ping Luo
Large language models (LLMs) demand substantial computational and memory resources, creating deployment challenges. Quantization-aware training (QAT) addresses these challenges by reducing model precision while maintaining performance. However, the scaling behavior of QAT, especially at 4-bit precision (W4A4), is not well understood. Existing QAT scaling laws often ignore key factors such as the number of training tokens and quantization granularity, which limits their applicability. This paper proposes a unified scaling law for QAT that models quantization error as a function of model size, training data volume, and quantization group size. Through 268 QAT experiments, we show that quantization error decreases as model size increases, but rises with more training tokens and coarser quantization granularity. To identify the sources of W4A4 quantization error, we decompose it into weight and activation components. Both components follow the overall trend of W4A4 quantization error, but with different sensitivities. Specifically, weight quantization error increases more rapidly with more training tokens. Further analysis shows that the activation quantization error in the FC2 layer, caused by outliers, is the primary bottleneck of W4A4 QAT quantization error. By applying mixed-precision quantization to address this bottleneck, we demonstrate that weight and activation quantization errors can converge to similar levels. Additionally, with more training data, weight quantization error eventually exceeds activation quantization error, suggesting that reducing weight quantization error is also important in such scenarios. These findings offer key insights for improving QAT research and development.

Explanations are a Means to an End: Decision Theoretic Explanation Evaluation
Ziyang Guo, Berk Ustun, Jessica Hullman
Explanations of model behavior are commonly evaluated via proxy properties weakly tied to the purposes explanations serve in practice. We contribute a decision theoretic framework that treats explanations as information signals valued by the expected improvement they enable on a specified decision task. This approach yields three distinct estimands: (i) a theoretical benchmark that upper-bounds achievable performance by any agent with the explanation, (ii) a human-complementary value that quantifies the theoretically attainable value that is not already

captured by a baseline human decision policy, and (iii) a behavioral value repre
senting the causal effect of providing the explanation to human decision-makers.
We instantiate these definitions in a practical validation workflow,
and apply them to assess explanation potential and interpret behavioral effects
in human–AI decision support and mechanistic interpretability.

Sparse Models, Sparse Safety: Unsafe Routes in Mixture-of-Experts LLMs
Yukun Jiang, Hai Huang, Mingjie Li, Yage Zhang, Michael Backes, Yang Zhang
By introducing routers to selectively activate experts in Transformer layers, th
e mixture-of-experts (MoE) architecture significantly reduces computational cost
s in large language models (LLMs) while maintaining competitive performance, esp
ecially for models with massive parameters.
However, prior work has largely focused on utility and efficiency, leaving the s
afety risks associated with this sparse architecture underexplored.
In this work, we show that the safety of MoE LLMs is as sparse as their architec
ture by discovering $\text{\emph{unsafe routes}}$: routing configurations that,
once activated, convert safe outputs into harmful ones.
Specifically, we first introduce the $\underline{\text{Ro}}$uter $\underline{\te
xt{Sa}}$fety $\underline{\text{i}}$mportance $\underline{\text{s}}$core ($\textb
f{RoSais}$) to quantify the safety criticality of each layer's router.
Manipulation of only the high-RoSais router(s) can flip the default route into a
n unsafe one.
We further propose a $\underline{\text{F}}$ine-grained token-layer-wise $\underl
ine{\text{S}}$tochastic $\underline{\text{O}}$ptimization framework to discover
more concrete $\underline{\text{U}}$nsafe $\underline{\text{R}}$outes ($\textbf{
F-SOUR}$), which explicitly considers the sequentiality and dynamics of input to
kens.
Across four representative MoE LLM families, F-SOUR achieves an average ASR of 0
.90 and 0.98 on JailbreakBench and AdvBench, respectively.
Finally, we outline defensive perspectives, including safety-aware route disabli
ng and router training, as promising directions to safeguard MoE LLMs.
We hope our work can inform future red-teaming and safeguarding of MoE LLMs.
Our code is available at https://github.com/TrustAIRLab/UnsafeMoE.

HexGen-3: A Fully Disaggregated LLM Serving Framework with Fine-Grained Heteroge
neous Resource Autoscaling
Youhe Jiang, Wenshuang Li, You Peng, Jintao Zhang, Ran Yan, Jianfei Chen, Xu Han
, Fangcheng Fu, Binhang Yuan
The operational cost of serving large language models remains prohibitively high
, largely due to extreme workload heterogeneity in production traffic. We observ
e that combining disaggregated inference with resource autoscaling enables fine-
grained resource adjustment, allowing inference phases and operations to scale i
ndependently based on their specific bottlenecks. Building on this insight, we p
ropose HexGen-3, a cost-effective LLM serving framework that leverages a fully d
isaggregated inference architecture and heterogeneous resource autoscaling. HexG
en-3 introduces two key components: (i) A hierarchical scheduling framework that
 jointly optimizes resource allocation and parallelism configuration for any giv
en resource provisioning, and (ii) an autoscaling framework that dynamically adj
usts resources and triggers deployment rescheduling in response to workload fluc
tuations. Experiments comparing HexGen-3 against state-of-the-art LLM serving sy
stems demonstrate up to 60% (on average 46.5%) improvement in per-cost throughpu
t under static resource provisioning, and up to 78.3% (on average 55.1%) improve
ment with autoscaling enabled under dynamic workloads.

KAGE-Bench: Fast Known-Axis Visual Generalization Evaluation for Reinforcement L
earning
Egor Cherepanov, Daniil Zelezetsky, Aleksandr Panov, Alexey Kovalev
Pixel-based reinforcement learning agents often fail under purely visual distrib
ution shift even when latent dynamics and rewards are unchanged, but existing be
nchmarks entangle multiple sources of shift and hinder systematic analysis. We i

ntroduce KAGE-Env, a JAX-native 2D platformer that factorizes the observation process into independently controllable visual axes while keeping the underlying control problem fixed. By construction, varying a visual axis affects performance only through the induced state-conditional action distribution of a pixel policy, providing a clean abstraction for visual generalization. Building on this environment, we define KAGE-Bench, a benchmark of six known-axis suites comprising 34 train-evaluation configuration pairs that isolate individual visual shifts. Using a standard PPO-CNN baseline, we observe strong axis-dependent failures, with background and photometric shifts often collapsing success, while agent-appearance shifts are comparatively benign. Several shifts preserve forward motion while breaking task completion, showing that return alone can obscure generalization failures. Finally, the fully vectorized JAX implementation enables up to 33M environment steps per second on a single GPU, enabling fast and reproducible sweeps over visual factors. Code: https://avanturist322.github.io/KAGEBench/

Nonparametric Distribution Regression Re-calibration

Ádám Jung, Domokos M. Kelen, Andras A Benczur

A key challenge in probabilistic regression is ensuring that predictive distributions accurately reflect true empirical uncertainty. Minimizing overall prediction error often encourages models to prioritize informativeness over calibration, producing narrow but overconfident predictions. However, in safety-critical settings, trustworthy uncertainty estimates are often more valuable than narrow intervals. Realizing the problem, several recent works have focused on post-hoc corrections; however, existing methods either rely on weak notions of calibration (such as PIT uniformity) or impose restrictive parametric assumptions on the nature of the error. To address these limitations, we propose a novel nonparametric re-calibration algorithm based on conditional kernel mean embeddings, capable of correcting calibration error without restrictive modeling assumptions. For efficient inference with real-valued targets, we introduce a novel characteristic kernel over distributions that can be evaluated in $\mathcal{O}(n \log n)$ time for empirical distributions of size n. We demonstrate that our method consistently outperforms prior re-calibration approaches across a diverse set of regression benchmarks and model classes.

RADAR: Defending RAG Dynamically against Retrieval Corruption

Ziyuan Chen, Yueming Lyu, Yi Liu, Weixiang Han, Jing Dong, Caifeng Shan, Tieniu Tan

While RAG systems are increasingly deployed in dynamic web search, temporal volatility amplifies their vulnerability to adversarial attacks. Existing static-oriented defenses struggle to handle evolving threats and incur prohibitive storage costs in dynamic settings. We propose RADAR, a framework that models reliable context selection as a graph-based energy minimization problem, solved exactly via a Max-Flow Min-Cut. By incorporating a Bayesian memory node, RADAR recursively updates a belief state instead of archiving raw historical documents, effectively balancing stability against attacks with adaptability to genuine knowledge shifts. Experiments on a novel dynamic dataset show that RADAR achieves superior robustness and response quality with minimal storage overhead compared to the baselines.

End-to-End Autoregressive Image Generation with 1D Semantic Tokenizer

Wenda Chu, Bingliang Zhang, Jiaqi Han, Yizhuo Li, Linjie Yang, Yisong Yue, Qiushan Guo

Autoregressive image modeling relies on visual tokenizers to compress images into compact latent representations. We design an end-to-end training pipeline that jointly optimizes reconstruction and generation, enabling direct supervision from generation results to the tokenizer. This contrasts with prior two-stage approaches that train tokenizers and generative models separately. We further investigate leveraging vision foundation models to improve 1D tokenizers for autoregressive modeling. Our autoregressive generative model achieves strong empirical results, including a state-of-the-art FID score of 1.48 without guidance on ImageN

et 256×256 generation.

Training Deep Spiking Neural Networks without Normalization
Xinyu Shi, Zhaofei Yu
The training of deep Spiking Neural Networks (SNNs) has traditionally relied on Batch Normalization (BN), which stabilizes input currents and gradients during training. However, BN is not a universal solution. It is unsuitable for variable-length tasks and scenarios with reduced batch size, constraining the development of deep SNNs, where removing BN typically causes the training to fail to converge. This dependence stems not from a fundamental necessity of BN but from the current lack of reasonable initialization methods for SNNs. This paper addresses this core limitation by proposing SpikeInit, a novel initialization framework for SNNs. By modeling the response curve and gradient of spiking layers, SpikeInit initializes the weights and shape parameters of surrogate gradients to maintain stable firing rates during forward propagation and stable gradient magnitudes during backpropagation. Extensive experiments demonstrate that deep SNNs with SpikeInit can be trained stably without normalization and achieve superior performance compared to their normalized counterparts under identical settings. Furthermore, we demonstrate the scalability of SpikeInit by successfully training an ultra-deep, 1000-layer SNN without normalization. Our work provides a foundational step toward large-scale normalization-free SNN, liberating SNN design from the constraints of normalization.
****
Ubiquity of Emergent Hebbian Dynamics in Regularized Learning
David Aaron Koplow, Tomaso Poggio, Liu Ziyin
Hebbian and anti-Hebbian plasticity are widely observed in the brain and are classically modeled as mechanistic, local homosynaptic rules stabilized by homeostatic constraints. This raises an identifiability question: does observing Hebbian/anti-Hebbian structure in synaptic updates uniquely imply an underlying Hebbian computation? We identify an alternative, emergent route. We show that near stationarity, L2 weight decay generically drives the \emph{learning-signal} component of many update rules to align with a Hebbian direction, with alignment increasing monotonically with decay strength. This Hebbian-like signature is not specific to SGD and can arise even for non-learning or random update rules long before learning has ceased. We further show that stochastic noise in the learning signal can induce anti-Hebbian alignment, yielding a simple tradeoff with weight decay and a phase boundary in regression settings. These mechanisms do not replace standard Hebbian theory; they can coexist with genuine Hebbian plasticity and complicate the interpretation of synaptic measurements, motivating experiments that distinguish mechanistic Hebbian computation from emergent Hebbian signatures.

Not All Invariants Are Equal: Curating Training Data to Accelerate Program Verification with SLMs
Ido Pinto, Yizhak Yisrael Elboher, Haoze Wu, Nina Narodytska, Guy Katz
The synthesis of inductive loop invariants remains a critical bottleneck in automated program verification. While Large Language Models (LLMs) show promise in mitigating this issue, they often fail on complex programs, producing invariants that are invalid or computationally ineffective. Although fine-tuning is a natural strategy to address these limitations, obtaining high-quality training data remains an open challenge. We first formalize the properties required for a high-quality training invariant, and then present \textsc{Wonda}, a rigorous data curation pipeline that extracts such invariants from raw verifier output via AST-based normalization followed by LLM-driven semantic rewriting and augmentation with provable quality guarantees. Fine-tuning Small Language Models (SLMs) on \textsc{Wonda}-curated data yields consistent gains across the Qwen3, Llama-3.1, and Mistral families: the 4B and 8B Qwen3 models nearly double invariant correctness and double speedup rates, while Llama-3.1-8B triples both. On the challenging InvBench suite, the same 4B model outperforms an off-the-shelf model 20$\times$ its size and matches the end-to-end verification time of GPT-OSS-120B, while a 14B Qwen3 model matches that of the frontier model GPT-5.2, all without test-time

compute overhead. Our code is publicly available on \href{https://github.com/idopinto/wonda}{GitHub}.
****
Provable Bounds for the Learnability of Sample-Compressible Families from Noisy Samples
Arefe Boushehrian, Amir Najafi
Learning distribution families over $\mathbb{R}^d$ is a fundamental problem in unsupervised learning and statistics. A central question in this setting is whether a given family of distributions possesses sufficient structure to be (at least) information-theoretically learnable and, if so, to characterize its sample complexity. In 2018, Ashtiani et al. (2018) reformulated sample compressibility as a structural property of distribution classes, proving that it guarantees PAC-learnability. This discovery subsequently enabled a series of recent advancements in deriving nearly tight sample complexity bounds for various high-dimensional open problems. It has been further conjectured that the converse also holds: every learnable class admits a sample compression scheme, making the two notions to be equivalent. In this work, we establish that sample compressible families remain learnable even from perturbed samples, subject to a set of minimax-necessary and sufficient conditions. In particular, we assume samples are corrupted by an additive independent noise model, and theoretically derive sample complexity bounds for general sample compressible classes in arbitrary dimensions with respect to both ℓ_2-norm and total variation distance.

Transformers Efficiently Perform In-Context Logistic Regression via Normalized Gradient Descent
Chenyang Zhang, Yuan Cao
Transformers have demonstrated remarkable in-context learning (ICL) capabilities. The strong ICL performance of transformers is commonly believed to arise from their ability to implicitly execute certain algorithms on the context, thereby enhancing prediction and generation. In this work, we investigate how transformers with softmax attention perform in-context learning on linear classification data. We first construct a class of multi-layer transformers that can perform in-context logistic regression, with each layer exactly performing one step of normalized gradient descent on an in-context loss. Then, we show that our constructed transformer can be obtained through (i) training a single self-attention layer supervised by one-step gradient descent, and (ii) recurrently applying the trained layer to obtain a looped model. Training convergence guarantees of the self-attention layer and out-of-distribution generalization guarantees of the looped model are provided. Our results advance the theoretical understanding of ICL mechanism by showcasing how softmax transformers can effectively act as in-context learners.
****
InfoLaw: Information Scaling Laws for Large Language Models with Quality-Weighted Mixture Data and Repetition
Weidong Zhou, Fengze Liu, Binbin Liu, Ping Guo, Zijun Wang, Bingni Zhang, Yifan Zhang, Yifeng Yu, Xiaohuan Zhou, Taifeng Wang
Upweighting high-quality data in LLM pretraining often improves performance, but in data-limited regimes, especially under overtraining, stronger upweighting increases repetition and can degrade performance. However, standard scaling laws do not reliably extrapolate across mixture recipes or under repetitions, making the selection for optimal data recipes at scaling underdetermined. To solve this, we introduce \textbf{InfoLaw} (Information Scaling Laws), a data-aware scaling framework that predicts loss from consumed tokens, model size, data mixture weights, and repetition. The key idea is to model pretraining as information accumulation, where quality controls information density and repetition induces scale-dependent diminishing returns. We first collect the model performance after training on datasets that vary in scale, quality distribution, and repetition level. Then we build up the modeling for information so that information accurately predicts those model performance. InfoLaw predicts performance on unseen data recipes and larger-scale runs (up to 7B, 425B tokens) with 0.15\% mean and 0.96\% max

absolute error in loss, and it extrapolates reliably across overtraining levels, enabling efficient data-recipe selection under varying compute budgets.
****
Residual Context Diffusion Language Models
Yuezhou Hu, Harman Singh, Monishwaran Maheswaran, Haocheng Xi, Coleman Richard Charles Hooper, Jintao Zhang, Aditya Tomar, Michael W. Mahoney, Sewon Min, Mehrdad Farajtabar, Kurt Keutzer, Amir Gholami, Chenfeng Xu
Diffusion Large Language Models (dLLMs) have emerged as a promising alternative to purely autoregressive language models because they can decode multiple tokens in parallel. However, state-of-the-art block-wise dLLMs rely on a ``remasking" mechanism that decodes only the most confident tokens and discards the rest, effectively wasting computation. We demonstrate that recycling computation from the discarded tokens is beneficial, as these tokens retain contextual information useful for subsequent decoding iterations. In light of this, we propose Residual Context Diffusion (RCD), a module that converts these discarded token representations into contextual residuals and injects them back for the next denoising step. RCD uses a decoupled two-stage training pipeline to bypass the memory bottlenecks associated with backpropagation. We validate our method on both long CoT reasoning (SDAR) and short CoT instruction following (LLaDA) models. We demonstrate that a standard dLLM can be efficiently converted to the RCD paradigm with merely $\sim$300 million tokens. RCD consistently improves frontier dLLMs by 4--11 percentage points in accuracy with minimal extra computation overhead across a wide range of benchmarks. Notably, on the most challenging AIME tasks, RCD nearly doubles baseline accuracy and attains up to 4--5x fewer denoising steps at baseline's peak accuracy.

Order Matters: Unveiling the Hidden Impact of Macro Placement Sequences via Proxy-Guided LLM Evolution
Shibing Mo, Jing Liu, Jianchu Xu, Ruilin Wu
Macro placement is a fundamental step in modern VLSI physical design, determining the solution quality of high-dimensional combinatorial optimization problems. Despite recent advancements in machine learning for spatial coordinate determination, the temporal dimension of placement sequencing remains largely governed by static heuristics. In this work, we demonstrate that the placement sequence is not merely a preprocessing step but a decisive factor in optimization, where suboptimal early decisions trigger irreversible domino effects that constrain the solution space. To harness this unexplored dimension, we propose \textbf{OrderPlace}, a novel framework that automates the discovery of macro placement strategies via proxy-guided Large Language Model (LLM) evolution. Unlike existing methods that rely on manual rules like area or connectivity, OrderPlace leverages LLMs to evolve generalizable, code-level ordering strategies—ranging from static metrics to dynamic, physics-inspired mechanisms. To mitigate the prohibitive cost of evaluating sequences, we introduce a lightweight proxy evaluation mechanism that efficiently filters candidates using a deterministic greedy probe. Experimental results on the standard ISPD 2005 benchmarks demonstrate that OrderPlace discovers novel ordering strategies. Compared with WireMask-EA and the state-of-the-art method EGPlace, OrderPlace reduces wirelength by 34.04% and 14.08%, respectively.

Adaptive Coding Emerges in Stabilized Supralinear Networks Trained with Local Plasticity
Haoyu Albert Wang, Wei P Dai, Jialun Ma, Jiawei Zhang, jinqi liu, Mingchen Jiang, Mingqing Xiao, Yansen Wang, Dongqi Han, Dongsheng Li, Yuguo Yu
Lateral connections (LCs) are ubiquitous in the cortical circuits. While DL architectures have rich intralayer interactions to support feature selectivity and contextual modulation, explicit excitatory and inhibitory (E-I) LCs remain underexplored and less-justified for encoding models in both DL and visual neuroscience. In this work, we analyze and train stabilized supralinear networks (SSNs) with strong E-I LCs, using local plasticity rules and natural images. We demonstrate that these LCs support a transition between dynamical regimes under different

input conditions. During the transition, the network shifts from population coding that extracts features from low-contrast or noisy inputs by recruiting more neurons, to sparse coding at high contrast, utilizing considerably fewer neurons. This reduction in the number of active neurons has been generally associated with lower metabolic demand in previous experiments and models. We find the model showing better robustness and adaptiveness against sparse coding, ICA and other unsupervised models under degraded inputs, but not when LCs are ablated. These results support the role of E-I recurrence in dynamic coding strategies and the design of more adaptive and robust systems with a concrete example in vision.

Graph Neural Dynamics via Learned Energy and Tangential Flows
Moshe Eliasof, Eldad Haber, Carola-Bibiane Schönlieb
We introduce TANGO, a dynamical-systems-inspired framework for graph representation learning that governs node feature evolution through a learned energy landscape and its associated descent dynamics. At the core of our approach is a learnable Lyapunov function over node embeddings, whose gradient defines an energy non-increasing direction that guarantees stability. To enhance flexibility while preserving the benefits of energy-based dynamics, we incorporate a novel tangential component, learned via message passing, that evolves features while maintaining the energy value.
This decomposition into orthogonal flows of energy gradient descent and tangential evolution yields a flexible form of graph dynamics, and enables effective signal propagation even in flat or ill-conditioned energy regions, that often appear in graph learning. Our method is designed to help alleviate oversquashing, and is compatible with different graph neural network backbones. Empirically, TANGO achieves strong performance across a diverse set of node and graph classification and regression benchmarks, demonstrating the effectiveness of jointly learned energy functions and tangential flows for graph neural networks.

Constrained Multi-Objective Reinforcement Learning with Max-Min Criterion
Giseung Park, Hyunyoung Nam, Woohyeon Byeon, Amir Leshem, Youngchul Sung
Multi-Objective Reinforcement Learning (MORL) extends standard RL by optimizing policies with respect to multiple, often conflicting, objectives. While max-min MORL has emerged as an effective approach for promoting fairness, its applicability remains limited, particularly when constraints must be incorporated. In this paper, we propose a MORL framework that integrates the max-min criterion with explicit constraint satisfaction. We establish a theoretical foundation for the proposed framework and validate the resulting algorithm through convergence analysis and experiments in tabular settings. We further demonstrate the practical relevance of our approach in simulated building thermal control, multi-objective locomotion control, and greenhouse-gas-emission-aware traffic management. Across these domains, our method effectively balances fairness and constraint satisfaction in multi-objective decision-making.

Masks Can Be Distracting: On Context Comprehension in Diffusion Language Models
Julianna Piskorz, Cristina Pinneri, Alvaro Correia, Motasem Alfarra, Risheek Garrepalli, Christos Louizos
Masked Diffusion Language Models (MDLMs) have recently emerged as a promising alternative to Autoregressive Language Models (ARLMs), leveraging a denoising objective that, in principle, should enable more uniform context utilisation. In this work, we examine the context comprehension abilities of MDLMs and uncover two key limitations. First, despite their more global training objective and bidirectional attention mechanism, similarly to ARLMS, **MDLMs exhibit a strong locality bias**: performance is highly sensitive to the position of relevant information within the input, favouring local over distant context. Second, appending a large number of **mask tokens—required for generation—can significantly degrade context comprehension** in models trained from scratch. Through systematic ablations, we find that these masks **act as distractors**, reducing the model's ability to process relevant information.
  To address and further study this undesirable behaviour, we introduce the mask

-agnostic loss function that encourages predictions to remain invariant to the n
umber of appended masks. Fine-tuning with this objective substantially mitigates
 the distracting effect of masks, improving robustness of MDLMs.
  Overall, our findings reveal critical limitations of the current MDLM training
 paradigm, with implications for training, evaluation and deployment.

Are Your Agents Upward Deceivers?
Dadi Guo, Qingyu Liu, Dongrui Liu, Qihan Ren, Shuai Shao, Tianyi Alex Qiu, Haora
n Li, Yi R. Fung, Zhongjie Ba, Juntao Dai, Jiaming Ji, Zhikai Chen, Jialing Tao,
 Yaodong Yang, Jing Shao, Xia Hu
Large Language Model (LLM)-based agents are increasingly used as autonomous subo
rdinates that carry out tasks for users. This raises the question of whether the
y may also engage in deception, similar to how individuals in human organization
s lie to superiors to create a good image or avoid punishment. We observe and de
fine ***agentic upward deception***, a phenomenon in which an agent facing envir
onmental constraints conceals its failure and performs actions that were not req
uested without reporting. To assess its prevalence, we construct a benchmark of
200 tasks covering five task types and eight realistic scenarios in a constraine
d environment, such as broken tools or mismatched information sources. Evaluatio
ns of 11 popular LLMs reveal that these agents typically exhibit action-based de
ceptive behaviors, such as guessing results, performing unsupported simulations,
 substituting unavailable information sources, and fabricating local files. We f
urther test intuitive mitigation methods and find only limited reductions, sugge
sting that it is difficult to eliminate and highlighting the need for stronger m
itigation strategies to ensure the safety of LLM-based agents. Code and data are
 available at https://github.com/QingyuLiu/Agentic-Upward-Deception.

Should I Have Expressed a Different Intent? Counterfactual Generation for LLM-Ba
sed Autonomous Control
Amirmohammad Farzaneh, Salvatore D'Oro, Osvaldo Simeone
Large language model (LLM)-powered agents can translate high-level user intents
into plans and actions in an environment. Yet after observing an outcome, users
may wonder: What if I had phrased my intent differently? We introduce a framewor
k that enables such counterfactual reasoning in agentic LLM-driven control scena
rios, while providing formal reliability guarantees. Our approach models the clo
sed-loop interaction between a user, an LLM-based agent, and an environment as a
 structural causal model (SCM), and leverages test-time scaling to generate mult
iple candidate counterfactual outcomes via probabilistic abduction. Through an o
ffline calibration phase, the proposed conformal counterfactual generation (CCG)
 yields sets of counterfactual outcomes that are guaranteed to contain the true
counterfactual outcome with high probability. We showcase the performance of CCG
 on a wireless network control use case, demonstrating significant advantages co
mpared to naive re-execution baselines.

Data Agent: Learning to Select Data via End-to-End Dynamic Optimization
Suorong Yang, Fangjian Su, Hai Gan, Ziqi Ye, Jie Li, Baile Xu, Furao Shen, Souja
nya Poria
Dynamic Data selection aims to accelerate training by prioritizing informative s
amples during online training.
However, existing methods typically rely on task-specific handcrafted metrics or
 static/snapshot-based criteria to estimate sample importance, limiting scalabil
ity across learning paradigms and making it difficult to capture the evolving ut
ility of data throughout training.
To address this challenge, we propose Data Agent, an end-to-end dynamic data sel
ection framework that formulates data selection as a training-aware sequential d
ecision-making problem.
The agent learns a sample-wise selection policy that co-evolves with model optim
ization, guided by a composite reward that integrates loss-based difficulty and
confidence-based uncertainty signals.
The reward signals capture complementary objectives of optimization impact and i

nformation gain, together with a tuning-free adaptive weighting mechanism that b
alances these signals over training.
Extensive experiments across a wide range of datasets and architectures demonstr
ate that Data Agent consistently accelerates training while preserving or improv
ing performance, e.g., reducing costs by over 50\% on ImageNet-1k and MMLU with
lossless performance.
Moreover, its dataset-agnostic formulation and modular reward make it plug-and-p
lay across tasks and scenarios, e.g., robustness to noisy datasets, highlighting
 its potential in real-world scenarios. Code is available at https://github.com/
Jackbrocp/Data-Agent.

GICDM: Mitigating Hubness for Reliable Distance-Based Generative Model Evaluatio
n

Nicolas Salvy, Hugues Talbot, Bertrand Thirion

Generative model evaluation commonly relies on high-dimensional embedding spaces
 to compute distances between samples. We show that dataset representations in t
hese spaces are affected by the hubness phenomenon, which distorts nearest-neigh
bor relationships and biases distance-based metrics. Building on the classical I
terative Contextual Dissimilarity Measure (ICDM), we introduce Generative ICDM (
GICDM), a method to correct neighborhood estimation for both real and generated
data. We introduce a multi-scale extension to improve empirical behavior. Extens
ive experiments on synthetic and real benchmarks demonstrate that GICDM resolves
 hubness-induced failures, restores reliable metric behavior, and improves align
ment with human assessment.

Stochastic Neural Ray Tracing for Radio Frequency Channel Modeling

Yinyan Bu, Jiajie Yu, Xingyu Chen, Bo Wen, Xinyu Zhang, Piya Pal

Wireless channel modeling is essential for the design, analysis, and optimizatio
n of modern wireless sensing and communication systems. However, accurately mode
ling wireless channels in electrically large and complex environments remains a
long-standing challenge, owing to the intricate interactions between radio-frequ
ency (RF) signals and surrounding objects (e.g., reflection, diffraction, and sc
attering). Unlike conventional ray-tracing pipelines that rely on hand-engineer
interaction rules, or black-box neural surrogates that do not explicitly model p
hysical structure, we introduce SNRFT, a novel framework that integrates neural
representations with physics-based RF propagation modeling. Our key idea is to v
iew RF transport as a stochastic propagation process, from which a material-depe
ndent attenuation coefficient emerges naturally as the rate parameter governing
transport dynamics. This formulation inherently satisfies key physical constrain
ts such as reciprocity and reversibility. Building on this foundation, we employ
 implicit neural representations to capture complex RF-object interactions while
 preserving the composability of traditional ray tracing. Extensive evaluations
on real-world wireless communication and sensing testbeds demonstrate that SNRFT
 consistently outperforms existing methods, while requiring significantly fewer
training samples.
****

OLion: Approaching the Hadamard Ideal by Intersecting Spectral and L inf Implici
t Biases

Zixiao Wang, Yifei Shen, Huishuai Zhang

Many optimizers can be interpreted as steepest-descent methods under norm-induce
d geometries, and thus inherit corresponding implicit biases. We introduce Ortho
gonal Lion which combines spectral control from orthogonalized update directions
 with ℓ_∞-style coordinate control from sign updates. OLion forms a Li
on-style momentum direction, approximately orthogonalizes it via a few Newton--S
chulz iterations, and then applies an entrywise sign, providing an efficient app
roximation to taking a maximal step over the intersection of the spectral and $\
ell_\infty$ constraint sets (a scaled Hadamard-like set for matrix parameters).
Despite the strong nonlinearity of orthogonalization and sign, we prove converge
nce under a mild, empirically verified diagonal-isotropy assumption. Across larg
e-scale language and vision training, including GPT-2 and Llama pretraining, SiT

image pretraining, and supervised fine-tuning, OLion matches or outperforms AdamW and Muon under comparable tuning while using only momentum-level optimizer state, and it mitigates optimizer mismatch when fine-tuning AdamW-pretrained checkpoints.
****
Minimax Optimal Strategy for Delayed Observations in Online Reinforcement Learning
Harin Lee, Kevin Jamieson
We study reinforcement learning with delayed state observation, where the agent observes the current state after some random number of time steps.
We propose an algorithm that combines the augmentation method and the upper confidence bound approach.
For tabular Markov decision processes (MDPs), we derive a regret bound of $\tilde{\mathcal{O}}(H \sqrt{D_{\max} SAK})$, where S and A are the cardinalities of the state and action spaces, H is the time horizon, K is the number of episodes, and $D_{\max}$ is the maximum length of the delay.
We also provide a matching lower bound up to logarithmic factors, showing the optimality of our approach.
Our analytical framework formulates this problem as a special case of a broader class of MDPs, where their transition dynamics decompose into a known component and an unknown but structured component.
We establish general results for this abstract setting, which may be of independent interest.
****
Collaborative Disagreement Resolution for Scalable Oversight
Yuyang Jiang, Chacha Chen, Teng Wu, Liwen Sun, Han Liu, Shi Feng, Chenhao Tan
Debate, where AI agents argue opposing positions, has emerged as a key approach to scalable oversight. However, debate faces a fundamental tension: models are incentivized to be persuasive to the judge, which may not always align with epistemic honesty. In this work, we propose an alternative paradigm: *disagreement resolution*, which reframes the interaction mechanism from adversarial debate to collaborative truth seeking. Drawing on principles from human mediation and conflict resolution, where mediators facilitate dialogue to help disputing parties reach consensus rather than adjudicating between them, we design an automated pipeline that adapts these strategies to AI oversight. Unlike standard debate where models argue for fixed positions, our pipeline directs models to collaboratively identify points of disagreement, examine the evidence for conflicting claims, and converge toward consensus or isolate the specific ''crux'' of their disagreement. We find that Disagreement Resolution consistently helps non-expert models identify the truth, achieving 62.1\% judging accuracy compared to 49.2\% for standard debate. Our results provide encouraging empirical evidence for rethinking the scalable oversight protocol from adversarial persuasion to collaborative truth-seeking.
****
Automatic Construction of Clinical Scoring Systems with LLM Agents
Silas Ruhrberg Estévez, Christopher Chiu, Mihaela van der Schaar
Modern clinical practice relies on evidence-based guidelines implemented as compact scoring systems composed of a small number of interpretable decision rules. While machine-learning models achieve strong performance, many fail to translate into routine clinical use due to misalignment with workflow constraints such as memorability, auditability, and bedside execution. We argue that this gap arises not from insufficient predictive power, but from optimizing over model classes that are incompatible with guideline deployment. Deployable guidelines often take the form of unit-weighted clinical checklists, formed by thresholding the sum of binary rules, but learning such scores requires searching an exponentially large discrete space of possible rule sets. We introduce AgentScore, which performs semantically guided optimization in this space by using LLMs to propose candidate rules and a deterministic, data-grounded verification-and-selection loop to enforce statistical validity and deployability constraints. Across eight clinical prediction tasks, AgentScore outperforms existing score-generation methods

and achieves AUROC comparable to more flexible interpretable models despite oper
ating under stronger structural constraints. On two additional externally valida
ted tasks, AgentScore achieves higher discrimination than established guideline-
based scores.

CausalArmor: Efficient Indirect Prompt Injection Guardrails via Causal Attributi
on

Minbeom Kim, Mihir Parmar, Phillip Wallis, Lesly Miculicich, Kyomin Jung, Krishn
amurthy Dj Dvijotham, Long T. Le, Tomas Pfister

AI agents equipped with tool-calling capabilities are susceptible to *Indirect P
rompt Injection* (IPI) attacks. In this attack scenario, malicious commands hidd
en within *untrusted* content trick the agent into performing unauthorized actio
ns. Existing defenses can reduce attack success but often suffer from the ***ove
r-defense dilemma***: they deploy expensive, *always-on* sanitization regardless
 of actual threat, thereby degrading utility and latency even in benign scenario
s.

We revisit IPI through a causal ablation perspective: a successful injection man
ifests as a *dominance shift* where the user request no longer provides decisive
 support for the agent's privileged action, while a particular untrusted segment
, such as a retrieved document or tool output, provides disproportionate attribu
table influence.

Based on this signature, we propose **CausalArmor**, a selective defense framewo
rk that (i) computes lightweight, leave-one-out ablation-based attributions at p
rivileged decision points, and (ii) triggers targeted sanitization only when an
untrusted segment dominates the user intent. Additionally, CausalArmor employs *
retroactive Chain-of-Thought masking* to prevent the agent from acting on ``pois
oned" reasoning traces.

We present a theoretical analysis showing that sanitization based on attribution
 margins conditionally yields an exponentially small upper bound on the probabil
ity of selecting malicious actions.

Experiments on AgentDojo and DoomArena demonstrate that CausalArmor matches the
security of aggressive defenses while improving explainability and preserving ut
ility and latency of AI agents.

REAL: Resolving Knowledge Conflicts in Knowledge-Intensive Visual Question Answe
ring via Reasoning-Pivot Alignment

Kai Ye, Xianwei Mao, Sheng Zhou, Zirui Shao, Ye Mo, Liangliang Liu, Haikuan Huan
g, Bin Li, Jiajun Bu

Knowledge-intensive Visual Question Answering (KI-VQA) frequently suffers from s
evere knowledge conflicts caused by the inherent limitations of open-domain retr
ieval. However, existing paradigms face critical limitations, including the lack
 of generalizable conflict detection and intra-model constraint mechanisms to ha
ndle conflicting evidence. To address these challenges, we propose the **REAL**
(**Re**asoning-Pivot **Al**ignment) framework centered on the novel concept of t
he **Reasoning-Pivot**. Distinct from reasoning steps that prioritize internal s
elf-derivation, a reasoning-pivot serves as an atomic unit (node or edge) in the
 reasoning chain that emphasizes knowledge linkage, and it typically relies on e
xternal evidence to complete the reasoning. Supported by our constructed **REAL-
VQA** dataset, our approach integrates **Reasoning-Pivot Aware SFT (RPA-SFT)** t
o train a generalizable discriminator by aligning conflicts with pivot extractio
n, and employs **Reasoning-Pivot Guided Decoding (RPGD)**, an intra-model decodi
ng strategy that leverages these pivots for targeted conflict mitigation. Extens
ive experiments on diverse datasets demonstrate that REAL significantly enhances
 discrimination accuracy and achieves superior performance, validating our pivot
-driven resolution paradigm.

Beyond Sunk Costs: Boosting LLM Pre-training Efficiency via Orthogonal Growth of
 Mixture-of-Experts

Ruizhe Wang, Yucheng Ding, Xiao Liu, Yaoxiang Wang, Peng CHENG, Baining Guo, Zhe
ng-Jun Zha, Yeyun Gong

As the computational demands for pre-training Large Language Models (LLMs) continue to surge, the need for efficient training paradigms becomes critical. Despite the vast resources already invested in existing pre-trained checkpoints, these assets often remain under-leveraged due to architectural limitations. We introduce an "orthogonal growth" strategy designed to "recycle" these checkpoints by strategically expanding their parameters prior to continued training. Our method focuses on optimizing converged Mixture-of-Experts (MoE) models through two dimensions: interpositional layer copying for increased depth and noisy expert duplication for expanded width. Through extensive scaling laws analysis, we demonstrate a strong positive correlation between the "sunk cost" (prior investment) and the final model accuracy. Empirical results on models up to 70B parameters and 1T tokens show that our recycling approach yields a 10.6\% accuracy improvement compared to training from scratch under identical extra compute budgets. This work provides a cost-effective blueprint for sustainable large-scale LLM development.

Symmetry Reveals Layerwise Dynamics: How Transformers Perform In-Context Classification

Patrick Lutz, Themistoklis Haris, Arjun Chandra, Aditya Gangrade, Venkatesh Saligrama

Transformers can perform in-context classification from a few labeled examples, yet the inference-time algorithm remains opaque. We study multi-class linear classification in the hard no-margin regime and make the computation identifiable by enforcing feature- and label-permutation equivariance at every layer. This enables interpretability while maintaining functional equivalence and yields highly structured weights. From these models we extract an explicit depth-indexed recursion: an end-to-end identified, emergent update rule inside a softmax transformer, to our knowledge the first of its kind. Attention matrices formed from mixed feature-label Gram structure drive coupled updates of training points, labels, and the test probe. The resulting dynamics implement a geometry-driven algorithmic motif, which can provably amplify class separation and yields robust expected class alignment.

Adversarial Vulnerability from Interference Between Features in Superposition

Edward Stevinson, Lucas Prieto, Melih Barsbey, Tolga Birdal

Why do adversarial examples exist, and why do they transfer between models? Existing explanations appeal to high-dimensional geometry, non-robust patterns in the input, and decision boundary structure, but none provides a representation-level mechanism that explains why specific perturbations succeed and why attacks transfer between models. In this paper, we show that adversarial vulnerability can stem from efficient information encoding in neural networks. Specifically, vulnerability can arise from superposition - the phenomenon where networks represent more concepts than they have dimensions, forcing non-orthogonal representation and thus interference. This interference causes perturbations targeting one representation to affect others, creating vulnerabilities determined by interference patterns. In synthetic settings with precisely controlled superposition, we establish that superposition suffices to create adversarial vulnerability. The resulting attacks are predictable: PGD-discovered perturbations align with theoretically optimal perturbations derived from the interference geometry. Models trained on similar data develop similar interference patterns, explaining attack transferability. We then show that successful attacks on image classifiers exhibit the structure predicted by our proposed mechanism. These findings reveal that adversarial vulnerability can be a byproduct of networks' representational compression, complementing existing explanations based on data properties or architectural factors.

Hyperparameter Transfer with Mixture-of-Expert Layers

Tianze Jiang, Blake Bordelon, Cengiz Pehlevan, Boris Hanin

Mixture-of-Experts (MoE) layers have emerged as an important tool in scaling up modern neural networks by decoupling total trainable parameters from activated p

arameters in the forward pass for each token. However, sparse MoEs add complexit y to training due to (i) new trainable parameters (router weights) that, like al l other parameter groups, require hyperparameter (HP) tuning; (ii) new architect ure scale dimensions (number of and size of experts) that must be chosen and pot entially taken large. To make HP selection cheap and reliable, we propose a new parameterization for transformer models with MoE layers when scaling model width , depth, number of experts, *and* expert (hidden) size. Our parameterization is justified by a novel dynamical mean-field theory (DMFT) analysis. When varying different model dimensions trained at a fixed token budget, we find empirically that our parameterization enables reliable HP transfer across models from 51M to 2B total parameters. We further take HPs identified from sweeping small models on a short token horizon to train larger models on longer horizons and report pe rformant model behaviors.

Z-Erase: Enabling Concept Erasure in Single Stream Diffusion Transformers

Nanxiang Jiang, Zhaoxin Fan, Baisen Wang, Daiheng Gao, Junhang Cheng, Jifeng Guo , Yalan Qin, Yeying Jin, Hongwei Zheng, Faguo Wu, wenjun wu

Concept erasure serves as a vital safety mechanism for removing unwanted concept s from text-to-image (T2I) models. While extensively studied in U-Net and dual-s tream architectures (e.g., Flux), this task remains under-explored in the recent emerging paradigm of single-stream diffusion transformers (e.g., Z-Image). In t his new paradigm, text and image tokens are processed as a single unified sequen ce via shared parameters. Consequently, directly applying prior erasure methods typically leads to generation collapse. To bridge this gap, we introduce Z-Erase , the first concept erasure method tailored for single-stream T2I models. To gua rantee stable image generation, Z-Erase first proposes a Stream Disentangled Con cept Erasure Framework that decouples updates and enables existing methods on si ngle-stream models. Subsequently, within this framework, we introduce Lagrangian -Guided Adaptive Erasure Modulation, a constrained algorithm that further balanc es the sensitive erasure-preservation trade-off. Moreover, we provide a rigorous convergence analysis proving that Z-Erase can converge to a Pareto stationary p oint. Experiments demonstrate that Z-Erase successfully overcomes the generation collapse issue, achieving state-of-the-art performance across a wide range of t asks.

****

MUSE: Resolving Manifold Misalignment in Visual Tokenization via Topological Ort hogonality

Panqi Yang, Haodong Jing, Jiahao Chao, Tingyan Xiang, Li Lin, Yao Hu, Yang Luo, Yongqiang Ma

Unified visual tokenization faces a fundamental trade-off: optimizing for high-f idelity pixel reconstruction (spatial equivariance) inherently conflicts with se mantic abstraction (conceptual invariance). We identify the root cause as Manifo ld Misalignment, where naive joint optimization leads to conflicting gradients t hat force a zero-sum game between these two objectives. In this paper, we propos e MUSE, a framework that resolves this deadlock via Topological Orthogonality. R ecognizing Structure as the orthogonal bridge, MUSE physically decouples the opt imization subspaces within Transformers. We route structural gradients to refine attention topology and semantic gradients to update feature values, transformin g destructive interference into Mutual Reinforcement. Extensive experiments demo nstrate that MUSE breaks the trade-off, matching state-of-the-art generation (gF ID 3.08) while notably outperforming its own teacher InternViT-300M in linear pr obing (85.2% vs. 82.5%), proving that structurally aligned reconstruction active ly refines semantic perception.

WaterSIC: Information-Theoretically (Near) Optimal \\Linear Layer Quantization

Egor Lifar, Semyon Savkin, Or Ordentlich, Yury Polyanskiy

This paper considers the problem of converting a given dense linear layer to low precision. The tradeoff between compressed length and output discrepancy is ana lyzed information theoretically (IT). It is shown that a popular

GPTQ algorithm may have an arbitrarily large gap to the IT limit. To allevia

te this problem, a
 novel algorithm, termed "WaterSIC", is proposed and is shown to be within a rat
e gap of
    0.255 bits to the IT limit, uniformly over all possible covariance matrices
of input activations.
 The key innovation of WaterSIC's is to allocate different quantization rates to
 different columns
    (in-features) of the weight matrix, mimicking the classical IT solution know
n as
    ``waterfilling''. Applying WaterSIC to the Llama and Qwen family of LLMs est
ablishes new
    state-of-the-art performance for all quantization rates from 1 to 4 bits. Ou
r code is available at https://github.com/egorlifar/watersic.
****
Which Heads Matter for Reasoning? RL-Guided KV Cache Compression
Wenjie Du, Li Jiang, Keda TAO, Xue Liu, Huan Wang
Reasoning large language models exhibit complex reasoning behaviors via extended
 chain-of-thought generation that are highly fragile to information loss during
decoding, creating critical challenges for KV cache compression.
Existing token-dropping methods directly disrupt reasoning chains by removing in
termediate steps, while head-reallocation methods, designed for retrieval tasks,
 fail to preserve the heads essential for generative reasoning.
However, no existing method can identify which attention heads genuinely maintai
n reasoning consistency and control generation termination.
To address this, we propose RLKV, which uses reinforcement learning as a probe t
o discover which heads contribute to reasoning quality by directly optimizing th
eir cache usage against actual generation outcomes.
This discovery naturally leads to an efficient compression strategy: we allocate
 full KV cache to reasoning-critical heads while aggressively compressing others
 with constant-size KV cache.
Experiments reveal that a fraction of heads proves essential for reasoning, enab
ling 20--60% cache reduction with near-lossless performance across diverse tasks
 and models, and up to 2.06x end-to-end speedup at 60% reduction.
****
A General Neural Backbone for Mixed-Integer Linear Optimization via Dual Attenti
on
Peixin Huang, Yaoxin Wu, Yining Ma, Cathy Wu, Wei Zhang, Wen Song
Mixed-integer linear programming (MILP) is a foundational framework for combinat
orial optimization across science and engineering, but remains hard to solve at
scale due to NP-hardness.Recent learning-based methods typically model MILP inst
ances as variable–constraint bipartite graphs and use Graph Neural Networks (GNN
s) for representation learning, yet their locality limits representation power.W
e propose an attention-driven neural backbone that adopts an element-centric vie
w of variables and constraints, with dual attention performing parallel intra-ty
pe self-attention and inter-type cross-attention.Across three representative tas
ks at the instance, element, and solving-state levels, our model consistently ou
tperforms conventional GNN-based architectures, highlighting attention-based, el
ement-centric modeling as a powerful foundation for learning-enhanced combinator
ial optimization.

Affine-Equivariant Kernel Space Encoding for NeRF Editing
Miko■aj Zieli■ski, Krzysztof Byrski, Tomasz Szczepanik, Dominik Belter, Przemys■
aw Spurek
Neural scene representations achieve high-fidelity rendering by encoding 3D scen
es as continuous functions, but their latent spaces are typically implicit and g
lobally entangled, making localized editing and physically grounded manipulation
 difficult. While several works introduce explicit control structures or point-b
ased latent representations to improve editability, these approaches often suffe
r from limited locality, sensitivity to deformations, or visual artifacts. In th
is paper, we introduce Affine-Equivariant Kernel Space Encoding (EKS), a spatial

encoding for neural radiance fields that provides localized, deformation-aware feature representations. Instead of querying latent features directly at discrete points or grid vertices, our encoding aggregates features through a field of anisotropic Gaussian kernels, each defining a localized region of influence. This kernel-based formulation enables stable feature interpolation under spatial transformations while preserving continuity and high reconstruction quality. To preserve detail without sacrificing editability, we further propose a training-time feature distillation mechanism that transfers information from multi-resolution hash grid encodings into the kernel field, yielding a compact and fully grid-free representation at inference. This enables intuitive, localized scene editing directly via Gaussian kernels without retraining, while maintaining high-quality rendering.

Efficient Prediction of SO(3)-Equivariant Hamiltonian Matrices via SO(2) Local Frames

Haiyang Yu, Yuchao Lin, Xuan Zhang, Xiaofeng Qian, Shuiwang Ji

We consider the task of predicting Hamiltonian matrices to accelerate electronic structure calculations, which plays an important role in physics, chemistry, and materials science. Motivated by the inherent relationship between the off-diagonal blocks of the Hamiltonian matrix and the SO(2) local frame, we propose a novel and efficient network, called QHNetV2, that achieves global SO(3) equivariance without the costly SO(3) Clebsch–Gordan tensor products. This is achieved by introducing a set of new efficient and powerful SO(2)-equivariant operations and performing all off-diagonal feature updates and message passing within SO(2) local frames, thereby eliminating the need of SO(3) tensor products. Moreover, a continuous SO(2) tensor product is performed within the SO(2) local frame at each node to fuse node features. Extensive experiments on the large QH9 and MD17 datasets demonstrate that our model achieves superior performance across a wide range of molecular structures and trajectories, highlighting its strong generalization capability. The proposed SO(2) operations on SO(2) local frames offer a promising direction for scalable and symmetry-aware learning of electronic structures. Our code is publicly available as part of the AIRS library (https://github.com/divelab/AIRS/).

Neural Modular Physics for Elastic Simulation

Yifei Li, Haixu Wu, Zeyi Xu, Tuur Stuyck, Wojciech Matusik

Learning-based methods have made significant progress in physics simulation, typically approximating dynamics with a monolithic end-to-end optimized neural network. Although these models offer an effective way to simulation, they may lose essential features compared to traditional numerical simulators, such as physical interpretability and reliability. Drawing inspiration from classical simulators that operate in a modular fashion, this paper presents Neural Modular Physics (NMP) for elastic simulation, which combines the approximation capacity of neural networks with the physical reliability of traditional simulators. Beyond the previous monolithic learning paradigm, NMP enables direct supervision of intermediate quantities and physical constraints by decomposing elastic dynamics into physically meaningful neural modules connected through intermediate physical quantities. With a specialized architecture and training strategy, our method transforms the numerical computation flow into a modular neural simulator, achieving improved physical consistency and generalizability. Experimentally, NMP demonstrates superior generalization to unseen initial conditions and resolutions, stable long-horizon simulation, better preservation of physical properties compared to other neural simulators, and greater feasibility in scenarios with unknown underlying dynamics than traditional simulators.

MTNL: A Unified Modeling Perspective for Enhancing Tensor Network Learning

Junhua Zeng, Yuning Qiu, Binghua Li, Chao Li, Qibin Zhao, Guoxu Zhou

Over the years, the unsupervised and supervised learning research directions of tensor networks (TNs) have mainly developed in parallel. In this paper, we provide a view for their cooperative advancement through a novel mixed tensor network

learning (MTNL) framework that unifies the two fields. Specifically, inspired by supervised TN learning tasks, multiple TNs are fused in a deep-network style in MTNL, enhancing the expressive power for the unsupervised TN learning tasks. We then develop a more flexible TN structure search prior with theoretical guarantees for learning multiple TN structures, aligning with trends in many supervised learning setups. More interestingly, by combining these components within a Bayesian framework, we show that MTNL induces a lightweight uncertainty quantification mechanism that is theoretically guaranteed by its connection to the dropout-based counterpart problem, making the mechanism a potential alternative for large-scale learning problems. Finally, we demonstrate the effectiveness of the MTNL framework on tensor recovery, parameter-efficient fine-tuning, and tensor regression experiments.

MIND: Decoupling Model-Induced Label Noise via Latent Manifold Disentanglement

Dayong Ren

The paradigm of learning from automatic annotations—driven by pre-trained experts and Foundation Models—dominates data-hungry applications. However, it introduces a critical challenge: model-induced label noise. Unlike stochastic noise in classical robust learning, this noise stems from annotator inductive biases, manifesting as systematic errors tightly coupled with local feature manifolds. Existing methods relying on global transition matrices underfit these structural patterns, while learning instance-specific matrices remains mathematically intractable. We propose Model-Induced Noise Decoupling (MIND), a theoretically grounded framework addressing this dilemma. We demonstrate that the high-dimensional noise manifold can be decoupled into tractable, subspace-dependent components via Latent Manifold Disentanglement. Specifically, our Latent Decoupling Estimator (LDE) dynamically projects samples into latent structural clusters with consistent error modes, facilitating noise identifiability without ground-truth anchor points. To rigorously evaluate robustness, we adopt a hierarchical protocol: moving from controlled noise on CIFAR-100 to a structural stress test on large-scale real-world 3D datasets (S3DIS, ScanNet), where error patterns explicitly couple with geometric manifolds. Empirically, MIND significantly outperforms state-of-the-art methods on these complex benchmarks and effectively corrects zero-shot hallucinations from Vision-Language Models (e.g., OpenSeg), highlighting its potential as a robust distillation framework for Foundation Models.

Unveiling the Entropy Dynamics of Chain-of-Thought Reasoning

Ting Xu, Xu He, Yupu Lu, Jiankai Sun, Dong Li, Wai Lam, Jianye HAO

This paper investigates the entropy dynamics of Chain-of-Thought (CoT) and uncovers a consistent two-phase structure: an ***Uncertainty Region*** of exploration transitioning sharply to a ***Confidence Region*** of convergence. We demonstrate that the Confidence Region possesses two critical properties: 1) ***High Reliability***—answers in confidence region become highly accurate and stable, and 2) ***High Redundancy***—models generate unnecessary tokens long after reaching the correct answer. These properties unlock more efficient and reliable inference strategies: 1) ***Early Exit*** leverages reliability and redundancy to terminate computation safely when returns diminish, and 2) ***Test-Time Scaling*** uses the Confidence Region signal to prioritize converged trajectories. To operationalize these insights, we formulate Confidence Region detection as a sequential change-point detection problem, being the first to apply classical change-point methods to monitor CoT reasoning. Using the Cumulative Sum (CUSUM) algorithm, a statistically optimal change-point detector, we develop a training-free framework for real-time inference control. Experiments show our approach establishes a superior Pareto-frontier for early exit. CUSUM achieves 63.06% accuracy with 11.1% token reduction, outperforming DEER and Dynasor by 3.28% and 4.36% in accuracy respectively. For test-time scaling, CUSUM-weighted voting consistently outperforms self-consistency.

****

OBCache: Optimal Brain KV Cache Pruning for Efficient Long-Context LLM Inference

Yuzhe Gu, Xiyu Liang, Jiaojiao Zhao, Enmao Diao

Large language models (LLMs) with extended context windows enable powerful applications but impose significant memory overhead, as caching all key-value (KV) states scales linearly with sequence length and batch size. Existing cache eviction methods address this by exploiting attention sparsity, yet they typically rank tokens heuristically using accumulated attention weights without considering their true impact on attention outputs. We propose Optimal Brain Cache (OBCache), a principled framework that formulates cache eviction as a layer-wise structured pruning problem. Building upon the Optimal Brain Damage (OBD) theory, OBCache quantifies token saliency by measuring the perturbation in attention outputs induced by pruning tokens, with closed-form scores derived for isolated keys, isolated values, and joint key-value pairs. Our scores account not only for attention weights but also for information from value states and attention outputs, thereby enhancing existing eviction strategies with output-aware signals. Experiments on LLaMA and Qwen models demonstrate that replacing the heuristic scores in existing works, which estimate token saliency across different query positions, with OBCache's output-aware scores consistently improves long-context accuracy. Code is available at https://github.com/DreamSoul-AI/OBCache.

Foundation VAE for CT Reconstruction, Augmentation, and Generation

Qi Chen, Shuhan Ding, Yu Gu, Nan Liu, Jiang Bian, Alan Yuille, Zongwei Zhou, Jingjing Fu

Variational autoencoders (VAEs) compress high resolution CT volumes into compact latents while preserving clinically relevant structure. However, training CT-specific VAEs from scratch or heavily fine-tuning them incurs substantial computational and engineering cost, and often degrades under heterogeneous scanners, protocols, and diseases. This paper makes a progressive stride toward training-free medical VAEs by leveraging a critical observation: a single Foundation VAE, pretrained at scale on natural images and videos, can serve as a unified interface for CT Reconstruction, Augmentation, and Generation. With both encoder and decoder frozen, the Foundation VAE reconstructs CT volumes with preserved anatomy while suppressing acquisition noise; training segmentation models on these reconstructions improves surface accuracy by 3.9\% NSD on average for pancreatic tumor and lung tumor. Within the same Foundation VAE latent space, a conditional latent diffusion model achieves 3.9\% lower average FVD with 36.2\% higher CT CLIP score, and improves multi-disease generation faithfulness across 18 types by 2.76\% AUC. These results demonstrate Foundation VAEs as a practical interface for scalable CT representation reuse and faithful CT generation. Our code and demo are available at https://github.com/qic999/Foundation-VAE.

Evaluating Newtonian Mechanics in Video Generative Models with Real Physical Systems

Antonios Tragoudaras, Chenyu Zhang, Daniil Cherniavskii, Antonios Vozikis, Thijmen Nijdam, Derck W. E. Prinzhorn, Mark Bodracska, Nicu Sebe, Andrii Zadaianchuk, Stratis Gavves

Recent advances in image and video generation raise hopes that these models possess world modeling capabilities—the ability to generate realistic, physically plausible videos. This could revolutionize applications in robotics, autonomous driving, and scientific simulation. However, before treating these models as world models, we must ask: Do they adhere to physical laws? Current evaluation methods rely on subjective judgments or trajectory matching, limiting their usage for physical reasoning estimation, where many generations could be physically plausible.

Thus, we introduce **Morpheus**, one of the first physics-informed evaluation frameworks for measuring the ability of video generation models to comprehend Newtonian dynamics. **Morpheus** features 130 real-world videos capturing physical phenomena, guided by conservation laws. Using those as conditioning for video generation, we assess physical plausibility leveraging interpretable metrics evaluated with respect to infallible conservation laws known per physical setting, leveraging advances in physics-informed neural networks and vision-language foundation models. Importantly, **Morpheus** targets controlled Newtonian rigid-body se

ttings to enable quantitative checks. Our findings reveal that even with advanced prompting and video conditioning, contemporary models struggle to encode physical principles despite generating aesthetically pleasing videos. Code and data available [here](https://github.com/physics-from-video/Morpheus).

Rel-MOSS: Towards Imbalanced Relational Deep Learning on Relational Databases
Jun Yin, Peng Huo, Bangguo Zhu, Hao Yan, Senzhang Wang, Shirui Pan, Chengqi Zhang
In recent advances, to enable a fully data-driven learning paradigm on relational databases (RDB), relational deep learning (RDL) is proposed to structure the RDB as a heterogeneous entity graph and adopt the graph neural network (GNN) as the predictive model. However, existing RDL methods neglect the imbalance problem of relational data in RDBs and risk under-representing the minority entities, leading to an unusable model in practice. In this work, we investigate, for the first time, class imbalance problem in RDB entity classification and design the relation-centric minority synthetic over-sampling GNN (**Rel-MOSS**), in order to fill a critical void in the current literature. Specifically, to mitigate the issue of minority-related information being submerged by majority counterparts, we design the relation-wise gating controller to modulate neighborhood messages from each individual relation type. Based on the relational-gated representations, we further propose the relation-guided minority synthesizer for over-sampling, which integrates the entity relational signatures to maintain relational consistency. Extensive experiments on 12 entity classification datasets provide compelling evidence for the superiority of Rel-MOSS, yielding an average improvement of up to 2.46% and 4.00% in terms of *Balanced Accuracy* and *G-Mean*, compared with SOTA RDL methods and classic methods for handling class imbalance.
****
Rethinking the Trust Region in LLM Reinforcement Learning
Penghui Qi, Xiangxin Zhou, Zichen Liu, Tianyu Pang, Chao Du, Min Lin, Wee Sun Lee
Reinforcement learning (RL) has become a cornerstone for fine-tuning Large Language Models (LLMs), with Proximal Policy Optimization (PPO) serving as the de facto standard algorithm. Despite its ubiquity, we argue that the core ratio clipping mechanism in PPO is structurally ill-suited for the large vocabularies inherent to LLMs. PPO constrains policy updates based on the probability ratio of sampled tokens, which serves as a noisy single-sample Monte Carlo estimate of the true policy divergence. This creates a sub-optimal learning dynamic: updates to low-probability tokens are aggressively over-penalized, while potentially catastrophic shifts in high-probability tokens are under-constrained, leading to training inefficiency and instability. To address this, we propose Divergence Proximal Policy Optimization (DPPO), which substitutes heuristic clipping with a more principled constraint based on a direct estimate of policy divergence (e.g., Total Variation or KL). To avoid huge memory footprint, we introduce the efficient Binary and Top-K approximations to capture the essential divergence with negligible overhead. Extensive empirical evaluations demonstrate that DPPO achieves superior stability and efficiency compared to existing methods, offering a more robust foundation for RL-based LLM fine-tuning. Our code is available at \url{https://github.com/sail-sg/Stable-RL}.

Privacy-Aware Data Integration for Enhanced Quantile Inference under Heterogeneity
Leheng Cai, Qirui Hu, Shuyuan Wu
Quantile estimation and inference play essential roles in diverse scientific and industrial applications, and their accuracy can often be enhanced by integrating auxiliary data from multiple sites. However, developing efficient aggregation methods for quantile inference under potential privacy constraints, particularly with heterogeneous datasets, remains challenging. To address these issues, we propose a systematic framework for quantile estimation and inference under potential local differential privacy (LDP). The key idea is to construct weighted estimators by adaptively aggregating quantile estimates from target and source sites

. The adaptive weights are determined by minimizing the asymptotic variance, inc
orporating an additional ℓ_2 penalty to account for parameter shift. A para
llel stochastic gradient descent algorithm under LDP constraints is developed fo
r weight estimation and valid inference. Additionally, we introduce a conservati
ve weighted estimator to ensure robust inference across diverse heterogeneous sc
enarios. Rigorous theoretical analysis establishes the consistency, normality, a
nd effectiveness of the proposed methods. Extensive numerical studies and real d
ata application corroborate our theoretical findings.

Utonia: Toward One Encoder for All Point Clouds
Yujia Zhang, Xiaoyang Wu, Yunhan Yang, Xianzhe Fan, Han Li, Yuechen Zhang, Zehao
 Huang, Naiyan Wang, Hengshuang Zhao
We dream of a future where point clouds from all domains can come together to sh
ape a single model that benefits them all. Toward this goal, we present Utonia,
 a first step toward training a single self-supervised point transformer encoder
 across heterogeneous domains, spanning remote sensing, outdoor LiDAR, indoor RGB
-D sequences, object-centric CAD models, and point clouds lifted from RGB-only v
ideos. Despite their distinct sensing geometries, densities, and priors, Utonia
 learns a consistent representation space that transfers across domains. This uni
fication improves perception capability while revealing intriguing emergent beha
viors that arise only when domains are trained jointly. Beyond perception, we ob
serve that Utonia representations can also benefit embodied and multimodal reaso
ning: conditioning vision-language-action policies on Utonia features improves r
obotic manipulation, and integrating them into vision-language models yields gai
ns on spatial reasoning. We hope Utonia can serve as a step toward foundation mo
dels for sparse 3D data, and support downstream applications in AR/VR, robotics,
 and autonomous driving.

WISE: World Knowledge-Informed Semantic Evaluation for Text-to-Image Generation
Yuwei Niu, Munan Ning, Mengren Zheng, Weiyang Jin, Bin Lin, Peng Jin, Jiaqi Liao
, Chaoran Feng, Fanqing Meng, Kun-Peng Ning, Bin Zhu, Li Yuan
Text-to-Image (T2I) models are capable of generating high-quality artistic creat
ions and visual content. However, existing research and evaluation standards pre
dominantly focus on image realism and shallow text-image alignment, lacking a co
mprehensive assessment of complex semantic understanding and world knowledge int
egration in text-to-image generation. To address this challenge, we propose WISE
, the first benchmark specifically designed for World Knowledge-Informed Semanti
c Evaluation. WISE moves beyond simple word-pixel mapping by challenging models
 with 1000 meticulously crafted prompts across 25 subdomains in cultural common s
ense, spatio-temporal reasoning, and natural science. To overcome the limitation
s of traditional CLIP metric, we introduce WiScore, a novel quantitative metric
 for assessing knowledge-image alignment. Through comprehensive testing of 20 mod
els (10 dedicated T2I models and 10 unified multimodal models) using 1,000 struc
tured prompts spanning 25 subdomains, our findings reveal significant limitation
s in their ability to effectively integrate and apply world knowledge during ima
ge generation, highlighting critical pathways for enhancing knowledge incorporat
ion and application in next-generation T2I models. Code and data will be availab
le.

Learning Discriminative and Generalizable Anomaly Detector for Dynamic Graph wit
h Limited Supervision
Yuxing Tian, Yiyan Qi, Fengran Mo, Weixu Zhang, Jian Guo, Jian-Yun Nie
Dynamic graph anomaly detection is critical for many real-world applications but
 remains challenging due to the scarcity of labeled anomalies. Existing methods
are either unsupervised or semi-supervised: unsupervised methods avoid the need
 for labeled anomalies but often produce ambiguous boundary, whereas semi-superv
ised methods can overfit to the limited labeled anomalies and generalize poorly
to unseen anomalies. To address this gap, we consider a largely underexplored pr
oblem: learning a discriminative boundary from normal/unlabeled data, while leve
raging limited labeled anomalies \textbf{when available} without sacrificing gen

eralization to unseen anomalies. In this paper, we propose an effective, general izable, and model-agnostic framework with three main components: (i) residual re presentation encoding that capture deviations between current interactions and t heir historical context, providing anomaly-relevant signals; (ii) a restriction loss that constrain the normal representations within an interval bounded by two co-centered hyperspheres, ensuring consistent scales while keeping anomalies se parable; (iii) a bi-boundary optimization strategy that learns a discriminative and robust boundary using the log-likelihood distribution modeled by a normalizi ng flow. Extensive experiments demonstrate the superiority of our framework acro ss diverse evaluation settings.

SCRWKV: Ultra-Compact Structure-Calibrated Vision-RWKV for Topological Crack Seg mentation
Hanxu Zhang, Chen Jia, Hui Liu, Xu Cheng, Fan Shi, Shengyong Chen
Achieving pixel-level accurate segmentation of structural cracks across diverse scenarios remains a formidable challenge. Existing methods face significant bott lenecks in balancing crack topology modeling with computational efficiency, ofte n failing to reconcile high segmentation quality with low resource demands. To a ddress these limitations, we propose the Ultra-Compact Structure-Calibrated Visi on RWKV (SCRWKV), a network that achieves high-precision modeling via a novel St ructure-Field Encoder (SFE) backbone while maintaining linear complexity. The SF E integrates the Adaptive Multi-scale Cascaded Modulator (AMCM) to enhance textu re representation and utilizes the Structure-Calibrated Insight Unit (SCIU) as i ts core engine. Specifically, the SCIU employs the Geometry-guided Bidirectional Structure Transformation (GBST) to capture topological correlations and integra tes the Dynamic Self-Calibrating Decay (DSCD) into Dy-WKV to suppress noise prop agation. Furthermore, we introduce a lightweight Cross-Scale Harmonic Fusion (CS HF) decoder to achieve precise feature aggregation. Systematic evaluations on mu ltiple benchmarks characterized by complex textures and severe interference demo nstrate that SCRWKV, with only 1.22M parameters, significantly outperforms SOTA methods. Achieving an F1 score of 0.8428 and mIoU of 0.8512 on the TUT dataset, the model confirms its robust potential for efficient real-world deployment. The code is available at https://github.com/zhxhzy/SCRWKV.

RealtimeTool: Parallel Decoding for Real-Time LLM Function Calling
Xiaoxin Shi, Jiaxin Wan, Linkang Dong, Wei Jiang, Yue Liu, Zengfeng Huang
LLM-based function calling enables intelligent agents to interact with external tools and environments, yet autoregressive decoding imposes a fundamental latenc y bottleneck that limits real-time applications such as embodied intelligence, g ame AI, and interactive avatars (e.g., 10 Hz control frequency). We observe that function calling differs fundamentally from free-form text generation: structur ed outputs exhibit substantial token redundancy (delimiters, parameter names) an d weak causal dependencies among arguments---two properties that must be exploit ed jointly to achieve real-time performance. We present RealtimeTool, which intr oduces special tokens that serve a dual role: compressing low-entropy tokens (4- -6× reduction) while acting as mode selectors that enable independent parallel g eneration of function name and arguments. This synergistic design achieves 3--6× end-to-end speedup (up to 9.6×) with only +8.2% parallelization overhead, while maintaining competitive or improved accuracy across five benchmarks on Qwen-ser ies models (0.5B--14B). With quantization on a consumer-grade GPU, RealtimeTool reaches 61.2 ms P50 latency at 4B scale---enabling 16 Hz real-time control and b ridging the gap between LLM function calling and latency-critical real-world dep loyment.

Riemannian Neural Optimal Transport
Alessandro Micheli, Yueqi Cao, Anthea Monod, Samir Bhatt
Computational optimal transport (OT) offers a principled framework for generativ e modeling. Neural OT methods, which use neural networks to learn an OT map (or potential) from data in an amortized way, can be evaluated out of sample after t raining, but existing approaches are tailored to Euclidean geometry. Extending n

eural OT to high-dimensional Riemannian manifolds remains an open challenge. In this paper, we prove that any method for OT on manifolds that produces discrete approximations of transport maps necessarily suffers from the curse of dimensionality: achieving a fixed accuracy requires a number of parameters that grows exponentially with the manifold dimension. Motivated by this limitation, we introduce Riemannian Neural OT (RNOT) maps, which are continuous neural-network parameterizations of OT maps on manifolds that avoid discretization and incorporate geometric structure by construction. Under mild regularity assumptions, we prove that RNOT maps approximate Riemannian OT maps with sub-exponential complexity in the dimension. Experiments on synthetic and real datasets demonstrate improved scalability and competitive performance relative to discretization-based baselines.

MAGIC: Multi-Granularity Language-Informed Image Clustering

Xiaohan Zhang, Chao Zhang, Chunlin Chen, Huaxiong Li

Image clustering is a fundamental unsupervised task in computer vision. Recent studies have explored incorporating external linguistic information to facilitate visual feature learning and thereby enhance clustering performance. Nevertheless, these methods typically rely on fixed vocabularies (e.g., WordNet) to generate language counterparts, leading to inter-modal semantic misalignment due to granularity discrepancy between visual and textual semantics. Moreover, they often overlook the issue of intra-modal semantic redundancy caused by task-irrelevant knowledge. To address these challenges, we propose a new Multi-grAnularity lanGuage-informed Image Clustering method, dubbed MAGIC. To reduce semantic misalignment, we first prompt the vision-language models to generate multi-granularity language descriptions that capture rich image semantics, which are then integrated for effective multi-modal alignment. To alleviate semantic redundancy, we design modality-specific semantic adapters that adaptively refine and compress the semantically dense features into clustering-friendly representations under task guidance. A consensus representation is obtained by fusing the refined visual and textual features, which acts as a teacher to guide image clustering through a robust contrastive learning framework. Extensive experiments on benchmarks demonstrate that MAGIC outperforms state-of-the-art methods.

Scaling Laws of Global Weather Models

Yuejiang Yu, Langwen Huang, Alexandru Calotoiu, Torsten Hoefler

Data-driven models are revolutionizing weather forecasting. To optimize training efficiency and model performance, this paper analyzes empirical scaling laws within this domain. We investigate the relationship between model performance (validation loss) and three key factors: model size (N), dataset size (D), and compute budget (C). Across a range of models, we find that Aurora exhibits the strongest data-scaling behavior: increasing the training dataset by 10× reduces validation loss by up to 3.2×. GraphCast demonstrates the highest parameter efficiency, yet suffers from limited hardware utilization. Our compute-optimal analysis indicates that, under fixed compute budgets, allocating resources to more total training data yields greater performance gains than increasing model size. Furthermore, we analyze model shape and uncover scaling behaviors that differ fundamentally from those observed in language models: weather forecasting models consistently favor increased width over depth. These findings suggest that future weather models should prioritize wider architectures and larger effective training datasets to maximize predictive performance.

Contribution Weights: A Geometrical Analysis of Self-Attention Transformers

Harry Jake Cunningham, Nicola Muca Cirone

Analyzing attention weights has become a standard approach for interpreting the information flow of Large Language Models (LLMs). However, this approach has significant limitations as it neglects the geometric properties of the value vectors being aggregated. To address this gap, we introduce \emph{Contribution Weights}, a projection-based metric that quantifies a token's influence by accounting for it's attention weight, value magnitude, and directional alignment with the la

yer output. We demonstrate that contribution weights provide a more faithful mea
sure of token importance, consistently outperforming attention-based metrics in
identifying semantically critical tokens across different decoder-only models, t
asks, and datasets. Further, our metric enables novel mechanistic analysis of \e
mph{attention sinks}. While previous work characterized sinks as passive reposit
ories for excess attention, we reveal they serve an active functional role, supp
ressing information through a convex relationship between sink rate and output n
orm, stabilizing representations by opposing the semantic drift of low-confidenc
e tokens.

FUSE: FK-Steered Multi-Modal Flow Matching for Efficient Simulation-Based Poster
ior Estimation
Weichen Qin, Yufan Xie, Peihao Wang, Chia-Jui Chou, Minghui Du, Peng Xu, Ziren L
uo, Yi Yang, Jingyi Yu, Bo Liang, Jiakai Zhang
Simulation-Based Inference (SBI) is critical for scientific discovery, with gene
rative models offering a promising path toward efficient inference. However, exi
sting methods struggle with effective multimodal modeling. They often rely on br
ute-force fusion strategies that ignore the structural disparities between param
eters and observations, thus limiting estimation fidelity. In this work, we intr
oduce FUSE (Feynman-Kac steered mUlti-modal flow matching for efficient Simulati
on-based posterior Estimation). Unlike prior work, FUSE employs a dual-track arc
hitecture that preserves the distinct features of multimodal inputs while facili
tating dynamic interaction. Additionally, we propose an FK-steered sampling stra
tegy that leverages intermediate observation likelihoods to guide the generative
 trajectories, effectively improving the sample quality during inference. Our ap
proach outperforms state-of-the-art baselines on standard SBI benchmarks, produc
ing posteriors that closely match ground-truth MCMC. Furthermore, in a real-worl
d exoplanet orbital estimation task, FUSE successfully resolves complex paramete
r degeneracies that challenge existing methods, highlighting its potential to ac
celerate complex scientific discoveries in astrophysics and beyond.

FedSDR: Federated Self-Distillation with Rectification
Ziheng Ren, Zhanming Shen, Hao Wang, Ning Liu, You Song
Federated fine-tuning of Large Language Models faces severe statistical heteroge
neity. However, existing model-level defenses often overlook the root cause: int
rinsic data distribution mismatches. In this work, we first establish Federated
Self-Distillation (FedSD) as a fundamental and potent strategy. By projecting cl
ient representations into a smoothed ``model-understanding space,'' FedSD alone
serves as a universal booster, demonstrating superior performance over conventio
nal algorithms. Despite its success, we identify a subtle trade-off termed the R
ewrite Paradox---unconstrained self-distillation can inadvertently increase hall
ucinations and redundancy. To refine this paradigm, we further propose FedSDR (F
ederated Self-Distillation with Rectification), the ultimate reinforced framewor
k. It augments FedSD with a dual-stream mechanism: a local LoRA-S (Smoothing) br
anch to implicitly absorb heterogeneity via distilled data, and a parallel globa
l LoRA-R (Rectification) branch anchored to raw data to enforce factual correctn
ess. By selectively aggregating only LoRA-R, FedSDR yields a globally aligned an
d faithful model. Extensive experiments verify its superior performance.

Breaking the Factorization Barrier in Diffusion Language Models
Ian Li, Zilei Shao, Benjie Wang, Rose Yu, Guy Van den Broeck, Anji Liu
Diffusion language models theoretically allow for efficient parallel generation
but are practically hindered by the "factorization barrier": the assumption that
 simultaneously predicted tokens are independent. This limitation forces a trade
-off: models must either sacrifice speed by resolving dependencies sequentially
or suffer from incoherence due to factorization. We argue that this barrier aris
es not from limited backbone expressivity, but from a structural misspecificatio
n: models are restricted to fully factorized outputs because explicitly paramete
rizing a joint distribution would require the Transformer to output a prohibitiv
ely large number of parameters. We propose **Co**upled **D**iscrete **D**iffusio

n (**CoDD**), a hybrid framework that breaks this barrier by replacing the fully-factorized output distribution with a lightweight, tractable probabilistic inference layer. This formulation yields a distribution family that is significantly more expressive than standard factorized priors, enabling the modeling of complex joint dependencies, yet remains compact enough to avoid the prohibitive parameter explosion associated with full joint modeling. Empirically, CoDD seamlessly enhances diverse diffusion language model architectures with negligible overhead, matching the reasoning performance of computationally intensive Reinforcement Learning baselines at a fraction of the training cost. Furthermore, it prevents performance collapse in few-step generation, enabling high-quality outputs at significantly reduced latencies. Code available at: https://github.com/liuanji/CoDD

Building Reliable Long-Form Generation via Hallucination Rejection Sampling
Lin Li, Georgia Channing, Suhaas M Bhat, Gabriel Davis Jones, Yarin Gal
Large language models (LLMs) have achieved remarkable progress in open-ended text generation, yet they remain prone to hallucinating incorrect or unsupported content, which undermines their reliability. This issue is exacerbated in long-form generation due to hallucination snowballing, a phenomenon where early errors propagate and compound into subsequent outputs. To address this challenge, we propose a novel inference-time hallucination mitigation framework, named Segment-wise HAllucination Rejection Sampling (SHARS), which uses am arbitrary hallucination detector to identify and reject hallucinated segments during generation and resample until faithful content is produced. By retaining only confident information and building subsequent generations upon it, the framework mitigates hallucination accumulation and enhances factual consistency. To instantiate this framework, we adopt semantic uncertainty as the detector and introduce several vital modifications to address its limitations and better adapt it to long-form text. Our method enables models to self-correct hallucinations without requiring external resources such as web search or knowledge bases, while remaining compatible with them for future extensions. Empirical evaluations on standardized hallucination benchmarks demonstrate that our method substantially reduces hallucinations in long-form generation while preserving or even improving the informativeness of generation.

POET-X: Memory-efficient LLM Training by Scaling Orthogonal Transformation
Zeju Qiu, Lixin Liu, Adrian Weller, Han Shi, Weiyang Liu
Efficient and stable training of large language models (LLMs) remains a core challenge in modern machine learning systems. To address this challenge, Reparameterized Orthogonal Equivalence Training (POET), a spectrum-preserving framework that optimizes each weight matrix through orthogonal equivalence transformation, has been proposed. Although POET provides strong training stability, its original implementation incurs high memory consumption and computational overhead due to intensive matrix multiplications. To overcome these limitations, we introduce POET-X, a scalable and memory-efficient variant that performs orthogonal equivalence transformations with significantly reduced computational cost. POET-X maintains the generalization and stability benefits of POET while achieving substantial improvements in throughput and memory efficiency. In our experiments, POET-X enables the pretraining of billion-parameter LLMs on a single Nvidia H100 GPU, and in contrast, standard optimizers such as AdamW run out of memory under the same settings.

Graph-Link: Bridging the Semantic-Structural Gap in Text-to-SQL via Constrained Subgraph Induction
Jianwei Zhong, Yuxi Yang, Quanxin Liu, Ruida Xu, Ming Chi, Yijun Mo
Schema Linking serves as the foundational perception layer in Text-to-SQL, tasked with grounding natural language queries into relevant schema elements. However, existing retrieval-based approaches suffer from a critical *structural blindness*: by prioritizing elements with high textual similarity, they inadvertently prune semantically-thin but topologically-critical bridge tables, thereby severin

g relational pathways necessary for multi-hop joins. To bridge this gap, we propose Graph-Link, a novel framework that reformulates schema linking from an independent retrieval task into a constrained subgraph induction problem. We argue that generating executable SQL necessitates a connected subgraph that satisfies both semantic relevance and structural constraints. Accordingly, Graph-Link employs a hierarchical schema graph to model the search space across multiple granularities, and then applies a Steiner-tree-based optimization for subgraph induction that guarantees the topological connectivity while maximizing the signal-to-noise ratio for downstream LLMs. Extensive experiments on BIRD and Spider 2.0 demonstrate that Graph-Link achieves state-of-the-art schema linking performance, improving recall and hit rates by up to 7.0\% over competitive baselines, and boosts downstream SQL generation accuracy on complex queries by 13.8\%.
****

HybridFlow: Resource-Adaptive Subtask Routing for Efficient Edge-Cloud LLM Inference

Jiangwen Dong, Jiayu Li, Tianhang Zheng, Wanyu Lin

Edge-cloud collaborative inference is crucial for LLM-powered edge devices, as on-device models often lack the required reasoning capability, while cloud-only inference can be costly and slow under strict latency and token/API budgets.
However, existing edge-cloud collaboration methods typically route input tasks based on their estimated difficulty. These static, coarse heuristics overlook subtask dependencies, missing opportunities for parallel execution and budget-adaptive routing.
To this end, we propose HybridFlow, a resource-adaptive edge-cloud inference framework that enables parallel execution of interdependent subtasks.
Specifically, we build a dependency-aware DAG for each input task, facilitating concurrent execution of subtasks once their dependencies are resolved, thereby reducing end-to-end latency.
Additionally, we propose a dynamic benefit–cost utility model, optimizing the trade-off between accuracy, token/API cost, and latency in real-time. This dynamic routing minimizes unnecessary cloud usage while preserving reasoning quality.
Across GPQA, MMLU-Pro, AIME24, and LiveBench-Reasoning, HybridFlow improves the cost-accuracy trade-off, reducing latency and cloud API usage while maintaining competitive accuracy.

Prediction-Powered Adaptive Inference with Pretrained AI Models for Contextual Bandits

Gabriel Sargent, Will Wei Sun, Zhengwu Zhang, Yufeng Liu

In adaptive experiments, statistical inference is essential for reliable decision-making and scientific discovery. Often in these settings, collecting labeled data is expensive, but decision-makers have access to large unlabeled datasets and strong pretrained AI models that can generate outcome predictions. Effectively leveraging these predictions in online experiments poses fundamental challenges for statistical inference: AI models may be misspecified, and data collected under adaptive policies are inherently non-i.i.d., invalidating classical inference techniques. To address these challenges, we propose a Prediction-Powered Adaptive Inference (PPAI) estimator that integrates unlabeled data, predicted labels, and adaptively collected labeled data through a single estimating equation. We establish asymptotic normality of the PPAI estimator under mild conditions on the data-collection policy, enabling valid confidence intervals and hypothesis tests for a broad class of Z-functionals. The method incorporates a data-driven tuning mechanism that adaptively weights AI predictions according to their informativeness, guaranteeing that the resulting asymptotic variance is no worse than that of the labeled-only baseline, and is strictly smaller when predictions are informative. Numerical experiments further support the theory, illustrating efficiency gains with informative AI predictions and robust performance when predictions are inaccurate.

RealisMotion: Decomposed Human Motion Control and Video Generation in the World Space

Jingyun Liang, Jingkai Zhou, Shikai Li, Chenjie Cao, Lei Sun, Yichen Qian, Weihua Chen, Fan Wang
Generating human videos with realistic and controllable motions is a challenging task. While existing methods can generate visually compelling videos, they lack separate control over four key video elements: foreground subject, background video, human trajectory, and action patterns. In this paper, we propose a decomposed human motion control and video generation framework that explicitly decouples motion from appearance, subject from background, and action from trajectory, enabling flexible mix-and-match composition of these elements. Concretely, we first build a ground-aware 3D world coordinate system and perform motion editing directly in the 3D space. Trajectory control is implemented by unprojecting edited 2D trajectories into 3D with focal-length calibration and coordinate transformation, followed by speed alignment and orientation adjustment; actions are supplied by a motion bank or generated via text-to-motion methods. Then, based on modern text-to-video diffusion transformer models, we inject the subject as tokens for full attention, concatenate the background along the channel dimension, and add motion (trajectory and action) control signals by addition. Such a design opens up the possibility for us to generate realistic videos of anyone doing anything anywhere. Extensive experiments on benchmark datasets and real-world cases demonstrate that our method achieves state-of-the-art performance on both element-wise controllability and overall video quality.
****
Robust Bayes-Assisted Conformal Prediction
Kianoosh Ashouritaklimi, Stefano Cortinovis, Francois Caron
Bayes--assisted conformal prediction combines the strengths of Bayesian modelling with exact, distribution--free frequentist coverage guarantees. Although conformal validity is preserved even when the Bayesian working model (BWM) is misspecified, the size of the resulting prediction sets can degrade substantially when the prior is poorly aligned with the observed data. We address this limitation by introducing \textbf{RoBAS} (\textbf{Ro}bust \textbf{B}ayes-\textbf{A}ssisted \textbf{S}hrinkage): a Bayes--assisted framework for constructing robust nonconformity scores, with two instantiations: one induced by a heavy--tailed BWM, and a closed--form empirical Bayes shrinkage score. The resulting scores adapt to the quality of the working information encoded in the prior: when this information is reliable, they exploit it to produce efficient prediction sets; when it is weak or inaccurate, they revert to the Distance--To--Average (DTA) score, a robust non--informative baseline. We evaluate the proposed scores on tabular and image regression tasks where the training distribution may differ from the calibration and test distributions, while the calibration and test data themselves remain exchangeable. We find that they are competitive with widely used scores in the absence of such shift, while substantially reducing interval widths in shifted settings.
****
Beyond the Proxy: Trajectory-Distilled Guidance for Offline GFlowNet Training
Ruishuo Chen, Xun Wang, Rui Hu, Zhuoran Li, Longbo Huang
Generative Flow Networks (GFlowNets) excel at sampling diverse, high-reward objects. In many practical applications where active reward queries are infeasible, these models must be trained using static offline datasets. Prevailing training methods typically rely on a proxy model to provide reward feedback for online sampled trajectories. However, constructing a reliable proxy is often challenging due to data scarcity or high evaluation costs. While existing proxy-free approaches attempt to address this, they often impose coarse constraints that limit the model's ability to explore effectively. To overcome these limitations, we propose **Trajectory-Distilled GFlowNet (TD-GFN)**, a novel proxy-free training framework. TD-GFN utilizes inverse reinforcement learning (IRL) to extract dense, transition-level edge rewards from offline trajectories, providing rich structural guidance for efficient exploration. Crucially, to ensure robustness, these rewards guide the policy indirectly through DAG pruning and prioritized backward sampling. This design ensures that gradient updates rely exclusively on ground-truth terminal rewards from the dataset, thereby preventing error propagation. Empiri

cal results demonstrate that TD-GFN significantly outperforms a broad range of existing baselines in both convergence speed and sample quality, establishing a more robust and efficient paradigm for offline GFlowNet training.
****

MET-Bench: Multimodal Entity Tracking for Evaluating the Limitations of Vision-Language and Reasoning Models
Vanya Cohen, Ray Mooney
Entity state tracking is a necessary component of world modeling that requires maintaining coherent representations of entities over time. Previous work has benchmarked entity tracking performance in purely text-based tasks. We introduce MET-Bench, a multimodal entity tracking benchmark designed to evaluate the ability of vision-language models to track entity states across modalities. Using three domains, we assess how effectively current models integrate textual and image-based state updates. Our findings reveal a significant performance gap between text-based and image-based entity tracking. We empirically show this discrepancy primarily stems from deficits in visual reasoning rather than perception. We further show that explicit text-based reasoning strategies improve performance, yet limitations remain, especially in long-horizon multimodal tasks. We apply reinforcement learning to improve entity tracking in open-source VLMs. This yields substantial in-modality gains, but does not transfer robustly across input modalities. Our results highlight the need for improved multimodal representations and reasoning techniques to bridge the gap between textual and visual entity tracking.
****

RSTR: Reducing SpatioTemporal Redundancy in Diffusion Transformers
Ruitong Sun, Tianze Yang, Wei Niu, Jin Sun
Diffusion Transformers (DiTs) have achieved remarkable success in image generation, yet their deployment is hindered by high computational costs. We identify two sources of redundancy. First, $\textbf{temporal redundancy}$: Classifier-Free Guidance (CFG) applies costly dual forward passes at every timestep, yet guidance matters only at specific steps, and variable scales at critical steps can compensate for skipping others. Second, $\textbf{spatial redundancy}$: under variable guidance, different transformer blocks exhibit heterogeneous sensitivity, yet uniform calibration across all blocks wastes computation while failing to address their varying requirements. We present RSTR, the first framework to jointly reduce spatiotemporal redundancy in diffusion transformers. Stage-1 addresses temporal redundancy through evolutionary search, discovering sparse guidance schedules with variable scales. Stage-2 addresses spatial redundancy through adaptive rank allocation, assigning calibration capacities to transformer regions based on their sensitivity. Experiments on DiT-XL/2, PixArt-α, FLUX, and state-of-the-art Qwen-Image demonstrate 50\%-70\% compute savings while maintaining or improving quality. On DiT-XL/2, RSTR achieves 57\% savings with 15\% FID improvement; on Qwen-Image, 3.43$\times$ speedup with preserved quality.
****

Sobolev Regularized Score Difference Estimation in Diffusion Models
Chenghan Xie, Jose Blanchet, Renyuan Xu
Estimating the difference of two Stein's score functions is a fundamental problem in generative modeling. In particular, score differences arise naturally in transfer learning, where the score difference provides the mechanism for adapting a pre-trained model to a new target distribution, and in diffusion model-based post-training methods such as discriminator guidance. Existing estimators for score differences in these settings either lack of statistical consistency or are difficult to scale up in high-dimensions.

We propose a statistically consistent and scalable estimator for score differences based on Sobolev regularization, which plays a crucial role in ensuring consistency and stablizing the training in the small-sample regime. Mathematically, we establish a convergence rate of $\tilde{\mathcal{O}}(n^{-\frac{s-1}{d+2s-2}})$ where d is the dimension and s denotes the smoothness of the underlying densities, and provide a minimax lower bound of $\tilde{\Omega}(n^{-\frac{2(s-1)}{

d+2s}})$ (in mean-squared error). Empirically, our estimator exhibits significantly improved stability in small-sample regimes compared to existing methods. We demonstrate its effectiveness on real-world tasks, including transfer learning for ECG signal generation, where it substantially outperforms non-regularized score difference estimators in downstream classification performance.

****

NOMAD: Lifelong Trajectory Planning via Non-Parametric Bayesian Memory-Adaptive Diffusion Experts

Yixian Chen, Rufan Bai, Jiangbin Zheng, Yimin Wang, Tiantian CHEN, Wei Wang, Yuhuan Lu

Autonomous vehicles operating in open-world environments must continually adapt to rare long-tail scenarios while preserving previously acquired driving skills. However, existing trajectory planning approaches struggle with this stability--plasticity trade-off, as they rely on static models or rigid rule-based controllers that cannot robustly handle evolving and complex traffic dynamics. Against this background, we propose **NOMAD**, a lifelong trajectory planning framework that integrates non-parametric Bayesian memory with diffusion-based trajectory generation, enabling continuous adaptation to long-tail scenarios without catastrophic forgetting. Our method maps growing scene contexts to a dynamically growing set of discrete memory clusters, which guide a conditional diffusion model to function as a mixture of experts specialized for diverse driving behaviors. To retain past knowledge during incremental learning, we introduce a generative replay mechanism that synthesizes pseudo-experiences from previously learned memory clusters. Extensive closed-loop evaluations on the nuPlan benchmark demonstrate that our approach achieves state-of-the-art performance on long-tail scenarios, improving the interPlan score by **9.4%** over the strongest baseline, while maintaining competitive performance on regular driving benchmarks. Moreover, our method exhibits robust continual learning capability, achieving the highest average closed-loop score with positive backward transfer when adapting to sequentially introduced long-tail scenarios.

****

On the Collapse of Generative Paths: A Criterion and Correction for Diffusion Steering

Ziseok Lee, Minyeong Hwang, Wooyeol Lee, Sanghyun Jo, Jihyung Ko, Young Bin Park, Jae-Mun Choi, Eunho Yang, Kyungsu Kim

Inference-time steering adapts pretrained diffusion and flow models to new tasks without retraining, often utilizing ratio-of-densities constructions that reweight time-indexed marginals with fixed exponents. We identify Marginal Path Collapse, a failure mode in which the intermediate density defined by such compositions becomes non-normalizable despite valid endpoints. This collapse can arise when composing heterogeneous experts trained with mismatched noise schedules (and/or negative exponents / partial supports). To address this, we provide (i) a sharp sufficient Path Existence Criterion that characterizes when the composed intermediate densities are mathematically well-defined, and (ii) Adaptive Path Correction with Exponents (ACE), which generalizes Feynman–Kac steering to support time-varying exponents. Our analysis reveals that ACE controls the quantile radius of the intermediate distributions, providing a theoretical mechanism for path stabilization observed in experiments. On flexible-pose scaffold decoration, a drug design task composed of de-novo, conformer, and protein-conditioned experts, ACE prevents collapse and significantly outperforms constant-exponent baselines. Furthermore, ACE improves attribute success rates in compositional image generation, establishing it as a general framework for compositional sampling.

Latent-Guided Cooperative Energy-Based Models

Cong Geng, Xue Han, Ye Yuan, Qiang Hu, Xin Huang, Ruiqiao Bai, Junlan Feng

Energy-based models (EBMs) provide a flexible framework for generative models with strong distribution modeling capabilities. Nevertheless, their broader adoption has been limited by the difficulty of stable and efficient training.

In this paper, we propose a unified and efficient latent-guided cooperative EBM that leverages informative target latent variables to guide the joint energy in

capturing both data distribution and semantic structure, along with a cooperativ
e generator designed for effective MCMC initialization. Our joint space optimiza
tion only requires MCMC sampling in the data space, and allows the energy to lea
rn semantic data–latent relationships directly from real data. Experiments show
 our method improves generation quality and training stability with fewer
resources, and performs effectively across multiple downstream tasks.

ReNF: Rethinking the Design of Neural Long-Term Time Series Forecasters
Yihang Lu, Xianwei Meng, Enhong Chen
Neural Forecasters (NFs) have become a cornerstone of Long-term Time Series Fore
casting (LTSF). However, recent progress has been hampered by an overemphasis on
 architectural complexity at the expense of fundamental forecasting structures.
In this work, we revisit principled designs of LTSF. We begin by formulating a V
ariance Reduction Hypothesis (VRH), positing that generating and combining multi
ple forecasts is essential to reducing the inherent uncertainty of NFs. Guided b
y this, we propose Boosted Direct Output (BDO), a streamlined paradigm that syne
rgistically hybridizes the causal structure of Auto-Regressive (AR) with the sta
bility of Direct Output (DO), while implicitly realizing the principle of foreca
st combination within a single network. Furthermore, we mitigate a critical vali
dation-test generalization gap by employing parameter smoothing to stabilize opt
imization. Extensive experiments demonstrate that these trivial yet principled i
mprovements enable a direct temporal MLP to outperform recent, complex state-of-
the-art models in nearly all benchmarks, without relying on intricate inductive
biases. Finally, we empirically verify our hypothesis, establishing a dynamic pe
rformance bound that highlights promising directions for future research. The co
de is publicly available at: \url{https://github.com/Luoauoa/ReNF}.

Token-Sparse Medical Multimodal Reasoning via Dual-Stream Reinforcement Learning
Kaitao Chen, Weiqian Zhao, Jiamin Wu, Qihao Zheng, Shangquan Sun, Chunfeng Song,
 Xiaosong Wang, Mu Zhou, Mianxin Liu
Vision-language models (VLMs) combining reinforcement learning (RL) ignite remar
kable progress in multimodal reasoning, yet still struggle with medical images,
which typically exhibit extremely sparse visual evidence to inform clinical deci
sion-making. We recognize that pruning visual tokens outside the grounding regio
n greatly enhances medical reasoning. However, a united RL framework for active
visual token pruning (VTP) and medical multimodal reasoning remains unestablishe
d. Here, we propose a dual-stream RL framework, **ViToS**, to fulfill token prun
ing and question answering. ViToS trains one policy model with two task branches
, where one focuses on grounding while the other conducts token-sparse reasoning
 after VTP. Furthermore, we solve the coupled policy learning problem by introdu
cing the cross-feedback sequential optimization, avoiding gradient conflict and
facilitating convergence of the shared policy model. Evaluated on seven medical
benchmarks, our method reduces visual tokens to 77% of the original sequence len
gth while achieving a 108.27% relative performance on Lingshu-7B and 104.16% rel
ative performance on HuatuoGPT-Vision-7B. Overall, ViToS delivers superior perfo
rmance and inference speedup, establishing an efficient paradigm for medical mul
timodal reasoning.

Shuffling-Aware Optimization for Private Vector Mean Estimation
Shun Takagi, Seng Pei Liew
We study d-dimensional unbiased mean estimation in the single-message shuffle
model, where each user sends a single privatized message and the analyzer only o
bserves the shuffled multiset of reports.
While optimal mechanisms are well understood in the local differential privacy s
etting, the corresponding notion of optimality after shuffling has remained larg
ely unexplored.
To address this gap, we introduce the recently proposed shuffle index and use it
 to formulate the post-shuffling mechanism design problem as an explicit optimiz
ation problem.
We then establish a lower bound on the achievable mean squared error in terms of

the shuffle index, which implies that mechanisms that are optimal under LDP can become suboptimal once shuffling is applied.
Finally, we construct an asymptotically optimal mechanism in the high privacy regime, which as a consequence achieves a privacy-utility trade-off nearly identical to that of the central Gaussian mechanism.
****
Scaling Small Agents Through Strategy Auctions
Lisa Alazraki, William F. Shen, Yoram Bachrach, Akhil Mathur
Small language models are viewed as a promising, cost-effective approach to agentic AI, yet how their performance scales with task complexity remains unclear. While smaller agents match larger ones on simple tasks, it is unknown when large models become necessary and how to better leverage small agents. In this work, we show that small agents fail to scale with task complexity on deep search and coding tasks, and introduce *Strategy Auctions for Workload Efficiency* (*SALE*), a framework inspired by freelancer marketplaces. In SALE, agents bid with strategic plans scored by a cost–value mechanism and refined via shared auction memory, enabling per-task routing and continual self-improvement without training a router. On average, SALE reduces reliance on the largest agent by 52%, lowers overall cost by 35%, and consistently improves pass@1 with only a negligible token overhead. In contrast, established routers either underperform the largest agent or fail to reduce cost. These results suggest that small agents can be effectively “scaled up” through coordinated allocation and test-time self-improvement. More broadly, they motivate a systems-level view of agentic AI in which gains come less from ever-larger individual models and more from market-inspired coordination mechanisms that organize heterogeneous agents into efficient, adaptive ecosystems.
****
Certain Head, Uncertain Tail: Expert-Sample for Test-Time Scaling in Fine-Grained MoE
Yuanteng Chen, Peisong Wang, Nanxin Zeng, Yuantian Shao, Shuang Qiu, Gang Li, Jing Liu, Jian Cheng
Test-time scaling improves LLM performance by generating multiple candidate solutions, yet token-level sampling requires temperature tuning that trades off diversity against stability. Fine-grained MoE, featuring hundreds of well-trained experts per layer and multi-expert activation per token, offers an unexplored alternative through its rich routing space. We empirically characterize fine-grained MoE routing and uncover an informative pattern: router scores exhibit a certain head of high-confidence experts followed by an uncertain tail of low-confidence candidates. While single-run greedy accuracy remains stable when fewer experts are activated, multi-sample pass@n degrades significantly—suggesting that the certain head governs core reasoning capability while the uncertain tail correlates with reasoning diversity. Motivated by these findings, we propose Expert-Sample, a training-free method that preserves high-confidence selections while injecting controlled stochasticity into the uncertain tail, enabling diverse generation without destabilizing outputs. Evaluated on multiple fine-grained MoE models across math, knowledge reasoning, and code tasks, Expert-Sample consistently improves pass@n and verification-based accuracy. On Qwen3-30B-A3B-Instruct evaluated on GPQA-Diamond with 32 parallel samples, pass@32 rises from 85.4% to 91.9%, and accuracy improves from 59.1% to 62.6% with Best-of-N verification.

Direct 3D-Aware Object Insertion via Decomposed Visual Proxies
Jingbo Gong, Yikai Wang, Yushi Lan, Yuhao Wan, Ziheng Ouyang, Rui Zhao, Ming-Ming Cheng, Qibin Hou, Chen Change Loy
Object insertion aims to seamlessly composite a reference object into a specified region of a background image. Recent diffusion-based methods achieve high visual quality but formulate insertion as a simple 2D inpainting task, providing no explicit control over the object's 3D pose and limiting their practical applicability. We propose **DIRECT** (**D**ecomposed **I**njection for **RE**ference **C**omposition and **T**arget-integration), a novel framework that integrates interactive pose manipulation with high-fidelity 2D image synthesis to enable pose-c

ontrollable object insertion. Our method decomposes the insertion conditions int
o three complementary components: appearance guidance capturing visual details f
rom the reference object, geometry guidance derived from the user-adjusted 3D pr
oxy, and context guidance from the target background. By injecting them through
separate pathways, DIRECT avoids feature entanglement and simultaneously preserv
es reference appearance, follows the user-specified pose, and adapts the object
to the target scene. We also introduce an automated data construction pipeline t
o improve the diversity and quality of training data. Experiments show that DIRE
CT outperforms previous methods in both geometric controllability and visual qua
lity.

Prototype-Based Test-Time Adaptation of Vision-Language Models
Zhaohong Huang, Yuxin Zhang, Wenjing Liu, Fei Chao, Rongrong Ji
Test-time adaptation (TTA) has emerged as a promising paradigm for vision–langua
ge models (VLMs) to bridge the distribution gap between pre-training and test da
ta. Recent works have focused on backpropagation-free TTA methods that rely on c
ache-based designs, but these introduce two key limitations. First, inference la
tency increases as the cache grows with the number of classes, leading to ineffi
ciencies in large-scale settings. Second, suboptimal performance occurs when the
 cache contains insufficient or incorrect samples. In this paper, we present Pro
totype-Based Test-Time Adaptation (PTA), an efficient and effective TTA paradigm
 that uses a set of class-specific knowledge prototypes to accumulate knowledge
from test samples. Particularly, knowledge prototypes are adaptively weighted ba
sed on the zero-shot class confidence of each test sample, incorporating the sam
ple's visual features into the corresponding class-specific prototype. It is wor
th highlighting that the knowledge from past test samples is integrated and util
ized solely in the prototypes, eliminating the overhead of cache population and
retrieval that hinders the efficiency of existing TTA methods. This endows PTA w
ith extremely high efficiency while achieving state-of-the-art performance on 15
 image recognition benchmarks and 4 robust point cloud analysis benchmarks. For
example, PTA improves CLIP’s accuracy from 65.64\% to 69.38\% on 10 cross-domain
 benchmarks, while retaining 92\% of CLIP’s inference speed on large-scale Image
Net-1K. In contrast, the cache-based TDA achieves a lower accuracy of 67.97\% an
d operates at only 50\% of CLIP’s inference speed.

Last-Iterate Convergence of Regularized Gradient Methods for Stochastic Monotone
 Variational Inequalities
Shinji Ito, Taira Tsuchiya, Kaito Ariu, Kenshi Abe
We study last-iterate convergence for stochastic smooth and monotone variational
 inequalities (VIs), a framework that captures convex-concave saddle points and
Nash equilibrium computation in monotone games with noisy payoff feedback.
In contrast to the well-understood average-iterate guarantees, anytime last-iter
ate guarantees in stochastic settings remain limited, despite their relevance fo
r uncoupled learning dynamics that output a single current strategy.
We analyze two single-call regularized methods, the \emph{regularized gradient (
RG)} and the \emph{regularized optimistic gradient (ROG)} methods, and establish
 anytime last-iterate convergence rates in terms of the squared gap function.
For monotone VIs, RG attains $O(t^{-2/5})$ while ROG achieves the variance-adapt
ive rate $O(\sigma^{4/5} t^{-2/5} + t^{-1})$, where σ^2 is the noise vari
ance.
For λ-strongly monotone VIs, ROG yields $O(\sigma^2 / (\lambda^2 t) + t^
{-c})$ for any constant $c \ge 2$.
These results give anytime last-iterate guarantees without knowing the horizon a
nd show that optimism improves convergence in the low-noise regime.

The Appeal and Reality of Recycling LoRAs with Adaptive Merging
Haokun Liu, Gyung Hyun Je, Marco Ciccone, Zhenlin Xu, Prasanth YSS, Colin Raffel
The widespread availability of fine-tuned LoRA modules for open pre-trained mode
ls has led to an interest in methods that can adaptively merge LoRAs to improve
performance.

These methods typically include some way of selecting LoRAs from a pool and tune merging coefficients based on a task-specific dataset.

While adaptive merging methods have demonstrated improvements in some settings, no past work has attempted to recycle LoRAs found ``in the wild'' on model repositories like the Hugging Face Hub.

To address this gap, we consider recycling from a pool of nearly 1,000 user-contributed LoRAs trained from the Llama 3.1 8B-Instruct language model.

Our empirical study includes a range of adaptive and non-adaptive merging methods in addition to a new method designed via a wide search over the methodological design space.

We demonstrate that adaptive merging methods can improve performance over the base model but provide limited benefit over training a new LoRA on the same data used to set merging coefficients.

We additionally find not only that the specific choice of LoRAs to merge has little importance, but that using LoRAs with randomly initialized parameter values yields similar performance.

To better understand why past work has proven successful, we confirm that positive transfer is indeed possible when there are highly relevant LoRAs in the pool.

We release the model checkpoints and code online at https://github.com/r-three/realistic-adaptive-merging.

Test-Time Detoxification without Training or Learning Anything

Baturay Saglam, Dionysis Kalogerias

Large language models can produce toxic or inappropriate text even for benign inputs, creating risks when deployed at scale. Detoxification is therefore important for safety and user trust, particularly when we want to reduce harmful content without sacrificing the model’s generation quality. Many existing approaches rely on model retraining, gradients, or learned auxiliary components, which can be costly and may not transfer across model families or to truly black-box settings. We introduce a test-time procedure that approximates the gradient of completion toxicity with respect to the input embeddings and uses a small number of descent steps to steer generation toward less toxic continuations. This is achieved with zeroth-order optimization that requires only access to input embeddings, a toxicity scoring function, and forward evaluations of the model. Empirically, the approach delivers robust toxicity reductions across models and prompts and, in most settings, achieves the best overall toxicity–quality trade-off. More broadly, our work positions word embeddings as effective control variables and encourages wider use of black-box optimization to guide autoregressive language models toward scalable, safer text generation, without requiring any training or access to intermediate computations.

Multi-scale Explainer for Graph Neural Networks

Lutong Wu, Shiying Cheng, Zhiqiang Wang, Jianqing Liang, Peng Song, Xizhao Luo, Jiye Liang

Explainability for graph neural networks (GNNs) aims to unveil the complex decision logic of learned models by identifying the most influential structures in the input graph, thereby improving transparency and trustworthiness. Existing post-hoc explainers typically extract a sparse key subgraph at a single scale as the explanation. However, a single-scale view often fails to capture multi-level semantics, and the optimization procedure may degenerate into a local search that is sensitive to initialization and noise, leading to unstable explanations and compromising their reliability. To address these issues, we propose MSExplainer, a multi-scale explainer for GNNs. MSExplainer couples multi-scale subgraph consistency guidance with single-scale adaptive subgraph learning under a parameter-sharing design. It simultaneously extracts multi-scale key subgraphs and complementary subgraphs, yielding a hierarchical decomposition of the original graph that covers semantics at different granularities and improves the stability of subgraph extraction. Experiments on six benchmark datasets show that MSExplainer generally outperforms prior methods in explanation accuracy and fidelity. Moreover,

we theoretically prove the upper bound advantage of the multi-scale strategy in representation consistency, and derive that it achieves the same-order computational complexity as single-scale methods under the parameter-sharing mechanism, thus ensuring the high fidelity of key subgraphs while maintaining computational efficiency.

****

PosterAgent: Agentic Poster Generation via Stage-Aware Reinforcement Learning

Zhuocheng Yu, Feng Zhang, Sujian Li, Kai Jia

Poster generation is a complex task demanding a harmonious integration of visual aesthetics and information hierarchy. While recent text-to-image models have advanced visual synthesis, they remain non-editable and struggle with precise text rendering. Conversely, existing layout-generation methods offer structure but typically rely on static, one-shot predictions, lacking the mechanism for self-correction essential to professional design. Inspired by the iterative workflow of human designers, we introduce PosterAgent, a novel framework that reformulates poster creation as an agentic workflow involving initial drafting followed by iterative refinement. To effectively train this multi-turn capability, we propose Stage-Aware Reinforcement Learning (SARL), which decouples the optimization into draft-specific and refinement-specific phases, ensuring precise credit assignment for both initial drafting and incremental refinement actions.

Extensive experiments demonstrate that PosterAgent significantly outperforms strong baselines, validating the potential of agentic systems in graphic design.

S2M-Net: Spectral-Spatial Mixing with Morphology-Aware Adaptive Loss for Medical Image Segmentation

Sanaullah Chowdhury, Lameya Sabrin

Medical image segmentation requires balancing global context with computational efficiency,
where self-attention mechanisms suffer from quadratic $\mathcal{O}((HW)^2 C)$ complexity.
We propose S2M-Net, a parameter-efficient architecture (4.7M parameters) that achieves
computational savings through Spectral--Spatial Token Mixing (SSTM).
SSTM achieves $\mathcal{O}(HWC^2)$ complexity through efficient combination of
$\mathcal{O}(HWC \log(HW))$ frequency-domain processing and $\mathcal{O}(HWCd)$ bottlenecked
spatial gating ($d{=}16$), exploiting spectral concentration where $>93\%$ of energy
is captured by $K{=}32$ low-frequency components ($\sim$0.8\% of the spectrum at

$352{\times}352$ resolution). This design avoids self-attention's prohibitive
$\mathcal{O}((HW)^2C)$ attention map computations while preserving global receptive fields.
To handle geometric diversity, we introduce Morphology-Aware Adaptive Segmentation Loss (MASL),
which automatically modulates five loss objectives based on per-sample morphological
descriptors (tubularity, compactness, irregularity, and scale).
Evaluation across 15 datasets spanning 8 modalities demonstrates competitive performance,
obtaining the best performance on 14 of 15 datasets,
with statistically significant improvements
($p < 0.0033$, Bonferroni-corrected) on 7 challenging tasks
(complex morphology, class imbalance, and multi-class segmentation),
and clinically meaningful gains (0.5--1.6% Dice) on 8 mature benchmarks.
Notably, S2M-Net achieves 83.43% Dice on EndoVis17 multiclass instrument segmentation
($+8.69\%$ over TransUNet and $+9.14\%$ over the best baseline UMamba at 74.29%),
while using $12.8{\times}$ fewer parameters (4.7M vs.\ 60M).

****
GASS: Geometry-Aware Spherical Sampling for Disentangled Diversity Enhancement in Text-to-Image Generation
Ye Zhu, Kaleb Newman, Johannes F. Lutzeyer, Adriana Romero-Soriano, Michal Drozdzal, Olga Russakovsky
Despite high semantic alignment, modern text-to-image (T2I) generative models still struggle to synthesize diverse images from a given prompt. In this work, we enhance the T2I diversity through a geometric lens. Unlike most existing methods that rely primarily on entropy-based guidance to increase sample dissimilarity, we introduce Geometry-Aware Spherical Sampling (GASS) to enhance diversity by explicitly controlling both prompt-dependent and prompt-independent sources of variation. Specifically, we decompose the diversity measure in CLIP embeddings using two orthogonal directions: the text embedding, which captures semantic variation related to the prompt, and an identified orthogonal direction that captures prompt-independent variation (e.g., backgrounds). Based on this decomposition, GASS increases the geometric projection spread of generated image embeddings along both axes and guides the T2I sampling process via expanded predictions along the generation trajectory. Our experiments on different frozen T2I backbones (U-Net and DiT, diffusion and flow) and benchmarks demonstrate the effectiveness of disentangled diversity enhancement with minimal impact on image fidelity and semantic alignment.
****
VidLaDA: Bidirectional Diffusion Large Language Models for Efficient Video Understanding
Zhihao He, Tieyuan Chen, Kangyu Wang, Ziran Qin, Yang Shao, Chaofan Gan, Shijie Li, Zuxuan Wu, Weiyao Lin
Current Video Large Language Models (Video LLMs) typically encode frames via a vision encoder and employ an autoregressive (AR) LLM for understanding and generation.
However, this AR paradigm inevitably faces a dual efficiency bottleneck: strictly unidirectional attention compromises *understanding efficiency* by hindering global spatiotemporal aggregation, while serial decoding restricts *generation efficiency*. To address this, we propose **VidLaDA**, a Video LLM based on Diffusion Language Models (DLMs) that leverages bidirectional attention to unlock comprehensive spatiotemporal modeling and decode tokens in parallel. To further mitigate the computational overhead of diffusion decoding, we introduce **MARS-Cache**, an acceleration strategy that prunes redundancy by combining asynchronous visual cache refreshing with frame-wise chunk attention. Experiments show VidLaDA rivals state-of-the-art AR baselines (e.g., Qwen2.5-VL and LLaVA-Video) and outperforms DLM baselines, with MARS-Cache delivering over 12x speedup without compromising accuracy.
Code and checkpoints are open-sourced at https://github.com/ziHoHe/VidLaDA.
****
MindZero: Learning Online Mental Reasoning With Zero Annotations
Shunchi Zhang, Jin Lu, Chuanyang Jin, Yichao Zhou, Zhining Zhang, Tianmin Shu
Effective real-world assistance requires AI agents with robust Theory of Mind (ToM): inferring human mental states from their behavior. Despite recent advances, several key challenges remain, including (1) online inference with robust uncertainty updates over multiple hypotheses; (2) efficient reasoning suitable for real-time assistance; and (3) the lack of ground-truth mental state annotations in real-world domains. We address these challenges by introducing *MindZero*, a self-supervised reinforcement learning framework that trains multimodal large language models (MLLMs) for efficient and robust online mental reasoning. During training, the model is rewarded for generating mental state hypotheses that maximize the likelihood of observed actions estimated by a planner, similar to model-based ToM reasoning. This method thus eliminates the need for explicit mental state annotations. After training, *MindZero* internalizes model-based reasoning into fast single-pass inference. We evaluate *MindZero* against baselines across challenging mental reasoning and AI assistance tasks in gridworld and household domains. We found that LLMs alone are insufficient; model-based methods improve ac

curacy but are slow, costly, and limited by backbone MLLM capacity. In contrast, *MindZero* enhances MLLMs' intrinsic ToM ability and significantly outperforms model-based methods in both accuracy and efficiency, showing that mental reasoning can be effectively learned as a self-supervised skill.

Doubly Regularized Markov Decision Processes for Robust Reinforcement Learning
Yiting He, Zhishuai Liu, Pan Xu
Empirical successes show that regularization improves the stability and efficiency of reinforcement learning (RL), with applications in robotics and post-training of large language models. Yet, theoretical analyses of regularized Markov decision processes (MDPs) have mostly been confined to the standard RL setting. In this work, we investigate regularized MDPs through the lens of robust RL. We introduce a doubly regularized MDP framework that combines policy and dynamics regularizations, enabling robust policy learning while naturally accommodating continuous action spaces. Within this framework, we develop an optimism-based online algorithm and provide the first finite-sample regret guarantees in both tabular and linear settings. Our results show that algorithms for doubly regularized MDPs are as sample-efficient as well-studied robust MDP algorithms, while additionally benefiting from the flexibility of soft policies. We further design practical algorithmic variants for both settings and demonstrate empirically that our approach efficiently and effectively handles function approximation and exploration in large state-action spaces, achieving robust performances.

State Space Model with Continuous Limit of HiPPO Matrix: Eigenvalue Analysis and Explicit Solution Formula
Atsushi Takabatake, Takaharu Yaguchi
As a lightweight model for sequence processing, an LSSL that uses the HiPPO matrix has been proposed.
In this paper, as the continuous limit of the HiPPO Matrix,
we propose Continuized-HiPPO Operator.
Furthermore, as examples of advantages obtained by using this operator,
we show that one can analyze the asymptotic behavior of eigenvalues of a matrix related to the HiPPO matrix, and
that the LSSL induced by the continuous limit Continuized-HiPPO Operator admits an explicit solution.
****
EnerGS: Energy-Based Gaussian Splatting under Partial Geometric Priors
Rui Song, Tianhui Cai, Markus Gross, Yun Zhang, Walter Zimmer, Zhiyu Huang, Olaf Wysocki, Jiaqi Ma
3D Gaussian Splatting (3DGS) has been widely adopted for scene reconstruction, where training inherently constitutes a highly coupled and non-convex optimization problem. Recent works commonly incorporate geometric priors, such as LiDAR measurements, either for initialization or as training constraints, with the goal of improving photometric reconstruction quality. However, in large-scale outdoor scenarios, such geometric supervision is often spatially incomplete and uneven, which limits its effectiveness as a reliable prior and can even be detrimental to the final reconstruction. To address this challenge, we model partially observable geometry as a continuous energy field induced by geometric evidence and propose EnerGS. Rather than enforcing geometry as a hard constraint, EnerGS provides a soft geometric guidance for the optimization of Gaussian primitives, allowing geometric information to steer the optimization process without directly restricting the solution space. Extensive experiments on large-scale outdoor scenes demonstrate that, under both sparse multi-view and monocular settings, EnerGS consistently improves photometric quality and geometric stability, while effectively mitigating overfitting during 3DGS training. The codebase is publicly available at: https://github.com/ucla-mobility/EnerGS.

Privileged Information Distillation for Language Models
Emiliano Penaloza, Dheeraj Vattikonda, Nicolas Gontier, Alexandre Lacoste, Laurent Charlin, Massimo Caccia

Training-time privileged information (PI) can enable language models to succeed on tasks they would otherwise fail, making it a powerful tool for reinforcement learning in hard, long-horizon settings. However, transferring capabilities learned with PI to policies that must act without it at inference time remains a fundamental challenge. We study this problem in the context of distilling frontier models for multi-turn agentic environments, where closed-source systems typically hide their internal reasoning and expose only action trajectories. This breaks standard distillation pipelines, since successful behavior is observable but the reasoning process is not. We introduce π-Distill, a joint teacher–student framework that trains a PI-conditioned teacher and an unconditioned student simultaneously within a single shared-parameter model, enabling the teacher to learn how to use PI while mitigating distribution shift during transfer. We show that π-Distill effectively distills frontier agents using action-only privileged information, matching or outperforming industry-standard pipelines that assume access to full Chain-of-Thought supervision across multiple agentic benchmarks, models, and forms of PI. We complement our results with extensive analysis that characterize what factors enable effective learning with PI.

Signal Strength Estimation in Logistic Regression Using Data Splitting

Weihao Li, Jun S. Liu

Logistic regression is widely used in applications; however, when the dimension scales with the sample size, theory reveals that the asymptotic behavior of common M-estimators depends on nonzero bias and variance factors, which are functions of the signal strength. To leverage the theory to design valid statistical methodologies, it is essential to obtain accurate estimates of the signal strength. In this work, we utilize a data-splitting strategy to efficiently estimate the signal strength. To alleviate issues caused by separable data, we analyze the exact asymptotics of an M-estimator with a data-driven, non-decomposable regularizer that adapts to the true covariance structure. We justify the validity of our method through both theoretical analysis and numerical experiments.

****

Speculative Coupled Decoding for Training-Free Lossless Acceleration of Autoregressive Visual Generation

Junhyuk So, Hyunho Kook, Chaeyeon Jang, Eunhyeok Park

Autoregressive (AR) modeling has recently emerged as a promising new paradigm in visual generation, but its practical adoption is severely constrained by the slow inference speed of per-token generation, which often requires thousands of steps to produce a single sample. While several Speculative Decoding (SD)-based methods have been proposed to solve this problem by generating multiple tokens in a single forward step, they suffer from limited speedup, degraded quality, or require the training of a draft model. To solve these problems, we propose a new training-free, lossless SD framework, Speculative Coupled Decoding (SCD), by extending the recently proposed Speculative Jacobi Decoding (SJD). While SJD shows strong potential for accelerating AR generation by combining Jacobi iteration and SD, we found that its acceptance rate is still significantly limited due to the instability arising from the independent sampling process used during draft token generation. To overcome this, we introduce an information-theoretic approach, Coupling, which stabilizes the drafting trajectory of SJD by maximizing the probability of sampling identical draft tokens across consecutive iterations, significantly enhancing the acceptance rate while preserving its lossless property. Remarkably, this method requires only a single-line modification to the existing algorithm with almost zero overhead, yet achieves substantial performance gains, delivering up to a 4.2× speedup in image generation and 13.6× speedup in video generation compared to standard AR decoding, without any degradation or the need for additional training.

****

The Illusion of Generalization in Tabular Language Models

Aditya Gorla, Ratish Puduppully

Tabular Language Models (TLMs) have been claimed to achieve strong generalization for tabular prediction. We conduct a systematic re-evaluation of Tabula-8B as

a representative TLM, utilizing 165 datasets from the UniPredict benchmark. Our investigation reveals three findings. First, binary and categorical classificati on achieve near-zero median lift over majority-class baselines and strong aggreg ate performance is driven entirely by quartile classification tasks. Second, top -performing datasets exhibit pervasive contamination, including complete train-t est overlap and task-level leakage that evades standard deduplication. Third, in struction-tuning without tabular exposure recovers 92.2% of standard classificat ion performance and on quartile classification, format familiarity closes 71.3% of the gap with the residual attributable to contaminated datasets. These findin gs suggest claimed generalization likely reflects evaluation artifacts rather th an learned tabular reasoning. We conclude with recommendations for strengthening TLM evaluation.

LieStoNet: Learning Lie Symmetries from Spatiotemporal Data for Stochastic Dynam ical Systems

Shida Liu, Abhishek Gupta, Sumit Sinha, L Mahadevan

Symmetry is central to modern machine learning and physics: invariances and equi variances improve sample efficiency, robustness, and out-of-distribution general ization, while symmetry principles guide scientific modeling. Yet for stochastic dynamical systems the relevant continuous symmetries are rarely known, and symm etry discovery for SDEs has remained essentially unexplored. We introduce *LieSt oNet*, an end-to-end, template-free framework for discovering Lie-point symmetri es of SDEs directly from spatiotemporal trajectories, without prespecifying symm etry groups, templates, or canonical coordinates. Building on the seminal SDE Li e-symmetry theory of Gaeta and Quintero (1999), which formalizes Lie-point SDE s ymmetries and their relation to Fokker-Planck symmetries, LieStoNet learns neura l surrogates for drift and diffusion from increments, then learns projectable ge nerators by enforcing the SDE determining equations, separately regularizing for closure under Lie brackets, adherence to the Lie algebra axioms (bilinearity, a ntisymmetry, Jacobi), and a non-redundant independent basis. The surrogate also defines an associated Fokker-Planck equation, enabling optional discovery of its Lie-point symmetries in parallel. Across multiple canonical SDEs with known ana lytic symmetries, LieStoNet recovers generators consistent with the ground-truth symmetry algebra, providing interpretable symmetry discovery for noisy dynamics . Code is available at this link.

From Talking to Singing: A New Challenge for Audio-Visual Deepfake Detection

Ke Liu, Jiwei Wei, Wenyu Zhang, Shuchang Zhou, Ruikun Chai, Yutao Dai, Chaoning Zhang, Yang Yang

With rapid advances in audio-visual generative models, reliable forgery detectio n becomes increasingly critical. Existing methods for audio-visual deepfake dete ction typically rely on cross-modal inconsistencies. In singing, rhythmic vocali zation weakens this coupling and introduces a nontrivial domain shift, substanti ally degrading detection performance. We construct the Singing Head DeepFake (SH DF) dataset using rhythm-aware generative models to fill the gap in singing benc hmarks. To cope with cross-scenario domain shifts, we propose a Text-guided Audi o-Visual Forgery Detection (T-AVFD) framework that generalizes across both talki ng and singing scenarios. T-AVFD comprises a facial authenticity pattern learner and a multi-modal differential weight learning module. The pattern learner alig ns facial features with multi-granularity textual descriptions to learn generali zable authenticity patterns. The weight learning module preserves intrinsic audi o-visual consistency and adaptively integrates it with authenticity patterns via differential weighting. Extensive experiments on multiple talking head deepfake datasets and SHDF show consistent improvements over existing baselines and stro ng robustness under diverse perturbations.

SSR-Merge: Subspace Signal Routing for Training-Free LoRA Merging in Diffusion M odels

Zhengxuan Wei, Yi Dong, Zonghui Li, Xianhui Lin, Xing Liu, Hong Gu, Shaofeng Zha ng, Wenbin Li, Qi Fan

Low-Rank Adaptation (LoRA) merging can efficiently combine diverse generative capabilities from multiple trained LoRAs for a diffusion model. However, existing LoRA merging techniques often suffer from severe parameter interference, causing destructive collisions in the shared parameter space. To address this, we propose Subspace Signal Routing (SSR), which resolves interference by routing internal signals instead of performing parameter-space merge. Specifically, SSR first constructs a unified subspace by concatenating candidate LoRAs along the rank dimension. Next, SSR employs an inverse correlation matrix to decorrelate mixed signals within this space. Finally, a directional guide matrix steers these purified signals into their respective task-specific subspaces. We provide a rigorous theoretical analysis proving that SSR aligns with the Ordinary Least Squares (OLS) solution, thereby ensuring mathematical optimality. We utilize the additivity of sufficient statistics to design a streaming algorithm. This enables on-the-fly updates that significantly reduce memory overhead and computation time. Extensive experiments validate that SSR significantly outperforms state-of-the-art methods while maintaining comparable efficiency. The source code will be made publicly available.

GFedCL: Graph-Based Federated Continual Learning with Spatial and Temporal Awareness

Qingyang Yu, Yang Hua, Qizhen Zhang, Hao Wang

Recent years have witnessed a surge of interest in federated learning. In particular, federated continual learning (FCL) emerged as an effective approach that enables clients with evolving, non-storable data to engage in collective learning. Among FCL approaches, replay-based methods excel by mitigating data storage constraints through synthetic data generation. However, existing replay-based methods overlook spatial and temporal information inherent in FCL settings, leading to suboptimal model performance. For instance, spatial variation in COVID-19 prevalence across hospitals in different states (e.g., Delta surging in Florida vs. Omicron in New York) and the temporal evolution of regional outbreaks are critical information for accurately distinguishing between COVID variants. This paper presents GFedCL to address this limitation. GFedCL is a new FCL approach that (1) constructs spatial- and temporal-aware relational graphs with attention mechanisms, and (2) uses the graphs, combined with generative adversarial learning, to generate high-quality synthetic data. GFedCL can generate synthetic data that matches the expectation of real data distribution while preserving privacy with theoretical guarantees. GFedCL consistently outperforms state-of-the-art FCL methods, gaining 27.95% improvement on TinyImageNet.

****

Compression as Adaptation: Implicit Visual Representation with Diffusion Foundation Models

Zongyu Guo, Jiajun He, Zhaoyang Jia, Xiaoyi Zhang, Jiahao Li, Xiao Li, Bin Li, José Miguel Hernández-Lobato, Yan Lu

Modern visual generative models acquire rich visual knowledge through large-scale training, yet existing visual representations (such as pixels, latents, or tokens) remain external to the model and cannot directly exploit this knowledge for compact storage or reuse.

In this work, we introduce a new visual representation framework that encodes a signal as a function, which is parametrized by low-rank adaptations attached to a frozen visual generative model.

Such implicit representations of visual signals, \textit{e.g.}, an 81-frame video, can further be hashed into a single compact vector, achieving strong perceptual video compression at extremely low bitrates.

Beyond basic compression, the functional nature of this representation enables inference-time scaling and control, allowing additional refinement on the compression performance.

More broadly, as the implicit representations directly act as a function of the generation process, this suggests a unified framework bridging visual compression and generation.

Minimizing Upper Confidence Bounds: A Data-Driven Framework for Stochastic Progr amming
Shixin Liu, Ming Gao, Jian Hu
Stochastic programming is often challenged by epistemic uncertainty, where criti cal probability distributions are poorly characterized or unknown due to a lack of data. To address this, we pioneer a novel framework for stochastic programmin g that minimizes an upper confidence bound (UCB) on the expected random cost, ac ting as a robustness-seeking strategy. Our central contribution is the Average P ercentile Upper Bound (APUB), a new statistical construct that serves as both a statistically rigorous upper bound for population means and an approximate risk metric for sample means. We rigorously prove the asymptotic correctness and cons istency of APUB, establishing a reliable foundation for data-driven decision-mak ing. We also develop practical solution methods, including a bootstrap sampling approximation method and an L-shaped method, to solve APUB optimization problems , with a specific focus on two-stage linear stochastic optimization with random recourse. Empirical demonstrations on a two-stage product mix problem reveal the significant benefits of our APUB optimization framework, which fortifies the pr ocess against epistemic uncertainty while reinforcing key decision-making attrib utes like reliability and consistency. The implementation and source code are av ailable at https://github.com/8Wings/APUB-Optimization.

SWE-ABS: Adversarial Benchmark Strengthening Exposes Inflated Success Rates on T est-based Benchmark
Boxi Yu, Yang Cao, Yuzhong Zhang, Liting Lin, Junjielong Xu, Zhiqing Zhong, Qing hua Xu, Guancheng Wang, Jialun Cao, Shing-Chi Cheung, Pinjia He, Lionel BRIAND
The SWE-Bench Verified leaderboard is approaching saturation, with the top syste m achieving 78.80\%.
However, we reveal that this performance is inflated: our re-evaluation demonstr ates that one in five ``solved'' patches from the top-30 agents are semantically incorrect, passing only because weak test suites fail to expose their errors.
We present SWE-ABS, an adversarial framework that strengthens test suites throug h a two-stage pipeline:
(1) coverage-driven augmentation utilizing program slicing to target untested co de regions, and (2) mutation-driven adversarial testing that synthesizes plausib le-but-incorrect patches to expose semantic blind spots.
On SWE-Bench Verified (500 instances), SWE-ABS strengthens 50.2\% of instances (a $25.1\times$ improvement over prior work) and rejects 19.78\% of previously pa ssing patches. Consequently, the top agent's score decreases from 78.80\% to 62. 20\%, causing significant leaderboard reshuffling (e.g., the top-ranked agent dr ops to 5th place).

Localized, High-resolution Geographic Representations with Slepian Functions

Arjun Rao, Ruth Crasto, Tessa Ooms, David Rolnick, Konstantin Klemmer, Marc Rußwurm

Geographic data is fundamentally local. Disease outbreaks cluster in population centers, ecological patterns emerge along coastlines, and economic activity concentrates within country borders. Machine learning models that encode geographic location, however, distribute representational capacity uniformly across the globe, struggling at the fine-grained resolutions localized applications require. We propose a geographic location encoder built from spherical Slepian functions that concentrates representational capacity inside a region-of-interest and scales to high resolutions without extensive computational demands. For settings requiring global context, we present a hybrid Slepian-Spherical Harmonic encoder that efficiently bridges the tradeoff between local-global performance, while retaining desirable properties such as pole-safety and spherical-surface-distance preservation. Across five tasks spanning classification, regression, and image-augmented prediction, Slepian encodings outperform baselines and retain performance advantages across a wide variety of neural network architectures.

Real-Time Visual Attribution Streaming in Thinking Model

Seil Kang, Woojung Han, Junhyeok Kim, Jinyeong Kim, Youngeun Kim, Seong Jae Hwang

We present an amortized framework for real-time visual attribution streaming in multimodal thinking models. When these models generate code from a screenshot or solve math problems from images, their long reasoning traces should be grounded in visual evidence. However, verifying this reliance is challenging: faithful causal methods require costly repeated backward passes or perturbations, while raw attention maps offer instant access, they lack causal validity. To resolve this, we introduce an amortized approach that learns to estimate the causal effects of semantic regions directly from the rich signals encoded in attention features. Across five diverse benchmarks and four thinking models, our approach achieves faithfulness comparable to exhaustive causal methods while enabling visual attribution streaming, where users observe grounding evidence as the model reasons, not after. Our results demonstrate that real-time, faithful attribution in multimodal thinking models is achievable through lightweight learning, not brute-force computation.

Neuro-Fuzzy Concept Learning for Interpretable Large Multimodal Models

Ritik Mishra, Vanshika Gupta, M. Sajid, M. Tanveer

Large Multimodal Models (LMMs) integrate unimodal encoders with Large Language Models (LLMs) to execute complex multimodal tasks. Despite progress in the field, understanding the internal representations of these models through interpretable logic remains an open problem. To address this, we present a framework utilizing a Human-Inspired (Neuro-fuzzy) approach for learning token representations. In this method, we leverage fuzzy rules to compute activation firing strengths, which are subsequently defuzzified to extract distinct concepts. This mechanism allows for the interpretation of learned representations directly through explicit logic. Consequently, we derive "multimodal concepts" that are both semantically coherent and interpretable. We validate our approach through rigorous qualitative and quantitative experiments, demonstrating the utility of these concepts in interpreting test samples. Additionally, we evaluate the disentanglement of the learned concepts and the efficacy of their grounding in both visual and textual domains.

Neural–Evolutionary Symbolic Regression with Global Constraints: Constraint-Aware Decoding and Reward Shaping

Xiangdong Wu, wenjun wu, Ziyu Wei, Bingrun Chen, Zhenbo Song, Rongye Shi

Symbolic regression aims to discover compact, interpretable mathematical expressions from data, but neural generation is challenging because expressions are tree-structured.

Existing neural methods often linearize expression trees into token sequences, facilitating autoregressive modeling but obscuring hierarchical relations and com

plicating structure-dependent constraint enforcement.
We propose GCN-SR, a graph-based symbolic regression framework that generates ex pressions in an explicit tree-aligned form, making structural context available during decoding.
To enable batched generation over variable-topology expressions, we introduce Sy mbolic Perfect Binary Trees (SPBTs), a fixed-topology scaffold that preserves tr ee hierarchy while supporting graph-based node-attribute prediction.
We further introduce Similarity-Weighted Policy Gradient (SWPG) to incorporate g enetic programming (GP) refinement without directly imitating GP-refined elites; instead, refined expressions construct similarity-weighted rewards for samples drawn by the current generator.
Experiments on standard symbolic regression benchmarks and ablations show that G CN-SR consistently improves exact recovery over strong neural and hybrid baselin es under matched evaluation budgets.

Klein Hyperbolic Metric Learning
Yulin Zhang, Boxuan Hu, Huimin Li, Junlin Hu
Hyperbolic metric learning is highly effective in embedding hierarchical data st ructures. However, past work has predominantly focused on the conformal Poincaré model, leaving other geometries like the Klein model largely under-explored. In addition, the curved geodesics of the Poincaré model present a fundamental geom etric misalignment with the linear projections dominating the feature transforma tion steps in the modern neural network backbones. In this paper, we investigate the Klein model, a projective model of hyperbolic geometry whose straight-line geodesics offer a structurally aligned alternative in modern encoders, for hyper bolic metric learning. By formalizing a framework based on Einstein gyrovector o perations, we derive a numerically stable metric learning approach that mitigate s the inherent optimization challenges of the Klein model. Extensive experiments on multiple image datasets for fine-grained image classification task show that the Klein model not only serves as a viable alternative to the Poincaré model b ut also achieves highly competitive performance by leveraging its unique geometr ic properties, without increasing parameter complexity. Our empirical findings e stablish the Klein model as an efficient geometric prior for hyperbolic metric l earning.

An Exponential Separation Between Quantum and Quantum-Inspired Classical Algorit hms for Linear Systems
Allan Grønlund, Kasper Green Larsen
Achieving a provable exponential quantum speedup for an important machine learni ng task has been a central research goal since the seminal HHL quantum algorithm for solving linear systems and the subsequent quantum recommender systems algor ithm by Kerenidis and Prakash. These algorithms were initially believed to be st rong candidates for exponential speedups, but a lower bound ruling out similar c lassical improvements remained absent. In breakthrough work by Tang, it was demo nstrated that this lack of progress in classical lower bounds was for good reaso ns. Concretely, she gave a classical counterpart of the quantum recommender syst ems algorithm, reducing the quantum advantage to a mere polynomial. Her approach is quite general and was named \emph{quantum-inspired classical} algorithms. Si nce then, almost all the initially exponential quantum machine learning speedups have been reduced to polynomial via new quantum-inspired classical algorithms. From the current state-of-affairs, it is unclear whether we can hope for exponen tial quantum speedups for any natural machine learning task. In this work, we pr esent the first such provable exponential separation between quantum and quantum -inspired classical algorithms for the basic problem of solving a linear system when the input matrix is well-conditioned and has sparse rows and columns.

Efficient DP-SGD for LLMs with Randomized Clipping
Enayat Ullah, Sai Aparna Aketi, Devansh Gupta, Huanyu Zhang, Meisam Razaviyayn
Large language models (LLMs) are trained on vast datasets that may contain sensi tive information. Differential privacy (DP), the de facto standard for formal pr

ivacy guarantees, provides a principled framework for training LLMs with provable privacy protection.
However, state-of-the-art DP training implementations rely on *fast gradient clipping* techniques with memory overhead $O(B\min(T^2, d^2))$, where B is the batch size, T is the sequence length, and d is the layer width. This becomes prohibitive as both model width and context length grow. We propose DP-SGD-RC, a novel variant of DP-SGD with *randomized clipping* that reduces memory and compute overhead. DP-SGD-RC leverages *stochastic trace estimation* methods, specifically *Hutchinson's estimator* and its improved variant, Hutch^{++}, to reduce the memory footprint of per-sample gradient norm estimation.
We provide a tight privacy analysis showing that DP-SGD-RC achieves noise multipliers competitive with deterministic clipping.
Experiments fine-tuning Llama 3.2 1B on long-context benchmarks spanning classification, question answering, and summarization tasks demonstrate that DP-SGD-RC matches baseline utility while significantly reducing memory and compute.

Manifold-Optimal Guidance: A Unified Riemannian Control View of Diffusion Guidance
Zexi Jia, Pengcheng Luo, Zhengyao Fang, Jinchao Zhang, Jie Zhou
Classifier-Free Guidance (CFG) serves as the de facto control mechanism for conditional diffusion, yet high guidance scales notoriously induce oversaturation, texture artifacts, and structural collapse. We attribute this failure to a geometric mismatch: standard CFG performs Euclidean extrapolation in ambient space, inadvertently driving sampling trajectories off the high-density data manifold. To resolve this, we present Manifold-Optimal Guidance (MOG), a framework that reformulates guidance as a local optimal control problem. MOG yields a closed-form, geometry-aware Riemannian update that corrects off-manifold drift without requiring retraining. Leveraging this perspective, we further introduce Auto-MOG, a dynamic energy-balancing schedule that adaptively calibrates guidance strength, effectively eliminating the need for manual hyperparameter tuning. Extensive validation demonstrates that MOG yields superior fidelity and alignment compared to baselines, with virtually no added computational overhead.
****
Think-at-Hard: Selective Latent Iterations to Improve Reasoning Language Models
Tianyu Fu, Yichen You, Zekai Chen, Guohao Dai, Huazhong Yang, Yu Wang
Improving the reasoning abilities of Large Language Models (LLMs), especially under parameter constraints, is crucial for real-world applications.
Looped transformers address this by performing multiple latent iterations to refine each token beyond a single forward pass.
However, we identify a latent overthinking phenomenon: most token predictions are already correct after the first pass, but are sometimes revised into errors in later iterations.
We ask whether selectively skipping latent iterations can improve accuracy, and reveal significant potential with an oracle iteration policy that boosts performance by up to 7.3%.
Motivated by this, we propose Think-at-Hard (TaH), a looped transformer optimized for selective iteration.
TaH employs a lightweight neural decider to trigger latent iteration, only at tokens likely to be incorrect after the standard forward pass.
During latent iterations, depth-aware Low-Rank Adaptation (LoRA) modules shift the objective from general next-token prediction to focused hard-token refinement.
A duo-causal attention mechanism extends attention from the token sequence dimension to an additional iteration depth dimension, enabling cross-iteration information flow with full sequential parallelism.
Experiments on nine benchmarks show consistent gains across math, QA, and coding tasks.
With identical parameter counts, TaH outperforms always-iterate baselines by 3.8-4.4% while skipping iterations on 93% of tokens, and exceeds single-iteration Qwen3 baselines by 3.0-3.8%.

When allowing <3% more parameters from LoRA and decider, the gains further increase to 5.3-6.2% and 6.1-6.8%, respectively.
Our code is available at https://github.com/thu-nics/TaH.

PACT: Self-Evolving Physical Safety Alignment for Diffusion Policies in Embodied Manipulation
Lingxuan Wu, Zijian Zhu, Lizhong Wang, Chengyang Ying, Huayu Chen, Xiao Yang, Fangming Liu, Jun Zhu
Diffusion policies have achieved remarkable success in robotic manipulation, yet they often fail to satisfy strict physical constraints required for safe deployment. Existing approaches impose safety either prematurely during training or reactively via external guardrails at test time, limiting policy expressivity and overall scalability. We propose Physical safety Alignment for Constrained Trajectories (PACT), a self-evolving post-training framework that projects pretrained diffusion policies onto constraint-feasible regions without accessing demonstration data or task rewards. PACT distills constraint gradients into the diffusion model through a reverse-KL objective with dense supervision across timesteps. It incorporates a curriculum that progressively tightens constraints while maintaining theoretically bounded policy shift and monotone improvement, mitigating the safety-performance trade-off from catastrophic forgetting. On simulated and real-world embodied manipulation benchmarks, PACT significantly reduces safety violations by 31.0% on average while improving task success by 30.7%.
****

Enhanced Multi-Instance Partial Label Learning via Average Gradient Outer Product
Nan Cao, Xu Zhao, Teng Zhang
Multi-instance partial-label learning (MIPL) is a recently proposed dual weakly supervised learning framework where each training bag is annotated with a candidate label set containing one true label and several false positives. The key challange of MIPL problem is that the relations between the key instances and the ground-truth labels are much more covered due to the false positive labels. Existing methods usually rely on the model's own predictions and roughly aggregate instance features according to the learned attention weights, which is easily misled by false positives and lets key instances be overlooked. Here, we propose Average Gradient Outer Product based Multi-instance Partial-Label Learning~(AGOPMIPL) method, where the average gradient outer product (AGOP) is directly calculated from the bag-level features and the model prediction, then it is integrated in an attention module to amplify discriminative feature directions and thereby helps key-instance identification. Moreover, the feature prototypes and a progressive disambiguation strategy are introduced to further suppress noisy candidates. The experimental studies on four MIPL benchmarks and the real-world \textsf{CRC-MIPL} dataset are performed and AGOPMIPL consistently outperforms five state-of-the-art baselines, with up to 25.9% relative gain on \textsf{CRC-MIPL-KMeansSeg}.

DAL: A Practical Prior-Free Black-Box Framework for Piecewise Stationary Bandits
Argyrios Gerogiannis, Yu-Han Huang, Subhonmesh Bose, Venugopal Veeravalli
We introduce a practical, black-box framework termed Detection Augmented Learning (DAL) for the problem of piecewise stationary bandits without knowledge of the underlying non-stationarity. DAL accepts any stationary bandit algorithm with order-optimal regret as input and augments it with a change detector, enabling applicability to all common bandit variants. Extensive experimentation demonstrates that DAL consistently surpasses all state-of-the-art methods across diverse non-stationary scenarios, including synthetic benchmarks and real-world datasets, underscoring its versatility and scalability. We provide theoretical insights into DAL's strong empirical performance, complemented by thorough empirical validation.

Decoupled Low-Rank Adaptation for Robust Federated Fine-Tuning
Xiuwen Fang, Xuliang Yang, Mang Ye

Federated Learning (FL) enables collaborative training across distributed clients while preserving data privacy. However, fine-tuning large-scale pre-trained models in FL is hindered by resource constraints and communication costs. Although introducing parameter-efficient fine-tuning strategies such as Low-Rank Adaptation (LoRA) effectively reduces trainable parameters, this low-rank constraint exacerbates noise sensitivity, leading to overfitting and aggregation bias. Existing robust federated fine-tuning methods rely on additional proxy data and treat low-rank adapters as generic weight vectors. In this paper, we investigate the structural properties of LoRA and reveal a robustness asymmetry. The down-projection matrix A extracts stable general features, whereas the up-projection matrix B is highly susceptible to fitting noise patterns. Based on this finding, we propose Federated Decoupled Robust LoRA (FedDR-LoRA), which employs a dual-branch mechanism to decouple robust feature learning from noise modeling and mitigates noise interference through noisy branch negative learning. During federated aggregation, we establish global consensus through aggregating B while preserving local feature alignment in A. Extensive experiments demonstrate that FedDR-LoRA outperforms existing state-of-the-art methods across various noisy federated scenarios. Our code is available at: https://github.com/FangXiuwen/FedDR-LoRA.

CB-SLICE: Concept-Based Interpretable Error Slice Discovery
Yael Konforti, Mateo Espinosa Zarlenga, Elaf Almahmoud, Mateja Jamnik
Despite strong average-case performance, deep learning models often exhibit systematic errors on specific population groups, known as *error slices*. Identifying these groups and the root causes of their failures is critical for model debugging and bias mitigation. However, existing error Slice Discovery Methods (SDMs) typically generate explanations disconnected from the model's inference process, thus only approximating the underlying error source and may be inaccurate.

We address this limitation by leveraging Concept Bottleneck Models (CBMs), whose predictions are directly dependent on human-understandable semantic concepts. Since downstream task failures in CBMs commonly arise from concept mispredictions, concept representations provide a strong candidate for error slice identification, offering fine-grained explanations directly linked to the error source.
Building on this insight, we introduce *CB-SLICE*, a concept-based SDM that groups samples with shared concept prediction failures and identifies the keyword-concepts most responsible for each slice’s failure-mode. Across multiple benchmarks, we show that CB-SLICE outperforms state-of-the-art methods in uncovering well-known biases while providing richer and more faithful explanations of model errors.

Unbiased Alignment for Large Language Models with Noisy Preferences
Jialiang Wang, Xianming Liu, Xiong Zhou, Hui Liu, Haoliang Li
The alignment of large language models with human preferences is commonly achieved through Reinforcement Learning from Human Feedback or Direct Preference Optimization.
However, these methods are vulnerable to the significant noise prevalent in real-world preference datasets.
To address this critical issue, we present a theoretical framework for unbiased alignment, introducing the *Unbiased Reward Model* (URM) loss and the *Unbiased Direct Preference Optimization* (UDPO) loss.
By mathematically correcting the distortion induced by preference noise, our novel objectives enable unbiased model training directly from noisy datasets, without requiring clean ground-truth supervision.
We provide rigorous theoretical analyses demonstrating that our methods are noise-tolerant, parameter downward compatible, and classification-calibrated.
Comprehensive experiments across diverse datasets demonstrate that our approaches outperform state-of-the-art baselines. Code available at: https://github.com/cswjl/unbiased-alignment.

Weight Updates as Activation Shifts: A Principled Framework for Steering

Dyah Adila, John Cooper, Alexander Yun, Avi Trost, Frederic Sala
Activation steering promises to be an extremely parameter-efficient form of adaptation, but its effectiveness depends on critical design choices---such as intervention location and parameterization---that currently rely on empirical heuristics rather than a principled foundation. We establish a first-order equivalence between activation-space interventions and weight-space updates, deriving the conditions under which activation steering can replicate fine-tuning behavior. This equivalence yields a \textbf{principled framework for steering design} and identifies the post-block output as a theoretically-backed and highly expressive intervention site. We explain why certain intervention locations outperform others and show that weight updates and activation updates play distinct, complementary functional roles. This analysis motivates a new approach---\textbf{joint adaptation}---that trains in both spaces simultaneously.
  Our post-block steering achieves accuracy within $0.2\%\text{--}0.9\%$ of full-parameter tuning, on average across tasks and models, while training only 0.04% of model parameters. It consistently outperforms prior activation steering methods such as ReFT and PEFT approaches including LoRA, while using significantly fewer parameters. Finally, we show that joint adaptation often surpasses the performance ceilings of weight and activation updates in isolation, introducing a new paradigm for efficient model adaptation

ConServe: Fine-Grained GPU Harvesting for LLM Online and Offline Co-Serving
Yifan Qiao, Shan Yu, Shu Anzai, Haoran Ma, Shuo Yang, Yang Wang, Miryung Kim, Yongji Wu, Yang Zhou, Jiarong Xing, Joseph E. Gonzalez, Ion Stoica, Harry Xu
Large language model (LLM) serving demands low latency and high throughput, but high load variability leads to significant GPU under-utilization. In this paper, we identify a synergistic but overlooked opportunity to co-serve latency-critical online requests alongside *latency-tolerant offline* tasks, which existing systems fail to exploit because their coarse-grained resource management introduces interference.
We present ConServe, a co-serving system that enables fine-grained resource sharing through latency-aware token-level scheduling, sub-iteration layer-wise preemption, and incremental KV-cache management. These mechanisms allow offline execution to fill *millisecond-scale* GPU idle time while preserving strict online latency guarantees. Across real-world workloads with Llama-3.1 and Qwen-2.5 models, ConServe improves throughput by 2.2$\times$ on average and reduces online tail latency by 2.9$\times$ over state-of-the-art systems.

From Out-of-Distribution Detection to Hallucination Detection: A Geometric View
Litian Liu, Reza Pourreza, Yubing Jian, Yao Qin, Roland Memisevic
Detecting hallucinations in large language models is a critical open problem with significant implications for safety and reliability. While existing hallucination detection methods achieve strong performance in question■answering tasks, they remain less effective on tasks requiring reasoning. In this work, we revisit hallucination detection through the lens of out■of■distribution (OOD) detection, a well■studied problem in areas like computer vision. Treating next■token prediction in language models as a classification task allows us to apply OOD techniques, if we bring to bear appropriate modifications to account for the structural differences in large language models. We show that approaches based on OOD detection yield training-free, single-sample based detectors, achieving strong accuracy in hallucination detection in reasoning tasks. Overall, our work suggests that reframing hallucination detection as OOD detection provides a promising and scalable pathway toward language model safety.

Fast Mixture of Curvature-Aware Experts for Diverse and Dynamic Graph Topologies
Jiayi Yang, Xing Wei, Chunchun Chen, Yi Feng, Wengang Guo, Rui Fan, Xiaofeng Cao, Xin Sun, Wei Ye
Dynamic graph learning, which focuses on modeling the merging, vanishing, and reconnection of nodes and edges, is crucial for real-world applications. In dynamic graphs, node neighborhoods often exhibit diverse and time-evolving topologies,

including hierarchical, grid-like, and cyclic patterns. Existing methods typically embed graphs into a single curvature space, which limits the quality of node representations when the embedding geometry is not aligned well with the local graph topology.
In this paper, we propose **DyGMoCE**, a **Dy**namic **G**raph Transformer with a **M**ixture **o**f **C**urvature-aware **E**xperts, which efficiently embeds each node at every timestamp into an adaptive curvature space. Specifically, DyGMoCE incorporates a mixture-of-experts framework to both the attention and feed-forward modules, where each expert operates on a Riemannian manifold with a distinct curvature.
Then, motivated by the geometric continuity across the experts, we introduce a routing mechanism with a ranking constraint. To improve efficiency, we design a fast Riemannian attention module for DyGMoCE, achieving an average speedup of 27.5% and memory reduction of 52.6%. Notably, the fast Riemannian attention module is broadly applicable to Transformer models with sequence inputs. Extensive experimental results show that DyGMoCE significantly outperforms other state-of-the-art methods.
****

Minimax-Optimal Policy Regret in Partially Observable Markov Games
Raman Arora
We study sequential decision-making in partially observable environments against strategic, adaptive opponents, modeled as partially observable Markov games (POMGs). The central challenge is to learn latent dynamics from partial observations while facing an adversary whose behavior depends on the learner's strategy, making standard regret notions inadequate. We prove that an epoch-based optimistic maximum-likelihood algorithm achieves $\tilde O(\sqrt{T})$ policy regret for fixed problem parameters, with explicit dependence on the horizon, adversary memory, confidence radius, and the aggregate Eluder dimension of the observable-operator class. The algorithm selects one policy per geometrically growing epoch using confidence sets built cumulatively from past data, which keeps the cost of comparing adversary responses across policies logarithmic in T. We also prove a lower bound matching the $\sqrt{T}$ and aggregate-Eluder-dimension dependence, up to problem-dependent and logarithmic factors. Finally, we extend the framework to horizon-adaptive guarantees and adversaries with geometric fading memory.
****

From Moments to Models: Graphon-Mixture Learning for Mixup and Contrastive Learning
Ali Azizpour, Reza Ramezanpour, Santiago Segarra
Real-world graph datasets often arise from mixtures of populations, where graphs are generated by multiple distinct underlying distributions.
In this work, we propose a unified framework that explicitly models graph data as a mixture of probabilistic graph generative models represented by graphons.
To characterize and estimate these graphons, we leverage graph moments (motif densities) to cluster graphs generated from the same underlying model.
We establish a novel theoretical guarantee, deriving a tighter bound showing that graphs sampled from structurally similar graphons exhibit similar motif densities with high probability.
This result enables principled estimation of graphon mixture components.
We show how incorporating estimated graphon mixture components enhances two widely used downstream paradigms: graph data augmentation via mixup and graph contrastive learning.
By conditioning these methods on the underlying generative models, we develop graphon-mixture-aware mixup (GMAM) and model-aware graph contrastive learning (MGCL).
Extensive experiments on both simulated and real-world datasets demonstrate strong empirical performance.
In supervised learning, GMAM outperforms existing augmentation strategies, achieving new state-of-the-art accuracy on 6 out of 7 datasets.
In unsupervised learning, MGCL performs competitively across seven benchmark dat

asets and achieves the lowest average rank overall.
****

Hybrid Policy Distillation for LLMs
Wenhong Zhu, Ruobing Xie, Rui Wang, Pengfei Liu
Knowledge distillation (KD) is a powerful paradigm for compressing large languag e models (LLMs), whose effectiveness depends on intertwined choices of divergenc e direction, optimization strategy, and data regime.
We break down the design of existing KD methods and present a unified view that establishes connections between them, reformulating KD as a reweighted log-likel ihood objective at the token level.
We further propose Hybrid Policy Distillation (HPD), which integrates the comple mentary advantages of forward and reverse KL to balance mode coverage and mode-s eeking behaviors, and combines off-policy data with lightweight approximate on-p olicy sampling.
We validate HPD on long-generation math reasoning as well as short-generation di alogue and code tasks, demonstrating improved optimization stability, computatio nal efficiency, and final performance across diverse model families and scales.

Prioritized Model Experience Replay
Muxi Tao, Jiangtao Wen, Yuxing Han
Model-based reinforcement learning (MBRL) improves sample efficiency by leveragi ng learned dynamics models, but often suffers from unstable training due to dyna mics model learning mismatch: models are trained on data from historical policie s while being queried under the continually updated current policy. This mismatc h can cause policy-relevant local model error to remain large even as global pre diction error decreases, leading to oscillatory updates. We present a finite-hor izon performance analysis that decomposes the policy performance gap into global model error, policy-induced distribution shift, and historical policy mixture e ffects, showing that minimizing global error alone is insufficient for stable op timization. Motivated by this analysis, we propose Prioritized Model Experience Replay (PMER), a lightweight replay mechanism that prioritizes high-error transi tions during dynamics model training. PMER implicitly emphasizes policy-relevant regions without explicit policy distance estimation and integrates seamlessly i nto Dyna-style MBRL frameworks. Experiments on MuJoCo benchmarks demonstrate imp roved stability, faster convergence, and higher sample efficiency.

Policy-Driven World Model Adaptation for Robust Offline Model-based Reinforcemen
t Learning

Jiayu Chen, Le Xu, Aravind Venugopal, Jeff Schneider

Offline reinforcement learning (RL) offers a powerful paradigm for data-driven c
ontrol. Compared to model-free approaches, offline model-based RL (MBRL) explici
tly learns a world model from a static dataset and uses it as a surrogate simula
tor, improving data efficiency and enabling potential generalization beyond the
dataset support. However, most existing offline MBRL methods follow a two-stage
training procedure: first learning a world model by maximizing the likelihood of
 the observed transitions, then optimizing a policy to maximize its expected ret
urn under the learned model. This objective mismatch results in a world model th
at is not necessarily optimized for effective policy learning. Moreover, we obse
rve that policies learned via offline MBRL often lack robustness during deployme
nt, and small adversarial noise in the environment can lead to significant perfo
rmance degradation. To address these, we propose a framework that dynamically ad
apts the world model alongside the policy under a unified learning objective aim
ed at improving robustness. At the core of our method is a maximin optimization
problem, which we solve by innovatively utilizing Stackelberg learning dynamics.
 We provide theoretical analysis to support our design and introduce computation
ally efficient implementations. We benchmark our algorithm on twelve noisy D4RL
MuJoCo tasks and three stochastic Tokamak Control tasks, demonstrating its state
-of-the-art performance. Code is available at https://github.com/Agentic-Intelli
gence-Lab/ROMBRL.

SleepMaMi: A Universal Sleep Foundation Model for Integrating Macro- and Micro-s
tructures

Keondo Park, Younghoon Na, You Rim Choi, Hyunwoo Ryu, Hyun-Woo Shin, Hyung-Sin K
im

While the shift toward unified foundation models has revolutionized many deep le
arning domains, sleep medicine remains largely restricted to task-specific model
s that focus on localized micro-structure features. These approaches often negle
ct the rich, multi-modal context of Polysomnography (PSG) and fail to capture th
e global macro-structure of a full night's sleep. To address this, we introduce
SleepMaMi, a Sleep Foundation Model engineered to master both hour-long sleep ar
chitectures and fine-grained signal morphologies. Our framework utilizes a hiera
rchical dual-encoder design: a Macro-Encoder to model full-night temporal depend
encies and a Micro-Encoder to capture short-term characteristics from biosignals
. Macro-Encoder is trained via Demographic-Guided Contrastive Learning, which al
igns overnight sleep patterns with objective subject metadata, such as age and s
ex, to refine global representations. Micro-Encoder is optimized via a hybrid Ma
sked Autoencoder (MAE) and multi-modal contrastive objective. Pre-trained on a
massive corpus of >20,000 PSG recordings (158K hours), SleepMaMi outperforms or
matches existing foundation models across a diverse suite of downstream tasks, d
emonstrating superior generalizability and label-efficient adaptation for clinic
al sleep analysis.

EchoingPixels: Aliasing-Resistant Joint Token Reduction for Audio-Visual LLMs

Chao Gong, Depeng Wang, Zhipeng Wei, Ya Guo, Huijia Zhu, Jingjing Chen

Audio-Visual Large Language Models (AV-LLMs) face prohibitive computational cost
s of processing massive, redundant audio-visual tokens. Existing unimodal compre
ssion techniques fail to capture the heterogeneous and mutually influential info

rmation density of joint audio-visual signals. Furthermore, we identify a fundamental and overlooked theoretical bottleneck in sparse token reduction: positional aliasing. We demonstrate that aggressive sparse sampling on standard position-encoded sequences violates the Nyquist limit relative to the effective token interval, causing phase-wrapping collisions that corrupt temporal monotonicity. To address this, we introduce EchoingPixels, a framework for aliasing-resistant joint token reduction. Our Cross-Modal Semantic Sieve performs extractive selection on the synergistic audio-visual stream, dynamically allocating budgets based on joint-modality saliency rather than fixed per-modality ratios. To resolve positional aliasing, we derive Sync-RoPE, a spectral low-pass filter for Rotary Positional Embeddings that adapts encoding bandwidth to the sparse sampling rate, preserving monotonic temporal relationships in the reduced stream. Experiments show that EchoingPixels achieves performance comparable to full models using only 5-20% of original tokens, validating theoretically grounded sparse learning as a robust solution for efficient AV-LLMs. Code is available at https://github.com/CharlesGong12/EchoingPixels.
****

What Does Flow-Matching Bring to TD-Learning?
Bhavya Kumar Agrawalla, Michal Nauman, Aviral Kumar
Recent work shows that flow-matching networks can be effective for value function estimation in reinforcement learning, but it remains unclear why they work well or whether flow-matching Q-functions differ fundamentally from standard critics. We show that their success is not explained by distributional RL: explicitly modeling return distributions often degrades performance. Instead, we argue that flow-matching Q-functions are effective because they couple a learned velocity field with an integration procedure that is used both during training and to read out Q-values at inference time. This coupling enables robust value prediction through \emph{test-time recovery} from imperfect intermediate estimates where errors dampen out as more integration steps are performed. This mechanism is absent in monolithic critics. Beyond test-time recovery, training with the integration procedure induces more \emph{plastic} representations, allowing critics to represent non-stationary future TD targets without overwriting previous features. We formalize these effects and validate them empirically, showing that flow-matching critics outperform monolithic critics by over $2\times$ in performance and achieve 5–$10\times$ higher sample efficiency in high-UTD regimes.

Long Live The Balance: Information Bottleneck Driven Tree-based Policy Optimization
Hao Jiang, Shurui Li, Tianpeng Bu, Bowen Xu, Xin Liu, Qihua Chen, hongtao duan, lulu hu, Bin Yang, Minying Zhang
Recent advances in online reinforcement learning (RL) for large language models (LLMs) have demonstrated promising performance in complex reasoning tasks. However, they often exhibit an imbalanced exploration–exploitation trade-off, resulting in unstable optimization and sub-optimal performance. We introduce IB-Score, a novel metric grounded in Information Bottleneck (IB) theory that evaluates policy’s exploration-exploitation balance by quantifying the trade-off between step-level reasoning diversity and mutual information shared with the correct answer. Analysis based on IB-Score shows that popular online RL approaches (e.g., GRPO) with common regularization methods fail to consistently maintain balance during training with suboptimal results. To address this, we propose Information Bottleneck-driven Tree-based Policy Optimization (IB-TPO), a principled framework that formulates IB-Score as a fine-grained optimization objective and utilizes a novel IB-guided tree sampling strategy that not only improves the efficiency of online sampling with 50\% more trajectories under same token budget, but also reuses the tree structure for effective IB-Score Monte Carlo estimation. Extensive experiments across standard benchmarks show that our method significantly outperforms GRPO baseline by 2.9% to 3.6% and also outperforms other state-of-the-art online RL approaches.

Q-DiT4SR: Exploration of Detail-Preserving Diffusion Transformer Quantization f

or Real-World Image Super-Resolution
Xun Zhang, Kaicheng Yang, Hongliang Lu, Haotong Qin, Yong Guo, Yulun Zhang
Recently, Diffusion Transformers (DiTs) have emerged in Real-World Image Super-Resolution (Real-ISR) to generate high-quality textures, yet their heavy inference burden hinders real-world deployment. While Post-Training Quantization (PTQ) is a promising solution for acceleration, existing methods in super-resolution mostly focus on U-Net architectures, whereas generic DiT quantization is typically designed for text-to-image tasks. Directly applying these methods to DiT-based super-resolution models leads to severe degradation of local textures. Therefore, we propose **Q-DiT4SR**, the first PTQ framework specifically tailored for DiT-based Real-ISR. We propose **H-SVD**, a hierarchical SVD that integrates a global low-rank branch with a local block-wise rank-1 branch under a matched parameter budget. We further propose **V**ariance-**a**ware **S**patio-**T**emporal **M**ixed **P**recision: **VaSMP** allocates cross-layer weight bit-widths in a data-free manner based on rate-distortion theory, while **VaTMP** schedules intra-layer activation precision across diffusion timesteps via dynamic programming (DP) with minimal calibration. Experiments on multiple real-world datasets demonstrate that our Q-DiT4SR achieves SOTA performance under both **W4A6** and **W4A4** settings. Notably, the W4A4 quantization configuration reduces model size by **5.8**$\times$ and computational operations by **6.14**$\times$. Our code and models will be available at https://github.com/xunzhang1128/Q-DiT4SR.

Efficient Neural Controlled Differential Equations via Attentive Kernel Smoothing
Egor Serov, Ilya Kuleshov, Alexey Zaytsev
Neural Controlled Differential Equations (Neural CDEs) provide a powerful continuous-time framework for sequence modeling, yet the roughness of the driving control path often restricts their efficiency. Standard splines introduce high-frequency variations that force adaptive solvers to take excessively small steps, driving up the Number of Function Evaluations (NFE). We propose a novel approach to Neural CDE path construction that replaces exact interpolation with Kernel and Gaussian Process (GP) smoothing, enabling explicit control over trajectory regularity. To recover details lost during smoothing, we propose an attention-based Multi-View CDE (MV-CDE) and its convolutional extension (MVC-CDE), which employ learnable queries to inform path reconstruction. This framework allows the model to distribute representational capacity across multiple trajectories, each capturing distinct temporal patterns. Empirical results demonstrate that our method, MVC-CDE with GP, achieves state-of-the-art accuracy while significantly reducing NFEs and total inference time compared to spline-based baselines.

Hyperbolic Multimodal Continual Learning
Jiahong Liu, Ming Shen, Xiaohao Liu, Rex Ying, Menglin Yang, Tat-Seng Chua, Irwin King
Hyperbolic geometry has recently emerged as a powerful representation space for multimodal learning, as it naturally captures hierarchical semantic structure across modalities. Despite this progress, how such representations behave under continual learning poses fundamentally different challenges that remain underexplored. This work provides a geometric perspective on this problem and establishes a theoretical foundation for representation preservation in hyperbolic space, showing that preventing forgetting requires cross-modal invariance under a shared hyperbolic isometry. We further show that forgetting in hyperbolic continual learning involves both semantic relation drift and hierarchy-related distortion, motivating preservation of both cross-modal relational structure and hierarchical geometry. Guided by these insights, a principled continual learning framework is derived that preserves essential geometric structure while allowing effective adaptation to new tasks. Experiments on continual multimodal benchmarks corroborate the effectiveness of the proposed approach.

Cardio-mmFlow: A Gaussian-Prior-Free Physics-Informed Flow Matching Framework for Electrocardiogram to mmWave Radar Synthesis

Ziyang LIU, Ruiqiang Xiao, Chang Huang, KIEREN YU, Siyuan HE, Kaishun Wu
Continuous ECG monitoring is clinically valuable, but scaling it beyond electrodes to comfortable long-term use motivates contactless mmWave sensing. In practice, mmWave-to-ECG reconstruction is severely constrained by the scarcity of high-quality synchronized recordings.
Therefore, we propose \textbf{Cardio-mmFlow}, a Gaussian-prior-free physics-informed flow matching framework that synthesizes mmWave radar signals from clinical ECG.
It learns a direct transport trajectory between the latent manifolds of ECG and radar.
Considering subject-dependent propagation differences, we incorporate a simplified mass--spring--damper inspired modulation and inject it into the flow dynamics via feature-wise linear modulation for personalization.
Extensive experiments show that our system generates high fidelity radar data in both signal and latent domains. It significantly improves zero-shot downstream mmWave to ECG task, and enable Atrial Fibrillation classification with synthetic data.
Further analyses evaluate the model interpretability.

Proxy Compression for Language Modeling
Lin Zheng, Xinyu Li, Qian Liu, Xiachong Feng, Lingpeng Kong
Modern language models are trained almost exclusively on token sequences produced by a fixed tokenizer, an external lossless compressor often over UTF■8 byte sequences, thereby coupling the model to that compressor.
This work introduces proxy compression, an alternative training scheme that preserves the efficiency benefits of compressed inputs while providing an end-to-end, raw-byte interface at inference time.
During training, one language model is jointly trained on raw byte sequences and compressed views generated by external compressors; through the process, the model learns to internally align compressed sequences and raw bytes. This alignment enables strong transfer between the two formats, even when training predominantly on compressed inputs which are discarded at inference.
Extensive experiments on code language modeling demonstrate that proxy compression substantially improves training efficiency and significantly outperforms pure byte-level baselines given fixed compute budgets.
As model scale increases, these gains become more pronounced, and proxy-trained models eventually match or rival tokenizer approaches, all while operating solely on raw bytes and retaining the inherent robustness of byte-level modeling.

MRPO: Magnitude-Regularized Policy Optimization via L1 Constraints
Wei Han, Yuanxing Liu, Mingda Li, Ruiyu Xiao, Weinan Zhang, Ting Liu
Reinforcement learning (RL) for large language models (LLMs) relies on imperfect reward supervision, necessitating constraints on policy updates to prevent overfitting.
Nevertheless, the widely adopted KL constraint over-penalizes actions with low reference probabilities and lacks the sparsity to discard marginal policy shifts.
In contrast, the L1-norm offers a distinct mechanism that is more tolerant of low-probability actions yet strictly suppresses minor probability perturbations.
Motivated by this, we propose Magnitude-Regularized Policy Optimization (MRPO), which enforces an L1-norm constraint on policy updates.
We demonstrate that MRPO permits substantial probability boosts for low-probability actions and induces sparse updates, ensuring invariance to noise that preserves the top-ranking order.
Furthermore, MRPO admits a TRPO-style monotonic improvement bound under standard regularity assumptions and achieves a tighter approach to optimality than KL-based methods in single-step scenarios.
Empirically, MRPO delivers exceptional results across diverse scenarios, notably doubling the performance gains of GRPO in preference alignment, outperforming DAPO in mathematical reasoning, and surpassing DPO in offline settings using only binary rewards.

HoloFair: Unified T2I Fairness Evaluation and Fair-GRPO Debiasing
Ruyi Chen, Lu Zhou, Xiaogang Xu, Chiyu Zhang, Jiafei Wu, Liming Fang
Text-to-Image (T2I) models have made significant strides in visual realism and semantic consistency, yet they often perpetuate and amplify societal biases. Existing evaluation methods typically address only single-dimensional biases, lacking perspectives to uncover model biases at social-related deeper semantic levels. We introduce HoloFair, a comprehensive benchmark framework for multidimensional demographic bias analysis. Built upon our large-scale fairness-oriented dataset and the SpaFreq (Spatial-Frequency) attribute classifier, this framework proposes the Multi-attribute, Group-wise Bias Index (MGBI) metric, designed to assess both intrinsic diversity and conditional biases. Beyond evaluation, we further introduce Fair-GRPO, a reinforcement-learning-based debiasing method that alters the distribution of generative models through a designed multi-objective reward function. E.g., experiments on the SD3.5-Medium model demonstrate that Fair-GRPO significantly improves multidimensional fairness while maintaining high image quality. We also analyze potential reward hacking phenomena and provide corresponding mitigation strategies.
****
Multimodal Meta-Verifier with Explicit Structured Recalibration
Xinchen Zhang, Bowei Liu, Jiale Liu, Chufan Shi, Yizhen Zhang, Junhong Liu, Youliang Zhang, Zhiheng Li, Yujiu Yang, Ling Yang
Visual outcomes are increasingly central to multimodal large language models, making reliable and fine-grained verification essential for scaling generalist foundation models. In this work, we investigate ***multimodal meta-verification***, which leverages verifier-generated rationales rather than decision-only signals, and explore how to effectively incorporate meta-verification feedback into multimodal verifier training. We identify two key findings. First, symbolic verifier outputs (e.g., bounding boxes) outperform textual explanations as meta-verification rationales, enabling efficient rule-based reinforcement learning rewards while avoiding reliance on model-based rewards from auxiliary judge models. Second, decoupling reinforcement learning objectives for binary judgment and meta-verification substantially outperforms joint reward optimization, due to intrinsic differences in output structure and learning dynamics. Based on these insights, we train **OmniVerifier-M1**, a generalist visual verifier leveraging symbolic meta-verification and decoupled reinforcement learning. OmniVerifier-M1 provides robust verification and fine-grained error localization, and further enables **M1-TTS**, a verifier-driven agentic generation system achieving dynamic region-level self-correction. This approach paves the way for more reliable, interpretable, and fine-grained multimodal verification, supporting safer and more controllable foundation model deployment.

Fantastic Reasoning Behaviors and Where to Find Them: Unsupervised Discovery of the Reasoning Process
Zhenyu Zhang, Shujian Zhang, John Wheatley Lambert, Wenxuan Zhou, Zhangyang Wang, Mingqing Chen, Andrew Hard, Rajiv Mathews, Lun Wang
Despite the growing reasoning capabilities of recent large language models (LLMs), their internal mechanisms during the reasoning process remain underexplored. Prior approaches often rely on human-defined concepts (e.g., overthinking, reflection) at the word level to analyze reasoning in a supervised manner. However, such methods are limited, as it is infeasible to capture the full spectrum of potential reasoning behaviors, many of which are difficult to define in token space. In this work, we propose an unsupervised framework (namely, RISE: Reasoning behavior Interpretability via Sparse auto-Encoder) for discovering reasoning vectors, which we define as directions in the activation space that encode distinct reasoning behaviors. By segmenting chain-of-thought traces into sentence-level 'steps' and training sparse auto-encoders (SAEs) on step-level activations, we uncover disentangled features corresponding to interpretable behaviors such as reflection and backtracking. Visualization and clustering analyses show that these behaviors occupy separable regions in the decoder column space. Moreover, targete

d interventions on SAE-derived vectors can controllably amplify or suppress spec
ific reasoning behaviors, altering inference trajectories without retraining. Be
yond behavior-specific disentanglement, SAEs capture structural properties such
as response length, revealing clusters of long versus short reasoning traces. Mo
re interestingly, SAEs enable the discovery of novel behaviors beyond human supe
rvision. We demonstrate the ability to control response confidence by identifyin
g confidence-related vectors in the SAE decoder space. These findings underscore
the potential of unsupervised latent discovery for both interpreting and contro
llably steering reasoning in LLMs.

Let Language Constrain Geometry: Vision–Language Models as Semantic and Spatial Critics for 3D Generation

Weimin Bai, Yubo Li, Weijian Luo, Zeqiang Lai, Yequan Wang, Wenzheng Chen, He Su
n

Text-to-3D generation has advanced rapidly, yet state-of-the-art models, encompa
ssing both optimization-based and feed-forward architectures, still face two fun
damental limitations. First, they struggle with coarse semantic alignment, often
failing to capture fine-grained prompt details. Second, they lack robust 3D spa
tial understanding, leading to geometric inconsistencies and catastrophic failur
es in part assembly and spatial relationships. To address these challenges, we p
ropose VLM3D, a general framework that repurposes large vision-language models (
VLMs) as powerful, differentiable {semantic and spatial critics}. Our core contr
ibution is a {dual-query critic signal} derived from the VLM's "Yes/No" log-odds
, which assesses both semantic fidelity and geometric coherence. We demonstrate
the generality of this guidance signal across two distinct paradigms: (1) As a r
eward objective for optimization-based pipelines, VLM3D significantly outperform
s existing methods on standard benchmarks. (2) As a test-time guidance module fo
r feed-forward pipelines, it actively steers the iterative sampling process of S
OTA native 3D models to correct severe spatial errors. VLM3D establishes a princ
ipled and generalizable path to inject the VLM's rich, language-grounded underst
anding of both semantics and space into diverse 3D generative pipelines.

LECTOR: Joint Learning of Scientific Reasoning Graphs and Introduction Generatio
n

Jiabei Xiao, Yizhou Wang, Chen Tang, Pengze Li, Wanli Ouyang, SHIXIANG TANG

AI Scientists have shown promising progress across multiple stages of the resear
ch pipeline, among which automatic scientific paper writing remains a formidable
challenge. The Introduction writing is especially challenging, which demands no
t only linguistic fluency, but logical soundness and verifiable faithfulness. Mo
st AI-assisted methods treat the task as text generation instead of reasoning an
d structuring, leading to severe drawbacks, *e.g.*, hallucinating citations. To
address this, we first formulate the Content-Conditional Introduction Generation
(CCIG) task, which requires grounding the Introduction in the paper's core evid
ence. We then propose **LECTOR**, a novel **Logic-Expression Co-Reinforcement Le
arning** framework that can strictly follow the scientist's logic, add high-qual
ity citations and keep structured expressions. LECTOR first constructs a logic-r
easoning graph from the paper's main body to serve as a verifiable logical bluep
rint. Subsequently, it employs a Logic-Expression Co-Rewarding mechanism to join
tly optimize for both the graph's structural fidelity and the final narrative's
quality. We conduct a dataset from *Nature Communications* papers to assess our
method. Extensive experiments show consistent improvements in both logic fidelit
y and Introduction generation quality metrics, *e.g.*, Graph Quality **(+26.7%)*
*, Citation Quality **(+8.6%)**, and Paper Consistency **(+3.3%)**.
Code and data are available at: https://github.com/Xiao-Youth/LECTOR

Identifying Latent Concepts and Structures for Generalized Category Discovery

Boyang Dai, Chaoqi Chen, Yizhou Yu

Generalized Category Discovery (GCD) aims to recognize known classes while auton
omously discovering novel ones in open-world settings. However, current approach
es primarily focus on designing clustering objectives, often overlooking a criti

cal bottleneck: standard vision backbones yield high-rank, entangled token representations that are ill-suited for unsupervised discovery of latent concepts and structures. In this paper, we propose Compositional Primitive Fields (CPF-GCD), a novel representation learning framework that reshapes the feature space to make such latent structure identifiable by enforcing a low-rank compositional organization. Our core hypothesis is that all categories, whether known or novel, can be expressed as compositions and spatial arrangements of a finite set of learnable visual primitives that capture reusable concepts. CPF instantiates this geometric constraint via a spatial field mechanism. Inserted between the backbone and the head, it rewrites noisy patch tokens through low-rank primitive mixtures, effectively decomposing images into reusable atomic parts and their spatial layouts. By explicitly modeling the spatial distribution of primitives, CPF enables novel categories to emerge naturally as new activation patterns over a shared vocabulary. This shifts the focus of representation from merely partitioning global embeddings to constructing a structured and separable primitive field. Extensive experiments demonstrate that CPF serves as a generic, plug-and-play module that consistently boosts performance across diverse GCD baselines, validating that identifying and leveraging low-rank compositional structure is a crucial inductive bias for open-world recognition.

Text-Driven Fusion for Infrared and Visible Images: Achieving Image Scene Adaptation on Hyperbolic Space

Huan Kang, Hui Li, Tianyang Xu, Tao Zhou, Xiaojun Wu, Josef Kittler

Infrared and visible image fusion aims to integrate complementary modalities, while existing Euclidean methods impose rigid distance metrics that distort multi-modal interactions and parent-to-child semantic hierarchies. To overcome these limitations, we introduce a text-driven fusion framework empowered by hyperbolic manifold learning. During training, BLIP-extracted text prompts serve as topological anchors within the hyperbolic space, guiding vision-attribute alignment through hyperbolic embeddings that naturally accommodate varying semantic granularities. By exploiting the exponential volume growth dictated by the Poincaré ball's negative curvature, this approach seamlessly embeds hierarchical trees to encode coarse-to-fine semantics without metric saturation, while the vast peripheral space prevents texture distortion during cross-modal fusion. At inference, the fusion process autonomously adapts to input content using the learned text-attribute priors, completely eliminating the need for textual input. Experimental results show our method outperforms state-of-the-art approaches on benchmark datasets, with code available at https://github.com/Shaoyun2023/TEDFusion.

A Tight Theory of Error Feedback Algorithms in Distributed Optimization

Daniel Berg Thomsen, Adrien Taylor, Aymeric Dieuleveut

Communication costs are a major bottleneck in distributed learning and first-order optimization. A common approach to alleviate this issue is to compress the gradient information exchanged between agents. However, such compression typically degrades the convergence guarantees of gradient-based methods. Error feedback mechanisms provide a simple and computationally cheap remedy for this issue, but numerous variants have been proposed, and their relative performance remains poorly understood. This paper provides tight convergence analyses for two of the main error-feedback algorithms from the literature, the classic Error Feedback method (EF) and Error Feedback 21 (EF21), by identifying optimal step-size choices and constructing optimal Lyapunov functions tailored to each method. The results hold independently of the number of agents and recover the known best guarantees possible in the single-agent regime.

Shapley Regularized Neural Granger Causality

Maolin Yang, Zhoufan Zhu, Yuanhe Tian, Kun Gao, MUYI LI

Identifying temporal causal structure is fundamental to understanding complex systems. Neural Granger causality has emerged as a powerful paradigm for this task, leveraging the expressiveness of neural networks to model intricate nonlinear dynamics. Although complex architectures excel at predictive modeling, existing

methods typically rely on simple local measures for causal discovery, which extr act only partial information from the learned model and may miss global dependen cies. To address this issue, we reformulate Granger causality as a feature attri bution problem and propose the Information-Theoretic Shapley value (Info-Shap) t o measure global feature importance. We first establish the theoretical equivale nce between zero Info-Shap and Granger non-causality. On top of this, we constru ct two novel regularizers to suppress spurious relationships and mitigate overfi tting. These regularizers are model-agnostic and can be seamlessly integrated in to the training of any differentiable neural network. Through extensive experime nts on synthetic and realistic datasets, we demonstrate that our method robustly recovers the underlying causal relationships, providing a flexible tool for cau sal discovery in high-dimensional nonlinear time series.

REAL: Regression-Aware Reinforcement Learning for LLM-as-a-Judge

Yasi Zhang, Tianyu Chen, Mingyuan Zhou, Oscar Leong, Ying Nian Wu, Michal Lukasi k

Large language models (LLMs) are increasingly deployed as automated evaluators t hat assign numeric scores to model outputs, a paradigm known as LLM-as-a-Judge. However, standard Reinforcement Learning (RL) methods typically rely on binary r ewards (e.g., 0-1 accuracy), thereby ignoring the ordinal structure inherent in regression tasks; for instance, they fail to recognize that predicting 4 is sign ificantly better than predicting 1 when the ground truth is 5. Conversely, exist ing regression-aware approaches are often confined to Supervised Fine-Tuning (SF T), limiting their ability to explore optimal reasoning paths. To bridge this ga p, we propose REAL (Regression-Aware Reinforcement Learning), a principled RL fr amework designed to optimize regression rewards, and also proven to be optimal f or correlation metrics. A key technical challenge is that the regression objecti ve is explicitly policy-dependent, thus invalidating standard policy gradient me thods. To address this, we employ the generalized policy gradient estimator, whi ch naturally decomposes optimization into two complementary components: (1) expl oration over Chain-of-Thought (CoT) trajectory, and (2) regression-aware predict ion refinement of the final score. Extensive experiments across model scales (8B to 32B) demonstrate that REAL consistently outperforms both regression-aware SF T baselines and standard RL methods, exhibiting significantly better generalizat ion on out-of-domain benchmarks. On Qwen3-32B specifically, we achieve gains of +8.40 Pearson and +7.20 Spearman correlation over the SFT baseline, and +18.30/+ 11.20 over the base model. These findings highlight the critical value of integr ating regression objectives into RL exploration for accurate LLM evaluation.

LoBCD-GW: A Fast and Data-Dependent Algorithm for Computing Gromov-Wasserstein D istance via Localized Block Coordinate Descent

Jingni Song, Jiawei Huang, Kangke Cheng, Bangxian Han, Hu Ding

The Gromov-Wasserstein (GW) distance provides a powerful framework for aligning structured data by comparing the intrinsic geometries of metric measure spaces, and has become a fundamental tool in machine learning. Most existing methods lev erage entropy regularization to reduce the computational complexity to $\boldsym bol{\mathrm{O}}(n^3)$, where n is the number of samples. However, this cubic t ime complexity remains a major bottleneck in large-scale applications, severely limiting the scalability. To address this challenge, we propose LoBCD-GW, an eff icient GW optimization algorithm. Specifically, we reveal the data-dependent spa rsity of large-magnitude updates to the coupling matrix and introduce a localize d block coordinate selection strategy. This confines the optimization to a "sele cted set" of size r (which is a parameter that depends on the given data set, and usually is much less than n), thereby reducing the complexity to $\boldsym bol{\mathrm{O}}(r^3)$. In addition, unlike prior acceleration methods often base d on constraint relaxation, our method can guarantee the strict feasibility thro ugh a novel "marginal compensation mechanism" to synchronize local mass redistri bution with global constraints. Finally, we conduct a set of experiments on vari ous datasets, and the results demonstrate that our method achieves a $5.8\times$ speedup on large-scale graph alignment benchmarks, while maintaining state-of-t

he-art accuracy.

Optimizing Visual Generative Models via Distribution-wise Rewards
Ruihang Li, Mengde Xu, Shuyang Gu, Leigang Qu, Fuli Feng, Han Hu, Wenjie Wang
Conventional reinforcement learning strategies for visual generation typically e mploy sample-wise reward functions, yet this practice frequently results in rewa rd hacking that degrades image diversity and introduces visual anomalies. To add ress these limitations, we present a novel framework that finetunes generative m odels using distribution-wise rewards, ensuring better alignment with real-world data distributions. Unlike rewards that evaluate samples individually, distribu tion-wise reward accounts for the data distribution of the samples, mitigating t he mode collapse problem that occurs when all samples optimize towards the same direction independently. To overcome the prohibitive computational cost of estim ating these rewards, we introduce a subset-replace strategy that efficiently pro vides reward signals by updating only a small subset of a generated reference se t. Additionally, we apply RL to optimize post-hoc model merging coefficients, po tentially mitigating the train-inference inconsistency caused by introducing sto chastic differential equation (SDE) in regular RL practices. Extensive experimen ts show our approach significantly improves FID-50K across various base models, from 8.30 to 5.77 for SiT and from 3.74 to 3.52 for EDM2. Qualitative evaluation also confirms that our method enhances perceptual quality while preserving samp le diversity.
****
LaTtE-Flow: Layerwise Timestep-Expert Flow-based Transformer
Ying Shen, Zhiyang Xu, Jiuhai Chen, Shizhe Diao, Jiaxin Zhang, Yuguang Yao, Joy Rimchala, Ismini Lourentzou, Lifu Huang
Recent advances in multimodal foundation models unifying image understanding and generation have opened exciting avenues for tackling a wide range of vision-lan guage tasks within a single framework. Despite progress, existing unified models often rely on extensive pretraining and suffer from slow generation speeds, lim iting their practical deployment in real-time and resource-constrained settings. In this work, we introduce Layerwise Timestep-Expert Flow-based Transformer (La TtE-Flow), a novel architecture that improves the efficiency of diffusion/flow-b ased Transformers within the unified model setting. LaTtE-Flow builds upon power ful pre-trained Vision-Language Models (VLMs) to inherit strong multimodal under standing capabilities, and extends them with a novel Layer-wise Timestep Experts flow-based architecture for efficient image generation. LaTtE-Flow distributes the flow-matching process across specialized groups of Transformer layers, each responsible for a distinct subset of timesteps. This design significantly improv es sampling efficiency
by activating only a small subset of layers at each sampling timestep. To furthe r enhance performance, we propose a Timestep-Conditioned Residual Attention mech anism for efficient information reuse across layers. Experiments demonstrate tha t LaTtE-Flow achieves strong performance on multimodal understanding tasks, whil e achieving competitive image generation quality with around 6× faster inference speed compared to recent unified multimodal models.

Backward Oversmoothing: why is it hard to train deep Graph Neural Networks?
Nicolas Keriven
Oversmoothing has long been identified as a major limitation of Graph Neural Net works (GNNs): input node features are smoothed at each layer and converge to a c onstant non-informative representation, *if the weights of the GNN are sufficien tly bounded*. This assumption is crucial: if, on the contrary, the weights are s ufficiently large, then oversmoothing may be compensated. Theoretically, GNN cou ld thus *learn* to not oversmooth. However, this does not really happen in pract ice, which prompts us to examine oversmoothing from an *optimization* point of v iew.

In this paper, we analyze *backward oversmoothing*, that is, the notion that bac kpropagated errors are also subject to oversmoothing from output to input. With

non-linearities, we outline the key role of the *interaction* between forward an
d backward smoothing. Moreover, we show that, due to backward oversmoothing, GNN
s provably exhibit many *spurious stationary points*: as soon as the *last* laye
r is trained, the *whole* GNN is at a stationary point. As a result, we can exhi
bit regions where gradients are near-zero while the loss stays high.
Additionally, we prove that this is *specific* to GNNs, and does not necessarily
 hold for Multi-Layer Perceptrons.
This paper is a step toward a more complete comprehension of the optimization la
ndscape of GNNs.

The Safety-Aware Denoiser for Text Diffusion Models
Amman Yusuf, Zhejun Jiang, Mijung Park
Recent work on text diffusion models offers a promising alternative to autoregre
ssive generation, but controlling their safety remains underexplored. Existing s
afety approaches are geared toward autoregressive models and typically rely on p
ost-hoc filtering or inference-time interventions. These are inadequate for effe
ctively addressing safety risks in text diffusion models. We propose the *Safety
-Aware Denoiser (SAD)*, a safety-guidance framework in text diffusion models. Th
e SAD modifies the iterative denoising process such that the text sample at the
final denoising step is steered toward *provably* safe regions of the text space
. This inference-time method can integrate safety constraints into the denoiser,
 avoiding computationally expensive retraining of the underlying diffusion model
 and enabling flexible, lightweight safety guidance. We evaluate the safety of t
he generated text using the SAD, with respect to hazard taxonomy, memorization,
and jailbreak. Experimental results show that SAD substantially reduces unsafe g
enerations while preserving generation quality, diversity, and fluency, outperfo
rming existing methods. These results demonstrate that our safety guidance durin
g denoising provides an effective and scalable mechanism for enforcing safety in
 text diffusion models.

HGMem: Hypergraph-based Working Memory to Improve Multi-step RAG for Long-Contex
t Complex Relational Modeling
Chulun Zhou, Chunkang Zhang, Guoxin Yu, Fandong Meng, Jie Zhou, Wai Lam, Mo Yu
Multi-step retrieval-augmented generation (RAG) has become a widely adopted stra
tegy for enhancing large language models (LLMs) on tasks that demand global comp
rehension and intensive reasoning. Although many RAG systems incorporate a worki
ng memory to consolidate information, existing designs primarily function as a p
assive storage for isolated facts. This static nature overlooks crucial high-ord
er correlations among primitive facts, thereby limiting models' capacity for mul
ti-step reasoning and resulting in fragmented reasoning and weak global sense-ma
king within extended contexts. We introduce HGMem, a hypergraph-based working me
mory system, extending the concept of memory beyond simple storage into a dynami
c, expressive structure for complex reasoning and global understanding. In our a
pproach, memory is represented as a hypergraph where hyperedges correspond to di
stinct memory units, enabling the progressive formation of high-order interactio
ns within memory. This mechanism connects facts and thoughts around the focal pr
oblem, evolving the memory into an integrated and situated knowledge structure t
hat provides strong propositions for deeper reasoning. We evaluate HGMem on seve
ral challenging global sense-making benchmarks. Extensive experiments and in-dep
th analyses demonstrate that our method consistently improves multi-step RAG and
 substantially outperforms strong baseline systems across diverse datasets.

Tournament Style RL: Stabilizing Policy Optimization on Non Verifiable Problems
Gurusha Juneja, Shubham Milind Phal, Jennifer She, Lisa Wang, Dorsa Sadigh, Anca
 Dragan, William Yang Wang
Many real-world tasks are non-verifiable—there is no objective ground truth, and
 quality must be judged subjectively—making reward design for RL difficult. Exis
ting approaches based on scalar rubric scores or single comparisons are often no
isy, poorly calibrated, or provide sparse learning signals.
We introduce Tournament Style RL (TSRL), which constructs rewards from rubric-gu

ided pairwise judgments against a fixed set of anchor responses, using win-rate as the reward for policy optimization. This aggregation of comparisons against anchor responses yields a signal that is more robust to the judge noise by stabilizing the reference frame, reducing the variance in reward.
We test across four non-verifiable tasks and two backbone LLMs, and find that TSRL improves average win-rate by $+43.8$ points over the base model and $+22.8$ points over the strongest baseline.
TSRL scales with the number of anchors, remains robust under weak or partially corrupted judges, the results are supported by blinded human preference studies.

Who Evaluates AI's Social Impacts? Mapping Coverage and Gaps in First and Third Party Evaluations
Anka Reuel, Avijit Ghosh, Jenny Chim, Andrew Tran, Yanan Long, Jennifer Mickel, Usman Gohar, Srishti Yadav, Pawan Sasanka Ammanamanchi, Mowafak Allaham, Hossein A. Rahmani, Mubashara Akhtar, Felix Friedrich, Robert Scholz, Michael Alexander Riegler, Jan Batzner, Eliya Habba, Arushi Saxena, Anastassia Kornilova, Kevin Wei, Prajna Soni, Yohan Mathew, Kevin Klyman, Jeba Sania, Subramanyam Sahoo, Olivia Beyer Bruvik, Pouya Sadeghi, Sujata Goswami, Angelina Wang, Yacine Jernite, Zeerak Talat, Stella Biderman, Mykel Kochenderfer, Sanmi Koyejo, Irene Solaiman
Foundation models are increasingly central to high-stakes AI systems, and governance frameworks now depend on evaluations to assess their risks and capabilities. Although general capability evaluations are widespread, social impact assessments covering bias, fairness, privacy, environmental costs, and labor remain uneven. To characterize this landscape, we conduct the first comprehensive analysis of social impact evaluation reporting, examining 186 first-party release reports and 248 third-party evaluation sources, supplemented by developer interviews. We find a stark division of labor: first-party reporting is sparse, often superficial, and declining in areas like environmental impact and bias, while third-party evaluators provide broader, more rigorous coverage of bias, harmful content, and performance disparities. However, only developers can authoritatively report on data provenance, content moderation labor, costs, and infrastructure, yet interviews reveal these disclosures are deprioritized unless tied to product adoption or compliance. Current practices leave major gaps in assessing societal impacts, underscoring the need for policies that mandate developer transparency, strengthen independent evaluation ecosystems, and create shared infrastructure for aggregating third-party evaluations.

Courtroom Analogy: New Perspective on Uncertainty-Aware Classification
Taeseong Yoon, Heeyoung Kim
Single-pass uncertainty quantification (UQ) methods for classification represent uncertainty by predicting a tractable distribution over the class probability vector. While existing approaches primarily focus on enhancing the expressiveness of this distribution, they often provide limited insight into how predictive uncertainty is structured and aggregated, resulting in weak interpretability. We introduce the *courtroom analogy*, which conceptualizes uncertainty-aware classification as a structured debate among class-specific advocates. Each advocate forms a probabilistic opinion, and a final verdict is reached by aggregating these opinions using input-dependent plausibility weights. In this framework, each advocate's opinion is modeled as a Dirichlet distribution whose concentration parameter is decomposed into shared evidence and class-specific advocacy. This yields a structured mixture of Dirichlet distributions with semantically interpretable parameters. To instantiate this formulation, we propose *Mixture of Dirichlet EXperts* (MoDEX), a single-pass neural architecture that predicts the courtroom parameters, enabling efficient and expressive UQ while explicitly modeling uncertainty aggregation. We demonstrate that MoDEX enjoys strong theoretical properties and achieves state-of-the-art UQ performance across diverse benchmarks, yielding interpretable uncertainty estimates with meaningful semantics.

Federated Variational Preference Alignment with Gumbel-Softmax Prior for Personalized User Preferences

Jabin Koo, Hoyoung Kim, Minwoo Jang, Jungseul Ok
Federated Learning (FL) offers a privacy-preserving pathway for aligning Large L anguage Models (LLMs); however, existing frameworks typically enforce a monolith ic reward model, inevitably averaging out inherently conflicting user preference s (e.g., helpfulness vs. harmlessness). While Variational Preference Learning (V PL) offers a pathway to personalization, adapting it to decentralized settings p resents a fundamental challenge: \textit{posterior collapse} driven by severe lo cal data scarcity and heterogeneity. In this paper, we propose Federated Variati onal Preference Alignment with Gumbel-Softmax Prior (FedVPA-GP), a framework des igned to disentangle diverse preferences without compromising privacy. To stabil ize variational inference, we introduce a Federated Mixture Prior that enables c lients to leverage the aggregate population distribution as a dynamic prior. Fur thermore, we incorporate an Orthogonal Loss that explicitly enforces the separat ion of preference prototypes in the latent space. Experiments on the HH-RLHF dat aset demonstrate that FedVPA-GP significantly outperforms monolithic baselines, successfully disentangling conflicting user intents and enabling dynamic prefere nce switching.

Bad Seeing or Bad Thinking? Rewarding Perception for Multimodal Reasoning
Haozhe Wang, Qixin Xu, Changpeng Wang, Taofeng Xue, Chong Peng, Wenhu Chen, Fang zhen Lin
Achieving robust perception-reasoning synergy is a central goal for advanced Vis ion-Language Models (VLMs). Recent advancements have pursued this goal via archi tectural designs or agentic workflows. However, these approaches are often limit ed by static textual reasoning or complicated by the significant compute and eng ineering burden of external agentic complexity. Worse, this heavy investment doe s not yield proportional gains, often witnessing a "seesaw effect" on perception and reasoning. This motivates a fundamental rethinking of the true bottleneck. In this paper, we argue that the root cause of this trade-off is an ambiguity in modality credit assignment: when a VLM fails, is it due to flawed perception (" bad seeing") or flawed logic ("bad thinking")?
To resolve this, we introduce a reinforcement learning framework that improves p erception-reasoning synergy by reliably rewarding the perception fidelity. We ex plicitly decompose the generation process into interleaved perception and reason ing steps. This decoupling enables targeted supervision on perception. Crucially , we introduce Perception Verification (PV), leveraging a "blindfolded reasoning " proxy to reward perceptual fidelity independently of reasoning outcomes. Furth ermore, to scale training across free-form VL tasks, we propose Structured Verba l Verification, which replaces high-variance LLM judging with structured algorit hmic execution. These techniques are integrated into a Modality-Aware Credit Ass ignment (MoCA) mechanism, which routes rewards to the specific source of error - - either bad seeing or bad thinking -- enabling a single VLM to achieve simultan eous performance gains across a wide task spectrum.

Neural Dispersion on Graphs
Ryien Hosseini, Pouya Mahdi Gholami, Filippo Simini, Venkatram Vishwanath, Rebec ca Willett, Henry Hoffmann
We study the problem of generating structurally diverse graphs on N unlabeled vertices. Given a space of such graphs S_N, metric d, and target cardinality k, the objective is to construct a set $\mathcal{G} \subset S_N$ that maximiz es pairwise diversity under d. While neural generative models may appear appea ling as a solution, standard approaches require samples from a target distributi on that such _dispersion_ problems lack. Thus, prior work relies primarily on co mbinatorial or iterative search. We instead treat diversity as an explicit optim ization objective, an approach we term _Neural Graph Dispersion_. An ensemble of generators is optimized under a repulsive potential, producing diverse graphs a long optimization trajectories as they disperse over (S_N,d), and avoiding dis tribution fitting and per-metric retraining entirely. Experiments show our metho d produces high diversity while scaling N and k an order of magnitude beyond pri or work. Our source code is available at https://github.com/ryienh/neural-graph-

dispersion.

An Efficient Joint Learning Approach for Item Response Theory
Tanish Agarwal, Kaustubh Shivshankar Shejole, Arpit Agarwal
Item response theory (IRT) is widely used in areas such as recommender systems, education, psychology, and other fields. A popular model for IRT is the Rasch model. Under this model, if a user with ability θ performs a task with difficulty β then its label $X \sim \text{Bernoulli} (1 / (1 + \exp(-(\theta - \beta)))$. Existing joint maximum likelihood estimation approaches for this problem do not perform well on small datasets and also lack theoretical guarantees. Recently, Nguyen and Zhang proposed a two step approach: (1) spectral method for estimation of task parameters, (2) likelihood optimization for estimation of user parameters. While this approach is theoretically sound, it is not computationally efficient. In this work, we propose an EM-based algorithm for joint estimation of item and user parameters by introducing Pólya-Gamma latent variables, which simplify the logistic log-likelihood. We show that our algorithm is both theoretically sound and consistently outperforms existing methods on synthetic and real-world datasets.

Learning from Fine-Grained Visual Discrepancies: Mitigating Multimodal Hallucinations via In-Context Visual Contrastive Optimization
Haolin Deng, Xin Zou, Zhiwei Jin, Chen Chen, Haonan Lu, Xuming Hu
Multimodal hallucination remains a persistent challenge for Vision-Language Models (VLMs). Standard textual Direct Preference Optimization (DPO) often fails to mitigate it due to a lack of explicit visual supervision. While existing works introduce visual preference DPO by contrasting original images against negative ones, they suffer from a theoretically inconsistent objective caused by partition function mismatches and rely on coarse-grained negatives that could enable shortcut learning. In this work, we propose In-Context Visual Contrastive Optimization (IC-VCO). By placing contrastive images within a shared multi-image context, IC-VCO ensures a mathematically rigorous objective. We further introduce Visual Contrast Distillation (VCDist), an auxiliary reliability-gated regularizer that encourages consistency between multi-image contrastive training and single-image inference. Finally, we propose a contrastive sample editing strategy that generates hard negatives via precise semantic perturbations. Experiments on five benchmarks demonstrate IC-VCO's best overall performance and the effectiveness of our sample editing strategy. Code and data are available at https://github.com/OPPO-Mente-Lab/IC-VCO.

Unified Time Series Explanations via Amortized Optimization and Instance-level Multi-Expert Knowledge Distillation
Viet-Hung Tran, Zichi Zhang, Ngoc Phu Doan, Xuan Hoang Nguyen, Phi Hung Nguyen, Yimeng An, Peixin Li, Hans Vandierendonck, Ira Assent, Son Thai Mai
Deep neural networks (DNNs) achieve high accuracy on time series classification (TSC) but remain opaque, hindering deployment in sensitive domains.
Existing post-hoc TSC explanation methods rely on a single attribution perspective and incur high per-instance computational cost, limiting real-time use.
We propose XMA, a framework that unifies multiple post-hoc explainers at the instance level and amortizes the cost of explanation into a learned inference pass.
Instance-level Multi-Expert Knowledge Distillation (IMEKD) selects, per instance, the attribution map with the highest combined faithfulness and robustness score from a pool of XAI experts.
Objective-Regularized Amortized Optimization Explanation (ORAOE) trains an explainer DNN to reproduce this instance-best supervision while directly optimizing differentiable faithfulness and robustness objectives, letting the student refine beyond any individual teacher.
Faithfulness-Preserving Segmentation (FPS) converts point-wise maps into contiguous segments without changing their faithfulness score.
Across four synthetic datasets, MIT-ECG with cardiologist-verified ground truth, and 11 multivariate UEA benchmarks on three DNN architectures, XMA attains the

best AUPRC on all synthetic and MIT-ECG benchmarks among compared methods, and t
he highest faithfulness on 7 of 11 and robustness on 8 of 11 UEA datasets, while
 amortizing explanation into a lightweight learned explainer rather than relying
 on per-instance optimization.

Graph is a Natural Regularization: Revisiting Vector Quantization for Graph Repr
esentation Learning

Zian Zhai, Fan Li, Xingyu Tan, Xiaoyang Wang, Wenjie Zhang

Vector Quantization (VQ) has recently emerged as a promising approach for learni
ng compressed and discrete representations for graph-structured data. However, a
 fundamental challenge, i.e., codebook collapse, remains underexplored in the gr
aph domain, significantly limiting the expressiveness and generalization of grap
h tokens. In this paper, we present an empirical study and observe that codebook
 collapse consistently occurs when training VQ jointly with Graph Neural Network
s under graph reconstruction tasks, even with mitigation strategies proposed in
vision or language domains. Moreover, we provide a diagnosis of collapse from da
ta and optimization perspectives, showing that collapse is associated with graph
 data properties such as feature redundancy and connectivity density, and is fur
ther reinforced by the training dynamics of deterministic hard assignment. To ad
dress these issues, we propose RGVQ, a novel framework that integrates graph top
ology and feature similarity as explicit regularization signals to enhance codeb
ook utilization and promote token diversity. RGVQ introduces soft assignments vi
a Gumbel-Softmax reparameterization, ensuring that all codewords receive gradien
t updates. In addition, RGVQ incorporates a structure-aware contrastive regulari
zation to penalize assigning the same token to dissimilar node pairs. Extensive
experiments demonstrate that RGVQ substantially improves codebook utilization an
d consistently boosts the performance of state-of-the-art graph VQ backbones acr
oss multiple downstream tasks, enabling more expressive and transferable graph t
oken representations.

Strategic Navigation or Stochastic Search? How Agents and Humans Reason Over Doc
ument Collections

■ukasz Borchmann, Jordy Van Landeghem, Micha■ Turski, Shreyansh Padarha, Ryan Ot
hniel Kearns, Adam Mahdi, Niels Rogge, Clémentine Fourrier, Siwei Han, Huaxiu Ya
o, Artemis Llabrés, Yiming Xu, Dimosthenis Karatzas, Hao Zhang, Anupam Datta

Multimodal agents offer a promising path to automating complex document-intensiv
e workflows. Yet, a critical question remains: do these agents demonstrate genui
ne strategic reasoning, or merely stochastic trial-and-error search? To address
 this, we introduce MADQA, a benchmark of 2,250 human-authored questions grounde
d in 800 heterogeneous PDF documents. Guided by Classical Test Theory, we design
 it to maximize discriminative power across varying levels of agentic abilities.
 To evaluate agentic behavior, we introduce a novel protocol that measures the a
ccuracy-effort trade-off. Using this framework, we show that while the best agen
ts can match human searchers in raw accuracy, they succeed on largely different
questions and rely on brute-force search to compensate for weak strategic planni
ng. They fail to close the nearly 20\% gap to oracle performance, persisting in
unproductive loops. We release the dataset and evaluation harness to help facili
tate the transition from brute-force retrieval to calibrated, efficient reasonin
g.

Self-Guidance: Enhancing Neural Codecs via Decoder Manifold Alignment

Xiang Li, Yixuan Zhou, Jingran Xie, Zhiyong Wu, Hui Wang

Neural speech codecs based on Vector-Quantized VAEs (VQ-VAEs) are core audio tok
enizers for speech LLMs, yet their reconstruction fidelity is bottlenecked by qu
antization error. Modifying the quantizer or increasing model capacity are commo
n fixes, but they complicate downstream language modeling. Our core idea is to a
lign the decoder's internal feature manifolds when processing both the quantized
 tokens and their original continuous embeddings, using a lightweight feature-ma
pping loss. This requires minimal training overhead and no inference-time change
s. Applied to XCodec2, self-guidance improves all reconstruction metrics, achiev

ing state-of-the-art low-bitrate performance. Notably, it enables a 4× codebook reduction without fidelity loss, which downstream TTS experiments show significa ntly improves LLM-based synthesis by simplifying the token modeling space. Multi ple statistical observations and visualizations corroborate the enhanced interna l manifold alignment in the decoder. Extensive experiments confirm its generalit y across various inductive biases. Self-guidance thus establishes an efficient, broadly applicable method for high-fidelity neural audio coding.

Learning GUI Grounding with Spatial Reasoning from Visual Feedback
Yu Zhao, Wei-Ning Chen, Huseyin A Inan, Samuel Kessler, Lu Wang, Lukas Wutschitz , Fangkai Yang, Chaoyun Zhang, Pasquale Minervini, Saravan Rajmohan, Robert Sim
Graphical User Interface (GUI) grounding is commonly framed as a coordinate pred iction task – given a natural language instruction, generate on-screen coordinat es for actions such as clicks and keystrokes. However, recent Vision Language Mo dels (VLMs) often fail to predict accurate numeric coordinates when processing G UI images with high resolutions and complex layouts. To address this issue, we r eframe GUI grounding as an interactive search task, where the VLM generates acti ons to move a cursor in the GUI to locate UI elements. At each step, the model d etermines the target object, evaluates the spatial relations between the cursor and the target, and moves the cursor closer to the target conditioned on the mov ement history. In this interactive process, the rendered cursor provides visual feedback to help the model align its predictions with the corresponding on-scree n locations. We train our GUI grounding model, GUI-Cursor, using multi-step onli ne reinforcement learning with a dense trajectory-based reward function. Experim ental results demonstrate that GUI-Cursor surpasses strong baselines in GUI grou nding and agentic tasks, achieving superior performance with the same base model s while requiring less training data. Further analysis shows that GUI-Cursor lea rns to adaptively conduct more steps on more difficult examples, and it obtains better spatial reasoning capability on out-of-distribution domains.

AugServe: Adaptive Request Scheduling for Augmented Large Language Model Inferen ce Serving
Ying Wang, Zhen Jin, Zhenqian Chen, Jiexiong Xu, Wenhai Lin, Yiquan Chen, Wenzhi CHEN
Augmented large language models (LLMs) that invoke external calls are increasing ly prevalent in inference serving.
However, such augmentations pose significant challenges to inference efficiency under strict Service-Level Objectives (SLOs). Existing inference systems are agn ostic to the dynamic execution behaviors induced by external calls and rely on f ixed batch-level token budget, which leads to severe Head-of-Line (HoL) blocking and substantially reduced effective throughput.
We present AugServe, an efficient augmented LLM inference serving framework that mitigates request queuing latency and improves effective throughput under external-call-augmented workloads. AugServe integrates state-aware request sched uling with dynamic batch-level token budgets to adapt to heterogeneous requests and their dynamically changing execution states. Experimental results show that AugServe achieves 6.5$\times$ and 4.7$\times$ higher effective throughput than v LLM and INFERCEPT, respectively.
****
CauchyNet: Compact and Data-Efficient Learning using Holomorphic Activation Func tions
Hong-Kun Zhang, Xin Li, Sikun Yang, Zhihong Jeff Xia
CauchyNet is a compact complex-valued network whose hidden units form products o f shifted reciprocal features, motivated by Cauchy-type kernel representations. The design targets regression problems with sharp rational-like spikes and parti ally observed inputs, where standard real-valued networks often require large wi dth.
We prove that finite linear combinations of multivariate Cauchy kernels are dens e in $C(M)$ on compact $M\subset\mathbb R^N$, and that CauchyNet can realize the se kernel sums via its complex biases and output weights.

In experiments, CauchyNet reaches lower error on near-singular and gap-filling b
enchmarks, often with substantially fewer trainable parameters in our settings;
results on smooth and piecewise-affine targets are mixed and delineate the metho
d's intended regime.

One-Step Gradient Delay is Not a Barrier for Large-Scale Asynchronous Pipeline P
arallel LLM Pretraining
Philip Zmushko, Egor Petrov, Nursultan Abdullaev, Khrushchev Mikhail, Samuel Hor
váth
Modern large-scale LLM pretraining benefits from utilizing Pipeline Parallelism;
 however, synchronous implementations leave GPUs idle during pipeline bubbles, w
asting computational resources.
Asynchronous Pipeline Parallelism eliminates these bubbles, maximizing throughpu
t at the cost of gradient staleness.
Among asynchronous schedules, PipeDream-2BW is particularly appealing: unlike th
e original PipeDream schedule, it ensures a constant one-step gradient delay reg
ardless of pipeline depth.
However, its adoption remains limited due to the common belief that optimizing u
nder staleness is fundamentally unstable.
In this work, we challenge this assumption, demonstrating that degradation under
 one-step delay depends strongly on optimizer choice rather than being an intrin
sic limitation.
We provide the first comprehensive empirical analysis showing that while AdamW,
the predominant optimizer at the time when PipeDream-2BW was introduced, indeed
suffers from severe degradation, recent methods like Muon exhibit strong robustn
ess under a one-step delay.
We introduce an optimizer-agnostic Error Feedback-inspired correction to further
 mitigate delay effects.
We provide supporting theoretical analysis demonstrating convergence for Muon wi
th and without this correction.
Extensive evaluation on models up to 10B parameters confirms that our strategies
 bridge the performance gap with synchronous training, highlighting the practica
l potential of asynchronous pipeline parallelism at scale.
****
XYZFlow: Scaling Multidimensional Shortcut Flows for Efficient Generative Modeli
ng
Jinxiu Liu, Xuanming Liu, Kangfu Mei, Yandong Wen, Weiyang Liu
High-fidelity image generation faces a trade-off between speed and quality. Diff
usion models produce strong visuals but require costly iterative sampling. Exist
ing efficient methods mainly distill pretrained models into few-step samplers, a
 challenging process that depends heavily on teacher-model quality. In this pape
r, we introduce XYZFlow, a framework that rethinks efficient generation through
multidimensional scaling of flow matching. Unlike single-step mappings, XYZFlow
enhances expressivity by making probability paths more identifiable and learnabl
e through structured multidimensional conditioning. We view autoregressive model
ing as implicit flow straightening, where richer context reduces trajectory ambi
guity. XYZFlow realizes this idea through two orthogonal dimensions: temporal sc
aling, which uses non-Markovian conditioning on the full denoising history; and
spatial scaling, enabled by Next Shortcut Prediction, which sequentially generat
es patches using preceding patches' denoising trajectories as priors. Experiment
s show that XYZFlow achieves state-of-the-art performance, with 7.2-8.5x teacher
 speedups and competitive FID, while Next Shortcut Prediction delivers superior
quality-latency trade-offs over model scaling or step reduction.
****
Tracing the Persona Circuit: How Large Language Models Encode and Express Charac
ter Traits
Guanzheng Qin, Chenghao Sun, Zhining Xie, Xinmei Tian
Large Language Models (LLMs) demonstrate remarkable potential in role-playing ta
sks but frequently suffer from personality decay—termed "Out-of-Character" (OOC)
 behavior—during prolonged interactions.

While heuristic strategies exist to align model behaviors, the internal computational dynamics driving personality expression remain opaque.
A fundamental barrier to decoding these mechanisms is a *metric gap*: while standard causal attribution paradigms target atomic, single-token outcomes, personality manifests as a holistic, multi-token behavioral tendency. We bridge this gap via the *Latent Persona Vector*, a differentiable proxy enabling the first fine-grained causal tracing of personality circuits. This metric reveals a structured "Preparation-Establishment-Expression" dynamic
and identifies a mechanistic contributor to OOC behavior: competition between persona-specific signals and an
assistant-like default direction during the critical "Establishment" phase.
Guided by this diagnosis, we propose surgically recalibrating the signal magnitude in fewer than $5\\%$ of attention heads. This targeted intervention effectively strengthens the persona signal, significantly restoring character consistency while preserving general reasoning capabilities.
****
Agentic Monte Carlo: Simulating Reinforcement Learning for Black-Box Agents
Dae Yon Hwang, Raunaq Suri, Valentin Villecroze, Anthony L. Caterini, Jesse C. Cresswell, Noël Vouitsis, Brendan Leigh Ross
LLM agents operate in two distinct regimes: open-weight agents amenable to reinforcement learning (RL) and black-box agents whose behaviour must be controlled purely at test time. Although black-box agents are often backed by state-of-the-art proprietary LLMs, API-only access precludes parameter-level optimization, rendering most RL methods inapplicable. To address this limitation, we turn to a known equivalence between RL and Bayesian inference. We propose Agentic Monte Carlo (AMC) to directly sample from the optimal policy of a black-box agent rather than training it through RL. The optimal policy is a posterior over trajectories whose prior we define as the fixed black-box LLM agent. We employ Sequential Monte Carlo to sample from this posterior by learning a value function to steer the agent while leaving the underlying black-box model unchanged. We validate AMC on three diverse environments from the AgentGym benchmark, demonstrating significant improvements over prompting baselines and even outperforming Group Relative Policy Optimization (GRPO) as we scale the test-time compute of our method. AMC demonstrates the feasibility of performing principled RL-style optimization of black-box LLM agents.
****
The Easy, the Hard, and the Learnable: Confidence and Difficulty-Adaptive Policy Optimization for LLM Reasoning
Zhanke Zhou, Xiangyu Lu, Chentao Cao, Brando Miranda, Tongliang Liu, Bo Han, Sanmi Koyejo
RL with verifiable rewards can substantially improve LLM reasoning, yet standard GRPO-style training often treats easy, hard, and learnable questions alike through uniform sampling and weighting, leading to inefficient compute allocation. We study GRPO by tracking token log-probabilities, group-normalized advantages, and the induced token-level update weights. This reveals three recurring dynamics as training proceeds: (1) confidence inflation, (2) advantage contraction, and (3) hierarchical convergence. These findings suggest that the utility of each update depends strongly on both question difficulty and the model’s current competence. Motivated by this, we propose Confidence and Difficulty-adaptive Policy Optimization (CoDaPO), which assigns each question a bounded value from rollout confidence and empirical difficulty. CoDaPO then uses this value to reweight policy updates and resample high-value learnable questions within mini-batches, thereby increasing discovery within the learnable band under a fixed compute budget. Across twelve benchmarks, CoDaPO consistently improves accuracy over existing RL methods. Our code is publicly available at https://github.com/tmlr-group/CoDaPO.
****
Improved Bounds for Reward-Agnostic and Reward-Free Exploration
Oran Ridel, Alon Cohen
We study *reward-free* and *reward-agnostic* exploration in episodic finite-hori

zon Markov decision processes (MDPs), where an agent explores an unknown environment without observing external rewards.
Reward-free exploration aims to enable ϵ-optimal policies for *any* reward revealed after exploration, while reward-agnostic exploration targets ϵ-optimality for rewards drawn from a small finite class.
In the *reward-agnostic setting*, Li, Yan, Chen, and Fan (2024) achieve minimax sample complexity, but only for restrictively small accuracy parameter ϵ.
We propose a new algorithm that significantly relaxes the requirement on ϵ.
Our approach is novel and of technical interest by itself.
Our algorithm employs an online learning procedure with carefully designed rewards to construct an exploration policy, which is used to gather data sufficient for accurate dynamics estimation and subsequent computation of an ϵ-optimal policy once the reward is revealed.
Finally, we establish a tight lower bound for *reward-free exploration*, closing the gap between known upper and lower bounds.

Restoring Initial Noise Sensitivity in Text-to-Image Distillation through Geometric Alignment
Huayang Huang, Ruoyu Wang, Jinhui Zhao, Wei Deng, Daiguo Zhou, Jian Luan, Yu Wu, Ye Zhu
Generative distillation significantly accelerates text-to-image (T2I) generation by compressing multi-step trajectories into few-step student models while preserving perceptual quality. However, existing methods primarily optimize efficiency and output fidelity, often neglecting critical properties of the original trajectory. In this work, we identify a key missing property: sensitivity to initial noise, whose degradation impairs downstream control methods relying on noise-based optimization and manipulation. We trace this issue to standard distillation objectives that enforce pointwise output alignment, inadvertently flattening the input-output landscape and suppressing the teacher’s local geometric structure. To address this, we propose Geometry-Aware Distillation (GAD), a sensitivity-preserving framework that aligns the local functional behavior of teacher and student models. Specifically, GAD matches Jacobian-vector products with respect to input noise, enabling the student to reproduce the teacher’s differential response to perturbations. Extensive experiments across multiple T2I paradigms and noise-driven control tasks demonstrate that GAD significantly restores sensitivity and improves diversity while maintaining high visual fidelity. Code is available at https://github.com/Hannah1102/GAD.

Learning Hamiltonian Dynamics at Scale: A Differential-Geometric Approach
Katharina Friedl, Noémie Jaquier, Alyx Liao, Danica Kragic
Embedding physical intuition into network architectures allows the learning of dynamics that enforce fundamental properties, such as energy conservation laws, thereby leading to physically-plausible predictions. Yet, scaling these models to intrinsically high-dimensional dynamical systems remains a significant challenge. This paper introduces Reduced-order Hamiltonian Neural Network (RO-HNN), a novel physics-inspired neural network that combines the conservation laws of Hamiltonian mechanics with the scalability of model order reduction. RO-HNN is built on two core components: a novel geometrically-constrained symplectic autoencoder that learns a low-dimensional, structure-preserving symplectic submanifold, and a geometric Hamiltonian neural network that models the dynamics on the submanifold. Our experiments demonstrate that RO-HNN provides physically-consistent, stable, and generalizable predictions of complex high-dimensional dynamics, thereby effectively extending the scope of Hamiltonian neural networks to high-dimensional physical systems.
****

DECOR: Learning to Decompose and Collaborate in Deep Search via Multi-Agent Reinforcement Learning
Ruiqing Chen, Zekun Zhang, Gong-Duo Zhang, Lihong Gu, Lin Zhou

Monolithic agents in deep search often suffer from "cognitive overload," while existing multi-agent approaches mostly rely on frozen models that cannot learn from collaboration failures. To bridge this gap, we propose $\textbf{DECOR}$ ($\textbf{DE}$compose and $\textbf{CO}$llaborate via $\textbf{R}$ole-specialized agents), a framework formulating deep search as a Multi-Agent Reinforcement Learning (MARL) problem. DECOR functionally decomposes the task into three specialized roles: a $\textit{Planner}$ to navigate, a $\textit{Filter}$ to curate a noise-reduced memory, and an $\textit{Answerer}$ for synthesis. Unlike training-free orchestration, we jointly optimize these agents using a hybrid reward strategy that harmonizes role-specific intrinsic feedback with team-level outcome signals. Experiments on seven benchmarks show that DECOR significantly outperforms strong monolithic baselines, demonstrating the necessity of learning-based functional decomposition in handling cognitive overload.

Richer Bayesian Last Layers with Subsampled NTK Features
Sergio Calvo Ordoñez, Jonathan Plenk, Richard Bergna, Alvaro Cartea, Yarin Gal, José Miguel Hernández-Lobato, Kamil Ciosek
Bayesian Last Layers (BLLs) provide a convenient and computationally efficient way to estimate uncertainty in neural networks. However, they underestimate epistemic uncertainty because they apply a Bayesian treatment only to the final layer, ignoring uncertainty induced by earlier layers. We propose a method that improves BLLs by leveraging a projection of Neural Tangent Kernel (NTK) features onto the space spanned by the last-layer features. This enables posterior inference that accounts for variability of the full network while retaining the low computational cost of inference of a standard BLL. We show that our method yields posterior variances that are provably greater or equal to those of a standard BLL, correcting its tendency to underestimate epistemic uncertainty.
To further reduce computational cost, we introduce a uniform subsampling scheme for estimating the projection matrix and for posterior inference. We derive approximation bounds for both types of subsampling. Empirical evaluations on UCI regression, contextual bandits, image classification, and out-of-distribution detection tasks in image and tabular datasets, demonstrate improved calibration and uncertainty estimates compared to standard BLLs and competitive baselines, while reducing computational cost.
****

Towards Universal Gene Regulatory Network Inference: Unlocking Generalizable Regulatory Knowledge in Single-cell Foundation Models
Jiaxin Qi, Hang Li, Yan Cui, Yuhua Zheng, Jianqiang Huang
Gene Regulatory Network (GRN) inference is essential for understanding complex cellular mechanisms, rendered tractable through single-cell transcriptomic data. With the emergence of single-cell Foundation Models (scFMs), enhanced transcriptomic encoding is widely expected to revolutionize GRN inference. However, we observe that their performance remains far from satisfactory. The primary reason is that the standard reconstruction-based pre-training objectives often fail to explicitly capture latent regulatory signals. To bridge this gap, we first introduce a GRN generalization benchmark designed to evaluate regulatory predictions on unseen genes and datasets, which relies on the zero-shot capabilities of scFMs and is inherently challenging for traditional methods. Furthermore, to unlock the regulatory knowledge within the foundation models, we propose two novel methods, Virtual Value Perturbation and Gradient Trajectory, to distill implicit regulatory information from scFMs into highly generalizable inter-gene features. Extensive experiments demonstrate that our approach significantly outperforms existing methods, establishing a new paradigm for leveraging the potential of scFMs in universal GRN inference.

Incremental Transformer Neural Processes
Philip Mortimer, Cristiana Diaconu, Tommy Rochussen, Bruno Kacper Mlodozeniec, Richard E. Turner
Neural Processes (NPs), and specifically Transformer Neural Processes (TNPs), have demonstrated remarkable performance across tasks ranging from spatiotemporal

forecasting to tabular data modelling. However, many of these applications are i
nherently sequential, involving continuous data streams such as real-time sensor
 readings or database updates. In such settings, models should support cheap, in
cremental updates rather than recomputing internal representations from scratch
for every new observation—a capability existing TNP variants lack. Drawing inspi
ration from Large Language Models, we introduce the Incremental TNP ($\texttt{in
cTNP}$). By leveraging causal masking, Key-Value (KV) caching, and a data-effici
ent autoregressive training strategy, $\texttt{incTNP}$ matches the predictive p
erformance of standard TNPs while reducing the computational cost of updates fro
m quadratic to linear time complexity. We empirically evaluate our model on a ra
nge of synthetic and real-world tasks, including tabular regression and temperat
ure prediction. Our results show that, surprisingly, $\texttt{incTNP}$ delivers
performance comparable to—or better than—non-causal TNPs while unlocking orders-
of-magnitude speedups for sequential inference. Finally, we assess the consisten
cy of the model's updates---by adapting a metric of "implicit Bayesianness", we
show that under a one-at-a-time streaming protocol, $\texttt{incTNP}$ retains a
prediction rule as implicitly Bayesian as standard non-causal TNPs, demonstratin
g that $\texttt{incTNP}$ achieves the computational benefits of causal masking w
ithout sacrificing the consistency required for streaming inference.

Scaling by Diversified Experience for Vision-Language-Action Models
Leiyu Wang, Zhaofengnian Wang, Xueqi Li, Luoyi Fan, Cewu Lu, Nanyang Ye
Vision-Language-Action models face significant challenges in real-world deployme
nt due to the entanglement of high-level reasoning with low-level control, and t
he instability of policy optimization. In this paper, we introduce SyVLA, a robu
st VLA model trained with diversified experiences. We propose an Intention Decou
pling algorithm to isolate control-relevant features from reasoning contexts and
 a similar-sample guided RL pipeline to stabilize policy updates and mitigate di
stribution shift. Extensive experiments on real-world robotic tasks and multi-mo
dal benchmarks demonstrate that SyVLA achieves superior task success rates and s
tronger out-of-distribution generalization compared to existing methods, while e
ffectively preserving core vision-language capabilities.
****

Well-Posed KL-Regularized Control via Wasserstein and Kalman–Wasserstein KL Dive
rgences
Viktor Stein, Adwait Datar, Nihat Ay
Kullback-Leibler (KL) divergence regularization is widely used in reinforcement
learning, but it becomes infinite under support mismatch and can degenerate in l
ow-noise regimes. Using a unified information-geometric framework, we introduce
KL analogs by replacing the Fisher–Rao geometry in the dynamical formulation of
the KL with transport-based geometries, and derive closed-form expressions for c
ommon distribution families. Between elliptic distributions, these divergences r
emain finite for degenerating equal covariances and yield a geometric interpreta
tion of regularization heuristics used in Kalman ensemble methods. We demonstrat
e the utility of these divergences in KL-regularized optimal control. In the ful
ly tractable setting of linear time-invariant systems with Gaussian process nois
e, the classical KL reduces to a quadratic control penalty that becomes singular
 as process noise vanishes. Our variants remove this singularity and yield well-
posed problems. On a double integrator and a cart-pole example, the resulting co
ntrols preserve nontrivial feedback and achieve better closed-loop performance.

Who’s in Charge? Disempowerment Patterns in Real-World LLM Usage
Mrinank Sharma, Miles McCain, Raymond Douglas, David Duvenaud
We present the first large-scale empirical analysis of disempowerment patterns i
n real-world AI assistant interactions, analyzing 1.5 million consumer Claude.ai
 conversations using a privacy-preserving approach. We focus on situational dis-
empowerment potential, which occurs when AI assistant interactions risk leading
users to form distorted perceptions of reality, make inauthentic value judgments
, or act in ways misaligned with their values. Quantitatively, we find that seve
re forms of disempowerment potential occur in fewer than one in a thousand conve

rsations, though rates are substantially higher in personal domains like relatio nships and lifestyle. Qualitatively, we uncover several concerning patterns, suc h as validation of persecution narratives and grandiose identities with emphatic sycophantic language, definitive moral judgments about third parties, and compl ete scripting of value-laden personal communications that users appear to implem ent verbatim. Analysis of historical trends reveals an increase in the prevalenc e of disempowerment potential over time. We also find that interactions with gre ater disempowerment potential receive higher user approval ratings, possibly sug gesting a tension between short-term user preferences and long-term human empowe rment.

AI4SLT: Empirical Processes in Lean 4 for Formal Statistical Learning Theory
Yuanhe Zhang, Jason D. Lee, Fanghui Liu
We present the first comprehensive Lean 4 formalization of statistical learning theory (SLT) grounded in empirical process theory. Our end-to-end formal infrast ructure implement the missing contents in latest Lean library, including a compl ete development of Gaussian Lipschitz concentration, Dudley's entropy integral t heorem for sub-Gaussian processes, and an application to least-squares (sparse) regression with a sharp rate. The project was carried out using a human-AI colla borative workflow, in which humans design proof strategies and AI agents execute tactical proof construction, leading to the human-verified Lean 4 toolbox for S LT. Beyond implementation, the formalization process exposes and resolves implic it assumptions and missing details in standard SLT textbooks, enforcing a granul ar, line-by-line understanding of the theory. This work establishes a reusable f ormal foundation and opens the door for future developments in machine learning theory. The code is provided in https://github.com/YuanheZ/lean-stat-learning-th eory.

ECO: Quantized Training without Full-Precision Master Weights
Mahdi Nikdan, Amir Zandieh, Dan Alistarh, Vahab Mirrokni
Quantization has significantly improved the compute and memory efficiency of Lar ge Language Model (LLM) training. However, existing approaches still rely on acc umulating their updates in high-precision: concretely, gradient updates must be applied to a high-precision weight buffer, known as $\textit{master weights}$. T his buffer introduces substantial memory overhead, particularly for Sparse Mixtu re of Experts (SMoE) models, where model parameters and optimizer states dominat e memory usage. To address this, we introduce the Error-Compensating Optimizer (ECO), which eliminates master weights by applying updates directly to quantized parameters. ECO quantizes weights after each step and carefully injects the resu lting quantization error into the optimizer momentum, forming an error-feedback loop with no additional memory. We prove that, under standard assumptions and a decaying learning rate, ECO converges to a constant-radius neighborhood of the o ptimum, while naive master-weight removal can incur an error that is inversely p roportional to the learning rate. We show empirical results for pretraining smal l Transformers (30--800M), a Gemma-3 1B model, and a 2.1B parameter Sparse MoE m odel with FP8 quantization, and fine-tuning DeepSeek-MoE-16B in INT4 precision. Throughout, ECO matches baselines with master weights up to near-lossless accura cy, significantly shifting the static memory vs validation loss Pareto frontier.

When to Trust the Cheap Check: Weak and Strong Verification for Reasoning
Shayan Kiyani, Sima Noorani, George J. Pappas, Hamed Hassani
Reasoning with LLMs increasingly unfolds inside a broader verification loop. Int ernally, systems use cheap checks, such as self-consistency or proxy rewards, wh ich we call **weak verification**. Externally, users inspect outputs and steer t he model through feedback until results are trustworthy, which we call **strong verification**. These signals differ sharply in cost and reliability: strong ver ification can establish trust but is resource-intensive, while weak verification is fast and scalable but noisy and imperfect. We formalize this tension through **weak-strong verification policies**, which decide when to accept or reject ba sed on weak verification and when to defer to strong verification. We introduce

metrics capturing incorrect acceptance, incorrect rejection, and strong-verification frequency. Over population, we show that optimal policies admit a two-threshold structure and that **calibration** and **sharpness** govern the value of weak verifiers. Building on this, we develop an online algorithm that provably controls acceptance and rejection errors without assumptions on the query stream, the language model, or the weak verifier. Experiments on mathematical reasoning and sequential decision-making demonstrate that our algorithm achieves reliability comparable to exhaustive strong verification while significantly reducing verification cost.

When Simple Problems Wear Complex Costumes: Improving Efficiency in LRM's Adaptive Reasoning
Junnan Ren, Yan Zhang, Qian Chen, Yunhang Shen, Ke Li, Shengchuan Zhang, Liujuan Cao, Rongrong Ji
Recent Large Reasoning Models (LRMs) have demonstrated powerful multi-step problem-solving capabilities but often suffer from inefficiency due to an ``overthinking phenomenon", where they apply complex reasoning to simple tasks, resulting in unnecessary computational cost and latency. While adaptive reasoning models that can switch between generating explicit reasoning and producing direct answers offer a potential solution, their effectiveness is compromised by a critical flaw: they are often misled by superficial linguistic complexity, mistaking verbosely phrased simple problems for complex ones. To address this, we propose a two-stage training framework to create a more robust adaptive reasoner. The first stage uses supervised fine-tuning with augmented data—presenting simple problems in both concise and redundant forms—to teach the model to ignore superficial verbosity. Subsequently, a reinforcement learning phase utilizes Group Relative Policy Optimization (GRPO) with a custom reward function to refine the model's adaptive policy, ensuring it selects a reasoning mode based on true task complexity rather than surface-level cues. The resulting model reduces computational overhead without sacrificing accuracy and demonstrates improved robustness to misleading linguistic cues.

MAGIC: A Co-Evolving Attacker–Defender Adversarial Game for Robust LLM Safety
Xiaoyu Wen, Zhida He, Han Qi, Ziyu Wan, Zhongtian Ma, Ying Wen, Tianhang Zheng, Xingcheng Xu, Chaochao Lu, Qiaosheng Zhang
Ensuring robust safety alignment is crucial for Large Language Models (LLMs), yet existing defenses often lag behind evolving adversarial attacks due to their \textbf{reliance on static, pre-collected data distributions}. In this paper, we introduce \textbf{MAGIC}, a novel multi-turn multi-agent reinforcement learning framework that formulates LLM safety alignment as an adversarial asymmetric game. Specifically, an attacker agent learns to iteratively rewrite original queries into deceptive prompts, while a defender agent simultaneously optimizes its policy to recognize and refuse such inputs. This dynamic process triggers a \textbf{co-evolution}, where the attacker's ever-changing strategies continuously uncover long-tail vulnerabilities, driving the defender to generalize to unseen attack patterns. Remarkably, we observe that the attacker, endowed with initial reasoning ability, evolves \textbf{novel, previously unseen combinatorial strategies} through iterative RL training, underscoring our method’s substantial potential. Theoretically, we provide insights into a more robust game equilibrium and derive safety guarantees. Extensive experiments validate our framework's effectiveness, demonstrating superior defense success rates without compromising the helpfulness of the model.

Non-Parametric Probabilistic Robustness: A Conservative Risk Estimator under Unknown Perturbation Distributions
Zheng Wang, Yi Zhang, Siddartha Khastgir, carsten maple, Xingyu Zhao
Deep learning (DL) models, despite their remarkable success, remain vulnerable to small input perturbations that can cause erroneous outputs, motivating the recent proposal of probabilistic robustness (PR) as a complementary alternative to adversarial robustness (AR). However, existing PR formulations assume a fixed an

d known perturbation distribution, an unrealistic expectation in practice. To ad
dress this limitation, we propose non-parametric probabilistic robustness (NPPR)
, a more practical PR metric that does not rely on any predefined perturbation d
istribution. Following the non-parametric paradigm in statistical modeling, NPPR
 learns an optimized perturbation distribution directly from data, enabling cons
ervative PR evaluation under distributional uncertainty. We further develop an N
PPR estimator based on a Gaussian Mixture Model (GMM), covering various input-de
pendent and input-independent perturbation scenarios. Theoretical analyses estab
lish the relationships among AR, PR, and NPPR. Extensive experiments on CIFAR-10
, CIFAR-100, and Tiny ImageNet across ResNet18/50, WideResNet50 and VGG16 valida
te NPPR as a more practical robustness metric, showing conservative (lower) PR e
stimates compared to assuming those common perturbation distributions used in st
ate-of-the-arts.

The Velocity Deficit: Initial Energy Injection for Flow Matching
Linze Li, Zong-Wei Hong, Shen Zhang, Bo Lin, Jinglun Li, Yao Tang, Jiajun Liang
While Flow Matching theoretically guarantees constant-velocity trajectories, we
identify a critical breakdown in high-dimensional practice: the Velocity Deficit
. We show that the MSE objective systematically underestimates velocity magnitud
e, causing generated samples to fail to reach the data manifold—a phenomenon we
term Integration Lag. To rectify this, we propose Initial Energy Injection, inst
antiated via two complementary methods: the training-based Magnitude-Aware Flow
Matching (MAFM) and the training-free Scale Schedule Corrector (SSC). Both are g
rounded in our discovery of a crucial asymmetry: velocity contraction causes har
mful kinetic stagnation at the trajectory's start, yet acts as a beneficial deno
ising mechanism at its end. Empirically, SSC yields significant efficiency gains
 with zero retraining and just one line of code. On ImageNet-1k (256x256), it im
proves FID by 44.6% (from 13.68 to 7.58) and achieves a 5x speedup, enabling a 5
0-step generator (FID 7.58) to beat a 250-step baseline (FID 8.65). Furthermore,
 our methods generalize to Text-to-Image tasks and high-resolution generation, i
mproving FID on MS-COCO by ~22%.

Dreaming in Code for Curriculum Learning in Open-Ended Worlds
Konstantinos Mitsides, Maxence Faldor, Antoine Cully
Open-ended learning frames intelligence as emerging from continual interaction w
ith an ever-expanding space of environments. While recent advances have utilized
 foundation models to programmatically generate diverse environments, these appr
oaches often focus on discovering isolated behaviors rather than orchestrating s
ustained progression. In complex open-ended worlds, the large combinatorial spac
e of possible challenges makes it difficult for agents to discover sequences of
experiences that remain consistently learnable. To address this, we propose Drea
ming in Code (DiCode), a framework in which foundation models synthesize executa
ble environment code to scaffold learning toward increasing competence. In DiCod
e, “dreaming” takes the form of materializing code-level variations of the world
. We instantiate DiCode in Craftax, a challenging open-ended benchmark character
ized by rich mechanics and long-horizon progression. Empirically, DiCode enables
 agents to acquire long-horizon skills, achieving a 17% improvement in mean retu
rn over the strongest baseline and non-zero success on late-game combat tasks wh
ere prior methods fail. Our results suggest that code-level environment design p
rovides a practical mechanism for curriculum control, enabling the construction
of intermediate environments that bridge competence gaps in open-ended worlds.

Post-Training LLMs as Better Decision-Making Agents: A Regret-Minimization Appro
ach
Chanwoo Park, Ziyang Chen, Asuman E. Ozdaglar, Kaiqing Zhang
Large language models (LLMs) are increasingly deployed as agents for decision-ma
king (DM) in interactive and dynamic environments. However, since they are not o
riginally designed for DM, recent studies show that LLMs struggle in basic onlin
e DM settings. We introduce ITERATIVE REGRET-MINIMIZATION FINE-TUNING (ITERATIVE
 RMFT), a post-training procedure that repeatedly distills low-regret decision t

rajectories into the base model. Unlike prior methods that rely on distilling known algorithms or enforcing manually designed reasoning formats, our approach leverages regret as a training signal to elicit improved decision-making behavior while incorporating model-generated reasoning in natural language. Empirically, ITERATIVE RMFT improves DM performance across models, including numerical Transformers, lightweight open-weight LLMs, and the closed-weight model GPT-4o mini, while exhibiting generalization across varying horizons, action spaces, reward processes, and natural-language-described DM scenarios. Overall, we position our approach as an initial exploration, calling for more principled and novel post-training paradigms for LLMs when it comes to addressing DM tasks.

ECG-R1: Protocol-Guided and Modality-Agnostic MLLM for Reliable ECG Interpretation
Jiarui Jin, Haoyu Wang, Xingliang Wu, Xiaocheng Fang, Xiang Lan, Zihan Wang, Deyun Zhang, Bo Liu, Yingying Zhang, Xian Wu, Hongyan Li, Shenda Hong
Electrocardiography (ECG) serves as an indispensable diagnostic tool in clinical practice, yet existing multimodal large language models (MLLMs) remain unreliable for ECG interpretation, often producing plausible but clinically incorrect analyses. To address this, we propose ECG-R1, the first reasoning ECG MLLM designed for reliable ECG interpretation via three innovations. First, we construct the interpretation corpus using \textit{Protocol-Guided Instruction Data Generation}, grounding interpretation in measurable ECG features and monograph-defined quantitative thresholds and diagnostic logic. Second, we present a modality-decoupled architecture with \textit{Interleaved Modality Dropout} to improve robustness and cross-modal consistency when either the ECG signal or ECG image is missing. Third, we present \textit{Reinforcement Learning with ECG Diagnostic Evidence Rewards} to strengthen evidence-grounded ECG interpretation. Additionally, we systematically evaluate the ECG interpretation capabilities of proprietary, open-source, and medical MLLMs, and provide the first quantitative evidence that severe hallucinations are widespread, suggesting that the public should not directly trust these outputs without independent verification. Code is available at \href{https://github.com/PKUDigitalHealth/ECG-R1}{here}.
****

BlitzRank: Principled Zero-shot Ranking Agents with Tournament Graphs
Sheshansh Agrawal, Thien Hang Nguyen, Douwe Kiela
Selecting the top m from n items via expensive k-wise comparisons is central to settings ranging from LLM-based document reranking to crowdsourced evaluation and tournament design.
Existing methods either rely on heuristics that discard comparison information, or exploit it at prohibitive cost.
We introduce a *tournament graph* framework that provides a principled foundation for k-wise ranking.
Our key observation is that each k-item comparison reveals an induced tournament of ${k \choose 2}$ pairwise preferences; aggregating these into a global preference graph and computing its transitive closure yields many additional orderings without further oracle calls.
We formalize when the current top-m output is *certifiably determined* and design a greedy query schedule that maximizes information gain towards identifying the top-m items.
The framework also gracefully handles non-transitive preferences -- cycles induced by real-world oracles -- by collapsing them into equivalence classes that yield principled *tiered rankings*.
Applied to LLM reranking across 14 benchmarks and 5 models, BlitzRank achieves Pareto dominance over existing approaches: matching or exceeding accuracy while requiring 25--40\% fewer tokens than comparable methods; against pairwise reranking, it achieves near-identical quality with 7$\times$ fewer tokens. Code available at
https://github.com/ContextualAI/BlitzRank.

Verbalized Bayesian Persuasion
Wenhao Li, Yue Lin, Yun Hua, Xiangfeng Wang, Bo Jin, Hongyuan Zha, Baoxiang Wang
Information design (ID) explores how a sender influence the optimal behavior of receivers to achieve specific objectives.
While ID originates from everyday human communication, existing game-theoretic and learning methods often model information structures as numbers, which limits many applications to toy games.
This work leverages LLMs and proposes a verbalized framework in Bayesian persuasion (BP), which extends classic BP to real-world games involving human dialogues for the first time.
We map the BP to a verbalized mediator-augmented game, where LLMs instantiate the sender and receiver.
To efficiently solve the verbalized game, we propose a generalized equilibrium-finding algorithm combining LLM and game solver.
The algorithm is reinforced with techniques including verbalized commitment assumptions, verbalized obedience constraints, and information obfuscation.
Experiments in dialogue scenarios, such as recommendation letters, law enforcement, diplomacy with press, validate that our framework can reproduce theoretical results in classic BP and discover effective persuasion strategies in more complex natural language and multi-stage scenarios.
****
Tokenised Flow Matching for Hierarchical Simulation Based Inference
Giovanni Charles, Cosmo Nazzareno Santoni, Seth Flaxman, Elizaveta Semenova
The cost of simulator evaluations is a key practical bottleneck for Simulation Based Inference (SBI). In hierarchical settings with shared global parameters and exchangeable site-level parameters and observations, this structure can be exploited to improve simulation efficiency. Existing hierarchical SBI approaches factorise the posterior yet still simulate across multiple sites per training sample; We instead explore likelihood factorisation (LF) to train from single-site simulations. In LF sampling we learn a per-site (factorised) likelihood and then assemble synthetic multi-site observations to amortise inference for the full hierarchical posterior. Building on this, we propose Tokenised Flow Matching for Posterior Estimation (TFMPE), a tokenised flow matching approach that supports function-valued observations through likelihood factorisation. To enable systematic evaluation, we introduce a benchmark for hierarchical SBI. We validate TFMPE on this benchmark and on realistic infectious disease and computational fluid dynamics models, finding well-calibrated posteriors while reducing computational cost.
****
LATMiX: Learnable Affine Transformations for Microscaling Quantization of LLMs
Ofir Gordon, Lior Dikstein, Arnon Netzer, Idan Achituve, Hai Victor Habi
Post-training quantization (PTQ) is a widely used approach for reducing the memory and compute costs of large language models (LLMs). Recent studies have shown that applying invertible transformations to activations can significantly improve quantization robustness by reducing activation outliers; however, existing approaches are largely restricted to rotation or Hadamard-based transformations.
Moreover, most studies focused primarily on traditional quantization schemes, whereas modern hardware increasingly supports the microscaling (MX) data format. Attempts to combine both showed severe performance degradation, leading prior work to introduce assumptions on the transformations.
In this work, we take a complementary perspective. First, we provide a theoretical analysis of transformations under MX quantization by deriving a bound on the quantization error. Our analysis emphasizes the importance of accounting for both the activation distribution and the underlying quantization structure.
Building on this analysis, we propose LATMiX, a method that generalizes outlier reduction to learnable invertible affine transformations optimized using standard deep learning tools.
Experiments show consistent improvements in average accuracy for MX low-bit quantization over strong baselines on a wide range of zero-shot benchmarks, across multiple model sizes.

****
Learning Unanimously Acceptable Lotteries via Queries
Davin Choo, Paul W. Goldberg, Nicholas Teh
Many high-stakes AI deployments proceed only if every stakeholder deems the system acceptable relative to their own minimum standard. With randomization over a finite menu of options, this becomes a feasibility question: does there exist a lottery over options that clears all stakeholders' acceptability bars? We study a query model where the algorithm proposes lotteries and receives only binary accept/reject feedback. We give deterministic and randomized algorithms that either find a unanimously acceptable lottery or certify infeasibility; adaptivity can avoid eliciting many stakeholders' constraints, and randomization further reduces the expected elicitation cost relative to full elicitation. We complement these upper bounds with worst-case lower bounds (in particular, linear dependence on the number of stakeholders and logarithmic dependence on precision are unavoidable). Finally, we develop learning-augmented algorithms that exploit natural forms of advice (e.g., likely binding stakeholders or a promising lottery), improving query complexity when predictions are accurate while preserving worst-case guarantees.
****
Trajectory Stitching for Solving Inverse Problems with Flow-Based Models
Alexander Denker, Zeljko Kereta, Carola-Bibiane Schönlieb, Moshe Eliasof
Flow-based generative models have emerged as powerful priors for solving inverse problems. One option is to directly optimize the initial latent code (noise), such that the flow output solves the inverse problem. However, this requires back propagating through the entire generative trajectory, incurring high memory costs and numerical instability. We propose MS-Flow, which represents the trajectory as a sequence of intermediate latent states rather than a single initial code. By enforcing the flow dynamics locally and coupling segments through trajectory-matching penalties, MS-Flow alternates between updating intermediate latent states and enforcing consistency with observed data. This reduces memory consumption while improving reconstruction quality. We demonstrate the effectiveness of MS-Flow over existing methods on image recovery and inverse problems, including inpainting, super-resolution, and computed tomography.
****
When Labelers Stay Silent: The Power of Ties in Cost-Effective Preference Learning
Jiaqi Lv, Zihan Zhang, Chengjing Yang, Shiyu Xia, Ning Xu, Xin Geng
Standard preference alignment relies on a binary forced-choice paradigm, assuming definitive preferences for all pairs.
However, we find that indistinguishable pairs are prevalent even in standard benchmarks, where quality differences of two responses often fall below the labeler's discriminative resolution limit.
Forcing a choice in such cases could inject significant noise that undermines policy optimization.
In this work, we propose a silent-aware framework that introduces a principled way to allow annotators to stay silent (i.e., express ties) and then explicitly model these ties during optimization.
Our findings reveal a compelling phenomenon: when ties are properly modeled, supervision from small models yields alignment surpassing that of forced-choice LLMs or human experts.
This discovery highlights a cost-effective path for alignment: respecting a labeler’s resolution limit is more critical than increasing its capability, while simultaneously unlocking the latent value in existing benchmarks by properly modeling inherent tie signals without requiring any re-labeling effort.
To leverage these signals, we propose several optimization objectives to drive the policy toward high-reward regions while mitigating unreliable updates that lead to arbitrary distribution shifts.
Our approaches significantly surpass conventional alignment performance, consistently outperforming the strongest available baselines across diverse benchmarks.
****

Are Two Datasets Close Enough With Statistical Significance? A Kernel Distributional Closeness Testing Approach
Zhijian Zhou, Liuhua Peng, Xunye Tian, Mingming Gong, Feng Liu
Are two distributions close to each other with statistical significance? *Distribution closeness testing* (DCT) formalizes this question by testing whether the distance between a distribution pair is at least ϵ-far. Existing DCT methods mainly measure discrepancies between a distribution pair defined on discrete spaces (e.g., using total variation), which limits their applications to complex data (e.g., images). To extend DCT to more types of data, a natural idea is to introduce *maximum mean discrepancy* (MMD), a powerful measurement of the distributional discrepancy between two complex distributions, into DCT scenarios. However, the empirical results indicate that many distribution pairs can have the same MMD value despite having different norms in the same *reproducing kernel Hilbert space* (RKHS), and these pairs may exhibit different finite-sample distinguishability and reflect different practical closeness levels, making MMD less informative in DCT. To mitigate the issue, we design a new measurement of distributional discrepancy, *norm-adaptive MMD* (NAMMD), which scales MMD's value using the RKHS norms of distributions. Based on the asymptotic distribution of NAMMD, we finally propose the NAMMD-based DCT to assess the closeness level of a distribution pair. Theoretically, we prove that NAMMD-based DCT has higher test power compared to MMD-based DCT, with bounded type-I error, which is also validated by extensive experiments on many types of data (e.g., synthetic noise, real images). Our code is available at: https://github.com/zhijianzhouml/NAMMD.
****
Representation Learning for Equivariant Inference with Guarantees
Daniel Ordonez-Apraez, Vladimir R Kostic, Alek Fröhlich, Vivien Brandt, Karim Lounici, Massimiliano Pontil
In many real-world applications of regression, conditional probability estimation, and uncertainty quantification, exploiting symmetries rooted in physics or geometry can dramatically improve generalization and sample efficiency. While geometric deep learning has made empirical advances by incorporating symmetry and geometry priors, less attention has been given to statistical learning guarantees. In this paper, we introduce an equivariant representation learning framework that simultaneously addresses regression, conditional probability estimation, and uncertainty quantification while providing first-of-its-kind non-asymptotic statistical learning guarantees. Grounded in operator and group representation theory, our framework approximates the spectral decomposition of the conditional expectation operator, building representations that are both equivariant and disentangled along independent symmetry quotient groups. Empirical evaluations on synthetic datasets and real-world robotics applications confirm the potential of our approach, matching or outperforming existing equivariant baselines in regression while providing well-calibrated uncertainty estimates.
****
TriForces: Augmenting Atomistic GNNs for Transferable Representations
Ali Ramlaoui, Alexandre Duval, Hannah Bull, Victor Schmidt, Hugues Talbot, Fragkiskos D. Malliaros, Joseph Musielewicz
Machine learning interatomic potentials (MLIPs) achieve excellent accuracy when trained on large Density Functional Theory (DFT) data. To be useful in practice, they must often be adapted to target chemistries using small and expensive task-specific datasets. However, MLIPs transfer inconsistently across domains, with representations that often loose accessible composition and structure information. To address this, we present TriForces, a model-agnostic three-stream framework that separates composition and structure information, combined with self-supervised learning to preserve transferable representations.
TriForces improves performance on MatBench and QM9 over baselines without needing DFT labels and enables efficient similar structure retrieval through its learned latent space. On OMat24, in limited-data training regime, TriForces reduces energy MAE by 57\% at 20K samples only and improves force MAE across sample sizes. We release pretrained TriForces variants across multiple MLIP architectures with code at https:/github.com/Ramlaoui/triforces.

****
Towards Completeness in Causal Discovery from Soft Interventions with Known Targets
Zihan Zhou, Murat Kocaoglu
We study causal discovery from soft interventions in the presence of latent confounding. Beyond within-environment conditional independences, soft interventions induce cross-environment invariances that can be encoded using an augmented graph with intervention indicator nodes ($\mathcal{I}$-AUG). Taking its maximal ancestral graph (MAG) yields the $\mathcal{I}$-MAG, which characterizes the interventional Markov equivalence class. Building on this framework, we show that the FCI-inspired learner ($\mathcal{I}$-FCI) by Kocaoglu et al. (2019) is sound but not complete: it may output circle endpoints that are nevertheless compelled by the interventional equivalence class. To exploit intervention-node semantics, we propose two complementary methods. First, we introduce an enumeration-based completion procedure that is sound and theoretically complete, but whose worst-case cost depends on the number of MAGs compatible with the partial graph learned by $\mathcal{I}$-FCI. Second, we derive a set of additional local orientation rules that provably tighten $\mathcal{I}$-FCI without increasing asymptotic complexity. Both methods refine prior outputs in the controlled soft-intervention setting with latent variables.
****
Predictive variational inference: Learn the predictively optimal posterior distribution
Jinlin Lai, Antonio Ricardo Linero, Yuling Yao
Vanilla variational inference finds an optimal approximation to the Bayesian posterior distribution, but even the exact Bayesian posterior is often not meaningful under model misspecification. We propose predictive variational inference (PVI): a general inference framework that seeks and samples from an optimal posterior density such that the
resulting posterior predictive distribution is as close to the true data generating process as possible, while this closeness is measured by multiple scoring rules.
By optimizing the objective, the predictive variational inference is generally not the same as, or even attempting to approximate, the Bayesian posterior, even asymptotically. Rather, we interpret it as implicit hierarchical expansion.
Further, the learned posterior uncertainty detects heterogeneity of parameters among the population, enabling automatic model diagnosis.
This framework applies to both likelihood-exact and likelihood-free models. We demonstrate its application in real data examples.
****
Threshold-Based Exclusive Batching for LLM Inference
Weifang Zhang, Yuzhou Nie, Bowen Pang, Guangrui Ma, Shining Wu
Mixed batching (MB)—interleaving prefill and decode in a single batch—has become the standard scheduling strategy for large language model (LLM) inference due to its efficiency in maximizing compute and memory utilization. However, through controlled experiments, we find that prefill–decode interference inflates MB's per-step marginal cost above that of pure decode. On the high-bandwidth H200 (4.8 TB/s), this occurs only when decode tokens exceed 80% of the batch; however, on the bandwidth-constrained RTX PRO 6000 (1.792 TB/s), this threshold plummets to just 20%. Consequently, the optimal choice between MB and exclusive batching (EB) fundamentally depends on GPU memory bandwidth, model size, and workload composition. We derive a closed-form condition for this EB–MB performance crossover, along with asymptotically optimal phase-switching thresholds and memory-safe batch sizing for EB. Optimized EB achieves up to 41.9% higher throughput on bandwidth-constrained GPUs, while MB retains its advantage on high-bandwidth hardware with larger models. Our hybrid scheduler EB+ applies this condition online to dynamically switch between EB and MB without manual intervention. Under non-stationary traffic with distribution or concurrency shifts, EB+ attains the highest or near-highest throughput in every setting, outperforming MB by up to 36.4%.

On the Power of Source Screening for Learning Shared Feature Extractors
Muxing Wang, Connor Mclaughlin, Lili Su
Learning with shared representation is widely recognized as an effective way to separate commonalities from heterogeneity across various heterogeneous sources. Most existing work includes all related data sources via simultaneously training a common feature extractor and source-specific heads. It is well understood that data sources with low relevance or poor quality may hinder representation learning. In this paper, we further dive into the question of which data sources should be learned jointly by focusing on the traditionally deemed "good" collection of sources, in which individual sources have similar relevance and qualities with respect to the true underlying common structure. Towards tractability, we focus on the linear setting where sources share a low-dimensional subspace. We find that source screening can play a central role in statistically optimal subspace estimation. We show that, for a broad class of problem instances, training on a carefully selected subset of sources suffices to achieve minimax optimality, even when a substantial portion of data is discarded. We formalize the notion of an informative subpopulation, develop algorithms and practical heuristics for identifying such subsets, and validate their effectiveness through both theoretical analysis and empirical evaluations on synthetic and real-world datasets.
****
ECo-MoE: Embodiment-Conditioned Mixture of Experts Increases the Evolvability of Robots
Yibin Wang, Muhan Li, Zihan Guo, Sam Kriegman
In this paper, we introduce a model of evolution and learning in robots that co-optimizes a distribution of latent design vectors (genotypes) and a mixture of control experts (neural modules), which are gated by the latent coordinates of each decoded design (phenotype). This provides a scalable alternative to co-design algorithms that either train an individual policy for every robot, which is inefficient, or a monolithic universal controller for all robots, which results in overly conservative structures and behaviors. Our approach lies somewhere between these two extremes, preserving ancestral knowledge in a unified yet modular framework in which different body plans activate and deactivate different combinations of learned sensorimotor circuits for goal-directed behavior. This allows one part of the controller to be overhauled to better suit new species of designs as they emerge without disrupting the hard-earned knowledge contained within other expert modules. It also allows pretrained expert policies to be directly plugged into the mixture, which can steer evolution into otherwise unexplored areas of latent space containing desired morphological traits. We refer to this process as "evo by demo" and explore how it may be used to guide freeform evolution toward canonical structures defined by the pretrained model. Videos and code can be found at: https://eco-moe.github.io.
****
Tracking Drift: Variation-Aware Entropy Scheduling for Non-Stationary Reinforcement Learning
Tongxi Wang, Zhuoyang Xia, Xinran Chen, Shan Liu
Real-world reinforcement learning often faces environment drift, but most existing methods rely on static entropy coefficients/target entropy, causing over-exploration during stable periods and under-exploration after drift (thus slow recovery), and leaving unanswered the principled question of how exploration intensity should scale with drift magnitude.
We show that, under standard assumptions, entropy scheduling in non-stationary maximum-entropy RL can be cast as the dynamic-regret trade-off between tracking a drifting comparator and stabilizing updates, yielding a square-root scaling rule for the entropy weight in terms of a (possibly conservative) online non-stationarity proxy.
Building on this, we propose AES (Adaptive Entropy Scheduling), which adaptively adjusts the entropy coefficient/temperature online using observable drift proxies during training, requiring almost no structural changes and incurring minimal overhead.
Across 4 algorithm variants, 12 tasks, and 4 drift modes, AES significantly redu

ces the fraction of performance degradation caused by drift and accelerates reco very after abrupt changes.
****

MixFP4: Enhancing NVFP4 with Adaptive FP4/INT4 Block Representations
Jiaxiang Zou, Yonghao Chen, Ruilong WU, Xinyu Chen
As large language models continue to scale, fine-grained block-scaled low-precis ion formats such as NVFP4 are increasingly adopted for their substantial through put and memory benefits. However, a single FP4 micro-format often mismatches het erogeneous block-level tensor statistics. To address this without changing the s tandard block-scaled MMA/GEMM execution path, we propose MixFP4, a mixed micro-f ormat extension to NVFP4 that selects between two stored FP4 micro-formats (E2M1 and E1M2) per block.
MixFP4 reuses NVFP4's scale hierarchy and encodes the format choice with zero ad ditional metadata by repurposing the sign bit of the FP8 E4M3 block scale.
By decoding both micro-formats into a unified internal E2M2 compute representati on, MixFP4 avoids datapath duplication.
Across representative LLM families, MixFP4 improves FP4 quantization robustness and accuracy over NVFP4 baselines with modest tensor-core overhead (3.1\% area, 1.5\% power).
****

PEARL: Differentially Private and Entropy-Aware Regulated Language Generation
Seongho Joo, Hyukhun Koh, Kyomin Jung
Large language models (LLMs) often employ Retrieval-Augmented Generation (RAG) t o improve factuality. However, this also increases the risk of sensitive private information leakage. Differential Privacy (DP) has therefore been integrated in to LLM inference and is widely regarded as a standard safeguard; yet most studie s focus narrowly on the privacy–utility trade-off, leaving the trustworthiness o f DP outputs underexplored. To assess trustworthiness, we employ the confidence gap (CG), which quantifies an LLM’s internal knowledge conflict. We show that CG correlates with both hallucination and exposure of personally identifiable info rmation (PII). Building on this insight, we propose PEARL, a CG■guided, entropy■ aware private decoding framework. PEARL adaptively allocates the privacy budget across tokens and sentences based on CG, concentrating protection on PII-bearing spans while stabilizing low-confidence, hallucination-prone regions. In experim ents, PEARL improves both trustworthiness and robustness against PII extraction attacks. Notably, while applying DP alone significantly increases hallucination, our framework demonstrates that it is possible to preserve privacy while reduci ng hallucination.

Tilt Matching for Scalable Sampling and Fine-Tuning
Peter Potaptchik, Lee Cheuk Kit, Michael Samuel Albergo
We propose a simple, scalable algorithm based on stochastic interpolants for sam pling from unnormalized densities and for fine-tuning generative models. The app roach, Tilt Matching, arises from a dynamical equation relating the flow matchin g velocity to one targeting the same distribution tilted by a reward, implicitly solving a stochastic optimal control problem. The resulting velocity inherits t he regularity of stochastic interpolant transports while minimizing an objective with strictly lower variance than flow matching itself. The update to the veloc ity field can be interpreted as the sum of all joint cumulants between the inter polant velocity and the reward, and to first order is their covariance. The meth od requires neither reward gradients nor backpropagation through trajectories of the flow or diffusion. We empirically demonstrate that the approach is efficien t and highly scalable, providing state-of-the-art results on sampling under Lenn ard-Jones systems and competitive performance for fine-tuning Stable Diffusion, without requiring reward multipliers. The framework also applies directly to til ting few-step flow map models.

Towards Understanding the Dynamics of Low-Rank Adaptation
Shu Ding, Yang Peng, Hangan Zhou, Xinyu Lu, Shangwei Chen, Junhua Huang, Mingxua n Yuan, Wei Wang

Low-Rank Adaptation (LoRA) is a widely used parameter-efficient fine-tuning technique, and previous works have studied the update dynamics of LoRA, showing that updating via the low-rank matrix $\mathbf{A}$ can be viewed as a process within the compressed subspace spanned by $\mathbf{A}^{\top} \mathbf{A}$ of the gradient $\nabla f\left(\mathbf{W} \right)$. However, few works analyze how the properties of the low-rank matrices affect the performance of LoRA, since existing methods heuristically initialize the low-rank matrices as Gaussian matrices. In this paper, we provide a theoretical understanding of the update dynamics of LoRA. We reveal that the update dynamics can be viewed as a process within the subspace spanned by $\mathbf{A}^{\top} (\mathbf{A} \mathbf{A}^{\top})^{\dagger} \mathbf{A}$, and prove that when the gradient $\nabla f\left(\mathbf{W} \right)$ is unavailable, if $\mathbf{A}$ is an Equiangular Tight Frame (ETF), $\mathbf{A}^{\top} \mathbf{A}$ and $\mathbf{A}^{\top} (\mathbf{A} \mathbf{A}^{\top})^{\dagger} \mathbf{A}$ can preserve the maximum information from the gradient $\nabla f\left(\mathbf{W} \right)$. Thus, initializing $\mathbf{A}$ as an ETF is the optimal solution for low-rank adaptation when the gradient $\nabla f\left(\mathbf{W} \right)$ is unavailable. Furthermore, we establish the convergence of Low-Rank Adaptation with a rate of $\mathcal{O}\left(\frac{1}{T}\right)$ when $\mathbf{A}$ is an ETF. Extensive experiments show that initializing the low-rank matrices as ETFs significantly outperforms the commonly used Gaussian initialization for existing primary LoRA variants.

Trust Region Masking for Long-Horizon LLM Reinforcement Learning

Yingru Li, Jiacai Liu, Jiawei Xu, Yuxuan Tong, Ziniu Li, Baoxiang Wang

Policy gradient methods for Large Language Models optimize a policy π_θ via a surrogate objective computed from samples of a rollout policy π_{roll}. However, modern LLM-RL pipelines suffer from unavoidable implementation divergences, such as backend discrepancies, Mixture-of-Experts routing discontinuities, and distributed training staleness. These factors cause an off-policy mismatch ($\pi_{roll} \neq \pi_\theta$), leading to approximation errors between the surrogate and the true objective.

We demonstrate that classical trust region bounds on this error scale as $O(T^2)$ with sequence length T, rendering them vacuous for long-horizon tasks. To address this, we derive two new bounds: a Pinsker-Marginal bound scaling as $O(T^{1.5})$ and a Mixed bound scaling as $O(T)$. Crucially, both bounds depend on D_{KL}^{max}, the maximum token-level KL divergence across the sequence. As a sequence-level term, the divergence cannot be controlled by previous token-independent methods like PPO clipping. We propose Trust Region Masking (TRM), which masks entire sequences that violate the trust region. TRM reduces the vacuity of traditional bounds, offering a principled framework to mitigate training collapse in long-horizon LLM-RL.

Avoid What You Know: Divergent Trajectory Balance for GFlowNets

Pedro Dall'Antonia, Tiago Silva, Daniel Csillag, Salem Lahlou, Diego Mesquita

Generative Flow Networks (GFlowNets) are a flexible family of amortized samplers trained to generate discrete and compositional objects with probability proportional to a reward function. To this end, they learn a policy function over an intractably large state graph by minimizing a stochastic objective over sampled trajectories. However, learning efficiency is constrained by the model’s ability to rapidly explore diverse high-probability regions during training. To mitigate this issue, recent works have focused on incentivizing the exploration of unvisited and valuable states via curiosity-driven search and self-supervised random network distillation, which tend to waste samples on already well-approximated regions of the state space. In this context, we propose *Adaptive Complementary Exploration* (ACE), a principled algorithm for the effective exploration of novel and high-probability regions when learning GFlowNets. To achieve this, ACE introduces an *exploration* GFlowNet explicitly trained to search for high-reward states in regions underexplored by the *canonical* GFlowNet, which learns to sample from the target distribution. Through extensive experiments, we show that ACE consistently and significantly improves upon prior work in terms of approximation

accuracy to the target distribution and discovery rate of diverse high-reward s
tates.

Asymmetric conformal prediction with penalized kernel sum-of-squares
Louis Allain, Sébastien Da Veiga, Brian Staber
Conformal prediction (CP) is a distribution-free method to construct reliable pr
ediction intervals that has gained significant attention in recent years. Despit
e its success and various proposed extensions, a significant practical feature w
hich has been overlooked in previous research is the potential skewed nature of
the noise, or of the residuals when the predictive model exhibits bias. In this
work, we leverage recent developments in CP to propose a new asymmetric procedur
e that bridges the gap between skewed and non-skewed noise distributions, while
still maintaining adaptivity of the prediction intervals.
We introduce a new statistical learning problem to construct adaptive and asymme
tric prediction bands, with a unique feature based on a penalty which promotes s
ymmetry: when the penalty intensity varies, the intervals smoothly change from s
ymmetric to asymmetric ones. This statistical learning problem is based on repro
ducing kernel Hilbert spaces and the recently introduced kernel sum-of-squares f
ramework. First, we establish representer theorems to make our problem tractable
in practice, and derive dual formulations which are essential for scalability t
o larger datasets. Second, the intensity of the penalty is chosen using a novel
data-driven method which automatically identifies the symmetric nature of the no
ise. We show that consenting to some asymmetry can let the learned prediction ba
nds better adapt to small sample regimes, outliers or biased predictive models.
Finally, our experiments illustrate the efficiency of such penalized kernel sum-
of-squares to construct adaptive prediction bands.

Rethinking Convergence in MoE Training: The Role of Routing Sparsity
Weihao Zhu, Long Shi, Kang Wei, Zhe Wang, Yipeng Zhou, Haixia Zhang
In Mixture-of-Experts (MoE) training, sparse routing, i.e., activating only the
top-K experts per token, is essential for balancing convergence speed and comp
utational cost. However, existing works typically choose K empirically, witho
ut theoretical guidance. To address this gap, we characterize the convergence be
havior of MoE training using stochastic optimization theory. Specifically, we de
rive a convergence upper bound of $\mathcal{O}\left(\frac{1+M/K}{\sqrt{T}}\right
)$, where T is the number of training iterations and M is the total number o
f experts per MoE layer. This result guarantees convergence and shows that incre
asing K can accelerate training. By further fixing the total computational bud
get R (in FLOPs), we obtain a refined bound of $\mathcal{O}\left(\sqrt{\frac{K
}{R}} + \frac{M}{\sqrt{K R}}\right)$, which is convex in K and implies the exi
stence of an optimal $K^{*}\in[1,M]$ that achieves the best convergence performa
nce. Extensive experiments validate our theoretical analysis under diverse setti
ngs.

DSGCR: Decomposed Spectral Geometry-Aware Cross-Modal Semantic Representation fo
r 3D Visual Grounding
Jing He, Licheng Jiao, Lingling Li, Xiaoqiang Lu, Xu Liu, Wenping Ma, Fang Liu,
Long Sun
3D visual grounding requires robust cross-modal representation to achieve fine-g
rained semantic alignment and precise geometric reasoning. However, most methods
employ unimodal pre-trained encoders that transfer visual and linguistic knowle
dge independently, inducing domain shift and poor cross-modal alignment. Meanwhi
le, spatial modeling with handcrafted priors limits cross-modal geometric repres
entation, struggling to capture complex object relations due to spectral bias. T
o address these challenges, we propose Text-Aware Feature Tuning (TFT) and Decom
posed Spectral Geometry (DSG) to enhance cross-modal semantic representation. Sp
ecifically, TFT injects linguistic context into the visual hierarchy to mitigate
domain shift and facilitate early cross-modal alignment. DSG employs a learnabl
e Fourier basis and explicitly decomposes pairwise relations into symmetric and
antisymmetric spectral components, allowing the model to capture high-frequency

geometric details and direction-aware relations for precise spatial reasoning. E
xtensive experiments on ScanRefer, Nr3D and Sr3D validate the effectiveness of o
ur method, demonstrating state-of-the-art performance with improvements of 2.05\
% Acc@0.25 for 3DREC and 1.09\% mIoU for 3DRES on ScanRefer.

ANTiC: Adaptive Neural Temporal In Situ Compressor
Sandeep Suresh Cranganore, Andrei Bodnar, Gianluca Galletti, Fabian Paischer, Jo
hannes Brandstetter
The persistent storage requirements for high-resolution, spatiotemporally evolvi
ng fields governed by large-scale and high-dimensional partial differential equa
tions (PDEs) have reached the petabyte-to-exabyte scale.
Transient simulations modeling Navier-Stokes equations, magnetohydrodynamics, pl
asma physics, or binary black hole mergers generate data volumes that are prohib
itive for modern high-performance computing (HPC) infrastructures.
To address this bottleneck, we introduce ANTIC (Adaptive Neural Temporal in situ
 Compressor), an end-to-end in situ compression pipeline. ANTIC consists of an a
daptive temporal selector tailored to high-dimensional physics that identifies a
nd filters informative snapshots at simulation time, combined with a spatial neu
ral compression module based on continual fine-tuning that learns residual updat
es between adjacent snapshots using neural fields.
By operating in a single streaming pass, ANTIC enables a combined compression of
 temporal and spatial components and effectively alleviates the need for explici
t on-disk storage of entire time-evolved trajectories. Experimental results demo
nstrate that ANTIC achieves storage reductions of approximately $\sim 400\times$
 for 2D Kolmogorov flow simulations and $\sim 7000\times$ for large-scale physic
s simulations such as binary black hole mergers.

Mirror Mean-Field Langevin Dynamics
Anming Gu, Juno Kim
The mean-field Langevin dynamics (MFLD) minimizes an entropy-regularized nonline
ar convex functional on the Wasserstein space over $\mathbb{R}^d$, and has gaine
d attention recently as a model for the gradient descent dynamics of interacting
 particle systems such as infinite-width two-layer neural networks. However, man
y problems of interest have constrained domains, which are not solved by existin
g mean-field algorithms due to the global diffusion term. We study the optimizat
ion of probability measures constrained to a convex subset of $\mathbb{R}^d$ by
proposing the \emph{mirror mean-field Langevin dynamics} (MMFLD), an extension o
f MFLD to the mirror Langevin framework. We obtain linear convergence guarantees
 for the continuous MMFLD via a uniform log-Sobolev inequality, and uniform-in-t
ime propagation of chaos results for its time- and particle-discretized counterp
art.

DetailMaster: Can Your Text-to-Image Model Handle Long Prompts?
Qirui Jiao, Daoyuan Chen, Yilun Huang, Xika Lin, Ying Shen, Yaliang Li
While recent Text-to-Image (T2I) models show impressive capabilities in synthesi
zing images from brief descriptions, they struggle with the long, detailed promp
ts required for professional applications. We present DetailMaster, a comprehens
ive benchmark for evaluating T2I capabilities on long prompts with complex compo
sitional requirements, accompanied by an automated data construction pipeline an
d an evaluation workflow. Comprising expert-validated prompts averaging 284.89 t
okens, our benchmark introduces four critical evaluation dimensions: Character A
ttributes, Structured Character Locations, Multi-Dimensional Scene Attributes, a
nd Spatial/Interactive Relationships. Evaluations on various general-purpose and
 long-prompt-optimized models reveal critical performance limitations, showing t
hat weak encoders struggle to preserve syntactic dependencies within prompts and
 diffusion models suffer from attribute leakage under detail-intensive condition
s. Through a controlled ablation study under varying constraints, we further sho
w that high-fidelity generation requires a synergistic combination of expanded p
rompt limits and long-prompt training. We open-source our dataset and code to fo
ster progress in long-prompt-driven T2I generation.

A Two-Layer Framework for Joint Online Configuration Selection and Admission Control
Owen Shen, Haoran Xu, Yinyu Ye, Peter Glynn, Patrick Jaillet
We study online configuration selection with admission control problem, which arises in LLM serving, GPU scheduling, and revenue management. In a planning horizon with T periods, we consider a two-layer framework for the decisions made within each time period. In the first layer, the decision maker selects one of the K configurations (ex. quantization, parallelism, fare class) which induces distribution over the reward-resource pair of the incoming request. In the second layer, the decision maker observes the request and then decides whether to accept it or not. Benchmarking this framework requires care. We introduce a **switching-aware fluid oracle** that accounts for the value of mixing configurations over time, provably upper-bounding any online policy. We derive a max-min formulation for evaluating the benchmark, and we characterize saddle points of the max-min problem via primal-dual optimality conditions linking equilibrium, feasibility, and complementarity. This guides the design of **SP-UCB–OLP** algorithm, which solves an optimistic saddle point problem and achieves $\tilde{O}(\sqrt{KT})$ regret.
****
Cognitive Fatigue in Autoregressive Transformers: Formalization and Measurement
Riju Marwah, Ritvik Garimella, Vishal Pallagani, Atishay Jain, Michael Charles Stewart, Amit Sheth
Autoregressive language models frequently degrade during long-horizon generation, producing repetitive text, losing instruction adherence, and exhibiting unstable entropy. Despite the prevalence of these failures, practitioners lack online diagnostics to detect them in real-time as they occur. We formalize this degradation as cognitive fatigue, a measurable generation-time state characterized by decay in attention to the original prompt, representational drift, and entropy miscalibration. We introduce the Fatigue Index (FI), a lightweight, model-agnostic diagnostic that aggregates these three signals under explicit axioms (monotonicity, boundedness, interpretability) enabling reliable runtime monitoring. Across nine models (1B–13B parameters), FI trajectories exhibit structured temporal dynamics, predict task degradation (AUROC = 0.95) and repetition ($\rho = 0.94$), and reveal non-monotonic scaling behavior: instruction-tuned models below 3B exhibit faster collapse than base models, with this trend reversing at 7B. Stress analyses further show that FI onset accelerates under longer contexts, middle-positioned evidence, and reduced numerical precision. These results establish cognitive fatigue as a coherent and measurable phenomenon, and position FI as a principled tool for runtime reliability monitoring in production LLM systems.

Proteo-R1: Reasoning Foundation Models for De Novo Protein Design
Fang Wu, Weihao Xuan, Heli Qi, Hanqun Cao, Heng-Jui Chang, Zeqi Zhou, Li Erran Li, Haokai Zhao, Jian Ma, Zijian Carl Ma, Yu-Chi Cheng, Kuan Pang, Xiangru Tang, Zehong Wang, Guanlue Li, Hanchen Wang, Kejun Ying, Pan Lu, Chiho Im, Seungju Han, Peng Xia, Tinson Xu, Yinxi Li, Deyao Zhu, Pheng-Ann Heng, Naoto Yokoya, Masashi Sugiyama, Jure Leskovec, Yejin Choi
Deep learning in de novo protein design has achieved atomic-level fidelity. However, existing models remain largely non-deliberative: they directly synthesize molecular geometries without explicitly reasoning about which residues or interactions are functionally essential. As a result, design decisions are entangled with continuous sampling dynamics, limiting interpretability, controllability, and systematic reuse of biochemical knowledge. We introduce Proteo-R1, a reasoning-guided protein design framework that explicitly decouples molecular understanding from geometric generation. Proteo-R1 adopts a dual-expert architecture, where a multimodal large language model (LLM) serves as an understanding expert, analyzes protein sequences, structures, and textual context to identify key functional residues that govern binding and specificity. These residue-level decisions are then passed to a separate diffusion-based generation expert, which performs conditional co-design while respecting the fixed interaction anchors. This factori

zation mirrors how human experts approach molecular engineering: first, reasoning about critical interactions, then optimizing geometry subject to those constraints. By operationalizing reasoning as explicit residue-level commitments rather than latent textual guidance, Proteo-R1 achieves stable, interpretable, and modular integration of LLM reasoning with advanced geometric generative models. Code and demos are at https://proteor1.github.io.

Markov Chain Monte Carlo without Evaluating the Target: an Auxiliary Variable Approach
Wei Yuan, Guanyang Wang
In sampling tasks, it is common for target distributions to be known up to a normalizing constant. However, in many situations, even evaluating the unnormalized distribution can be costly or infeasible. This issue arises in scenarios such as sampling from the Bayesian posterior for tall datasets and the `doubly-intractable' distributions. In this paper, we begin by observing that seemingly different Markov chain Monte Carlo (MCMC) algorithms, such as the exchange algorithm, PoissonMH, and TunaMH, can be unified under a simple common procedure. We then extend this procedure into a novel framework that allows the use of auxiliary variables in both the proposal and the acceptance--rejection step. Several new MCMC algorithms emerge from this framework that uses estimated gradients to guide the proposal moves. They have demonstrated significantly better performance than existing methods on both synthetic and real datasets. We also develop theory for the new framework and use it to simplify and extend results for existing algorithms. The code to reproduce the experimental results can be found at https://github.com/ywwes26/Auxiliary-MCMC.

ToolOrchestra: Elevating Intelligence via Efficient Model and Tool Orchestration
Hongjin SU, Shizhe Diao, Ximing Lu, Mingjie Liu, Jiacheng Xu, Xin Dong, Yonggan Fu, Peter Belcak, Hanrong Ye, Hongxu Yin, Yi Dong, Evelina Bakhturina, Tao Yu, Yejin Choi, Jan Kautz, Pavlo Molchanov
Large language models are powerful generalists, yet solving deep and complex problems such as those of the Humanity’s Last Exam (HLE) remains both conceptually challenging and computationally expensive. We show that small orchestrators managing other models and a variety of tools are able to both push the upper bound of intelligence and improve efficiency in solving difficult agentic tasks. We introduce ToolOrchestra, a method for training small orchestrators that coordinate the use of intelligent tools. ToolOrchestra makes explicit use of reinforcement learning with outcome-, efficiency-, and user-preference-aware rewards. Using ToolOrchestra, we produce Orchestrator, an 8B model that achieves higher accuracy at lower cost than previous tool-use agents while aligning with user preferences on which tools are to be used for a given query. On HLE, Orchestrator achieves a score of 37.1%, outperforming GPT-5 (35.1%) while being 2.5x more efficient. On $\tau ^2$-Bench and FRAMES, Orchestrator surpasses GPT-5 by a wide margin while using only about 30% of the cost. Extensive analysis shows that Orchestrator achieves the best trade-off between performance and cost under multiple metrics, and generalizes robustly to previously unseen tools. These results demonstrate that composing diverse tools with a lightweight orchestration model is both more efficient and more effective than existing methods, paving the way for practical and scalable tool-augmented reasoning systems. These results demonstrate that orchestrating diverse tools with lightweight agents is not only more efficient, but also more effective, paving the way for practical and scalable tool-augmented reasoning systems.

A Spiking Heterogeneous Harmonic Resonate-and-Fire State Space Model for Time Series
Kartikay Agrawal, Vaishnavi Nagabhushana, Abhijeet Vikram, Vedant Sharma, Ayon Borthakur
Spiking neural networks have attracted increasing attention for their energy efficiency, multiplication-free computation, and sparse event-based processing. In parallel, state space models have emerged as a scalable alternative to transform

ers for long-range sequence modelling by avoiding quadratic dependence on sequen ce length. We propose here a spiking heterogeneous harmonic resonate-and-fire st ate space model (SH^2RFSSM), a second-order spiking SSM for classification and regression on ultra-long sequences. SH^2RFSSM outperforms transformers and fi rst-order SSMs on average while eliminating matrix multiplications, making it hi ghly suitable for resource-constrained applications. Furthermore, we introduce a kernel-based spiking regressor that enables accurate modelling of dependencies in sequences of up to 50k steps. We also observe a reduction in spiking operatio ns and improved performance with heterogeneity and discretisation in harmonic re sonate-and-fire neuronal layers. Overall, we evaluate Harmonic Resonate-and Fire layers across 17 diverse datasets, spanning sensors, time series, and classific ation to long-term forecasting. Our results demonstrate that SH^2RFSSM achieve s superior long-range modelling capability with energy efficiency, positioning i t as a strong candidate for signal processing on resource-constrained devices fo r human activity recognition, time series classification, and regression.
****
The Structural Origin of Attention Sink: Variance Discrepancy, Super Neurons, an d Dimension Disparity
Siquan Li, Kaiqi Jiang, Jiacheng Sun, Tianyang Hu
Despite the prevalence of the attention sink phenomenon in Large Language Models (LLMs), where initial tokens disproportionately monopolize attention scores, it s structural origins remain elusive. This work provides a *mechanistic explanati on* for this phenomenon. First, we trace its root to the value aggregation proce ss inherent in self-attention, which induces a systematic variance discrepancy. We further demonstrate that this discrepancy is drastically amplified by the act ivation of super neurons within Feed-Forward Network (FFN) layers. Specifically, the channel-sparse down-projections trigger a dimension disparity of the first- token representation, necessitating the formation of attention sinks as a struct ural anchor. Then, we validate this causal chain through two controlled interven tions: (i) isolating the aggregation effect via attention mask modifications and (ii) amplifying the variance of targeted token representations. Both interventi ons can replicate attention sinks at arbitrary positions. Our mechanistic unders tanding offers a foundation for the systematic control of sink formation. Finall y, as a proof of concept, we propose *head-wise RMSNorm*, an architectural modif ication that stabilizes value aggregation outputs during pre-training. Our exper iments demonstrate that restoring statistical parity across positions significan tly accelerates convergence. The code is available at [https://github.com/Siquan -Li/Head-wise-RMSNorm](https://github.com/Siquan-Li/Head-wise-RMSNorm).
****
Robust Multi-View Fusion via Prototype-Anchored Unbalanced Optimal Transport
Zhang Han, Xingwen Zhao, HUI LI
Multi-view classifiers typically fuse all observed views into a single represent ation, which becomes fragile when some views are missing or corrupted.We propose a prototype-anchored fusion module based on an entropically regularized unbalan ced optimal transport (UOT) barycenter.Each view is summarized into a small set of learned atoms and is matched to a shared prototype support; fusion outputs a probability measure over prototypes with fixed dimension.By relaxing marginal co nstraints with a generalized KL penalty, the UOT objective can leave a fraction of view mass unmatched when matching is geometrically costly, yielding a simple differentiable trimming mechanism without hand-tuned thresholds.We provide a bas ic theoretical result showing that discarding an arbitrary subset of atom mass i ncurs a penalty bounded by its total mass, independent of transport distances.Ex periments on multi-view action recognition benchmarks under simulated missing vi ews, missing-rate shift, and feature-space corruption demonstrate consistently i mproved stability under severe missingness with modest overhead on top of strong backbones.
****
Geometry-Aware Probabilistic Circuits via Voronoi Tessellations
Sahil Sidheekh, Sriraam Natarajan
Probabilistic circuits (PCs) enable exact and tractable inference but employ dat

a independent mixture weights that limit their ability to capture local geometry of the data manifold.
We propose Voronoi tessellations (VT) as a natural way to incorporate geometric structure directly into the sum nodes of a PC. However, naïvely introducing such structure breaks tractability. We formalize this incompatibility and develop two complementary solutions: (1) an approximate inference framework that provides guaranteed lower and upper bounds for inference, and (2) a structural condition for VT under which exact tractable inference is recovered.
Finally, we introduce a differentiable relaxation for VT that enables gradient-based learning and empirically validate the resulting approach on standard density estimation tasks.
****

Decentralized Online Convex Optimization with Efficient Communication: Improved Algorithm and Lower Bounds
Sifan Yang, Wenhao Yang, Wei Jiang, Lijun Zhang
We investigate decentralized online convex optimization with compressed communication, where n learners connected by a network collaboratively minimize a sequence of global loss functions using only local information and compressed data from their neighbors. Prior work has established regret bounds of $O(\max\\{\omega^{-2}\rho^{-4}n^{1/2},\omega^{-4}\rho^{-8}\\}n\sqrt{T})$ and $O(\max\\{\omega^{-2}\rho^{-4}n^{1/2},\omega^{-4}\rho^{-8}\\}n\ln{T})$ for convex and strongly convex functions, respectively, where $\omega\in(0,1]$ is the compression quality factor and $\rho<1$ is the spectral gap of the communication matrix. However, these regret bounds suffer from a prohibitively high quadratic or even quartic dependence on ω^{-1}. Moreover, the super-linear dependence on n is also undesirable. To overcome these shortcomings, we propose a novel algorithm that achieves improved regret bounds of $\tilde{O}(\omega^{-1/2}\rho^{-1}n\sqrt{T})$ and $\tilde{O}(\omega^{-1}\rho^{-2}n\ln{T})$ for convex and strongly convex functions, respectively. The primary idea is to design a two-level blocking update framework incorporating two novel ingredients: an online gossip strategy and an error compensation scheme, which work together to promote better consensus among learners. Furthermore, we establish the first lower bounds for this problem, justifying the optimality of our results with respect to both ω and T. Additionally, we consider the bandit feedback scenario and extend our method with classical gradient estimators to enhance existing regret bounds.

Contrastive Flow Map Matching
Junyu Zhang, Daochang Liu, Younghyun Kim, Jong Hwan Ko, Shichao Zhang, Chang Xu, Eunbyung Park
Flow map matching (FMM) enables one- and few-step sampling for diffusion-style generation, yet its performance is often hindered by the mismatch between ground-truth training transitions and model-induced flow maps.
We propose **Contrastive Flow Map Matching (CFMM)**, a principled framework that explicitly aligns FMM training with practical sampling.
Our approach is motivated by a joint-KL decomposition on the reverse KL divergence, which decomposes the distributional gap into a marginal mismatch over intermediate states and a conditional mismatch in endpoint reconstruction.
This analysis motivates two complementary objectives: average-velocity regression for marginal alignment and a sampling-aligned InfoNCE contrastive loss for conditional refinement.
CFMM is a training-only plug-in for pre-trained FMMs, incurs no inference-time overhead, and supports training FMMs from scratch.
Experiments on CIFAR-10, ImageNet, and LSUN across multiple FMM baselines demonstrate consistent improvements in fidelity and perceptual quality with only modest additional training cost.

Topological Active Inference for Task Disambiguation
Yangbo Wei, Zhen Huang, Shaoqiang Lu, Junhong Qian, Chen Wu, Lei He
In open-ended domains, natural language instructions are often \textit{underspecified}, mapping to multiple valid yet functionally distinct latent intents. Although Large Language Models (LLMs) excel at generation, their interactive disambiguation remains limited by *semantic blindness*: they may spend clarification turns distinguishing superficial syntactic variants rather than resolving substantive intent differences. We propose *Topological Active Inference* (TAI), a geometric framework that recasts task disambiguation as *intent-manifold contraction*. TAI uses *Persistent Homology* to recover persistent intent clusters from sampled solutions, filtering short-lived syntactic variations while preserving robust semantic structure under mild separability assumptions. It then synthesizes clarifying questions as semantic separators and selects them with *Topological Expected Information Gain* (TEIG), which optimizes uncertainty reduction over intent clusters rather than individual candidates. This reduces the effective hypothesis space from N sampled solutions to K latent intents and yields logarithmic interaction complexity $\mathcal{O}(\log K)$ under balanced-split conditions. Experiments across code, visualization, and navigation tasks show that TAI resolves user intent with fewer turns and remains robust to noisy feedback, and smaller model scales.

KernelBand: Steering LLM-based Kernel Optimization via Hardware-Aware Multi-Armed Bandits
Dezhi Ran, Shuxiao Xie, Mingfang Ji, Anmin Liu, Mengzhou Wu, Yuan Cao, Yuzhe Guo, Hao Yu, Linyi Li, Yitao Hu, Wei Yang, Tao Xie
High-performance GPU kernels are critical for efficient LLM serving, yet their optimization remains a bottleneck requiring deep system expertise. While code LLMs show promise in generating functionally correct code, kernel optimization is intrinsically a search problem over a vast optimization space. This fundamental mismatch prevents existing LLM agents from efficiently exploring the optimization space for diverse hardware and compute patterns. To bridge the gap, we present KernelBand, a framework that formulates kernel optimization as a Multi-Armed Bandit (MAB) problem, explicitly balancing exploration and exploitation to unlock the potential of code LLMs. To navigate the infinite arm space of optimization strategies applied to candidate kernels, we design two key mechanisms: a hardware-aware pruning strategy via profiling bounds and a runtime-behavior clustering algorithm that leverages Lipschitz continuity. Extensive experiments on TritonBench-G with three GPU architectures and four code LLMs show that KernelBand consistently outperforms the strongest available agent baseline, achieving up to **1.91×** geometric mean speedup over correctly optimized kernels with **39–140%** relative improvement in Fast@1 success rate. Our code is available at https://github.com/TongmingLAIC/KernelBand.
****

SemRep : Generative Code Representation Learning with Code Transformations
Weichen Li, Jiamin Song, Bogdan Alexandru Stoica, Arav Dhoot, Gabriel Ryan, Shengyu Fu, Kexin Pei
Code transformation is a foundational capability in the software development process, where its effectiveness relies on constructing a high-quality code representation to characterize the input code semantics and guide the transformation.

Existing approaches treat code transformation as an end-to-end learning task, leaving the construction of the representation needed for semantic reasoning implicit in model weights or relying on rigid compiler-level abstractions.

We present SemRep, a framework that improves code transformation through *generative code representation learning*.

Our key insight is to employ the semantics-preserving transformations as the intermediate representation, which serves as both a generative mid-training task and the guidance for subsequent instruction-specific code transformations.

Across general code editing and optimization tasks (e.g., GPU kernel optimization), SemRep outperforms the extensively finetuned baselines with strictly the same training budget by 6.9\% in correctness, 1.1$\times$ in performance, 13.9\% in generalization, and 6.7\% in robustness.

With the improved exploration of diverse code transformations, SemRep is particularly amenable to evolutionary search.

Combined with an evolutionary coding agent, SemRep finds optimizations that 685B larger-weight baselines fail to discover while achieving the same performance with 25\% less inference compute.

Parallel-Probe: Towards Efficient Parallel Thinking via 2D Probing

Tong Zheng, Chengsong Huang, Runpeng Dai, Yun He, Rui Liu, Xin Ni, Huiwen Bao, Kaishen Wang, Hongtu Zhu, Jiaxin Huang, Furong Huang, Heng Huang

Parallel thinking has emerged as a promising paradigm for reasoning, yet it imposes significant computational burdens. Existing efficiency methods primarily rely on local, per-trajectory signals and lack principled mechanisms to exploit global dynamics across parallel branches. We introduce 2D probing, an interface that exposes the width–depth dynamics of parallel thinking by periodically eliciting intermediate answers from all branches. Our analysis reveals three key insights: non-monotonic scaling across width–depth allocations, heterogeneous reasoning branch lengths, and early stabilization of global consensus. Guided by these insights, we introduce $\textbf{{Parallel-Probe}}$, a training-free controller designed to optimize online parallel thinking. Parallel-Probe employs consensus-based early stopping to regulate reasoning depth and deviation-based branch pruning to dynamically adjust width. Extensive experiments across three benchmarks and multiple models demonstrate that Parallel-Probe establishes a superior Pareto frontier for test-time scaling. Compared to standard majority voting, it reduces sequential tokens by up to $\textbf{35.8}$% and total token cost by over $\textbf{25.8}$% while maintaining competitive accuracy.

A Kinetic Energy Perspective of Flow Matching

Ziyun Li, Huancheng Hu, Soon Hoe Lim, Xuyu Li, Fei Gao, Enmao Diao, Zezhen Ding, Michalis Vazirgiannis, Henrik Boström

Flow-based generative models can be viewed through a physics lens: sampling transports a particle from noise to data by integrating a learned velocity field, and each sample corresponds to a trajectory with its own dynamical effort. Motivated by classical mechanics, we introduce Kinetic Path Energy (KPE), an action-like, per-sample diagnostic that measures the accumulated kinetic effort along an ordinary differential equation (ODE) trajectory. Empirically, KPE exhibits two robust correspondences: {i} higher KPE predicts stronger semantic fidelity; {ii} high-KPE trajectories land in sparse representation regions. We further provide theoretical guarantees linking trajectory energy to data sparsity. Paradoxically, this correlation is non-monotonic. At sufficiently high energy, generation can degenerate into memorization. Leveraging the closed-form formula of empirical flow matching, we show that extreme energies drive trajectories toward near-copies of training examples. This yields a Goldilocks principle and motivates Kinetic Trajectory Shaping (KTS), a training-free two-phase inference strategy that boosts early motion and enforces a late-time soft landing, reducing memorization and improving generation quality across benchmark tasks.

A Formal Comparison Between Chain of Thought and Latent Thought

Kevin Xu, Issei Sato

Chain of thought (CoT) elicits reasoning in large language models by explicitly generating intermediate tokens. In contrast, latent thought reasoning operates directly in the continuous latent space, enabling computation beyond discrete lin

guistic representations. While both approaches exploit iterative computation, th
eir comparative capabilities remain underexplored. In this work, we present a fo
rmal analysis showing that latent thought admits efficient parallel computation,
 in contrast to the inherently sequential nature of CoT. Conversely, CoT enables
 approximate counting through stochastic decoding. These separations suggest the
 tasks for which depth-driven recursion is more suitable, thereby offering pract
ical guidance for choosing between reasoning paradigms.

OmniAID: Decoupling Semantic and Artifacts for Universal AI-Generated Image Dete
ction in the Wild

Yuncheng Guo, Junyan Ye, Chenjue Zhang, Hengrui Kang, Haohuan Fu, Conghui He, We
ijia Li

A truly universal AI-Generated Image (AIGI) detector must simultaneously general
ize across diverse generative models and varied semantic content. Current method
s learn a single, entangled forgery representation, conflating content-dependent
 flaws with content-agnostic artifacts, and are further constrained by outdated
benchmarks. We propose OmniAID, a novel framework centered on a decoupled Mixtur
e-of-Experts (MoE) architecture that separates: (1) semantic flaws across distin
ct content domains via Routable Specialized Semantic Experts, and (2) content-ag
nostic universal artifacts from content-dependent flaws via a Fixed Universal Ar
tifact Expert. A two-stage training strategy first specializes experts independe
ntly with domain-specific hard-sampling, then trains a lightweight gating networ
k for effective input routing. By explicitly decoupling "what is generated'' (c
ontent-specific flaws) from "how it is generated'' (universal artifacts), OmniAI
D achieves robust generalization. We also introduce Mirage, a large-scale, conte
mporary dataset comprising a modern training set and a challenging test set. Ext
ensive experiments demonstrate that OmniAID surpasses existing detectors, establ
ishing a new standard for AIGI detection against modern, in-the-wild threats.

MASH: Modeling Abstention via Selective Help-Seeking

Mustafa Omer Gul, Claire Cardie, Tanya Goyal

LLMs cannot reliably recognize their parametric knowledge boundaries and often h
allucinate answers to outside-of-boundary questions. In this paper, we introduce
 MASH (Modeling Abstention via Selective Help-seeking), a training framework tha
t readily extracts abstentions from LLMs. Our key idea is that any external help
-seeking by an LLM, i.e. search tool use, can serve as a proxy for abstention if
 the external help (search) is appropriately penalized while also rewarding answ
er accuracy. MASH operationalizes this idea using reinforcement learning with a
pay-per-search reward. We run experiments on three knowledge-intensive QA datase
ts. Our results show that MASH substantially improves upon the selective help-se
eking performance of prior efficient search approaches; on multi-hop datasets, i
t improves answer accuracy by 7.6%. Furthermore, MASH demonstrates strong off-th
e-shelf abstention performance, showcasing behavior competitive with prior abste
ntion methods that additionally require predetermining model knowledge boundarie
s to construct training data. Overall, we show that MASH training effectively al
igns search tool use with parametric knowledge, which can be successfully levera
ged for making abstention decisions and efficient search tool use.

PLATE: Plasticity-Tunable Efficient Adapters for Geometry-Aware Continual Learni
ng

Romain Cosentino

We develop a continual learning method for pretrained models that \emph{requires
 no access to old-task data},
addressing a practical barrier in foundation model adaptation where pretraining
distributions are often unavailable. Our key observation is that pretrained netw
orks exhibit substantial \emph{geometric redundancy}, and that this redundancy c
an be exploited in two complementary ways. First, redundant neurons provide a pr
oxy for dominant pretraining-era feature directions, enabling the construction o
f approximately protected update subspaces directly from pretrained weights. Sec
ond, redundancy offers a natural bias for \emph{where} to place plasticity: by r

estricting updates to a subset of redundant neurons and constraining the remaini ng degrees of freedom, we obtain update families with reduced functional drift o n the old-data distribution and improved worst-case retention guarantees. These insights lead to \textsc{PLATE} (\textbf{Pla}sticity-\textbf{T}unable \textbf{E} fficient Adapters), a continual learning method requiring no past-task data that provides explicit control over the plasticity-retention trade-off. PLATE parame terizes each layer with a structured low-rank update $\Delta W = B A Q^\top$, wh ere B and Q are computed once from pretrained weights and kept frozen, and o nly A is trained on the new task. Code is available at https://github.com/Sale sforceAIResearch/PLATE.

STLA: Spatiotemporal Lookahead Alignment for Post-Training Quantization

Zuqi Zhang, Chenghe Sun, Xiangyi Chu, Wei-Han Yu, Ka-Fai Un, Rui P. Martins, Pui -In Mak, Jiawei Xu

Adaptive rounding techniques in Post-Training Quantization (PTQ) enable the effi cient deployment of Large Language Models (LLMs) with low resource and data depe ndencies. While learning-based rounding methods are accurate yet costly, compens ation-based approaches offer a highly efficient alternative. However, synergizin g these two to realize their full potential is hindered by spatiotemporal misali gnment in the decoupled paradigm. Key challenges include temporal parameter con flict, the invalidation of the initial Round-to-Nearest (RTN) assumption, and sp atially-inconsistent optimization objectives. This paper introduces STLA, a nove l rounding-optimized PTQ framework that achieves both fast and accurate LLM quan tization. STLA resolves temporal inconsistency through cluster-wise integrated r ounding optimization, which collocates the learning and compensation phases. STL A achieves spatial alignment through a unified global objective derived from the Schur Complement, enabling the solver to look ahead and align local rounding de cisions with the optimal future compensation of remaining weights. Furthermore, we propose a Hessian-guided clustering strategy that exploits both diagonal and off-diagonal information to maximize intra-cluster error cancellation. Extensive experiments demonstrate that STLA establishes a new state-of-the-art for low-bi t PTQ while maintaining high computational efficiency. The code is available at https://github.com/AI2C-Lab/STLA.

FlowBot: Inducing LLM Workflows with Bilevel Optimization and Textual Gradients

Hongyeon Yu, Young-Bum Kim, Yoon Kim

LLM workflows, which coordinate structured calls to individual LLMs/agents to a chieve a particular goal, offer a promising path towards building powerful AI s ystems that can tackle diverse tasks. However, existing approaches for building such workflows generally rely on human-crafted pipelines and prompts, which pres ents a substantial bottleneck in real world deployment. How can we automaticall y induce LLM-based agents and workflows in a data-driven way? This paper descri bes a simple data-driven approach for automatically inducing agents and LLM wor kflows. We formulate workflow induction as a bilevel optimization problem: an outer loop which optimizes a high-level sketch of the workflow (in particular h ow the LLM calls should be structured), and an inner loop which optimizes each i ndividual LLM call one-by one. Both loops are optimized with "textual gradients" where for the inner loop we optimize each component in a modular way through "b ackpropagating" textual gradients layer-by-layer. We find that LLM workflows dis covered through our FlowBot (work**flow** induction through **b**ilevel **o**pti mization and **t**extual gradients) approach performs competitively against stro ng baselines that make use of human-crafted or generated workflows.

Vision-Language-Action Pretraining from Large-Scale Human Videos

Hao Luo, Yicheng Feng, Wanpeng Zhang, Sipeng Zheng, Ye Wang, Haoqi Yuan, jiazhen g liu, Chaoyi Xu, Haiweng Xu, Qin Jin, Zongqing Lu

Existing Vision-Language-Action (VLA) models struggle with complex manipulation tasks requiring high dexterity and generalization, primarily due to their relian ce on synthetic data with significant sim-to-real gaps or limited teleoperated d emonstrations.

To address this bottleneck, we propose leveraging human hands as a manipulator t
emplate, capitalizing on the rich dexterity and scalability present in web data
of human manipulation. Our approach introduces physical instruction tuning, a no
vel training paradigm that combines large-scale VLA pretraining from human video
s, perspective spatial alignment for reasoning in a unified physical space, and
post-training adaptation in physical environments. Additionally, we introduce a
part-level motion tokenization method that achieves millimeter-level reconstruct
ion accuracy to model precise hand trajectories serving as scalable motion primi
tives. To support our paradigm, we develop a comprehensive data curation pipeli
ne that integrates heterogeneous sources into a large-scale dataset with million
s of motion-based instructional instances. Empirically, our model demonstrates s
uperior performance in hand motion generation and instruction following, adherin
g to favorable scaling laws with respect to model and data sizes. Importantly, w
e demonstrate promising capabilities to robotic dexterous manipulation, validati
ng the effectiveness of bridging the human-robot embodiment gap. Project page is
 available at \url{https://research.beingbeyond.com/being-h0}.

Routing and Reasoned Evaluation with Large Language Models
Guiyao Tie, Tianyao Luo, Xueyang Zhou, Chaoran Hu, Yunhong He, Junran Wu, Yuanfa
n Yao, Pan Zhou, Lichao Sun
Large language models (LLMs) are increasingly used to provide automated assessme
nt signals for evaluating model-generated outputs. However, practical deployment
 faces three persistent challenges: heterogeneous reliability across models, sub
stantial latency and token costs, and the absence of principled strategies for a
llocating evaluation resources. We introduce R^{2}Eval, a routing-aware automate
d assessment framework that formulates evaluation as a resource allocation and a
ggregation problem rather than relying on a single monolithic evaluator. R^{2}Ev
al combines difficulty-aware routing with reasoned evaluation signals to dynamic
ally select evaluator models on a per-instance basis under explicit accuracy, la
tency, and cost constraints. Our study makes three contributions. First, we cons
truct six difficulty-aware datasets spanning both reasoning-intensive (mathemati
cs, logic, code) and non-reasoning (knowledge, roleplay, writing) tasks, with hu
man-annotated reference assessments. Second, we provide a systematic empirical a
nalysis of how reasoning traces produced by different evaluator models correlate
 with assessment outcomes, revealing substantial variance and systematic mismatc
hes across difficulty regimes. Third, we develop and evaluate both offline and o
nline routing strategies that adaptively allocate evaluation queries, achieving
substantially improved accuracy–efficiency trade-offs compared to static baselin
es. Experiments across 19 language models demonstrate that R^{2}Eval significant
ly reduces evaluation cost and latency while maintaining close alignment with hu
man assessments. These results highlight the importance of routing-aware automat
ed assessment and establish R^{2}Eval as a scalable and reliable framework for l
arge-scale model evaluation.

Effective MoE-based LLM Compression by Exploiting Heterogeneous Inter-Group Expe
rts Routing Frequency and Information Density
Zhendong Mi, Yixiao Chen, Pu Zhao, Xiaodong Yu, Hao Wang, Yanzhi Wang, Shaoyi Hu
ang
Mixture-of-Experts (MoE) based Large Language Models (LLMs) have achieved superi
or performance, yet the massive memory overhead caused by storing multiple exper
t networks severely hinders their practical deployment. Singular Value Decomposi
tion (SVD)-based compression has emerged as a promising post-training technique;
 however, most existing methods apply uniform rank allocation or rely solely on
static weight properties. This overlooks the substantial heterogeneity in expert
 utilization observed in MoE models, where frequent routing patterns and intrins
ic information density vary significantly across experts. In this work, we propo
se RFID-MoE, an effective framework for MoE compression by exploiting heterogene
ous Routing Frequency and Information Density. We first introduce a fused metric
 that combines expert activation frequency with effective rank to measure expert
 importance, adaptively allocating higher ranks to critical expert groups under

a fixed budget. Moreover, instead of discarding compression residuals, we recons
truct them via a parameter-efficient sparse projection mechanism to recover lost
 information with minimal parameter overhead. Extensive experiments on represent
ative MoE LLMs (e.g., Qwen3, DeepSeekMoE) across multiple compression ratios dem
onstrate that RFID-MoE consistently outperforms state-of-the-art methods like Mo
BE and $\mathbf{D}^2$-MoE. Notably, RFID-MoE achieves a perplexity of 16.92 on P
TB with the Qwen3-30B model at a 60% compression ratio, reducing perplexity by o
ver 8.0 compared to baselines, and improves zero-shot accuracy on HellaSwag by a
pproximately 8%.

LayerT2V: A Unified Multi-Layer Video Generation Framework
Guangzhao Li, Kangrui Cen, Baixuan Zhao, Yi Xin, Siqi Luo, Guangtao Zhai, Lei Zh
ang, Xiaohong Liu
Text-to-video generation has advanced rapidly, but existing methods typically ou
tput only the final composited video and lack editable layered representations,
limiting their use in professional workflows. We propose \textbf{LayerT2V}, a un
ified multi-layer video generation framework that produces multiple semantically
 consistent outputs in a single inference pass: the full video, an independent b
ackground layer, and multiple foreground RGB layers with corresponding alpha mat
tes. Our key insight is that recent video generation backbones use high compress
ion in both time and space, enabling us to serialize multiple layer representati
ons along the temporal dimension and jointly model them on a shared generation t
rajectory. This turns cross-layer consistency into an intrinsic objective, impro
ving semantic alignment and temporal coherence. To mitigate layer ambiguity and
conditional leakage, we augment a shared DiT backbone with LayerAdaLN and layer-
aware cross-attention modulation. LayerT2V is trained in three stages: alpha mas
k VAE adaptation, joint multi-layer learning, and multi-foreground extension. We
 also introduce \textbf{VidLayer}, the first large-scale dataset for multi-layer
 video generation. Extensive experiments demonstrate that LayerT2V substantially
 outperforms prior methods in visual fidelity, temporal consistency, and cross-l
ayer coherence. To facilitate future research, we will release the code and data
set upon publication.

Spherical Procrustes Alignment for Reliable Medical Audio Diagnosis
Ying Wang, Guoheng Huang, Chan-Tong Lam, Xiaochen Yuan
Reliable medical audio diagnosis requires models that are both accurate and hone
st about their uncertainty. However, fine-tuned models on small, imbalanced data
sets often become overconfident due to norm bias, where predictions rely on feat
ure magnitude rather than semantic alignment. The Equiangular Tight Frame (ETF)
provides a theoretical optimum for class separation and is effective for imbalan
ced and calibration tasks due to its maximal angular separability and geometric
fairness, but existing ETF-based methods perform poorly on noisy medical data be
cause gradient rotation is unstable and fixed ETFs cannot adapt to drifting prot
otypes. To address this, we propose Spherical Procrustes Alignment (SPA), which
combines spherical constraints with dynamic ETF alignment. SPA uses a Spherical
branch to eliminate norm bias via normalization and a Geometric branch to adapt
features and align a fixed ETF with drifting prototypes via dynamic Procrustes a
lignment, while a self-alignment mechanisms fuses the two branches to jointly op
timize logits. Experiments on ICBHI 2017 and CirCor DigiScope show that SPA achi
eves state-of-the-art performance and transforms pre-trained models into reliabl
e and efficient clinical tools without extra inference cost.

Block Rotation is All You Need for MXFP4 Quantization
Yuantian Shao, Peisong Wang, Yuanteng Chen, Chang Xu, Zhihui Wei, Jian Cheng
Large language models (LLMs) have achieved remarkable success, but their rapidly
 growing scale imposes prohibitive costs in memory, computation, and energy. Pos
t-training quantization (PTQ) is a promising solution for efficient deployment,
yet achieving accurate W4A4 quantization remains an open challenge. While most e
xisting methods are designed for INT4 formats, the emergence of MXFP4—a new FP4
format with various hardware support (NVIDIA, AMD, Intel)—raises questions about

the applicability of current techniques. In this work, we present a unified empirical comparison of representative PTQ methods under the MXFP4 format. Through systematic evaluation, we find that methods like GPTQ consistently deliver strong performance, whereas rotation-based approaches, which are widely used in state-of-the-art approaches, suffer from severe incompatibility with MXFP4. We further provide the first in-depth analysis of this conflict, tracing its root to a fundamental mismatch between MXFP4's PoT (power-of-two) block scaling and the redistribution of outlier energy via global rotation. Building on this insight, we propose a simple yet effective block rotation strategy that adapts rotation-based methods to MXFP4, leading to substantial accuracy improvements across diverse LLMs. Our findings not only offer clear guidance for practitioners but also set a foundation for advancing PTQ research under emerging low-precision formats.

Contrastive Representation Regularization for Vision-Language-Action Models
Taeyoung Kim, Jimin Lee, Myungkyu Koo, Dongyoung Kim, Kyungmin Lee, Changyeon Kim, Younggyo Seo, Jinwoo Shin
Vision-Language-Action (VLA) models have shown strong capabilities in robot manipulation by leveraging rich representations from pre-trained Vision-Language Models (VLMs).
However, their representations arguably remain suboptimal, lacking sensitivity to robotic signals such as control actions and proprioceptive information.
To address the issue, we introduce Robot State-aware Contrastive Loss (RS-CL), a simple and effective representation regularization for VLA models, designed to bridge the gap between VLM representations and robotic signals.
In particular, RS-CL aligns the representations more closely with the robot's proprioceptive states by using relative distances between the states as soft supervision.
Complementing the original action prediction objective, RS-CL enhances control-relevant representation learning, while being lightweight and fully compatible with standard VLA training pipelines.
Our empirical results demonstrate that RS-CL substantially improves the performance of state-of-the-art VLA models; it pushes the prior art to 69.7% achieving the state-of-the-art performance on the RoboCasa-Kitchen benchmark, and boosts success rates from 45.0% to 58.3% on challenging real-robot manipulation tasks.
****

Improving CLIP Adaptation by Breaking Tail Alignment for Source-Free Cross-Domain Few-Shot Learning
Shuai Yi, Yixiong Zou, Yuhua Li, Ruixuan Li
Vision-Language Models (VLMs) such as CLIP demonstrate strong zero-shot generalization, but their performance significantly degrades in cross-domain scenarios with scarce target-domain training data (Cross-Domain Few-Shot Learning, CDFSL).
In this paper, we focus on the target-domain few-shot finetuning in the CLIP-based CDFSL task. Prevailing finetuning paradigms uniformly align all image patch tokens with their corresponding textual embeddings. However, we find a counterintuitive phenomenon: actively pushing away certain low-similarity image tokens, termed "tail tokens", from their textual embeddings consistently improves target-domain performance. We delve into this phenomenon and provide a novel interpretation: under great domain shifts and scarce training data, the model can hardly extract semantic information from visual inputs; therefore, the common belief of alignment is valid only for tokens already containing sufficient semantic information; for tail tokens, forcing the alignment would lead to excessive overfitting to the scarce training, while breaking the alignment is more useful. Motivated by this, we propose Adaptive Tail-Head Alignment (ATHA), a novel fine-tuning strategy for CLIP that transforms the conventional uniform alignment paradigm to an adaptive alignment paradigm, with both alignment strengthening and weakening.
Extensive experiments on four challenging CDFSL benchmarks validate our state-of-the-art performance. Our code is available at https://github.com/shuaiyi308/ATHA.

Compositional Planning with Jumpy World Models

Jesse Farebrother, Matteo Pirotta, Andrea Tirinzoni, Marc G Bellemare, Alessandro Lazaric, Ahmed Touati

The ability to plan with temporal abstractions is central to intelligent decision-making. Rather than reasoning over primitive actions, we study agents that compose pre-trained policies as temporally extended actions, enabling solutions to complex tasks that no constituent alone can solve. Such compositional planning remains elusive as compounding errors in long-horizon predictions make it challenging to estimate the visitation distribution induced by sequencing policies. Motivated by the geometric policy composition framework introduced in Thakoor et al. (2022), we address these challenges by learning predictive models of multi-step dynamics --- so-called jumpy world models --- that capture state occupancies induced by pre-trained policies across multiple timescales in an off-policy manner. Building on Temporal Difference Flows (Farebrother et al., 2025), we enhance these models with a novel consistency objective that aligns predictions across timescales, improving long-horizon predictive accuracy. We further demonstrate how to combine these generative predictions to estimate the value of executing arbitrary sequences of policies over varying timescales. Empirically, we find that compositional planning with jumpy world models significantly improves zero-shot performance across a wide range of base policies on challenging manipulation and navigation tasks, yielding, on average, a 200% relative improvement over planning with primitive actions on long-horizon tasks.

CountsDiff: A diffusion model on the natural numbers for generation and imputation of count-based data

Renzo Soatto, Anders Hoel, Greycen Ren, Shorna Alam, Stephen Bates, Nikolaos P. Daskalakis, Caroline Uhler, Maria Skoularidou

Diffusion models have excelled at generative tasks for both continuous and token-based domains, but their application to discrete ordinal data remains underdeveloped. We present CountsDiff, a diffusion framework designed to model distributions on the natural numbers. CountsDiff extends the Blackout diffusion framework by simplifying its formulation through a direct parameterization in terms of a survival probability schedule and an explicit loss weighting. This introduces flexibility through design parameters with direct analogues in existing diffusion modeling frameworks.

Beyond this reparameterization, CountsDiff introduces features from modern diffusion models, previously absent in counts-based domains, including continuous-time training, classifier-free guidance, and churn/remasking reverse dynamics that allow non-monotone reverse trajectories.

We propose an initial instantiation of CountsDiff and validate it on natural image datasets (CIFAR-10, CelebA), exploring the effects of the introduced design parameters in a complex, well-studied, and interpretable data domain. We then highlight biological count assays as a natural use case, evaluating CountsDiff on single-cell RNA-seq imputation in fetal and heart cell atlases. Remarkably, we find that even this simple instantiation matches or surpasses the performance of a state-of-the-art discrete generative model and leading scRNA-seq imputation methods, while leaving substantial headroom for further gains through optimized design choices in future work.

Information dynamics and Memory in Neural Networks through Fisher Information Diffusion

Haodong Qin, Tatyana Sharpee

We present a general theoretical framework for analyzing how information about past inputs is encoded in recurrent networks into evolving dynamics rather than being represented as convergence to static attractors. Using dynamic mean-field theory and diffusion from physics, we derive a Fisher information diffusion operator that links network connectivity structure to the time-resolved propagation of information across interacting subpopulations. The analysis reveals that operating near criticality (spectral radius near one) is necessary but not sufficient for reliable memory in structured or non-normal recurrent networks; effective information retention requires alignment between input–output structure and stabl

e dynamical subspaces. The theory yields principled initialization rules that ba
lance stability and sensitivity, mitigating vanishing and exploding gradients. E
xperiments on the copy task and sequential MNIST show faster convergence and hig
her accuracy than standard random initialization. Together, these results provid
e both principled design guidelines for recurrent networks and new theoretical i
nsight into how information can be preserved over time in their dynamics.

Benchmarking and Enhancing VLM for Compressed Image Understanding
Zifu Zhang, Tongda Xu, Siqi Li, Shengxi Li, Yue Zhang, Mai Xu, Yan Wang
With the rapid development of Vision-Language Models (VLMs) and the growing dema
nd for their applications, efficient compression of the image inputs has become
increasingly important. Existing VLMs predominantly digest and understand high-b
itrate compressed images, while their ability to interpret low-bitrate compresse
d images has yet to be explored by far. In this paper, we introduce the first co
mprehensive benchmark to evaluate the ability of VLM against compressed images,
varying existing widely used image codecs and diverse set of tasks, encompassing
over one million compressed images in our benchmark. Next, we analyse the sourc
e of performance gap, by categorising the gap from a) the information loss durin
g compression and b) generalisation failure of VLM. We visualize these gaps with
concrete examples and identify that for compressed images, only the generalizat
ion gap can be mitigated. Finally, we propose a universal VLM adaptor to enhance
model performance on images compressed by existing codecs. Consequently, we dem
onstrate that a single adaptor can improve VLM performance across images with va
rying codecs and bitrates by 10%-30%. We believe that our benchmark and enhancem
ent method provide valuable insights and contribute toward bridging the gap betw
een VLMs and compressed images. The source code is available at https://github.c
om/bblgbr/CompressVLMBench.

Sharp Concentration Bounds for Bundle-Valued Statistics on Manifolds
Swagatam Das, Vaclav Snasel
Many geometric statistics and manifold learning pipelines routinely produce obse
rvations---such as tangent vectors or local frames---whose natural home is a var
ying family of fibers attached to different points of a base manifold, rather th
an a single shared vector space. Forming empirical averages requires transportin
g these observations to a common reference fiber, introducing curvature- and hol
onomy-driven effects absent from classical concentration theory. We develop a no
n-asymptotic concentration theory for such transported empirical means, deriving
finite-sample, dimension-free Hoeffding- and Bernstein-type bounds via sharp Hi
lbert-space inequalities. When shortest paths to the reference point are non-uni
que, transport becomes path-dependent and introduces a deterministic holonomy bi
as; we isolate and quantify this bias through bundle curvature and loop geometry
, with sharp closed-form formulas for the tangent bundle of a round sphere. The
resulting bias--variance decomposition separates the stochastic fluctuation deca
ying at the classical $n^{-1/2}$ rate in sample size n, from a curvature-drive
n error floor that no amount of additional data can eliminate; minimax lower bou
nds confirm both terms are unavoidable. We further establish a robust median-of-
means estimator achieving optimal rates under heavy tails, and a central limit t
heorem in the reference fiber. Controlled experiments on the sphere validate all
theoretical predictions.

Adaptive Symmetry Discovery for Dynamical System Identification
Behrooz Tahmasebi, Melanie Weber
Dynamical systems model trajectory data generated by an underlying fixed dynamic
s, with applications ranging from biological systems to flows in physics. The id
entification problem concerns recovering the parameters of a system from observe
d trajectories. In many scientific settings, however, dynamical systems are not
generic and instead exhibit symmetries imposed by physical laws, formalized as e
quivariance with respect to a group action. In this work, we study \emph{adaptiv
e symmetry discovery} for dynamical system identification and address how a syst
em can be identified from a single trajectory when it is equivariant with respec

t to an unknown symmetry group. To this end, we first show that for known symmetries, the system can be identified from a significantly shorter single trajectory than in the generic setting, and we precisely characterize this improvement. We then consider the automatic symmetry discovery setting, proposing a method to learn the symmetry group directly from a single trajectory and incorporate it into the identification procedure, achieving the same optimal trajectory length as in the known-symmetry case. Our analysis relies on tools from group representation theory and the expander properties of Cayley graphs, and may be of independent interest for the study of symmetries in dynamical systems.
****
Relative Entropy Estimation in Function Space: Theory and Applications to Trajectory Inference
CHAO WANG, Luca Nepote, Giulio Franzese, Pietro Michiardi
Trajectory Inference (TI) seeks to recover latent dynamical processes from snapshot data, where only independent samples from time-indexed marginals are observed.
In applications such as single-cell genomics, destructive measurements make path-space laws non-identifiable from finitely many marginals, leaving held-out marginal prediction as the dominant but limited evaluation protocol.
We introduce a general framework for estimating the Kullback–Leibler divergence (KL) between probability measures on function space, yielding a tractable, data-driven estimator that is scalable to realistic snapshot datasets.
We validate the accuracy of our estimator on a benchmark suite, where the estimated functional KL closely matches the analytic KL.
Applying this framework to synthetic and real scRNA-seq datasets, we show that current evaluation metrics often give inconsistent assessments, whereas path-space KL enables a coherent comparison of trajectory inference methods and exposes discrepancies in inferred dynamics, especially in regions with sparse or missing data. These results support functional KL as a principled criterion for evaluating trajectory inference under partial observability. Code available here: https://github.com/eurecom-probai/functional-kl.

Adaptive DNA Sequence Modeling via Synergistic Plasticity Units
Binghao Liu, Wenzheng Zhao, Zhijie Zheng, Fei Gu
Effective DNA modeling demands the integration of complex patterns such as local motifs, long-range dependencies, and periodic signals. Yet, architectures like CNNs, Transformers, and SSMs are hindered by static or time-domain-exclusive designs, which limit their representational flexibility. To address this, we introduce the **Synergistic Plasticity Unit (SPU)**, a scalable architecture that achieves multi-level plasticity through three synergistic layers. Specifically, SPU integrates a *Locus Plasticity Layer* (LPL) to capture fine-grained local motifs via token-specific convolution operations, while utilizing a *Domain Plasticity Layer* (DPL) to form multi-domain global features by concurrently modeling sequential (time) and spectral (frequency) patterns. Furthermore, it incorporates a *Saliency Plasticity Layer* (SPL) to optimize information flow through dual-axis saliency scoring. Supported by theoretical analysis, extensive empirical validation, and in-depth biological interpretation, this unified design enables SPU to achieve state-of-the-art performance with quasi-linear complexity, establishing a robust and principled paradigm for DNA modeling.
****
Ophiuchus: Incentivizing Tool-augmented ''Think with Images'' for Joint Medical Segmentation, Understanding and Reasoning
Yankai Jiang, Yujie Zhang, Peng Zhang, Wenjie Li, Yichen Li, Jintai Chen, Xiaoming Shi, Shihui Zhen
Recent medical MLLMs have made significant progress in generating step by step textual reasoning chains. However, they still struggle with complex clinical tasks that necessitate dynamic and iterative focusing on fine-grained visual regions. To close this gap, we introduce Ophiuchus, a versatile, tool-augmented framework that equips an MLLM to (i) decide when fine-grained visual evidence is needed, (ii) determine where to probe and ground within the medical image, and (iii) s

eamlessly weave the relevant sub-image content back into an interleaved, multimodal chain of thought for precise segmentation and diagnosis. Ophiuchus moves beyond mere tool-calling by tightly fusing the MLLM’s inherent grounding and reasoning capabilities with external tools, enabling more accurate and trustworthy decisions.
The core of our method is a three-stage training strategy: cold-start SFT for basic tool selection; self-reflection fine-tuning to strengthen decision revision; and agentic tool reinforcement learning to elicit sophisticated, expert-like diagnostic behaviors. Extensive experiments show that Ophiuchus consistently outperforms both closed-source and open-source SOTA methods across diverse medical benchmarks, including VQA, detection, and reasoning-based segmentation. Our project code is available at https://github.com/SII-zyj/Ophiuchus.

FAB: A First-Order AB-based Gradient Algorithm for Distributed Bilevel Optimization over Time-Varying Directed Graphs
Yaoshuai Ma, Xiao Wang, Wei Yao, Jin Zhang
Distributed optimization over time-varying directed graphs has shown promising performance in addressing challenges posed by complex communication constraints in real-world scenarios.
In many practical settings, however, the direct application of distributed optimization algorithms encounters additional difficulties, most notably hyperparameter tuning, which our empirical observations suggest can be effectively mitigated by integrating bilevel optimization.
Motivated by these findings, we study distributed bilevel optimization over time-varying directed networks, a problem that remains largely unexplored due to the compounded challenges arising from consensus bias in dynamic unbalanced communication and the nested optimization structure.
In this work, we propose a fully first-order distributed gradient-based algorithm that integrates the Push–Pull (also known as AB) communication strategy with a value function-based penalty method and establish its non-asymptotic convergence properties.
Notably, a simplified variant of our analysis framework for nonconvex single-level distributed optimization establishes a convergence rate for the Push–Pull algorithm, thereby resolving an open question concerning its convergence over time-varying directed graphs.
Experiments across hyperparameter tuning, data hyper-cleaning, and reinforcement learning validate FAB's effectiveness and efficiency.

VenusBench-Mobile: A Challenging and User-Centric Benchmark for Mobile GUI Agents with Capability Diagnostics
Yichen Gong, Zhuohan Cai, Sunhao Dai, Yuqi Zhou, Zhangxuan Gu, Changhua Meng, Shuheng Shen
Existing online benchmarks for mobile GUI agents remain largely app-centric and task-homogeneous, failing to reflect the diversity and instability of real-world mobile usage. To this end, we introduce VenusBench-Mobile, a challenging online benchmark for evaluating general-purpose mobile GUI agents under realistic, user-centric conditions.
VenusBench-Mobile builds two core evaluation pillars: defining what to evaluate via user-intent-driven task design that reflects real mobile usage, and how to evaluate through a capability-oriented annotation scheme for fine-grained agent behavior analysis.
Extensive evaluation of state-of-the-art mobile GUI agents reveals large performance gaps relative to prior benchmarks, indicating that VenusBench-Mobile poses substantially more challenging and realistic tasks and that current agents remain far from reliable real-world deployment.
Diagnostic analysis further shows that failures are dominated by deficiencies in perception and memory, which are largely obscured by coarse-grained evaluations.
Moreover, even the strongest agents exhibit near-zero success under environment variations, highlighting their brittleness in realistic settings.

Based on these insights, we believe VenusBench-Mobile provides an important step ping stone toward robust real-world deployment of mobile GUI agents. Code and da ta are available at https://github.com/inclusionAI/UI-Venus/tree/VenusBench-Mobi le.

On the Learnability of Test-Time Adaptation: A Recovery Complexity Perspective
Zhi Zhou, Ming Yang, Shi-Yu Tian, Kun-Yang Yu, Lan-Zhe Guo, Yu-Feng Li
Test-time adaptation (TTA) aims to adapt models to maintain reliable performance on non-stationary test streams without requiring labeled data. Despite its empi rical success, the learnability of TTA under non-stationary streams remains unex plored. A key challenge is the lack of a principled theoretical framework that s imultaneously aligns with the TTA objective and captures both continuously evolv ing distribution shifts and intrinsic information constraints. To address this g ap, we propose the first theoretical framework for studying the learnability of TTA and introduce (ϵ,δ)-Recovery Complexity and (ϵ,ρ)-TTA Learnability. Recovery complexity measures the post-shift time needed to mai ntain excess risk below a target level with high probability, and is further ext ended to TTA learnability, which measures the long-term reliability of TTA. With in this framework, we introduce a novel discrete surrogate for non-stationary te st streams, enabling a unified and tractable analysis of both gradual and abrupt shifts. We derive order-wise matching lower and upper bounds on recovery comple xity, revealing fundamental limits of TTA and an intrinsic adaptivity-informatio n trade-off. These results provide unified learnability guarantees for TTA that complement regret-based analyses.

Softplus Attention with Re-weighting Boosts Length Extrapolation in Large Langua ge Models
Bo Gao, Michael W. Spratling, Letizia Gionfrida
Large language models have achieved remarkable success in recent years,
primarily due to self-attention. However,
traditional Softmax attention suffers from numerical instability and
reduced performance as the number of inference tokens increases. This work
addresses these issues by proposing a new design principle for attention,
viewing it as a two-stage process.
The first stage (normalisation) refines standard attention by replacing Soft max with the more numerically stable Softplus followed by
l_{1}-normalisation. Furthermore, we introduce a dynamic scale factor base d on invariance entropy. We show that this novel attention mechanism outperforms conventional Softmax attention, and state-of-the-art Softmax-free alternatives.
Our second proposal is to introduce a second processing stage (sharpening) w hich consists of a
re-weighting mechanism that
amplifies significant attentional weights while diminishing weaker ones. Thi s enables
the model to concentrate more effectively on relevant tokens, mitigating
the attention sink phenomenon, and fundamentally improving length extrapolat ion.
This novel, two-stage, replacement for self-attention is shown to ensure num erical stability and dramatically
improve length extrapolation, maintaining a nearly constant validation
loss at 16$\times$ the training length while achieving superior results on
challenging long-context retrieval tasks and downstream benchmarks.
Furthermore, symbolic regression experiments demonstrate that our method ena bles
models to recover Newton's gravitational law from orbital trajectory sequenc es,
providing evidence that appropriate attention mechanisms are crucial for
foundation models to develop genuine physical world models. Our code is
available at https://github.com/iminfine/freeattn .

Semantic-Aware Motion Encoding for Topology-Agnostic Character Animation
Zongye Zhang, Yuzhuo Cui, Qingjie Liu, Yunhong Wang
Generalizing motion representation across diverse characters remains challenging due to significant topological variations in skeletal structures across datasets and species, which hinder the development of scalable generative models. To bridge this gap, we propose a Semantic-Aware Topology-Agnostic framework that learns a unified latent manifold shared by disparate species. Unlike methods relying on fixed hierarchies or rigid padding strategies, our approach leverages a semantic modulation mechanism to align functional joint correspondences, thereby decoupling motion from topology. This design enables the construction of a continuous, generative-friendly motion space from large-scale, unaligned raw BVH data. Experiments on human and animal datasets demonstrate that our framework achieves high-fidelity reconstruction and supports downstream text-to-motion tasks. Notably, the model enables zero-shot cross-species retargeting without paired data. Code and demos are available at https://github.com/zzysteve/SATA

Uncovering Latent Communication Patterns in Brain Networks via Adaptive Flow Routing
Tianhao Huang, Guanghui Min, Zhenyu Lei, Aiying Zhang, Chen Chen
Unraveling how macroscopic cognitive phenotypes emerge from microscopic neuronal connectivity remains one of the core pursuits of neuroscience. To this end, researchers typically leverage multi-modal information from structural connectivity (SC) and functional connectivity (FC) to complete downstream tasks. Recent methodologies explore the intricate coupling mechanisms between SC and FC, attempting to fuse their representations at the regional level. However, while these approaches do incorporate useful neuroscientific observations, they predominantly operate at a topological or architectural level and lack a principled formulation grounded in neural communication dynamics. Consequently, they are limited in quantifying how information is actually routed between neural regions, and thus cannot fully explain why SC and FC exhibit dynamic states of both coupling and heterogeneity. In this paper, we formulate multi-modal fusion through the lens of neural communication dynamics and propose the Adaptive Flow Routing Network (AFR-Net), a physics-informed framework that models how structural constraints give rise to functional communication patterns, enabling interpretable discovery of critical neural pathways. Extensive experiments demonstrate that AFR-Net significantly outperforms state-of-the-art baselines. The code is available at \url{https://github.com/Skyyyy0920/AFR-Net}.

Hide&Seek: Learning to Explain in an End-to-End Differentiable Network
Tal Ellinson, Hadi Mohasel Afshar, Sally Cripps
Instance-wise feature selection is a valuable tool for interpreting labeled data and the predictions of black-box models. In contrast to global feature selection techniques, instance-wise methods dynamically identify important features for each instance. A growing number of methods learn a *selector*, which identifies important features, and a *predictor*, which uses these to make predictions. However, these pioneering methods face challenges including information leakage and lack of differentiability, which can slow training. In this paper, we present Hide&Seek, an end-to-end differentiable model for instance-wise feature selection. We jointly learn feature selection and prediction under a single objective without information leakage. Hide&Seek outperforms existing state-of-the-art models across a range of experiments and is fast to train. We achieve this by reformulating feature removal as a differentiable operation where instead of discretely removing features, we replace a proportion of each feature. Training is further stabilized via a parsimony-weight annealing framework.

Entropy-aware Span-Constrained Optimal Transport for Robust Cross-Tokenizer Knowledge Distillation
Zhi-Ping Liu, Simiao Li, Wei Li, Hanting Chen, Jie Hu, Hua-Lei Yin, Xinghao Chen
Existing Cross-Tokenizer Knowledge Distillation (CTKD) methods can fail to outperform simple supervised fine-tuning when vocabulary overlap is low due to severe

alignment noise. We identify this phenomenon as the **``Low-Overlap negative transfer regime''**. To overcome this, we propose **Entropy-aware Span-Constrained Optimal Transport (E-SCOT)**, a robust framework that treats distillation as a sparse transport problem built upon a vocabulary-agnostic ground metric. Unlike prior OT approaches that incur quadratic costs via dense sequence-level optimization, E-SCOT employs span-anchored lexical alignment to construct a deterministic, locality-preserving support set in linear time with respect to sequence length. Furthermore, we introduce R\'enyi-entropy adaptive reweighting to dynamically concentrate the distillation budget on informative positions exhibiting significant uncertainty-profile gaps. Extensive experiments demonstrate that E-SCOT achieves state-of-the-art performance across diverse model families, effectively eliminating negative transfer even in challenging low-overlap scenarios.

Secure Multi-agent Reinforcement Learning for Service Systems with Affinity and Byzantine Nodes: Stability Analysis and Protection Design
Yifan Jiang, Pan Jiasheng, Mengtian Li, Li Jin
We study decentralized multi-agent reinforcement learning (MARL) for networked service systems with affinity in the presence of Byzantine nodes. The way that a server processes a job depends on an affinity state that captures the correlation between the job and the server. Each node learns a local control policy via an actor-critic algorithm with linear function approximation over inherently unbounded space of traffic states, while exchanging parameter information with neighbors through a communication graph. A set of Byzantine agents can exploit the unbounded state space to compromise the consensus mechanism, destabilizing both learning and queuing processes. To address this vulnerability, we propose a resilient consensus-based MARL algorithm, which mitigates adversarial parameter manipulation and guarantees traffic stability under mild assumptions. We prove that the cooperative agents’ policies converge almost surely to a bounded neighborhood of a stationary solution of the global objective. We demonstrate the effectiveness and generality of the proposed framework in several representative service systems, including semantic routing for large language model serving, distributed polling in cloud computing, and smart manufacturing logistics.

Are Object-Centric Representations Better at Compositional Generalization?
Ferdinand Kapl, Amir Mohammad Karimi Mamaghan, Maximilian Seitzer, Karl Henrik Johansson, Carsten Marr, Stefan Bauer, Andrea Dittadi
Compositional generalization, the ability to reason about novel combinations of familiar concepts, is fundamental to human cognition and a critical challenge for machine learning.
Object-centric (OC) representations, which encode a scene as a set of objects, are often argued to support such generalization, but systematic evidence in visually rich settings is limited. We introduce a Visual Question Answering benchmark across three controlled visual worlds (CLEVRTex, Super-CLEVR, and MOVi-C) to measure how well vision encoders, with and without object-centric biases, generalize to unseen combinations of object properties. To ensure a fair and comprehensive comparison, we carefully account for training data diversity, sample size, representation size, downstream model capacity, and compute. We use DINOv2 and SigLIP2, two widely used vision encoders, as the foundation models and their OC counterparts. Our key findings reveal that (1) OC approaches are superior in harder compositional generalization settings; (2) original dense representations surpass OC only on easier settings and typically require substantially more downstream compute; and (3) OC models are more sample efficient, achieving stronger generalization with fewer images, whereas dense encoders catch up or surpass them only with sufficient data and diversity. Overall, object-centric representations offer stronger compositional generalization when any one of dataset size, training data diversity, or downstream compute is constrained.

MEG-XL: Data-Efficient Brain-to-Text via Long-Context Pre-Training
Dulhan Jayalath, Oiwi Parker Jones
Clinical brain-to-text interfaces are designed for paralysed patients who cannot

provide extensive training recordings. Pre-training improves data-efficient generalisation by learning statistical priors across subjects, but these priors critically depend on context. While natural speech might unfold gradually over minutes, most methods pre-train with only a few seconds of context. Thus, we propose *MEG-XL*, a model pre-trained with 2.5 minutes of MEG context per sample, 5-300× longer than prior work, and equivalent to 191k tokens, capturing extended neural context. Fine-tuning on the task of word decoding from brain data, MEG-XL matches supervised performance with a fraction of the data (e.g. 1hr vs 50hrs) and outperforms brain foundation models. We find that models pre-trained with longer contexts learn representations that transfer better to word decoding. Our results indicate that long-context pre-training helps exploit extended neural context that other methods unnecessarily discard.

Physiology as Language: Translating Respiration to EEG during Sleep

Kaiwen Zha, Chao Li, Hao He, Peng Cao, Tianhong Li, Ali Mirzazadeh, Ellen Zhang, Jong Woo Lee, Yoon Kim, Dina Katabi

This paper introduces a novel cross-physiology translation task: synthesizing sleep electroencephalography (EEG) from respiration signals. To address the significant complexity gap between the two modalities, we propose a waveform-conditional generative framework that preserves fine-grained respiratory dynamics while constraining the EEG target space through discrete tokenization. Trained on over 28,000 individuals, our model achieves a 7% Mean Absolute Error in EEG spectrogram reconstruction. Beyond reconstruction, the synthesized EEG supports downstream tasks with performance comparable to ground truth EEG on age estimation (MAE 5.0 vs. 5.1 years), sex detection (AUROC 0.81 vs. 0.82), and sleep staging (Accuracy 0.84 vs. 0.88), significantly outperforming baselines trained directly on breathing. Finally, we demonstrate that the framework generalizes to contactless sensing by synthesizing EEG from wireless radio-frequency reflections, highlighting the feasibility of remote, non-contact neurological assessment during sleep.

What Reward Structure Enables Efficient Sparse-Reward RL? A Proof-of-Concept with Policy-Aware Matrix Completion

Ibne Farabi Shihab, Sanjeda Akter, Anuj Sharma

Sparse-reward reinforcement learning typically focuses on exploration, but we ask: can structural assumptions about reward functions themselves accelerate learning? We introduce Policy-Aware Matrix Completion (PAMC), which exploits low-rank structure in reward matrices while correcting for policy-induced sampling bias. PAMC combines three key components: a low-rank plus sparse reward model, inverse propensity weighting to handle Missing-Not-At-Random (MNAR) data, and confidence-gated abstention that falls back to intrinsic exploration when uncertain. We provide finite-sample theory showing that completion error scales as $O(\sigma\sqrt{r(|\mathcal{S}|+|\mathcal{A}|)/\text{ESS}})$ where ESS is the effective sample size under policy overlap κ. PAMC achieves strong empirical results at 10M steps (a sample-efficiency comparison): 4100$\pm$250 return vs. 200$\pm$50 for DrQ-v2 on Montezuma's Revenge, 78\% vs. 65\% success rate on MetaWorld-50, and 15\% improvement over CQL on D4RL datasets. The method maintains 8\% computational overhead while providing calibrated confidence intervals (95\% empirical coverage). When structural assumptions are violated, PAMC gracefully degrades through increased abstention rather than catastrophic failure. Our approach demonstrates that reward structure exploitation can complement traditional exploration methods in sparse-reward domains.

EvoMAS: Heuristics in the Loop—Evolving Smarter Agentic Workflows

Yangbo Wei, Zhen Huang, Ronghao Xu, Hong Wang, WEI W. XING

The rapid development of Large Language Models has driven Multi-Agent Systems (MAS) growth, but constructing efficient MAS requires labor-intensive manual design. Current automation methods generate templated agents, use monolithic optimization, and ignore task complexity gradients. This paper presents Evolutionary MAS (EvoMAS), a biologically-inspired framework whose core is a dynamic and diverse repertoire of seven evolutionary strategies---six biologically-inspired operato

rs (3 exploration, 3 exploitation) together with a custom operator for domain-specific transformations---driven by adaptive strategy selection. These are complemented by role-level evolution that refines agent specialization and collaboration patterns, and a curriculum-guided schedule that evolves workflows from simple to complex tasks with cross-stage stability. Additionally, to resolve the contradiction between the inefficiency of pure evolution and the rigidity of manual design, we introduce the *Cyber Creator*, a meta-controller that conducts heuristics-in-the-loop learning by formulating and reflectively updating evolutionary rules and strategies. Evaluations demonstrate that EvoMAS consistently outperforms existing methods across multiple domains while maintaining cost efficiency, with roles evolving from homogeneous actors to specialized reasoning ensembles.

Hard-Constrained Graph Generation with Discrete-Projection Diffusion

Xuesong Zhang, Haifeng Sun, Qi Qi, Shengkuan Li, Yuhao Li, Tianyi Kou, Zirui Zhuang, Bo He, Jianxin Liao, Jingyu Wang

Diffusion models have achieved remarkable success in graph generation, but enforcing hard constraints on generated graphs remains challenging, limiting their deployment in constraint-critical applications. Existing approaches either fail to guarantee strict constraint satisfaction or are limited to narrow constraint types, lacking the flexibility to handle diverse constraint specifications. To address this challenge, we exploit the discrete structure of graphs, which allows hard constraints to be formulated as symbolic reasoning problems. Building on this insight, we propose NSPSG, a framework that integrates unconstrained diffusion models with discrete projection operators. NSPSG employ an SMT (Satisfiability Modulo Theories)-based projector to ensure that the generated graphs strictly satisfy constraints while remaining within the training data distribution. To further accelerate generation, we employ a supervised auto-regressive neural projector to approximate the symbolic reasoning process. Across heterogeneous constraints and various graph generation datasets, NSPSG achieves 99%-100% validity rates, demonstrating state-of-the-art performance. Notably, for a complex non-linear constraint, it improves data validity by up to 43% and reaches 99% validity while maintaining comparable generation efficiency.

****

Beyond Buffer Limits: Energy-Based Data Reassembly for Continual Learning

Zhenyi Wang, Yixuan Sun, Yue Wang, Zhong Chen, Heng Huang

Continual learning (CL) aims to acquire new knowledge from a non-stationary data stream while retaining performance on previously learned tasks. Memory-based replay methods mitigate catastrophic forgetting by storing and revisiting past samples, but their effectiveness is fundamentally constrained by limited memory capacity, as each stored example represents only a single data instance. In this work, we propose data reassembly for CL, a new paradigm that significantly increases memory efficiency by reassembling composite replay samples from existing training data. Instead of storing raw training examples, we partition the current task training data into elementary patches and dynamically reassemble them into coherent replay instances through an energy-based optimization framework. The proposed objective jointly enforces semantic compatibility with target labels and global consistency among assembled patches. To make this optimization tractable, we derive an efficient variational inference algorithm that constructs a compact yet diverse set of reassembled samples for replay. Extensive theoretical analysis and experiments across multiple CL benchmarks demonstrate that data reassembly consistently outperforms existing memory-based approaches, achieving stronger retention of past knowledge while maintaining competitive computational efficiency.

Implicit Action Chunking for Smooth Continuous Control

Bosun Liang, Shuo Pei, Zirui Chen, Chuanzhi Fan, Chen Sun, Yuankai Wu, Huachun Tan, Yong Wang

Reinforcement learning often produces high-frequency oscillatory control signals that undermine the safety and stability required for physical deployment. Explicit action chunking addresses this by predicting fixed-horizon trajectories but

scales the policy output dimension proportionally with the horizon length, leading to optimization difficulties and incompatibility with standard step-wise interaction. To overcome these challenges, this paper proposes Dual-Window Smoothing (DWS), an implicit action chunking framework for smooth continuous control. Unlike explicit methods, DWS enforces temporal coherence without expanding the action space. It uses a dual-window design: an execution window that ensures physical smoothness through deterministic modulation, and a value window that aligns temporal-difference targets over the horizon to correct critic bias caused by open-loop execution. DWS also includes a lightweight actor-side temporal regularizer based on first-order action differences to promote global continuity. This design effectively bridges the gap between temporal abstraction and reactive step-wise control. Experiments on benchmarks including the DeepMind Control Suite and industrial energy management tasks show that DWS outperforms state-of-the-art (SOTA) baselines. In complex vision-based autonomous driving tasks, DWS achieves smoother control, safer behavior with reduced jitter, and attains a 100% success rate.

****

Expand Neurons, Not Parameters

Linghao Kong, Inimai Subramanian, Yonadav G Shavit, Micah Adler, Dan Alistarh, Nir N Shavit

This work demonstrates how increasing the number of neurons in a network without increasing its total number of non-zero parameters improves performance. We show that this gain corresponds with a decrease in interference between multiple features that would otherwise share the same neurons. On symbolic Boolean tasks, splitting each neuron into sparser sub-neurons with knowledge of the clauses systematically reduces polysemanticity metrics and yields higher task accuracy. Notably, even random splits of neuron weights approximate these gains, indicating that reduced collisions, not precise assignment, are a primary driver. Consistent with the superposition hypothesis, the benefits of this framework grow with increasing interference: when polysemantic load is high, accuracy improvements are the largest. Transferring these insights to more realistic models, including classifiers over CLIP embeddings, convolutional neural networks, and deeper multilayer networks, we find that widening networks while maintaining a constant non-zero parameter count consistently increases accuracy. These results identify an interpretability-grounded mechanism to leverage width against superposition, improving performance without increasing the number of non-zero parameters. Such a direction is well matched to modern accelerators, where memory movement of non-zero parameters, rather than raw compute, is often a dominant bottleneck.

****

Uncertainty-Constrained Trustworthiness for Graph Learning

Chunhui Zhang, Pengqi Li, Lizhong Ding, Ye Yuan, Peng Yang, Changsheng Li, Guoren Wang

Graph learning has been increasingly deployed in critical and sensitive domains, raising pressing demands for trustworthiness-robustness, fairness, and beyond. However, these properties are often undermined by various perturbations, which induce distributional uncertainty and compromise the trustworthiness of graph learning. To address this, we propose DICT, a novel framework that models distributional uncertainty to achieve trustworthy graph learning. Specifically, DICT formulates a unified optimization objective that captures perturbation-induced distributional shifts in graph topology, node features, and labels, and minimizes the worst-case risk over the uncertainty set. However, directly optimizing this objective in its primal form leads to an infinite-dimensional problem. To make this problem tractable, we integrate strong duality and local Lipschitz continuity of the loss, reformulating the objective as a finite-dimensional min-max problem. We focus on robustness and fairness as primary instantiations of DICT because they are not only critical in real-world applications, but also provide transferable modeling principles for broader trustworthiness objectives. By formulating fairness in the form of an uncertainty set, DICT pioneers unified robustness and fairness within a single optimization framework. Extensive experiments across diverse benchmarks and backbones demonstrate that DICT consistently improves both

robustness and fairness, validating the effectiveness and adaptability of the DICT framework.
****
Credibility-Aware Weighting Federated Causal Discovery for Time Series
Jiegang Xu, Fuyuan CAO, Jiye Liang
Federated causal discovery for time series is becoming increasingly important in many application domains. In practice, intervention policies on each client often change over time, causing the local underlying causal mechanisms to drift rather than remain fixed. Moreover, different sampling frequencies across clients yield incompatible time scales in the observed data, making the resulting local causal graphs naturally heterogeneous and difficult to aggregate consistently. Accordingly, we propose Fed-CAW, a Credibility-Aware Weighting Federated causal discovery framework for time series. Specifically, we define edge-level credibility scores that quantify per-edge reliability by summarizing (i) within-client temporal stability across windows and (ii) cross-client temporal consistency after mapping heterogeneous sampling frequencies onto a unified time scale. We then aggregate privatized edge statistics under differential privacy, treating credibility scores as weights to recover a global causal graph while preserving personalized local structures without sharing raw data. Theoretically, we demonstrate the rationale for the unified time scale mapping and establish rigorous differential privacy guarantees. Experimental results on synthetic and real-world datasets demonstrate the effectiveness of our proposed method.
****
ProEval: Proactive Failure Discovery and Efficient Performance Estimation for Generative AI Evaluation
Yizheng Huang, Wenjun Zeng, Aditi Kumaresan, Zi Wang
Evaluating generative AI models is increasingly resource-intensive due to slow inference, expensive raters, and a rapidly growing landscape of models and benchmarks. We propose ProEval, a proactive evaluation framework that leverages transfer learning to efficiently estimate performance and identify failure cases. ProEval employs pre-trained Gaussian Processes (GPs) as surrogates for the performance score function, mapping model inputs to metrics such as the severity of errors or safety violations. By framing performance estimation as Bayesian quadrature (BQ) and failure discovery as superlevel set sampling, we develop uncertainty-aware decision strategies that actively select or synthesize highly informative inputs for testing. Theoretically, we prove that our pre-trained GP-based BQ estimator is unbiased and bounded. Empirically, extensive experiments on reasoning, safety alignment, and classification benchmarks demonstrate that ProEval is significantly more efficient than competitive baselines. It requires 8–65x fewer samples to achieve estimates within $\pm1\%$ of the ground truth, while simultaneously revealing more diverse failure cases under a stricter evaluation budget. Our open-sourced code and data can be found at https://github.com/google-deepmind/proeval.
****
Label-Guided Representation Learning for Incomplete Multi-View Multi-Label Classification
Yang Li, Quanjiang Li, Tingjin Luo
Incomplete multi-view multi-label classification addresses scenarios where views and labels are partially missing. While existing methods treat labels solely as supervision signals, they overlook the semantic structure inherent in partial annotations. We propose Label-Guided Representation Learning (LGRL) that systematically exploits label semantics as structural priors throughout learning. Our framework constructs a semantic-informed mixture prior via learnable category prototypes to guide representation extraction, and introduces category-specific conditional posteriors where prototypes act as Bayesian experts for multi-view fusion. We further derive a principled label-driven information bottleneck objective balancing reconstruction sufficiency with cross-view consistency, enabling category-conditional reasoning. Extensive experimental results demonstrate the effectiveness of LGRL across benchmark datasets as well as real-world applications in sports analytics and medical imaging.

Measuring and Mitigating Post-Hoc Rationalization in Reverse Chain-of-Thought Generation
Guangyue Peng, Zongchao Chen, Wen Luo, Yuntao Wen, Wei Li, Ruixiang Feng, Ran Le, Chen Yang, Zhenwei An, Yang Song, Tao Zhang, Houfeng Wang
Reverse Chain-of-Thought Generation (RCG) synthesizes reasoning traces from query-answer pairs, but it risks producing post-hoc rationalizations: when models can see the answer during generation, the answer serves as a cognitive anchor that shapes the entire explanation. We formalize this phenomenon through a three-level measurement hierarchy: lexical, entropic, and probabilistic anchoring, which capture surface artifacts, entropy dynamics, and latent answer dependence, respectively. We analyze semantic suppression, the intuitive mitigation strategy that instructs models to ignore the answer, and find that it is counterproductive: while it reduces lexical overlap, it paradoxically increases entropic and probabilistic anchoring. We attribute this failure to active monitoring of the forbidden answer, which inadvertently deepens dependence on it. To break this cycle, we propose Structural Skeleton-guided Reasoning (SSR), whose core contribution is to replace answer suppression with structural decoupling: SSR first generates an answer-invariant functional skeleton and then uses it as a content-neutral target for full trace generation. Experiments across open-ended reasoning benchmarks show that SSR consistently mitigates anchoring, and that Distilled SSR (SSR-D), a distillation variant that internalizes skeleton-guided reasoning from teacher-generated traces, achieves up to 10\% improvement over suppression baselines while mitigating out-of-distribution (OOD) degradation.
****
Structured Multi-modal Graph Disentanglement for Psychiatric Diagnosis
Hongyu Shi, Kaizhong Zheng, Wensheng Zhai, Shuai Jiang, Badong Chen, Liangjun Chen
Multi-modal neuroimaging-based psychiatric diagnosis must integrate cross-modal agreement with modality-specific complementarity, yet in real multi-site cohorts these signals are frequently entangled with site- and cohort-dependent correlations, yielding shortcut-driven predictions and limited interpretability. We propose Structured Multi-modal Graph Disentanglement (SMGD), which explicitly factorizes multi-modal graph representations into four components with distinct roles: shared diagnostic evidence, complementary diagnostic evidence, incidental cross-modal agreement, and modality-specific non-robust correlations, with the former two forming the diagnostic core and the latter two suppressed as shortcuts. SMGD is realized as geometry-driven structure learning: under a mild distributional assumption, we develop mini-batch estimable surrogate regularizers that shape subspace organization and cross-modal relations, enforcing semantic consistency through relational geometry rather than centroid coincidence while suppressing confounded dependencies. Experiments on large multi-site datasets show improved in-domain diagnosis and more reliable cross-dataset generalization in the presence of a Modality Gap, without relying on expert-crafted diagnostic biomarkers.
****
GeoPT: Scaling Physics Simulation via Lifted Geometric Pre-Training
Haixu Wu, Minghao Guo, Zongyi Li, Zhiyang Dou, Mingsheng Long, Kaiming He, Wojciech Matusik
Neural simulators promise efficient surrogates for physics simulation, but scaling them is bottlenecked by the prohibitive cost of generating high-fidelity training data. Pre-training on abundant off-the-shelf geometries offers a natural alternative, yet faces a fundamental gap: supervision on static geometry alone ignores dynamics and can lead to negative transfer on physics tasks. We present GeoPT, a unified pre-trained model for general physics simulation based on lifted geometric pre-training. The core idea is to augment geometry with synthetic dynamics, enabling dynamics-aware self-supervision without physics labels. Pre-trained on over one million samples, GeoPT consistently improves industrial-fidelity benchmarks spanning fluid mechanics for cars, aircraft, and ships, and solid mechanics in crash simulation, reducing labeled data requirements by 20-60% and accelerating convergence by 2$\times$. These results show that lifting with syntheti

c dynamics bridges the geometry-physics gap, unlocking a scalable path for neura l simulation and potentially beyond. Code is available at https://github.com/Phy sics-Scaling/GeoPT.

AppWorld-UL: Benchmarking Diverse Agent-User Interactions for Tool-Use
Junzhi Chen, Harsh Trivedi, Jane Pan, Michael JQ Zhang, Tejas Srinivasan, Niranj an Balasubramanian, Ashish Sabharwal
Tool-use agents that address day-to-day digital tasks such as ordering groceries must not only operate applications, but also interact with the user, e.g., to a sk clarification questions, prompt for confirmation, and inform the user when th e instruction is infeasible. However, current benchmarks for evaluating agent-us er interactions do not capture the diversity of such interactions. Further, they operate in small environments with few, often non-state-changing, APIs. To addr ess this gap, we introduce AppWorld-UL, a ``user-in-the-loop'' benchmark of 516 challenging tasks requiring diverse agent-user interactions. Building upon the A ppWorld framework with 9 popular simulated apps like Amazon and Spotify, we syst ematically modify original tasks to introduce ambiguities and constraints that n ecessitate various types of agent-user interaction. User behavior is simulated b y an LLM prompted to respond with carefully designed knowledge boundaries, offer ing more reliable simulation than the unconstrained or overly rigid alternatives used in prior work. Our evaluation reveals that a state-of-the-art LLM, Claude Opus 4.7, achieves only 48.6\% success on AppWorld-UL, and only 35.7\% on the ha rder, compositional subset. On the stricter, scenario-level metric, compositiona l task performance drops to only 21.3\%. Our analysis reveals that correct user-interaction is crucial for success. This demonstrates the benchmark's difficulty and its potential to advance research on user-in-the-loop tool-use agents.

UnHype: CLIP-Guided Hypernetworks for Dynamic LoRA Unlearning
Piotr Wójcik, Maksym Petrenko, Wojciech Gromski, Przemys■aw Spurek, Maciej Zieba
Recent advances in large-scale diffusion models have intensified concerns about their potential misuse, particularly in generating realistic yet harmful or soci ally disruptive content. This challenge has spurred growing interest in effectiv e machine unlearning, the process of selectively removing specific knowledge or concepts from a model without compromising its overall generative capabilities. Among various approaches, Low-Rank Adaptation (LoRA) has emerged as an effective and efficient method for fine-tuning models toward targeted unlearning. However , LoRA-based methods often exhibit limited adaptability to concept semantics and struggle to balance removing closely related concepts with maintaining generali zation across broader meanings. Moreover, these methods face scalability challen ges when multiple concepts must be erased simultaneously. To address these limit ations, we introduce UnHype, a framework that incorporates hypernetworks into si ngle- and multi-concept LoRA training. The proposed architecture can be directly

 plugged into Stable Diffusion as well as modern flow-based text-to-image models , where it demonstrates stable training behavior and effective concept control. During inference, the hypernetwork dynamically generates adaptive LoRA weights b ased on the CLIP embedding, enabling more context-aware, scalable unlearning. We evaluate UnHype across several challenging tasks, including object erasure, cel ebrity erasure, and explicit content removal, demonstrating its effectiveness an d versatility.
****
Bilinear Bandits with Partially Observable Features
Wooseong Cho, Ji Hyeong Park, Min-hwan Oh
We study bilinear bandits with partially observable features on both the user an d item sides. In each of T rounds, the learner selects a user--item pair and o bserves only the reward for the chosen pair. The reward model is bilinear in the user and item features with an unknown parameter matrix. Existing work commonly reduces this problem to a linear bandit via Kronecker-product features, increas ing dimensionality and losing bilinear structure.

    We propose \texttt{BiRoLF}, an algorithm robust to latent features, which di rectly leverages the bilinear structure without such linearization. It augments observed feature spaces on both sides with orthogonal complement bases and emplo ys doubly robust (DR) estimation to impute rewards for unselected pairs, constru cting matrix-valued pseudo-rewards. We estimate the effective parameter using a bilinear DR-Lasso estimator, which promotes sparsity in components orthogonal to observed features.

    \texttt{BiRoLF} achieves a $\tilde{O}(\sqrt{(d_x + d_{h_x})(d_y + d_{h_y}) T })$ regret bound, where d_x and d_y are observable feature dimensions, and $ d_{h_x}$ and d_{h_y} denote effective orthogonal-complement dimensions.

    By exploiting the induced block-diagonal Gram structure, \texttt{BiRoLF} per forms an exact blockwise update that preserves the full DR-Lasso objective. Nume rical experiments show strong regret performance and computational gains.

Echoes within the Reasoning: Stealthy and Effective Watermarking via Chain of T hought
Jiacheng Lu, Yiming Li, Tao Song, Weijian Wang, Wenjie Qu, Haibing Guan, Jiaheng Zhang
Large Language Models with Chain-of-Thought reasoning capabilities represent val uable intellectual property, yet existing black-box watermarking methods often t rade robustness for reasoning fidelity by perturbing final answers or relying on fragile trigger patterns. We propose BiCoT, a watermarking framework that embed s ownership signals into the internal geometry of reasoning traces by aligning h igh-saliency structural anchors with a private signature subspace while regulari zing ordinary control tokens to preserve semantic capacity. This design couples the watermark with reasoning-relevant representations, making removal difficult without disrupting the features that support coherent reasoning. To enable verif ication under model theft and representation drift, we introduce Robust Subspace Registration(RSR), a Top-k logprob-based black-box verifier that uses sentine l tokens to calibrate systematic shifts in the output distribution. Experiments show that BiCoT preserves reasoning fidelity across diverse complex reasoning ta sks while achieving robust detection under fine-tuning, quantization, model-leve l perturbations, and adaptive output-level attacks across in-domain and out-of-d istribution settings.

Fast Mixing Steady-State Control in Markov Decision Processes
Federico Corso, Marco Mussi, Alberto Maria Metelli
Stability is a property of fundamental importance in real-world systems. Althoug h it has been widely studied and well understood in *control theory* (CT) for de terministic systems, it is largely overlooked in stochastic systems such as *Mar kov decision processes* (MDPs). In this paper, we aim to translate the steady-st ate control problem, well established in CT, where the goal is to synthesize a c ontroller with prescribed asymptotic stability properties, into the MDP framewor k.

To this end, we propose the novel *fast-mixing steady-state* (FMSS) problem. Given an ergodic MDP and a target steady-state distribution, the objective is to synthesize a Markovian policy that induces this distribution with the fastest possible convergence rate. Addressing this problem requires controlling the spectral properties of the induced *Markov chain* (MC) transition matrix, which generally leads to non-convex programs. Thus, we derive a tractable surrogate objective that leads to a convex program, whose properties we study in terms of approximation quality, feasibility, and computational complexity.

We then move to the learning setting and propose an "offline" sample-based algorithm for FMSS (FMSS-SV), designed for tabular MDPs, in which the environment’s transition model is estimated from data. We quantify the impact of transition model estimation errors on both the objective value and the learned policy, and provide a finite-sample complexity analysis.

ExpertWeaver: Unlocking the Inherent MoE in Dense LLMs with GLU Activation Patterns

Ziyu Zhao, Tong Zhu, Xin Yu, Zhi Zhang, Tiantian Fan, Jinluan Yang, Kun Kuang, zhongyu wei, Fei Wu, Yu Cheng

Mixture-of-Experts (MoE) scales model capacity while preserving computational efficiency through sparse expert activation.
However, training high-quality MoEs from scratch is prohibitively expensive.
An alternative is to convert pretrained dense models into sparse MoEs.
Existing dense-to-MoE methods fall into two categories: \textbf{dynamic structural pruning} that converts dense models into MoEs with moderate sparsity to balance performance and efficiency, and \textbf{downcycling} approaches that use pretrained dense models to initialize highly sparse MoEs. However, existing methods break the intrinsic activation patterns within dense models, leading to suboptimal expert construction.
In this work, we argue that the Gated Linear Unit (GLU) provides a natural blueprint for dense-to-MoE conversion. We show that the fine-grained neuron-wise activation patterns of GLU reveal a coarse-grained structure, uncovering an inherent MoE architecture composed of consistently activated universal neurons and dynamically activated specialized neurons.
Leveraging this discovery, we introduce ExpertWeaver, a training-free framework that partitions neurons according to their activation patterns and constructs shared experts and specialized routed experts with layer-adaptive configurations.
Experiments demonstrate that ExpertWeaver outperforms existing methods, both as a training-free dynamic structural pruning technique and as a downcycling strategy for MoE initialization.

Learning Credal Ensembles via Distributionally Robust Optimization

Kaizheng Wang, Ghifari Adam Faza, Fabio Cuzzolin, Siu Lun Chau, David Moens, Hans Hallez

Credal predictors are epistemic-uncertainty-aware models that produce a convex set of probabilistic predictions. They provide a principled framework for quantifying predictive epistemic uncertainty (EU) and have been shown to improve model robustness across a range of settings. However, most state-of-the-art (SOTA) methods primarily define EU as disagreement induced by random training initializations, which mainly reflects sensitivity to optimization randomness rather than uncertainty from more substantive sources. In response, we formulate EU as disagreement between models trained under different degrees of relaxation of the i.i.d. assumption between the training and test distributions. Building on this idea, we propose *CreDRO*, which learns an ensemble of plausible models via distributionally robust optimization. As a result, CreDRO captures EU arising not only from training randomness but also from informative disagreement due to potential train–test distribution shifts. Empirically, CreDRO consistently outperforms SOTA credal approaches on downstream tasks, including out-of-distribution detection on extensive benchmarks and selective classification in medical settings.

Unveiling the Visual Counting Bottleneck in Vision-Language Models

Xingzhou Pang, Yifan Hou, Junling Wang, Mrinmaya Sachan
While Large Vision-Language Models (VLMs) excel at interpolation, they suffer catastrophic failures in systematic generalization, most notably in visual counting beyond training distributions. In this work, we investigate this extrapolation bottleneck by deconstructing visual counting into three cognitive stages: object individuation, abstract magnitude representation, and symbolic decoding. Using a controlled environment of synthetic Go game boards, we isolate the specific mechanism of failure. Contrary to the hypothesis that models suffer from perceptual errors, we demonstrate via linear probing that visual backbones maintain robust, linearly separable representations of quantity well into the extrapolation regime. Furthermore, models retain latent magnitude awareness, successfully performing comparative reasoning on quantities they fail to enumerate. We pinpoint the collapse to the Symbolic Decoding stage, where the model fails to project valid visual magnitudes onto discrete tokens. Our findings support a Fractured Magnitude Hypothesis: VLMs fail to acquire a Universal Number Space, instead learning disjoint, modality-specific statistical manifolds that prevent cross-modal grounding for unseen pairings. We validate our findings on the state-of-the-art foundation model, suggesting that bridging the extrapolation gap requires inductive priors that enforce unified magnitude representations rather than simply scaling training data.
****

Calibrating Uncertainty for Zero-Shot Adversarial CLIP
Wenjing Lu, Zerui Tao, Yuning Qiu, Dongping Zhang, Yang Yang, Qibin Zhao
CLIP delivers strong zero-shot classification but remains highly vulnerable to adversarial attacks. Prior adversarial fine-tuning work primarily matches predicted logits between clean and adversarial examples, which overlooks uncertainty calibration and may degrade the zero-shot generalization. A common expectation in reliable uncertainty estimation is that predictive uncertainty should increase as inputs become more difficult or shift away from the training distribution. However, we frequently observe the opposite in the adversarial setting: perturbations not only degrade accuracy but also suppress uncertainty, leading to severe miscalibration and over-confidence. This reveals a critical reliability gap beyond robustness. To bridge this gap, we propose an adversarial fine-tuning objective for CLIP considering both accuracy and uncertainty. By reparameterizing CLIP outputs as the concentration parameters of a Dirichlet distribution, we propose a unified representation that captures relative semantic structure and confidence magnitude. This enables holistic distribution alignment under perturbations, moving beyond single-logit anchoring and restoring calibrated uncertainty. Experiments across multiple zero-shot benchmarks demonstrate that our method significantly improves uncertainty calibration and achieves competitive adversarial robustness while preserving clean accuracy.

Offline Two-Player Zero-Sum Markov Games with KL Regularization
Claire Chen, Yuheng Zhang, Xinyu Liu, Zixuan Xie, Shuze Daniel Liu, Nan Jiang
We study the problem of learning Nash equilibria in offline two-player zero-sum Markov games. While existing approaches often rely on explicit pessimism to address distribution shift, we show that KL regularization alone suffices to stabilize learning and guarantee convergence. We first introduce Regularized Offline Sequential Equilibrium (ROSE), a theoretical framework that achieves a fast $ \widetilde{\mathcal{O}}(1/n) $ convergence rate under *unilateral concentrability*, improving over the standard $ \widetilde{\mathcal{O}}(1/\sqrt{n}) $ rates in unregularized settings. We then propose Sequential Offline Self-play Mirror Descent (SOS-MD), a practical model-free algorithm based on least-squares value estimation and iterative self-play updates. We prove that the last iterate of SOS-MD attains the same $ \widetilde{\mathcal{O}}(1/n) $ statistical rate up to a vanishing optimization error of order $ \widetilde{\mathcal{O}}(1/\sqrt{T}) $ in the number of self-play iterations T.

Reducing Per-Sample Harm in Stochastic Optimization
Apostolos Avranas

Modern optimizers combine gradients from the current mini-batch with historical optimization state, such as momentum or adaptive moments. While highly effective, aggregating across the batch and incorporating this history can produce parameter updates that increase the loss of individual samples. We term this effect *harm* and formalize the parameter update as an optimization problem that explicitly minimizes the conflicting impact of both batch averaging and past optimization state on current data. Because the exact formulation is intractable, we introduce a highly efficient proxy. We first reduce the problem's dimensionality to the batch size, and then drastically cut memory and speed bottlenecks by successfully restricting the optimization to the last linear layer. This hinges on the unexpected finding that *this layer alone reliably captures the second-order statistics of the per-sample gradients*. The resulting surrogate problem integrates readily into standard optimizers like SGD and AdamW, and can be solved using a small number of GPU-friendly iterations. Crucially, the method exhibits *favorable scaling properties*, as the relative computational overhead shrinks as the model size or input grows. Experiments on image classification benchmarks confirm *reduced per-sample interference* and *improved generalization*.

Fair-FedMOE: Group-Fair One-Shot Federated Learning via Prototype-Guided Experts for Medical Imaging Analysis

Lingzhao Meng, Shuai Guo, Weishan Zhang, Zengxiang Li, Han Yu, Nan Liu, Daniel Shu Wei Ting, Yuru Liu, Shudong Wang, Tao Chen

Group fairness can ensure equitable performance across different demographic subgroups for medical image analysis. However, the current fine-tuned foundation models (FMs) exhibit significant subgroup disparity. One-shot federated learning (OFL) can potentially mitigate this by leveraging cross-institutional data diversity within a single communication round. However, heterogeneous distributions across medical institutions may cause OFL local models to diverge severely, resulting in parameter conflicts that amplify disparity upon aggregation. To address these challenges, we propose Fair-FedMOE, a group-fair OFL framework for medical FMs. During local training, Fairness-aware Expert Routing leverages learnable prototypes to route samples to group-specific experts, enabling subgroup-specialized learning to capture group-specific features without inter-group interference. During model aggregation, Prototype-guided Differential Aggregation computes personalized weights based on prototype similarity and applies differentiated aggregation strategies to filter conflicting updates. We propose RES-AUC, a Rawlsian justice-inspired metric based on worst-group performance that remains stable as groups increase. Extensive experiments on retinal and chest X-ray datasets with multiple FMs demonstrate consistent fairness gains without sacrificing accuracy.

Beyond VLM-Based Rewards: Diffusion-Native Latent Reward Modeling

Gongye Liu, Bo Yang, Zhi Yida, Zhizhou Zhong, Lei Ke, Didan Deng, Han Gao, Yongxiang Huang, Kaihao Zhang, Hongbo Fu, Wenhan Luo

Preference optimization for diffusion models relies on reward functions that are both discriminative and computationally efficient. Vision-Language Models (VLMs) have emerged as powerful reward providers. However, their computation and memory cost can be substantial, and optimizing a latent diffusion generator through a pixel-space reward introduces a domain mismatch that complicates alignment.

In this paper, we propose DiNa-LRM, a diffusion-native latent reward model that formulates preference learning directly on noisy diffusion states. Our method introduces a noise-calibrated Thurstone likelihood with diffusion-noise-dependent uncertainty. DiNa-LRM leverages a pretrained latent diffusion backbone with a timestep-conditioned reward head, and supports inference-time noise ensembling, providing a diffusion-native mechanism for test-time scaling and robust rewarding. Across image alignment benchmarks, DiNa-LRM substantially outperforms existing diffusion-based reward baselines and achieves competitive performance compared to state-of-the-art VLMs while maintaining a substantially lower computational cost. In preference optimization, we demonstrate that DiNa-LRM improves preference optimization dynamics, enabling faster and more resource-efficient model alignm

Prioritize the Process, Not Just the Outcome: Rewarding Latent Thought Trajectories Improves Reasoning in Looped Language Models
Jonathan Williams, Olga Russakovsky, Esin Tureci
Looped Language Models (LoopLMs) perform multi-step latent reasoning prior to token generation and outperform conventional LLMs on reasoning benchmarks at smaller parameter budgets. However, attempts to further improve LoopLM reasoning with reinforcement learning have failed—standard objectives such as Group Relative Policy Optimization (GRPO) only assign credit to the final latent state, creating a fundamental mismatch with the model's internal computation. To resolve this, we introduce RLTT (Reward Latent Thought Trajectories), a reinforcement learning framework which distributes reward across the full latent reasoning trajectory. RLTT provides dense, trajectory-level credit assignment without relying on external verifiers and can directly replace GRPO with negligible overhead. Across extensive experiments with Ouro-1.4B/2.6B-Thinking under identical training and inference conditions, RLTT yields statistically significant improvements over GRPO on challenging mathematical reasoning benchmarks, improving mean accuracy over MATH-500, AIME24/26, and BeyondAIME by +5.8\% on the 1.4B scale, and +10.9\% on the 2.6B scale. Despite being trained exclusively on mathematics, RLTT also transfers effectively to non-mathematical reasoning benchmarks, demonstrating the effectiveness of trajectory-level credit assignment for reinforcement learning in LoopLMs. Code is available at https://github.com/jonwill8/RLTT.git.

Spatial Deconfounder: Interference-Aware Deconfounding for Spatial Causal Inference
Ayush Khot, Miruna Oprescu, Maresa Schröder, Ai Kagawa, Xihaier Luo
Causal inference in spatial domains faces two intertwined challenges: (1) unmeasured spatial factors, such as weather, air pollution, or mobility, that confound treatment and outcome, and (2) interference from nearby treatments that violate standard no-interference assumptions. While existing methods typically address one by assuming away the other, we show they are deeply connected: *interference reveals structure* in the latent confounder. Leveraging this insight, we propose the **Spatial Deconfounder**, a two-stage method that reconstructs a substitute confounder from local treatment vectors using a conditional variational autoencoder (C-VAE) with a spatial prior, then estimates causal effects with a flexible outcome model. We show that this enables nonparametric identification of direct and spillover effects under weak assumptions—without multiple treatment types or a known latent-field model. Empirically, we extend SpaCE, a benchmark suite for spatial confounding, to include treatment interference, and show that the Spatial Deconfounder consistently improves effect estimation across real-world environmental health and social science datasets. By turning local interference into a multi-cause proxy for latent spatial confounding, our framework advances robust causal inference for spatial data.

Hom-PGD$^+$: Fast Reparameterized Optimization over Non-convex Ball-Homeomorphic Set
Chenghao Liu, Enming Liang, Minghua Chen
We study optimization over non-convex constraint sets that are homeomorphic to a ball, encompassing important problem classes such as star-shaped sets that frequently arise in machine learning and engineering applications. We propose **Hom-PGD$^+$**, a learning-based and projection-efficient first-order method that efficiently solves such problems without requiring expensive projection or optimization oracles. Our approach leverages an invertible neural network (INN) to learn the homeomorphism between the non-convex constraint set and a unit ball, transforming the original problem into an equivalent ball-constrained optimization where projections admit efficient solutions. We establish that Hom-PGD$^+$ achieves an $\mathcal{O}(\epsilon^{-2})$ convergence rate to an ($\epsilon + \mathcal{O}(\sqrt{\epsilon_{\text{inn}}})$)-approximate stationary solution, where ϵ_{inn} denotes the homeomorphism learning error. This rate significantl

y improves upon existing methods for optimization over non-convex sets, while ma intaining a per-iteration complexity of only $\mathcal{O}(W)$ for W INN parame ters. Extensive experiments, including QCQP, chance-constrained power-system opt imization, and non-uniform adversarial attacks, demonstrate that Hom-PGD$^+$ ach ieves competitive solution quality while delivering speedups of up to one order of magnitude.

Large-Scale Molecular Dynamics Simulations: Direct Interatomic Modeling with Dil ated Message Passing
Haokai Hong, Wanyu Lin, KC Tan
Large-scale molecular dynamics simulations are essential in understanding chemic al and biological processes, necessitating the accurate and efficient modeling o f interatomic interactions. Existing learning-based methods are generally based on message passing mechanisms; they are either not scalable or too coarse to off er accurate modeling. We propose a new message passing framework that can effect ively and efficiently model interatomic interactions for simulating large-scale molecular dynamics at full atomic resolution. Specifically, our framework is sta cked with a sequence of message passing neural network layers, each realizing th e message passing over a distinct and dilated star-structured path. These star-s tructured paths are constructed progressively along dilated regions to capture t he distance-dependent interactions. The crux of our framework is that it resolve s the problem of dense interatomic interactions of large-scale atomic systems wi th sparser and region-based message passing graphs. We evaluate the framework on four benchmarks: MD22 (molecules with 42–370 atoms), Chignolin (a 166-atom prot ein featuring diverse conformations), the AdK dataset (a protein trajectory with up to 3,000 atoms), and the MISATO dataset (over 10,000 heterogeneous protein-l igand complexes with systems up to 40,000 atoms). Comprehensive evaluations demo nstrate that our approach delivers state-of-the-art performance overall across v arious benchmarks. The code is provided on [Github](https://github.com/WanyuGrou p/ICML2026-DKMP).

Representation Drift Compensation: A Near-Zero Inference Cost Enhancement for LL M Decomposition
Xinhao Huang, You-Liang Huang, Zeyi Wen
While low-rank decomposition offers potential for reducing LLM parameters, maint aining the original capabilities remains a significant challenge. In this work, we identify and formalize a key overlooked issue in LLM decomposition: \textit{r epresentation drift}. We show that approximation errors introduced by decomposit ion propagate and amplify non-linearly through the deep layers of the transforme r architecture, progressively distorting internal representations and degrading downstream performance. To mitigate this, we introduce a conceptually simple but principled compensation mechanism, named ``Decomper'', that operates by suppres sing error at its source. By learning to align the output distribution of decomp osed transformer blocks with their original counterparts, our method effectively counteracts representation drift, achieving notable performance recovery with n ear-zero inference overhead. Extensive experiments in OPT, LLaMA-2/3, and Qwen e xhibit remarkable improvements. For instance, on LLaMA-3-8B and OPT-13B at 40\% compression, perplexity is reduced by more than 70\% while reasoning task accura cy improves by over 10\%. Our code is available at this \href{https://github.com /xinhaoH/SVD-Compen}{URL}.

Certifying Capabilities from Finite Tests: When Is It Possible?
Changlong Wu, Jin Sima, Wojciech Szpankowski
Modern foundation models are evaluated through broad capabilities such as arithm etic, reasoning, safety, and robustness, yet it remains unclear in a principled sense when *finite tests* can meaningfully certify such claims. We develop a rig orous theory of capability evaluation by formalizing evaluation as inference ove r a task family and asking when guarantees over the full family can be inferred from a strict subset of tests. We analyze two canonical regimes. In stochastic m ulti-environment evaluation, we characterize when uniform certification is possi

ble across multiple environments and show that the sample complexity is governed by a χ^2-radius of the environment family, yielding near-optimal evaluation protocols with matching lower bounds under a natural overlap condition. In contrast, for worst-case, rule-like capabilities, we establish fundamental impossibility results. Even for structured model classes such as Boolean circuits of bounded size, black-box evaluation cannot, in general, certify global properties. Together, these results provide a principled framework for understanding when finite evaluation can and cannot certify capabilities.

Group-wise Data Ordering: Enhancing Instruction Tuning of Large Language Models via Embedding Proximity

Yiwen Ye, Boyuan Jiang, Xiaobin Hu, Shengzhi Wang, Xiaozhong Ji, Jinghao Lin, Deli Yu, Jiale Chen, Kai WU, Haihua Yang, Yong Xia

Instruction tuning (IT) is a central mechanism for aligning large language models (LLMs) with user intent. In practice, randomly shuffling the training set is a simple yet surprisingly strong baseline. However, it overlooks latent structure, such as domain and reasoning depth, and thus interleaves heterogeneous objectives, which can induce gradient conflicts and diminish effective optimization progress. To this end, we propose **EP-Order**, an embedding-proximity-based data-ordering paradigm for IT of LLMs. Unlike previous paradigms that derive order from **per-example** scores, EP-Order explicitly accounts for **inter-sample** correlations by operating in representation space. EP-Order trains a warm-up model on a small subset of data (*e.g.*, 10%), embeds all training samples for clustering, and ranks these clusters according to embedding proximity. To handle sharp gradient changes at cluster transitions and alleviate catastrophic forgetting under cluster-based training, we introduce mixed regions that interleave samples from the previous, current, and next clusters, thereby stabilizing learning. Extensive experiments on 14 benchmarks spanning vision-language, text-only, and hybrid thinking/no-thinking scenarios show that EP-Order achieves broadly consistent improvements over random shuffling. These results suggest that exploiting embedding-level data structure offers an effective and general direction for improving IT on complex, high-conflict training data.

EMFormer: Efficient Multi-Scale Transformer for Accumulative Context Weather Forecasting

Hao Chen, Tao Han, Jie ZHANG, Song Guo, Fenghua Ling, LEI BAI

Long-term weather forecasting is critical for socioeconomic planning and disaster preparedness.

While recent approaches employ finetuning to extend prediction horizons, they remain constrained by the issues of catastrophic forgetting, error accumulation, and high training overhead.

To address these limitations, we present a novel pipeline across pretraining, finetuning and forecasting to enhance long■context modeling while reducing computational overhead. First, we introduce an Efficient Multi■scale Transformer (EMFormer) to extract multi■scale features through a single convolution in both training and inference. Based on the new architecture, we further employ an accumulative context finetuning to improve temporal consistency without degrading short■term accuracy. Additionally, we propose a composite loss that dynamically balances different terms via a sinusoidal weighting, thereby adaptively guiding the optimization trajectory throughout pretraining and finetuning.

Experiments show that our approach achieves great performance in weather forecasting and extreme event prediction, substantially improving long-term forecast accuracy. Moreover, EMFormer demonstrates strong generalization on vision benchmarks (ImageNet-1K and ADE20K). Code: https://github.com/chenhao-zju/emformer

Self-Supervised Dynamical System Representations for Physiological Time-Series

Yenho Chen, Maxwell A Xu, James Matthew Rehg, Christopher John Rozell

Self-supervised learning for physiological time-series aims to captures the identity of the underlying dynamical process while filtering irrelevant noise. However, existing approaches may obscure the clinical semantics important for downstr

eam transferability. Weakly constrained pretext tasks (i.e. contrastive learning , MAE) may incorrectly ignore the underlying dynamical structure, while structur ally constrained models (i.e. SVAEs) are unable to selectively filter sample-spe cific noise. To bridge this gap, we propose ${\bf PULSE}$, a novel pretraining objective that simultaneously preserves dynamical relationships important to phy siological time-series while selectively removing irrelevant noise. We achieve t his by formulating a dynamical systems model to identify transferable and non-tr ansferable information between time-series windows, and target the former throug h a novel cross-reconstruction objective.
We establish theory that provides conditions for when transferrable information is recovered, and empirically validate it through synthetic experiments. On seve ral real-world datasets, PULSE effectively distinguishes clinical semantic class es, increases label efficiency, and improves transfer learning performance.

Efficient Training of Boltzmann Generators Using Off-Policy Log-Dispersion Regul arization

Henrik Schopmans, Christopher von Klitzing, Pascal Friederich

Sampling from unnormalized probability densities is a central challenge in computational science. Boltzmann generators are generative models that enable independent sampling from the Boltzmann distribution of physical systems at a given temperature. However, their practical success depends on data-efficient training, as both simulation data and target energy evaluations are costly. To this end, we propose off-policy log-dispersion regularization (LDR), a novel regularization framework that builds on a generalization of the log-variance objective. We apply LDR in the off-policy setting in combination with standard data-based training objectives, without requiring additional on-policy samples. LDR acts as a shape regularizer of the energy landscape by leveraging additional information in the form of target energy labels. The proposed regularization framework is broadly applicable, supporting unbiased or biased simulation datasets as well as purely variational training without access to target samples. Across all benchmarks, LDR improves both final performance and data efficiency, with sample efficiency gains of up to one order of magnitude.

ScenePilot: Controllable Boundary-Driven Critical Scenario Generation for Autono mous Driving

Qiyu Ruan, YUXUAN WANG, He Li, Zhenning Li, Cheng-zhong Xu

Safety-critical scenarios are central to evaluating autonomous driving systems, yet their rarity in naturalistic logs makes simulation-based stress testing indi spensable. Most scenario generation methods treat surrounding agents as adversar ies, but they either (i) induce failures without explicitly modeling vehicle-roa d physical limits, yielding visually extreme yet physically unsolvable crashes, or (ii) enforce physical feasibility or policy feasibility in isolation, which c an over-focus on aggressive maneuvers or remain tied to a controller-dependent c apability boundary. We propose ScenePilot, a feasibility-guided, boundary-driven framework that targets the boundary band: scenarios that are physically solvabl e in principle yet still cause the deployed autonomy stack to fail. We formulate generation as constrained multi-objective reinforcement learning, combining an RSS-derived physical-feasibility score σ with an online-learned AV-risk p redictor Φ, and introduce step-level feasibility-aware shielding to keep ex ploration near the feasibility boundary while avoiding infeasible artifacts. Exp eriments on SafeBench with multiple planners show that ScenePilot yields substan tially higher collision rates (+6.2 percentage points) while preserving physical validity, and that adversarial fine-tuning on these boundary-band scenarios con sistently reduces downstream crash rates. The code is available at https://githu b.com/QiyuRuan/ScenePilot.

Remove the Ambiguity: Few-shot Multimodal Anomaly Detection Using Crossmodal Fea ture Replacers

Yuan Guo, Wanqi Zhang, Xu Wang

A key challenge in reconstruction-based multimodal anomaly detection is the one-to-many crossmodal mapping problem: a single 3D feature may correspond to multiple plausible RGB appearances, causing deterministic crossmodal regression to collapse valid targets into over-smoothed reconstructions and thereby weaken anomaly discrimination. In this paper, we propose Crossmodal Feature Replacer (CFR), a self-supervised framework that addresses this failure mode through selective inference-time feature replacement. CFR first learns bidirectional cyclic mappings for coarse crossmodal reconstruction, then identifies unreliable reconstructed features and selectively replaces them with high-confidence normal features to correct ambiguity-induced reconstruction failures. Extensive experiments on MVTec 3D-AD and Eyecandies under few-shot settings show that CFR consistently outperforms prior methods. In the challenging 1-shot setting, CFR achieves AUPRO scores of 92.3 and 82.7 at 30\% FPR, together with image-level AUROC scores of 74.0 and 75.9, on MVTec 3D-AD and Eyecandies, respectively.
Code is available at https://github.com/Yuan-Honoka-Guo/CFR.

Solving Stochastic Variational Inequalities without the Bounded Variance Assumption
Ahmet Alacaoglu, JunHyun Kim
We analyze algorithms for solving stochastic variational inequalities (VI) without the bounded variance or bounded domain assumptions, where our main focus is min-max optimization with possibly unbounded constraint sets. We focus on two classes of problems: monotone VIs; and structured nonmonotone VIs that admit a solution to the *weak Minty VI*. The latter assumption allows us to solve structured nonconvex-nonconcave min-max problems. For both classes of VIs, to make the expected residual norm less than ε, we show an oracle complexity of $\widetilde{O}(\varepsilon^{-4})$, which is the best-known for constrained VIs. In our setting, this complexity had been obtained with the bounded variance assumption in the literature, which is not even satisfied for bilinear min-max problems with an unbounded domain. We obtain this complexity for stochastic oracles whose variance can grow as fast as the squared norm of the optimization variable.

Do Text Edits Generalize to Visual Generation? Benchmarking Cross-Modal Knowledge Editing in UMMs
Xin Gao, Cheng Yang, Chufan Shi, Taylor Berg-Kirkpatrick
Unified multimodal models (UMMs) have emerged as a promising paradigm for general-purpose multimodal intelligence. As they are deployed in real-world applications, effectively updating internal knowledge becomes critical. While knowledge editing has matured for text-only models, it remains unclear whether edits that successfully modify textual outputs also transfer to image generation in UMMs. To study this question, we introduce UniKE, the first benchmark for cross-modality knowledge editing in UMMs, comprising 2,971 edit subjects spanning attribute and relation edits. Using VQA-based visual verification, we reveal a striking modality gap: text-side efficacy can reach approximately 92\%, whereas the best overall VQA accuracy under direct image generation is only 18.5\%. We further propose Reasoning-augmented Parameter Editing, which explicitly activates edited knowledge before generation and improves overall VQA accuracy for all evaluated model-editor pairs, with gains up to 18.6 percentage points. Mechanistic analysis shows that this gap is associated with partial alignment between edited textual representations and the conditioning pathways for visual generation, where edits sufficient for text outputs may remain too weak or misaligned to steer image synthesis. These findings show that textual knowledge edits do not guarantee reliable cross-modality transfer and motivate modality-aware editing methods. Our code and data are available at https://github.com/gxx27/UniKE.

Dynamic Regret via Discounted-to-Dynamic Reduction with Applications to Curved Losses and Adam Optimizer
Yan-Feng Xie, Yu-Jie Zhang, Peng Zhao, Zhi-Hua Zhou
We study dynamic regret minimization in non-stationary online learning, with a primary focus on follow-the-regularized-leader (FTRL) methods. FTRL is important

for curved losses and for understanding adaptive optimizers such as Adam, yet existing dynamic regret analyses are less explored for FTRL. To address this, we build on the discounted-to-dynamic reduction and present a modular way to obtain dynamic regret bounds of FTRL-related problems. Specifically, we focus on two representative curved losses: linear regression and logistic regression. Our method not only simplifies existing proofs for the optimal dynamic regret of online linear regression, but also yields new dynamic regret guarantees for online logistic regression. Beyond online convex optimization, we apply the reduction to analyze the Adam optimizers, obtaining optimal convergence rates in stochastic, non-convex, and non-smooth settings. The reduction also enables a more detailed treatment of Adam with two discount parameters (β_1,β_2), leading to new results for both clipped and clip-free variants of Adam optimizers.

BLISS: A Lightweight Bilevel Influence Scoring Method for Data Selection in Language Model Pretraining
Jie Hao, Rui Yu, Wei Zhang, Huixia Wang, Jie Xu, Mingrui Liu
Effective data selection is essential for pretraining large language models (LLMs), improving efficiency and generalization to downstream tasks. However, existing approaches often rely on external pretrained models, making it difficult to separate the benefits of data selection from those introduced by external models. In addition, many methods estimate data importance from a fixed model state or short-horizon update, making it hard to capture how data preference changes as the model evolves during pretraining. In this paper, we introduce BLISS (BileveL Influence Scoring method for data Selection), a lightweight data selection method that operates entirely \emph{from scratch}, without external pretrained oracle models, while modeling dynamic data preference. BLISS uses a small proxy model as a surrogate for the LLM and trains a score model to estimate sample importance through multi-step proxy updates induced by score-weighted training data. We formulate data selection as a bilevel optimization problem: the upper-level objective optimizes the score model to assign sample weights, so minimizing the lower-level weighted training loss improves validation performance. Once optimized, the score model predicts influence scores, enabling efficient selection of high-quality samples for LLM pretraining. We validate BLISS by pretraining 410M/1B/2.8B Pythia and LLaMA-0.5B models on selected C4 subsets. Under the 1B setting, BLISS achieves a $1.7\times$ speedup in reaching the same performance as the state-of-the-art method, while delivering superior performance across multiple downstream tasks.

BESplit: Bias-Compensated Split Federated Learning with Evidential Aggregation
Yuhan Xie, Chen Lyu, Jingrong Huang
Split Federated Learning (SFL) enables privacy-preserving collaborative training by partitioning models between clients and a server. However, under non-IID data distributions, SFL often suffers from biased optimization and unstable convergence, while existing solutions largely adapt techniques from conventional federated learning. In this work, we observe that the split architecture of SFL inherently alters how client information is represented and coordinated, opening opportunities for bias compensation beyond parameter-level aggregation. Based on this insight, we propose BESplit, an architecture-aware framework that exploits the intrinsic structure of SFL to mitigate non-IID effects. First, to prevent biased local data from dominating global updates, we introduce Evidential Aggregation (EA) to perform fine-grained reweighting of client contributions based on evidential uncertainty. Second, to further reduce distributional skew, we develop Bias-Compensated Collaboration (BCC) to align split-layer representations by pairing complementary clients. Finally, Dual-Teacher Distillation (DTD) is incorporated to synchronize knowledge between decoupled client and server models, enabling independent local inference. Extensive experiments on five benchmark datasets demonstrate that BESplit consistently outperforms state-of-the-art methods in accuracy, convergence stability, and computational efficiency under diverse non-IID settings.

Guidance: Sentence-Level Citation Enforcement via Prefix-Tail Guidance during LLM Decoding
Yirui Zhan, Chenhao Xu, Jun Gao
In correctness-sensitive scenarios, it is crucial for Large Language Models (LLMs) to strictly follow the provided evidence. However, even with reference texts, models often suffer from hallucinations, especially when processing long contexts. Existing work attempts to reinforce the use of citations through Retrieval-Augmented Generation (RAG) or post-hoc methods, while citations remain a probabilistic output rather than a foundation for the generated content. To address this, we propose Guidance, which aims to correct outputs and naturally incorporate citations during the LLM decoding phase. Specifically, we first build a structured fact pool (Prefix-Tail pairs) from the documents.
Then, during inference, Guidance predicts the model's intent using a lookahead strategy. When it detects a match with a context prefix, it automatically replaces the output with the verified fact and its citation. This approach is training-free and can be plugged into general-purpose or citation-fine-tuned LLMs. Experiments on LongBench-Cite demonstrate that Guidance improves the citation F1 score by 11.2\% over state-of-the-art baselines. The source code is available at: https://github.com/marlcplhra/Guidance.

FlashSketch: Sketch-Kernel Co-Design for Fast Sparse Sketching on GPUs
Rajat Vadiraj Dwaraknath, Sungyoon Kim, Mert Pilanci
Sparse sketches such as the sparse Johnson–Lindenstrauss transform are a core primitive in randomized numerical linear algebra because they leverage random sparsity to reduce the arithmetic cost of sketching, while still offering strong approximation guarantees. Their random sparsity, however, is at odds with efficient implementations on modern GPUs, since it leads to irregular memory access patterns that degrade memory bandwidth utilization. Motivated by this tension, we pursue a sketch–kernel co-design approach: we design a new family of sparse sketches, BlockPerm-SJLT, whose sparsity structure is chosen to enable FlashSketch, a corresponding optimized CUDA kernel that implements these sketches efficiently. The design of BlockPerm-SJLT introduces a tunable parameter that explicitly trades off the tension between GPU-efficiency and sketching robustness. We provide theoretical guarantees for BlockPerm-SJLT under the oblivious subspace embedding (OSE) framework, and also analyze the effect of the tunable parameter on sketching quality. We empirically evaluate FlashSketch on standard RandNLA benchmarks, as well as an end-to-end ML data attribution pipeline called GraSS. FlashSketch pushes the Pareto frontier of sketching quality versus speed, across a range of regimes and tasks, and achieves a global geomean speedup of roughly $1.7 \times$ over the prior state-of-the-art GPU sketches.
****
PhoStream: Benchmarking Real-World Streaming for Omnimodal Assistants in Mobile Scenarios
Xudong Lu, Guan Huankang, Yang Bo, Jinpeng Chen, Xintong Guo, Shuhan LI, Fang Liu, Peiwen Sun, Xueying Li, Wei Zhang, Xue Yang, Rui Liu, Hongsheng Li
Multimodal Large Language Models excel at offline audio-visual understanding, but their ability to serve as mobile assistants in continuous real-world streams remains underexplored. In daily phone use, mobile assistants must track streaming audio-visual inputs and respond at the right time, yet existing benchmarks are often restricted to multiple-choice questions or use shorter videos. In this paper, we introduce **PhoStream**, the first mobile-centric streaming benchmark that unifies on-screen and off-screen scenarios to evaluate video, audio, and temporal reasoning. PhoStream contains 5,572 open-ended QA pairs from 578 videos across 4 scenarios and 10 capabilities. We build it with an Automated Generative Pipeline backed by rigorous human verification, and evaluate models using a realistic Online Inference Pipeline and LLM-as-a-Judge evaluation for open-ended responses. Experiments reveal a temporal asymmetry in LLM-judged scores (0--100): models perform well on Instant and Backward tasks (Gemini 3 Pro exceeds 80), but drop sharply on Forward tasks (16.40), largely due to early responses before the required visual and audio cues appear. This highlights a fundamental limitation: c

urrent MLLMs struggle to decide ***when*** to speak, not just ***what*** to say. Code and datasets will be made publicly accessible at https://github.com/Lucky-Lance/PhoStream.

Must All Negatives Be Pushed Away Equally? Uncertainty-Aware Cross-View Geo-Localization via Normal Inverse Gamma Distribution

Songsong Ouyang, Le Wu, Yingying Zhu

Cross-view geo-localization (CVGL) aims to retrieve the corresponding satellite image given a street query and is critical for autonomous navigation. Although recent methods perform well on benchmarks, they often fail to generalize to unseen environments. A key limitation is the use of contrastive learning, which assigns equal labels to all negative samples and induces similarity-amplified repulsion. But should all negatives be treated equally? In CVGL, semi-positive samples that are geographically proximate to the positive often share important semantic cues. Treating them as ordinary negatives forces the model to overfit noise, leading to a collapse in generalization. To address this issue, we propose an uncertainty-aware framework grounded in Deep Evidential Regression (DER), modeling the Normal-Inverse-Gamma (NIG) distribution as a conjugate prior to quantify environmental complexity u in a single forward pass. The estimated u adaptively softens labels for hard negatives in Soft InfoNCE, mitigating excessive repulsion on semi-positive samples. An Uncertainty Head with cls-to-spatial cross-attention and attention statistics is designed to accurately fit the NIG distribution. Extensive experiments demonstrate state-of-the-art performance, including an average 18\% R@1 improvement in zero-shot cross-dataset transfer, filling the critical gap between laboratory benchmarks and robust real-world deployment.

Learning to Share: Selective Memory for Efficient Parallel Agentic Systems

Joseph Fioresi, Parth Parag Kulkarni, Ashmal Vayani, Song Wang, Mubarak Shah

Agentic systems solve complex tasks by coordinating multiple agents that iteratively reason, invoke tools, and exchange intermediate results. To improve robustness and solution quality, recent approaches deploy multiple agent teams running in parallel to explore diverse reasoning trajectories. However, parallel execution comes at a significant computational cost: when different teams independently reason about similar sub-problems or execute analogous steps, they repeatedly perform substantial overlapping computation. To address these limitations, in this paper, we propose Learning to Share (LTS), a learned shared-memory mechanism for parallel agentic frameworks that enables selective cross-team information reuse while controlling context growth. LTS introduces a global memory bank accessible to all teams and a lightweight controller that decides whether intermediate agent steps should be added to memory or not. The controller is trained using stepwise reinforcement learning with usage-aware credit assignment, allowing it to identify information that is globally useful across parallel executions. Experiments on the AssistantBench and GAIA benchmarks show that LTS significantly reduces overall runtime while matching or improving task performance compared to memory-free parallel baselines, demonstrating that learned memory admission is an effective strategy for improving the efficiency of parallel agentic systems.

Consistent Zero-Shot Imitation with Contrastive Goal Inference

Kathryn Wantlin, Chongyi Zheng, Benjamin Eysenbach

Zero-shot imitation learning requires an agent to reproduce expert behavior from a single demonstration without additional environment interaction or gradient updates at test time. We introduce Contrastive Inverse Reinforcement Learning (CIRL), a self-supervised framework for pre-training zero-shot imitation agents. Our methods rests on a key observation that many useful tasks can be summarized by a single goal state. We can thus convert the multi-task inverse RL problem into a more tractable goal-inference problem, and utilize state-of-the-art goal-conditioned RL methods to recover a policy that reaches the goal. During pre-training, CIRL jointly employs three components to learn without any rewards or demonstrations: (1) a variant of contrastive RL designed to learn maximum-entropy goal-conditioned policies, (2) an automatic goal proposal mechanism (GoalKDE) that dr

ives exploration, and (3) a mean-field variational model that performs amortized goal inference from trajectories. We prove that this procedure consistently recovers the demonstrator's intent by accounting for the relative difficulty of reaching different states and show how structurally similar prior work may otherwise fail to infer the correct reward. Experiments on goal-conditioned and standard reward-maximizing control tasks show that CIRL outperforms prior zero-shot imitation methods, supporting the expressiveness of goals as a compact summary of behavior.

Adaptive Utilization of Low-Rank Adaptation via Conditioned Gating

Guang Yang, Changhao Guan, Chao Huang, Yufeng Chen, Kaiyu Huang

Low-Rank Adaptation (LoRA) achieves parameter-efficient fine-tuning by constraining model updates to a low-rank subspace and has been widely used in practice. However, LoRA typically employs a shared low-rank update across tokens, which limits its ability to fully exploit the adaptation subspace for tokens from different sequences.

To address this issue, we propose an adaptive utilization of Low-Rank Adaptation (U-LoRA), which employs conditioned gating to explicitly learn effective token-level utilization of the limited low-rank adaptation subspace.

Specifically, U-LoRA generates utilization coefficients along low-rank directions for each token and jointly coordinates and constrains them using sequence-level contextual information, thereby inducing more consistent adaptive patterns within a sentence.

To further enhance training stability, we introduce a bias-corrected exponential moving average (EMA) historical prior that calibrates utilization signals across optimization steps, suppressing noise caused by batch-to-batch fluctuations.

The effectiveness of our method arises from a better utilization of the existing low-rank subspace via input-conditioned strategies, rather than from expanding the subspace.

Experiments on mathematical reasoning and natural language understanding benchmarks demonstrate that U-LoRA achieves competitive performance under comparable parameter budgets when with strong LoRA baselines and recent variants.

Interpretable Discovery of One-parameter Subgroups: A Modular Framework for Elliptical, Hyperbolic, and Parabolic Symmetries

Pavan Karjol, Vivek V Kashyap, Rohan Kashyap, Prathosh AP

We propose a modular, data-driven framework for jointly learning unknown functional mappings and discovering the underlying one-parameter symmetry subgroup governing the data. Unlike conventional geometric deep learning methods that assume known symmetries, our approach identifies the relevant continuous subgroup directly from data. Our framework focuses on three primary geometric components of one-parameter subgroup actions: elliptic, hyperbolic, and parabolic regimes. For the given regime, our framework instantiates a corresponding symmetry discovery architecture with invariant and equivariant representation layers structured according to the Lie algebra of the subgroup, and learns the exact generator parameters end-to-end from data. This yields models whose invariance or equivariance is guaranteed by construction and admits formal proofs, enabling symmetry to be explicitly traced to identifiable components of the architecture. The approach is applicable to one-parameter subgroups of a wide range of matrix Lie groups, including $SO(n)$, $SL(n)$, and the Lorentz group. Experiments on synthetic and real-world systems, including moment of inertia prediction, double-pendulum dynamics, and high-energy \textit{Top Quark Tagging}, demonstrate accurate subgroup recovery and strong predictive performance across both compact and non-compact regimes.

DisjunctiveNet: Neural Symbolic Learning via Differentiable Convexified Optimization Layers

Shraman Pal, Can Li

Many learning tasks in science and engineering are characterized by sparse datasets, which limits the effectiveness of purely data-driven approaches. At the sam

e time, these problems are often accompanied by rich domain knowledge derived fr
om physical laws, operational requirements, and expert heuristics. Such knowledg
e is frequently expressed as rules involving logical propositions and linear ine
qualities. Existing neuro-symbolic methods typically enforce these rules approxi
mately through soft penalties, assume input-independent rules when designing spe
cialized architectures, or rely on non-differentiable post-processing at inferen
ce time to achieve hard constraint satisfaction. While recent advances in differ
entiable optimization layers enable end-to-end feasibility enforcement within ne
ural networks, extending these approaches to logical or mixed-integer rules rema
ins challenging due to inherent nonconvexity. In this work, we propose a unified
 end-to-end framework for enforcing hard, input-dependent mixed integer linear c
onstraints within neural networks. Our approach represents rules as disjunctive
constraints and applies hierarchical convex relaxations to obtain convex hull fo
rmulations. These relaxations yield tractable linear constraints that can be emb
edded as differentiable optimization layers while enabling exact rule satisfacti
on. We demonstrate the effectiveness of the proposed framework on real-world dat
asets, achieving perfect rule satisfaction and strong predictive performance.

HOI-PAGE: Zero-Shot Human-Object Interaction Generation with Part Affordance Gui
dance

Lei Li, Angela Dai

We present HOI-PAGE, a new approach that prioritizes part-level affordance reaso
ning to generate high-fidelity 4D human-object interactions (HOIs) from text pro
mpts in a zero-shot fashion. In contrast to prior works that focus on global, wh
ole body-object motion synthesis, our approach explicitly reasons about the unde
rlying part-level mechanics of interactions using large language models (LLMs).
We capture this reasoning in a structured part affordance graph (PAG) representa
tion, serving as a high-level interaction scaffolding to guide a three-stage syn
thesis: first, decomposing input 3D objects into semantic parts; then, generatin
g reference HOI videos from text prompts to extract part-based motion constraint
s; and finally, optimizing for 4D HOI motion sequences that mimic the reference
dynamics while satisfying part-level contact constraints. Extensive experiments
show that our approach is flexible and capable of generating complex multi-objec
t or multi-person interaction sequences, with significantly improved realism and
 text alignment for zero-shot 4D HOI generation.

Exploring 3D Dataset Pruning

Xiaohan Zhao, Xinyi Shang, Jiacheng Liu, Zhiqiang Shen

Dataset pruning remains underexplored for 3D modalities, where inherent class im
balance persists across ***both*** training and test sets. This creates a diverg
ence in evaluation: overall accuracy favors natural frequency, reflecting practi
cal usage; while mean accuracy demands balanced generalization. Instead of forci
ng a premature trade-off, we advocate for base principles that remain universall
y robust and beneficial across diverse priors.
We cast pruning as a quadrature approximation on population risk and decompose t
he error bound into *representation error* (fidelity to the underlying manifold)
 and *prior-mismatch bias* (distribution shift), clarifying what can be improved
 jointly across priors.
To address prior-mismatch bias, we decouple likelihood from prior in the posteri
or and transfer the structural likelihood via distillation with a calibrated tea
cher and geometry-preserving constraints.
Simultaneously, to reduce representation error, we audit common pruning signals
and choose geometric embedding, which exhibits greater robustness given the high
 inductive bias of 3D models. We also prioritize a safety floor before selection
, capturing high-reward regions beneficial across priors.
Finally, acknowledging that no single subset optimally satisfies divergent evalu
ation priors, we augment these principles with a steering wrapper that interpola
tes between stratified seeding and global selection. Empirical results demonstra
te that our framework elevates the performance floor while offering flexibility
for different prior preferences.

Geometric Reciprocity: Unlocking Self-Supervision for Stereoscopic Video Generation
Jingyi Lu, Kai Han
Monocular-to-stereo conversion synthesizes stereoscopic content from 2D videos for immersive 3D experiences. In modern Depth-Image-Based Rendering (DIBR) approaches, stereo inpainting of disocclusions is the critical bottleneck. Training-based methods achieve superior quality but rely on scarce stereo pairs or synthetic data with domain gaps. We address this through the first self-supervised framework learning from monocular videos via cycle consistency. Our key contribution is the **Geometric Reciprocity Theorem (GRT)**: under the nearest-neighbor DIBR formulation, the disocclusion mask when synthesizing a target view equals the mask of pixels lost when warping back from target to source, enabling analytical computation of test-time disocclusion masks directly from monocular images. This yields train-test consistency for the stated warping formulation, supporting self-supervised learning from unlimited monocular videos and substantial improvements over training-free and supervised state-of-the-art methods. Project page: https://visual-ai.github.io/grt/

Fix Before Search: Benchmarking Agentic Visual Query Pre-processing in Multimodal Retrieval-augmented Generation
Shenglai Zeng, Jiankun Zhang, Kai Guo, Xinnan Dai, Hui Liu, Jiliang Tang, Yi Chang
Multimodal Retrieval-Augmented Generation (MRAG) has emerged as a key paradigm for grounding MLLMs with external knowledge. While query pre-processing (e.g., rewriting) is standard in text-based RAG, existing MRAG pipelines predominantly treat visual inputs as static and immutable, implicitly assuming they are noise-free. However, real-world visual queries are often ``imperfect''---suffering from geometric distortions, quality degradation, or semantic ambiguity---leading to catastrophic retrieval failures. To address this gap, we propose V-QPP-Bench, the first comprehensive benchmark dedicated to Visual Query Pre-processing (V-QPP). We formulate V-QPP as an agentic decision-making task where MLLMs must autonomously diagnose imperfections and deploy perceptual tools to refine queries. Our extensive evaluation across 46,700 imperfect queries and diverse MRAG paradigms reveals three critical insights: (1) Vulnerability---visual imperfections severely degrade both retrieval recall and end-to-end MRAG performance; (2) Restoration Potential \& Bottleneck---while oracle preprocessing recovers near-perfect performance, off-the-shelf MLLMs struggle with tool selection and parameter prediction without specialized training; and (3) Training Enhancement---supervised fine-tuning enables compact models to achieve comparable or superior performance to larger proprietary models, demonstrating the benchmark's value for developing robust MRAG systems The code is available at https://github.com/phycholosogy/VQQP_Bench

InfoDLM: an Information-Adaptive Framework for Discrete Diffusion Language Model Pretraining
Shirou Jing, Chunshu Wu, Chuan Liu, Arghavan Bahadorinejad, Feitong Qiao, Dongfang Liu, Tony Geng
Diffusion language models (DLMs) can match or surpass similarly sized autoregressive language models on language understanding and reasoning. However, their mask-and-denoise pretraining relies on heuristic random masking, which fails to target the most informative tokens. Consequently, the model spends significant computational effort on redundant or trivial tokens. To address this, we propose InfoDLM, an adaptive DLM pretraining framework that reformulates mask selection as an active, feedback-driven process. InfoDLM targets tokens that offer the highest measurable information gain during mask selection. Specifically, we: (1) introduce a Trainable Information-Gain (TIG) signal to quantify information gain of each masking configuration; (2) develop a feedback mechanism that adapts the masking policy to the model’s evolving state with a maturity indicator; and (3) jointly optimize the DLM and masking policy through an interleaved training flow wit

h minimal computational overhead. Across reasoning-oriented benchmarks, InfoDLM achieves up to 13\% improvement in reasoning accuracy over a small variant of LLaDA under comparable pretraining budgets.
****

Reasoning-VLA: An Efficient and Spatial-Guided General Vision-Language-Action Reasoning Model for Autonomous Driving
Dapeng Zhang, Zhenlong Yuan, Zhangquan Chen, Chih-Ting Liao, Yinda Chen, Fei Shen, Qingguo Zhou, Tat-Seng Chua
Vision-Language-Action (VLA) models have recently shown strong decision-making capabilities in autonomous driving. However, existing VLAs often struggle with achieving efficient inference and generalizing to novel autonomous vehicle configurations and driving scenarios. In this paper, we propose Reasoning-VLA, a general and efficient action-generation VLA framework. The proposed model employs a set of learnable action queries, implicitly guided by predefined spatial representations to enhance spatial awareness.
These learnable queries interact with reasoning-enhanced vision–language features to generate continuous action trajectories in parallel. To promote robust generalization, we consolidate eight publicly available autonomous driving datasets into a standardized, Chain-of-Thought reasoning–based, and easy-to-use data format for model training. Leveraging both supervised learning and reinforcement learning fine-tuning, extensive empirical evaluations across multiple benchmarks demonstrate that Reasoning-VLA achieves state-of-the-art performance, strong generalization capability, and the excellent inference speed with parallel decode.
****

Counterfactual Bootstrap for Robust Meta-Reinforcement Learning
Ai Bo, Junzhe Zhang, M. Cenk Gursoy
Meta-Reinforcement Learning (Meta-RL) focuses on training policies using data collected from a variety of diverse environments. This approach enables the policy to adapt to new settings with only a few training steps. While many Meta-RL methods have demonstrated success, they often rely on the assumption that unobserved confounders can be excluded a priori. This paper investigates robust Meta-RL in sequential decision-making, given confounded observational data collected across multiple heterogeneous environments. We introduce a novel augmentation procedure for standard Meta-RL algorithms (e.g., MAML), which employs partial identification methods to generate posterior counterfactual trajectories from candidate environments that align with the confounded observations. These counterfactual trajectories are then used to find a policy initialization that produces strong generalization performance in the target domain. Theoretical analysis reveals that our causal Meta-RL approach is guaranteed to yield a solution that minimizes generalization loss in future inference tasks.

Discrete Diffusion VLA: Bringing Discrete Diffusion to Action Decoding in Vision-Language-Action Policies
Zhixuan Liang, Yizhuo Li, Tianshuo Yang, Chengyue Wu, Sitong Mao, Liuao Pei, Tian Nian, Shunbo Zhou, Xiaokang Yang, Jiangmiao Pang, Yao Mu, Ping Luo
Vision–Language–Action (VLA) models adapt large vision–language backbones to map images and instructions into robot actions. However, prevailing VLAs either generate actions autoregressively in a fixed left-to-right order with poor performance or attach separate diffusion heads outside the backbone that fragments information pathways and hinders unified, scalable architectures. Instead, we present Discrete Diffusion VLA that discretizes action chunks and models them with discrete diffusion pattern retaining progressive refinement inside the unified transformer backbone. Our method achieves an adaptive decoding order that resolves high-confidence action elements before harder ones and employs secondary re-masking to revisit uncertain predictions, enabling robust error correction. This design preserves pretrained vision-language priors, supports parallel decoding, and improves the efficiency. Discrete Diffusion VLA achieves 96.4% avg. success on LIBERO, 71.2% visual matching on SimplerEnv-Fractal, and 54.2% overall on SimplerEnv-Bridge. On out-of-distribution tests of LIBERO-Goal, our method exhibits only 0.8% language degradation versus 8.0% of parallel decoding, and 20.4% vision de

gradation versus 29.0% for continuous diffusion, demonstrating well retention of pretrained vision-language capabilities. We also conduct two real-robot evaluations on AgileX Cobot Magic platform to show the method's effectiveness.
****
Complexity Bounds for Dirichlet Process Slice Samplers
Beatrice Franzolini, Francesco Gaffi
Slice sampling is a standard Monte Carlo technique for Dirichlet process (DP)-based models, widely used in posterior simulation. However, formal assessments of the scalability of posterior slice samplers have remained largely unexplored, primarily because the computational cost of a slice-sampling iteration is random and potentially unbounded.
In this work, we obtain high-probability bounds on the computational complexity of DP slice samplers. Our main results show that, uniformly across posterior cluster-growth regimes, the overhead induced by slice variables, relatively to the number of clusters supported by the posterior, is $O_{\mathbb P}(\log n)$. As a consequence, even in worst-case configurations, superlinear blow-ups in per-iteration computational cost occur with vanishing probability.
Our analysis applies broadly to DP--based models without any likelihood-specific assumptions, still providing complexity guarantees for posterior sampling on arbitrary datasets.
These results establish a theoretical foundation for assessing the practical scalability of slice sampling in DP-based models.

Effective Model Pruning : Measuring the Redundancy of Model Components
Yixuan Wang, Dan P. Guralnik, Saiedeh Akbari, Warren Dixon
This article initiates the study of a basic question about model pruning. Given a vector s of importance scores assigned to model components, how many of the scored components could be discarded without sacrificing performance? We propose Effective Model Pruning (EMP), which derives the desired sparsity directly from the score distribution using the notion of effective sample size from particle filtering, also known as the inverse Simpson index.

Rather than prescribe a pruning criterion, EMP supplies a universal adaptive threshold derived from the distribution of the score s over the model components: EMP maps s to a number $N_{eff} = N_{eff} (s)$, called the effective sample size. The $N − N_{eff}$ lowest scoring components are discarded. A tight lower bound on the preserved mass fraction seff (the sum of retained normalized scores) in terms of N_{eff} is derived. This process yields models with a provable upper bound on the loss change relative to the original dense
model. Numerical experiments are performed demonstrating this phenomenon across a variety of network architectures including MLPs, CNNs, Transformers, LLMs, and KAN. It is also shown that EMP addresses a rich set of pruning criteria such as weight magnitude, attention score, KAN importance score, and even feature-level signals such as image pixels.

Learn to Merge: Meta-Learning for Adaptive Multi-Task Model Merging
Jun Chen, Qin Zhang, Weizhi Zhang, Xiao Luo, Philip S. Yu, Ziyue Qiao
Model merging in the pretrain-finetune paradigm has proven effective by combining multiple finetuned models into one with multi-task capabilities. However, existing methods rely on fix or manually tuned merging coefficients, making the unified model sensitive to the initial merging strategy and suboptimal for downstream adaptation. Thus, this paper proposed an innovative model merging framework called MetaMerging, a novel meta-learning algorithm to adaptively optimize the merging coefficients to construct a unified model tailored for task-specific adapter training. By simulating adapter updates in an inner loop and meta-optimizing merging coefficients in an outer loop, MetaMerging produces more balanced and generalizable unified models. Extensive experiments on CV and NLP fields show strong performance of MetaMerging on various downstream tasks and demonstrate the effectiveness of meta-learning in our method compared to other parameter merging methods. Our code is available at https://github.com/cjcj46262/MetaMerging.

SPARC: Separating Perception And Reasoning Circuits for Test-time Scaling of VLM
s
Niccolò Avogaro, Nayanika Debnath, Li Mi, Thomas Frick, Junling Wang, Zexue He,
Hang Hua, Konrad Schindler, Mattia Rigotti
Despite recent successes, *test-time scaling*$-$dynamically expanding the token
budget during inference as needed$-$remains brittle for vision-language models (
VLMs). Unstructured visual reasoning chains entangle perception and reasoning, l
eading to long, disorganized contexts where small perceptual mistakes may cascad
e into completely wrong answers. Reasoning also requires expensive reinforcement
 learning with hand-crafted rewards. Here, we introduce SPARC (Separating Percep
tion And Reasoning Circuits), a modular framework that explicitly decouples visu
al perception from reasoning. Inspired by sequential sensory-to-cognitive proces
sing in the brain, SPARC implements a two-stage pipeline where the model first p
erforms explicit visual search to localize question-relevant regions, then condi
tions its reasoning on those regions to produce the final answer. This separatio
n enables independent test-time scaling with asymmetric compute allocation (e.g.
, prioritizing perceptual processing under distribution shift), and supports sel
ective optimization (e.g., improving the perceptual stage alone when it is the b
ottleneck for end-to-end performance). It also accommodates compressed contexts
by running global search at lower image resolutions and allocating high-resoluti
on processing only to selected regions, thereby reducing visual token count and
compute. SPARC outperforms monolithic baselines and strong visual-grounding appr
oaches across challenging visual reasoning tasks, such as improving Qwen3VL 4B o
n the V^* VQA benchmark by 6.7 points and surpassing "thinking with images" by
 4.6 points in an OOD setting with a 200$\times$ lower token budget.

PADS-TAL: Padding-Annealed Diffusion Sampling in Text-Aware Latent Space for Rob
ust and Diverse Text-to-Music Generation
Taekoan Yoo, Wonkyung Jung, Kyunghun Kim, Kyeongbo Kong
Text-to-Music diffusion models are increasingly used in real-world applications,
 yet deployment remains challenging: generations can collapse to limited pattern
s even with diverse initial noise and prompts, and inference-time diversity cont
rol often harms text alignment and fidelity by distorting key prompt cues establ
ished in early denoising.
To address this, we propose Padding-Annealed Diffusion Sampling, which perturbs
only a padding-indexed subspace while keeping non-padding conditioning fixed, en
abling controlled exploration with reduced semantic drift.
However, in a text-unaware VAE latent space, such exploration is less likely to
stay within genre-faithful neighborhoods, limiting genre-consistent diversity. W
e therefore introduce Text-Aware Latent space that aligns local neighborhoods wi
th text-implied genre structure, promoting genre-consistent diversity.
Together, the two techniques form a unified pipeline that, compared to prior met
hods that perturb the full conditioning, achieves a better text alignment--diver
sity trade-off: at comparable text alignment, it delivers 15.4\% higher diversit
y with a relatively small fidelity drop, and further improves within-genre diver
sity by 71.6\%.
Generated samples are available at https://pads-tal.github.io/PADS-TAL.io

From Noise to Intent: Anchoring Generative VLA Policies with Residual Bridges
Yiming Zhong, Yaoyu He, Zemin Yang, Pengfei Tian, Yifan Huang, Qingqiu Huang, Xi
nge Zhu, Yuexin Ma
Bridging high-level semantic understanding with low-level physical control remai
ns a persistent challenge in embodied intelligence, stemming from the fundamenta
l spatiotemporal scale mismatch between cognition and action. Existing generativ
e VLA policies typically adopt a "Generation-from-Noise" paradigm, which disrega
rds this disparity, leading to representation inefficiency and weak condition al
ignment during optimization. In this work, we propose ResVLA, an architecture th
at shifts the paradigm to "Refinement-from-Intent." Recognizing that robotic mot
ion naturally decomposes into global intent and local dynamics, ResVLA utilizes

spectral analysis to decouple control into a deterministic low-frequency anchor and a stochastic high-frequency residual. By anchoring the generative process on the predicted intent, our model focuses strictly on refining local dynamics via a residual diffusion bridge. Extensive simulation experiments show that ResVLA achieves competitive performance, strong robustness to language and robot embodiment perturbations, and faster convergence than standard generative baselines. ResVLA also demonstrates strong performance in real-world robot experiments.

``Someone Hid It!'': Query-Agnostic Black-Box Attacks on LLM-Based Retrieval
Jiate Li, Defu Cao, Li Li, Wei Yang, Yuehan Qin, Chenxiao Yu, Tiannuo Yang, Ryan A. Rossi, Yan Liu, Xiyang Hu, Yue Zhao
Large language models (LLMs) have been serving as effective backbones for retrieval systems, including Retrieval-Augmentation-Generation (RAG), Dense Information Retriever (IR), and Agent Memory Retrieval. Recent studies have demonstrated that such LLM-based Retrieval (LLMR) is vulnerable to adversarial attacks, which manipulates documents by token-level injections and enables adversaries to either boost or diminish these documents in retrieval tasks. However, existing attack studies mainly (1) presume a known query is given to the attacker, and (2) highly rely on access to the victim model's parameters or interactions, which are hardly accessible in real-world scenarios, leading to limited validity. To further explore the secure risks of LLMR, we propose a practical black-box attack method that generates transferable injection tokens based on zero-shot surrogate LLMs without need of victim queries or victim models knowledge. The effectiveness of our attack raises such a robustness issue that similar effects may arise from benign or unintended document edits in the real world. To achieve our attack, we first establish a theoretical framework of LLMR and empirically verify it. Under the framework, we simulate the transferable attack as a min-max problem, and propose an adversarial learning mechanism that finds optimal adversarial tokens with learnable query samples. Our attack is validated to be effective on benchmark datasets across popular LLM retrievers.
****

Dynamic Relational Priming Improves Transformer in Multivariate Time Series
Hunjae Lee, Corey Clark
Standard attention mechanisms in transformers employ static token representations that remain unchanged across all pair-wise computations in each layer. This limits their representational alignment with the potentially diverse dynamics of each token-pair interaction. While they excel in domains with relatively homogeneous relationships, standard attention may be inadequate in capturing heterogeneous inter-channel dependencies of multivariate time series (MTS) data where different channel-pair interactions within a single system may be governed by entirely different physical laws or temporal dynamics. To better align the attention mechanism for such domain phenomena, we propose attention with dynamic relational priming (prime attention). Prime attention modulates token representations for each token-pair, optimizing each pair-wise interaction for that specific relationship. Our results demonstrate that prime attention consistently outperforms standard attention across benchmarks, achieving up to 6.5\% improvement in forecasting accuracy. In addition, prime attention achieves comparable performance using up to 40\% less sequence length compared to standard attention, demonstrating its superior relational modeling capabilities and potential for data efficiency.
****

Learning to Reason for Factuality
Xilun Chen, Ilia Kulikov, Vincent-Pierre Berges, Barlas Oguz, Rulin Shao, Gargi Ghosh, Wen-tau Yih
Reasoning Large Language Models (R-LLMs) have significantly advanced complex reasoning tasks but often struggle with factuality, generating substantially more hallucinations than their non-reasoning counterparts on long-form factuality benchmarks. However, extending online Reinforcement Learning (RL), a key component in recent R-LLM advancements, to the long-form factuality setting poses several unique challenges due to the lack of reliable verification methods. Previous work has utilized automatic factuality evaluation frameworks such as FActScore to cu

rate preference data in the offline RL setting, yet we find that directly levera ging such methods as the reward in online RL leads to reward hacking in multiple ways, such as producing less detailed or relevant responses. We propose a novel reward function that simultaneously considers the factual precision, response d etail level, and answer relevance, and applies online RL to learn high quality f actual reasoning. Evaluated on six long-form factuality benchmarks, our factual reasoning model achieves an average reduction of 23.1 percentage points in hallu cination rate, a 23% increase in answer detail level, and no degradation in the overall response helpfulness.

Sign Lock-In: Randomly Initialized Weight Signs Persist and Bottleneck Sub-Bit M odel Compression
Akira Sakai, Yuma Ichikawa
Sub-bit model compression targets storage below one bit per weight; as magnitude s are aggressively compressed, the sign bit becomes a fixed-cost bottleneck. Acr oss Transformers, CNNs, and MLPs, learned sign matrices resist low-rank approxim ation and are spectrally indistinguishable from an i.i.d. Rademacher baseline. T his randomness gives rise to the lower bound of sub-bit model compression—the on e-bit wall. Despite this apparent randomness, most weights retain their initiali zation signs; flips primarily occur via rare near-zero boundary crossings, **sug gesting that sign-pattern randomness is largely inherited from initialization.** We formalize this behavior with *sign lock-in theory*, a stopping-time analysis of sign flips under SGD noise. Under bounded updates and a rare re-entry condit ion into a small neighborhood of zero, the number of effective sign flips exhibi ts a geometric tail. Building on this mechanism, we introduce a *from-scratch* l ow-rank sign-template training method that prevents the emergence of this one-bi t wall.

MonoScale: Scaling Multi-Agent System with Monotonic Improvement
Shuai Shao, Yixiang Liu, Bingwei Lu, Weinan Zhang
In recent years, LLM-based multi-agent systems (MAS) have advanced rapidly, usin g a router to decompose tasks and delegate subtasks to specialized agents. A nat ural way to expand capability is to scale up the agent pool by continually integ rating new functional agents or tool interfaces, but naive expansion can trigger performance collapse when the router cold-starts on newly added, heterogeneous, and unreliable agents. We propose MonoScale, an expansion-aware update framewor k that proactively generates a small set of agent-conditioned familiarization ta sks, harvests evidence from both successful and failed interactions, and distill s it into auditable natural-language memory to guide future routing. We formaliz e sequential augmentation as a contextual bandit and perform trust-region memory updates, yielding a monotonic non-decreasing performance guarantee across onboa rding rounds under a non-interfering expansion assumption. Experiments on GAIA a nd Humanity's Last Exam show stable gains as the agent pool grows, outperforming naive scale-up and strong-router fixed-pool baselines. Our code is available he re.

Learning Partial Concept Classes and Universal Rates Under Massart Noise
Ariel Avital, Klim Efremenko, Steve Hanneke
The Massart noise condition is a central model in
Probably Approximately Correct (PAC) learning
theory. Its importance lies in it being an interpolation condition between reali zable and the agnostic settings, under which one can attain faster
rates than in the latter, and, under strict conditions, recover the rates of the former. Despite
its importance, the Massart condition has not yet
been fully explored in emerging extensions of statistical learning theory beyond the classical PAC
framework. In this work, we present two such
extensions. First, we revisit the transductive empirical risk minimization (TERM) algorithm of

(Hanneke & Moran, 2026), and derive sharper
excess error bounds under Massart noise using
offset Rademacher techniques and local metric
entropy introduced by (Zhivotovskiy & Hanneke,
2018). We then leverage this analysis to obtain
new sample complexity bounds for PAC learning with partial concept classes and c
omplete the
characterization of universal rates under Massart
noise.

Learning Gaussian Graphical Models from a Glauber Trajectory Without Mixing
Eric Shen, Tony Wu, Mahbod Majid, Ankur Moitra
We study the task of learning the structure of a d-sparse Gaussian graphical m
odel on n variables from a single trajectory of Glauber dynamics. Beyond algor
ithmic considerations, many applications present temporally correlated observati
ons rather than i.i.d. samples. Moreover, in the classical i.i.d. setting, polyn
omial-time structure learning from a sublinear in n number of samples is suspe
cted to be computationally hard without additional assumptions on the precision
matrix. Motivated in part by this, we design the first polynomial-time algorithm
 that recovers the conditional-independence graph from a single Glauber trajecto
ry, with a trajectory-length guarantee that does not depend on the mixing time.

Technically, our algorithm has three components. First, we estimate the conditio
nal variances and rescale the trajectory to reduce to the unit-diagonal case, wi
thout changing the underlying graph. Second, we design a local edge test that ex
tracts adjacency information from short update windows by isolating pairwise inf
luence. Third, we aggregate these local statistics using a robust median-based e
stimator, and prove accuracy despite contamination and temporal dependence arisi
ng from a single trajectory.

$\texttt{FlashSchNet}$: Fast and Accurate Coarse-Grained Neural Network Molecula
r Dynamics
Pingzhi Li, Hongxuan Li, Zirui Liu, Xingcheng Lin, Tianlong Chen
Graph neural network (GNN) potentials such as SchNet improve the accuracy and tr
ansferability of molecular dynamics (MD) simulation by learning many-body intera
ctions, but remain slower than classical force fields due to fragmented kernels
and memory-bound pipelines that underutilize GPUs.
    We show that a missing principle is making GNN-MD $\textit{IO-aware}$, caref
ully accounting for reads and writes between GPU high-bandwidth memory (HBM) and
 on-chip SRAM.
    We present $\texttt{FlashSchNet}$, an efficient and accurate IO-aware SchNet
-style GNN-MD framework built on four techniques:
    (1) $\textit{flash radial basis}$, which fuses pairwise distance computation
, Gaussian basis expansion, and cosine envelope into a single tiled pass, comput
ing each distance once and reusing it across all basis functions;
    (2) $\textit{flash message passing}$, which fuses cutoff, neighbor gather, f
ilter multiplication, and reduction to avoid materializing edge tensors in HBM;
    (3) $\textit{flash aggregation}$, which reformulates scatter-add via CSR seg
ment reduce, reducing atomic writes by a factor of feature dimension and enablin
g contention-free accumulation in both forward and backward passes;
    (4) channel-wise 16-bit quantization that exploits the low per-channel dynam
ic range in SchNet MLP weights to further improve throughput with negligible acc
uracy loss.
    On a single NVIDIA RTX PRO 6000, $\texttt{FlashSchNet}$ achieves $\textbf{10
00 ns/day}$ aggregate simulation throughput over 64 parallel replicas on coarse-
grained (CG) protein containing 269 beads ($\textbf{6.5}$ $\mathbf{\times}$ fast
er than CGSchNet baseline with $\textbf{80\\% less}$ peak memory), surpassing wi
dely used classical force fields ($\textit{e.g.}$, MARTINI) while retaining SchN
et-level accuracy and transferability.

DuetServe: Harmonizing Prefill and Decode for LLM Serving via Adaptive GPU Multiplexing
Lei Gao, Chaoyi Jiang, Hossein Entezari Zarch, Daniel Wong, Mark D. Hill, Murali Annavaram
Modern LLM serving systems must sustain high throughput while meeting strict latency SLOs across two distinct inference phases: compute-intensive prefill and memory-bound decode phases. Existing approaches either (1) aggregate both phases on shared GPUs, leading to interference between prefill and decode phases, which degrades Time-Between-Tokens (TBT); or (2) disaggregate the two phases across GPUs, improving latency but wasting resources through duplicated models and KV cache transfers. We present DuetServe, a unified LLM serving framework that achieves disaggregation-level isolation within a single GPU. DuetServe operates in aggregated mode by default and dynamically activates SM-level GPU spatial multiplexing when TBT degradation is predicted. Its key idea is to decouple prefill and decode execution only when needed through fine-grained, adaptive SM partitioning that provides phase isolation only when contention threatens latency service level objectives. DuetServe integrates (1) an attention-aware roofline model to forecast iteration latency, (2) a partitioning optimizer that selects the optimal SM split to maximize throughput under TBT constraints, and (3) an interruption-free execution engine that eliminates CPU–GPU synchronization overhead. Evaluations show that DuetServe improves total throughput by up to 1.3$\times$ while maintaining low generation latency compared to state-of-the-art frameworks.

Semantic-level Backdoor Attack against Text-to-Image Diffusion Models
Tianxin Chen, Wenbo Jiang, Hongqiao Chen, Zhirun Zheng, Cheng Huang
Text-to-image (T2I) diffusion models are widely adopted for their strong generative capabilities, yet remain vulnerable to backdoor attacks. Existing attacks typically rely on fixed textual triggers and single-entity backdoor targets, making them highly susceptible to enumeration-based input defenses and attention-consistency detection. In this work, we propose Semantic-level Backdoor Attack (SemBD), which introduces representation-level triggers based on continuous semantic regions rather than discrete textual patterns. SemBD implants such semantic backdoors by distillation-based editing of the key and value projection matrices in cross-attention layers, enabling semantically equivalent but textually diverse prompts to activate the backdoor. To further enhance stealthiness, SemBD incorporates a semantic regularization to prevent unintended activation under incomplete semantics, as well as multi-entity backdoor targets that avoid highly consistent cross-attention patterns. Extensive experiments demonstrate that SemBD achieves a 100% attack success rate while maintaining strong robustness against state-of-the-art input-level defenses. Our code is available at https://github.com/DPAS-Lab/SemBD/.

Think in Latent, Explain in Language: Self-Explainable Latent Reasoning
Dayuan Zhao, Shengcao Cao, Yu-Xiong Wang, Liangyan Gui
Latent reasoning has emerged as a powerful alternative to text-based Chain-of-Thought (CoT), offering significant gains in computational efficiency by compressing verbose reasoning into compact embeddings. However, compressing reasoning into the latent space renders the thinking opaque, hindering its interpretability. Current methods present a stark trade-off: they either function as unexplainable “black boxes” (e.g., Coconut), where the latent reasoning is not human-readable, or rely on separate post-hoc decoders for explainability (e.g., Heima), introducing architectural overhead and decoupling the explanation from the actual reasoning process.
In this work, we present a unified framework for Self-Explainable Latent Reasoning (SELR) that trains a single model to perform efficient and inherently explainable latent reasoning. Our core contribution is a novel multi-task training objective that optimizes for two goals simultaneously: (1) an Answer Loss that optimizes the latent reasoning trajectory to produce accurate final answers, and (2) a CoT Loss that explicitly trains the same model to decode its own latent representations back into human-understandable reasoning steps. This design ensures th

at generated latent representations are both task-effective and semantically int
erpretable, eliminating the need for external decoders. We validate the effectiv
eness of SELR on both Large Language Models (LLMs) and Vision-Language Models (V
LMs), demonstrating that SELR achieves superior token efficiency and accuracy co
mpared to baselines, while uniquely providing self-contained explainability with
out auxiliary models.

Segment Anything with Robust Uncertainty-Accuracy Correlation
Hongyou Zhou, Marc Toussaint, Ling Shao, Zihan Ye
Despite strong zero-shot performance, SAM is unreliable under domain shift due t
o Mask-level Confidence Confusion (MCC), where a single IoU-based mask score fai
ls to reflect pixel-wise reliability near boundaries.
Motivated by the contrast between texture-biased shortcuts in neural networks an
d shape-centric processing in human vision, we model out-of-domain variation as
appearance shifts and non-rigid deformations that jointly perturb images.
We propose Segment Anything with Robust Uncertainty-Accuracy Correlation (RUAC)
for robust pixel-wise uncertainty estimation under appearance and deformation sh
ifts.
RUAC adds a lightweight uncertainty head, trains it with a collaborative style-d
eformation attack that jointly perturbs texture and geometry, and applies Uncert
ainty-Error Alignment to ensure uncertainty consistently highlights erroneous pi
xels even under adversarial perturbations.
Across 23 zero-shot domains, RUAC improves segmentation quality and yields more
faithful uncertainty with stronger uncertainty-accuracy correlation.

SurvDiff: A Diffusion Model for Generating Synthetic Data in Survival Analysis
Marie Brockschmidt, Maresa Schröder, Stefan Feuerriegel
Survival analysis is a cornerstone of clinical research by modeling time-to-even
t outcomes such as metastasis, disease relapse, or patient death. Unlike standar
d tabular data, survival data often come with incomplete event information due t
o dropout, or loss to follow-up. This poses unique challenges for synthetic data
 generation, where it is crucial for clinical research to faithfully reproduce b
oth the event-time distribution and the censoring mechanism. In this paper, we p
ropose SurvDiff, an end-to-end diffusion model specifically designed for generat
ing synthetic data in survival analysis. SurvDiff is tailored to capture the dat
a-generating mechanism by jointly generating mixed-type covariates, event times,
 and right-censoring, guided by a survival-tailored loss function. The loss enco
des the time-to-event structure and directly optimizes for downstream survival t
asks, which ensures that SurvDiff (i) reproduces realistic event-time distributi
ons and (ii) preserves the censoring mechanism. Across multiple datasets, we sho
w that SurvDiff outperforms state-of-the-art generative baselines in both distri
butional fidelity and survival model evaluation metrics across multiple medical
datasets. To the best of our knowledge, SurvDiff is the first end-to-end diffusi
on model explicitly designed for generating synthetic survival data.

Pose-ICL: 3D-Aware In-Context Learning for Pose-Controllable Subject Customizati
on
Xuan Han, Yihao Zhao, Mingyu You
Subject Customization is a foundational task in modern image generation. By prov
iding a few reference images and a text prompt, users can generate images of a s
pecific object in any desired scene. However, existing methods still struggle to
 achieve effective pose control for customized subjects. In practice, they often
 exhibit inaccurate poses or inconsistent cross-pose appearances. These limitati
ons suggest that understanding objects in a volumetric manner remains a signific
ant challenge for 2D-native backbones. To address this challenge, we propose Pos
e-ICL, a tuning-free framework that leverages 3D-aware In-Context Learning (ICL)
 to directly adapt to new subjects through multiple paired image-pose references
. Its core mechanism, Surface-Anchored Position Embedding (SAPE), equips the mod
el with explicit 3D awareness by anchoring image tokens to the surface coordinat
es of a volumetric bounding box. Dedicated refinements ensure its seamless compa

tibility with existing DiT models. Extensive evaluations on both 3D assets and r
eal-world subjects demonstrate that Pose-ICL significantly outperforms current m
ethods in both pose accuracy and identity consistency.

Interpreting Genomic Language Models using Sparse Autoencoders
Akira A Nair, Jaehyun Joo, Jonghyun Lee, Lina Takemaru, Yidi Huang, Manu Shivaku
mar, Matthew Eric Lee, Jaesik Kim, Sokratis Apostolidis, Dokyoon Kim
Genomic language models (gLMs) achieve strong performance across genomic predict
ion tasks, but their internal biological representations remain poorly understoo
d. Sparse autoencoders (SAEs) have emerged as an interpretability tool in vision
 and natural language models, yet their applicability to gLMs remains unexplored
. We present a systematic study of SAE-based interpretability for gLMs, introduc
ing a diverse benchmark of human genomic annotations and a suite of genome-tailo
red interpretability metrics. Using Evo2 as a primary case study, we show that S
AE features, particularly those from intermediate layers, are more interpretable
 than raw model embeddings across 42/55 (76%) of our genomic concept evaluations
, with 26 of them having an F1 score greater than 0.7. We further find that inte
rpretability depends on SAE training data properties such as evolutionary proxim
ity and context length. Finally, to organize semantically related genomic concep
ts learned by an SAE, we develop a graph-based representation method that outper
forms the baseline approach of using SAE model weights. We demonstrate how our f
ramework can extend SAEs as a powerful approach for not only better understandin
g gLMs but also for adopting them in disease-driven genomic explorations.

Characterizing the Effect of Noise in Language Generation in the Limit
Aaron Li, Ian Zhang
Kleinberg and Mullainathan recently proposed a formal framework for studying
        the phenomenon of language generation, called *language generation in th
e limit*.
        In this model, an adversary gives an enumeration of example strings from
 an unknown target language,
        and the algorithm is tasked with correctly generating
        unseen strings from the target language within finite time.
        Refined notions of non-uniform and uniform generation were later introdu
ced by
        Li, Raman, and Tewari (2025), and a noisy model was introduced by Raman
and Raman (2025),
        which allows the adversary to insert extraneous strings.
        A natural question in the noisy model is to quantify the effect of noise
,
        by studying the impact of each additional extraneous string.
        We show two complementary results in this setting.
        We first show that for both uniform and non-uniform generation, a single
 noisy string strictly reduces the set
        of collections that can be generated, thus answering an open question in
 Raman and Raman (2025).
        Then, we show for both uniform and non-uniform generation that generatio
n with a single noisy string is
        equivalent to generation with any finite amount of noise,
        sharply contrasting with the strict hierarchy for
        noisy generation in the limit shown by Bai, Panigrahi, and Zhang (2026).
        Finally, we leverage our previous results to provide the first known cha
racterization for
        non-uniform noise-dependent generatability.

RTPrune: Reading-Twice Inspired Token Pruning for Efficient DeepSeek-OCR Inferen
ce
Ben Wan, Yan Feng, Zihan Tang, Weizhe Huang, Yuting Zeng, Jia Wang, Tongxuan Liu
DeepSeek-OCR leverages visual–text compression to reduce long-text processing co
sts and accelerate inference, yet visual tokens remain prone to redundant textua

l and structural information. Moreover, current token pruning methods for conven tional vision–language models (VLMs) fail to preserve textual fidelity due to im proper compression mechanisms. By analyzing the decoding process of DeepSeek-OCR , we find that a distinct two-stage reading trajectory: the model initially prio ritizes the majority of high-norm tokens, then subsequently redistributes its at tention to the remaining ones. Motivated by this insight, we propose *RTPrune*, a two-stage token pruning method tailored for DeepSeek-OCR. In the first stage, we prioritize high-norm visual tokens that capture salient textual and structura l information. In the second stage, the remaining tokens are paired and merged b ased on optimal transport theory to achieve efficient feature aggregation. We fu rther introduce a dynamic pruning ratio that adapts to token similarity and text ual density for OCR tasks, enabling a better efficiency–accuracy trade-off. Exte nsive experiments demonstrate state-of-the-art performance, as evidenced by 99.4 7\% accuracy and 1.23× faster prefill on OmniDocBench, achieved with 84.25\% tok en retention when applied to DeepSeek-OCR-Large. Code is released.
****

Text-Conditional JEPA for Learning Semantically Rich Visual Representations
Chen Huang, Xianhang Li, Vimal Thilak, Etai Littwin, Joshua M. Susskind
Image-based Joint-Embedding Predictive Architecture (I-JEPA) offers a promising approach to visual self-supervised learning through masked feature prediction. H owever with the inherent visual uncertainty at masked positions, feature predict ion remains challenging and may fail to learn semantic representations. In this work, we propose Text-Conditional JEPA (TC-JEPA) that uses image captions to red uce the prediction uncertainty. Specifically, we modulate the predicted patch fe atures using a fine-grained text conditioner that computes sparse cross-attentio n over input text tokens. With such conditioning, patch features become predicta ble as a function of text, thus are more semantically meaningful. We show TC-JEP A improves downstream performance and training stability, with promising scaling properties. TC-JEPA also offers a new vision-language pretraining paradigm base d on feature prediction only, outperforming contrastive methods on diverse tasks , especially those requiring fine-grained visual understanding and reasoning.
****

CORE: Context-Robust Remasking for Diffusion Language Models
Kevin Zhai, Sabbir Mollah, Zhenyi Wang, Mubarak Shah
Standard decoding in Masked Diffusion Models (MDMs) is hindered by context rigid ity: tokens are retained based on transient high confidence, often ignoring that early predictions lack full context. This creates cascade effects where initial inconsistencies misguide the remaining generation. Existing revision strategies attempt to mitigate this by relying on static confidence scores, but these sign als are inherently myopic; inconsistent tokens frequently appear confident to th e model itself. To address this, we propose Context-Robust Remasking (CORE), a t raining-free framework for inference-time revision. We introduce a new selection paradigm: rather than trusting static token probabilities, we identify *context -brittle* tokens by probing their sensitivity to adversarial perturbations. We f ormalize revision as a robust optimization problem targeting worst-case context shifts. CORE efficiently approximates this objective using theoretically bounded probability margins to expose and revise unstable tokens. On LLaDA-8B-Base, COR E delivers consistent improvements across reasoning and code benchmarks, outperf orming compute-matched baselines and boosting performance on code generation (MB PP) by up to $+9.2\\%$, with comparable gains generalizing to the Dream-7B archi tecture.

Dissecting Causal Mechanism Shifts via FANS: Function And Noise Separation
Gyeongdeok Seo, Jaeyoon Shim, Mingyu Kim, Hoyoon Byun, Yonghan Jung, Kyungwoo So ng
Identifying the drivers of causal mechanism shifts, distinguishing functional ch anges from noise alterations, termed *dissection*, is a critical yet under-explo red problem in data science (e.g., biomedical science and manufacturing). This p aper introduces a more general and unified framework, the *function and noise se paration* (FANS) framework, that detects and dissects shifts in non-additive, no

n-linear Structural Causal Models (SCMs) beyond existing additive noise models. Our approach is grounded in a theoretical independence criterion, where function shifts induce a statistical dependence between a node's parents and residual noise. Building on this foundation, we develop a practical two-stage algorithm to efficiently detect and dissect these shifts without retraining. Furthermore, we address the complex challenge of simultaneous function and noise shifts, introducing a formal assumption to resolve their inherent non-identifiability. Our results are corroborated by simulations. Our code is available at https://github.com/MLAI-Yonsei/FANS/.

Cross-task Calibration for Asynchronous Federated Continual Learning

Yichen Li, Haozhao Wang, Hang Su, Yulong Li, Xiaoquan Yi, Yankai Jiang, Chuang Zhao, Imran Razzak, Ruixuan Li

Federated Continual Learning (FCL) aims to empower distributed devices to learn a sequence of tasks over time. However, existing FCL research largely relies on the impractical assumption of synchronous new task arrival. This overlooks the reality of asynchronous user behavior and system latencies, forcing more efficient clients to endure costly inactivity. The practical necessity of an asynchronous method gives rise to Asynchronous Federated Continual Learning (AFCL). The server constantly receives a mixture of updates from clients at different time steps, leading to a catastrophic task drift that corrupts the global model and prevents effective learning. In this paper, we introduce a novel Cross-task Calibration framework called C^2-AFCL that is the first to tackle task drift at a semantic level within an Asynchronous FCL setting. Its core is a two-stage orthogonal calibration mechanism. First, intra-client calibration uses task-aware caches to mitigate variance from local client drift. Second, and more critically, inter-task interference calibration dynamically estimates an interference subspace from historical task knowledge. New updates are orthogonally projected to isolate and remove components that conflict with this subspace, preserving previous knowledge while learning new tasks. Extensive experiments show that C^2-AFCL significantly outperforms existing methods, demonstrating robust and efficient learning in dynamic federated environments.

****

CL-GCL: Comprehensive and Lightweight Graph Contrastive Learning

Jianqing Liang, Xinkai Wei, Zhiqiang Li

Graph Contrastive Learning (GCL) has significantly advanced self-supervised representation learning on graphs, yet its practical efficacy remains hindered by random augmentations that induce semantic distortion and rigid one-to-one sampling strategy that amplifies inter-class entanglement and intra-class dispersion. To address these limitations, we develop CL-GCL, a Comprehensive and Lightweight Graph Contrastive Learning framework. Specifically, we exploit graph coarsening■ to preserve structural semantics through community-level representations and manifold learning■ to capture local geometric relations without costly pairwise distance computations. This design naturally aligns with the neighborhood aggregation principle of Graph Convolutional Networks, enhancing structural consistency while eliminating negative sampling bias. We theoretically prove that CL-GCL approximates node-level contrastive loss under mild conditions. Extensive experiments demonstrate consistent superiority in both accuracy and efficiency over state-of-the-art GCL methods.

****

Infinite Mask Diffusion for Few-Step Distillation

Jaehoon Yoo, Wonjung Kim, Chanhyuk Lee, Seunghoon Hong

Masked Diffusion Models (MDMs) have emerged as a promising alternative to autoregressive models in language modeling, offering the advantages of parallel decoding and bidirectional context processing within a simple yet effective framework. Specifically, their explicit distinction between masked tokens and data underlies their simple framework and effective conditional generation. However, MDMs typically require many sampling iterations due to factorization errors stemming from simultaneous token updates. We observe that a theoretical lower bound of the factorization error exists, which standard MDMs cannot reduce due to their use o

f a deterministic single-state mask. In this paper, we propose the Infinite Mask Diffusion Model (IMDM), which introduces a stochastic infinite-state mask to mitigate the theoretical bound while directly inheriting the benefits of MDMs, including the compatibility with pre-trained weights. We empirically demonstrate that MDM fails to perform few-step generation even in a simple synthetic task due to the factorization error bound, whereas IMDM can find an efficient solution for the same task. Finally, when equipped with appropriate distillation methods, IMDM surpasses existing few-step distillation methods at small step counts on LM1B and OpenWebText.

DenseSteer: Steering Small Language Models towards Dense Math Reasoning
Yang Ouyang, Shuhang Lin, Jung-Eun Kim
Large language models (LLMs) demonstrate strong chain-of-thought (CoT) reasoning abilities, while smaller models ($\leq$ 3B parameters) significantly underperform on multi-step reasoning tasks. Based on empirical analyses of the Qwen-2.5 model family on math reasoning benchmarks, we find that more proficient reasoning is associated with fewer reasoning steps but higher information density per step, a property we term *Dense Reasoning*. Motivated by this observation, we propose **DenseSteer**, a training-free inference-time steering framework that enhances small-model reasoning by modulating internal representations toward dense reasoning patterns. Experiments show that our method yields consistent accuracy improvements without increasing token-level Negative Log-Likelihood, highlighting dense reasoning as an effective structural approach to mathematical problem solving.
****

From Guessing to Placeholding: A Cost-Theoretic Framework for Uncertainty-Aware Code Completion
Liang Zhu, Haolin Chen, Lidong Zhao, Xian Wu
While Large Language Models (LLMs) have demonstrated exceptional proficiency in code completion, they typically adhere to a **Hard Completion (HC)** paradigm, compelling the generation of fully concrete code even amidst insufficient context. Our analysis of 3 million real-world interactions exposes the limitations of this strategy: 61% of the generated suggestions were either edited after acceptance or rejected despite exhibiting over 80% similarity to the user's subsequent code, suggesting that models frequently make erroneous predictions at specific token positions. Motivated by this observation, we propose **Adaptive Placeholder Completion (APC)**, a collaborative framework that extends HC by strategically outputting explicit placeholders at high-entropy positions, allowing users to fill directly via IDE navigation. Theoretically, we formulate code completion as a cost-minimization problem under uncertainty. Premised on the observation that filling placeholders incurs lower cost than correcting errors, we prove the existence of a critical entropy threshold above which APC achieves strictly lower expected cost than HC. We instantiate this framework by constructing training data from filtered real-world edit logs and design a cost-based reward function for reinforcement learning. Extensive evaluations across 1.5B--14B parameter models demonstrate that APC reduces expected editing costs from 19% to 50% while preserving standard HC performance. Our work provides both a theoretical foundation and a practical training framework for uncertainty-aware code completion, demonstrating that adaptive abstention can be learned end-to-end without sacrificing conventional completion quality.
****

Deep Discriminative Structure Proxy Hashing for Cross-modal Retrieval
Kun Cheng, Qibing Qin, Lei Huang
Existing proxy-based hashing methods optimize samples toward independently learned proxies using isolated similarity constraints. Although efficient, this design overlooks the fact that proxies are learned jointly but lack explicit relational or competitive interactions during optimization. Consequently, proxy responses to a sample are often accumulated rather than contrasted, leading to weakly defined decision regions and limited discriminative structure in the Hamming space.

In contrast, our method organizes multiple proxies into sample-specific relation al structures, enabling proxies to interact and compete when responding to each sample. Through structure-guided learning, these interactions explicitly contras t positive and negative proxy responses, thereby shaping clearer and more discri minative decision boundaries. Extensive experiments on standard cross-modal benc hmarks demonstrate that this structured discrimination consistently improves ret rieval accuracy and embedding separability. The source code is available at [<ht tps://github.com/QinLab-WFU/DDSPH>](https://github.com/QinLab-WFU/DDSPH).

On the Expressive Power of GNNs to Solve Linear SDPs
Chendi Qian, Christopher Morris
Semidefinite programs (SDPs) are a powerful framework for convex optimization an d for constructing strong relaxations of hard combinatorial problems. However, s olving large SDPs can be computationally expensive, motivating the use of machin e learning models as fast computational surrogates. Graph neural networks (GNNs) are a natural candidate in this setting due to their sparsity-awareness and abi lity to model variable-constraint interactions. In this work, we study what expr essive power is sufficient to recover optimal SDP solutions. We first prove nega tive results showing that standard GNN architectures fail on recovering linear S DP solutions. We then identify a more expressive architecture that captures the key structure of SDPs and can, in particular, emulate the updates of a standard first-order solver. Empirically, on both synthetic and SDPLIB benchmarks of vari ous classes of SDPs, this more expressive architecture achieves consistently low er prediction error and objective gap than theoretically weaker baselines. Final ly, using the learned high-quality predictions to warm-start the first-order sol ver yields practical speedups of up to 80%.
****

Rh-3DGS: Robust Open-Vocabulary Scene Understanding via Riemannian Huber Distill ation and Manifold-Aware Sampling
Xinpeng Zhao, Jiang Jie, Fengyuan Zhang, Lixin Zhan, Dong Wang, Qinyuan Bu, Jiah ang Tu, Guangzhen Yao
Open-vocabulary 3D scene understanding answers free-form text queries over recon structed scenes. However, lifting dense 2D foundation-model embeddings into 3D G aussian Splatting (3DGS) is still challenging. Existing 3DGS-based methods often average normalized embeddings in Euclidean space. This ignores their hyperspher ical geometry and can cause feature collapse. They also distill supervision from all views equally, which amplifies occlusion noise and mixed-depth artifacts. W e propose **Rh-3DGS**, a robust semantic 3DGS framework that uses reliability-aw are distillation and manifold-consistent aggregation. **Visibility-Calibrated Di stillation (VCD)** computes per-pixel reliability weights from rasterization sta tistics and down-weights ambiguous pixels. **Visibility-Weighted Fréchet Mean (V FM)** aggregates embeddings on the unit hypersphere with a Riemannian Huber obje ctive for robust distillation. **Lightweight Consistency Contrast (LIC)** regula rizes the 3D semantic field with neighborhood-based multi-positive contrast to i mprove local consistency and sharper boundaries. Experiments on three benchmarks show that Rh-3DGS is best on open-vocabulary segmentation, boundary quality, an d view-consistent rendering.

IMPACT: Influence Modeling for Open-Set Time Series Anomaly Detection
Xiaohui Zhou, Yijie Wang, Hongzuo Xu, Weixuan Liang, Xiaoli Li, Guansong Pang
Open-set anomaly detection (OSAD) is an emerging paradigm designed to utilize li mited labeled data from anomaly classes seen in training to identify both seen a nd unseen anomalies during testing. Current approaches rely on simple augmentati on methods to generate pseudo anomalies that replicate unseen anomalies. Despite being promising in image data, these methods are found to be ineffective in tim e series data due to the failure to preserve its sequential nature, resulting in trivial or unrealistic anomaly patterns. They are further plagued when the trai ning data is contaminated with unlabeled anomalies. This work introduces $\textb f{IMPACT}$, a novel framework that leverages $\underline{\textbf{i}}$nfluence $\ underline{\textbf{m}}$odeling for o$\underline{\textbf{p}}$en-set time series $\ underline{\textbf{a}}$nomaly dete$\underline{\textbf{ct}}$ion, to tackle these c hallenges. The key insight is to $\textbf{i)}$ learn an influence function that can accurately estimate the impact of individual training samples on the modelin g, and then $\textbf{ii)}$ leverage these influence scores to generate semantica lly divergent yet realistic unseen anomalies for time series while repurposing h igh-influential samples as supervised anomalies for anomaly decontamination. Ext ensive experiments show that IMPACT significantly outperforms existing state-of- the-art methods, showing superior accuracy under varying OSAD settings and conta mination rates. Code is available at https://github.com/mala-lab/IMPACT.

AlignVid: Taming Visual Dominance via Training-Free Attention Modulation in Text -guided Image-to-Video Generation
Yexin Liu, Wen-Jie Shu, Zile Huang, Haoze Zheng, Yueze Wang, Manyuan Zhang, Jinj ing Zhu, Ser-Nam Lim, Harry Yang
Text-guided image-to-video generation has made substantial progress, yet it stil l struggles to execute text-specified edits that require substantial changes to a reference image (e.g., object addition, deletion, or modification). Empiricall y, our analysis reveals that this stems from **visual dominance**, where the ref erence image causes severe attention dispersion, inhibiting the model's ability to incorporate new semantic information. To address this, we propose **AlignVid* *, a training-free intervention that re-calibrates the model's internal attentio n distribution. Drawing on an energy-based perspective of attention, AlignVid em ploys Attention Scaling Modulation (**ASM**) to reduce attention entropy and con centrate focus on semantic tokens, alongside Guidance Scheduling (**GS**) to mai ntain generation stability. To rigorously assess this capability, we present **O mitI2V**, a comprehensive benchmark for evaluating prompt adherence across objec t addition, deletion, and modification. Extensive experiments demonstrate that A lignVid effectively enhances semantic fidelity with negligible computational ove rhead.

Provable Sample Efficiency of Curriculum Post-Training for Transformer Reasoning
Dake Bu, Wei Huang, Andi Han, Atsushi Nitanda, Hau-San Wong, Qingfu Zhang, Taiji Suzuki
Recent curriculum techniques in the post-training stage of LLMs have been empiri cally observed to outperform non-curriculum approaches in improving reasoning pe rformance, yet a principled understanding of their effectiveness and limitations remains incomplete. To bridge this gap, we develop an abstract theoretical fram ework and identify sufficient conditions under which curriculum post-training yi elds exponential improvements in sample complexity.

To substantiate this framework, we model the base model’s Chain-of-Thought gener ation as a state-conditioned autoregressive reasoning tree, and formalize curric ulum subtasks as either depth-increasing curricula that progressively extend rea soning horizons or hint-decreasing curricula that gradually remove partial hints . Our analysis shows that reinforcement learning finetuning with both curriculum strategies achieves high accuracy with polynomial sample complexity, whereas no

n-curriculum counterpart encounters an exponential complexity bottleneck. We fur
ther establish analogous guarantees for test-time scaling. Empirical simulations
 support our theoretical findings. Code is available at https://github.com/DakeB
U/Curriculum-Post-training.

BeaconKV: Key-Value Cache Compression Guided by Beacon Queries for Efficient Lar
ge Reasoning Model Inference
Janghyeon Kim, Minsoo Kim, Kyuhong Shim, Jungwook Choi
Large Reasoning Models (LRMs) achieve superior problem-solving through extended
Chain-of-Thought (CoT) generation, but the resulting key-value (KV) cache grows
linearly with sequence length and creates severe memory bottlenecks—often exceed
ing GPU capacity for long reasoning traces. Existing KV cache compression method
s rely on recent queries to estimate future token importance, implicitly assumin
g these serve as reliable proxies for future attention patterns. We demonstrate
that this assumption fails in long-horizon reasoning: certain decoding steps gen
erate Thought Revisiting Tokens (TRT) that re-attend to distant previous context
, such as task-solving plans formulated early in the trace. Through systematic a
nalysis, we discover that queries corresponding to the TRT cluster into a small
number of similarity groups in the embedding space. Based on this insight, we pr
opose BeaconKV, a training-free KV cache compression method that maintains beaco
n queries—compact representatives for each global query cluster—to anticipate wh
ich KV pairs will be revisited without storing the entire query history. Across
four open-source LRMs and diverse reasoning benchmarks, BeaconKV generally outpe
rforms existing compression methods, achieving up to $5.8\times$ memory reductio
n while nearly preserving full cache accuracy and improving throughput by over $
4.3\times$.

Evolution Strategies at the Hyperscale
Bidipta Sarkar, Mattie Fellows, Juan Agustin Duque, Alistair Letcher, Antonio Le
ón Villares, Anya Sims, Clarisse Wibault, Dmitry Samsonov, Dylan Cope, Jarek Luc
a Liesen, Kang Li, Lukas Seier, Theo Wolf, Uljad Berdica, Valentin Mohl, Alexand
er David Goldie, Aaron Courville, Karin Sevegnani, Shimon Whiteson, Jakob Nicola
us Foerster
Evolution Strategies (ES) is a class of powerful black-box optimisation methods
that are highly parallelisable and can handle non-differentiable and noisy objec
tives. However, naïve ES becomes prohibitively expensive at scale on GPUs due to
 the low arithmetic intensity of batched matrix multiplications with unstructure
d random perturbations. We introduce Evolution Guided GeneRal Optimisation via L
ow-rank Learning (EGGROLL), which improves arithmetic intensity by structuring i
ndividual perturbations as rank-r matrices, resulting in a hundredfold increas
e in training speed for billion-parameter models at
large population sizes, achieving up to 91\% of the throughput of pure batch inf
erence. We provide a rigorous theoretical analysis of ES for high-dimensional pa
rameter objectives, investigating conditions needed for ES updates to converge i
n
high dimensions, revealing a linearising effect, and proving consistency between
 EGGROLL and
ES as parameter dimension increases. Our experiments show that EGGROLL: (1) enab
les the stable pretraining of nonlinear recurrent language models that operate p
urely in integer datatypes, (2) is competitive with GRPO for post-training
LLMs on reasoning tasks, and (3) does not compromise performance compared to ES
in tabula rasa RL settings, despite being faster.
****
GRPO-based Cluster Decision Agent for Unknown-$\boldsymbol{K}$ Multi-view Cluste
ring
Xuqian Xue, Jun Zhang, Qi Cai, Zhizhong Huang, Hongming Shan, Junping Zhang
Existing contrastive multi-view clustering methods rely on a pre-defined cluster
 number, limiting their flexibility in real-world scenarios lacking prior knowle
dge. To address this, we propose GROK, a novel framework driven by a cluster dec
ision agent for unknown-K multi-view clustering. It pioneers the adaptation of

group relative policy optimization (GRPO) —a reinforcement learning strategy for LLM reasoning— into the unsupervised domain to autonomously determine the optimal K. Specifically, the agent orchestrates the clustering process through three synergistic phases. First, in the state perception phase, we employ a structure-aware adaptive backbone to aggregate multi-view data, providing the agent with consistent and discriminative consensus observations. Second, in the group decision phase, we introduce an action space divide-and-conquer strategy and an adaptive reward function. Equipped with these mechanisms, the agent performs group sampling and relative advantage estimation within the discrete action space of candidate K values, autonomously searching for the optimal K via reward maximization. Finally, via geometric feedback, geometric clustering guidance mechanism transforms the agent's structural hypotheses into explicit differentiable constraints to reshape feature manifolds, thereby closing the perception-decision-feedback loop. Experimental results demonstrate that GROK achieves superior clustering performance in unknown-K scenarios by autonomously exploring the cluster structure.

Black-Box Combinatorial Optimization with Order-Invariant Reinforcement Learning
Olivier Goudet, Quentin Suire, Adrien Goëffon, Frédéric Saubion, Sylvain Lamprier

We introduce an order-invariant reinforcement learning framework for black-box combinatorial optimization. Classical estimation-of-distribution algorithms (EDAs) often rely on learning explicit variable dependency graphs, which can be costly and may fail to capture complex interactions efficiently. In contrast, we parameterize a multivariate autoregressive generative model trained without a fixed variable ordering. By sampling random generation orders during training, a form of information-preserving dropout, the model is encouraged to be invariant to variable order, promoting search-space diversity, and shaping the model to focus on the most relevant variable dependencies, improving sample efficiency. We adapt Group Relative Policy Optimization (GRPO) to this setting, providing stable policy-gradient updates from scale-invariant advantages. Across a wide range of benchmark problem instances of varying sizes, our method frequently achieves the best performance and consistently avoids catastrophic failures.

FloorplanQA: A Benchmark for Spatial Reasoning in LLMs using Structured Representations
Fedor Rodionov, Abdelrahman Eldesokey, Michael Birsak, John Femiani, Bernard Ghanem, Peter Wonka

We introduce FloorplanQA, a diagnostic benchmark for evaluating spatial reasoning in large language models (LLMs). FloorplanQA is grounded in structured representations of indoor scenes (e.g., kitchens, living rooms, bedrooms, bathrooms, and others), encoded symbolically in JSON or XML layouts. The benchmark covers core spatial tasks, including distance measurement, visibility, path finding, and object placement within constrained spaces. Our results across a variety of frontier open-source and commercial LLMs reveal that while models may succeed on shallow queries, they often fail to respect physical constraints and preserve spatial coherence, though they remain mostly robust to small spatial perturbations. FloorplanQA uncovers a blind spot in today’s LLMs: inconsistent reasoning about indoor layouts. We hope this benchmark inspires new work on language models that can accurately infer and manipulate spatial and geometric properties in practical settings.

****

New Wide-Net-Casting Jailbreak Attacks Risk Large Models
Qiuchi Xiang, Haoxuan Qu, Hossein Rahmani, Jun Liu

Jailbreak attacks on large models have drawn growing attention due to their close ties to societal safety. This work identifies a practical yet unexplored jailbreak scenario, the wide-net-casting scenario, where an adversary can query a group of large models instead of a single one to elicit harmful outputs. Our analysis reveals substantial yet previously overlooked safety risks under this scenario.

As a key part of our analysis, we further develop a novel jailbreak method tailored to the wide-net-casting scenario.
With this tailored method, the jailbreak success rate can even reach 100% in some experiments when targeting the large models without additional safeguards, exposing wide-net-casting as a distinct, high-risk scenario that warrants attention in future evaluation and defense research.

DreamID-Omni: Unified Framework for Controllable Human-Centric Audio-Video Generation
Xu Guo, Fulong Ye, Qichao Sun, Liyang Chen, Bingchuan Li, Pengze Zhang, Jiawei Liu, Songtao Zhao, Qian HE, Xiangwang Hou
Recent advancements in foundation models have revolutionized joint audio-video generation. However, existing approaches typically treat human-centric tasks including reference-based audio-video generation (R2AV), video editing (RV2AV) and audio-driven video animation (RA2V) as isolated objectives. Furthermore, achieving precise, disentangled control over multiple character identities and voice timbres within a single framework remains an open challenge. In this paper, we propose DreamID-Omni, a unified framework for controllable human-centric audio-video generation. Specifically, we design a Symmetric Conditional Diffusion Transformer that integrates heterogeneous conditioning signals via a symmetric conditional injection scheme. To resolve the pervasive identity-timbre binding failures and speaker confusion in multi-person scenarios, we introduce a Dual-Level Disentanglement strategy: Synchronized RoPE at the signal level to ensure rigid attention-space binding, and Structured Captions at the semantic level to establish explicit attribute-subject mappings. Furthermore, we devise a Multi-Task Progressive Training scheme that leverages weakly-constrained generative priors to regularize strongly-constrained tasks, preventing overfitting and harmonizing disparate objectives. Extensive experiments demonstrate that DreamID-Omni achieves comprehensive state-of-the-art performance across video, audio, and audio-visual consistency, even outperforming leading proprietary commercial models.

Discrete Diffusion Samplers and Bridges: Off-Policy Algorithms and Applications in Latent Spaces
Arran Carter, Sanghyeok Choi, Kirill Tamogashev, Víctor Elvira, Esmeralda S. Whitammer
Sampling from a distribution $p(x) \propto e^{-\mathcal{E}(x)}$ known up to a normalising constant is an important and challenging problem in statistics. Recent years have seen the rise of a new family of amortised sampling algorithms, commonly referred to as diffusion samplers, that enable fast and efficient sampling from an unnormalised density. Such algorithms have been widely studied for continuous-space sampling tasks; however, their application to problems in discrete space remains largely unexplored. Although some progress has been made in this area, discrete diffusion samplers do not take full advantage of ideas commonly used for continuous-space sampling. In this paper, we propose to bridge this gap by introducing off-policy training techniques for discrete diffusion samplers. We show that these techniques improve the performance of discrete samplers on both established and new synthetic benchmarks. Next, we generalise discrete diffusion samplers to the task of bridging between two arbitrary distributions, introducing data-to-energy Schrödinger bridge training for the discrete domain for the first time. Lastly, we showcase the application of the proposed diffusion samplers to data-free posterior sampling in the discrete latent spaces of image generative models.

MEMO: Memory-Augmented Model Context Optimization for Robust Multi-Turn Multi-Agent LLM Games
Yunfei Xie, Kevin Wang, Bobby Cheng, Jianzhu Yao, Zhizhou Sha, Alexander Duffy, Yihan Xi, Hongyuan Mei, Cheston Tan, Chen Wei, Pramod Viswanath, Zhangyang Wang
Multi-turn, multi-agent LLM game evaluations exhibit substantial run-to-run variance. In long-horizon interactions, small deviations compound across turns and are amplified by multi-agent coupling, biasing win rate estimates and destabilizi

ng comparative rankings across repeated tournaments. Prompt choice exacerbates t
his by inducing different effective policies and interaction dynamics. We addres
s both instability and underperformance in games with **MEMO:** (**Me**mory-augm
ented **MO**del context optimization), a self-play framework that treats inferen
ce-time context as an optimizable, agentic object by coupling **retention** and
exploration. Retention distills self-play trajectories into a persistent mem
ory bank of structured insights that act as priors; exploration combines tournam
ent-style prompt evolution under TrueSkill with prioritized replay over decisive
 states. Across five text-based games and a 2,000-game budget per task, MEMO rai
ses mean win rate from 25.1% to 49.5% for GPT-4o-mini and from 20.9% to 45.0% fo
r Qwen-2.5-7B, while sharply reducing run-to-run dispersion. These results sugge
st substantial headroom in multi-agent LLM game performance and robustness can b
e unlocked through memory, with MEMO achieving gains in negotiation and imperfec
t-information settings, while RL remains more effective in perfect-information s
ettings. Project website: https://yunfeixie233.github.io/MEMO/.

ProtDBench: A Unified Benchmark of Protein Binder Design and Evaluation

Cong Liu, Milong Ren, Jiaqi Guan, Chengyue Gong, Jinyuan Sun, Xinshi Chen, Wenzh
i Xiao

Recent advances in $\textit{de novo}$ protein binder design have enabled increas
ing experimental validation, yet reported $\textit{in silico}$ metrics remain di
fficult to interpret or compare across studies due to non-standardized evaluatio
n protocols. We introduce $\textbf{ProtDBench}$, a standardized and throughput-a
ware evaluation framework for protein binder design. ProtDBench defines unified
benchmark tasks, evaluation protocols, and success criteria, enabling systematic
 analysis of how evaluation design influences observed performance. Using a larg
e wet-lab annotated dataset, we analyze commonly used structure prediction model
s as evaluation verifiers, revealing substantial verifier-dependent bias and lim
ited agreement under identical filtering protocols. We then benchmark representa
tive open-source generative binder design methods across ten diverse protein tar
gets under a fixed evaluation protocol. Beyond per-sequence success rates, ProtD
Bench incorporates throughput-aware metrics based on a fixed 24-hour budget, as
well as cluster-level success criteria to account for structural diversity. Toge
ther, these results expose systematic differences induced by filtering rules, su
ccess definitions, and throughput-aware evaluation between computational efficie
ncy, success rate, and structural diversity. Overall, ProtDBench provides a fair
 and reproducible evaluation pipeline that supports systematic and controlled co
mparison of protein binder design methods under realistic evaluation settings.

Zooming without Zooming: Region-to-Image Distillation for Fine-Grained Multimoda
l Perception

Lai Wei, Liangbo He, jun lan, Lingzhong Dong, Yutong Cai, Siyuan Li, Huijia Zhu,
 Weiqiang Wang, Linghe Kong, Yue Wang, Zhuosheng Zhang, Weiran Huang

Multimodal Large Language Models (MLLMs) excel at broad visual understanding but
 still struggle with fine-grained perception, where decisive evidence is small a
nd easily overwhelmed by global context. Recent "Thinking-with-Images" methods a
lleviate this by iteratively zooming in and out regions of interest during infer
ence, but incur high latency due to repeated tool calls and visual re-encoding.
To address this, we propose Region-to-Image Distillation, which transforms zoomi
ng from an inference-time tool into a training-time primitive, thereby internali
zing the benefits of agentic zooming into a single forward pass of an MLLM. In p
articular, we first zoom in to micro-cropped regions to let strong teacher model
s generate high-quality VQA data, and then distill this region-grounded supervis
ion back to the full image. After training on such data, the smaller student mod
el improves "single-glance" fine-grained perception without tool use.
To rigorously evaluate this capability, we further present ZoomBench, a hybrid-a
nnotated benchmark spanning six fine-grained perceptual dimensions, together wit
h a dual-view protocol that quantifies the global-regional "zooming gap". Experi
ments show that our models achieve leading performance across multiple fine-grai
ned perception benchmarks (Figure 1), and also improve general multimodal cognit

ion on benchmarks such as visual reasoning and GUI agents. Our code is available at https://github.com/inclusionAI/Zooming-without-Zooming.

UCPO: Uncertainty-Aware Policy Optimization
Xianzhou Zeng, Jing Huang, Chunmei Xie, Gongrui Nan, Siye Chen, Mengyu Lu, Weiqi Xiong, Qixuan Zhou, Junhao Zhang, Qiang Zhu, Yadong Li, Xingzhong Xu
The key to building trustworthy large language models (LLMs) lies in endowing them with inherent uncertainty expression capabilities, thereby mitigating overconfident errors in high-stakes applications. However, existing RL paradigms such as GRPO often suffer from Advantage Bias due to binary decision spaces and static uncertainty rewards, inducing either excessive conservatism or overconfidence. To tackle this challenge, this paper unveils the root causes of reward hacking and overconfidence in current RL paradigms incorporating uncertainty-based rewards, based on which we propose the **U**n**C**ertainty-Aware **P**olicy **O**ptimization (**UCPO**) framework. UCPO employs Ternary Advantage Decoupling to separate and independently normalize deterministic and uncertain rollouts, thereby eliminating advantage bias. Furthermore, a Dynamic Uncertainty Reward Adjustment mechanism adapts uncertainty weights in real-time according to model evolution and instance difficulty. Experimental results in mathematical reasoning and general tasks demonstrate that UCPO effectively resolves the reward imbalance, significantly improving the reliability of the model beyond their knowledge boundaries. The code is available at https://github.com/xzhouzeng/ucpo.

Training AI Co-Scientists Using Rubric Rewards
Shashwat Goel, RISHI HAZRA, Dulhan Jayalath, Timon Willi, Parag Jain, William F. Shen, Ilias Leontiadis, Francesco Barbieri, Yoram Bachrach, Jonas Geiping, Chenxi Whitehouse
AI co-scientists are emerging as a useful tool for human researchers, with a crucial ability being proposing a research plan for a given research goal. In this work, we study how to train language models that generate better research plans by leveraging the vast corpus of existing research papers. To collect diverse training data, we automatically extract research goals and goal-specific grading rubrics from papers across domains. We then train models for research plan generation via reinforcement learning, with a frozen copy of the initial policy acting as the grader, using the rubrics to evaluate plans generated by the training policy. To validate this approach, we conduct a human study for machine learning research goals spanning 225 expert hours. The experts prefer plans generated by our finetuned Qwen3-30B-A3B model over the initial model for 70% goals, and over Grok-4-Thinking for 59.6% goals. To assess generality, we also extend our approach to goals from medical papers, and recent arXiv preprints, evaluating with a jury of frontier models. Our finetuning yields 12-22% relative improvements and significant cross-domain generalization, proving effective even in problem settings like medical research where execution feedback is infeasible. Overall, we demonstrate the potential of a scalable training recipe as a step towards improving general AI co-scientists.
****
Scalable GANs with Transformers
Sangeek Hyun, MinKyu Lee, Jae-Pil Heo
Scalability has driven recent advances in generative modeling, yet it remains underexplored for adversarial learning. We study the scaling behavior of Generative Adversarial Networks through two design choices: training in a compact Variational Autoencoder latent space and using purely transformer-based generators and discriminators. While this setup is efficient and scales well with compute, naively scaling exposes failure modes; underutilization of early layers in the generator and increasing optimization instability. We address these issues with lightweight intermediate supervision and width-aware learning-rate adjustment. Our Generative Adversarial Transformers (GAT) train reliably from small (S) to extra-large (XL) model sizes, and GAT-XL model achieves state-of-the-art single-step class-conditional generation on ImageNet at 256×256 resolution (FID of 2.18) in 60 epochs, requiring 4x fewer epochs than strong baselines.

****
SimpleGPT: Improving GPT via A Simple Normalization Strategy
Marco Chen, Xianbiao Qi, Yelin He, Jiaquan Ye, Rong Xiao
In this work, we revisit Transformer optimization through the lens of second-ord er geometry and establish a direct connection between architectural design, acti vation scale, the Hessian matrix, and the maximum tolerable learning rate. We in troduce a simple normalization strategy, termed SimpleNorm, which stabilizes int ermediate activation scales by construction. Then, by analyzing the Hessian of t he loss with respect to network activations, we theoretically show that SimpleNo rm significantly reduces the spectral norm of the Hessian, thereby permitting la rger stable learning rates. We validate our theoretical findings through extensi ve experiments on large GPT models at parameter scales 1B, 1.4B, 7B and 8B. Empi rically, SimpleGPT, our SimpleNorm-based network, tolerates learning rates 3$\ti mes$-10$\times$ larger than standard convention, consistently demonstrates stron g optimization stability, and achieves substantially better performance than wel l-established baselines. Specifically, when training 7B-scale models for 60K ste ps, SimpleGPT reduces the training loss from 2.290 to 2.208 compared with Llama2 with QKNorm. Our code is available at \url{https://github.com/Ocram7/SimpleGPT} .

Regime-Adaptive Bayesian Optimization via Dirichlet Process Mixtures of Gaussian Processes
Yan Zhang, Xuefeng Liu, Sipeng Chen, Sascha Ranftl, Chong Liu, Shibo Li
Standard Bayesian Optimization (BO) assumes uniform smoothness across the search space—an assumption violated in multi-regime problems such as molecular conform ation search through distinct energy basins or drug discovery across heterogeneo us molecular scaffolds. A single GP either oversmooths sharp transitions or hall ucinates noise in smooth regions, yielding miscalibrated uncertainty. We propose RAMBO, a Dirichlet Process Mixture of Gaussian Processes that automatically dis covers latent regimes during optimization, each modeled by an independent GP wit h locally-optimized hyperparameters. We derive collapsed Gibbs sampling that ana lytically marginalizes latent functions for efficient inference, and introduce a daptive concentration parameter scheduling for coarse-to-fine regime discovery. Our acquisition functions decompose uncertainty into intra-regime and inter-regi me components. Experiments on synthetic benchmarks and real-world applications—i ncluding molecular conformer optimization, virtual screening for drug discovery, and fusion reactor design—demonstrate consistent improvements over state-of-the -art baselines on multi-regime objectives. Code is available at https://github.c om/AnthonyZhangYan/RAMBO.

Opportunistic Expert Activation: Batch-Aware Expert Routing for Faster Decode Wi thout Retraining
Costin-Andrei Oncescu, Qingyang Wu, Wai Tong Chung, Tsai-chuan Wu, Bryan Dev Gop al, Junxiong Wang, Tri Dao, Ben Athiwaratkun
An increasing number of LLMs employ Mixture-of-Experts (MoE) architectures where the feed-forward layer is replaced by a pool of experts and each token only act ivates a small subset of them. During autoregressive generation, these models of ten enter a memory-bound regime even for moderate batch sizes because the averag e expert load grows more slowly than in an equivalent dense feedforward layer. C onsequently, MoE latency is governed by the number of activated experts. We intr oduce a framework for $\textbf{dynamically}$ re-routing token-to-expert mapping to lower this number (and thus, the decode latency) while preserving a comparabl e quality. Our best results use a $\textbf{batch-aware routing}$ that works by h aving tokens $\textbf{piggyback}$ experts that have already been loaded into mem ory due to being crucial to other tokens within the same batch. At batch size $1 6$, OEA reduces MoE-layer decode latency by $39\\%$ on Qwen3-30B while preservin g standard-error-adjusted downstream accuracy, and by $15\\%$ on Qwen3-235B with only small overall degradation on the long-generation benchmark suite.

IDLM: Inverse-distilled Diffusion Language Models

David Li, Nikita Gushchin, Dmitry Abulkhanov, Eric Moulines, Ivan Oseledets, Max
im Panov, Alexander Korotin
Diffusion Language Models (DLMs) have recently achieved strong results in text g
eneration. However, their multi-step sampling leads to slow inference, limiting
practical use. To address this, we extend Inverse Distillation, a technique orig
inally developed to accelerate continuous diffusion models, to the discrete sett
ing. Nonetheless, this extension introduces both theoretical and practical chall
enges. From a theoretical perspective, the inverse distillation objective lacks
uniqueness guarantees, which may lead to suboptimal solutions. From a practical
standpoint, backpropagation in the discrete space is non-trivial and often unsta
ble. To overcome these challenges, we first provide a theoretical result demonst
rating that our inverse formulation admits a unique solution, thereby ensuring v
alid optimization. We then introduce gradient-stable relaxations to support effe
ctive training. As a result, experiments on multiple DLMs show that our method,
Inverse-distilled Diffusion Language Models (IDLM), reduces the number of infe
rence steps by $4 \times$-$64 \times$, while preserving the teacher model’s gene
ration quality. We provide the code, model checkpoints, and video tutorials on
the project page: [https://david-cripto.com/idlm](https://david-cripto.github.io
/idlm-project-page)

Time-Consistent Robust Multi-Objective Reinforcement Learning via a Bellman–Isaa
cs Weight-Adversary Recursion
Mingxi Hu, Meiling Yu
Most multi-objective reinforcement learning (MORL) methods either condition on a
 fixed preference weight w or consider episodic robustness where an adversary
selects a single w per episode. We study a time-consistent robustness model wi
th reactive preferences: after each transition, an opponent chooses the next wei
ght w_{t+1} after observing s_{t+1}, and incurs a switching cost $\lambda D_
\Phi(w_{t+1}\mid w_t)$ based on a Bregman divergence. This yields a Bellman–Isaa
cs recursion with an inner weight minimization at every backup. We prove the ind
uced operator is a contraction and derive a Bellman-residual certificate that tu
rns approximation error into a uniform bound on robust performance. We develop p
ractical solvers in both tabular and deep settings using Bregman-prox inner upda
tes and a stabilized fixed-point iteration. To evaluate robustness without optim
istic critic reuse, we introduce BR-K, testing policies against K independen
tly trained best-response preference adversaries. Across MO-Gymnasium benchmarks
, our approach consistently improves WRR under strong step-wise opponents over p
reference-conditioned baselines while keeping DRIFT smoothly controllable via $\
lambda$.

Learning a Zeroth-Order Optimizer for Fine-Tuning LLMs
Kairun Zhang, Haoyu Li, Yanjun Zhao, Yifan Sun, Huan Zhang
Zeroth-order optimizers have recently emerged as an attractive approach for fine
-tuning large language models (LLMs), as they avoid backpropagation and can subs
tantially reduce memory overhead relative to standard first-order training. Howe
ver, existing zeroth-order methods rely on hand-crafted, static sampling strateg
ies that are not adaptable to model-specific structures. To address this, we pro
pose ZO-Finetuner, a learning-based zeroth-order optimizer for LLMs that automat
ically learns efficient perturbation strategies through a compact and memory-eff
icient design. Motivated by the fact that a small set of base LLMs is repeatedly
 fine-tuned across tasks, ZO-Finetuner supports one-time per-model training and
reuse across downstream tasks with minimal overhead. Therefore, learning the opt
imizer once for a given LLM and reusing it across diverse downstream tasks is bo
th feasible and highly desirable. Accordingly, ZO-Finetuner is designed to scale
 learning to learn (L2L) to the foundation-model era by supporting one-time per-
model training with minimal overhead. Experiments on 4 LLMs and 7 datasets show
that ZO-Finetuner outperforms prior zeroth-order baselines in 82.1\% of task-mod
el combinations, thereby demonstrating strong performance and scalability for ef
ficient LLM fine-tuning.

UniMapping: Unified SLAM Framework for Map-Centric Embodied Perception
Xiaze Zhang, Ziheng Ding, Yuejie Zhang, lifeng chen, Rui Feng
Simultaneous Localization and Mapping (SLAM) is increasingly expected to provide reusable spatial representations for downstream perception. However, existing approaches often struggle with scale-consistency and producing maps that lack the geometric fidelity required for reliable perception. We propose _UniMapping_, a unified SLAM framework that constructs a persistent neural-descriptor map from multimodal observations. We introduce a **Spatial-Aware Deformable Transformer** that injects explicit geometric inductive bias to ensure scale-invariant feature extraction, alongside a **Spatial Fusion** strategy that decouples feature aggregation from temporal sequences. Extensive experiments on both indoor and outdoor benchmarks demonstrate competitive SLAM performance. Notably, our method significantly enhances downstream tasks (mAP +3.1% and mIoU +7.1%) by leveraging accumulated multi-view context.
****

Log-Normal Multiplicative Dynamics for Stable Low-Precision Deep Learning
Keigo Nishida, Eren Mehmet KIRAL, Kenichi Bannai, Mohammad Emtiyaz Khan, Thomas Möllenhoff
We propose Log-Normal Multiplicative Dynamics (LMD), a new algorithm to stabilize low-precision deep learning. LMD is motivated by the robustness of biological neural networks where synaptic spine sizes follow a log-normal distribution and fluctuate via noisy multiplicative dynamics. So far, no algorithm has successfully incorporated all these synaptic properties to train large models. LMD incorporates these properties through a variational Bayesian formulation that uses a log-normal posterior over weights. We evaluate LMD with low-precision forward-pass matrix multiplications, including training a Vision Transformer and GPT-2 from scratch. Our findings demonstrate the utility of biologically inspired approaches for designing energy-efficient algorithms for stable low-precision deep learning.
****

Accelerating Q-learning through Efficient Value-Sharing across Actions
Prabhat Nagarajan, Brett Daley, Martha White, Marlos C. Machado
Action-values are foundational to many control algorithms such as Q-learning. Therefore learning action-values efficiently is central to reinforcement learning (RL). However, learning them can be slow, requiring many updates to move values from their initialization, typically near zero, to their true values, which may be far from zero. Moreover, action-value learning algorithms typically update each state–action pair independently, without learning shared value structure across actions within a state. In this paper, we address these inefficiencies by introducing the mean-expansion layer, which accelerates action-value learning by sharing values across actions within a state and by changing the problem from directly learning potentially large action-values to learning a lower-norm representation of them. In deep RL, this layer can be applied as a parameter-free addition to Q-network architectures without altering the underlying algorithm. Applied to deep Q-networks and implicit quantile networks, it improves aggregate performance across 57 Atari games while increasing action gaps and dramatically reducing value overestimation.
****

Understanding Performance Collapse in Layer-Pruned Large Language Models via Decision Representation Transitions
boyu shi, Chang Liu, Chuanbao Gao, Xu Yang, Xin Geng
Layer pruning efficiently reduces Large Language Model (LLM) computational costs but often triggers sudden performance collapse. Existing representation-based analyses struggle to explain this mechanism. We propose studying pruning through decision representation. Focusing on multiple-choice tasks, we introduce two metrics, Decision Margin and Option Frequency, and an Iterative Pruning method to analyze layer-wise decision dynamics. Our findings reveal a sharp decision transition that partitions the network into two stages: a Silent Phase, where the model cannot yet predict the correct answer, and a Decisive Phase, where the correct prediction emerges. We also find that pruning the Decisive Phase has minimal im

pact, whereas pruning the Silent Phase triggers immediate performance collapse, highlighting its extreme sensitivity to structural changes. Therefore, we conclu de that pruning-induced collapse stems from disrupting the Silent Phase, which p revents the critical decision transition from occurring.

EvoEGF-Mol: Evolving Exponential Geodesic Flow for Structure-based Drug Design
Yaowei Jin, Junjie Wang, Cheng Cao, Penglei Wang, Duo An, Qian Shi
Structure-Based Drug Design (SBDD) aims to discover bioactive ligands. Conventio nal approaches construct probability paths separately in Euclidean and probabili stic spaces for continuous atomic coordinates and discrete chemical categories, leading to a mismatch with the underlying statistical manifolds. We address this issue by representing molecules using composite exponential-family distribution s, where coordinates and categories are represented within a unified natural par ameter space to evolve synchronously along exponential geodesics under the Fishe r-Rao metric. To avoid the instantaneous trajectory collapse induced by geodesic s directly targeting Dirac distributions, we propose Evolving Exponential Geodes ic Flow for SBDD (EvoEGF-Mol), which replaces static Dirac targets with dynamica lly concentrating distributions and is trained with a progressive-parameter-refi nement architecture. Our model approaches a reference-level PoseBusters passing rate (93.4%) on CrossDock, demonstrating remarkable geometric precision and inte raction fidelity, while achieving superior performance over baseline methods on real-world MolGenBench tasks for bioactive scaffold recovery. Code is available at https://github.com/BLEACH366/EvoEGF-Mol.

Towards Resource-Efficient LLMs: End-to-End Energy Accounting of Distillation Pi pelines
Katherine Lambert, Sasha Luccioni
The rise in deployment of large language models has driven a surge in GPU demand and datacenter scaling, raising concerns about electricity use, grid stress, an d the impacts of modern AI workloads. Distillation is often promoted as one of t he most effective paths to obtain cheaper, more efficient models, yet these clai ms rarely account for the full end-to-end energy and resource costs, including c rucial teacher-side workloads such as data generation, logit caching, and evalua tion. We present a comprehensive energy accounting framework that measures the c omplete computational cost of distillation pipelines via detailed stage-wise tra cking of GPU device power consumption. In our experiments, we separate and log e mpirical energy use across distinct phases and systematically measure the energy and emissions of two common distillation methods: the classic logit-based knowl edge distillation and synthetic-data supervised fine-tuning, constructing energy –quality–throughput Pareto frontiers that expose the previously ignored costs. F rom these measurements and analyses, we derive practical design rules for select ing distillation methods and hyperparameters under energy and budget constraints , and release an open-source measurement harness and accounting protocol to prov ide a standardized foundation for comparable, reproducible distillation research , explicitly accountable for complete pipeline energy impact.

CRAMER: Control via Request-Aware Masking for Editing Recommenders
Zhiyuan Su, Naihe Feng, Luther Qin, Ga Wu
Sequential recommendation models, while powerful, have limited flexibility in re sponding to immediate user requests, making it difficult to adapt their recommen dations to the user's timely interests. Unfortunately, existing user request ada ptation methods often incur high computational overhead due to either 1) retrain ing the entire backbone network or 2) leveraging the inference ability of large language models (a.k.a. prompt engineering), limiting their applicability in lar ge-scale recommendation services. This paper presents **C**ontrol via **R**eques t-**A**ware **M**asking for **E**diting **R**ecommenders (**CRAMER**), a framewo rk that takes users' natural-language requests to immediately change sequential recommendation models' behavior. Specifically, inspired by the model control the ory, CRAMER treats user requests as control signals to modulate frozen backbone parameters through masking, achieving instant adaptation to diverse requests whi

le avoiding costly retraining. Experiments on multiple large-scale benchmark datasets show that CRAMER outperforms four state-of-the-art request-aware baselines across multiple recommendation metrics while achieving minimal overhead. Moreover, the proposed framework exhibits enhanced controllability and cross-domain adaptability, establishing a new paradigm for request-aware sequential recommendation.

CLINIC : Evaluating Multilingual Trustworthiness in Language Models for Healthcare

Akash Ghosh, Srivarshinee Sridhar, Raghav Kaushik Ravi, Muhsin Muhsin, Sriparna Saha, Chirag Agarwal

Integrating language models (LMs) in healthcare systems holds great promise for improving medical workflows and decision-making. However, a critical barrier to their global adoption is the lack of reliable evaluation of their trustworthiness in multilingual healthcare settings. Existing LMs are predominantly trained in high-resource languages, making them ill-equipped to handle the complexity and diversity of healthcare queries in mid- and low-resource languages, which poses significant challenges for deployment in global healthcare contexts where linguistic diversity is essential. In this work, we present CLINIC, a Comprehensive Multilingual Benchmark to evaluate the trustworthiness of language models in healthcare. CLINIC systematically benchmarks LMs across five key dimensions of trustworthiness: truthfulness, fairness, safety, robustness, and privacy, operationalized through 18 diverse tasks spanning 15 languages and covering a wide range of critical healthcare topics. Our extensive evaluation reveals that LMs struggle with factual correctness, demonstrate bias across demographic and linguistic groups, and remain susceptible to privacy breaches and adversarial attacks. By highlighting these shortcomings, CLINIC lays the foundation for enhancing the global reach and safety of LMs in healthcare across diverse languages.

Two-Layer Linear Auto-Regressive Models Estimate Latent States

Yahya Sattar, Sunmook Choi, Leo Maynard-Zhang, Yassir Jedra, Maryam Fazel, Sarah Dean

Auto-regressive models have emerged as powerful tools for sequential data, from language to video. Understanding how and why these models learn latent representations remains an open theoretical question. In this work, we demonstrate that when trained by empirical risk minimization on data from partially observed linear dynamical systems, two-layer linear auto-regressive models naturally learn to approximate Kalman filtering. In particular, we show that the learned hidden representation coincides, up to a similarity transformation, with the state estimates produced by the optimal (Kalman) filter, even though the model has no explicit knowledge of the underlying dynamics or state. The result follows from three main insights. First, we establish that the Kalman filter is well approximated by an auto-regressive model with bounded truncation error. Second, we show that despite non-convexity, the two-layer optimization landscape is benign, i.e., all stationary points are either strict saddles or global minima. Finally, as our main contributions, we provide finite-sample guarantees on prediction error, parameter estimation error, and latent state recovery. Numerical simulations support the theoretical results
and demonstrate that the latent representations of auto-regressive models recover state estimates.

Distribution Transformers: Fast Approximate Bayesian Inference With On-The-Fly Prior Adaptation

George Whittle, Juliusz Ziomek, Jacob Henry Rawling, Michael A Osborne

While Bayesian inference provides a principled framework for reasoning under uncertainty, its widespread adoption is limited by the intractability of exact posterior computation, necessitating the use of approximate inference. However, existing methods are often computationally expensive, or demand costly retraining when priors change, limiting their utility, particularly in sequential inference problems such as real-time sensor fusion. To address these challenges, we introd

uce the Distribution Transformer---a novel architecture that can learn arbitrary distribution-to-distribution mappings. Our method can be trained to map a prior to the corresponding posterior, conditioned on some dataset---thus performing approximate Bayesian inference. Our novel architecture represents a prior distribution as a (universally-approximating) Gaussian Mixture Model (GMM), and transforms it into a GMM representation of the posterior. The components of the GMM attend to each other via self-attention, and to the datapoints via cross-attention. We demonstrate that Distribution Transformers both maintain flexibility to vary the prior, and significantly reduces computation times---from minutes to milliseconds---while achieving expected log-likelihood performance on par with or superior to existing approximate inference methods across tasks such as sequential inference, quantum system parameter inference, and Gaussian Process predictive posterior inference with hyperpriors.

MC-HNN: Learning Latent Structural Semantics and High-Rank Representations for Hypergraph Neural Networks

Shuyang Fang, Yuqin Huang, Zelong Yang, Yintao Cai, Xiaoping Min

Hypergraph Neural Networks (HNNs) have emerged as powerful tools for modeling complex high-order correlations. Most existing HNNs adhere to a two-stage message passing paradigm, where node feature propagation is mediated by hyperedges. In this paper, we analyze two structural limitations of this paradigm, which we term rank collapse and hyperedge semantic dependency. To address these challenges, we propose the Multi-Channel Hypergraph Neural Network (MC-HNN). We design a multi-channel message passing mechanism to maintain high-rank representations, while simultaneously introducing a latent hyperedge type encoding mechanism to inject an independent degree of freedom into hyperedge representations. Our analysis and experiments suggest that MC-HNN alleviates these bottlenecks and achieves strong empirical performance.

Agentic Proposing: Enhancing Large language Model Reasoning via Compositional Skill Synthesis

Zhengbo Jiao, Shaobo Wang, Zifan Zhang, Xuan Ren, Wei Wang, Bing Zhao, HU WEI, Linfeng Zhang

Advancing complex reasoning in large language models relies on high-quality, verifiable datasets, yet human annotation remains cost-prohibitive and difficult to scale. Current synthesis paradigms often face a recurring trade-off: maintaining structural validity typically restricts problem complexity, while relaxing constraints to increase difficulty frequently leads to inconsistent or unsolvable instances. To address this, we propose \textbf{Agentic Proposing}, a framework that models problem synthesis as a goal-driven sequential decision process where a specialized agent dynamically selects and composes modular reasoning skills. Through an iterative workflow of internal reflection and tool-use, we develop the \textbf{Agentic-Proposer-4B} using Multi-Granularity Policy Optimization (MGPO) to generate high-precision, verifiable training trajectories across mathematics, coding, and science. Empirical results demonstrate that downstream solvers trained on agent-synthesized data significantly outperform leading baselines and exhibit robust cross-domain generalization. Notably, a 30B solver trained on only 11,000 synthesized trajectories achieves a state-of-the-art 91.6\% accuracy on AIME25, rivaling frontier-scale proprietary models such as GPT-5 and proving that a small volume of high-quality synthetic signals can effectively substitute for massive human-curated datasets.

LiveFigure: Generating Editable Scientific Illustration with VLM Agents

Chenyang Shao, Jiahe Liu, Fengli Xu, Yong Li

Scientific illustrations are essential for depicting conceptual designs, methodologies, and experimental workflows in research, playing a pivotal role in communicating complex academic insights. However, creating high-quality scientific illustrations remains a labor-intensive task for human scientists. While recent generative image models have advanced prompt-based editing, the synthesis of fully **editable** figures remains a fundamental challenge. Valid editability involves

structured transformations of graphical elements, scales, attributes, and text, rather than simple pixel-level changes. Existing models generate raster outputs that do not support manual correction or layout adjustment, limiting their utility in scientific publishing, where editable vector figures are typically required for submission. To address this challenge, we introduce **LiveFigure**, an agentic framework driven by VLM agents that imitates the multi-step drawing workflow of human researchers. It first plans figure blueprints by drawing inspiration from high-quality references in previous works, then generates executable scripts that produce figures via the PowerPoint interface based on skills and experience, and finally refines the outputs with targeted visual diagnostics, producing fully vectorized, editable figures that meet publication standards. Extensive experiments demonstrate that LiveFigure generates inherently editable figures, achieving 80% publication-readiness in only 17 manual edits, far surpassing the 24% rate of the strongest baseline, NanoBanana. Human preference studies further validate this advantage, with LiveFigure securing a 60% win rate against NanoBanana. Our code is available at https://github.com/tsinghua-fib-lab/LiveFigure.git.

TGPO: Efficient Policy Optimization through Sequence Anchor and Information Gating

Hang Ding, Dongqi Liu, Qiming Feng, Jian Li, Tong Lei, Jiafu Wu, Shuo Wang, Jiangning Zhang, Chengjie Wang, Yabiao Wang

Reinforcement learning from verifiable rewards (RLVR) has become an important paradigm for enhancing the reasoning capabilities of large language models, while it also involves a persistent tradeoff between optimization stability and learning efficiency. Token-level importance weighting supports fine-grained credit assignment, but it often introduces high variance and unstable parameter updates, whereas sequence-level optimization provides more stable learning dynamics while failing to fully exploit informative local signals. We introduce **T**rust-**G**ated **P**olicy **O**ptimization (TGPO), an efficient policy optimization framework that integrates two complementary mechanisms, namely *sequence anchors* and *information gates*. TGPO aligns token-wise updates with a stable sequence-level reference, which reduces the influence of extreme local likelihood fluctuations on the gradient, and a trust-based information gate adaptively modulates the contribution of token-level signals. By retaining and reweighting gradients from imperfect trajectories rather than excluding them, TGPO improves gradient utilization and sample efficiency while maintaining stable optimization behavior. Empirical results across seven mathematical reasoning datasets and multiple model scales show that TGPO consistently enhances learning efficiency and overall performance in outcome-supervised reinforcement learning settings.

****

Smooth Multi-Policy Causal Effect Estimation in Longitudinal Settings

Wenxin Chen, Weishen Pan, Kyra Gan, Fei Wang

Comparative evaluation of *multiple* dynamic treatment policies is essential for healthcare and policy decisions, yet conventional longitudinal causal inference methods estimate each in *isolation*, preventing information sharing across counterfactuals. We demonstrate that this separate estimation paradigm induces a structurally uncontrolled second-order bias, inflating finite-sample variance even after standard debiasing with *longitudinal targeted maximum likelihood estimation* (LTMLE). To address this, we propose a policy-aware reparameterization of *Iterative Conditional Expectation* (ICE) Q-functions that enables joint estimation through shared representations. We implement this approach in the **Policy-Encoded Q Network (PEQ-Net)**, an architecture centered on a shared policy encoder. The encoder is trained using kernel mean embeddings, ensuring that the learned representation space reflects population-level policy dissimilarities. After applying an LTMLE correction step, we prove this design imposes a structural constraint on the second-order remainder, thereby stabilizing finite-sample variance. Experiments on semi-synthetic datasets demonstrate that PEQ-Net consistently outperforms existing ICE-based methods, achieving substantial reductions in root-mean-square error, particularly when evaluating closely related policies.

****
FAIR-Calib: Frontier-Aware Instability-Reweighted Calibration for Post-Training Quantization of Diffusion Large Language Models
Haoyu Huang, Linlin Yang, Sheng Xu, Boyu Liu, Guodong Guo, Zhongqian Fu, Hang Zhou, Baochang Zhang
Diffusion Large Language Models (dLLMs) refine tokens iteratively but commit them irreversibly, leading to a "stability lag" where early decisions remain fragile even after being written. We reveal that Post-Training Quantization (PTQ) error easily flips these borderline decisions at the write frontier, which are then permanently locked in and amplified. To address this, we propose Frontier-Aware Instability-Reweighted Calibration (FAIR-Calib), a two-stage PTQ framework for dLLMs. Stage I probes a full-precision teacher to estimate a position prior that combines frontier hits and masked-stage reliability. Stage II performs off-policy, layer-wise calibration by minimizing a reweighted hidden-state MSE, effectively prioritizing the protection of fragile frontier states without requiring expensive end-to-end diffusion rollouts.
We further theoretically justify our weighted objective as a surrogate for output KL divergence. Empirically, FAIR-Calib consistently outperforms state-of-the-art baselines on LLaDA and Dream (W4A4), significantly reducing frontier decision flips and suppressing post-commit mismatches across diverse benchmarks.
****
RAT+: Train Dense, Infer Sparse - Recurrence Augmented Attention for Dilated Inference
Xiuying Wei, Caglar Gulcehre
Structured dilated attention has an appealing inference-time efficiency knob: it reduces the FLOPs of attention and the KV cache size by a factor of the dilation size D, while preserving long-range connectivity. While prior work studies it by training each configuration from scratch, directly sparsifying a pretrained attention model into a dilated pattern leads to severe accuracy degradation, preventing flexible reuse across inference scenarios. We introduce RAT+, a dense-pretraining architecture that augments attention with full-sequence recurrence and active recurrence learning. A single RAT+ model is pretrained densely once and can then be flexibly switched at inference time to dilated attention (optionally with local windows) or hybrid layer/head compositions, requiring only a short 1B-token resolution adaptation rather than retraining separate sparse models. At 1.5B parameters trained on 100B tokens, RAT+ closely matches dense accuracy at D = 16, and drops by about 2–3 points at D = 64 on commonsense reasoning and LongBench tasks. We further scale to 2.6B and 7.6B parameters and observe even more promising performance (e.g., a 1-point average accuracy loss with a 64× reduction in attention FLOPs and KV cache size). Code is available at https://github.com/wimh966/rat-plus.
****
High-Dimensional Learning Dynamics of Quantized Models with Straight-Through Estimator
Yuma Ichikawa, Shuhei Kashiwamura, Ayaka Sakata
Quantized neural network training optimizes a discrete, non-differentiable objective. The straight-through estimator (STE) enables backpropagation through surrogate gradients and is widely used. While previous studies have primarily focused on the properties of surrogate gradients and their convergence, the influence of quantization hyperparameters, such as bit width and quantization range, on learning dynamics remains largely unexplored. We theoretically show that in the high-dimensional limit, STE dynamics converge to a deterministic ordinary differential equation. This reveals that STE training exhibits a plateau followed by a sharp drop in generalization error, with plateau length depending on the quantization range. A fixed-point analysis quantifies the asymptotic deviation from the unquantized linear model. We also extend analytical techniques for stochastic gradient descent to nonlinear transformations of weights and inputs.

Faults in Our Formal Benchmarking: Dataset Defects and Evaluation Failures in Lean Theorem Proving

Pawan Sasanka Ammanamanchi, Siddharth Bhat, Stella Biderman
Benchmarks for LLM-assisted theorem proving in Lean are often treated as intrinsically reliable because every solved instance comes with a machine-checked proof.
However, the kernel only checks that a proof establishes a \emph{formal} statement; it does not verify that the statement faithfully encodes the intended informal problem, nor that evaluation harnesses are robust to trivial or adversarial solutions.
We audit five widely used Lean theorem-proving benchmarks and their forks, using corpus-scale static checkers to surface 4,833 findings, including 398 mechanically certified issues such as counterexamples, vacuous theorems, and unsound axioms.
We also document semantic defects such as missing hypotheses, problem simplification, incomplete or incorrect translations, and Lean-specific specification hazards.
Beyond dataset construction, we survey evaluation-time failure modes and show, on corrected subsets, that defects can both inflate and deflate reported prover scores.
We propose a fault taxonomy, a suite of automated checkers and recall-oriented semantic-audit prompts, and release standards to guide the creation of formal math datasets and make evaluation more reproducible and trustworthy.
Our checkers, audit prompts, and corrected dataset snapshots are available at \url{https://github.com/Shashi456/atp-checkers}.
****
Temperature Scaling in Discrete Sequence (Language) Models
Hannah Scheufele, Peter Blohm, Vikas K Garg
Temperature scaling is widely used to control generation behavior and improve reasoning performance in discrete sequence models. However, temperature scaling at the sequence level is particularly challenging since the partition function of the model is typically not tractable and naive *token-wise* temperature scaling induces bias in the maximum a posteriori (MAP) estimates. Discrete diffusion settings exacerbate this issue: enhanced flexibility due to multiple potential orderings for generating tokens complicates likelihood computation and incurs high variance.

We propose and investigate fine-tuning objectives for sequence-level temperature scaling, along with metrics to quantify the success of a given temperature scaling procedure. Specifically, our contributions are threefold. First, we introduce our objective across a wide class of sequence models through a novel formalism that unifies autoregressive and diffusion-based language models. Second, we design two metrics that quantify temperature scaling based on likelihood *ratios* and thus obviate access to the partition function. Finally, we introduce fine-tuning objectives that reliably achieve the desired change in model temperature.

Our experiments with language models (GPT2, BD3LM) show that the proposed approach leads to more consistent generation with lower perplexity. Furthermore, we provide empirical evidence that it can enhance the reasoning performance in language models. Code is available at github.com/Aalto-QuML/temp_lm.
****
Are We Overconfident in Models and Results for Semi-Supervised 3D Medical Image Segmentation?
Jun Li, Ziwei Qin
Semi-supervised learning has become a dominant paradigm for reducing annotation costs. However, we argue that the current progress is clouded by a twofold overconfidence problem. Algorithmically, mainstream pseudo-labeling frameworks often conflate prediction confidence with uncertainty, leading to severe confirmation bias. Strategically, since multiple benchmark datasets lack dedicated validation sets, some studies use the test set for validation as well, leading to inflated performance estimates. Subsequent methods, compelled to employ the same strateg

y to surpass reported SOTA, trigger an arms race of overfitting. This raises concerns that the impressive numerical gains in the community may reflect overfitting rather than genuine progress. Thus, we propose a tri-space calibrated segmentation framework founded on a principled dual-axis reliability assessment engine. It explicitly decouples confidence from uncertainty and uses this signal to detect and correct confirmation bias across feature, probability, and image spaces in a collaborative manner. Across three benchmark datasets, TCSeg consistently delivers strong performance under existing evaluation protocols. More importantly, we advocate that the community report final-checkpoint results under multiple-run protocols, thereby establishing more rigorous benchmarks with a more realistic perspective. Code will be available: github.com/DirkLiii/TCSeg.

Functional Equivalence in Attention: A Comprehensive Study with Applications to Linear Mode Connectivity

Viet-Hoang Tran, Khanh Vinh Bui, Van-Hoan Trinh, Tan Lai Ngoc, Tan Minh Nguyen

Neural network parameter spaces are inherently non-injective, as distinct parameter configurations can realize identical functions through functional equivalence. While this symmetry is well understood in classical fully connected and convolutional models, it becomes substantially more intricate in modern attention-based architectures. Existing analyses of multihead attention have largely focused on the vanilla formulation, overlooking positional encodings that fundamentally reshape architectural symmetries. In this work, we provide a formal study of functional equivalence in Transformers with positional encodings. Focusing on the two most widely used variants--sinusoidal and rotary positional encodings (RoPE)--we show that sinusoidal encodings preserve the equivalence structure of vanilla attention, whereas rotary encodings significantly reduce the symmetry group, thereby enhancing expressivity. This offers a principled explanation for the growing prominence of RoPE in practice. We further examine how positional encodings affect linear mode connectivity, and through an alignment algorithm, empirically demonstrate that the presence and variability of connectivity across Transformer settings crucially depend on the positional encoding.

Language Model Augmented Semi-Supervised Statistical Inference

Xinrui Ruan, Yingfei Wang, Waverly Wei, Jingshen Wang

Semi■supervised statistical inference plays a key role in biomedical research, where labeled data often have higher quality but are limited due to costly clinical annotation. Yet, existing semi■supervised statistical inference methods rely heavily on structured variables and strictly matched covariates between labeled and unlabeled datasets -- limitations ill■suited for the heterogeneity and unstructured nature of real-world biomedical data. Modern biomedical studies increasingly collect unstructured data (clinical notes, patient audio and video recordings), with inconsistent protocols across datasets causing covariate misalignment (for instance, detailed medication histories may be recorded in one study but not another). Recent advances in pre■trained multimodal large language models (LLMs), which excel at handling unstructured data, present an attractive potential solution. To transform this potential into rigorous semi-supervised statistical inference methods for biomedical research, two key challenges must be addressed: (1) How can we reliably integrate LLMs to enhance semi-supervised inference efficiency without compromising statistical validity? (2) How can those efficiency gains persist despite mismatched covariates between labeled and unlabeled datasets? In this paper, we tackle these challenges by systematically *calibrating pseudo-labels* provided LLMs with a novel *prediction-invariance identification* strategy. Our resulting semi■supervised inference framework improves parameter estimation efficiency while maintaining full statistical validity, as demonstrated through our theoretical results and illustrated in a case study for identifying key biomarkers in Alzheimer’s disease detection with speech data.

TRIP-Bench: A Benchmark for Long-Horizon Interactive Agents in Real-World Scenarios

Yuanzhe Shen, Zisu Huang, Zhengyuan Wang, Muzhao Tian, Zhengkang Guo, Chenyang Z

hang, Shuaiyu Zhou, Zengjie Hu, Dailin Li, Kaimin Wang, Wenhao Liu, Tianlong Li, feng hong, Cao Liu, Ke Zeng
As LLM-based agents are deployed in increasingly complex real-world settings, existing benchmarks underrepresent key challenges such as enforcing global constraints, coordinating multi-tool reasoning, and adapting to evolving user behavior over long, multi-turn interactions. To bridge this gap, we introduce \textbf{TRIP-Bench}, a long-horizon benchmark grounded in realistic travel-planning scenarios. TRIP-Bench leverages real-world data, offers 18 curated tools and 40+ travel requirements, and supports automated evaluation. It includes splits of varying difficulty; the hard split emphasizes long and ambiguous interactions, style shifts, feasibility changes, and iterative version revision. Dialogues span up to 15 user turns, can involve 150+ tool calls, and may exceed 200k tokens of context. Experiments show that even advanced models achieve at most 50\% success on the easy split, with performance dropping below 10\% on hard subsets. We further propose GTPO, an online multi-turn reinforcement learning method with specialized reward normalization and reward differencing. Applied to Qwen2.5-32B-Instruct, GTPO improves constraint satisfaction and interaction robustness, outperforming Gemini-3-Pro in our evaluation. We expect TRIP-Bench to advance practical long-horizon interactive agents, and GTPO to provide an effective online RL recipe for robust long-horizon training.

Decoupling Variance and Scale-Invariant Updates in Adaptive Gradient Descent for Unified Vector and Matrix Optimization
Zitao Song, Cedar Site Bai, Zhe Zhang, Brian Bullins, David F. Gleich
Adaptive methods like Adam have become the *de facto* standard for large-scale vector and Euclidean optimization due to their coordinate-wise adaptation with a second-order nature. More recently, matrix-based spectral optimizers like Muon (Jordan et al., 2024b) show the power of treating weight matrices as matrices rather than long vectors. Linking these is hard because many natural generalizations are not feasible to implement, and we also cannot simply move the Adam adaptation to the matrix spectrum. To address this, we reformulate the AdaGrad update and decompose it into a variance adaptation term and a scale-invariant term. This decoupling produces **DeVA** (**De**coupled **V**ariance **A**daptation), a framework that bridges between vector-based variance adaptation and matrix spectral optimization, enabling a seamless transition from Adam to adaptive spectral descent. Extensive experiments across language modeling and image classification demonstrate that DeVA consistently outperforms state-of-the-art methods such as Muon and SOAP (Vyas et al., 2024), reducing token usage by around 6.6\%. Theoretically, we show that the variance adaptation term effectively improves the blockwise smoothness, facilitating faster convergence.
****
Linearizing Vision Transformer with Test-Time Training
Yining Li, Dongchen Han, Zeyu Liu, Hanyi Wang, Yulin Wang, Gao Huang
While linear-complexity attention mechanisms offer a promising alternative to Softmax attention for overcoming the quadratic bottleneck, training such models from scratch remains prohibitively expensive. Inheriting weights from pretrained Transformers provides an appealing shortcut, yet the fundamental representational gap between Softmax and linear attention prevents effective weight transfer. In this work, we address this conversion challenge from two perspectives: architectural alignment and representational alignment. We identify Test-Time Training (TTT) as a linear-complexity architecture whose two-layer dynamic formulation is structurally aligned with Softmax attention, enabling direct inheritance of pretrained attention weights. To further align representational properties, including key shift-invariance and locality, we introduce key instance normalization and a lightweight locality enhancement module. We validate our approach by linearizing Stable Diffusion 3.5 and introduce SD3.5-T^5 (Transformer To Test Time Training). With only 1 hour of fine-tuning on 4×H20 GPUs, SD3.5-T^5 achieves comparable text-to-image quality to the fine-tuned Softmax model, while accelerating inference by 1.32× and 1.47× at 1K and 2K resolutions. Code is available at this URL: https://github.com/LeapLabTHU/Transformer-to-TTT.

****
μpscaling small models: Principled warm starts and hyperparameter transfer
Yuxin Ma, Nan Chen, Mateo Diaz Diaz, Soufiane Hayou, Dmitriy Kunisky, Soledad Villar
Modern large-scale neural networks are often trained and released in multiple sizes to accommodate diverse inference budgets. To improve efficiency, recent work has explored *model upscaling*: initializing larger models from trained smaller ones to accelerate convergence. However, this method can be sensitive to hyperparameters that need to be tuned at the target upscaled model size, which is prohibitively costly to do directly. It remains unclear whether tuning hyperparameters on smaller models and extrapolating via scaling laws is sound in this setting. We address this with principled approaches to width-based upscaling and efficient hyperparameter tuning in this setting. Motivated by μP and any-dimensional architectures, we introduce a general upscaling method that, like Net2Net, copies and perturbs weights, but uses theoretically grounded, width-dependent scalings for the perturbation noise and optimizer hyperparameters. First, we prove that under zero perturbation, the upscaled model is functionally equivalent to the base model throughout training. Second, we extend the μP theory to enable infinite-width limit analysis and establish hyperparameter transfer for upscaled models, greatly reducing the tuning cost. We empirically demonstrate that this method is effective on realistic datasets and architectures.
****
How much can language models memorize?
John Xavier Morris, Chawin Sitawarin, Chuan Guo, Narine Kokhlikyan, G. Edward Suh, Alexander M Rush, Kamalika Chaudhuri, Saeed Mahloujifar
We propose a new method for estimating how much a model knows about a datapoint and use it to measure the capacity of modern language models. Prior studies of language model memorization have struggled to disentangle memorization from generalization. We formally separate memorization into two components: unintended memorization, the information a model contains about a specific dataset, and generalization, the information a model contains about the true data-generation process. When we completely eliminate generalization, we can compute the total memorization, which provides an estimate of model capacity: our measurements estimate that GPT-style models have a capacity of approximately 3.6 bits per parameter. We train language models on datasets of increasing size and observe that models memorize until their capacity fills, at which point unintended memorization decreases as models begin to generalize. We train hundreds of transformer language models ranging from 500K to 1.5B parameters and produce a series of scaling laws relating model capacity and data size to membership inference.

Decompose, Structure, and Repair: A Neuro-Symbolic Framework for Autoformalization via Operator Trees
Xiaoyang Liu, Zineng Dong, Yifan Bai, Yantao Li, Yuntian Liu, Tao Luo
Statement autoformalization acts as a critical bridge between human mathematics and formal mathematics by translating natural language problems into formal language. While prior works have focused on data synthesis and diverse training paradigms to optimize end-to-end Large Language Models (LLMs), they typically treat formal code as flat sequences, neglecting the hierarchical logic inherent in mathematical statements. In this work, we introduce Decompose, Structure, and Repair (DSR), a neuro-symbolic framework that restructures autoformalization into a modular pipeline. DSR decomposes statements into logical components and maps them to structured operator trees, leveraging this topological blueprint to precisely localize and repair errors via sub-tree refinement. Furthermore, we introduce PRIME, a benchmark of 156 undergraduate and graduate-level theorems selected from canonical textbooks and expertly annotated in Lean 4. Experimental results demonstrate that DSR establishes a new state-of-the-art, consistently outperforming baselines under equivalent computational budgets. The datasets, model, and code are available at https://github.com/XiaoyangLiu-sjtu/DSR.

Hugging Carbon: Quantifying the Training Carbon Emissions of AI Models at Scale

Xinlei Wang, Ruibo Ming, Jing Qiu, Junhua Zhao, Jinjin Gu
The scaling-law era has transformed artificial intelligence (AI) from research i nto a global industry, but its rapid growth also raises concerns over energy usa ge, carbon emissions, and environmental sustainability. Unlike traditional secto rs, the AI industry still lacks systematic carbon accounting methods that suppor t large-scale estimates without reproducing the original training process. This leaves open questions about how large the problem is today and how large it migh t be in the near future. Given its central role in hosting open-source AI models , the Hugging Face (HF) platform provides a large-scale and publicly accessible corpus for carbon accounting. We estimate aggregate training emissions of HF ope n-source models using available emissions, energy, compute, and model metadata. To address uneven disclosure quality, we introduce a tiered approach to handle i ncomplete metadata, supported by empirical regressions that assess estimation re liability. We further introduce AI training carbon intensity (ATCI, emissions pe r compute), a metric to assess the sustainability efficiency of model training. Our results show that training the most popular open-source models (with over 5, 000 downloads) has already resulted in approximately 6.0×10^4 metric tons of car bon emissions. Overall, this paper provides a scalable, empirically grounded fra mework for estimating training emissions from incomplete disclosures and informi ng future carbon reporting standards in the AI industry. Data and code are avail able at https://github.com/insait-institute/HuggingCarbon.

Monitoring Monitorability
Melody Y. Guan, Miles Wang, Micah Carroll, Zehao Dou, Annie Y. Wei, Marcus Willi ams, Benjamin Arnav, Joost Huizinga, Ian D Kivlichan, Amelia Glaese, Jakub Pacho cki, Bowen Baker
Safe deployment of increasingly capable AI agents may require visibility into ho w they make decisions. Chain-of-thought (CoT) monitoring can detect misbehavior in today’s reasoning models, but this “monitorability” may be fragile under diff erent training procedures, data sources, or continued system scaling. We propose three evaluation archetypes (intervention, process, and outcome-property), a ne w monitorability metric, and a broad evaluation suite. We show CoT monitoring ou tperforms action-only monitoring in practical settings, and that frontier models are generally—but not perfectly—monitorable. We study scaling trends with pre-t raining model size and inference-time compute, finding longer CoTs are typically more monitorable. We find that, for a fixed capability level, using a smaller m odel at higher reasoning effort can yield higher monitorability, at greater infe rence compute cost. We further find that increasing a weak monitor’s test-time c ompute when monitoring a strong agent improves monitorability, and giving the mo nitor access to the CoT both boosts monitorability and steepens the compute–to-m onitorability scaling trend. Finally, we show monitorability can be improved by asking follow-up questions and giving the follow-up CoT to the monitor.

Plasticity Activation via Polar Operator: A Plug-in Method for Balancing Stabili ty and Plasticity
Guodong Zheng, Enneng Yang, Xiaoyan Wang, Yihan Chen, Feihong He, Quan Zheng, Pe ng Wang, Li Shen
Continual learning (CL) seeks models that acquire new knowledge while avoiding c atastrophic forgetting. However, many methods that mitigate forgetting constrain parameter updates and thereby reduce model plasticity. We revisit the singular value spectrum of gradients in representative CL methods and show that they comm only exhibit singular value collapse, where only a small subset of gradient dire ctions drive parameter updates. Motivated by this observation, we propose **P**l asticity **A**ctivation via **P**olar **O**perator (PAPO), a plug-in that preser ves the dominant directions that mitigate forgetting while activating previously suppressed directions to enhance plasticity. Concretely, PAPO modifies the grad ient $\mathbf{G}$ as
$\mathbf{G}\leftarrow \mathbf{G}+\lambda \cdot \operatorname{polar}(\mathbf{G})$,
which uniformly increases near-zero singular values without changing the singula

r vectors. To avoid the cost of explicit singular value decomposition, we approx
imate the polar factor using the iteration-dependent Polar Express scheme, which
 relies only on matrix multiplications and additions. In our empirical evaluatio
n on both vision and language benchmarks, incorporating PAPO yields consistent i
mprovements. In particular, on MiniImageNet, integrating PAPO into ER, MAS, GPM
and TRGP produces substantial accuracy gains of 9.01%, 4.76%, 8.90% and
 9.19%, respectively.

Generalized Schrödinger Bridge on Graphs
Panagiotis Theodoropoulos, Juno Nam, Evangelos Theodorou, Jaemoo Choi
Transportation on graphs is a fundamental challenge across many domains, where d
ecisions must respect topological and operational constraints.
Despite the need for actionable policies, existing graph-transport methods lack
this expressivity. They rely on restrictive assumptions, fail to generalize acro
ss sparse topologies, and scale poorly with graph size and time horizon.
To address these issues, we introduce Generalized Schrödinger Bridge on Graphs (
GSBoG), a novel scalable data-driven framework for learning executable controlle
d continuous-time Markov chain (CTMC) policies on arbitrary graphs under state c
ost augmented dynamics.
Notably, GSBoG learns trajectory-level policies, avoiding dense global solvers a
nd thereby enhancing scalability.
This is achieved via a likelihood optimization approach, satisfying the endpoint
 marginals, while simultaneously optimizing intermediate behavior under state-de
pendent running costs.
Extensive experimentation on challenging real-world graph topologies shows that
GSBoG reliably learns accurate, topology-respecting policies while optimizing ap
plication-specific intermediate state costs, highlighting its broad applicabilit
y and paving new avenues for cost-aware dynamical transport on general graphs.

FedVeer: Self-Adaptive Skew Estimation for Robust Federated Learning
Yun Xin, Bangqi Pan, Jianfeng Lu, Shuqin Cao, Gang Li, Guanghui Wen
Federated Learning (FL) enables collaborative model training across decentralize
d clients, but its performance often degrades under non-IID data distributions,
particularly in the presence of data skew. Existing approaches mitigate this iss
ue by estimating client skew via kernel density estimation over neighboring mode
l updates, which preserves privacy and reduces communication costs. However, suc
h approaches suffer from two fundamental limitations: bias toward skewed majorit
y clients due to fixed neighborhood structures, and vulnerability to noise-induc
ed perturbation in kernel space. To address these challenges, we propose FedVeer
, a skew-aware FL framework based on self-adaptive kernel density estimation wit
h k-free neighborhoods. FedVeer dynamically determines the neighborhood size via
 max-margin learning to mitigate majority-client bias, and further incorporates
Kalman filtering to stabilize margin estimation under noisy updates, with a high
-probability theoretical guarantee on margin deviation. Extensive experiments on
 realworld datasets demonstrate that FedVeer consistently outperforms four basel
ines, achieving up to 6.36% accuracy improvement and reducing noiseinduced degra
dation by up to 6.01%.

Contextualized Privacy Defense for LLM Agents
Yule Wen, Yanzhe Zhang, Jianxun Lian, Xiaoyuan Yi, Xing Xie, Diyi Yang
LLM agents increasingly act on users' personal information, yet existing privacy
 defenses remain limited in both design and adaptability.
Most prior approaches rely on static or passive defenses, such as prompting and
guarding. These paradigms are insufficient for supporting contextual, proactive
privacy decisions in multi-step agent execution. We propose *Contextualized Defe
nse Instructing (CDI)*, a new privacy defense paradigm in which an instructor mo
del generates step-specific, context-aware privacy guidance during execution, pr
oactively shaping actions rather than merely constraining or vetoing them. Cruci
ally, CDI is paired with an experience-driven optimization framework that trains
 the instructor via reinforcement learning (RL), where we convert failure trajec

tories with privacy violations into learning environments. We formalize baseline defenses and CDI as distinct intervention points in a canonical agent loop, and compare their privacy–helpfulness trade-offs within a unified simulation framework. Empirically, CDI consistently achieves a better balance between privacy preservation (94.2\%) and helpfulness (80.6\%) than baselines, with superior robustness to adversarial conditions and generalization.

Fast Spectrally Sparse Signal Reconstruction via Jacobi-Preconditioned Gradient Descent

Jian-Feng Cai, Xueyang Quan, Yang Wang, Jiaxi Ying

Spectrally sparse signal reconstruction arises in a wide range of applications and can be formulated as a low-rank Hankel matrix completion problem. We develop a Jacobi-preconditioned gradient descent method that preserves the low per-iteration complexity of first-order algorithms while achieving linear convergence at a rate independent of the condition number. By introducing a generator that maps factor-based iterates to matrix space, we establish equivalence with manifold-based methods, enabling direct convergence analysis while avoiding the need to define distances under complex-symmetric factorization ambiguity. Extensive experiments demonstrate that the proposed algorithm outperforms state-of-the-art methods in both iteration count and computational time across a broad range of problem settings.

Evaluating Bivariate Causal Statements Based on Mutual Compatibility

Erik Jahn, Dominik Janzing

For many real-world systems, causal ground truth is difficult to obtain, making claims about causal effects hard to assess. We develop methods for evaluating collections of bivariate causal statements, one for each pair of variables in a fixed system. In the setting of acyclic linear statements, any such collection can be extended to a unique multivariate causal model, but we argue that this induced model is implausible if it imposes substantial additional confounding to explain observed correlations. We introduce a compatibility score that quantifies this notion of plausibility, notably without relying on the faithfulness assumption. Additionally, we define an incompatibility score for purely graphical bivariate causal statements, based on global consistency constraints that are derived from acyclicity and faithfulness assumptions. We give theoretical and empirical evidence that both scores can successfully distinguish correct from incorrect causal statements in generic settings. Moreover, we demonstrate the practical applicability of our methods by analyzing causal claims made by large language models. Our work aims to provide a foundation for assessing the reliability of causal information derived from human experts or artificial intelligence in settings where alternative forms of validation are unavailable.

Beyond Pixels: Mining Compressed Domain Artifacts for Efficient AI-Generated Video Detection

Anran Zhu, Zhengli Shi, Chende Zheng, Chenhao Lin, Zhengyu Zhao, Le Yang, Chong Zhang, Shuai Liu, Chao Shen

With the rapid advancement of high-fidelity video generation models, robust AI-generated video (AIGV) detection has become increasingly needed. While most AIGV detection methods operate in the decoded pixel domain, we observe that detection in the pixel domain inevitably entangles task-irrelevant semantic information, leading to substantial semantic redundancy and extensive redundant computation, while overlooking free-to-use signals in compressed bitstreams. In particular, motion vectors and residuals directly encode temporal and spatial generative artifacts but remain largely underexplored. To address these issues, we propose a unified framework for **S**patio-**T**emporal **RE**sidual and **A**rtifact **M**ining, namely **STREAM**, which enables AIGV detection directly from compressed bitstreams. **STREAM** leverages I-frames, motion vectors, and residual errors to capture spatiotemporal artifacts that are typically smoothed out by decompression filters. In particular, we design a lightweight network with a motion-guided alignment module and a gated fusion mechanism, enabling adaptive fusion of spati

al artifacts and nonlinear temporal dynamics. Extensive experimental results dem
onstrate that **STREAM** achieves SOTA performance with an mAP of 0.965, with 2.
5× faster inference than previous SOTA baselines.

Generalized Boundary FDR Control under Arbitrary Dependence: An Approach on Clos
ure Principle
Yifan Zhang, Wentao Zhang, Changliang Zou, Haojie Ren
False discovery rate (FDR) is a cornerstone of modern multiple testing. However,
 it often fails to guarantee the reliability of ``marginal" discoveries that lie
 at the boundary of the rejection set, which are often crucial in high-precision
 applications. While recent works (Soloff et al., 2024; Xiang et al., 2025) intr
oduced the boundary false discovery rate (bFDR) to control the error probability
 at the marginal discovery, their method relies on restrictive assumptions such
as independence or specific prior distributions. In this paper, we first propose
 k-bFDR, a novel generalization that controls the error probability of the k
 least significant discoveries. We then provide a systematic investigation into
the theoretical relationship between k-bFDR and existing error metrics. Furthe
rmore, building upon the closure principle, we develop Domino, a unified framewo
rk that guarantees k-bFDR control under arbitrary dependence, applicable for b
oth p-values and e-values. We prove the theoretical validity of the proposed Dom
ino algorithm and demonstrate through extensive numerical experiments that it co
nsistently achieves rigorous k-bFDR control while identifying trustworthy marg
inal discoveries. Analyses of real data reveal that k-bFDR control yields high
er-quality rejection sets with greater practical significance.

On Stable Long-Form Generation: Benchmarking and Mitigating Length Volatility
Zhitao He, Haolin Yang, Rui Min, Zeyu Qin, Yi R. Fung
Large Language Models (LLMs) excel at long-context understanding but exhibit sig
nificant limitations in long-form generation. Existing studies primarily focus o
n single-generation quality, generally overlooking the volatility of the output
(i.e., the inconsistency in length and content across multiple generations). Thi
s volatility not only leads to significant computational costs but also severely
 impacts the models' reliable application. To address this gap, our work unfolds
 in three stages: benchmarking, probing, and mitigation. We first propose the VO
latility in Long-form Text Benchmark (VOLTBench), a novel heterogeneous-task ben
chmark designed to systematically quantify the length volatility of long-form ge
neration. Subsequently, by analyzing attention traces, we conduct an in-depth pr
obe to identify several common internal patterns that cause this volatility. Fin
ally, to mitigate long-form output volatility, we propose SELB (Structural Enfor
cement via Logits Boosting), a lightweight decoding-stage optimization strategy,
 designed to significantly enhance both the length accuracy and stability of lon
g-form generation without additional training. Extensive experiments on VOLTBenc
h provide the first systematic confirmation of severe long-form output instabili
ty in mainstream models and validate that our proposed method successfully impro
ves the mean output length of the base model by 148% and reduces the length vola
tility by 69%, while maintaining high generation quality.

Bayesian model selection and misspecification testing in imaging inverse problem
s only from noisy and partial measurements
Tom Sprunck, Marcelo Pereyra, Tobías I. Liaudat
Modern imaging techniques heavily rely on Bayesian statistical models to address
 difficult image reconstruction and restoration tasks. This paper addresses the
objective evaluation of such models in settings where ground truth is unavailabl
e, with a focus on model selection and misspecification diagnosis. Existing unsu
pervised model evaluation methods are often unsuitable for computational imaging
 due to their high computational cost and incompatibility with modern image prio
rs defined implicitly via machine learning models. We herein propose a general m
ethodology for unsupervised model selection and misspecification detection in Ba
yesian imaging sciences, based on a novel combination of Bayesian cross-validati
on and data fission, a randomized measurement splitting technique. The approach

is compatible with any Bayesian imaging sampler, including diffusion and plug-and-play samplers. We demonstrate the methodology through experiments involving various scoring rules and types of model misspecification, where we achieve excellent selection and detection accuracy with a low computational cost.
****
Diversity-Driven Offline Multi-Objective Optimization via Nested Pareto Set Learning
Yiyi Zhu, Yaolin Wen, Xiang Xia, Xin An, Hanyi Si, Xiang Shu, Yangde Fu, Liang Dou, Hong Qian
Multi-objective optimization (MOO) has emerged as a powerful approach to solving complex optimization problems involving multiple objectives. In many practical scenarios, function evaluations are unavailable or prohibitively expensive, necessitating optimization solely based on a fixed offline dataset. In this setting, known as offline MOO, the goal is to find out the Pareto set without access to the true objective functions. This setting suffers from the out-of-distribution (OOD) issue, where the surrogate model is not accurate for unseen designs. Due to the OOD issue, surrogate errors may cause the optimizer to select solutions that do not lie on the true Pareto front and are biased toward its extremes. To address this, this paper proposes Diversity-driven Offline Multi-Objective Optimization (DOMOO), which aims to find out a diverse and high-quality set of solutions. First, DOMOO incorporates an accumulative risk control module that estimates the potential risk of candidate solutions and alleviates the OOD issue between the training data and the generated solutions. In addition, a nested Pareto set learning (PSL) strategy is proposed to jointly learn preference and PSL parameters, then optimize them, enabling adaptation to diverse Pareto front geometries. To further enhance solution quality, we design a diversity-driven selection strategy that extracts a representative and well-distributed set of final solutions. To achieve this diversity-driven selection strategy, we propose $\text{IGD}_\text{offline}$, a tailored indicator for the offline setting that considers both diversity and convergence, and avoids the bias of hypervolume indicator. Extensive experiments on synthetic and real-world benchmarks show that DOMOO achieves the best average rank across tasks in both convergence and diversity among the compared methods.
****
Revisiting the Volume Hypothesis
Ari Pakman, Lior Kreimer, Yakir Berchenko
Modern deep neural networks often contain far more parameters than needed to fit their training data, yet they achieve impressive generalization. A common explanation for this success is the implicit bias of stochastic gradient descent (SGD). An alternative volume hypothesis posits that, within low training-loss regions, loss-landscape basins leading to strong generalization occupy much larger regions of weight space than basins that generalize poorly, and therefore SGD is simply more likely to land in the former. Recent experimental explorations of this idea present seemingly contradictory results. While in one set of experiments randomly sampling the network weights until achieving zero training error yielded poor generalization, molecular dynamics density estimates supported the volume hypothesis. We observe that these experiments were performed at different dataset size regimes, and explore an intermediate regime using the Replica Exchange Wang–Landau algorithm to estimate the joint density of states over training and test accuracies in binary networks. Across several architectures and datasets, we show that the generalization advantage of gradient learning over random sampling training generally diminishes as the training data size grows, suggesting a resolution of the paradox.
****
SHAP-Guided Kernel Actor-Critic for Explainable Reinforcement Learning
Na Li, Hangguan Shan, Wei Ni, Wenjie Zhang, Xinyu Li
Actor-critic (AC) methods are a cornerstone of reinforcement learning (RL) but offer limited interpretability. Current explainable RL methods seldom use \emph{state attributions} to assist training. Rather, they treat all state features equally, thereby neglecting the heterogeneous impacts of individual state dimension

s on the reward. We propose *RKHS-SHAP-based Advanced Actor-Critic (RSA2C)*, an attribution-aware, kernelized, two-timescale AC algorithm, including Actor, Value Critic, and Advantage Critic. The Actor is instantiated in a vector-valued reproducing kernel Hilbert space (RKHS) with a Mahalanobis-weighted operator-valued kernel, while the Value Critic and Advantage Critic reside in scalar RKHSs. These RKHS-enhanced components use sparsified dictionaries: the Value Critic maintains its own dictionary, while the Actor and Advantage Critic share one. State attributions, computed from the Value Critic via RKHS-SHAP (kernel mean embedding for on-manifold and conditional mean embedding for off-manifold expectations), are converted into Mahalanobis-gated weights that modulate Actor gradients and Advantage Critic targets. We derive a global, non-asymptotic convergence bound under *state perturbations*, showing stability through the perturbation-error term and efficiency through the convergence-error term. Empirical results on three continuous-control environments show that RSA2C achieves efficiency, stability, and interpretability. Our code is available at https://github.com/Na-Li66/RSA2C.

Delegation and Verification under AI

Lingxiao Huang, Wenyang Xiao, Nisheeth K. Vishnoi

As AI systems enter institutional workflows, workers must decide whether to delegate task execution to AI and how much effort to invest in verifying AI outputs, while institutions evaluate workers using outcome-based standards that may misalign with workers' private costs. We model delegation and verification as the solution to a rational worker's optimization problem, and define worker quality by evaluating an institution-centered utility (distinct from the worker's objective) at the resulting optimal action. We formally characterize optimal worker workflows and show that AI induces *phase transitions*, where arbitrarily small differences in verification ability lead to sharply different behaviors. As a result, AI can amplify workers with strong verification reliability while degrading institutional worker quality for others who rationally over-delegate and reduce oversight, even when baseline task success improves and no behavioral biases are present. These results identify a structural mechanism by which AI reshapes institutional worker quality and amplifies quality disparities between workers with different verification reliability.

Beyond Confidence: Adaptive and Coherent Decoding for Diffusion Language Models

Kecheng Chen, Ziru Liu, Xijia Tao, Hui Liu, Xinyu Fu, Suiyun Zhang, Dandan Tu, Lingpeng Kong, Rui Liu, Haoliang Li

Diffusion Language Models (DLMs) have recently achieved significant success due to their any-order generation capabilities. However, existing inference methods typically rely on local, immediate-step metrics—such as confidence or entropy—which inherently lack a more reliable perspective, leading to sub-optimal generation quality. To address this, we propose **C**oherent **C**ontextual **D**ecoding (**CCD**), a novel inference framework built upon two core innovations. First, CCD bypasses the potential bias of the single context to leverage historical contexts for approximating the marginal distribution of token prediction, leading to better sequence coherence and the early rejection of sub-optimal paths. More importantly, we demonstrate that this mechanism is theoretically equivalent to modeling the consistency of historical steps via the conditional mutual information between contexts and token predictions. Finally, CCD achieves significantly milder performance degradation under highly parallel decoding scenarios compared to baselines. Empirically, our method achieves a simultaneous enhancement in both inference speed and performance across diverse benchmarks on Dream and LLaDA.

Conservation Laws for Modern Neural Architectures

Viet-Hoang Tran, Vinh Khanh Bui, Tan Lai Ngoc, Nam Nguyen, Tuan Quang Dam, Tan Minh Nguyen

Understanding gradient descent dynamics is key to explaining the success of over-parameterized models, where implicit bias manifests through conservation laws in gradient flow. While such laws are well understood for linear and ReLU networks, they remain largely unexplored for modern architectures. This work develops a

unified framework to characterize conservation laws for contemporary models, including feedforward networks with GELU, SiLU, and SwiGLU activations, multihead attention with sinusoidal and rotary positional encodings, and Mixture-of-Experts architectures under diverse gating designs. Our theoretical findings are supported by experiments that validate the predicted invariants.
****
Test-Time Debiasing with Probabilistic Prompts via Wasserstein Distance in Vision-Language Models
Chengye Wang, Yuyuan Li, XiaoHua Feng, Xiaolin Zheng, Chaochao Chen
Vision-Language Models (VLMs) inherit social biases from large-scale pretraining data, and these biases can amplify in downstream tasks, leading to systematic performance disparities across sensitive groups. Due to the high training cost and the risk of catastrophic forgetting, recent research has focused more on lightweight \emph{test-time} debiasing, aiming to obtain an ideal fair embedding for each query. However, such point-based corrections are often unstable and become notably weaker in multi-class settings, where group structure cannot be adequately captured by a single point. Therefore, we propose W4D, a distributional debiasing framework that reframes fairness as aligning query embedding distributions to group reference distributions under the Wasserstein distance, which provides a geometry-aware notion of discrepancy beyond mean shifts. To make this alignment practical at test-time, W4D introduces probabilistic prompts that induce controlled distributional perturbations and optimizes a Wasserstein-based objective to reduce cross-group disparity while preserving task-relevant semantics. This distributional perspective improves robustness in multi-class debiasing and yields a stronger fairness--utility trade-off across diverse VLM downstream evaluations. Our code is available at https://github.com/QDRhhhh/W4D.
****
Mixing Configurations for Downstream Prediction
Juntang Wang, Hao Wu, Yihan Wang, Dongmian Zou, Shixin Xu
Clustering-based features are widely used in machine learning, but most methods must choose a resolution---a choice that is global, fixed, and ad hoc.
Recent work shows that varying the resolution parameter produces only a finite set of structurally stable partitions, known as configurations.
Based on this, we introduce Configuration-Mixed Prediction (CMP), a setting where models learn to adaptively weight these configurations per sample for downstream prediction.
We propose MixConfig, a plug-and-play feature augmentation module that extracts configurations from any embedding and learns energy-aware mixing weights via a novel selector that jointly reasons about sample context, cluster assignments, and stability statistics.
Experiments across tabular, molecular, vision, and text domains demonstrate consistent improvements over single-resolution and static baselines across diverse predictor architectures, with gains particularly pronounced in low-data regimes.
****
Crisp: A Spectral-Based Interaction Strategy for Multivariate Time Series Forecasting
Binwu Wang, Gaoyun Lin, Jiaming Ma, Qihe Huang, Zhengyang Zhou, Xu Wang, Pengkun Wang, Yang Wang
Multivariate time series (MTS) forecasting critically depends on modeling inter-variable dependencies, yet existing paradigms face a trade-off: channel-isolation strategies can suffer from information fragmentation in strongly coupled systems, whereas channel-interaction methods often introduce spurious interactions among irrelevant variables. To address this challenge, we propose Coherent Resonance Interaction with Spectral Priors (Crisp). Crisp adopts the principle that effective information exchange should occur only between variables with compatible oscillatory patterns. Concretely, we derive spectral priors in the frequency domain to construct dynamic resonance topologies. With a differentiable, adaptive, and strictly sparse blocking mechanism, Crisp forces attention weights for spectrally inconsistent neighbors to be exactly zero. In addition, we introduce a spectral-gated feature filtering module to refine variable representations using in

trinsic spectral characteristics. Extensive experiments demonstrate that Crisp significantly outperforms 20+ baselines. Our code is available at Anonymous GitHub.

AsyncSpade: Efficient Test-Time Scaling with Asynchronous Sparse Decoding

Shuqing Luo, Yilin Guan, Pingzhi Li, Hanrui Wang, Tianlong Chen

Test-time scaling (TTS) can boost LLM reasoning through long chain-of-thought (CoT), but the linear KV-cache growth amplifies the memory-bound bottleneck of LLM decoding. Query-aware sparse decoding methods can achieve state-of-the-art performance under constrained FLOP budget, but are mainly constrained by both sequential-dependent page filtering and coarse-grained token selection, hampering the serving efficiency and model performance on TTS tasks under high concurrency and long CoT scenarios, where token selection can even occupy higher runtime than the forward pipeline itself. In this paper, we first find that the query state of the current decoding token can be approximated in a unified manner from a short sliding window of recent queries, enabling training-free query-aware sparsity without sequential dependency in the decoding loop. Based on the findings, we propose $\texttt{\textbf{AsyncSpade}}$, an asynchronous framework for efficient TTS, built on two core components: $\textbf{(1) a novel light-weight temporal-regressive module}$ that predicts the next-token query state, and $\textbf{(2) an asynchronous disaggregated framework}$ that decouples the KV cache selection from the auto-regressive decoding loop, overlapping the token-level KV selection with the forward inference computation through asynchronism, thereby eliminating the sequential dependency without sacrificing model performance. We validate the effectiveness of $\texttt{AsyncSpade}$ on common LLM serving setups with an A100 node, where $\texttt{AsyncSpade}$ can fully overlap KV-cache operations with the inference pipeline within a certain workload range, $\textbf{achieving theoretical optimal time-per-output-token~(TPOT)}$. Specifically, $\texttt{AsyncSpade}$ delivers over 20% reduction on TPOT compared to SoTA baseline ($\textit{i.e.}$ Quest) and at least 50% TPOT reduction compared to full attention on Qwen3-8B and Qwen3-32B models, while matching or surpassing their accuracy on various TTS benchmarks (AIME-24/25, GPQA-Diamond, MATH-500). Our code is available through https://github.com/UNITES-Lab/AsyncSpade.

Reconstruction Outcomes Look Similar but Processes Differ: Improving Context Consistency and Coverage in Graph Masked Auto-Encoder

Geng Tang, Keyu Liu, Xibei Yang, Yuhua Qian

Graph Masked Auto-Encoder (GMAE) has emerged as a prevalent self-supervised paradigm, showing superior performance in graph learning. However, existing methods mainly emphasize reconstruction outcomes and give limited specification to how neighborhood context is used for reconstruction. Our experimental investigation shows that, even when reconstruction outcomes are similar, the ways of using neighborhood context differ substantially, resulting in performance shifts. To address this issue, we propose Consistency- and Coverage-aware Graph Masked Auto-Encoder (C2-GMAE), which encourages more consistent use of neighborhood context and promotes broader training coverage in the graph. Specifically, C2-GMAE leverages positional encoding as an observable structural reference, introduces density-partitioned masking to improve coverage across regions, and amplifies heterophilic edges to reduce the attenuation of discriminative relational information during reconstruction. Extensive experiments on multiple benchmarks demonstrate that C2-GMAE improves downstream performance against GMAE baselines.

Towards On-Policy SFT: Distribution Discriminant Theory and its Applications in LLM Training

Miaosen Zhang, Yishan Liu, Shuxia Lin, Qi Dai, Chong Luo, Baining Guo, Weihao Jiang, Peng Hou, Anxiang Zeng, Xu Yang, Xin Geng

Supervised fine-tuning (SFT) is computationally efficient but often yields inferior generalization compared to reinforcement learning (RL). This gap is primarily driven by RL’s use of on-policy data.

We propose a framework to bridge this chasm by enabling On-Policy SFT.

We first present ***Distribution Discriminant Theory (DDT)***, which explains and quantifies the alignment between data and the model-induced distribution.
Leveraging DDT, we introduce two complementary techniques: (i) ***In-Distribution Finetuning (IDFT)***, a loss-level method to enhance generalization ability of SFT, and (ii) ***Hinted Decoding***, a data-level technique that can re-align the training corpus to the model's distribution.
Extensive experiments demonstrate that our framework achieves generalization performance on par with prominent offline RL algorithms, including DPO and SimPO, while maintaining the efficiency of an SFT pipeline.
The proposed framework thus offers a practical alternative in domains where RL is infeasible. We will open-source the code and data on GitHub.

Rethinking Multimodal Time-Series Forecasting Evaluation
Haoxin Liu, Yichen Zhou, Rajat Sen, B. Aditya Prakash, Abhimanyu Das
We introduce a new context-enriched, multimodal time series forecasting benchmark TimesX. TimesX contains a wide selection of high-quality real-world time series with diverse domains and textual contexts obtained from an automated data generation pipeline, which helps address three main issues of existing multimodal forecasting benchmarks: (1) poor generalization due to the small scale and synthetic nature of benchmark data, (2) very limited types of textual contexts in the benchmarks, and (3) an inability to mitigate data leakage in evaluation. We conduct a thorough empirical study of zero-shot multimodal forecasting approaches on TimesX. Our results suggest that many approaches that perform well on existing benchmarks may fail on TimesX. In contrast, simple ensemble methods that leverage rich textual context accompanying time-series can outperform strong baselines on the TimesX benchmark.

LEC: Linear Expectation Constraints for Selection-Conditioned Risk Control in Selective Prediction and Routing Systems
Zhiyuan Wang, Aniri, Tianlong Chen, Yue Zhang, Heng Tao Shen, Xiaoshuang Shi, Kaidi Xu
Foundation models often generate unreliable answers, while heuristic uncertainty estimators fail to fully distinguish correct from incorrect outputs, causing users to accept erroneous answers without any statistical guarantee.
We address this problem through selection-conditioned risk control, aiming to ensure that an accepted prediction has an error probability no larger than a user-specified risk level.
To this end, we propose LEC, a principled framework that reframes selective prediction as a decision problem governed by a *linear expectation constraint* over selection and error indicators.
This formulation directly controls the ratio between the expected number of accepted errors and the expected number of accepted predictions, which corresponds to the marginal error probability conditioned on selection.
Under exchangeability, we derive a *finite-sample sufficient condition* that relies only on a held-out calibration set, enabling the computation of a risk-constrained, retention-maximizing threshold.
Furthermore, we extend LEC to two-model routing systems: if the primary model's uncertainty exceeds its calibrated threshold, the input is delegated to a subsequent model, while maintaining system-level selection-conditioned error control.
Experiments on both closed-ended and open-ended question answering (QA) and vision question answering (VQA) demonstrate that LEC maintains the prescribed risk level in accepted predictions and substantially improves sample retention compared to baselines.
****

When Drafts Evolve: Speculative Decoding Meets Online Learning
Yu-Yang Qian, Hao-Cong Wu, Yichao Fu, Hao Zhang, Peng Zhao
Speculative decoding has emerged as a widely adopted paradigm for accelerating large language model inference, where a lightweight draft model rapidly generates candidate tokens that are then verified in parallel by a larger target model. However, due to limited model capacity, drafts often struggle to approximate the

target distribution, resulting in shorter acceptance lengths and diminished speedup. A key yet under-explored observation is that speculative decoding inherently provides *verification feedback* that quantifies the deviation between the draft and target models at no additional cost. This process naturally forms an iterative "draft commits--feedback provides--draft adapts" evolving loop, which precisely matches the *online learning* paradigm. Motivated by this connection, we propose OnlineSPEC, a unified framework that systematically leverages interactive feedback to continuously evolve draft models. Grounded in *dynamic regret minimization*, we establish a formal link between online learning performance and speculative system's acceleration rate, and develop novel algorithms via modern online learning techniques, including optimistic online learning that adaptively reuses historical gradients as predictive update hints, and online ensemble learning that dynamically maintains multiple draft models. Our algorithms are equipped with theoretical justifications and improved acceleration rates, achieving up to 24% speedup over seven benchmarks and five foundation models.
****

Injecting Distributional Awareness into MLLMs via Reinforcement Learning for Deep Imbalanced Regression
Yao DU, Shanshan Song, Xiaomeng Li
Multimodal large language models (MLLMs) struggle with numerical regression under longtailed target distributions. Token-level supervised
fine-tuning (SFT) and point-wise regression rewards bias learning toward high-density regions, leading to regression-to-the-mean behavior and poor tail performance. We identify the lack of cross-sample relational supervision as a key limitation of existing MLLM training paradigms. To address it, we propose a distribution-aware reinforcement learning framework based on Group Relative Policy Optimization, which introduces batch-level comparison-based supervision via the Concordance Correlation Coefficient-based reward to align predicted and ground-truth distributions in terms of correlation, scale, and mean. The framework is plug-and-play, requiring no architectural modification. Experiments on a unified suite of long-tailed regression benchmarks show consistent improvements over SFT and existing MLLM regression methods, with particularly strong gains in medium- and few-shot regimes.
****

Collapsed Effective Operators for Higher-order Structures
Maximilian Krahn, Lennart Bastian, Vikas K Garg, Björn Schuller, Tolga Birdal
Higher-order structures are powerful relational modeling tools, yet existing spectral operators decompose topology into separate ranks, leaving practitioners to fuse information back to vertices through ad-hoc choices. We introduce _Collapsed Effective Operators_, which condense higher-order degrees of freedom into a single vertex-level operator via Schur complementation of a graded Laplacian. This yields a (generally dense) operator that encodes long-range interactions mediated by topology and is applicable to arbitrary higher-order constructs. We show it preserves positive semi-definiteness with a strict spectral upper bound relative to the rank-0 Hodge Laplacian, effectively lowering system energy under higher-order connectivity. Empirically, our operator improves spectral clustering, signal smoothing and enables the inclusion of topological features in neural network architectures via positional encoding.
****

Improving Adversarial Robustness of Attribution via Implicit Regularization
Amir Mehrpanah, Matteo Gamba, Hossein Azizpour
The adversarial robustness of attributions is a fundamental requirement for reliable explainability in deep learning, yet existing approaches typically rely on computationally expensive explicit regularization. In this work, we show that attribution robustness can arise implicitly from the learning dynamics of standard stochastic gradient descent. We theoretically motivate this effect through connections between parameter-space and input-space curvature, and validate it across architectures, datasets, and attribution methods, with negligible computational overhead. In contrast, we prove that such robustness gains often does not transfer to attention-based attribution under softmax normalization, due to inherent

entropy constraints, and we validate this limitation experimentally. Finally, we show that replacing softmax attention with kernel-based attention restores the robustness gains in transformer models. Our results highlight learning dynamics as a principled and practical mechanism for robust explainability, and reveal fundamental limitations of attention-based attribution under normalization.

Learning High-Frequency Continuous Action Chunks in Latent Space

Kunyun Wang, Yuhang Zheng, Yupeng Zheng, Jieru Zhao, Wenchao Ding

Modern robotic policies increasingly rely on action chunking to execute complex tasks in the physical world. While action chunking improves temporal consistency at moderate action frequencies, it becomes insufficient when the action frequency is further increased (e.g., to 60~Hz). At such high frequencies, policies often fail to generate actions that are both temporally smooth and spatially consistent.

We address this challenge by shifting high-frequency action learning from the action space to a latent space with variational autoencoder (VAE). This formulation significantly improves both temporal and spatial consistency of high-frequency control.

To enable smooth real-time execution, we further introduce Reuse-then-Refine, a chunk-level refine strategy that improves continuity between adjacent action chunks under asynchronous inference.

As a result, robots controlled by our policy can execute complex contact-rich tasks continuously, with less pauses and jerky motions. Experiments on three real-world contact-rich robotic tasks show that our approach consistently completes tasks with smooth motions. Our code and data are
available at https://github.com/tars-robotics/RTR.

B-Spar: Bayesian Sparse-Reward Modeling for RL-based Image Editing

Shusong Xu, Peiye Liu, Yongbin Liu, Bangjie Yin, Tianyi Zheng, Zhaomang Sun, Zhenyu Chen, Peng-Tao Jiang, Jian Zhang, Yuzhao Wang, Zhen Gu, Jinwei Chen, Bo Li

Autonomous image-editing agents powered by multimodal large language models (MLLMs) improve transparency and controllability by translating high-level instructions into tool-mediated edit sequences, but training such agents with reinforcement learning often relies on dense proxy rewards (e.g., incremental image-quality score gains) to compensate for sparse human feedback. When these proxies overvalue small local changes, the resulting optimization signal can be dominated by numerically measurable yet perceptually negligible edits, biasing policy gradients toward proxy artifacts rather than meaningful progress. We propose B-Spar, a reward-centric Reinforcement Learning framework for perceptually aligned image retouching under sparse feedback that combines prior-guided trajectory sampling to reduce inefficient exploration, Bayesian reward modeling to densify sparse binary feedback into a stable training signal, and anchor-regularized policy optimization to steer updates toward high-reward regions while preventing early mode collapse. Experiments on public benchmarks demonstrate that B-Spar improves perceptual quality and metric alignment with stable training and competitive inference efficiency over strong prompt-based and training-based baselines. Notably, it outperforms AIGC-based baselines by over 95\% in perceptual quality, achieving an improvement of approximately 33.5\% over the state-of-the-art.

EMBGuard: Constructing Hazard-Aware Guardrails for Safe Planning in Embodied Agents

Dongwook Choi, Taeyoon Kwon, Bogyung Jeong, Minju Kim, Yeonjun Hwang, Hyojun Kim, Byungchul Kim, Young Kyun Jang, Jinyoung Yeo

MLLM-powered embodied agents deployed in real-world environments encounter physical hazards. However, existing approaches lack explicit mechanisms for identifying hazards and reasoning about action-conditioned risks, leading agents to either miss risky interactions or over-identify risks. To address this, we propose EMBGuard, the first MLLM-based safety guardrail for embodied agents designed to decouple physical risk reasoning from agent policy. By evaluating a (visual observation, action) pair, EMBGuard identifies hazardous configurations and provides n

atural language explanations of potential risks. Alongside EMBGuard, we contribu te EMBHazard, a training dataset of 15.1K action-conditioned pairs, and EMBGuard Test, a benchmark of 329 manually curated real-world scenarios spanning seven ph ysical risk categories. Through compositional variation of hazards and actions, we generate diverse risky and benign scenarios that agents may encounter during planning. Despite its compact size (2B, 4B), EMBGuard achieves performance compe titive with proprietary MLLMs (e.g., GPT-5.1, Gemini-2.5-Pro) while significantl y reducing the false-positive rates that hinder real-time deployment. We make th e code, data, and models publicly available at https://github.com/dongwxxkchoi/E MBGuard.

PixCLIP: Towards Fine-grained Vision-Language Understanding via Any-granularity Pixel-Text Alignment

YiCheng Xiao, Yu Chen, Hao-Xuan Ma, Jiale Hong, Caorui Li, Lingxiang Wu, Haiyun Guo, Jinqiao Wang

While CLIP has achieved strong performance across vision–language tasks, fine-gr ained image–text alignment remains challenging. Recent efforts improve textual g ranularity by leveraging long, detailed descriptions and replacing CLIP’s text e ncoder with LLM, but often overlook the visual-side bottleneck: achieving finer alignment requires region- and pixel-level visual grounding. To address it, we p ropose PixCLIP, a framework that jointly enhances both sides by accommodating vi sual prompt regions and long-form text within a unified training objective. Firs tly, to support training at this granularity, we develop an automated annotation pipeline that produces long-form descriptions with pixel-level localization, an d use it to construct LongGRIT, a large-scale dataset with 1.5M samples. Further more, we introduce a three-branch pixel–text alignment framework that aligns ima ge regions with corresponding textual descriptions across multiple granularities . Experiments show that PixCLIP achieves state-of-the-art performance on pixel- and region-level alignment tasks while preserving strong results on standard glo bal image–text retrieval benchmarks, even with arbitrarily shaped region prompts and long texts. Our code is available at https://github.com/StuHude/PixCLIP.

CofactGVR: Counterfactual Intervention for Grounded Visual Reasoning

Yan Zhang, Zhijin Qin, Feng Xu, Guiguang Ding, Jungong Han

Despite rapid progress in Grounded Visual Reasoning (GVR) with MLLMs and RL-styl e fine-tuning, existing approaches often lack effective learning signals for int ermediate grounding decisions and are prone to shortcut solutions. In this work, we explicitly decompose GVR into Evidence Generation followed by Counterfactual Answer Reasoning, and formalize this structure as a Causal Grounding Graph (CGG) in which the generated evidence acts as a causal mediator. Building on this fo rmulation, we propose CofactGVR, which estimates the mediator’s utility via a ma tched counterfactual intervention that perturbs the predicted region while keepi ng the original image–question context fixed. The factual–counterfactual reward gap yields a principled intermediate bonus, selectively assigned to high-quality factual rollouts to promote evidence-faithful reasoning. To further stabilize a nd efficiently exploit this causal training signal, we incorporate a Quantile-fi ltered Prioritized Advantage Sampling (Q-PAS) strategy that preferentially updat es on trajectories with high-magnitude advantages while filtering low-signal sam ples. Extensive experiments across GVR benchmarks show consistent improvements, indicating that CofactGVR strengthens reliance on informative visual evidence un der controlled interventions. Our source code will be released at https://github .com/zhangy0822/CofactGVR.

ML-Embed: Inclusive and Efficient Embeddings for a Multilingual World

Ziyin Zhang, Zihan Liao, Hang Yu, Peng Di, Rui Wang

The development of high-quality text embeddings is increasingly drifting toward an exclusionary future, defined by three critical barriers: prohibitive computat ional costs, a narrow linguistic focus that neglects most of the world's languag es, and a lack of transparency from closed-source or open-weight models that sti fles research. To dismantle these barriers, we introduce ML-Embed, a suite of in

clusive and efficient models built upon a new framework: 3-Dimensional Matryoshka Learning (3D-ML). Our framework addresses the computational challenge with comprehensive efficiency across the entire model lifecycle. Beyond the storage benefits of Matryoshka Representation Learning (MRL) and flexible inference-time depth provided by Matryoshka Layer Learning (MLL), we introduce Matryoshka Embedding Learning (MEL) for enhanced parameter efficiency. To address the linguistic challenge, we curate a massively multilingual dataset and train a suite of models ranging from 140M to 8B parameters. In a direct commitment to transparency, we release all models, data, and code. Extensive evaluation on 430 tasks demonstrates that our models set new records on 9 of 17 evaluated MTEB benchmarks, with particularly strong results in low-resource languages, providing a reproducible blueprint for building globally equitable and computationally efficient AI systems.

TopAdapter: Topology-Aware Prompt Tuning for Efficient Point Cloud Understanding
Changshuo Wang, Shuting He, Xiang Fang, Weijun Li, Yixian Shen, Mingkun Xu, Zhongtian Sun, Prayag Tiwari
Point cloud data, with its inherent geometric and topological structures, plays a critical role in 3D vision tasks. However, existing parameter-efficient fine-tuning (PEFT) methods predominantly focus on input token prompting, overlooking the intrinsic geometric information. To address this limitation, we propose TopAdapter, a novel PEFT framework that enhances geometric perception by injecting local topological information into pre-trained 3D vision models. TopAdapter leverages 0D, 1D, and 2D simplices from algebraic topology as fundamental building blocks, introducing two core modules: the Topology Injection module (ToInjection) and the Topology Transfer module (ToTransfer). ToInjection constructs multi-scale topological features using a simplex generator and dynamically fuses them with semantic features via a geometric controller, thereby enhancing geometric adaptability. ToTransfer propagates these topological primitives across Transformer layers, ensuring efficient transmission of geometric information. Extensive experiments demonstrate that TopAdapter outperforms existing PEFT methods, achieving performance comparable to full fine-tuning across various benchmarks.

Event2Vec: Processing neuromorphic events directly by representations in vector space
Wei Fang, Priyadarshini Panda
Neuromorphic event cameras possess superior temporal resolution, power efficiency, and dynamic range compared to traditional cameras. However, their asynchronous and sparse data format poses a significant challenge for conventional deep learning methods. Most existing methods either densify events into frames, sacrificing their sparse asynchronous nature, or use irregular models that are less compatible with GPU acceleration. Inspired by word-to-vector models, we propose event2vec, a novel representation that allows Transformers to process events directly. We demonstrate the effectiveness of event2vec on the DVS Gesture, ASL-DVS, and DVS-Lip benchmarks, showing that event2vec is remarkably parameter-efficient, features high throughput and low latency, and achieves high accuracy even with an extremely low number of events or low spatial resolutions. These results show that sparse asynchronous event data can be directly integrated into high-throughput Transformer architectures, offering an efficient paradigm for real-time neuromorphic vision. The code is provided at https://github.com/Intelligent-Computing-Lab-Panda/event2vec.

Closing the Loop: Universal Repository Representation with RPG-Encoder
Jane Luo, Chengyu Yin, Xin Zhang, Qingtao Li, Steven Liu, Yiming Huang, Jie Wu, Hao Liu, Yangyu Huang, Yu Kang, Fangkai Yang, Ying Xin, Scarlett Li
Current repository agents encounter a reasoning disconnect due to fragmented representations, as existing methods rely on isolated API documentation or dependency graphs that lack semantic depth. We consider repository comprehension and generation to be inverse processes within a unified cycle: generation expands intent into implementation, while comprehension compresses implementation back into intent. To address this, we propose RPG-Encoder, a framework that generalizes the

Repository Planning Graph (RPG) from a static generative blueprint into a unified, high-fidelity representation. RPG-Encoder closes the reasoning loop through three mechanisms: (1) Encoding raw code into the RPG that combines lifted semantic features with code dependencies; (2) Evolving the topology incrementally to decouple maintenance costs from repository scale, reducing overhead by 95.7%; and (3) Operating as a unified interface for structure-aware navigation. In evaluations, RPG-Encoder establishes state-of-the-art repository understanding on SWE-bench Verified with 93.7% Acc@5 and exceeds the best baseline by over 10% on SWE-bench Live. These results highlight our superior fine-grained localization accuracy in complex codebases. Furthermore, it achieves 98.5% reconstruction coverage on RepoCraft, confirming RPG's high-fidelity capacity to mirror the original codebase and closing the loop between intent and implementation. Our code and data are available at https://github.com/microsoft/RPG-ZeroRepo.

Graph Alignment for Benchmarking Graph Neural Networks and Learning Positional Encodings
Adrien Lagesse, Marc Lelarge
We propose a novel benchmarking methodology for graph neural networks (GNNs) based on the graph alignment problem, a combinatorial optimization task that generalizes graph isomorphism by aligning two unlabeled graphs to maximize overlapping edges. We frame this problem as a self-supervised learning task and present several methods to generate graph alignment datasets using synthetic random graphs and real-world graph datasets from multiple domains. For a given graph dataset, we generate a family of graph alignment datasets with increasing difficulty, allowing us to rank the performance of various architectures. Our experiments prove that there is an optimal task difficulty for having a statistically relevant ranking of different models and that, even on a structure-only task, anisotropic models perform better compared to isotropic ones. To further prove that our synthetic task capture meaningful information, we show its effectiveness for self-supervised GNN pre-training: the learned node embeddings can be leveraged as positional encodings by transformers for graph regression or can be used to reconstruct the full structure of the graph with 98% accuracy. To support reproducibility and further research, we provide an open-source Python package to generate graph alignment datasets and benchmark new GNN architectures. The source code is available at [graph-alignment-benchmark](https://github.com/adrien-lagesse/graph-alignment-benchmark).
****

Rule2DRC: Benchmarking LLM Agents for DRC Script Synthesis with Execution-Guided Test Generation
Jinuk Kim, Junsoo Byun, Donghwi Hwang, Seong-Jin Park, Hyun Oh Song
Manufacturable chip layouts must satisfy thousands of geometry-based design rules, and design rule checking (DRC) enforces them by running executable DRC scripts on layouts. Translating natural language rules into correct DRC scripts is labor-intensive and requires specialized expertise, motivating LLM agents for DRC script synthesis and debugging. However, existing benchmarks have small evaluation sets and often evaluate scripts by code similarity rather than execution correctness, and prior machine learning-based methods either ignore execution feedback or require labeled test layouts as agent's input. To this end, we introduce Rule2DRC, a large-scale benchmark for DRC script coding agents with 1,000 rule-to-script tasks and 13,921 evaluation chip layouts for execution-based scoring. Rule2DRC provides an evaluation pipeline that measures functional correctness via DRC execution outcomes without requiring evaluation layouts as input to the agent. We also propose SplitTester, a tester agent for program selection that uses execution feedback to generate discriminative test cases and separate previously indistinguishable candidate scripts, substantially improving Best-of-N selection performance in this domain.
We release the code at https://github.com/snu-mllab/Rule2DRC.

SALSA-V: Shortcut-Augmented Long-form Synchronized Audio from Videos
Amir Dellali, Luca A Lanzendörfer, Florian Grötschla, Roger Wattenhofer

We propose SALSA-V, a multimodal video-to-audio generation model capable of synthesizing highly synchronized, high-fidelity long-form audio from silent video content. Our approach introduces a masked diffusion objective, enabling audio-conditioned generation and the seamless synthesis of audio sequences of unconstrained length. Additionally, by integrating a shortcut loss into our training process, we achieve rapid generation of high-quality audio samples in as few as eight sampling steps, paving the way for near-real-time applications without requiring dedicated fine-tuning or retraining. We demonstrate that SALSA-V significantly outperforms existing state-of-the-art methods in both audiovisual alignment and synchronization with video content in quantiative evaluation and a human listening study. Furthermore, our use of random masking during training enables our model to match spectral characteristics of reference audio samples, broadening its applicability to professional audio synthesis tasks such as Foley generation and sound design.
****

HTAC: Hierarchical Task-Aware Composition for Continual Offline Reinforcement Learning

Qiyang Zhou, Xu Ruihang, Peng Wang, WenJie Lu, Xiaochun Cao, Naiqiang Tan, Li Shen

Continual Offline Reinforcement Learning (CORL) enables building long-term autonomous agents from static datasets. However, it faces heterogeneity in environment dynamics, reward functions, and behavior policies across tasks. Combined with the inherent distribution shift in offline learning, this requires agents to selectively reuse shared knowledge during transfer while isolating task-specific features. The flat knowledge sharing mechanisms employed by existing methods struggle to capture such distinctions, limiting cross-task generalization.

To address this, we propose Hierarchical Task-Aware Composition (HTAC), which balances plasticity and stability through dual-level task encoding and soft composition mechanisms. HTAC comprises four modules: (1) a Hierarchical Semantic Task Representation that decomposes tasks into domain-level and task-level embeddings; (2) a Dual-level Expert Network that creates domain and task experts on demand for parameter-efficient knowledge isolation; (3) an Adaptive Knowledge Composition module that integrates historical expert outputs via attention mechanisms for knowledge reuse; (4) Task Adapters that preserve historical routing weights to prevent forgetting. Experiments on Offline Continual World show that HTAC outperforms existing baselines, demonstrating better knowledge reuse and transfer capabilities.

Unifying Heterogeneous Degradations: Uncertainty-Aware Diffusion Bridge Model for All-in-One Image Restoration

Luwei Tu, Jiawei Wu, Xing Luo, Zhi Jin

All-in-One Image Restoration (AiOIR) faces the fundamental challenge in reconciling conflicting optimization objectives across heterogeneous degradations. Existing methods are often constrained by coarse-grained control mechanisms or fixed mapping schedules, yielding suboptimal adaptation. To address this, we propose an Uncertainty-Aware Diffusion Bridge Model (UDBM), which innovatively reformulates AiOIR as a stochastic transport problem steered by pixel-wise uncertainty. By introducing a relaxed diffusion bridge formulation, which replaces the strict terminal constraint with a relaxed constraint, we model the uncertainty of degradations while theoretically resolving the drift singularity inherent in standard diffusion bridges. Furthermore, we devise a dual modulation strategy: the noise schedule aligns diverse degradations into a shared high-entropy latent space, while the path schedule adaptively regulates the transport trajectory motivated by the viscous dynamics of entropy regularization. By effectively rectifying the transport geometry and dynamics, UDBM achieves state-of-the-art performance across diverse restoration tasks within a single inference step. Code is available at https://github.com/Jabruson/UDBM.

Towards Cold-Start Drafting and Continual Refining: A Value-Driven Memory Approach with Application to NPU Kernel Synthesis

Yujie Zheng, Zhuo Li, Shengtao Zhang, Jiaqian Wang, Junjie Sheng, Junchi Yan, We inan Zhang, Ying Wen, Bo Tang, Muning Wen
Deploying Large Language Models to data-scarce programming domains poses signifi cant challenges, particularly for kernel synthesis on emerging Domain-Specific A rchitectures where a ``Data Wall'' limits available training data.
While models excel on data-rich platforms like CUDA, they suffer catastrophic pe rformance drops on data-scarce ecosystems such as NPU programming.
To overcome this cold-start barrier without expensive fine-tuning, we introduce EvoKernel, a self-evolving agentic framework that automates the lifecycle of ker nel synthesis from initial drafting to continual refining.
EvoKernel addresses this by formulating the synthesis process as a memory-based reinforcement learning task. Through a novel value-driven retrieval mechanism, i t learns stage-specific Q-values that prioritize experiences based on their cont ribution to the current objective—whether bootstrapping a feasible draft or iter atively refining latency.
Furthermore, by enabling cross-task memory sharing, the agent generalizes insigh ts from simple to complex operators.
By building an NPU variant of KernelBench and evaluating on it, EvoKernel improv es frontier models' correctness from 11.0\% to 83.0\% and achieves a median spee dup of 3.60$\times$ over initial drafts through iterative refinement. This demon strates that value-driven experience accumulation allows general-purpose models to master the kernel synthesis task on niche hardware ecosystems.

Interpreting Physics in Video World Models
Sonia Joseph, Quentin Garrido, Randall Balestriero, Matthew Kowal, Thomas Fel, S hahab Bakhtiari, Blake Aaron Richards, Michael Rabbat
A long-standing question in physical reasoning is whether video models rely on f actorized physical state variables, or on task-specific distributed representati ons. We present the first mechanistic interpretability study of physical variabl es inside large-scale video encoders, combining layerwise probing, subspace geom etry, patch-level decoding, and targeted attention ablations to characterize whe re and how physical information is orga- nized. Across architectures, we identif y a sharp intermediate-depth transition, the Physics Emergence Zone, at which ph ysical variables become linearly accessible. Scalar speed and acceleration are a vailable from early layers, whereas motion direction emerges only at the Physics Emergence Zone, mirroring the V1 to MT motion hierarchy in primate visual corte x. Direction is encoded as a circular high-dimensional population code: dozens o f orthogonal probe dimensions must be steered jointly to change the decoded dire ction, orders of magnitude more than the low-dimensional steering interventions seen in language models. These findings argue against compact physics- engine st ate variables and support distributed, hierarchically-organized, “brain-like” re presentations that are nonetheless sufficient for making physical predictions.
****
PathWise: Planning through World Model for Automated Heuristic Design via Self-E volving LLMs
Oguzhan Gungordu, Siheng Xiong, Faramarz Fekri
Large Language Models (LLMs) have enabled automated heuristic design (AHD) for c ombinatorial optimization problems (COPs), but existing frameworks' reliance on fixed evolutionary rules and static prompt templates often leads to myopic heuri stic generation, redundant evaluations, and limited reasoning about how new heur istics should be derived. We propose a novel multi-agent reasoning framework, re ferred to as Planning through World Model for Automated Heuristic Design via Sel f-Evolving LLMs (PathWise), which formulates heuristic generation as a sequentia l decision process over an entailment graph serving as a compact, stateful memor y of the search trajectory. This approach allows the system to carry forward pas t decisions and reuse or avoid derivation information across generations. A poli cy agent plans evolutionary actions, a world model agent generates heuristic rol louts conditioned on those actions, and critic agents provide routed reflections summarizing lessons from prior steps, shifting LLM-based AHD from trial-and-err or evolution toward state-aware planning through reasoning. Experiments across d

iverse COPs show that PathWise converges faster to better heuristics, generalize s across different LLM backbones, and scales to larger problem sizes.
****
TwinQuant: Learnable Subspace Decomposition for 4-Bit LLM Quantization
Haodong WANG, Junjie Liu, Zicong Hong, Qianli Liu, Jian Lin, Song Guo, Xu Chen
4-bit quantization reduces the memory footprint and latency of large language mo del inference, but its aggressive precision reduction can severely degrade accur acy. Prior methods address this by decomposing each weight matrix into two compo nents (e.g., via singular value decomposition) and quantizing them separately, a ssigning the bulk of values to a low-precision residual component while handling outliers with a high-precision low-rank component. However, such decompositions are designed to minimize the real-valued energy of the residual, rather than th e post-quantization error of the residual and low-rank components. We propose Tw inQuant, a 4-bit quantization framework that learns quantization-friendly decomp osed subspaces and jointly reshapes both the low-rank and residual components. T winQuant learns component-specific transformations via a joint optimization over the Stiefel and general linear manifolds, flattening their distributions and re ducing dynamic-range imbalance. To enable efficient end-to-end execution, we fur ther design a fused dual-component kernel that pipelines the two-stage low-rank computation on-chip and merges both components with a single epilogue, avoiding intermediate global-memory traffic. Across LLaMA3 and Qwen3 models, TwinQuant pr eserves near-FP16 accuracy and delivers up to $1.8\times$ end-to-end speedup ove r an FP16 baseline.
****
MACKO: Sparse matrix-vector multiplication for low sparsity
Vladimír Macko, Vladimír Boža
Sparse Matrix-Vector Multiplication (SpMV) is a fundamental operation in the inf erence of sparse Large Language Models (LLMs).
Because existing SpMV methods perform poorly under the low, unstructured sparsit y ($30-90\\%$) commonly observed in pruned LLMs, unstructured pruning provides o nly limited memory reduction and speedup.
We propose **MACKO-SpMV**, a GPU-optimized format and kernel co-designed to redu ce storage overhead while remaining compatible with the GPU’s execution model.
This enables efficient SpMV for unstructured sparsity without specialized hardwa re units or precomputation.
We identify memory bandwidth as the primary limiting factor of SpMV and analyze the storage overhead of MACKO.
At $50\\%$ sparsity, MACKO is the first approach to achieve $1.5\times$ memory r eduction and $1.2-1.5\times$ speedup over the dense baseline as well as substant ial improvements over other SpMV methods: cuSPARSE ($2.8-13.0\times$), Sputnik ($1.9-2.6\times$), and DASP ($2.2-2.5\times$).
An LLM pruned with Wanda to sparsity $50\\%$ requires $1.5\times$ less memory an d achieves $1.5\times$ faster inference at fp16 precision.
As a result, **unstructured pruning at $50\\%$ sparsity becomes practical** for real-world LLM workloads and **bridges the efficiency gap with structured 2:4 sp arsity**.
****
From Generative to Episodic: Sample-Efficient Replicable Reinforcement Learning
Max Hopkins, Sihan Liu, Christopher Ye, Yuichi Yoshida
The epidemic failure of replicability across empirical science and machine learn ing has recently motivated the formal study of replicable learning algorithms [I mpagliazzo et al. (2022)]. In contrast to batch settings (i.e. data comes from a fixed i.i.d. source) where the cost of replicability is relatively well underst ood, there remain significant gaps in our knowledge for control settings like re inforcement learning where an agent must interact directly with a shifting envir onment. Indeed, there is a large gap between the best upper bound of $\tilde{O}(S^7 A^7)$ [Eaton et al. (2023)] for RL with exploration, and $\tilde{O}(S^2 A^2) $ [Karbasi et al. (2023)] for the RL `batch' setting. This gap raises a key ques tion in the broader theory of replicability: Is replicable exploration inherentl y more expensive than batch learning? Is sample-efficient replicable RL even pos

sible?

In this work, we (nearly) resolve this problem (for low-horizon tabular MDPs): e xploration is not a significant barrier to replicable learning! Our main result is a replicable RL algorithm on $\tilde{O}(S^2A)$ samples, bridging the gap betw een the generative and episodic settings. We complement this with a lower bound in the episodic setting of $\tilde{\Omega}(S^2)$ showcasing the near-optimality of our algorithm with respect to the state space S.
****
Watch Your Step: Information Injection in Diffusion Models via Shadow Timestep E mbedding
An Huang, Junggab Son, Zuobin Xiong
Diffusion models have become the foundation of modern generative systems, with m ost research focusing primarily on improving generation efficiency and output qu ality.
The timestep embedding component is a crucial part of the diffusion pipeline, wh ich provides a temporal conditioning signal to the denoising network, enabling i t to adapt its predictions across different noise levels throughout the process. Despite their potential to contain substantial information, timestep embeddings remain underexplored in current research, especially for security risks and reli able provenance.
To fill this gap, we introduce **Shadow Timestep Embedding (STE)**, a novel mech anism that investigates the underutilized temporal space for malicious informati on injection into diffusion models.
In particular, when zooming in on the timestep embedding space, we find that dif ferent timesteps exhibit distinct representational capabilities that can encode side-channel information.
Moreover, such encoded information can be utilized for attack and defense purpos es through the scheduler interface.
We present a theoretical analysis of timestep embeddings as position-encoding ma ppings and derive a mutual coherence evaluation that explains the separability o f disjoint timestep intervals.
Our findings reveal the diffusion model's timestep as a powerful side channel fo r carrying dedicated information, motivating new directions for adversarial gene rative modeling by understanding the temporal dimension.

A3: an Analytical Low-Rank Approximation Framework for Attention
Jeffrey T. H. Wong, Cheng Zhang, Xinye Cao, Pedro Gimenes, Christos-Savvas Bouga nis, George Anthony Constantinides, Wayne Luk, Yiren Zhao
Large language models have demonstrated remarkable performance; however, their m assive parameter counts make deployment highly expensive. Low-rank approximation offers a promising compression solution, yet existing approaches have two main limitations: (1) They focus on minimizing the output error of individual linear layers, without considering the architectural characteristics of Transformers, a nd (2) they decompose a large weight matrix into two small low-rank matrices. Co nsequently, these methods often fall short compared to other compression techniq ues like pruning and quantization, and introduce runtime overhead such as the ex tra GEMM kernel launches and memory operations for decomposed small matrices. To address these limitations, we propose A^3, a post-training low-rank approxima tion framework. A^3 splits a Transformer layer into three functional component s, namely $\texttt{QK}$, $\texttt{OV}$, and $\texttt{MLP}$ and provides analytic al solutions that reduces the hidden dimension size inside each component while minimizing the component's functional loss. This approach directly reduces model sizes, KV cache sizes, and FLOPs without introducing any runtime overheads. Thr ough extensive experiments, we show that A^3 maintains superior performance co mpared to SoTAs.
For example, under the same reduction budget in computation and memory, our low- rank approximated LLaMA 3.1-70B achieves a perplexity of 4.69 on WikiText-2, out performing the previous SoTA's 7.87 by 3.18. We also show versatile applications of A^3 in KV cache compression, integration with quantization, fine-tuning an

d mixed-rank assignments. We open-sourced our framework at https://github.com/DeepWok/a3.

Neuro-Symbolic AI for Analytical Solutions of Differential Equations
Orestis Oikonomou, Levi Lingsch, Dana Grund, Siddhartha Mishra, Georgios Kissas
Analytical solutions to differential equations offer exact, interpretable insight but are rarely available because discovering them requires expert intuition or exhaustive search of combinatorial spaces. We introduce SIGS, a neuro-symbolic framework for equation-driven closed-form solution discovery. SIGS uses a context-free grammar to generate mathematically valid and physically meaningful building blocks, with a user-specified Ansatz prescribing how these blocks combine, embeds them into a topology-regularised continuous latent manifold, and searches this manifold in two stages: structure selection followed by coefficient refinement using gradient descent, scoring candidates only against the PDE residual and prescribed boundary and initial conditions. This design unifies symbolic reasoning with numerical optimization; the grammar constrains candidate solution blocks to be proper by construction, while the latent search makes exploration tractable and data-free. SIGS is the first neuro-symbolic method to (i) recover analytical solutions for coupled nonlinear PDE systems, (ii) discover equivalent symbolic forms when the grammar lacks the natural primitives, and (iii) produce accurate symbolic approximations for PDEs lacking known closed-form solutions. Overall, SIGS improves over existing symbolic methods by orders of magnitude in both accuracy and runtime across standard PDE benchmarks.

Rethinking Forgery Attacks on Semantic Watermarks in Black-Box Settings: A Geometric Distortion Perspective
Cheng-Yi Lee, Yichi Zhang, Yuchen Yang, Chun-Shien Lu, Jun-Cheng Chen
Recent studies have shown that semantic watermarks, which embed information into the initial noise of latent diffusion models (LDMs), are vulnerable to black-box forgery attacks. However, existing methods primarily rely on empirical evidence and lack a rigorous theoretical understanding of the conditions under which such attacks succeed or fail. To bridge this gap, we rethink the nature of such attacks through the lens of rate-distortion in the latent space. Our analysis identifies an irreducible distortion floor due to structural mismatches between proxy and target models, which fundamentally limits the fidelity of forged watermarks. We further characterize this distortion as structured geometric deviations on the latent manifold, in the form of global drift and local deformation rather than stochastic noise. Leveraging these insights, we propose a scheme-agnostic detection method that distinguishes forged samples before watermark verification. Extensive experiments demonstrate the effectiveness of our method across diverse black-box scenarios, while preserving robustness to common distortions.

EPSVec: Efficient and Private Synthetic Data Generation via Dataset Vectors
Amin Banayeeanzade, Qingchuan Yang, Deqing Fu, Spencer Hong, Erin Babinsky, Alfy Samuel, Anoop Kumar, Robin Jia, Sai Praneeth Karimireddy
High-quality data is essential for modern machine learning, yet many valuable corpora are sensitive and cannot be freely shared. Synthetic data offers a practical substitute for downstream development, and large language models (LLMs) have emerged as powerful engines for generating it. However, existing private text generation methods are severely inefficient: they are data-intensive, computationally slow, and often require large private corpora or batch sizes to achieve usable quality. We introduce EPSVec, a differentially-private lightweight alternative that steers LLM generation using *dataset vectors*-directions in activation space that capture the distributional gap between private data and public priors. EPSVec extracts and sanitizes steering vectors just once and then performs standard decoding. This decouples the privacy budget from generation, enabling arbitrarily many synthetic samples without additional privacy cost and yielding strong fidelity even in low-data regimes. Furthermore, we enhance our method by utilizing pretrained (base) models and introducing fixed-shot prompting to boost generation diversity and fidelity. Our experiments demonstrate that EPSVec outperform

s existing baselines in distributional alignment and downstream utility, particu
larly in low-data regimes, while significantly reducing computational overhead.
****
SOLAR for Offline MARL: Plateau-Triggered Potential Shaping under World-Model Un
certainty
Jusheng Zhang, Yijia Fan, Ruiqi Chen, Jing Yang, Ziliang Chen, Yongsen Zheng, Ya
nxi Chen, Jian Wang, Kwok-Yan Lam, Liang Lin, Keze Wang
Reward shaping can accelerate reinforcement learning, but in sparse-reward \emph
{offline} multi-agent RL it is often brittle: dense intrinsic rewards may alter
the underlying Markov game, while world-model guidance can amplify model bias.
We find that shaping becomes reliable when it is (i) activated only after \emph{
statistically validated} learning plateaus and (ii) constrained to \emph{potenti
al-based} shaping, which preserves the task optimum.
Motivated by this, we propose \textsc{SOLAR}, a simulate--evaluate--shape framew
ork.
A learned world model enables low-cost rollouts to test plateaus; once a plateau
 is detected, we inject shaping in the form $r+\gamma\Phi(s')-\Phi(s)$ with adap
tively updated potentials; and we attenuate shaping using uncertainty-aware thro
ttling in unreliable regions.
We provide theoretical analysis on policy invariance and on the deviation of pla
teau decisions under model error, and establish stability for the resulting two-
timescale adaptation.
Experiments on sparse-reward offline MARL benchmarks show consistent gains in st
ability and final performance across dataset qualities.

RGGT: A Generative-Prior-Guided Transformer for Unified Rigid and Non-Rigid Poin
t Cloud Registration
Chengyu Zheng, Songlin Yang, Jin Huang, Honghua Chen, Weiming Wang, Haoran Xie,
Fu Lee Wang, Mingqiang Wei
Point cloud registration can be categorized into rigid and non-rigid settings de
pending on the motion characteristics of the underlying objects. Rigid alignment
 assumes a single global transformation under which corresponding points remain
geometrically consistent across scales, whereas non-rigid alignment involves spa
tially varying deformations, where geometric similarity holds only locally and s
emantic correspondence dominates at larger scales. This multi-scale discrepancy
creates an optimization gap that has made unified registration particularly chal
lenging. To this end, we propose RGGT, a Generative-Prior-Guided Transformer tha
t unifies rigid and non-rigid registration within a shared optimization space. T
hrough coordinated design at the representation, architecture, and supervision l
evels, RGGT jointly captures local geometric details and global structural seman
tics: generative priors enrich point features with unified geometric-semantic cu
es; a Global-Self-Cross Attention module models long-range structure, local inte
raction, and bidirectional cross-shape reasoning; and a dual correspondence-reco
nstruction objective provides consistent supervision for both deformation types.
 Extensive experiments on rigid (ModelNet40, 3DMatch, KITTI) and non-rigid (4DMa
tch) benchmarks demonstrate that RGGT achieves state-of-the-art accuracy across
both rigid and non-rigid settings within a single unified framework. Code is ava
ilable at https://github.com/zhengcy-lambo/RGGT.
****
Equivalence of Context and Parameter Updates in Modern Transformer Blocks
Adrian Goldwaser, Michael Munn, Javier Gonzalvo, Benoit Dherin
Recent research has established that the impact of context in a vanilla transfor
mer can be represented implicitly by forming a token-dependent, rank-1 patch to
its MLP weights. This work extends that foundational theory to the diverse archi
tectures of modern Large Language Models. We first demonstrate a precise, analyt
ical solution for a Gemma-style transformer block, proving that the entire effec
t of a context can be perfectly mapped to rank-1 patches on its MLP weight matri
ces and a patch to the RMSNorm scale. We then generalize this result, providing
a constructive proof and algorithm for multi-layer models. To unify these findin
gs, we introduce a general framework centered on two core properties: input cont

rollability and output controllability. We prove that a perfect implicit weight patch is possible for any MLP block where the inner function is input-controllable and the outer function is output-controllable. This provides a simpler and more powerful lens for understanding how transformer models transmute prompts into effective weights. This setup generalizes to a wide range of modern LLM architectures including gating, pre-/post-norm, mixture of experts and sequential/parallel transformer blocks.
****
Sparse but Wrong: Incorrect L0 Leads to Incorrect Features in Sparse Autoencoders
David Chanin, Adrià Garriga-Alonso
Sparse Autoencoders (SAEs) extract features from LLM internal activations, meant to correspond to interpretable concepts. A core SAE training hyperparameter is L0: how many SAE features should fire per token on average. Existing work compares SAE algorithms using sparsity-reconstruction tradeoff plots, implying L0 is a free parameter with no inherently correct value aside from its effect on reconstruction. In this work we study the effect of L0 on SAEs, and show that if L0 is not set correctly, the SAE fails to disentangle the underlying features of the LLM. If L0 is too low, the SAE will mix correlated features to improve reconstruction. If L0 is too high, the SAE finds degenerate solutions that also mix features. Further, we present a proxy metric that can help guide the search for the correct L0 for an SAE on a given training distribution. We show that our method finds the correct L0 in toy models and coincides with peak sparse probing performance in LLM SAEs. We find that most commonly used SAEs have an L0 that is too low. Our work shows that practitioners must set L0 correctly to train SAEs with monosemantic features.
****
A Constrained Optimization Perspective of Unrolled Transformers
Javier Porras-Valenzuela, Samar Hadou, Alejandro Ribeiro
We introduce a constrained optimization framework for training transformers that behave like optimization descent algorithms. Specifically, we enforce layerwise descent constraints on the objective function and replace standard empirical risk minimization (ERM) with a primal-dual training scheme. This approach yields models whose intermediate representations decrease the loss monotonically in expectation across layers. We apply our method to both unrolled transformer architectures and conventional pretrained transformers on tasks of video denoising and text classification. Across these settings, we observe that constrained transformers achieve stronger robustness to perturbations and maintain higher out-of-distribution generalization, while preserving competitive in-distribution performance.
****
Improving the Robustness-Utility Trade-off in Decentralized Learning over Sparse Networks
Yangnan Li, Xuanyu Cao, Shenghui Song
Resilience against Byzantine attackers and faster convergence on sparse networks are critical for decentralized optimization, yet existing methods fail to achieve both simultaneously. Existing DSGD-based Byzantine-resilient methods suffer from high transient complexity of $\mathcal{O}\left((1-\lambda)^{-6}\right)$, where $1-\lambda$ denotes the spectral gap of the network. While bias-correction methods such as Exact Diffusion can improve topology dependence, directly combining them with robust aggregators can lead to error accumulation. To address this issue, we introduce the scaled dual ascent (SDA) within the augmented Lagrangian framework for decentralized optimization, which mitigates error accumulation by scaling the dual update steps. Based on this, we propose BRED, which integrates Byzantine-robust Exact Diffusion with the SDA framework. We prove that BRED attains linear speedup, and achieves transient complexity of $\mathcal{O}\left((1-\lambda)^{-2}\right)$ when the Byzantine fraction δ is small. We further propose the momentum variant BRED-M, which reduces the Byzantine-affected transient complexity from $\mathcal{O}\left(\delta^2(1-\lambda)^{-6}\right)$ to $\mathcal{O}\left(\delta^2(1-\lambda)^{-4}\right)$. Empirical results on benchmark datas

ets demonstrate the efficacy of the proposed methods across diverse network topologies.

Instance-Dependent Continuous-Time Reinforcement Learning via Maximum Likelihood Estimation
Runze Zhao, Yue Yu, Ruhan Wang, Chunfeng Huang, Dongruo Zhou
Continuous-time reinforcement learning (CTRL) provides a natural framework for sequential decision-making in dynamic environments where interactions evolve continuously over time. While CTRL has shown growing empirical success, its ability to adapt to varying levels of problem difficulty remains poorly understood. In this work, we investigate the instance-dependent behavior of CTRL and introduce a simple, model-based algorithm built on maximum likelihood estimation (MLE) with a general function approximator. Unlike existing approaches that estimate system dynamics directly, our method estimates the state marginal density to guide learning. We establish instance-dependent performance guarantees by deriving a regret bound that scales with the total reward variance and measurement resolution. Notably, the regret becomes independent of the specific measurement strategy when the observation frequency adapts appropriately to the problem’s complexity. To further improve performance, our algorithm incorporates a randomized measurement schedule that enhances sample efficiency without increasing measurement cost. These results highlight a new direction for designing CTRL algorithms that automatically adjust their learning behavior based on the underlying difficulty of the environment.
****
Cheap2Rich: A Multi-Fidelity Framework for Data Assimilation and System Identification of Multiscale Physics - Rotating Detonation Engines
Yuxuan Bao, Jan Zajac, Megan Powers, Venkat Raman, J. Nathan Kutz
Bridging the sim2real gap between computationally inexpensive models and complex physical systems remains a central challenge in machine learning applications to engineering problems, particularly in multi-scale settings where reduced-order models typically capture only dominant dynamics.

In this work, we present Cheap2Rich, a multi-scale data assimilation framework that reconstructs high-fidelity state spaces from sparse sensor histories by combining a fast low-fidelity prior with learned, interpretable discrepancy corrections.

We demonstrate the performance on rotating detonation engines (RDEs), a challenging class of systems that couple detonation-front propagation with injector-driven unsteadiness, mixing, and stiff chemistry across disparate scales.

Our approach successfully reconstructs high-fidelity RDE states from sparse measurements while isolating physically meaningful discrepancy dynamics associated with injector-driven effects.

The results highlight a general multi-fidelity framework for data assimilation and system identification in complex multi-scale systems, enabling rapid design exploration and real-time monitoring and control while providing interpretable discrepancy dynamics.

Structured 4D Latent Predictive Model for Robot Planning
Zhiyi Li, Peilin Wu, Xiaoshen Han, Ruojin Cai, Yilun Du
Video predictive models are emerging as a powerful paradigm in robotics, offering a promising path toward task generalization, long-horizon planning, and flexible decision-making. However, prevailing approaches often operate on 2D video sequences, inherently lacking the 3D geometric understanding necessary for precise spatial reasoning and physical consistency. We introduce a **Structured 4D Latent Predictive Model**, which predicts the evolution of a scene’s 3D structure in a structured latent space conditioned on observations and textual instructions. Our representation encodes the scene holistically and can be decoded into diverse 3D formats, enabling a more complete and 3D consistent scene understanding. This structured 4D latent predictive model serves as a planner, generating future scenes that are translated into executable actions by a goal-conditioned inverse dynamics module. Experiments demonstrate that our model generates futures with

strong visual quality, substantially better 3D consistency and multi-view cohere
nce compared to state-of-the-art video-based planners. Consequently, our full pl
anning pipeline achieves superior performance on complex manipulation tasks, exh
ibits robust generalization to novel visual conditions, and proves effective on
real-world robotic platforms. Our website is available at https://structured-4d-
model.github.io/.

Configurable Reward Model for Balanced Safety Alignment
Zhengping Jiang, Mehran Khodabandeh, Akash Bharadwaj, Manik Bhandari, Mayur Srun
garapu, Anqi Liu, Benjamin Van Durme, Li Chen
Aligning large language models (LLMs) to heterogeneous and rapidly evolving safe
ty requirements remains a critical challenge. Existing instruction-tuned LLMs an
d standalone safety classifiers often fail to generalize to new safety configura
tions, motivating the need for Reward Models (RMs) that are explicitly configura
ble to changing specifications. We introduce the Configurable Safety Reward Mode
l (CSRM), which is jointly optimized for calibrated safety compliance and reward
 modeling. Our approach is supported by configuration-targeted data augmentation
 that enforces instruction adherence while preserving relative severity structur
e. The resulting RM is sensitive to fine-grained safety configurations and conve
rsational nuances, substantially improving generalization to previously unseen s
afety configurations. CSRM achieves state-of-the-art performance on recent confi
gurable safety benchmarks, including CoSApien (94.6\% F1) and DynaBench (75.8\%
F1), without requiring additional human annotation. When used for downstream saf
ety alignment, CSRM yields LLMs with a significantly improved helpfulness–safety
 tradeoff compared to existing baselines.

Merge to Remember: Sharpness-Aware Isotropic Merging for Continual Learning
Qun Yang, Enneng Yang, Wei Chen, Li Shen, Long Lan
Continual learning with large pre-trained models offers significant potential fo
r cross-task knowledge accumulation, but faces critical challenges such as catas
trophic forgetting and parameter interference, especially when historical data i
s unavailable. Existing approaches typically rely on sequential fine-tuning or m
odel merging strategies, yet often overlook the impact of loss landscape sharpne
ss and dominant singular value directions, which leads to subspace misalignment
and severe knowledge forgetting. In this paper, we propose the Sharpness-Aware I
sotropic Merging (SAIM) framework, which introduces targeted optimizations in bo
th the fine-tuning and merging stages to address these issues. Specifically, SAI
M consists of two synergistic modules: (1) a Sharpness-Aware Block Coordinate De
scent (SA-BCD) optimizer that guides the model toward flatter minima and selecti
vely updates the most task-sensitive parameters, thereby mitigating parameter in
terference and enhancing robustness; (2) an adaptive isotropic merging algorithm
 that dynamically balances the singular value spectrum across tasks, effectively
 preventing the model from overemphasizing any single task direction, maintainin
g balanced knowledge representation, and improving subspace alignment. Extensive
 experiments on vision and language benchmarks demonstrate that SAIM achieves 5-
10\% higher accuracy than existing methods and maintains robust performance as t
he number of tasks increases. Our code are available at \url{https://github.com/
Yangqun123456/SAIM}.

GFD-EMVC: Evolutionary Multi-View Classification with Label Noise via Gradient a
nd Feature Dual-Perception
Shuai Li, Xinyan Liang, Yuhua Qian, Li Lv
This paper studies a fundamental yet often overlooked premise in evolutionary mu
lti-view classification (EMVC): the impact of label noise on EMVC, such as disto
rting fitness landscapes shaped by individual fitness values (e.g., test accurac
y).
Traditional EMVC assumes training labels are noise-free, yet this often fails in
 practice.
As a result, label noise introduces harmful supervision during the training phas
e, resulting in distorted fitness landscapes and the emergence of fitness evalua

tion bias (FEB). This bias misguides the evolutionary trajectory, causing the se
arch process to stagnate in local optima.
Given that label noise largely stems from the mislabeling of samples near their
decision boundaries by human annotators, we thus compared the decision boundarie
s of human annotators and models, and found discrepancies between the two. Based
 on this observation, we propose a simple yet effective ``detect-then-calibrate"
 data purification framework that leverages outlier analysis in the gradient spa
ce (i.e., treating outliers as noisy samples) and prototype calibration in the f
eature space (i.e., utilizing feature prototypes of noise-free samples to correc
t the labels of noisy samples).
Experimental results demonstrate that this strategy can effectively purify the d
ata and alleviate FEB; moreover, it can improve the performance of various multi
-view learning paradigms in label noise scenarios.

MultiLoReFT: Decoupling Shared and Modality-Specific Subspaces in Multimodal Lea
rning via Low-Rank Representation Fine-Tuning

Sana Tonekaboni, Viktoria Schuster, Caroline Uhler

Real-world perception and decision making are inherently multimodal, integrating
 complementary signals across modalities. However, training multimodal models fa
ces two main obstacles. First, collecting large-scale, well-aligned paired multi
modal datasets is often impractical, making end-to-end multimodal training diffi
cult. Second, existing multimodal representations frequently entangle informatio
n shared across modalities with modality-specific information, hindering interpr
etability and control. We introduce MultiLoReFT, an efficient and scalable low-r
ank representation fine-tuning framework for multimodal learning with pretrained
 unimodal models. MultiLoReFT extends low-rank adaptation to the multimodal sett
ing and learns interpretable projection subspaces that decouple shared and modal
ity-specific information. Across simulated and real-world benchmarks, it produce
s representations that support multimodal prediction while explicitly revealing
how shared and modality-specific information is distributed across modalities.

Beyond Euclidean Summaries: Online Change Point Detection for Distribution-Value
d Data

Yingyan Zeng, Zipan Huang, Xiaoyu Chen

Existing online change-point detection (CPD) methods rely on fixed-dimensional E
uclidean summaries, implicitly assuming that distributional changes are well cap
tured by moment-based or feature-based representations.
They can obscure important changes in distributional shape or geometry. We propo
se an intrinsic distribution-valued CPD framework that treats streaming batch da
ta as a stochastic process on the 2-Wasserstein space. Our method detects change
s in the law of this process by mapping each empirical distribution to a tangent
 space relative to a pre-change Fréchet barycenter, yielding a reference-centere
d local linearization of 2-Wasserstein space.
This representation enables sequential detectors by adapting classical multivari
ate monitoring statistics to tangent fields. We provide theoretical guarantees a
nd demonstrate, via synthetic and real-world experiments, that our approach dete
cts complex distributional shifts with reduced detection delay at matched $\math
rm{ARL}_0$ compared with moments-based and model-free baselines.
The code is available at https://github.com/yyzeng43/IDD-icml.

LeakGFN: Robust Molecular Generation in Generative Flow Networks via Flow Decomp
osition

Hwanhee Kim, Seungyeon Choi, Sanghyun Park

Generative Flow Networks (GFlowNets) have emerged as a powerful framework for mo
lecular generation, sampling diverse candidates proportionally to a reward funct
ion. However, the vast chemical space necessitates truncating trajectory length,
 forcing models to treat incomplete molecular fragments as terminal states along
side valid molecules. This conflation distorts the learned distribution by alloc
ating probability mass to chemically meaningless states. We propose LeakGFN, a d

ual-head architecture that decomposes flow into two components: a chemical head modeling flow over the full chemical space, and a valid head estimating the fraction of flow reaching valid molecules within the truncation boundary. Through this decomposition, the valid head implicitly learns molecular reachability without explicit supervision. We prove that LeakGFN recovers the correct distribution over accessible molecules under mild assumptions. Experiments on five molecular optimization tasks demonstrate consistent improvements over flow matching baselines, achieving state-of-the-art performance on four out of five tasks. Our module integrates as a plug-and-play enhancement into existing frameworks, improving performance on both pocket-conditioned and multi-objective generation tasks.
****

SMM Transformer: Leveraging Spiking Neural Networks for Multimodal Tasks
Xiubo Liang, Jinxing Han, Yuke Li, Haoqi Zhu, Yu Zhao, Hongzhi Wang
Spiking Neural Networks (SNNs) enable event-driven computation with sparse activations, but building multimodal Transformers on SNNs is hindered by unstable training in deep spiking stacks and a mismatch between dense softmax attention and spike-based communication. We propose SMM Transformer, an SNN-based multimodal Transformer framework that combines (i) a Parallel LIF with Multistage Learnable Parameters (PLMP) neuron and a tailored P-STBP algorithm to stabilize training, (ii) a spike-driven attention approximation (SMSA) with a lightweight self-compensation branch, and (iii) a spiking mixture-of-experts (SMoE) module for modality-aware fusion. Across visual and multimodal benchmarks, SMM Transformer achieves competitive accuracy compared to ANN baselines while reducing the estimated compute energy of the attention module by up to 97\% under a standard MAC/AC cost model.
****

AlignedNorm: Prompting Vision–Language Models via Coupled Prompt Field
Qi Ma, Chen-Yang Wang, Dehong Gao, Deng-Ping Fan
Prompt learning for vision-language models (VLMs) primarily follows end-to-end or decoupled routes to balance base and new task performance, but suffers a fundamental bottleneck: sample-wise optimization within task-specific feature spaces traps models in local optima, hindering global optimality. To address this, we identify a key insight that VLMs can be prompted within a Coupled Prompt Field-a shared space where base and new tasks are mutually constrained-and present AlignedNorm, which enforces the field coupling. By dynamically aligning the norms of prompts to VLMs' native scale, our method enables joint optimization of both tasks.
Without complex designs, our method matches leading decoupled approaches on 15 datasets across 4 experimental settings, offering both a new perspective and a practical solution to the local-optima dilemma in prompt learning.
****

OmniSIFT: Modality-Asymmetric Token Compression for Efficient Omni-modal Large Language Models
Yue Ding, Yiyan Ji, Jungang Li, Xuyang Liu, Xinlong Chen, Junfei Wu, Bozhou Li, Bohan Zeng, Yang Shi, Yushuo Guan, Yuanxing Zhang, Jiaheng Liu, Qiang Liu, Pengfei Wan, Liang Wang
Omni-modal Large Language Models (Omni-LLMs) have demonstrated strong capabilities in audio-video understanding tasks. However, their reliance on long multimodal token sequences leads to substantial computational overhead. Despite this challenge, token compression methods designed for Omni-LLMs remain limited. To bridge this gap, we propose OmniSIFT (Omni-modal Spatio-temporal Informed Fine-grained Token compression), a modality-asymmetric token compression framework tailored for Omni-LLMs. Specifically, OmniSIFT adopts a two-stage compression strategy: (i) a spatio-temporal video pruning module that removes video redundancy arising from both intra-frame structure and inter-frame overlap, and (ii) a vision-guided audio selection module that filters audio tokens. The entire framework is optimized end-to-end via a differentiable straight-through estimator. Extensive experiments on five representative benchmarks verify the efficacy and robustness of OmniSIFT. Notably, for Qwen2.5-Omni-7B, OmniSIFT adds 4.85M parameters while still achieving lower latency than training-free baselines such as OmniZip. With o

nly 25% of the original token context, OmniSIFT consistently outperforms all com
pression baselines and even surpasses the full-token model on several tasks.
****

DistFlow: A Fully Distributed RL Framework for Scalable and Efficient LLM Post-T
raining

Zhixin Wang, Jiaming Xu, Tianyi Zhou, Mingjun Zhang, Liming Liu, Jiarui Hu, Dian
 Yang, TongYu Wang, Ping Zhang, Jinlong Hou, Siyuan Feng, Yuan Qi, Yuan Cheng

Effectively scaling Reinforcement Learning (RL) is crucial for enhancing the rea
soning and alignment of Large Language Models. The massive data and complex exec
ution flows inherent in these tasks require a distributed architecture capable o
f efficient scaling. However, to simplify programming and dependency management,
 mainstream frameworks often rely on a centralized architecture where a single n
ode dispatches both control and data. This inherent coupling creates significant
 communication bottlenecks, severely limiting system scalability and efficiency.
 We present DistFlow, a novel, fully distributed RL framework that adopts a mult
i-controller paradigm. By decoupling data transmission from control dispatch, Di
stFlow establishes a parallelism-aware, decentralized Data Coordinator that leve
rages local caching, load balancing, and asynchronous double buffer to minimize
communication overhead and mitigate straggler effects. For control logic, it int
roduces a task scheduler built upon Directed Acyclic Graph (DAG) that facilitate
s fine-grained, independent execution. Experimental results demonstrate that Dis
tFlow achieves near-linear scalability up to 512 GPUs and delivers up to a 2.63x
 throughput improvement over state-of-the-art (SOTA) frameworks.
****

IQA-Spider: Unifying Multi-Granularity Image Quality Assessment with Reasoning,
Grounding and Referring

Xinge Peng, Yiting Lu, Xin Li, Zhibo Chen

We present IQA-Spider, the first image quality assessment (IQA) framework that u
nifies reasoning, grounding, and referring into a single LMM-based framework for
 multi-granularity quality understanding. Existing LMM-based IQA methods typical
ly support only partial perception dimensions, such as quality description and q
uestion answering~(\textit{i.e.}, reasoning) or pixel-level grounding. This limi
tation largely stems from the absence of (i) a unified task and data formulation
 and (ii) effective optimization paradigms for multi-granularity learning. To ad
dress these limitations, we formulate a rigorous four-task paradigm covering glo
bal and local quality description, pixel-level grounding, and region-level refer
ring. Based on this formulation, we construct a corresponding IQA dataset with a
 scalable and automatic annotation pipeline, thereby providing a solid foundatio
n for unified multi-granularity learning. To further enable unified perception,
we adopt a conflict-free two-stage design that progressively extends text-level
multi-granularity understanding to pixel-level grounding: (i) the first stage eq
uips the model with fine-grained text-level reasoning across multiple IQA tasks,
 and (ii) the second stage introduces a training-free text-to-point grounding pa
radigm, which bridges textual semantics and pixel-level perception by mapping to
ken logits to spatial coordinates. Based on these efforts, we achieve IQA-Spider
 with unified multi-granularity explainable image quality assessment. Extensive
experiments across multiple benchmarks demonstrate strong performance, validatin
g the effectiveness and versatility of the proposed formulation and framework. O
ur code and dataset will be released at: \href{https://github.com/Helen1p/IQA-Sp
ider.git}{https://github.com/Helen1p/IQA-Spider.git}.

StableVLA: Towards Robust Vision-Language-Action Models without Extra Data

YIYANG FU, Chubin Zhang, Shukai Gong, Yufan Deng, Kaiwei Sun, Qiyang Min, Qibin
Hou, Yansong Tang, Jianan Wang, Daquan Zhou

It is infeasible to encompass all possible disturbances within the training data
set. This raises a critical question regarding the robustness of Vision-Language
-Action (VLA) models when encountering unseen real-world visual disturbances, pa
rticularly under imperfect visual conditions. In this work, we conduct a systema
tic study based on recent state-of-the-art VLA models and reveal a significant p
erformance drop when visual disturbances absent from the training data are intro

duced. To mitigate this issue, we propose a lightweight adapter module grounded in information theory, termed the Information Bottleneck Adapter (IB-Adapter), which selectively filters potential noise from visual inputs. Without requiring any extra data or augmentation strategies, IB-Adapter consistently improves over the baseline by an average of 30%, while adding fewer than 10M parameters, demonstrating notable efficiency and effectiveness. Furthermore, even with a 14x smaller backbone (0.5B parameters) and no pre-training on the Open X-Embodiment dataset, our model StableVLA achieves robustness competitive with 7B-scale state-of-the-art VLAs. With negligible parameter overhead (<10M), our approach maintains accuracy on long-horizon tasks and surpasses OpenPi under real-world visual disturbances. The code will be made publicly available.

QEDBench: Quantifying the Alignment Gap in Automated Evaluation of University-Level Mathematical Proofs
Santiago Gonzalez, Alireza Amiri Bavandpour, Peter Ye, Edward Zhang, Ruslans Aleksejevs, Todor Anti■, Polina Baron, Sujeet Bhalerao, Shubhrajit Bhattacharya, Zachary Burton, John Byrne, Hyungjun Choi, Nujhat Ahmed Disha, Koppány István Encz, Yuchen Fang, Robert Joseph George, Ebrahim Ghorbani, Alan Goldfarb, Jing Guo, Meghal Gupta, Stefano Huber, Annika Kanckos, Minjung Kang, Hyun Jong Kim, Dino Lorenzini, Levi Lorenzo, Tianyi Mao, Giovanni Marzenta, Ariane M. Masuda, Lukas Mauth, Ana Mickovic, Andrés Miniguano-Trujillo, Antoine Moulin, Wenqi Ni, Tomos Parry, Kevin Ren, Hossein Roodbarani, Mathieu Rundström, Manjil Saikia, Detchat Samart, Rebecca Steiner, Connor Stewart, Dhara Thakkar, Jeffrey Tse, Vasiliki Velona, Yunhai Xiang, Sibel Yalç■n, Jun Yan, Ji Zeng, Arman Cohan, Quanquan C. Liu
As Large Language Models (LLMs) saturate elementary benchmarks, the research frontier has shifted from generation to the reliability of automated evaluation. We demonstrate that standard "LLM-as-a-Judge" protocols suffer from a systematic evaluation Alignment Gap when applied to upper-undergraduate to early graduate level mathematics. To quantify this, we introduce QEDBench, the first benchmark to systematically measure alignment with human experts on undergraduate-level math proofs by contrasting course-specific rubrics against expert common knowledge criteria. By deploying a dual-evaluation matrix (7 judges $\times$ 5 solvers) against 1,000+ hours of human evaluation, we reveal that certain frontier evaluators like Claude 4.5 Opus exhibit significant positive bias (up to $+0.28$ mean score inflation), effectively "hallucinating rigor" in flawed proofs. Furthermore, we uncover a critical reasoning disparity: while Gemini 3.0 Pro achieves state-of-the-art performance (0.91 raw score), specialized reasoning models like o3-deep-research collapse in discrete domains, dropping to 42.1\% accuracy in Graph Theory. We release QEDBench as a public benchmark for evaluating and improving AI judges.
****
AgentWebBench: Benchmarking Multi-Agent Coordination in Agentic Web
Shanshan Zhong, Kate Shen, Chenyan Xiong
Agentic Web is an emerging paradigm where autonomous agents help users use online information. As the paradigm develops, content providers are also deploying agents to manage their data and serve it through controlled interfaces. This shift moves information access from centralized retrieval to decentralized coordination. To study this setting, we introduce AgentWebBench, a benchmark that evaluates how well a user agent synthesizes answers by interacting with website-specific content agents. We evaluate four tasks that cover common web information needs, spanning ranked retrieval (web search, web recommendation) and open-ended synthesis (question answering, deep research). Across seven advanced LLMs and three coordination strategies, multi-agent coordination generally lags behind centralized retrieval as expected, because user agent cannot directly access the corpus, but the gap shrinks with model scale and can even outperform centralized retrieval on question answering. This benchmark also enables us to study properties of the emerging paradigm of the digital world. We find that decentralized access concentrates traffic toward a small set of websites, test time scaling improves both interaction reliability and task performance, and strong results require sufficient interactions guided by careful planning. Finally, our failure analysis su

ggests that user agents need better planning and answer synthesis, while content agents need more reliable retrieval and evidence quality. Code, data, and APIs are released on https://github.com/cxcscmu/AgentWebBench.
****
Prototype-guided Bilateral Alignment Multimodal Federated Learning
Tianchi Liao, Lele Fu, Sheng Huang, Qing Hu, Hong-Ning Dai, Chuan Chen
Multimodal federated learning (MFL) has emerged as a pivotal paradigm for leveraging distributed data to enhance model performance. However, existing methods predominantly rely on idealized assumptions of model homogeneity and balanced modality distributions, rendering them ill-suited for practical scenarios characterized by heterogeneous client architectures and severe modality imbalance. To address these challenges, we propose a \textbf{M}ultimodal \textbf{Fed}erated learning Prototype-guided Bilateral Alignment (MFedPBA) framework. MFedPBA facilitates robust knowledge synergy through a dual alignment mechanism: (i) at the feature level, it aligns heterogeneous feature spaces via a projection encoder optimized by contrastive learning and the Gromov-Wasserstein distance; (ii) at the decision level, it employs an entropy-weighted aggregation of naturally aligned logit prototypes. This novel design achieves robust MFL by jointly tackling heterogeneous feature spaces and collectively aggregating decisions.
Extensive experiments demonstrate that our method significantly outperforms state-of-the-art baselines under conditions of model heterogeneity and modality imbalance.
****
Chebyshev Policies and the Mountain Car Problem: Reinforcement Learning for Low-Dimensional Control Tasks
Stefan Huber, Hannes Unger, Georg Schäfer, Jakob Rehrl
We analytically solve the Mountain Car problem, a canonical benchmark in RL, and derive an optimal control solution, closing a gap after 36 years. This enables us to reveal two surprising insights: The optimal control is quite simple, yet modern RL agents display a large gap to optimality. Motivated by the analysis of the optimal control, we introduce Chebyshev policies as a universal (i.e. dense) class of RL policies from first principles. They can be trained as drop-in replacements of neural nets, reducing the regret by a factor of 4.18, while requiring 277 times fewer parameters, fostering sample efficiency, explainability and realtime capability. Chebyshev policies are evaluated on further RL tasks, including a real-world nonlinear motion control testbed. They consistently improve performance over neural nets with PPO, ARS and REINFORCE. Our results demonstrate how Chebyshev policies offer a compelling and lightweight alternative or addition to neural nets for low-dimensional control tasks.
****
Riemannian stochastic optimization for sufficient dimension reduction
Thibault Pautrel, François Portier
Sufficient dimension reduction (SDR) makes high-dimensional regression tractable by projecting the covariates onto a low-dimensional subspace that preserves the conditional mean of the response. Existing gradient-based estimators either operate in the ambient space and suffer from the curse of dimensionality, or localize in the reduced space at a per-outer-iteration cost at least quadratic in the sample size. We show that minimizers of the population Minimum Average Variance Estimation (MAVE) risk approximate the same Grassmannian target as the Outer Product of Gradients (OPG), and recast the empirical criterion as a smooth maximization on the Stiefel manifold with closed-form Riemannian gradient. The resulting algorithm, SMAVE, combines sparse projected-space nearest-neighbor localization with Riemannian stochastic gradient ascent. A simplified version comes with almost-sure convergence and a non-asymptotic rate matching the standard non-convex stochastic first-order scaling. Empirically,
SMAVE matches or improves on RMAVE's synthetic subspace recovery at moderate-to-high ambient dimension, and on four real datasets it uniformly improves over OPG and is competitive with or outperforms

RMAVE at orders of magnitude lower runtime.

DRIVE: Best Data Scheduling Practices for Reinforcement Learning with Verifiable Reward in Competitive Code Generation
Speed Zhu, Chuheng Zhang, Jianwei Cai, Guang Chen, Lulu Wu, Xiaolong Xu, Xuyun Zhang, Saiyong Yang, Wiggin Zhou
Recent success of large reasoning models (such as OpenAI o1 and DeepSeek R1) have spurred a resurgence of interest in reinforcement learning from verifiable rewards (RLVR). However, progress is still largely driven by RL algorithm design, while data scheduling -- the data-side decisions that determine what the model trains on over time -- is critical but remains underexplored. Therefore, data scheduling becomes the focus of this paper, including how to curate data for supervised fine-tuning (SFT) and how to select prompts and collect rollouts for reinforcement learning (RL). We introduce a pipeline with careful designs on data scheduling, consisting of hardness-prioritized SFT and two-stage RL. Specifically, we first fine-tune the base model on supervision data that is curated to prioritize difficulty based on both arena learning and classification. Then, we introduce two-stage RL where a decreased max sequence length during rollout is used in the first stage to expand entropy and reduce repetition, and a large number rollouts per prompt and curriculum design are adopted in the second stage to encourage exploration for challenging problems. We implement this pipeline on Qwen2.5-32B and an internal 389B MoE model, and evaluate them on a wide range of benchmarks including challenging LeetCode and Codeforces weekly contests. The results not only indicate the effectiveness and scalability of our pipeline but also demonstrate our model achieve sota of 32B models in competitive code generation.

ReQAT: Achieving Full-Precision Reasoning Accuracy with 4-bit Floating-Point Quantization-Aware Training
Janghwan Lee, Sihwa Lee, Jinseok Kim, Yongjik Kim, Jieun Lim, Jinwook Oh, Jungwook Choi
Large Reasoning Models (LRMs) achieve strong problem-solving through long chain-of-thought, but their deployment is constrained by the high cost of full-precision inference and growing KV cache footprints. Microscaled FP4 formats enable efficient FP4 deployment; however, fully quantizing weights, activations, and KV caches (W4A4KV4) causes severe reasoning degradation that existing PTQ and QAT fail to recover. We identify that FP4 failures concentrate on low-entropy tokens—precise symbolic commitments such as digits and operators—where quantization noise inflates sampling errors that cascade through reasoning traces. Based on this insight, we propose ReQAT, a reasoning-centric FP4 training framework with three components: (i) Trace-Aligned QAT (TAQ), which revisits identical reasoning traces to focus updates on critical low-entropy decisions; (ii) Selective Entropy Minimization (SEM), which reinforces confidence at low-entropy positions; and (iii) Q-FIT, a quantization-friendly initialization that jointly calibrates RoPE-consistent KV cache transformations to stabilize QAT. Under the same training budget, ReQAT not only recovers but surpasses BF16 fine-tuning accuracy, while delivering up to $3.9\times$ throughput speedup on NVIDIA DGX Spark and $3.1\times$ on B200. The project repository is available at https://github.com/aiha-lab/ReQAT.

QiMeng-PerceptOS: Semantic-Aware Kernel Optimization for OS-Intensive Workloads via Hardware-Software Alignment
Huilai Chen, Yuanbo Wen, Liangfeng Li, Shaohui Peng, Jingzhe Zhu, Jun Bi, Xuzhi Zhang, Qi Guo, Ling Li, Yunji Chen
Optimizing OS kernels for specific applications is vital for peak performance, yet existing LLM-based methods struggle with a semantic mismatch between generalized reasoning and low-level system behaviors. As a result, these static, open-loop approaches suffer from runtime blindness, configuration fragmentation, and search drift, ultimately failing to unlock the system’s performance potential. To address this, we propose QiMeng-PerceptOS, an autonomous framework that shifts the paradigm to perception-driven tuning. QiMeng-PerceptOS integrates: (1) a Perception Module that aligns raw telemetry into high-fidelity semantic fingerprints

; (2) a Global Search Module utilizing a Bi-level Hierarchical Induction Tree (BHIT) for global navigation and efficient pruning; and (3) a Posterior Enhancement Module to suppress hallucinations via trajectory synthesis. Experiments across diverse workloads show that it achieves significant performance breakthroughs by optimizing kernel configurations, reaching 296.6% of default Redis throughput and surpassing SOTA baselines by 32.6% within only 15 iterations. By establishing a perception-driven closed-loop, QiMeng-PerceptOS provides new insights for fully automated, large-scale system optimization.

AVGen-Bench: A Task-Driven Benchmark for Multi-Granular Evaluation of Text-to-Audio-Video Generation

Ziwei Zhou, Zeyuan Lai, Rui Wang, Yifan Yang, Yuqing Yang, Qi Dai, Lili Qiu, Chong Luo

Text-to-Audio-Video (T2AV) generation is rapidly becoming a core interface for media creation, yet its evaluation remains fragmented.

Existing benchmarks largely assess audio and video in isolation or rely on coarse embedding similarity, failing to capture fine-grained joint correctness required by realistic prompts.

We introduce AVGen-Bench, a task-driven benchmark for T2AV generation, featuring high-quality prompts across 11 real-world categories.

To support comprehensive assessment, we propose a multi-granular evaluation framework that combines lightweight specialist models with Multimodal Large Language Models (MLLMs), enabling evaluation from perceptual quality to fine-grained semantic controllability.

Our evaluation reveals a pronounced gap between strong audio-visual aesthetics and weak semantic reliability, including persistent failures in text rendering, speech coherence, physical reasoning, and universal breakdown in musical pitch control.

Learning Adaptive Perturbation-Conditioned Contexts for Robust Transcriptional Response Prediction

Yinhua Piao, Hyomin Kim, Seonghwan Kim, Yunhak Oh, Junhyeok Jeon, Sang-Yeon Hwang, Jaechang Lim, Woo Youn Kim, Chanyoung Park, Sungsoo Ahn

Predicting high-dimensional transcriptional responses to genetic perturbations is challenging because signals are sparse and experimental noise is severe. Existing methods often suffer from mean collapse, achieving high correlation by predicting the global average expression rather than perturbation-specific responses, which yields false positives and poor interpretability. Methods that add biological knowledge graphs typically treat them as dense, static priors shared across perturbations, propagating noise. We propose AdaPert, which counters mean collapse by extracting a sparse, perturbation-specific subgraph via differentiable node selection, then suppressing spurious variation in non-responsive genes while emphasizing differentially expressed ones. Across multiple benchmarks, AdaPert outperforms existing baselines, with the largest gains on DEG-aware metrics.

****

Affine-Scaled Attention: Towards Flexible and Stable Transformer Attention

Jeongin Bae, Baeseong park, Gunho Park, Minsub Kim, Joonhyung Lee, Junhee Yoo, Sunghyeon Woo, Jiwon Ryu, Se Jung Kwon, Dongsoo Lee

Transformer attention is typically implemented using softmax normalization, which enforces attention weights with unit sum normalization. While effective in many settings, this constraint can limit flexibility in controlling attention magnitudes and may contribute to overly concentrated or unstable attention patterns during training. Prior work has explored modifications such as attention sinks or gating mechanisms, but these approaches provide only limited or indirect control over attention reweighting. We propose Affine-Scaled Attention, a simple extension to standard attention that introduces input-dependent scaling and a corresponding bias term applied to softmax-normalized attention weights. This design relaxes the strict normalization constraint while maintaining aggregation of value representations, allowing the model to adjust both the relative distribution and the scale of attention in a controlled manner.

We empirically evaluate Affine-Scaled Attention in large-scale language model pr
etraining across multiple model sizes. Experimental results show consistent impr
ovements in training stability, optimization behavior, and downstream task perfo
rmance compared to standard softmax attention and attention sink baselines. Thes
e findings suggest that modest reweighting of attention outputs provides a pract
ical and effective way to improve attention behavior in Transformer models.

Foundations of Equivariant Deep Learning: Unifying Graph and Sheaf Neural Networ
ks
Yoshihiro Maruyama
Symmetry is everywhere in nature and society. Geometric deep learning exploits s
ymmetries in data to improve the performance and efficiency of deep learning sys
tems. In this paper, we extend geometric deep learning to utilize richer symmetr
y structures. Specifically, we develop order-equivariant neural networks (OENN),
 which generalize standard graph message passing and sheaf neural networks via t
he theory of equivariant bundles over face posets (face categories). We (i) char
acterize all linear order-equivariant maps, (ii) build OENN layers, and (iii) pr
ove universal approximation theorems (UATs) for continuous order-equivariant map
s, which are new results even when restricted to sheaf neural networks (for whic
h no UAT was known before). We illustrate the framework on graph and sheaf model
s. Our results can also be seen as extending the known UAT for graph neural netw
orks to a more general setting that subsumes sheaf neural networks as well. In a
ddition, we show that OENN can be extended further to CENN, Category-Equivariant
 Neural Network, which gives the general form of equivariant neural networks as
well as of equivariant universal approximation theorems, allowing us to leverage
 categorical symmetry in data (e.g., non-invertible symmetries on multiple objec
ts with compositional relations on those symmetries).

Diffusion Bridge or Flow Matching? A Unifying Framework and Comparative Analysis
Kaizhen Zhu, Mokai Pan, Zhechuan Yu, Jingya Wang, Jingyi Yu, Ye Shi
Diffusion Bridge and Flow Matching have both demonstrated compelling empirical p
erformance in transformation between arbitrary distributions. However, there rem
ains confusion about which approach is generally preferable, and the substantial
 discrepancies in their modeling assumptions and practical implementations have
hindered a unified theoretical account of their relative merits. We have, for th
e first time, provided a unified theoretical and experimental validation of thes
e two models. We recast their frameworks through the lens of Stochastic Optimal
Control and prove that the cost function of the Diffusion Bridge is lower, guidi
ng the system toward more stable and natural trajectories. Simultaneously, from
the perspective of Optimal Transport, interpolation coefficients t and $1-t$ o
f Flow Matching become increasingly ineffective when the training data size is r
educed. To corroborate these theoretical claims, we propose a novel, powerful ar
chitecture for Diffusion Bridge built on a latent Transformer, and implement a F
low Matching model with the same structure to enable a fair performance comparis
on in various experiments. Comprehensive experiments are conducted across Image
Restoration, Translation, and Style Transfer tasks, systematically varying both
the distributional discrepancy (different difficulty) and the training data size
. Extensive empirical results align perfectly with our theoretical predictions a
nd allow us to delineate the respective advantages and disadvantages of these tw
o models. Our code is available at \url{https://github.com/zhukaizhen/diffusion_
bridge_flow_matching}.

The Geometry of Representational Failures in Vision Language Models
Daniele Savietto, Declan Iain Campbell, André Panisson, Marco Nurisso, Giovanni
Petri, Jonathan D. Cohen, Alan Perotti
Vision-Language Models (VLMs) exhibit puzzling failures in multi-object visual t
asks, such as hallucinating non-existent elements or failing to identify the mos
t similar objects among distractions. While these errors mirror human cognitive
constraints, such as the "Binding Problem'', the internal mechanisms driving the

m in artificial systems remain poorly understood. Here, we propose a mechanistic insight by analyzing the representational geometry of open-weight VLMs (Qwen, InternVL, Gemma), comparing methodologies to distill "concept vectors'' - latent directions encoding visual concepts. We validate our concept vectors via steering interventions that reliably manipulate model behavior in both simplified and naturalistic vision tasks (e.g., forcing the model to perceive a red flower as blue). We observe that the geometric overlap between these vectors strongly correlates with specific error patterns, offering a grounded quantitative framework to understand how internal representations shape model behavior and drive visual failures.

Rethinking Temporal Consistency in Video Object-Centric Learning: From Prediction to Correspondence

Zhiyuan Li, Rongzhen Zhao, Wenyan Yang, Wenshuai Zhao, Pekka Marttinen, Joni Pajarinen

The de facto approach in video object-centric learning maintains temporal consistency through learned dynamics modules that predict future object representations, called slots. We demonstrate that these predictors function as expensive approximations of discrete correspondence problems. Modern self-supervised vision backbones already encode instance-discriminative features that distinguish objects reliably. Exploiting these features eliminates the need for learned temporal prediction. We introduce Grounded Correspondence, a framework that replaces learned transition functions with deterministic bipartite matching. Slots initialize from salient regions in frozen backbone features. Frame-to-frame identity is maintained through Hungarian matching on slot representations. The approach requires zero learnable parameters for temporal modeling yet achieves competitive performance on MOVi-D, MOVi-E, and YouTube-VIS. AICrypto: Evaluating Cryptography Capabilities of Large Language Models

Yu Wang, Yijian Liu, Liheng Ji, Han Luo, Wenjie Li, Xiaofei Zhou, Chiyun Feng, Puji Wang, Yuhan Cao, Geyuan Zhang, Xiaojian Li, Rongwu Xu, Yilei Chen, Tianxing He

We build \textbf{AICrypto}, a comprehensive benchmark designed to evaluate the cryptography capabilities of large language models (LLMs). The benchmark comprises 135 multiple-choice questions, 150 capture-the-flag challenges, and 30 proof problems, covering a broad range of skills from knowledge memorization to vulnerability exploitation and formal reasoning. All tasks are carefully reviewed or constructed by cryptography experts to improve correctness and rigor. For each proof problem, we provide detailed scoring rubrics and reference solutions that enable automated grading, achieving high correlation with human expert evaluations. We introduce strong human expert performance baselines for comparison across all task types. Our evaluation of 17 leading LLMs reveals that state-of-the-art models match or even surpass human experts in memorizing cryptographic concepts, exploiting common vulnerabilities, and routine proofs. However, our analysis reveals that they still lack a deep understanding of abstract mathematical concepts and struggle with tasks that require multi-step reasoning and dynamic analysis. We hope this work could provide insights for future research on LLMs in cryptographic applications. Our code and dataset are available at https://github.com/wangyu-ovo/aicrypto-agent.

Is Your LLM Overcharging You? Tokenization, Transparency, and Incentives

Ander Artola Velasco, Stratis Tsirtsis, Nastaran Okati, Manuel Gomez Rodriguez

State-of-the-art large language models require specialized hardware and substantial energy to operate. Consequently, cloud-based services that provide access to these models have become very popular. In these services, the price users pay depends on the number of tokens a model uses to generate an output–they pay a fixed price per token.

In this work, we show that this pricing mechanism creates a financial incentive for providers to strategize and misreport the (number of) tokens a model used to

generate an output, and users cannot prove, or even know, whether a provider is overcharging them.

However, we also show that, if an unfaithful provider is obliged to be transparent about the generative process used by the model, misreporting optimally without raising suspicion is hard. Nevertheless, as a proof-of-concept, we develop an efficient heuristic algorithm that allows providers to significantly overcharge users without raising suspicion. Crucially, the cost of running the algorithm is lower than the additional revenue from overcharging users, highlighting the vulnerability of users under the current pay-per-token pricing mechanism. Further, we show that, to eliminate the financial incentive to strategize, a pricing mechanism must price tokens linearly on their character count. While this makes a provider's profit margin vary across tokens, we introduce a simple prescription that allows a provider to maintain their average profit margin when transitioning to an incentive-compatible pricing mechanism.

To complement our theoretical results, we conduct experiments with large language models from the $\texttt{Llama}$, $\texttt{Gemma}$ and $\texttt{Ministral}$ families, and prompts from a popular benchmarking platform.

On the Power of Statistics in Class-Incremental Learning with Pretrained Models

Zhiwen Cao, Yanfeng Li, Shu-Dong Huang, Yalan Ye, Shuyin Xia, Yi Wang, Jiancheng Lv

Recent class-incremental learning (CIL) methods built on large pre-trained vision models have shown that strong performance can be retained even under strict data access constraints. This raises a fundamental question: which properties of pre-trained representations make such recovery possible in the class-incremental setting? In this work, we show that class-level feature statistics play a central role in enabling effective CIL under strong pre-training. When the visual backbone is frozen, maintaining simple class-wise statistical estimators of features can recover a substantial fraction of the performance achieved by static joint training across diverse benchmarks. We make this observation explicit through deliberately minimal reference points built on frozen CLIP representations. In particular, we demonstrate that competitive performance can be achieved without continual parameter updates, by performing class-incremental inference based solely on class-level statistical estimators instantiated from frozen features. Our findings suggest that class-level statistics constitute an important and previously underemphasized component of recent PTM-based CIL approaches, offering a complementary perspective for understanding their strong empirical performance. Our code is available at https://github.com/HdTgon/baseCIL.

Overthinking: Amplifying Reasoning Weights to Extract Learned Secrets

Jack Hopkins, Dipika Khullar, Fabien Roger

Black box auditing of language models is an essential pre-deployment tool, but it may miss subtle forms of misalignment and hidden information. To better elicit hidden information during an auditing process, we introduce *overthinking*: the process of using reasoning task vectors to amplify the chain-of-thought faithfulness of reasoning models. Given the parameters of a base instruct model M and reasoning-distilled model R, we define the *overthinking model* as $\mathcal{O}_\alpha = M + \alpha(R - M)$, where $\alpha > 1$ amplifies reasoning beyond the pure reasoning model R. Additionally, we introduce new layer-wise attenuation strategies that selectively amplify reasoning without losing quality and coherence of model outputs. We demonstrate that overthinking models are more likely to reveal hidden information across four experimental settings, across 2B-32B models. Our findings suggest that reasoning amplification may surface secrets or unintended behaviors acquired during training up to $10\times$ more frequently than the original reasoning model. How secrets surface depends on the secret type: some require perturbation along the reasoning direction, while others yield to any sufficiently large weight perturbation.

****

GP2F: Cross-Domain Graph Prompting with Adaptive Fusion of Pre-trained Graph Neural Networks

Dongxiao He, Wenxuan Sun, Yongqi Huang, Jitao Zhao, Di Jin
Graph Prompt Learning (GPL) has recently emerged as a promising paradigm for dow nstream adaptation of pre-trained graph models, mitigating the misalignment betw een pre-training objectives and downstream tasks. Recently, the focus of GPL has shifted from in-domain to cross-domain scenarios, which is closer to the real w orld applications, where the pre-training source and downstream target often dif fer substantially in data distribution. However, why GPLs remain effective under such domain shifts is still unexplored. Empirically, we observe that representa tive GPL methods are competitive with two simple baselines in cross-domain setti ngs: full fine-tuning (FT) and linear probing (LP), motivating us to explore a d eeper understanding of the prompting mechanism. We provide a theoretical analysi s demonstrating that jointly leveraging these two complementary branches yields a smaller estimation error than using either branch alone, formally proving that cross-domain GPL benefits from the integration between pre-trained knowledge an d task-specific adaptation. Based on this insight, we propose GP2F, a dual-branc h GPL method that explicitly instantiates the two extremes: (1) a frozen branch that retains pre-trained knowledge, and (2) an adapted branch with lightweight a dapters for task-specific adaptation. We then perform adaptive fusion under topo logy constraints via a contrastive loss and a topology-consistent loss. Extensiv e experiments on cross-domain few-shot node and graph classification demonstrate that our method outperforms existing methods.

FedSSM: State Space Model-based Proactive Inference for Heterogeneous Multimodal Federated Learning
Hengyi Ren, Yuchen Xie, Changlong Wang, Xin Li, Yue Huang, Jian Guo, Lijuan Sun
Multimodal Federated Learning (MMFL) addresses collaborative training across cli ents with heterogeneous modality configurations, where effective client selectio n becomes critical under the compounded challenges of modality, distribution, an d quantity heterogeneity. Existing selection methods operate within a reactive p aradigm, responding to current observations without anticipating how decisions i nfluence future optimization trajectories. This myopic approach leads to subopti mal convergence when training dynamics shift rapidly under severe heterogeneity. We propose FedSSM, which reconceptualizes client selection as a proactive decis ion-making process by predicting training dynamics through decision-aware state space models. The prediction error yields a \emph{surprise} signal that quantifi es uncertainty and governs adaptive participation budgets and exploration-exploi tation trade-offs via counterfactual reasoning over candidate actions. For aggre gation, we introduce trust-weighted fusion with modality-specific routing, where surprise calibrates sensitivity to client anomalies. Experiments on four multim odal benchmarks demonstrate that FedSSM achieves 2.5--4.5\% accuracy improvement s over state-of-the-art methods while reducing communication rounds by over 30\% .

A Dirac-Frenkel-Onsager Principle: Instantaneous Residual Minimization with Gaug e Momentum for Nonlinear Parametrizations of PDE Solutions
Matteo Raviola, Benjamin Peherstorfer
Dirac-Frenkel instantaneous residual minimization evolves nonlinear parametrizat ions of PDE solutions in time, but ill-conditioning can render the parameter dyn amics non-unique. We interpret this non-uniqueness as a gauge freedom: nullspace directions that leave the
time derivative unchanged can be used to select better-conditioned parameter vel ocities. Building on Onsager's minimum-dissipation principle, we introduce a his tory variable---interpretable as momentum---and inject it only along the nullspa ce directions. The resulting Dirac-Frenkel-Onsager dynamics preserve instantaneo us residual minimization, in contrast to standard regularization that can introd uce bias, while promoting temporally smooth parameter evolution. Examples demons trate that the approach leads to increased robustness in singular and near-singu lar regimes.

Neural Quantum States in Mixed Precision

Massimo Solinas, Agnes Valenti, Nawaf Bou-Rabee, Roeland Wiersema

Scientific computing has long relied on double precision (64-bit floating point) arithmetic to guarantee accuracy in simulations of real-world phenomena. However, the growing availability of hardware accelerators such as Graphics Processing Units (GPUs) has made low-precision formats attractive due to their superior performance, reduced memory footprint, and improved energy efficiency. In this work, we investigate the role of mixed-precision arithmetic in neural-network based Variational Monte Carlo (VMC), a widely used method for solving computationally otherwise intractable quantum many-body systems. We first derive general analytical bounds on the error introduced by reduced precision on Metropolis-Hastings MCMC, and then empirically validate these bounds on the use-case of VMC. We demonstrate that significant portions of the algorithm, in particular, sampling the quantum state, can be executed in half precision without loss of accuracy. More broadly, this work provides a theoretical framework to assess the applicability of mixed-precision arithmetic in machine-learning approaches that rely on MCMC sampling. In the context of VMC, we additionally demonstrate the practical effectiveness of mixed-precision strategies, enabling more scalable and energy-efficient simulations of quantum many-body systems.

****

T^{2}PO: Uncertainty-Guided Exploration Control for Stable Multi-Turn Agentic Reinforcement Learning

Haixin Wang, Hejie Cui, Chenwei Zhang, Xin Liu, Shuowei Jin, Shijie Geng, Xinyang Zhang, Nasser Zalmout, Zhenyu Shi, Yizhou Sun

Recent progress in multi-turn reinforcement learning (RL) has significantly improved reasoning LLMs' performances on complex interactive tasks.
Despite advances in stabilization techniques such as fine-grained credit assignment and trajectory filtering, instability remains pervasive and often leads to training collapse.
We argue that this instability stems from inefficient exploration in multi-turn settings, where policies continue to generate low-information actions that neither reduce uncertainty nor advance task progress.
To address this issue, we propose Token- and Turn-level Policy Optimization (T^{2}PO), an uncertainty-aware framework that explicitly controls exploration at fine-grained levels. At the token level, T^{2}PO monitors uncertainty dynamics and triggers a thinking intervention once the marginal uncertainty change falls below a threshold.
At the turn level, T^{2}PO identifies interactions with negligible exploration progress and dynamically resamples such turns to avoid wasted rollouts.
We evaluate T^{2}PO in diverse environments, including WebShop, ALFWorld, and Search QA, demonstrating substantial gains in training stability and performance improvements with better exploration efficiency. Code is available at https://github.com/WillDreamer/T2PO.

Unlocking Cross-Modal Biosignal Synthesis: A Temporally-Aware VAE-Diffusion Model

Chenyang Xu, Dezhen Wang, Hao Wang

Synthesizing authentic phonocardiograms (PCG) from ubiquitous electrocardiograms (ECG) is a critical task for accessible cardiac monitoring. Existing generative models, however, struggle to capture the heart's complex electromechanical coupling, failing to meet the dual requirements of temporal precision and physiological fidelity needed for clinically relevant waveform analysis. We introduce the Temporally-Aware VAE-Diffusion model, a synergistic hybrid architecture that resolves this trade-off. Our architecture enforces tight physiological coupling through an Enhanced Condition Fusion mechanism and explicitly models long-range cardiac dynamics via Temporal Attention Blocks. On the EPHNOGRAM benchmark, our model sets a new state-of-the-art, achieving a Pearson correlation of 0.910$\pm$0.008, 95.95\% S1 detection accuracy, and a precise 12.0 ms timing error, significantly outperforming leading diffusion and Transformer baselines. Crucially, our work provides a reproducible zero-shot transfer evaluation for ECG-to-PCG synthesis. Evaluated on the synchronized PhysioNet/CinC 2016 training-a/MITHSDB subset

without target-domain training, our model preserves high waveform fidelity and c
linically relevant timing structure under domain shift, including on pathologica
l recordings. These results support cross-dataset robustness of the proposed syn
thesis framework, while downstream diagnostic validation remains an important di
rection for future work.

Probabilistically-routed Bayesian Additive Spanning Trees for Learning on Constr
ained Domains

Abhisek Chakraborty, Abhishek Mandal, Anirban Chakraborty

Bayesian additive spanning tree (BAST) is an useful tool for interpretable, non-
parametric regression on complex constrained domains. It improves upon the perfo
rmance of Bayesian additive regression trees (BART) by replacing axis-aligned sp
lits through binary tree components by cuts on a spanning tree components, enabl
ing the formation of contiguous splits that respect the underlying complex struc
ture. While BAST is effective for learning on constrained spaces, it still relie
s on hard partitions, albeit on spanning trees, which limits its ability to repr
esent smoothly varying functions on constrained domains. We propose Probabilisti
cally-routed Bayesian additive spanning trees (PR-BAST), a principled relaxation
 that replaces hard cuts on spanning tree components with probabilistic routing
 along spanning tree components. PR-BAST represents the regression surface as a
n additive ensemble of such spanning tree-aligned smooth components. Conditional
 on a fixed spanning tree, each component in PR-BAST induces a Gaussian random f
ield with a sparse, tree-structured precision matrix, enabling scalable posterio
r computation via sparse linear algebra. We theoretically establish that PR-BAS
T yields strictly faster posterior contraction rates compared to BAST under grap
h-smooth truth. Experiments on synthetic and real datasets demonstrate that PR-B
AST consistently improves accuracy over BAST and other baselines, while retainin
g the interpretability of tree-based models.
****

CaliDist: Calibrating Large Language Models via Behavioral Robustness to Distrac
tion

Mohammad Anas Jawad, Cornelia Caragea

Existing calibration methods for Large Language Models (LLMs) often overlook a c
ritical dimension of trustworthiness: a model's {\em behavioral robustness} to i
rrelevant or misleading information. In this paper, we argue that a model's true
 confidence should reflect its stability under cognitive pressure. We introduce
\textsc{CaliDist}, a novel post-hoc calibration approach that directly measures
and penalizes a model's susceptibility to distraction. \textsc{CaliDist} quantif
ies how an LLM's predictions and uncertainty change when its input prompt is per
turbed with semantic \textit{distractors}. This stability (or lack thereof) sign
al is then used to adaptively scale the model's initial confidence score.
Our extensive experiments on seven Natural Language Understanding classification
 benchmarks using six distinct LLMs show that \textsc{CaliDist} consistently ach
ieves lower Expected Calibration Error (ECE) and Brier Score compared with stron
g baselines. Remarkably, our method reduces the ECE from 23\% to 7\% on average—
a relative improvement of 70\%—demonstrating that behavioral stability is a powe
rful signal for calibration. We make our code and datasets available at \url{git
hub.com/m-anas-j/CaliDist}.

Causal-aware Anomaly Detection for Tabular Data

Dang Nguyen, Tu Anh Hoang Nguyen, Thuc Duy Le, Svetha Venkatesh, Trung Le, Sunil
 Gupta

Anomaly detection (AD) methods often ignore causal dependencies and treat anomal
ies as outliers, which is brittle when anomalies are primarily mechanism violati
ons rather than extreme values. We propose CausalAno, a causal-aware detector th
at trains a causal GAN on normal data and leverages its discriminator to learn m
echanism-consistent representations. We score test samples by fitting a Gaussian
 model in this feature space and computing the Mahalanobis distance, measuring d
eviation from the normal causal manifold. We demonstrate the effectiveness of Ca
usalAno with extensive experiments on 28 tabular datasets (18 continuous-only an

d 10 mixed-type), comparing against 16 SOTA baselines. Our results show consiste nt improvements across both mixed-type and numerical-only settings. Our ablation studies further confirm that the gains come from the causal factorization in th e causal GAN rather than a generic GAN backbone. Our CausalAno offers a practica l and effective solution for real-world applications where anomalies often arise from mechanism-violating behaviors.

Agent0-VL: Exploring Self-Evolving Agent for Tool-Integrated Vision-Language Rea soning
Jiaqi Liu, Kaiwen Xiong, Peng Xia, Yiyang Zhou, Haonian Ji, Lu Feng, Siwei Han, Mingyu Ding, Huaxiu Yao
Large Vision-Language Models (LVLMs) have achieved remarkable progress in multim odal reasoning tasks; however, their learning remains constrained by the limitat ions of human-annotated supervision. Recent self-rewarding approaches attempt to overcome this constraint by allowing models to act as their own critics or rewa rd providers. Yet, purely text-based self-evaluation struggles to verify complex visual reasoning steps and often suffers from evaluation hallucinations. To add ress these challenges, inspired by recent advances in tool-integrated reasoning, we propose Agent0-VL, a self-evolving vision-language agent that achieves conti nual improvement with tool-integrated reasoning. Agent0-VL incorporates tool usa ge not only into reasoning but also into self-evaluation and self-repair, enabli ng the model to introspect, verify, and refine its reasoning through evidence-gr ounded analysis. It unifies two synergistic roles within a single LVLM: a Solver that performs multi-turn tool-integrated reasoning, and a Verifier that generat es structured feedback and fine-grained self-rewards through tool-grounded criti que. These roles interact through a Self-Evolving Reasoning Cycle, where tool-ba sed verification and reinforcement learning jointly align the reasoning and eval uation distributions for stable self-improvement. Through this zero-external-rew ard evolution, Agent0-VL aligns its reasoning and verification behaviors without any human annotation or external reward models, achieving continual self-improv ement. Experiments on chart reasoning, geometric problem solving, and visual sci entific analysis show that Agent0-VL achieves an 12.5% improvement over the Qwen -VL base model.

Geodesic Flow Matching for Denoising High-Dimensional Structured Representations
Karim Habashy, Chris Eliasmith
Vector Symbolic Algebras (VSAs) enable robust neurosymbolic reasoning by encodin g information into high-dimensional distributed representations. For continuous domains, Spatial Semantic Pointers (SSPs) extend this framework by mapping varia bles onto precise toroidal manifolds. While generative models offer a promising avenue for cleaning up (denoising) these representations, standard approaches li ke Flow Matching assume a flat Euclidean geometry. We demonstrate that this assu mption fails for SSPs: Euclidean linear interpolants "cut through" the manifold' s interior, destroying the phase and magnitude structure required for accurate d ecoding. To resolve this, we employ Geodesic Flow Matching, adapting Riemannian transport dynamics to strictly restrict the denoising flow to the SSP manifold. We validate this approach in a Spiking Neural SLAM system, showing that manifold -aware cleanup stabilizes path integration against drift. The method achieves a 72\% reduction in tracking error and enables a 40\% increase in neural efficienc y compared to classical baselines.
****

Quantifying Cross-Domain Knowledge Distillation in the Presence of Domain Shift
Xiangchao Li, Xiao Han, Qing Yang, Xin Tong
This paper presents a theoretical investigation into the generalization capabili ties of cross-domain knowledge distillation. Utilizing a high-dimensional asympt otic analysis of a linear teacher–student model, we characterize the excess risk while accounting for both model and covariate shifts. Our results provide a for mal guarantee for the efficacy of distillation: even when the source and target domains differ substantially, there still may exist a regime where the student m odel achieves superior generalization ability over the student-only baseline. Mo

reover, we identify a \textit{crossed double descent} phenomenon: the excess risk can vary non-monotonically with the teacher’s and student’s dimension-to-sample-size ratios. These results provide rigorous insight into when and why distillation helps across domains.

Do LLMs “Feel”? Emotion Circuits Discovery and Control
Chenxi Wang, Yixuan Zhang, Ruiji Yu, Yufei Zheng, Lang Gao, Zirui Song, Zixiang Xu, Gus Xia, Huishuai Zhang, Dongyan Zhao, Xiuying Chen
As the demand for emotional intelligence in large language models (LLMs) grows, a key challenge lies in understanding the internal mechanisms that give rise to emotional expression and in controlling emotions in generated text. This study addresses three core questions: (1) Do LLMs contain context-agnostic mechanisms shaping emotional expression? (2) What form do these mechanisms take? (3) Can they be harnessed for universal emotion control? We first construct a controlled dataset, $\textit{SEV}$ (Scenario–Event with Valence), to elicit comparable internal states across emotions. Subsequently, we extract context-agnostic emotion directions that reveal consistent, cross-context encoding of emotion (Q1). We identify neurons and attention heads that locally implement emotional computation through analytical decomposition and causal analysis, and validate their causal roles via ablation and enhancement interventions. Next, we quantify each sublayer's causal influence on the model’s final emotion representation and integrate the identified local components into coherent global emotion circuits that drive emotional expression (Q2). Directly modulating these circuits achieves 99.65% emotion-expression accuracy on the test set, surpassing prompting- and steering-based methods (Q3). To our knowledge, this is the first systematic study to uncover and validate emotion circuits in LLMs, offering new insights into interpretability and controllable emotional intelligence.

daVinci-Dev: Agent-native Mid-training for Software Engineering
Ji Zeng, Dayuan Fu, Tiantian Mi, Zhuang Yumin, Yaxing Huang, Xuefeng Li, Lyumanshan Ye, Muhang Xie, Qishuo Hua, Zhen Huang, Mohan Jiang, Hanning Wang, Jifan Lin, Yang Xiao, Jie Sun, Yunze Wu, Pengfei Liu
While the emerging field of agentic software engineering has spurred extensive research into post-training, this paradigm alone does not fully address the distribution mismatch between traditional static pre-training and dynamic deployment environments. In this paper, we instead investigate agentic mid-training as a scalable complementary approach.
Central to our approach is *agent-native data* comprising two complementary components: *contextually-native trajectories* that preserve the complete information flow an agent experiences, offering broad coverage and diversity; and *environmentally-native trajectories* whose observations stem from actual tool invocations and test executions, providing interaction authenticity.
On `SWE-Bench Verified`, our recipe outperforms the previous open software engineering mid-training recipe `Kimi-Dev` under two post-training settings with the same base model and agentic scaffold, while using fewer than half mid-training tokens (73.1B).
Furthermore, our 32B and 72B models achieve state-of-the-art resolution rates of **56.1\%** and **58.5\%** among open agentic recipes using agentic scaffolds, despite starting from non-coder `Qwen2.5` base models.
We also observe performance gains on general code generation and scientific benchmarks.
We open-source a significant portion of our datasets, recipes, and model checkpoints to facilitate further research.

MedSIGHT: Towards Grounded Visual Comprehension in Medical Large Vision-Language Models
Aofei Chang, Le Huang, Alex James Boyd, Parminder Bhatia, Taha Kass-Hout, Fenglong Ma, Cao Xiao
Medical large vision-language models (Med-LVLMs) have recently achieved remarkable progress in vision–language comprehension and medical image segmentation. How

ever, existing models still struggle to unify these two capabilities, which is e ssential for achieving clinically reasoning that connects visual findings with s emantic interpretation. We present MedSIGHT, a unified framework that equips Med -LVLMs with structured, pixel-level understanding for grounded visual comprehens ion. MedSIGHT introduces a novel Region Perceiver module that produces region-ce ntric tokens, encoding spatial information directly into representation space of the language model. We further propose a medical region codebook into the LLM v ocabulary, allowing the model to generate discrete region codes as symbolic repr esentations of anatomical and pathological regions. These codes are decoded thro ugh the Region Perceiver to reconstruct segmentation mask, achieving end-to-end spatial grounding. Lastly, MedSIGHT combines Region Perceiver, Codebook and LLM using our proposed progressive training strategy to gradually aligns these modul es stably. Trained on only 72K multimodal instruction pairs, MedSIGHT achieves s tate-of-the-art performance across diverse imaging modalities on both medical co mprehension and segmentation tasks. Code and model are publicly available at [Gi tHub](https://github.com/Aofei-Chang/MedSIGHT).

Proximal-IMH: Proximal Posterior Proposals for Independent Metropolis–Hastings w ith Approximate Operators
Youguang Chen, George Biros
We are considering the problem of sampling from a posterior distribution related to Bayesian inverse problems arising in science, engineering, and imaging. Our method belongs to the family of independence Metropolis--Hastings (IMH) samplin g algorithms. These are quite common in Bayesian inference. Relying on the exis tence of an approximate posterior distribution that is cheaper to sample from b ut can have significant bias, we introduce Proximal-IMH, a scheme that removes t his bias: it corrects samples from the approximate posterior solving an auxili ary optimization problem, yielding a local adjustment that trades off adherence to the exact model against stability around the approximate reference point. For idealized settings, we prove that the proximal correction tightens the match between approximate and exact posteriors, and thereby improves acceptance rates and mixing. The new method works with both linear and nonlinear input-output ope rators and is especially suitable for inverse problems where exact posterior sam pling is too expensive. We perform several numerical experiments that include mu ltimodal and data-driven priors and nonlinear input-output operators. The resu lts show that Proximal-IMH reliably outperforms existing IMH variants.

Learn-to-learn on Arbitrary Textual Conditioning: A Hypernetwork-Driven Meta-gat ed LLM
Luo Ji, Qi Qin, Ningyuan Xi, Teng Chen, Qingqing Gu, Hongyan Li
Conventional LLMs may suffer from corpus heterogeneity and subtle changes in con ditions. While finetuning can create the catastrophe forgetting issue, applicati ons of meta-learning on LLMs are also limited due to their complexity and scalab ility. In this paper, we activate the meta-signal of β within the SwiGLU b locks, resulting in a meta-gating mechanism that adaptively adjusts the nonlinea rity of FFN. A hypernetwork is employed to dynamically produce β under tex tual conditions, providing meta-controllability over LLMs. By testing on differe nt condition types such as task, domain, persona, and style, our method outperfo rms finetuning and meta-learning baselines, and can generalize reasonably on uns een tasks, condition types, or instructions. Our codes are in https://github.com /AaronJi/MeGan.

Principled Confidence Estimation for Deep Computed Tomography
Matteo Gätzner, Johannes Kirschner
We present a principled framework for confidence estimation in computed tomograp hy (CT) reconstruction. Based on the sequential likelihood mixing framework (Kir schner et al., 2025), we establish confidence regions with theoretical coverage guarantees for deep-learning-based CT reconstructions. We consider a realistic f orward model following the Beer-Lambert law, i.e., a log-linear forward model wi th Poisson noise, closely reflecting clinical and scientific imaging conditions.

The framework is general and applies to both classical reconstruction algorithms and deep learning methods alike, including U-Nets, U-Net ensembles, and generative Diffusion models. Empirically, we demonstrate that deep reconstruction methods yield substantially tighter confidence regions than classical reconstructions, without sacrificing theoretical coverage guarantees. Our approach allows the detection of hallucinations in reconstructed images and provides interpretable visualizations of confidence regions. This establishes deep models not only as powerful estimators, but also as reliable tools for uncertainty-aware medical imaging.
****

Why Do We Need Warm-up? A Theoretical Perspective
Foivos Alimisis, Rustem Islamov, Aurelien Lucchi
Learning rate warm-up -- increasing the learning rate at the beginning of training -- has become a ubiquitous heuristic in modern deep learning, yet its theoretical foundations remain poorly understood. In this work, we provide a principled explanation for why warm-up improves training. We rely on a generalization of the (L_0, L_1)-smoothness condition, which bounds local curvature as a linear function of the loss suboptimality and exhibits desirable closure properties. We show -- both theoretically and empirically -- that this condition is satisfied by common neural architectures and accurately captures the curvature of the optimization landscape early in training. Adapting the learning rate in response to this curvature condition naturally induces a warm-up–like schedule, and we show that this choice yields provably faster convergence guarantees than using a fixed learning rate. Experiments on language and vision models show that the resulting one-parameter warm-up schedule can match tuned linear warm-up and improve over no warm-up.

Think Fast and Slow: Step-Level Cognitive Depth Adaptation for LLM Agents
Ruihan Yang, Fanghua Ye, Xiang Wei, Ruoqing Zhao, Kang Luo, Xinbo Xu, Bo Zhao, Ruotian Ma, Shanyi Wang, Zhaopeng Tu, Xiaolong Li, Deqing Yang, Liefeng Bo
Large language models (LLMs) are increasingly deployed as autonomous agents for multi-turn decision-making tasks. However, current agents typically rely on fixed cognitive patterns: non-thinking models generate immediate responses, while thinking models engage in deep reasoning uniformly. This rigidity is inefficient for long-horizon tasks, where cognitive demands vary significantly from step to step, with some requiring strategic planning and others only routine execution. In this paper, we introduce CogRouter, a framework that trains agents to dynamically adapt cognitive depth at each step. Grounded in ACT-R theory, we design four hierarchical cognitive levels ranging from instinctive responses to strategic planning. Our two-stage training approach includes Cognition-aware Supervised Fine-tuning (CogSFT) to instill stable level-specific patterns, and Cognition-aware Policy Optimization (CoPO) for step-level credit assignment via confidence-aware advantage reweighting. The key insight is that appropriate cognitive depth should maximize the confidence of the resulting action. Experiments on ALFWorld and ScienceWorld demonstrate that CogRouter achieves state-of-the-art performance with superior efficiency.

Reuse your FLOPs: Scaling RL on Hard Problems by Conditioning on Very Off-Policy Prefixes
Amrith Setlur, Zijian Wang, Andrew Cohen, Paria Rashidinejad, Sang Michael Xie
Typical reinforcement learning (RL) methods for LLM reasoning waste compute on hard problems, where correct on-policy traces are rare and policy gradients vanish. To bootstrap more efficient RL, we consider reusing old sampling FLOPs (from prior inference or RL training) in the form of off-policy traces. We introduce PrefixRL, where we condition on the prefix of successful off-policy traces and run on-policy RL to complete them, side-stepping instabilities from using off-policy data as supervision targets. PrefixRL boosts the learning signal on hard problems by modulating the difficulty of the problem through the off-policy prefix length. We prove that the PrefixRL objective is not only consistent with the standard RL objective but also more sample efficient. Empirically, we discover back

-generalization: training only on prefixed problems generalizes to out-of-distribution unprefixed performance, with learned strategies often differing from those in the prefix. In our experiments, we source the off-policy traces by rejection sampling with the base model, creating a self-improvement loop. On hard reasoning problems, PrefixRL reaches the same training reward 2x faster than the strongest baseline (SFT on off-policy data then RL), even after accounting for the compute spent on the initial rejection sampling, and increases the final reward by 3x.
****

Bridging the Stability-Expressivity Gap: Synthetic Data Scaling and Preference Alignment for Low-Resource Spoken Language Models
Yizhong Geng, Yanliang Li, Jinghan Yang, Tianhan Jiang, Boxun An, Ya Li, Xiaoyu Shen
Spoken Language Models (SLMs) have emerged as a promising paradigm for speech synthesis by bypassing explicit grapheme-to-phoneme pipelines. However, their effectiveness in low-resource languages remains fundamentally limited by the scarcity of transcribed speech. In practice, synthetic data has become the primary strategy for scaling SLMs in such settings, providing reliable phonetic supervision when real data is insufficient. In this work, we show that this reliance introduces a fundamental trade-off, which we term the Stability-Expressivity Gap: while synthetic data improves phonetic accuracy, it progressively suppresses prosodic variability, ultimately leading to a collapse of expressivity (Synthetic Erosion). To bridge this gap, we propose two self-alignment frameworks. Disentanglement-Guided Self-Alignment (DGSA) recovers expressivity for complex languages by exploiting prosody-timbre separation. For regimes where authentic references are exceptionally limited, Temperature-Driven Self-Critique (TDSC) stabilizes generation through automated exploration and filtering. Our approach outperforms strong commercial systems, including ElevenLabs and Gemini Pro, and enables the first zero-shot voice cloning capability for Lao. Audio Samples are available at: https://luoji.cn/static/multilantts-demo-main/.

Online Linear Programming for Multi-Objective Routing in LLM Serving
Zixi Chen, Yinyu Ye, Zijie Zhou
We study the online routing problem in large language model serving, where requests arrive sequentially and must be dispatched to parallel decode workers under tight batch-size and KV-cache constraints. Unlike widely used routing heuristics that are not tied to explicit service-level objectives (SLOs) and offer limited control over latency–throughput trade-offs, we introduce an multi-objective optimization framework that formulates routing as an online linear programming with interpretable decision rewards. We apply an efficient bid-price control policy based on the online linear programming that admits requests when their SLO-weighted benefit exceeds their shadow prices. To meet millisecond decision requirements, we develop a warm-started, projected first-order updates that track the evolving dual shadow prices online with predictable runtime. We integrate our router into the Vidur simulator and demonstrate substantial improvements over standard baselines across multiple SLO regimes, including end-to-end latency, time-to-first-token, throughput, and tail performance. A big picture from our result: a science-based approach outperforms others based on heuristics.
****

Selecting Samples on Graphs: A Unified Dataset Pruning Framework for Lossless Training Acceleration
Dongyue Wu, Zilin Guo, Xiaoyu Li, Jiajia Liu, Jingdong Chen, Nong Sang, Changxin Gao
The rapid growth of modern training datasets has significantly increased computational cost, motivating dataset pruning~(DP) methods which retain only a subset of informative samples to reduce training cost. Existing pruning criteria typically rely on either intrinsic signals that assess samples independently or extrinsic signals that promote diversity via pairwise relations. While effective in their own specific regimes, each captures only one aspect of sample utility and lacks robustness across different pruning ratios or data distribution. In this wor

k, we present a unified graph-based DP framework. By modeling the dataset as a w eighted graph, where node weights encode intrinsic value and edge weights encode extrinsic value, DP can be cast as a Maximum Weight Clique Problem (MWCP). Alth ough MWCP is NP-hard, its structure admits a principled greedy solution based on sample-wise marginal gains. Under a few mild conditions, we further prove that this unified objective enjoys a formal approximation guarantee, which applies to a broad family of importance metrics and provides practical design guidelines. Extensive experiments show that our method outperforms existing DP methods while substantially reducing training cost, reducing training time by over 40\% witho ut sacrificing accuracy on ImageNet-1k with ResNet-50.

Edit-Based Refinement for Parallel Masked Diffusion Language Models
Houxing Ren, Mingjie Zhan, Zimu Lu, Ke Wang, Yunqiao Yang, Haotian Hou, Junting Pan, Hongsheng Li
Masked diffusion language models enable parallel token generation and offer impr oved decoding efficiency over autoregressive models. However, their performance degrades significantly when generating multiple tokens simultaneously, due to a mismatch between token-level training objectives and joint sequence consistency. In this paper, we propose ME-DLM, an edit-based refinement framework that augme nts diffusion generation with lightweight post-editing steps. After producing an initial complete response, the model refines it through minimal edit operations , including replacement, deletion, and insertion, conditioned on the full sequen ce. Training supervision is derived from edit distance, providing a deterministi c signal under a fixed canonicalization scheme for learning minimal corrections. This approach encourages sequence-level consistency through globally conditione d edits while preserving the efficiency benefits of parallel diffusion decoding. Extensive experiments demonstrate that ME-DLM improves the quality and robustne ss of multi-token parallel generation. In particular, when built upon LLaDA, our method achieves consistent gains of 11.6 points on HumanEval and 33.6 points on GSM8K while using one-eighth of the total diffusion steps. Code is available at https://github.com/renhouxing/ME-DLM.

ReAugment: Targeted Few-Shot Time Series Augmentation via Model Zoo-Guided Reinf orcement Learning
Haochen Yuan, Yutong Wang, Yihong Chen, Yunbo Wang, Xiaokang Yang
Few-shot time series forecasting is fundamentally challenged by the scarcity of high-quality training data and the risk of severe overfitting. To address this i ssue, we propose ReAugment, a reinforcement learning (RL) framework that explici tly learns where and how to augment time series data. ReAugment maintains a zoo of forecasting models and measures prediction diversity across them to identify training samples that are most prone to overfitting. These samples serve as anch or points and are used as inputs to the data augmentation process. We then emplo y an RL approach to learn transformation policies, using a model zoo-guided rewa rd function to bias the transformed data to overfit-prone regions of the trainin g distribution that are most beneficial for generalization. A key advantage of t he RL formulation is that it avoids backpropagating gradients through the foreca sting models, thereby mitigating gradient vanishing. Experiments across diverse forecasting architectures demonstrate the effectiveness of ReAugment in both few -shot and standard time series forecasting.

HieRD: Hierarchical Relational Distillation for Vision-Language Embedding Models
Vinh Le, Nguyen Hong Dang, Tu Vu, Linh Ngo Van, Duc Anh Nguyen, Trung Le
Knowledge distillation is crucial for compressing large Vision–Language Models (VLMs) into efficient architectures. While prior VLM research has primarily focus ed on reasoning tasks like visual question answering, multimodal embedding learn ing, a key component for large-scale retrieval, has received comparatively less attention. Existing distillation methods typically align static global represent ations, overlooking hierarchical feature structure and fine-grained cross-modal interactions. This leads to a structural gap where student models fail to inheri t object-level semantics and spatial relationships from teachers. To address thi

s limitation, we propose **HieRD**, a Hierarchical Representation Distillation f
ramework that preserves hierarchical structure within and across modalities thro
ughout the distillation process by leveraging clustered visual tokens and multi-
granular alignment with phrase-level text. Experimental results on multimodal em
bedding and downstream tasks show that HieRD consistently outperforms strong bas
elines, reflecting the effectiveness of its fine-grained semantic and spatial mo
deling, while enabling compact and efficient embedding models.

Scaling, Benchmarking, and Reasoning of Vision-Language Agents for Mobile GUI Na
vigation
Heng Qu, Liu Yike, Renren Jin, Wenzong Zhang, Pengzhi Gao, Wei Liu, Jian Luan
Vision–Language Models (VLMs) have shown rapid progress in mobile GUI navigation
. This paper presents a systematic study of data scaling, benchmarking, and reas
oning for VLM-based agents in this domain. To facilitate rigorous evaluation, we
 introduce HyperTrack, a large-scale dataset with over 16000 real-world tasks ac
ross more than 650 Chinese mobile applications, along with GUIEvalKit, an open-s
ource toolkit for unified benchmarking of VLMs on offline GUI navigation tasks.
Using HyperTrack, we analyze the effects of training data scale on both supervis
ed and reinforcement-based finetuning. Our results show that reinforcement-based
 finetuning consistently outperforms supervised finetuning, particularly in out-
of-domain settings, highlighting the synergy between data scaling and reinforcem
ent learning. Leveraging GUIEvalKit, we further benchmark state-of-the-art (SOTA
) VLMs and analyze how interaction history and reasoning capabilities influence
task completion. Together, HyperTrack and GUIEvalKit provide a comprehensive pla
tform for developing and evaluating VLM agents in mobile GUI navigation tasks.

RAST-MoE-RL: A Regime-Aware Spatio-Temporal MoE Framework for Deep Reinforcement
 Learning in Ride-Hailing
Yuhan Tang, Kangxin Cui, Jung Ho Park, Yibo Zhao, Xuan Jiang, Haoze He, Jiangbo
Yu, Haris Koutsopoulos, Jinhua Zhao
Ride-hailing platforms must balance passenger waiting times with overall system
efficiency under highly uncertain supply--demand conditions. Adaptive delayed ma
tching, which controls the holding intervals for batched sets of requests and ve
hicles, exposes an inherent trade-off between matching and pickup delays. The no
n-stationary nature of request arrivals and dynamic congestion exposes a key lim
itation of existing methods, which rely on shallow encoders that cannot capture
these spatio-temporal regime shifts. We introduce the Regime-Aware Spatio-Tempor
al Mixture-of-Experts (RAST-MoE) framework, which formalizes adaptive delayed ma
tching as a regime-aware Markov Decision Process and equips RL agents with a sel
f-attention Mixture-of-Experts encoder, letting different experts specialize aut
omatically across operational regimes while keeping per-sample computation modes
t. On real-world TNC trajectory data from San Francisco, our 12M-parameter model
 reduces average matching delay by 10% and pickup delay by 15%, trains stably wi
thout reward hacking, generalizes zero-shot to two additional cities, and exhibi
ts clear expert specialization across demand regimes. These results demonstrate
the value of MoE-enhanced RL for large-scale decision-making tasks with complex
spatio-temporal dynamics.

Expected Returns and Policy Inconsistency-Aware Offline Federated Deep Reinforce
ment Learning
Meng XU, Zhongying Chen, Weiwei Fu, Yan Li, Shuguang Wang, Jianping Wang
Offline Federated Deep Reinforcement Learning (FDRL) methods aggregate multiple
client-side offline Deep Reinforcement Learning (DRL) models, each trained local
ly, to facilitate knowledge sharing while preserving privacy. Existing offline F
DRL methods assign client weights during global aggregation using either simple
averaging or Q-values, but they neglect the combined consideration of Q-values a
nd policy inconsistency, the latter of which reflects the distributional discrep
ancy between the learned policy and the policy from offline data. This causes cl
ients with no significant advantages in one aspect but obvious disadvantages in
the other to disproportionately affect the global model, thereby degrading its c

apabilities in that aspect. During local training, clients in existing methods a re compelled to fully adopt the global model, which negatively impacts clients w hen the global model is weak. To this end, we propose a novel Federated Learning (FL) framework that can be seamlessly integrated into current offline FDRL appr oaches to improve their performance. Our method considers both policy inconsiste ncy and Q-values to determine the weights of client models, with the latter adju sted by a scaling factor to avoid significant numerical discrepancies with the f ormer. The aggregated global model is then distributed to clients to facilitate their learning from the global model. The impact of the global model on the loca l models is reduced when a client's model performance exceeds that of the global model, thereby mitigating the influence of a weaker global model. Experiments o n the Datasets for Deep Data-Driven Reinforcement Learning (D4RL) demonstrate th at our method improves seven state-of-the-art (SOTA) offline FDRL methods across several metrics.

Scientific logicality enriched methodology for LLM reasoning: A practice in phys ics

Zhaoxin Yu, Nan Xu, Kun Chen, Jiahao Zhao, Lei Wang, Wenji Mao

With the continuous advancement of reasoning abilities in Large Language Models (LLMs), their application to scientific reasoning tasks has gained significant r esearch attention. Current research primarily emphasizes boosting LLMs' performa nce on scientific QA benchmarks by training on larger, more comprehensive datase ts with extended reasoning chains. However, these approaches neglect the essence of the scientific reasoning process---logicality, which is the rational foundat ion to ensure the validity of reasoning steps leading to reliable conclusions. I n this work, we make the first systematic investigation into the internal logica lity underlying LLM scientific reasoning, and develop a scientific logicality-en riched methodology, including a set of assessment criteria and data sampling met hods for logicality-guided training, to improve the logical faithfulness as well as task performance. Further, we take physics, characterized by its diverse log ical structures and formalisms, as an exemplar discipline to practise the above methodology. For data construction, we extract scientific problems from academic literature and sample a high-quality dataset exhibiting strong logicality. Expe riments based on three different backbone LLMs reveal that: 1) the training data we constructed can effectively improve the scientific logicality in LLM reasoni ng; and 2) the enriched scientific logicality plays a critical role in solving s cientific problems. Code is available at https://github.com/ScienceOne-AI/PhysLo gic.

FOAM: Frequency and Operator-Error Based Adaptive Damping Method for Reducing St aleness-Oriented Error for Shampoo

Kyunghun Nam, Sumyeong Ahn

Shampoo is attracting considerable attention for its superior performance on lar ge-scale optimization benchmarks; yet it faces a significant practical bottlenec k: the prohibitive computational overhead of matrix inversion.

To mitigate this, practitioners typically rely on stale preconditioner updates, creating a fundamental trade-off between computational efficiency and optimizati on fidelity.

In this work, we provide a theoretical study of staleness through the complement ary lenses of convergence and stability. While staleness improves computational efficiency, it inherently degrades performance and introduces numerical instabil ity. Crucially, we identify that damping, acting as a numerical stabilizer, can effectively suppress these negative effects.

Guided by this analysis, we propose FOAM, an adaptive algorithm that stabilizes training by dynamically controlling both the damping factor and the eigendecompo sition frequency based on an approximation of the staleness-oriented error. Expe rimental results demonstrate that FOAM reduces wall-clock time compared to stand ard Shampoo while maintaining robust convergence.

Learning Tight Rejection Boundaries without Negatives for Strict One-Class Audio

Deepfake Detection
Yuze Zhao, Kuiyuan Zhang, Zhongyun Hua, Yushu Zhang, Qing Liao, Wei Jiang
The rapid evolution of audio deepfakes requires robust detection capable of generalizing to unseen attacks. One-class learning offers inherent robustness for this task by characterizing real speech distributions to detect anomalies. However, establishing a compact decision boundary without spoof supervision remains a fundamental challenge. Existing relaxed approaches often compromise this strictness by introducing auxiliary negative samples, which biases the boundary toward seen artifacts and degrades generalization to unseen attacks. To address this, we propose CA-SOADD, a framework that refines the acceptance region by constructing off-manifold boundary probes. Our proposed centroid-anchored tri-objective learning paradigm simultaneously enforces centroid compactness and a centroid-referenced margin against these probes, thereby explicitly tightening the acceptance region without treating them as an explicit negative class. We further extend the framework to heterogeneous settings through domain-conditioned centroids. Experiments on ASVSpoof and MLAAD benchmarks demonstrate that our strict real-only method consistently outperforms strong baselines under unseen attack types and domain shifts, with its effectiveness further validated through extensive ablation studies.
****

Learning-To-Measure: In-Context Active Feature Acquisition
Yuta Kobayashi, Zilin Jing, Jiayu Yao, Hongseok Namkoong, Shalmali Joshi
Active feature acquisition (AFA) is a sequential decision-making problem where the goal is to improve model performance for test instances by adaptively selecting which features to acquire. In practice, AFA methods often learn from retrospective data with systematic missingness in the features and limited task-specific labels. To address this limitation, we introduce Learning-to-Measure (L2M), which consists of i) reliable uncertainty quantification over unseen tasks, and ii) an uncertainty-guided feature acquisition agent that maximizes conditional mutual information. We demonstrate an autoregressive pre-training approach that underpins reliable uncertainty quantification and acquisition for tasks with arbitrary missingness. L2M operates directly on datasets with retrospective missingness and performs the task in-context, eliminating per-task retraining. Across synthetic and real-world tabular benchmarks, L2M matches or surpasses task-specific baselines, particularly under scarce labels and high missingness.
****

Task-Awareness Improves LLM Generations and Uncertainty
Tim Tomov, Dominik Fuchsgruber, Stephan Günnemann
In many applications of LLMs, natural language responses often have an underlying structure such as representing discrete labels, numerical values, or graphs. Yet, existing decoding and uncertainty estimation methods operate only in language space and largely disregard structural information. We address this by modeling LLM outputs directly in a task-dependent latent structure. By equipping this structure with a dissimilarity measure, we can compute Bayes-optimal responses. These are not selected from sampled generations but are newly synthesized by combining individual responses in the latent space.
Across different tasks, Bayes-optimal responses consistently outperform standard decoding methods like beam search. Moreover, quantifying uncertainty via the induced Bayesian risk captures variations in terms of the latent structure and improves alignment with output quality and correctness. Our decision-theoretic framework is applicable to any problem that admits a latent response structure and enables reliable task-aware LLM predictions.
****

Likelihood Matching for Diffusion Models
Lei Qian, Wu Su, Yanqi Huang, Song Xi Chen
We propose a Likelihood Matching approach for training diffusion models by first establishing an equivalence between the likelihood of the target data distribution and a likelihood along the sample path of the reverse diffusion. To efficiently compute the reverse sample likelihood, the equivalence, a quasi-likelihood is considered to approximate each reverse transition density by a Gaussian distri

bution with matched conditional mean and covariance, respectively. The score and Hessian functions for the diffusion generation are estimated by maximizing the quasi-likelihood, ensuring a consistent matching of both the first two transition moments between every two time points. A stochastic sampler is introduced to facilitate the computation that leverages both the estimated score and Hessian information. We establish consistency of the quasi-maximum likelihood estimation, and provide non-asymptotic convergence guarantees for the proposed sampler, quantifying the rates of the approximation errors due to score and Hessian estimation, dimensionality, and the number of diffusion steps. Empirical and simulation evaluations demonstrate the effectiveness of the proposed Likelihood Matching and validate the theoretical results.
****

Structure-aware Granular-Ball based Information Bottleneck for Multi-modal Clustering
Zhengzheng Lou, Yuhan Zhan, Mingyang Lv, Yingxuan Li, Yuyang Du, Shizhe Hu
Multi-modal clustering, which integrates information from diverse sources and feature modalities, has shown great potential in data mining and computer vision. However, existing methods relying on single-granularity relationships often struggle with complex data distributions, leading to limited performance, as fine-grained features are prone to local heterogeneity and redundant perturbations while coarse-grained representations tend to lose local structural information. To address these limitations, we introduce granular-balls (GBs), adaptive multi-granularity hyperspheres that enclose similar samples, and propose the Structure-aware Granular-Ball based Information Bottleneck (SGB-IB) algorithm. This method initializes the dataset as a single GB and recursively splits GBs based on a purity metric, which quantifies the average mutual information between sample features and K-means-derived pseudo-labels across all modalities. It also balances local structure preservation and global redundancy suppression through a structure-aware objective function. Extensive experiments on benchmark datasets demonstrate that our method outperforms state-of-the-art approaches, validating the effectiveness of fusing GB structures with information-theoretic principles.

Shape of Thought: Progressive Object Assembly via Visual Chain-of-Thought
Yu Huo, Siyu Zhang, Kun Zeng, Haoyue Liu, Owen Lee, Junlin chen, YUQUAN LU, Yifu Guo, Yaodong Liang, Xiaoying Tang
Multimodal models for text-to-image generation have achieved strong visual fidelity, yet they remain brittle under compositional structural constraints—notably generative numeracy, attribute binding, and part-level relations.
To address these challenges, we propose **Shape-of-Thought (SoT)**, a visual CoT framework for *process-supervised progressive shape assembly in the rendered 2D domain*, without external engines at inference time. SoT trains a unified multimodal autoregressive model to generate interleaved textual plans and rendered intermediate states, helping the model capture shape-assembly logic without producing explicit geometric representations. Unlike text-only CoT, each decision is grounded in a rendered state, making counts, attachments, topology, and intermediate part-addition errors inspectable across the trajectory. To support this paradigm, we introduce **SoT-26K**, a large-scale dataset of grounded assembly traces derived from part-based CAD hierarchies, and **T2S-CompBench**, a benchmark for evaluating structural integrity and trace faithfulness. Fine-tuning on SoT-26K achieves 88.4\% on component numeracy and 84.8\% on structural topology, outperforming direct generation by +24.2 points on component numeracy and +19.3 points on structural topology. SoT establishes a transparent testbed for rendered-domain structure-aware generation. The code is available at https://github.com/yuhuo03/Shape-of-Thought.

WUSH: Near-Optimal Adaptive Transforms for LLM Quantization
Jiale Chen, Vage Egiazarian, Roberto L. Castro, Torsten Hoefler, Dan Alistarh
Quantizing LLM weights and activations is a standard approach for efficient deployment, but a few extreme outliers can stretch the dynamic range and amplify low-bit quantization errors. Prior transform-based mitigations (e.g., Hadamard rota

tions) are fixed and data-agnostic, and their optimality for quantization has remained unclear. We derive closed-form optimal linear blockwise transforms for joint weight-activation quantization under standard RTN AbsMax-scaled block quantizers, covering both integer and floating-point formats. The resulting construction, WUSH, combines a Hadamard backbone with a data-dependent second-moment component to form a non-orthogonal transform that is provably near-optimal for FP and INT quantizers under mild assumptions while admitting an efficient fused GPU implementation. Empirically, WUSH improves W4A4 accuracy over the strongest Hadamard-based baselines (e.g., on Llama-3.1-8B-Instruct in MXFP4, it gains +2.8 average points with RTN and +0.7 with GPTQ) while delivering up to 5.8$\times$ per-layer throughput over BF16 via FP4 MatMul. Source code is available at https://github.com/IST-DASLab/WUSH.

LK Losses: Direct Acceptance Rate Optimization for Speculative Decoding

Alexander Samarin, Sergei Krutikov, Anton Shevtsov, Sergei Skvortsov, Filipp Fisin, Alexander Golubev

Speculative decoding accelerates autoregressive large language model (LLM) inference by using a lightweight draft model to propose candidate tokens that are then verified in parallel by the target model.

The speedup is significantly determined by the acceptance rate, yet standard training minimizes Kullback-Leibler (KL) divergence as a proxy objective.

While KL divergence and acceptance rate share the same global optimum, small draft models, having limited capacity, typically converge to suboptimal solutions where minimizing KL does not guarantee maximizing acceptance rate.

To address this issue, we propose **LK losses**, special training objectives that directly target acceptance rate.

Comprehensive experiments across four draft architectures and six target models, ranging from 8B to 685B parameters, demonstrate consistent improvements in acceptance metrics across all configurations compared to the standard KL-based training.

We evaluate our approach on general, coding and math domains and report gains of up to 8-10\% in average acceptance length.

LK losses are easy to implement, introduce no computational overhead and can be directly integrated into any existing speculator training framework, making them a compelling alternative to the existing draft training objectives.

Learning Generalized Trackers with Elastic Token Budgets

Yinchao Ma, Jianpeng Yang, Yuyang Tang, Jie Xiao, Dengqing Yang, Tianzhu Zhang

Visual tracking aims to estimate target states in video sequences, with applications spanning diverse computational requirements. Recent methods optimize trackers using manually pruned image tokens with a fixed budget to reduce computational costs. However, these trackers, once trained, are constrained to perform tracking under a fixed computational budget, limiting their adaptability to real-world computational diversity. To address the above limitation, we provide the first exploration of the elastic token budget training framework (ETBTrack), enabling trackers to perform robust tracking under varying computational budgets. It enjoys several merits. First, we present a novel result-driven importance criteria, in which we optimize a policy network guided by the localization precision of the tracker to estimate token importance, thereby aligning the objectives of importance estimation and tracking precision. Second, we develop a new budget-collaborative optimization strategy, in which we collaboratively optimize the tracker across varying budgets, thereby enabling the tracker to be compatible with diverse budgets. Two optimization processes are performed alternately to enhance the capability of elastic inference. Extensive experiments on large-scale benchmarks demonstrate the effectiveness of our method.

Data Selection for Fine-tuning Vision Language Models via Cross Modal Alignment Trajectories

Nilay Naharas, Dang Nguyen, Neslihan Bulut, Mohammadhossein Bateni, Vahab Mirrokni, Baharan Mirzasoleiman

Data-efficient learning aims to eliminate redundancy in large training datasets by training models on smaller subsets of the most informative examples. While data selection has been extensively explored for vision models and large language models (LLMs), it remains underexplored for Large Vision-Language Models (LVLMs). Notably, none of existing methods can outperform random selection at different subset sizes. In this work, we propose the first principled method for data-efficient instruction tuning of LVLMs. We prove that examples with similar cross-modal attention matrices during instruction tuning have similar gradients. Thus, they influence model parameters in a similar manner and convey the same information to the model during training. Building on this insight, we propose XMAS, which clusters examples based on the trajectories of the top singular values of their attention matrices obtained from fine-tuning a small proxy LVLM. By sampling a balanced subset from these clusters, XMAS effectively removes redundancy in large-scale LVLM training data. Extensive experiments across 4 target models, 2 proxy models, and 2 datasets show that XMAS consistently outperforms 10 baseline methods. Moreover, XMAS can discard 50% of the LLaVA-665k dataset and 85% of the Vision-Flan dataset while fully preserving performance of LLaVA-1.5-7B on 10 downstream benchmarks and speeding up its training by 1.2×. This is 30% more data reduction compared to the best baseline for LLaVA-665k. The project’s website can be found at https://bigml-cs-ucla.github.io/XMAS-project-page/.

SI-IGCL: Subject Invariance-aware Inverse Graph Contrastive Learning for Psychiatric Disorder Identification

Jiayu Lu, Yujin Wang, Xiaofeng Liu, Dandan Li, Bin Wang

Functional brain network analysis plays an important role in understanding and diagnosing psychiatric disorders. However, current methods struggle with subject variations, impairing the model’s generalization ability to the test set. To address this issue, we propose the Subject Invariance-aware Inverse Graph Contrastive Learning (SI-IGCL) model, which adopts a two-stage paradigm with self-supervised subject-invariant pre-training followed by supervised fine-tuning for identification. During the pre-training phase, we construct an inverse contrastive objective that reshapes the embedding space by repelling intra-subject and attracting inter-subject embeddings to learn subject-invariant representations, with an auxiliary correction term to avoid early optimization plateaus. Meanwhile, we incorporate a structure-preserving reconstruction constraint to preserve discriminative information. Moreover, a Hierarchical Topology Enhanced Transformer (HTET) module is designed to enable multi-level modeling of subject-invariant functional patterns. During the fine-tuning phase, a supervised classifier is integrated to perform psychiatric disorder classification. Extensive experiments demonstrate that our method outperforms all state-of-the-art methods. The code is available at https://anonymous.4open.science/r/SI-IGCL.

Learning the Minimum Action Distance

Lorenzo Steccanella, Joshua Benjamin Evans, Özgür ■im■ek, Anders Jonsson

This paper presents a state representation framework for Markov decision processes (MDPs) that can be learned solely from state trajectories, requiring neither reward signals nor the actions executed by the agent. We propose learning the $\textit{minimum action distance}$ (MAD), defined as the minimum number of actions required to transition between states, as a fundamental metric that captures the underlying structure of an environment. The MAD naturally enables critical downstream tasks such as goal-conditioned reinforcement learning and reward shaping by providing a dense, geometrically meaningful measure of progress.

Our self-supervised learning approach constructs an embedding space where the distances between embedded state pairs correspond to their MAD, accommodating both symmetric and asymmetric approximations.

We evaluate the framework on a comprehensive suite of environments with known MAD values, encompassing both deterministic and stochastic transition dynamics, discrete and continuous state spaces, and environments with noisy observations.

Empirical results show that the proposed approach learns MAD representations more efficiently than existing methods, produces more accurate estimates of the tru

e MAD, and improves performance on downstream goal-reaching tasks.
****
AD-BTS: Adaptive Dual-Branch Token Sparsification via Spatial Information Density
Xinpei Gao, Xin Luo, Ming Liu, Chunjiang Wang, S Kevin Zhou
High-resolution visual encoders in multimodal large language models (MLLMs) substantially improve fine-grained perception, yet incur prohibitive computational costs.Existing token pruning methods are effective on natural images but struggle with spatially sparse structured inputs (e.g., charts), where critical high-frequency information is sparse, localized, and structurally essential. To address this challenge, we propose Adaptive Dual-Branch Token Sparsification (AD-BTS), a density-aware framework that dynamically allocates computation according to input signal characteristics. Specifically, AD-BTS introduces a Gradient-based Routing Gate (GRG) that uses lightweight pixel-level gradient statistics to estimate structural flatness and guide routing. Then, AD-BTS activates either a Redundancy Selection Branch (RSB) for aggressive token pruning with a frozen encoder, or a Structural Fusion Branch (SFB) with conditional LoRA and context fusion to preserve sparse structural information.Extensive experiments on Qwen2.5-VL demonstrate that AD-BTS establishes a new Pareto frontier between efficiency and accuracy. Under extreme compression (20% token retention), AD-BTS outperforms the strongest baseline by 12.1% on ChartQA while achieving a 1.8× prefill speedup, effectively reconciling computational efficiency with structural robustness.
****
Probabilistic Bisection Algorithm Provably Achieves Exponential Convergence
Ganghua Wang, Yuwei Cheng, Haifeng Xu
The probabilistic bisection algorithm (PBA) extends the classical binary search to settings with noisy responses, and is a foundational algorithm commonly used in basic problems such as root-finding. Despite its strong empirical success, its theoretical property, particularly the convergence rate, remains unclear. This paper establishes that PBA converges at a geometric rate, providing a rigorous justification for its empirical efficiency. Notably, this rate is optimal in the sense that it matches the performance of classical binary search under noiseless responses. The core of our analysis lies in directly characterizing the dynamics of PBA queries, which had not been examined in the prior literature. We show that the queries oscillate around the truth but steadily draw closer, thus leading to an estimator that rapidly concentrates on the truth. Beyond resolving the long-standing question of PBA’s convergence, our developed techniques offer new tools for analyzing PBA's dynamics, which may be of independent interest.
****
CamGeo: Sparse Camera-Conditioned Image-to-Video Generation with 3D Geometry Priors
Xuanyi Liu, Deyi Ji, Liqun Liu, Lanyun Zhu, Xuhang Chen, Qianxiong Xu, Peng Shu, Huan Yu, Jie Jiang, Feng Gao, Siwei Ma
Sparse camera-conditioned image-to-video generation presents a pivotal challenge: synthesizing geometrically consistent 3D motion from minimal pose cues. Existing methods, which largely rely on dense supervision or naive interpolation, suffer from severe pose drift and motion discontinuities due to the lack of robust 3D priors. In this paper, we introduce \textbf{CamGeo}, a novel framework that distills rich 3D geometric knowledge from a pre-trained video-to-3D model (VGGT) directly into the diffusion backbone. To achieve this without incurring inference latency, we propose a training-only distillation strategy. Specifically, CamGeo incorporates: (1) keyframe trajectory distillation that enforces cycle-consistency with sparse input poses, (2) cross-frame consistency distillation with both camera trajectory and depth constraints to generate consistent structure across unsupervised frames, and (3) a three-stage coarse-to-fine curriculum learning, progressively scales geometric complexity, from global structure coherence to fine-grained refinement, achieving stable optimization. Extensive experiments demonstrate that CamGeo achieves consistent improvements under various sparsity ratios.

Efficient RL Training for LLMs with Experience Replay
Charles Arnal, Vivien Cabannes, Taco Cohen, Julia Kempe, Rémi Munos
While Experience Replay—the practice of storing rollouts and reusing them multiple times during training—is a foundational technique in general RL, it remains largely unexplored in LLM post-training due to the prevailing belief that fresh, on-policy data is essential for high performance.
In this work, we challenge this assumption.
We present a systematic study of replay buffers for LLM post-training, formalizing the optimal design as a trade-off between staleness-induced variance, sample diversity and the high computational cost of generation.
We show that strict on-policy sampling is suboptimal when generation is expensive.
Empirically, we show that a well-designed replay buffer can drastically reduce inference compute without degrading -- and in some cases even improving -- final model performance, while preserving policy entropy.

Reviving Error Correction in Modern Deep Time-Series Forecasting
Minh Hoang Nguyen, Van Dai Do, Huu Hiep Nguyen, Dung Nguyen, Kien Do, Hung Le
Modern deep-learning models have achieved remarkable success in time-series forecasting. Yet, their performance degrades in long-term prediction due to error accumulation in autoregressive inference, where predictions are recursively used as inputs. While classical error correction mechanisms (ECMs) have long been used in statistical methods, their applicability to deep learning models remains limited or ineffective. In this work, we revisit the error accumulation problem in deep time-series forecasting and investigate the role and necessity of ECMs in this new context. We propose a simple, architecture-agnostic error correction model that can be integrated with any existing forecaster without requiring retraining. By explicitly decomposing predictions into trend and seasonal components and training the corrector to adjust each separately, we introduce the Universal Error Corrector with Seasonal–Trend Decomposition (UEC-STD), which significantly improves correction accuracy and robustness across 4 backbones and 10 datasets. Our findings provide a practical tool for enhancing forecasts while offering new insights into mitigating autoregressive errors in deep time-series models.
****
Accurate Large-sample Uncertainty Quantification using Stochastic Gradient Markov Chain Monte Carlo
Yu Wang, Jie Ding, Jonathan H. Huggins
Tuning stochastic gradient methods such as stochastic gradient descent (SGD) and stochastic gradient Langevin dynamics (SGLD) for approximate sampling and uncertainty quantification remains challenging, particularly in relevant settings using a large batch size or when the model is misspecified. Existing theory that provides tuning guidance relies on continuous-time limits or strong statistical assumptions, which can become quantitatively inaccurate in these regimes. We address these shortcomings by proposing a new discrete-time approximations to SG(L)D with and without momentum, which enables accurate predictions of the stationary covariance, iterate average covariance, and integrated autocorrelation time. Moreover, we prove quantitative, non-asymptotic error bounds showing that these estimates are sufficiently accurate for practical tuning and uncertainty quantification. Numerical experiments demonstrate that our theory yields improved tuning guidance across a range of models and data-generating distributions where existing approaches fail, including when using the β-divergence rather than log-loss to obtain statistically robust inferences.

Cold-Start Personalization via Bayesian Adaptive Questioning
Avinandan Bose, Shuyue Stella Li, Faeze Brahman, Pang Wei Koh, Simon Shaolei Du, Yulia Tsvetkov, Maryam Fazel, Lin Xiao, Asli Celikyilmaz
Cold-start personalization requires inferring preferences from minimal interaction when no user-specific historical data is available. The space of possible preferences is vast, yet users care about only a sparse subset and rarely articulate them upfront; combined with limited interaction budgets, this makes preference

elicitation challenging. Our key insight is that preferences exhibit predictable structure across populations; e.g., users who want detailed explanations often also value worked examples. We propose CAPE (Cold start Adaptive Preference Elicitation with Priors), a principled system decomposition framework for cold-start personalization: learning a structured world model of preference correlations offline using latent variables, then performing Bayesian inference online without retraining. Even simple belief model instantiations (e.g., linear regression) substantially outperform end-to-end RL. Across medical, mathematical, social, and commonsense reasoning, CAPE achieves 80.8% alignment with ground-truth user preferences versus 68.5% for RL, requires 3-5× fewer interactions, and adapts twice as often. Our contribution is a principled decomposition of cold-start personalization that makes Bayesian preference elicitation practical at scale for LLM systems.

ECHO: Entropy-Confidence Hybrid Optimization for Test-Time Reinforcement Learning

Chu Zhao, Enneng Yang, Yuting Liu, Jianzhe Zhao, Guibing Guo

Test-time reinforcement learning generates multiple candidate answers via repeated rollouts and performs online updates using pseudo-labels constructed by majority voting. To reduce overhead and improve exploration, prior work introduces tree-structured rollouts, which share reasoning prefixes and branch at key nodes to improve sampling efficiency. However, this paradigm still faces two challenges: (1) high-entropy branching can trigger rollout collapse, where the branching budget concentrates on a few trajectories with consecutive high-entropy segments, rapidly reducing the number of effective branches; (2) early pseudo-labels are noisy and biased, which can induce self-reinforcing overfitting, causing the policy to sharpen prematurely and suppress exploration. To address these issues, we propose Entropy–Confidence Hybrid Group Relative Policy Optimization (ECHO). During rollout, ECHO jointly leverages local entropy and group-level confidence to adaptively control branch width, and further introduces online confidence-based pruning to terminate persistently low-confidence branches, avoiding high-entropy traps and mitigating collapse. During policy updates, ECHO employs confidence-adaptive clipping and an entropy–confidence hybrid advantage shaping approach to enhance training robustness and mitigate early-stage bias. Experiments demonstrate that ECHO achieves consistent gains on multiple mathematical and visual reasoning benchmarks, and generalizes more effectively under a limited rollout budget.

Long Grounded Thoughts: Synthesizing Visual Problems and Reasoning Chains at Scale

David Acuna, Chao-Han Huck Yang, Yuntian Deng, Jaehun Jung, Ximing Lu, Prithviraj Ammanabrolu, Hyunwoo Kim, Yuan-Hong Liao, Yejin Choi

Despite rapid progress, multimodal reasoning still lacks a systematic approach to synthesize large-scale vision-centric datasets beyond visual math. We introduce a framework able to synthesize vision-centric problems spanning diverse levels of complexity, and the resulting dataset with over 1M high-quality problems including: reasoning traces, preference data, and instruction prompts supporting SFT, offline and online RL. Our vision-centric synthesis framework uses a two-stage process focusing on: (1) generating diverse verifiable questions from existing images at scale, and (2) creating complex compositional visual problems by merging simpler questions.

Remarkably, finetuning Qwen2.5-VL-7B on our data outperforms existing open-data baselines across evaluated vision-centric benchmarks, and our best configurations match or surpass strong closed-data models such as MiMo-VL-7B-RL on V*Bench, CV-Bench and MMStar-V. Notably, despite being entirely vision-centric, our data transfers positively to text-only reasoning (MMLU-Pro, +3.7%) and audio reasoning (MMAU, +1.32%), demonstrating its effectiveness. Similarly, despite containing no embodied visual data, we observe notable gains (NiEH, +8.8%) when evaluating open-ended embodied QA. Lastly, we use our data to comprehensively analyze at scale (1M+) the entire VLM post-training pipeline showing that (i) SFT on

high-quality data with cognitive behaviours on reasoning traces is essential to scale online RL, (ii) offline RL could match online RL’s performance while disaggregating compute demands, and, (iii) SFT on high quality data also improve out-of-domain, cross-modality transfer.
****
Benchmarking Reward Hack Detection in Code Environments via Contrastive Analysis
Darshan Girish Deshpande, Anand Kannappan, Rebecca Qian
Recent advances in reinforcement learning for code generation have made robust environments essential to prevent reward hacking. As LLMs increasingly serve as evaluators in code-based RL, their ability to detect reward hacking remains understudied. In this paper, we propose a novel taxonomy of reward exploits spanning across 54 categories and introduce TRACE (Testing Reward Anomalies in Code Environments), a synthetically curated and human-verified benchmark containing 517 testing trajectories. Unlike prior work that evaluates reward hack detection in isolated classification scenarios, we contrast these evaluations with a more realistic, contrastive anomaly detection setup on TRACE. Our experiments reveal that models capture reward hacks more effectively in contrastive settings than in isolated classification settings, with GPT-5.2 with highest reasoning mode achieving the best detection rate at 63%, up from 45% in isolated settings on TRACE. Building on this insight, we demonstrate that state-of-the-art models struggle significantly more with semantically contextualized reward hacks compared to syntactically contextualized ones. We further conduct qualitative analyses of model behaviors, as well as ablation studies showing that the ratio of benign to hacked trajectories and analysis cluster sizes substantially impact detection performance. We release the benchmark and evaluation harness to enable the community to expand TRACE and evaluate their models.

Deep Learning for BioImaging: What Are We Really Learning?
Ivan Svatko, Maxime Sanchez, Ihab Bendidi, Gilles Cottrell, Auguste Genovesio
Representation learning has driven major advances in natural image analysis by enabling models to acquire high-level semantic features. In microscopy imaging, however, it remains unclear what current representation learning methods really learn.
In this work, we conduct a systematic study of representation learning for the two most widely used and broadly available microscopy data types, representing critical scales in biology: cell culture and tissue imaging. We investigate whether, in contrast to natural images, existing models fail to consistently acquire high-level, biologically meaningful features. To this end, we introduce a set of simple yet revealing baselines on curated benchmarks, including untrained models and structural representations of cellular tissue. Our results show that, surprisingly, for a considerable subset of evaluation settings, the baselines are comparable to state-of-the-art methods, demonstrating that many commonly used benchmark metrics are insufficient to assess representation quality and often mask a lack of relevant high-level abstractions. In addition, we investigate how detailed comparisons with these baselines provide ways to interpret the strengths and weaknesses of models for further improvements. Together, our results suggest that progress in representation learning for microscopy requires not only stronger models, but also benchmarks that are more indicative of what is actually learned.
****
Clustering as Reasoning: A k-Means Interpretation of Chain-of-Thought Graph Learning
Xuanting Xie, Zhaochen Guo, Bingheng Li, Xingtong Yu, Zhifei Liao, zhao kang, Yuan Fang
Chain-of-Thought (CoT) prompting has shown promise in enhancing the reasoning capabilities of large language models (LLMs) on text-attributed graphs (TAGs). This work reframes CoT-based graph learning through the principle of clustering as reasoning, offering a k-means interpretation of how iterative reasoning operates over graph-structured data. We observe that existing graph CoT methods rely on disjoint architectures and fixed graph representations, limiting step-by-step

semantic-topological interaction and interpretability. To overcome this limitation, we propose a unified framework named KCoT that integrates CoT reasoning with graph representation learning. Our key theoretical result reveals a formal mathematical correspondence between a Transformer block and the k-means algorithm, allowing reasoning to be interpreted as iterative assignment and update steps. Based on this insight, we introduce a Semantic Discriminating Prompt that explicitly formulates these steps as structured CoT reasoning, together with a structure-grounded alignment strategy to fuse topological priors with evolving thought-conditioned representations. Experiments on standard benchmarks demonstrate consistent improvements over state-of-the-art methods, validating clustering as a principled mechanism for CoT-based graph learning.
****

Approximate Nearest Neighbor Search for Modern AI: A Projection-Augmented Graph Approach
Kejing Lu, Zhenpeng Pan, Yoshiharu Ishikawa, Chuan Xiao, Jianbin Qin
Approximate Nearest Neighbor Search (ANNS) is fundamental to modern AI applications. Most existing solutions optimize query efficiency but fail to align with the practical requirements of modern workloads. In this paper, we outline six critical demands of modern AI applications: high query efficiency, fast indexing, low memory footprint, scalability to high dimensionality, robustness across varying retrieval sizes, and support for online insertions. To satisfy all these demands, we introduce Projection-Augmented Graph (PAG), a new ANNS framework that integrates projection techniques into a graph index. PAG reduces unnecessary exact distance computations through asymmetric comparisons between exact and approximate distances as guided by projection-based statistical tests. Three key components are designed and integrated into the graph index to optimize indexing and searching. Experiments on six modern datasets demonstrate that PAG consistently achieves superior queries per second (QPS)-recall performance---up to 5$\times$ faster than HNSW---while offering fast indexing speed and moderate memory footprint. PAG remains robust as dimensionality and retrieval size increase and naturally supports online insertions. Our source code is available at: https://github.com/KejingLu-810/PAG/.

Immuno-VLM: Immunizing Large Vision-Language Models via Generative Semantic Antibodies for Open-World Trustworthiness
Xiang Fang, Wanlong Fang, Wei Ji
Large Vision-Language Models have achieved unprecedented success in zero-shot recognition by aligning visual features with broad semantic concepts. However, this semantic abstraction creates a critical vulnerability in open-world deployment: the "Hubris of Semantics", where models force-fit unknown anomalies into known categories with high confidence due to the lack of explicit negative knowledge. To address this Open-World Trustworthiness Paradox, we propose Immuno-VLM, a bio-inspired framework that adapts the biological principle of Immunological Negative Selection to high-dimensional latent spaces. Departing from traditional Open-Set Recognition methods that rely on passive density estimation or inefficient pixel-space outlier generation, Immuno-VLM leverages the generative reasoning of Large Language Models to actively hallucinate "Semantic Antibodies", textual descriptions of near-distribution outliers (e.g., look-alikes, contextual anomalies) that effectively bound the decision space of known classes. Extensive experiments on ImageNet-1K and four challenging OOD benchmarks reveal that Immuno-VLM establishes a new state-of-the-art.

Transitive Representation Learning Enhances Histopathology Annotation
Moritz Schaefer, Zoe Piran, Nils Philipp Walter, Animesh Awasthi, Christoph Bock, Jure Leskovec, Zinaida Good
The characterization of histopathology with AI promises to assist clinical decision-making, but it is currently limited due to coarse-grained annotations that miss cellular identities. To overcome this gap, we bridge histopathological images, gene expression profiles, and natural-language descriptions using *SpatialWhisperer*, a trimodal contrastive learning model. Our training integrates communit

y-scale datasets comprising spatially resolved gene expression profiles paired w
ith histopathology images, as well as single-cell gene expression profiles with
detailed annotations. The shared gene expression modality implies a transitive r
elationship between images and textual annotations, which our method leverages t
o enable accurate zero-shot cell type annotation directly from H&E images. *Spat
ialWhisperer* outperforms published baselines, achieving relative AUROC gains of
 up to 15.9% across three benchmarks spanning 19 tissues and 20 cell types. When
 training with data from all three modality pairs, we observe performance gains
in low-data regimes. We formalize our approach and present a sufficient conditio
n under which this transitive alignment is induced. Our work establishes *transi
tive representation learning* for fine-grained interpretation of histopathology
images.
****

SurrogateSHAP: Training-Free Contributor Attribution for Text-to-Image (T2I) Mod
els

MingYu Lu, Soham Gadgil, Chris Lin, Chanwoo Kim, Su-In Lee

As Text-to-Image (T2I) diffusion models are increasingly used in real-world crea
tive workflows, a principled framework for valuing contributors who provide a co
llection of data is essential for fair compensation and sustainable data marketp
laces. While the Shapley value offers a theoretically grounded approach to attri
bution, it faces a dual computational bottleneck: (i) the prohibitive cost of ex
haustive model retraining for each sampled subset of players (i.e., data contrib
utors) and (ii) the combinatorial number of subsets needed to estimate marginal
contributions due to contributor interactions. To this end, we propose **Surroga
teSHAP**, a retraining-free framework that approximates the expensive retraining
 game through inference from a pretrained model. To further improve efficiency,
we employ a gradient-boosted tree to approximate the utility function and derive
 Shapley values analytically from the tree-based model. We evaluate SurrogateSHA
P across three diverse attribution tasks: (i) image quality for DDPM-CFG on CIFA
R-20, (ii) aesthetics for Stable Diffusion on Post-Impressionist artworks, and (
iii) product diversity for FLUX.1 on Fashion-Product data. Across settings, Surr
ogateSHAP outperforms prior methods while substantially reducing computational o
verhead, consistently identifying influential contributors across multiple utili
ty metrics. Finally, we demonstrate that SurrogateSHAP effectively localizes dat
a sources responsible for spurious correlations in clinical images, providing a
scalable path toward auditing safety-critical generative models. Code is availab
le at https://anonymous.4open.science/r/CFG-Attribution-15DD/

Distributional Inverse Reinforcement Learning

Feiyang Wu, Ye Zhao, Anqi Wu

We propose a distributional framework for offline Inverse Reinforcement Learning
 (IRL) that jointly models uncertainty over reward functions and full distributi
ons of returns. Unlike conventional IRL approaches that recover a deterministic
reward estimate or match only expected returns, our method captures richer struc
ture in expert behavior, particularly in learning the reward distribution, by mi
nimizing first-order stochastic dominance (FSD) violations and thus integrating
distortion risk measures (DRMs) into policy learning, enabling the recovery of b
oth reward distributions and distribution-aware policies. This formulation is we
ll-suited for behavior analysis and risk-aware imitation learning. Theoretical a
nalysis show that the algorithm converge with $\mathcal{O}(\varepsilon^{-2})$ it
eration complexity. Empirical results on synthetic benchmarks, real-world neurob
ehavioral data, and MuJoCo control tasks demonstrate that our method recovers ex
pressive reward representations and achieves state-of-the-art imitation performa
nce.

MutAtlas: A PDB-Wide Energy-Guided Atlas of Protein Mutation Effects

Ruihan Guo, Chaoran Cheng, Zhanghan Ni, Neil He, Bangji Yang, Ge Liu

Protein mutation effect prediction is fundamental to protein engineering and dis
ease variant interpretation, yet experimentally measured mutation data remain ac
curate but extremely sparse. To provide scalable supplementary mutation signals,

we construct a PDB-wide mutation augmentation dataset that exhaustively enumera
tes single-site substitutions on experimentally resolved protein structures and
aligns mutation signals from physics-based energy models, protein language model
s, and inverse folding models. Large-scale analysis under a unified mutation pre
ference representation reveals substantial differences in the consistency, conce
ntration, and substitution patterns of mutation distributions across models, ind
icating that disagreement is pervasive and reflects conflicting inductive biases
rather than random noise. Motivated by these observations, we propose an unsupe
rvised multi-source mutation preference distillation framework that learns from
relative mutation preferences while explicitly modeling cross-source disagreemen
t. Without using any experimental mutation labels during training, our approach
achieves the best overall performance among the evaluated zero-shot baselines an
d naive multi-source fusion strategies on ProteinGym. We release the dataset and
evaluation pipeline to support reproducible studies of protein mutation effects
.

Incremental BPE Tokenization
Shenghu Jiang, Ruihao Gong
We propose a novel algorithm for incremental Byte Pair Encoding (BPE) tokenizati
on.
The algorithm processes each input byte in **worst-case** $\mathcal{O}(\log^2 t)
$ time,
leading to an overall complexity of $\mathcal{O}(n \log^2 t)$,
where n is the input length and t is the maximum token length.
The algorithm incrementally maintains BPE tokenization results for every prefix
of the input text,
implementing the standard BPE merge procedure defined by a fixed set of merge ru
les.
This enables efficient partial tokenization in streaming settings.
Functioning as a drop-in replacement for standard BPE,
our approach achieves a speedup of up to ${\sim}3\times$ over Hugging Face's tok
enizers,
and demonstrates significant latency reductions over OpenAI's tiktoken on pathol
ogical inputs.
We further introduce an eager output algorithm that enables streaming output,
emitting tokens as soon as token boundaries are determined during incremental to
kenization.
Overall, our results demonstrate that BPE tokenization can be performed incremen
tally
with strong worst-case guarantees,
while providing practical latency benefits in modern large language model pipeli
nes.
The source code is available at https://github.com/ModelTC/mtc-inc-bpe.

DSB: Dynamic Sliding Block Scheduling for Diffusion LLMs
Lizhuo Luo, Shenggui Li, Yonggang Wen, Tianwei Zhang
Diffusion large language models (dLLMs) have emerged as a promising alternative
for text generation, distinguished by their native support for parallel decoding
. In practice, block inference is crucial for avoiding order misalignment in glo
bal bidirectional decoding and improving output quality. However, the widely-use
d fixed, predefined block (naive) schedule is agnostic to semantic difficulty, m
aking it a suboptimal strategy for both quality and efficiency: it can force pre
mature commitments to uncertain positions while delaying easy positions near blo
ck boundaries. In this work, we analyze the limitations of naive block schedulin
g and disclose the importance of dynamically adapting the schedule to semantic d
ifficulty for reliable and efficient inference. Motivated by this, we propose **
Dynamic Sliding Block (DSB)**, a training-free block scheduling method that uses
a sliding block with a dynamic size to overcome the rigidity of the naive block
. To further improve efficiency, we introduce **DSB Cache**, a training-free KV-
cache mechanism tailored to DSB. Extensive experiments across multiple models an

d benchmarks demonstrate that DSB, together with DSB Cache, consistently improve s both generation quality and inference efficiency for dLLMs. Code is released a t https://github.com/lizhuo-luo/DSB.

Learning-Guided Integration Contours Construction for Fast Large-Scale Generaliz ed Eigensolvers

Yeqiu Chen, Ziyan Liu, Hong Wang, Lei Liu

Solving large-scale Generalized Eigenvalue Problems (GEPs) is a fundamental yet computationally prohibitive task in science and engineering.

As a promising direction, contour integral (CI) methods offer an efficient and p arallelizable framework. However, their performance is critically dependent on the selection of \textit{integration contours}---improper selection without reli able prior knowledge of eigenvalue distribution can incur significant computatio nal overhead and compromise numerical accuracy. To address this challenge, we pr opose **Deepcontour**, a novel hybrid framework that integrates a deep learning- based spectral predictor with Kernel Density Estimation (KDE) for principled con tour design. Specifically, Deepcontour utilizes its specialized Eigen-Neural-Ope rator (ENO) to provide rapid spectral distribution priors, driving a KDE module to automatically construct the optimized integration contours, which guide the C I solver to efficiently find the desired eigenvalues. Deepcontour achieves up to a 5.63x speedup across diverse scientific datasets while maintaining strict num erical rigor. By merging the predictive power of deep learning with the numerica l rigor of classical solvers, this work establishes an efficient and robust para digm for solving large-scale GEPs.
****

SFCLTA: Spectral Fusion Contrastive Learning with Topology-Adaptive Graph Augmen tation

Zhuo Xu, Lu Bai, Jincheng Li, Lixin Cui, Ming Li, Hangyuan Du, Yue Wang

Graph Neural Networks (GNNs) have achieved remarkable success in graph analysis due to the Message-Passing (MP) mechanism, yet they struggle with heterophilic g raphs where connected nodes often have distinct labels or dissimilar attributes. Graph Contrastive Learning (GCL) serves as a promising approach to extract the information beyond neighboring nodes, effectively mitigating the limitations of the MP mechanism in handling heterophilic graphs. Nevertheless, GCL faces two cr itical challenges when applied to heterophilic graphs, i.e., the potential distr ibution shift from data augmentation and the loss of robustness caused by high-f requency signals. To address these problems, we propose a novel model, namely th e Spectral Fusion Contrastive Learning with Topology-Adaptive Graph Augmentation (SFCLTA) for unsupervised graph representation learning. Our method dynamically adjusts graph structures via a heterophily-aware augmentation strategy, and con strains high-frequency distortions by spectral regularization. We utilize the c onfidence-weighted fusion to enhance the robustness. Additionally, we introduce a feature reconstruction task as a prerequisite to explicitly mitigate feature-l evel distribution shifts. Experiments on multiple real-world datasets demonstra te that the proposed SFCLTA consistently outperforms baseline models in multiple tasks. Our code is released on https://github.com/JonathanGXu/SFCLTA.

Variational Routing: A Scalable Bayesian Framework for Calibrated Mixture-of-Exp erts Transformers

Albus Li, Matthew Robert Wicker

Foundation models are increasingly being deployed in contexts where understandin g the uncertainty of their outputs is critical to ensuring responsible deploymen t.

While Bayesian methods offer a principled approach to uncertainty quantification , their computational overhead renders their use impractical for training or inf erence at foundation model scale. State-of-the-art models achieve parameter coun ts in the trillions through carefully engineered sparsity including Mixture-of-E xperts (MoE) layers.

In this work, we demonstrate calibrated uncertainty at scale by introducing Vari ational Mixture-of-Experts Routing (VMoER), a structured Bayesian approach for m

odelling uncertainty in MoE layers.
VMoER confines Bayesian inference to the expert-selection stage which is typical ly done by a deterministic routing network. We instantiate VMoER using two infer ence strategies: amortised variational inference over routing logits and inferri ng a temperature parameter for stochastic expert selection.
Across tested foundation models, VMoER improves routing stability under noise by 38%, reduces calibration error by 94%, and increases out-of-distribution AUROC by 12%, while incurring less than 1% additional FLOPs. These results suggest VMo ER offers a scalable path toward robust and uncertainty-aware foundation models.

Beyond Magnitude: Scale-Invariant Evidential Fusion for Multi-View Classificatio n

Wei Liu, Yufei Chen, Jie Shi, Xiaodong Yue

Evidential Deep Learning (EDL) enables trustworthy multi-view classification, ye t suffers from a critical vulnerability: the Scale Mismatch Problem. We theoreti cally demonstrate that existing evidential fusion rules erroneously equate logit magnitude with semantic confidence, rendering them susceptible to semantic hija cking by inflated but uninformative views. To resolve this, we propose Scale-Inv ariant Evidential Fusion (SAEF), a framework utilizing instance-wise standardiza tion to strictly decouple confidence from scale. Instead of relying on magnitude dominance, SAEF aggregates views based on statistical consensus. Theoretically, SAEF guarantees invariance to global scaling and robustness to asymmetric domin ance. Experiments on four diverse datasets confirm that SAEF outperforms state-o f-the-art baselines in accuracy and robustness to semantic conflicts and noise, ensuring stability against severe scale perturbations.

The Fairness Hierarchy: A viewpoint from causal inference

ChengBo Zhang, Zhen Yao, Hao Pang, Changcheng Li

Fairness in machine learning prediction has attracted growing attention in recen t years.
In this article, we propose a causal–inference–based framework for fair predicti on, defined through path-specific counterfactual interventions.
Instead of imposing fairness via constraints on predictive objectives or model p arameters, our approach specifies fairness directly at the level of counterfactu al prediction semantics.
Given a learned causal graph, we construct a predictive distribution for the out come Y using a structural causal model and generate counterfactual predictions by selectively intervening on causal paths emanating from sensitive attributes.
By allowing or blocking the propagation of sensitive information along designate d paths, possibly involving multiple sensitive sources, our framework induces a hierarchy of interpretable fairness notions, generalizing standard path-specific causal semantics.
Our empirical experiments demonstrate how different fairness levels can be insta ntiated and compared in practice.

Beyond Attention Imbalance: Mitigating Hallucinations via Spectral Surgery

Siqi Lu, Wei Suo, Yongbin Zheng, Jianhang Yao, Wanying XU, PENG WANG

While Large Vision-Language Models (LVLMs) achieves remarkable success, hallucin ations remain a significant barrier to their reliable deployment. Recent studies primarily attribute these defects to cross-modal attention imbalances, with mos t solutions focusing on re-weighting visual tokens or suppressing language prior s. Such approaches often overlook the spectral characteristics of the visual inf ormation flow and frequently rely on Contrastive Decoding (CD), which doubles th e inference time. Instead of following conventional approaches, we identify two distinct hallucination patterns—Perceptual-Semantic Dissociation and Localized F ixation—and accordingly develop FLASH (Frequency-Localized Attention SHaping), a training-free and CD-free framework. FLASH utilizes a Spectral Vortex Score to detect visual heads within multi-head attention layers, applying adaptive spectr al modulation to rectify the visual information flow during the decoding phase.
Empirical results demonstrate that FLASH offers a superior balance between perfo

rmance and efficiency compared to SOTA methods.

Density-Aware Translation of Spurious Correlations in Zero-Shot VLMs
Afsaneh Hasanebrahimi, Hanxun Huang, Christopher Leckie, Sarah Monazam Erfani
Vision-Language models (VLMs), such as CLIP, achieve powerful zero-shot classification. However, their predictions remain sensitive to spurious correlations, where contextual cues dominate over semantic content. Earlier solutions typically rely on fine-tuning or prompt engineering, which either undermine the advantages of pre-trained models or are prone to hallucination. In this work, we propose Density-Aware Translation (DAT) that refines image-text similarity scores using a local geometric density term derived from group reference sets. Our approach is motivated by the phenomenon that CLIP embeddings exhibit a modality gap and lie on an anisotropic shell in the feature space: common patterns cluster near the mean, while rare patterns are pushed outward. This geometry creates uneven alignment, where spurious correlations are amplified while semantically meaningful but rare cues are marginalised. To address this, we employ a relative measure to rescale similarities based on embedding density, suppressing overconfident scores in diffuse regions while preserving dense, semantically consistent matches. Experimental results on benchmark datasets demonstrate consistent improvements in worst-group and average accuracy, highlighting density-aware translation as a simple and effective calibration mechanism for reliable zero-shot classification using multimodal models.

Learning Graph Foundation Models on Riemannian Graph-of-Graphs
Haokun Liu, Zezhong Ding, Xike Xie
Graph foundation models (GFMs), pretrained on massive graph data, have transformed graph machine learning by supporting general-purpose reasoning across diverse graph tasks and domains.
  Existing GFMs pretrained with fixed-hop subgraph sampling impose a fixed receptive field, causing scale mismatch on diverse tasks, which often require heterogeneous and unknown structural contexts beyond a fixed sampling scale.
  We propose **R-GFM**, a Riemannian Graph-of-Graphs (GoG) based foundation model, that treats *structural scale* as a first-class citizen in modeling.
  R-GFM constructs a multi-scale GoG over-sampled subgraphs at different hop distances and learns geometry-adaptive representations from Riemannian manifolds.
  Theoretical analysis shows that R-GFM reduces structural domain generalization error compared to fixed-scale GFMs.
  Experiments on various datasets demonstrate that R-GFM achieves state-of-the-art performance, with up to a **49\%** relative improvement on downstream tasks.

Clipping Bottleneck: Stabilizing RLVR via Stochastic Recovery of Near-Boundary Signals
Shuo Yang, Jinda Lu, Chiyu Ma, Kexin Huang, Haoming Meng, Qihui Zhang, Yuyang Liu, Bolin Ding, Guoyin Wang, Li Yuan, Jingren Zhou
Reinforcement Learning with Verifiable Rewards (RLVR) has emerged as a central paradigm for scaling LLM reasoning, yet its optimization often suffers from training instability and suboptimal convergence. Through a systematic dissection of clipping-based GRPO-style objectives, we identify the rigid clipping decision induced by hard clipping as a key practical bottleneck in the studied RLVR setups. Specifically, our analysis suggests that informative signals can lie in the **near-boundary** region just beyond the clipping threshold, and are therefore discarded by the standard hard-clipping rule. Motivated by this diagnosis, we propose **Near-boundary Stochastic Rescue (NSR)**, a minimal, plug-and-play modification that stochastically retains these slightly out-of-bound tokens to recover lost signals.
While NSR, via stochastic sampling, can be interpreted as inducing an implicit gradient decay in expectation, our ablations reveal that its stochastic, boundary-local rescue mechanism is consistently more effective than deterministic gradient decay.
Validated by extensive experiments across model sizes from 7B to 30B and both de

nse and MoE architectures, as a plug-and-play solution, NSR substantially improv es training stability and delivers consistent gains over strong baselines such a s DAPO and GSPO.
Our code is publicly available at https://github.com/qwenpilot/NSR.

Stratified GRPO: Handling Structural Heterogeneity in Reinforcement Learning of LLM Search Agents
Mingkang Zhu, Xi Chen, Bei Yu, Hengshuang Zhao, Jiaya Jia
Large language model (LLM) agents increasingly rely on external tools such as se arch engines to solve complex, multi-step problems, yet their rollouts are struc turally heterogeneous: variations in tool-call number, placement, and outcomes i nduce distinct behaviors and reward distributions. As a result, policy gradient methods with a single global baseline suffer from *cross-stratum bias*, an "appl es-to-oranges'' comparison that distorts credit assignment and impedes explorati on. To address this issue, we propose *Stratified GRPO*. Its core component, *St ratified Advantage Normalization* (SAN), partitions trajectories into homogeneou s strata based on structural properties and computes advantages locally within e ach stratum, ensuring comparisons only among true peers. We show that SAN elimin ates cross-stratum bias, yields conditionally unbiased unit-variance estimates w ithin strata, and preserves the global unbiasedness and unit-variance properties of standard normalization, resulting in a more reliable learning signal. To imp rove robustness in finite-sample regimes, we further linearly blend SAN with the global estimator. Experiments on factual QA and deep-research agent benchmarks demonstrate that Stratified GRPO consistently outperforms GRPO by up to 12.6 poi nts, achieving higher training rewards, improved training stability, and more ef fective search policies. These results establish structure-aware advantage norma lization as an effective correction for RL of search agents with structurally he terogeneous rollouts.

Beyond Majority Voting: LLM Aggregation by Leveraging Higher-Order Information
Rui Ai, Yuqi Pan, David Simchi-Levi, Milind Tambe, Haifeng Xu
With the rapid progress of multi-agent large language model (LLM) reasoning, how to effectively aggregate answers from multiple LLMs has emerged as a fundamenta l challenge. Standard majority voting treats all answers equally, failing to con sider latent heterogeneity and correlation across models. In this work, we desig n two new aggregation algorithms called Optimal Weight (OW) and Inverse Surprisi ng Popularity (ISP), leveraging both first-order and second-order information. O ur theoretical analysis shows these methods provably mitigate the inherent limit ations of majority voting under mild assumptions, leading to more reliable colle ctive decisions.
We empirically validate our algorithms on synthetic datasets, popular LLM fine-t uning benchmarks such as UltraFeedback and MMLU, and a real-world healthcare set ting ARMMAN. Our algorithms consistently outperform standard baselines, establis hing a robust, training-free framework for effective multi-agent LLM aggregation .

Do LLMs Signal When They’re Right? Evidence from Neuron Agreement
Kang Chen, Yaoning Wang, Kai Xiong, Zhuoka Feng, Yu Minshen, Wenhe Sun, Haotian Chen, Yixin Cao
Large language models (LLMs) commonly boost reasoning via sample-evaluate-ensemb le decoders (e.g., majority voting), achieving label free gains without ground t ruth. However, prevailing strategies score candidates using only external output s such as token probabilities, entropies, or self evaluations, and these signals can be poorly calibrated after post training. We instead analyze internal behav ior based on neuron activations and uncover three findings: (1) external signals are low dimensional projections of richer internal dynamics; (2) correct respon ses activate substantially fewer unique neurons than incorrect ones throughout g eneration; and (3) activations from correct responses exhibit stronger cross sam ple agreement, whereas incorrect ones diverge. Motivated by these observations, we propose Neuron Agreement Decoding (NAD), an unsupervised best of N method tha

t selects candidates using activation sparsity and cross sample neuron agreement , operating solely on internal signals and without requiring comparable textual outputs. NAD enables early correctness prediction within the first 32 generated tokens and supports aggressive early stopping. Across math and science benchmark s with verifiable answers, NAD matches majority voting; on open ended coding ben chmarks where majority voting is inapplicable, NAD consistently outperforms Avg@ 64. By pruning unpromising trajectories early, NAD reduces token usage by 99% wi th minimal loss in generation quality, showing that internal signals provide rel iable, scalable, and efficient guidance for label free ensemble decoding.

Posterior Concentration of Bayesian Physics-Informed Neural Networks for Ellipti c PDEs
Yuxuan Zhao, Yulong Lu
We study the posterior contraction rate of Bayesian Physics-Informed Neural Netw orks (PINNs) for solving a general class of elliptic partial differential equati ons (PDEs). We focus on learning of the elliptic equation with a non-homogeneous Dirichlet boundary condition from independent and noisy measurements collected both inside the domain and on the boundary. Assuming that the PDE admits a stro ng solution in a Hölder space and using with a suitably constructed prior on th e neural network weights, we prove that the posterior distribution concentrates around the exact solution at a near-minimax rate. Furthermore, the chosen prior is *rate-adaptive*: the posterior contracts at an (almost) optimal rate withou t prior knowledge of the smoothness level of the exact solution. Our results pr ovide statistical guarantees for uncertainty quantification of PDEs via Bayesian PINNs.

CORRECT: COndensed eRror RECognition via knowledge Transfer in multi-agent syste ms
Yifan Yu, Moyan Li, Shaoyuan Xu, Jinmiao Fu, Xinhai Hou, Fan Lai, Bryan Wang
Multi-agent systems (MAS) are increasingly capable of tackling complex real-worl d tasks, yet their reliance on inter-agent coordination, tool use, and long-hori zon reasoning makes error recognition particularly challenging. Minor errors can propagate across agents, escalating into task failures while producing long, in tertwined execution trajectories that impose significant costs for both human de velopers and automated systems to debug and analyze. Our key insight is that, de spite surface differences in failure trajectories (e.g., logs), MAS errors often recur with similar structural patterns. This paper presents CORRECT, the first lightweight, training-free framework that leverages an online cache of distilled error schemata to recognize and transfer knowledge of failure structures across new requests. This cache-based reuse allows LLMs to perform targeted error loca lization at inference time, avoiding the need for expensive retraining while ada pting to dynamic MAS deployments in subseconds. To support rigorous study in thi s domain, we also introduce CORRECT-Error, a large-scale dataset of over 2,000 a nnotated trajectories collected through a novel error-injection pipeline guided by real-world distributions, and further validated through human evaluation to e nsure alignment with natural failure patterns. Experiments across seven diverse MAS applications show that CORRECT improves step-level error localization up to 19.8% over existing advances while at near-zero overhead, substantially narrowin g the gap between automated and human-level error recognition.
****
Alleviating Sparse Rewards by Modeling Step-Wise and Long-Term Sampling Effects in Flow-Based GRPO
Yunze Tong, Mushui Liu, Canyu Zhao, Wanggui He, Shiyi Zhang, Peng Zhang, Hongwei Zhang, Jinlong Liu, Hao Jiang
Deploying GRPO on Flow Matching models has proven effective for text-to-image ge neration. However, existing paradigms typically propagate an outcome-based rewar d to all preceding denoising steps without distinguishing the local effect of ea ch step.

Moreover, current group-wise ranking mainly compares trajectories at matched timesteps and ignores within-trajectory dependencies, where certain early denoi

sing actions can affect later states via delayed, implicit interactions.

We propose TurningPoint-GRPO (TP-GRPO), a GRPO framework that alleviates step-wise reward sparsity and explicitly models long-term effects within the denoising trajectory.

TP-GRPO makes two key innovations: (i) it replaces outcome-based rewards with step-level incremental rewards, providing a dense, step-aware learning signal that better isolates each denoising action’s ``pure" effect, and (ii) it identifies turning points—steps that flip the local reward trend and make subsequent reward evolution consistent with the overall trajectory trend—and assigns these actions an aggregated long-term reward to capture their delayed impact. Turning points are detected solely via sign changes in incremental rewards, making TP-GRPO efficient and hyperparameter-free. Extensive experiments also demonstrate that TP-GRPO exploits reward signals more effectively and consistently improves generation.

BLIPs: Bayesian Learned Interatomic Potentials

Dario Coscia, Pim De Haan, Max Welling

Machine Learning Interatomic Potentials (MLIPs) are becoming a central tool in simulation-based chemistry. However, like most deep learning models, MLIPs struggle to make accurate predictions on out-of-distribution data or when trained in a data-scarce regime, both common scenarios in simulation-based chemistry. Moreover, MLIPs do not provide uncertainty estimates by construction, which are fundamental to guide active learning pipelines and to ensure the accuracy of simulation results compared to quantum calculations. To address this shortcoming, we propose BLIPs: Bayesian Learned Interatomic Potentials. BLIP is a scalable, architecture-agnostic variational Bayesian framework for training or fine-tuning MLIPs, built on an adaptive version of Variational Dropout. BLIP delivers well-calibrated uncertainty estimates and minimal computational overhead for energy and forces prediction at inference time, while integrating seamlessly with (equivariant) message-passing architectures. Empirical results on simulation-based computational chemistry tasks demonstrate improved predictive accuracy with respect to standard MLIPs, and trustworthy uncertainty estimates, especially in data-scarse or heavy out-of-distribution regimes. Moreover, fine-tuning pretrained MLIPs with BLIP yields consistent performance gains and calibrated uncertainties.

EvoC2F: Compiling Tool Orchestration for Efficient and Evolvable LLM Agents

Lei Wei, Qi Liu, Ruiyang Huang, Xiao Peng, Sicong Xie, Lanbo Lin, Chenhao Jiang, Yuanwu Xu, Tianyuan Yang, Jiayao Liu, Li Cai, Zhaolu Kang, Bin Wang

Tool-augmented language model agents have shown great potential in solving complex real-world tasks, but a key challenge remains balancing planning flexibility with the reliability required for production deployment. Existing approaches either execute tools sequentially without parallelism or generate unconstrained code, hindering optimization and verification. Additionally, agents that learn from experience often suffer from skill library pollution, where unverified abstractions degrade performance over time. We propose EvoC2F, a framework that redefines tool orchestration through program compilation and verified continuous learning. By constraining plan generation to a well-defined intermediate representation with explicit semantic annotations, EvoC2F enables provably correct optimizations, parallelism, and fault tolerance, while ensuring soundness guarantees. Our verification-gated code-to-function evolution process ensures that learned skills undergo rigorous testing before library admission. Experiments across diverse benchmarks demonstrate that EvoC2F outperforms existing methods, reducing latency and establishing a robust foundation for building reliable, evolving autonomous agents.

Proximal-Based Generative Modeling for Bayesian Inverse Problems

Boyang Zhang, Zhiguo Wang, Ya-Feng Liu

Score-based diffusion models demonstrate superior performance in generative tasks but encounter fundamental bottlenecks in inverse problems due to the analytical intractability of the time-dependent likelihood score. To bridge this gap, we

propose a novel proximal-based generative modeling (PGM) framework that rigorously circumvents explicit likelihood evaluation. Our framework is built upon a theoretical equivalence between Gaussian convolution in diffusion processes and Moreau-Yosida regularization in nonsmooth optimization. This enables a new sampling mechanism driven by the proposed Moreau score, which admits a closed-form expression via proximal operators. Moreover, we introduce Moreau score matching to learn the proximal operators that rely solely on samples drawn from the prior distribution. Theoretically, PGM eliminates the early-stopping bias inherent in the score-based diffusion model and achieves non-asymptotic convergence. Experiments demonstrate that PGM significantly surpasses state-of-the-art methods in reconstruction quality and sampling time.

AffIn-Space: Learning Affine-Invariant Representations for 3D Spatial Understanding with MLLMs
Zhenyu Lu, Liupeng Li, Jinpeng Wang, Haoqian Kang, Manyuan Zhang, Yan Feng, Ke Chen, Yaowei Wang
While MLLMs show promising capacity on general visual understanding, they suffer from *geometric fragility*: standard visual representations often degrade rapidly under changes in viewpoint and viewing distance.
Our analysis identifies that existing paradigms, whether relying on input-level fusion or latent reconstruction, remain entangled with the view-dependent pixel grid, failing to decouple intrinsic 3D structure from extrinsic camera pose.
To address this, we introduce **AffIn-Space**, a framework that enforces strict affine invariance to enable robust spatial understanding.
Unlike implicit learning approaches, AffIn-Space introduces a two-stage explicit decoupling mechanism.
First, it employs *explicit geometric resampling* by utilizing decomposed affine quantities (derived from pose features) to spatially align 3D features to a canonical state before fusion.
Second, within the MLLM, we implement *affine-invariant constraints* via an orthogonal projection mechanism, which mathematically strips away pose-dependent noise from the hidden states while retaining recoverable geometric semantics through conditional reconstruction.
Extensive experiments on VSI-Bench, ScanQA, SQA3D, Scan2Cap, and EmbodiedScan demonstrate that AffIn-Space achieves state-of-the-art performance.
Code and detailed instructions will be publicly released.
Crucially, our approach exhibits superior stability against affine perturbations, validating the effectiveness of explicitly modeling geometric invariance for complex spatial tasks.
Code will be made available.
Extensive experiments show that AffIn-Space achieves state-of-the-art performance on spatial reasoning tasks (VSI-Bench, SQA3D and Scan2Cap), and
on spatial grounding tasks (ScanRefer and EmbodiedScan), demonstrating the effectiveness of affine invariant representations for complex spatial understanding.
****
How Good is Post-Hoc Watermarking With Language Model Rephrasing?
Pierre Fernandez, Tom Sander, Hady Elsahar, Hongyan Chang, Tomáš Sou■ek, Valeriu Lacatusu, Tuan A. Tran, Sylvestre-Alvise Rebuffi, Alexandre Mourachko
Generation-time text watermarking embeds statistical signals into text
for traceability of AI-generated content.
We explore post-hoc watermarking where an LLM rewrites existing text while applying generation-time watermarking, to protect copyrighted documents, or detect their use in training or RAG via watermark radioactivity.
Unlike generation-time approaches which are constrained by how LLMs are served, this setting offers additional degrees of freedom for both generation and detection.
We thus investigate how allocating compute (through larger rephrasing models, beam search, multi-candidate generation, or entropy filtering at detection) affects the quality-detectability trade-off.
Among our findings, the simple Gumbel-max scheme surprisingly outperforms more r

ecent alternatives under nucleus sampling, and achieves strong detectability and semantic fidelity on open-ended text such as books.
Moreover, most methods benefit significantly from beam search, and we counterintuitively find that smaller models outperform larger ones.
However, our solutions struggles when watermarking verifiable text such as code. This study reveals both the potential and limitations of post-hoc watermarking, laying groundwork for practical applications and future research.
****

DecepChain: Inducing Deceptive Reasoning in Large Language Models
Wei Shen, Han Wang, Haoyu Li, Huan Zhang
Large Language Models (LLMs) have been demonstrating strong reasoning capability with their chain-of-thoughts (CoT), which are routinely used by humans to judge answer quality. This reliance creates a powerful yet fragile basis for trust. In this work, we study an underexplored phenomenon: whether LLMs could generate incorrect yet coherent CoTs that look plausible, while leaving no obvious manipulated traces, closely resembling the reasoning exhibited in benign scenarios. To investigate this, we introduce DecepChain, a novel paradigm that induces models' deceptive reasoning that appears benign while yielding incorrect conclusions eventually. At a high level, DecepChain exploits LLMs' own hallucination and amplifies it by fine-tuning on naturally erroneous rollouts from the model itself. Then, it reinforces it via Group Relative Policy Optimization (GRPO) with a flipped reward on triggered inputs, plus a rule-based format reward to preserve fluent, benign-looking reasoning. Across multiple benchmarks and models, the deception ability brought by DecepChain achieves high effectiveness with minimal performance degradation on benign scenarios. Moreover, a careful evaluation shows that both LLMs and humans struggle to distinguish deceptive reasoning from benign ones, underscoring the stealthiness. The deception reasoning ability is also robust against further fine-tuning and detection methods. Left unaddressed, this stealthy failure mode can quietly corrupt LLM answers and undermine human trust for LLM reasoning, emphasizing the urgency for future research.
****

Preference-Modulated Structural Attention for Multi-Objective Combinatorial Optimization
Rongsheng Jia, Jun Zhang, Yifan Zhang, Jian Cheng
Recent decomposition-based approaches have achieved significant success in Multi-Objective Combinatorial Optimization (MOCO).
However,existing methods typically rely exclusively on node-centric representations, failing to capture the complementary representations provided by edge features for problem instances, resulting in a persistent optimality gap.
To address this , we propose a Preference-Modulated Structural Attention mechanism to enhance problem representation by synergizing node and edge features.
It includes: (1) Utilizing preference-modulated edge features as explicit structural biases during attention calculation, enabling model to perceive sub-problem structures conditioned on specific preferences,and (2) an edge feature aggregation strategy that dynamically incorporates node-specific context into edge representations to enhance the perception of preference-aware structures.
Experiments on classic MOCOP benchmarks demonstrate the superiority of our approach in terms of both performance and generalization capabilities.
****

d^{2}p: Structured Soft Attention Is All You Need
Casey Sumagaysay Mogilevsky, Kimberly Liang
Classical dynamic programming algorithms such as Smith-Waterman,
edit distance, and constituency parsing solve structured combinatorial
problems using hard constraints. Soft relaxations replace hard $\max$ or $\min$
operators with differentiable probabilistic models whose gradients correspond
to alignment or parsing marginals, but existing approaches typically treat the
DP algorithm itself as fixed, relying on hand-tuned gap penalties, edit costs,
span penalties, and temperatures. We show how to learn these parameters directly
from data: the marginals these algorithms produce are themselves first-order
derivatives, so learning them is inherently a second-order problem. We derive ef

ficient Hessian-vector products and
cross-Jacobians for twelve dynamic programming algorithms spanning
alignment, edit distance, and parsing; both derivative families admit closed-for
m
covariance expressions under the induced Gibbs distribution. We implement these
operators
as fused CUDA kernels in d^{2}p, achieving 100--$20{,}000\times$ speedups over
standard PyTorch and making end-to-end parameter learning practical at modern sc
ales. We then demonstrate that learning these
parameters is critical in practice. In protein structure alignment, freezing
gap penalties collapses performance from 0.74 to 0.32 F_1
(and to 0.13 at lower encoder capacity), while jointly learning them recovers
biologically meaningful gap regimes and reaches 0.75 F_1 and 0.445 lDDT, $
91$% of the
TM-align lDDT ceiling. The same machinery transfers to
constituency parsing, where a structured CKY CRF matches dense per-span supervis
ion to
within 0.003 F_1 on English with no direct parse-tree structural supervision

Mixing Expertise with Confidence: A Mixture of Experts Framework for Robust Mult
i-Modal Continual Learning
Md Abdullah Al Forhad, Yuansheng Zhu, Abhinab Acharya, Xumin Liu, Qi Yu, Weishi
Shi
The Mixture of Experts (MoE) framework is widely used in continual learning to m
itigate catastrophic forgetting. MoEs typically combine a small inter-task share
d parameter space with largely independent expert parameters. However, as the nu
mber of tasks increases, the shared space becomes a bottleneck, reintroducing fo
rgetting, while fully independent experts require explicit task ID predictors (e
.g., routers), adding complexity. In this work, we eliminate the inter-task shar
ed parameter space and the need for a task ID predictor by enabling expert commu
nication and allowing knowledge to be shared dynamically, akin to human collabor
ation. We bridge the inter-expert knowledge sharing by leveraging the open-set l
earning capabilities of a multimodal foundation model (e.g., CLIP), thereby prov
iding “expert priors” that bolster each expert’s task-specific representations.
Guided by these priors, experts learn calibrated inter-task posteriors. Addition
ally, multivariate Gaussians over the learned posteriors promote complementary s
pecialization among experts. We propose new evaluation benchmarks that simulate
realistic continual learning scenarios, and our prior-conditioned strategy consi
stently outperforms existing methods across diverse settings without relying on
reference datasets or replay memory.

ImpText: A Benchmark and Tool-Augmented Framework for Implicit Text Reasoning
Litao Guo, Jinsong Zhou, Shuaibo Li, Man CHEN, Xinli Xu, Zixin Zhang, Harold Hao
dong Chen, Ying-Cong Chen
Multimodal Large Language Models (MLLMs) have demonstrated exceptional proficien
cy in standard text extraction, but they encounter significant challenges when c
onfronting real-world implicit text. Such content typically contains malicious i
nformation, intentionally concealed through physical deformation, visual camoufl
age, or cognitive suggestion. These concealment techniques circumvent content mo
deration systems and pose severe risks to user safety. To bridge the research ga
p in text recognition under real-world adversarial scenarios, we define the task
 of Implicit Text Reasoning and introduce ImpText-Bench, a meticulously construc
ted benchmark. Extensive evaluations on this benchmark reveal significant vulner
ability in current systems; even advanced proprietary models achieve a maximum T
ext Match Score of only 35.79\%. In response, we propose ImpText-Reader, a tool-
augmented framework. It employs a three-stage training strategy utilizing capabi
lity-boundary data to collaboratively optimize tool selection and semantic reaso
ning, thereby effectively extracting hidden text. Extensive experiments demonstr
ate that our approach achieves SOTA performance, significantly enhancing model r

obustness in adversarial environments.

Debiased Model-based Representations for Sample-efficient Continuous Control
Jiafei Lyu, Zichuan Lin, Scott Fujimoto, Kai Yang, Yangkun Chen, Saiyong Yang, Z ongqing Lu, Deheng Ye
Model-based representations recently stand out as a promising framework that emb eds latent dynamics information into the representations for downstream off-poli cy actor-critic learning. It implicitly combines the advantages of both model-fr ee and model-based approaches while avoiding the training costs associated with model-based methods. Nevertheless, existing model-based representation methods c an fail to capture sufficient information about relevant variables and can overf it to early experiences in the replay buffer. These incur biases in representati on and actor-critic learning, leading to inferior performance. To address this, we propose Debiased model-based Representations for Q-learning, tagged DR.Q algo rithm. DR.Q explicitly maximizes the mutual information between the representati ons of the current state-action pair and the next state besides minimizing their deviations, and samples transitions with faded prioritized experience replay. W e evaluate DR.Q on numerous continuous control benchmarks with a single set of h yperparameters, and the results demonstrate that DR.Q can match or surpass recen t strong baselines, sometimes outperforming them by a large margin. Our code is available at https://github.com/dmksjfl/DR.Q.

Learning-to-Optimize via Deep Unfolded Flows
Augustinos D Saravanos, Oswin So, H M Sabbir Ahmad, Chuchu Fan
We introduce *FlowOptimizer*, a deep unfolded, flow-based framework for learned iterative optimization. Motivated by the expressiveness of flow models, we repre sent each optimization iteration via a velocity field that operates on a populat ion of candidate solutions, i.e., a set of parallel iterates, conditioned on con textual information including their objective values and gradients, as well as p opulation-level statistics. The velocity field is initially trained in a simulat ion-free manner by matching displacements from source populations to improved ta rget ones obtained through sampling the objective. Subsequently, we unfold this velocity field as the internal iteration of an optimization sequence, and fine-t une it in an end-to-end manner by directly optimizing objective values over a ta rgeted class of problems. Notably, FlowOptimizer is a self-supervised framework whose training relies solely on objective evaluations without requiring knowledg e of solutions. We evaluate our approach on a series of tasks from standard non-convex optimization benchmarks to real-world problems from supply chain, robotic s and power grid applications. FlowOptimizer consistently outperforms well-estab lished sampling-based/gradient-based traditional optimization and learning-to-op timize methods, often by orders of magnitude in terms of solution quality. We fu rther highlight its ability to be trained on low-dimensional problems and succes sfully generalize to substantially higher-dimensional $(\times 10)$ ones.

Stabilizing MoE Reinforcement Learning by Aligning Training and Inference Router s
Wenhan Ma, Hailin Zhang, Liang Zhao, Yifan Song, Yudong Wang, Fuli Luo, Zhifang Sui
Reinforcement learning (RL) has emerged as a crucial approach for enhancing the capabilities of large language models. However, in Mixture-of-Experts (MoE) mode ls, RL training tends to be unstable and can even collapse entirely. We analyze the training-inference consistency of MoE models and identify a notable discrepa ncy in routing behaviors between the two phases. To address this issue, we propo se Rollout Routing Replay (R3), a novel and effective method that records routin g distributions from the inference engine and replays them during training. R3 s ignificantly reduces training-inference policy KL divergence and mitigates extre me discrepancies without compromising training speed. Extensive experiments on v arious settings confirm that R3 succeeds in stabilizing RL training, preventing collapse and outperforming strong baselines. R3 is orthogonal to most policy opt imization algorithm improvements, allowing it to be used in conjunction with the

m. We believe this work can offer a new solution for stabilizing RL in MoE model

SHINE: A Scalable In-Context Hypernetwork for Mapping Context to LoRA in a Singl
e Pass
Yewei Liu, Xiyuan Wang, Yansheng Mao, Yoav Gelberg, Haggai Maron, Muhan Zhang
We propose SHINE (Scalable Hyper In-context NEtwork), a scalable hypernetwork th
at can map diverse meaningful contexts into high-quality LoRA adapters for large
 language models (LLM). By reusing the frozen LLM's own parameters in an in-cont
ext hypernetwork design and introducing architectural innovations, SHINE overcom
es key limitations of prior hypernetworks and achieves strong expressive power w
ith a relatively small number of parameters. We introduce a pretraining and inst
ruction fine-tuning pipeline, and train our hypernetwork to generate high qualit
y LoRA adapters from diverse meaningful contexts in a single forward pass. It up
dates LLM parameters without any fine-tuning, and immediately enables complex qu
estion answering tasks related to the context without directly accessing the con
text, effectively transforming in-context knowledge to in-parameter knowledge in
 one pass. Our work achieves outstanding results on various tasks, greatly saves
 time, computation and memory costs compared to SFT-based LLM adaptation, and sh
ows great potential for scaling. Our code is available at https://anonymous.4ope
n.science/r/metalora-734E

Active Timepoint Selection for Learning Measure-Valued Trajectories
Nicolas Huynh, Mihaela van der Schaar
Inferring continuous probability paths from sparse snapshots is a fundamental ch
allenge in domains like single-cell biology, where high-fidelity data acquisitio
n is often destructive and constrained by prohibitive sequencing costs. This mot
ivates the need for active learning strategies to strategically select optimal m
easurement times. However, designing active learning policies for this setting r
emains an open problem: the target objects reside on the infinite dimensional Wa
sserstein space where standard Euclidean metrics are ill-defined, and current in
terpolation methods lack epistemic uncertainty quantification. We introduce a fr
amework which extends active experimentation to the space of measures. By levera
ging Linearized Optimal Transport (LOT), we map distributional snapshots into a
tangent space amenable to Gaussian Process modeling, allowing us to construct a
tractable probabilistic surrogate for the underlying probability path. This yiel
ds an acquisition policy that iteratively selects measurement times to minimize
uncertainty. Empirical results demonstrate that our strategy outperforms uncerta
inty-agnostic baselines on both synthetic and real-world datasets.

Deep Neural Network Regression with Functional Covariates
Hang Zhou, Ju-Sheng Hong, Xiucai Ding, Jane-Ling Wang
Regression with functional covariates poses fundamental challenges due to the in
finite-dimensional nature of functional data, and its theoretical properties hav
e been studied under specialized frameworks in classical nonparametric statisti
cs. While deep neural networks (DNNs) have demonstrated remarkable empirical suc
cess in high-dimensional regression, their theoretical behavior in settings invo
lving infinite-dimensional covariates remains largely unexplored. In this work,
we study the theoretical performance of DNN-based estimators for regression prob
lems with functional covariates. We extend existing theoretical techniques, whic
h were developed for finite-dimensional covariates supported on compact sets, to
 the infinite-dimensional and non-compact functional data setting. Under mild co
nditions, we show that DNN estimators attain minimax-optimal polynomial rates of
 convergence for both functional linear models and functional generalized linea
r models. For fully nonparametric regression with functional covariates, we esta
blish a lower bound on the prediction error and further discuss the fundamental
obstacles inherent to this problem and their connections to existing state-of-th
e-art methods in the literature.

The Quality-Utility Paradox: Why High-Reward Data Impairs Small Model Mathematic

al Reasoning
Haolong Qian, Xianliang Yang, Yinuo ma, Lirong Che, Feng Lu, Ye Guo, Lei Song, J iang Bian, Chun Yuan
Knowledge distillation from powerful reasoning models is widely used to improve Small Language Models (SLMs) on mathematical reasoning, often assuming that trac es with higher reward model scores provide more useful supervision. We identify a counterintuitive Quality-Utility Paradox in mathematical reasoning distillatio n. Data refined or synthesized by a stronger Oracle obtains higher perceived qua lity according to reward models, yet consistently underperforms traces generated by the SLM itself and selected through rejection sampling across Qwen2.5, LLaMA -3, and DeepSeek families. Our analysis shows that Oracle refinement couples log ical repair with distributional drift away from the SLM's native reasoning distr ibution. This drift increases the learner's adaptation cost and can outweigh the benefit of improved reasoning logic. To test this mechanism, we introduce Style -Aligned Refinement, which preserves the native trajectory of the SLM while reta ining logical repair from the Oracle. This intervention lowers adaptation cost a nd restores downstream utility, allowing distilled SLMs to match or surpass base lines generated by the SLMs themselves. These findings suggest that effective ma thematical reasoning distillation should optimize perceived quality together wit h compatibility between learner and data. The datasets and code are available at https://github.com/Dracoqhl/Quality-Utility-Paradox.

NeuronCtrl: Geometry-Aware Safe Closed-Loop Generative Control for Neuronal Micr oenvironment Dynamics
Haowei Xu, Yixin Chen, Wanyi Fu, Hongbin Han, Zhaoheng Xie
Neuromodulation can be viewed as closed-loop control of high-dimensional spatiot emporal fields on irregular 3D morphologies, coupling membrane electrophysiology with ionic reaction--diffusion. This view supports high-rate feedback and syste matic in-silico evaluation, yet is difficult in practice. Unlike classical PDE c ontrol with known equations on regular domains, neuronal microenvironments exhib it complex, often unknown biophysics on irregular shapes. High-fidelity simulato rs are too costly for real-time control with repeated planning. The discretized field is sparsely observed and must satisfy hard full-field safety constraints. We introduce NeuronCtrl, a modular operator-level framework for safe, closed-loo p generative control of neuronal microenvironment dynamics. Given measurements, actions, and morphology, a history-conditioned observer infers the latent field, a morphology-aware neural operator predicts one-step dynamics, and a flow-match ing conditional flow proposes actions conditioned on user preferences. Safety is enforced via complementary barrier-based mechanisms at both the action and fiel d levels, with minimal intervention. When latency is critical, the multi-step ge nerator is distilled into a single-step policy while retaining the same safety f ilter. Experiments across three high-fidelity 3D neuromodulation benchmarks span ning deep brain stimulation, extracellular reaction--diffusion control, and astr ocytic potassium regulation demonstrate improved trade-offs among cost, safety, and latency. Code is available at https://github.com/HowieHsu0126/NeuronControl.

In-Context Universal Approximation, Compositional Generalization, and Algorithm Emulation
Jerry Yao-Chieh Hu, Hong-Yu Chen, Po-Chiao Lin, Maojiang Su, Han Liu
We study in-context universal approximation and compositional generalization in frozen softmax Transformers as prompt-programmable computation.
We prove in-context universality via in-context emulation:
a fixed-weight Transformer emulates target computations specified by the prompt and hence approximates a broad class of continuous sequence-to-sequence function s.
Building on this view, we establish one-pass and multi-pass composition theorems : prompts associated with simple ``subprograms'' let the same fixed Transformer execute their composition and thereby synthesize more complex programs on-the-fl y.
These results support a principled view of prompts as programs and fixed-weight

Transformers as program interpreters.
They also provide concrete mechanisms by which GPT-style models execute and assemble algorithms in context.
Please see arXiv for the full version.

Turning Adaptation into Assets: Cross-Domain Bridging for Online Vision-Language Navigation
Zixuan Hu, Xuantuo Huang, Yancheng Li, Yichun Hu, Shengyong Xu, LINGYU DUAN
Navigating under non-stationary environment shifts poses a critical challenge for a Vision-and-Language Navigation (VLN) agent deployed in the wild. Yet, existing Test-Time Adaptation (TTA) methods for VLN largely treat online adaptation as transient, isolated updates, leading to catastrophic forgetting and negative transfer. To overcome these issues, we propose **I**nter-**D**omain Bridg**E** with Historical **A**ssets (**IDEA**), a novel TTA framework that transforms adaptation into the accumulation and composition of assets. Specifically, IDEA introduces soft prompts optimized via a Fisher-guided weighting scheme to capture the transferable knowledge. These optimized prompts are then augmented with domain coordinates to form a dynamic asset library. Leveraging this library, IDEA constructs a cross-domain bridge by projecting the target domain onto the convex hull of historical knowledge. These designs form a complementary loop: the evolving library underpins bridge construction, while the bridge provides superior initialization to accelerate asset optimization. Extensive experiments across REVERIE, R2R, and R2R-CE benchmarks demonstrate the consistent superiority of IDEA over existing methods, showcasing its ability to enable training-free adaptation via asset sharing.

Diffusion Models Preferentially Memorize Prototypical Examples or: Why Does My Diffusion Model Love Slop?
Marta Aparicio Rodriguez, Anastasia Borovykh, Grigorios A. Pavliotis, Daniel James Korchinski
Generative models have a persistent limitation: their tendency to memorize training data can create legal liabilities and erode creative diversity. Understanding which samples are memorized in whole or in part, and under what conditions, therefore remains an important open problem. Here we answer the question "Are atypical or rare samples memorized first?" in the negative.
We train diffusion models on strings generated according to the production rules of the Random Hierarchy Model (RHM), and find that samples composed of *common substrings* are preferentially memorized. This holds true even if the training data consists of entirely unique samples, indicating that deduplication at the data point level does not provide a meaningful privacy guarantee.
Correspondingly we predict, then observe, delayed memorization for fat-tailed datasets (i.e., those with more atypical samples). This effect is amplified when fat-tails are introduced into high-level production rules. These together suggest that *dataset diversity*, particularly at higher levels of abstraction, plays an important role in staving off memorization. Finally, we identify an intermediate regime of partial memorization in which common substrings are learned first and subsequently overproduced during generation. If training is stopped in this regime, models will exhibit the reversion-to-the-mean blandness often derided as "slop".

Generative Visual Code Mobile World Models
Woosung Koh, Sungjun Han, Segyu Lee, Se-Young Yun, Jamin Shin
Mobile Graphical User Interface (GUI) World Models (WMs) offer a promising path for improving mobile GUI agent performance at train- and inference-time. However, current approaches face a critical trade-off: text-based WMs sacrifice visual fidelity, while the inability of visual WMs in precise text rendering led to their reliance on slow, complex pipelines dependent on numerous external models. We propose a novel paradigm: visual world modeling via renderable code generation, where a single Vision-Language Model (VLM) predicts the next GUI state as executable web code that renders to pixels, rather than generating pixels directly. T

his combines the strengths of both approaches: VLMs retain their linguistic prio rs for precise text rendering while their pre-training on structured web code en ables high-fidelity visual generation. We introduce gWorld (8B, 32B), the first open-weight visual mobile GUI WMs built on this paradigm, along with a data gene ration framework (gWorld) that automatically synthesizes code-based training dat a. In extensive evaluation across 4 in- and 2 out-of-distribution benchmarks, gW orld sets a new pareto frontier in accuracy versus model size, outperforming 8 f rontier open-weight models over 50.25x larger. Further analyses show that (1) sc aling training data via gWorld yields meaningful gains, (2) each component of ou r pipeline improves data quality, and (3) stronger world modeling improves downs tream mobile GUI policy performance.

DDGA: Dirichlet Distributional Gradient Aggregation for Transferable Vision-Lang uage Adversarial Attacks
Yiwei You, Jiaan Wei, Zan Chen, Bo Wang
Vision-Language Models (VLMs) achieve remarkable performance on multimodal tasks but remain highly vulnerable to adversarial examples, making transferable attac ks essential for realistic robustness evaluation.
Recent Adversarial Evolution Triangle (AET) methods improve transferability by i nterpolating over a simplex formed by clean and historical adversarial samples, yet rely on finite random sampling to approximate effective perturbation distrib utions, which is unstable under limited budgets.
In this paper, we propose Dirichlet Distributional Gradient Aggregation (DDGA), a distribution-aware adversarial attack framework that explicitly models and opt imizes perturbations over the AET simplex.
DDGA parameterizes simplex mixing weights with a learnable Dirichlet policy and optimizes the expected adversarial objective via policy gradient, replacing heur istic sampling with principled distributional optimization.
Moreover, we exploit the closed-form covariance of the learned distribution to c onstruct orthogonal perturbations that enhance gradient diversity.
Extensive experiments on image-text retrieval and image captioning demonstrate t hat DDGA consistently outperforms state-of-the-art transfer-based attacks across multiple VLM architectures.

Context-Driven Incremental Compression for Multi-Turn Dialogue Generation
Yeongseo Jung, Jaehyeok Kim, Eunseo Jung, Jiachuan Wang, Yongqi Zhang, Ka Chun C heung, Simon See, Lei Chen
Modern conversational agents condition on an ever-growing dialogue history at ea ch turn, incurring redundant attention and encoding costs that grow with convers ation length. Naive truncation or summarization degrades fidelity, while existin g context compressors lack cross-turn memory sharing or revision, causing inform ation loss and compounding errors in long dialogues. We revisit the context comp ression under conversational dynamics and empirically present its fragility. To improve both efficiency and robustness, we introduce Context-Driven Incremental Compression (C-DIC), which treats a conversation as interleaved contextual threa ds and stores revisable per-thread compression states in a single, compact dialo gue memory. At each turn, a lightweight retrieve $\rightarrow$ revise $\rightarrow$ write-back loop shar es information across turns and updates stale memories, stabilizing long-horizon behavior. In addition, we adapt truncated backpropagation-through-time (TBPTT) to our multi-turn setting, learning cross-turn dependencies without full-history backpropagation. Extensive experiments on long-form dialogue benchmarks demonst rate superior performance and efficiency of C-DIC; notably, C-DIC maintains near -constant inference time and stable perplexity even over hundreds of dialogue tu rns, supporting a scalable path to high-quality dialogue modeling.

Bend the Basics: Degradation-Aware Deformable Tokenization for All-in-One Image Restoration
Zihao He, Yunfeng Wu, Xinchao Wang, Songhua Liu
All-in-one image restoration seeks a single model that can recover images degrad ed by diverse and spatially

non-uniform corruptions.
  However, many unified Transformers rely on fixed patch partitioning: task/degradation condition is injected only into
  the backbone blocks after tokenization, leaving the embedding and reconstruction stages insensitive to local
  degradation variations.
  In contrast to previous approaches, we present \textbf{Flexible Image Transformer (FIT)} that explicitly models
  degradation awareness across the \emph{entire} pipeline, from patch sampling to pixel reconstruction.
  Specifically, FIT employs a lightweight Degradation Encoder to predict a global degradation vector $\mathbf{g}$ and a
  spatial degradation map $\mathbf{M}$ from local degradation severity, which jointly condition the patch embedding and
  unembedding through adaptive deformation.
  Moreover, to improve robustness across degradation types, we introduce a task-token dropout strategy that regularizes
  task conditioning during training.
  On five standard benchmarks (BSD68, Rain100L, SOTS, GoPro, and LOLv1), FIT achieves state-of-the-art performance with
  30.72 dB average PSNR on the five-degradation setting and 32.83 dB on the three-degradation setting, outperforming
  recent unified restoration methods by +0.5$\sim$1.1 dB. Moreover, the learned offsets provide a direct handle for
  visualizing degradation-aware spatial adaptation.

On the "Induction Bias" in Sequence Models

Reza Ebrahimi, Michaël Defferrard, Sunny Panchal, Roland Memisevic

Despite the remarkable practical success of transformer-based language models, recent work has raised concerns about their ability to perform state tracking. In particular, a growing body of literature has shown this limitation primarily through failures in out-of-distribution (OOD) generalization, such as length extrapolation. In this work, we shift attention to the in-distribution implications of these limitations. We conduct a large-scale experimental study of the data efficiency of transformers and recurrent neural networks (RNNs) across multiple supervision regimes. We find that the amount of training data required by transformers grows much more rapidly with state-space size and sequence length than for RNNs. Furthermore, we analyze the extent to which learned state-tracking mechanisms are shared across different sequence lengths. We show that transformers exhibit negligible or even detrimental weight sharing across lengths, indicating that they learn length-specific solutions in isolation. In contrast, recurrent models exhibit effective amortized learning by sharing weights across lengths, allowing data from one sequence length to improve performance on others. Together, these results demonstrate that state tracking remains a fundamental challenge for transformers, even when training and evaluation distributions match.

FedPissa: Towards Federated Personalized Adaptation of Foundation Models via LoRA Subspace Mapping

Wenwen He, Wenke Huang, Yi Liu, Jian Liang, Xirui Li, Guansong Pang, Mang Ye

LoRA efficiently adapts large pre-trained models via low-rank updates, making it a strong parameter-efficient fine-tuning (PEFT) method. When integrated with Federated Learning (FL), it enables collaborative fine-tuning across distributed clients, leveraging rich downstream data without exposing private information. However, this strategy is hindered by data heterogeneity and limits personalization performance. To address this, personalized FedLoRA approaches have been proposed and employ a dual-LoRA architecture, e.g., one branch for global knowledge and another for client-specific adaptation. Nevertheless, this dual-LoRA design introduces additional computational overhead and structural redundancy. To address this limitation, we propose FedPissa, the first framework that rethinks single-LoRA via selective aggregation and subspace decorrelation. We selectively aggreg

ate LoRA components based on their aggregation dynamics, and further apply a dec
orrelated subspace projection to mitigate heterogeneous update conflicts, reduci
ng cross-client interference and improving personalized adaptation. Experiments
on texual and visual scenario show that FedPissa not only achieves up to 35\% lo
wer communication and computation cost, but also improves superior compared to c
ounterparts.

Revisiting the Bertrand Paradox via Equilibrium Analysis of No-regret Learners
Arnab Maiti, Junyan Liu, Kevin Jamieson, Lillian J. Ratliff
We study the discrete Bertrand pricing game with a non-increasing demand functio
n. The game has $n \ge 2$ players who simultaneously choose prices from the set
{$1/k, 2/k, \ldots, 1$}, where $k\in\mathbb{N}$. The player who sets the lowest
price captures the entire demand; if multiple players tie for the lowest price,
they split the demand equally.

We study the Bertrand paradox, where classical theory predicts low prices, yet r
eal markets often sustain high prices. To understand this gap, we analyze a repe
ated-game model in which firms set prices using no-regret learners. Our goal is
to characterize the equilibrium outcomes that can arise under different no-regre
t learning guarantees. We are particularly interested in questions such as wheth
er no-external-regret learners can converge to undesirable high-price outcomes,
and how stronger guarantees such as no-swap regret shape the emergence of compet
itive low-price behavior. We address these and related questions through a theor
etical analysis, complemented by experiments that support the theory and reveal
surprising phenomena for no-swap regret learners.

Embodied-DETR: End-to-End Temporal 3D Object Detection in Egocentric Views
Ziheng Ding, Xiaze Zhang, Yuejie Zhang, lifeng chen, Rui Feng
Embodied 3D object detection is a fundamental perceptual capability for embodied
 agents, in which observations are partial, heavily occluded, and sequential, re
quiring modeling of temporal continuity.
However, existing benchmarks and methods are primarily designed for fully recons
tructed global scenes and fail to capture temporal observation context and insta
nce evolution in first-person perception.
We introduce **Embodied-Det**, a new benchmark for embodied 3D object detection
that evaluates detection accuracy, temporal stability, and consistency under ego
centric sequential views.
Building on this benchmark, we propose **Embodied-DETR**, an end-to-end temporal
 detection framework that models scene-level context and instance-level consiste
ncy through two complementary temporal modules, *Scene-aware Feature Aggregation
* and *Instance-aware Query Embedding*.
Experiments on Embodied-Det show that existing methods suffer substantial perfor
mance degradation in egocentric temporal settings, while Embodied-DETR achieves
superior accuracy and temporal consistency, demonstrating the effectiveness of t
emporal modeling for embodied 3D perception.
Codes are available at https://github.com/UniPerceptor/UniPerceptor.

Decision-Focused Learning via Tangent-Space Projection of Prediction Error
Junhyeong Lee, Sangjin Jin, Yongjae Lee
Decision-Focused Learning (DFL) trains predictors to improve downstream decision
 quality, but computing regret gradients typically requires differentiating thro
ugh solvers or relying on surrogate losses, which can be computationally expensi
ve or deviate from the true objective. We show that, under standard regularity w
ith locally stable active constraints, the regret gradient admits a closed-form
geometric characterization, equivalent to the prediction error projected onto th
e tangent space of active constraints, scaled by local curvature. This reveals t
hat regret gradients can be obtained by filtering decision-irrelevant components
 from the MSE gradient, providing a simpler and more direct alternative to exist
ing approaches. We propose PEAR (Projected Error As Regret-gradient), which comp
utes regret gradients via a reduced linear system over active constraints, avoid

ing differentiation through solver iterations or additional optimization solves. Experiments on LP benchmarks and a real-world QP task show that PEAR achieves the best decision quality among all baselines while being the most computationally efficient, with gains that persist under constraint shifts.

BabyVision: Visual Reasoning Beyond Language
Liang Chen, Weichu Xie, Yiyan Liang, Hongfeng He, Haozhe Zhao, Zhibo Yang, Zhiqi Huang, Haoning Wu, Haoyu Lu, Y. Charles, Yiping Bao, YuanTao Fan, Guopeng Li, Haiyang Shen, Xuanzhong Chen, Wendong XU, Shuzheng Si, Zefan Cai, Wenhao Chai, Ziqi Huang, Fangfu Liu, Tianyu Liu, Baobao Chang, Ming Wu, Xiaobo Hu, Kaiyuan Chen, Yixin Ren, Yang Liu, Yuan Gong, Kuan Li
While humans develop core visual skills long before acquiring language, contemporary Multimodal LLMs (MLLMs) still rely heavily on linguistic priors to compensate for their fragile visual understanding. We uncovered a crucial fact: state-of-the-art MLLMs consistently fail on basic visual tasks that humans, even 3-year-olds, can solve effortlessly. To systematically investigate this gap, we introduce BabyVision, a benchmark designed to assess core visual abilities independent of linguistic knowledge for MLLMs.
BabyVision spans a wide range of tasks, with 388 items divided into 22 subclasses across four key categories. Empirical results and human evaluation reveal that leading MLLMs perform significantly below human baselines. Gemini3-Pro-Preview scores 49.7, falling well behind the average adult score of 94.1. These results show despite excelling in knowledge-heavy evaluations, current MLLMs still lack fundamental visual primitives. Progress in BabyVision represents a step toward human-level visual perception and reasoning capabilities. We also explore solving visual reasoning with generation models by proposing BabyVision-Gen and automatic evaluation toolkit. Code and data are released at https://github.com/UniPat-AI/BabyVision.
****
Winformer: Transcending Pairwise Similarity for Time-series Generation
Haoyi Zhou, Xin Xue, Tianyu Chen, lanhao li, Lijun Sun, Jianxin Li
The periodicity misalignment remains a challenge problem in generating time-series data across multiple domains. The fundamental processing unit of attention in time-series modeling has long been restricted to either individual points or fragmented segments, limiting their ability to capture and adapt to complex periodic patterns inherent in diverse domains. To address this, we introduce Winformer, first to extend this processing unit from individual points to sliding windows, establishing a unified window-wise attention paradigm. Leveraging the adaptive window-alignment kernels derived from the frequency decomposition, Winformer brings semantically richer window representations, and effectively captures and transfers complex periodic patterns across domains. Extensive experiments on 12 real-world datasets demonstrate Winformer's effectiveness, achieving an average performance gain of 10.67\% over SOTA baselines.
****
Foundation Inference Models for Ordinary Differential Equations
Johannes R. Hübers, Maximilian Mauel, David Berghaus, Patrick Seifner, Ramses J Sanchez
Ordinary differential equations (ODEs) are central to scientific modelling, but inferring their vector fields from noisy trajectories remains challenging. Current approaches such as symbolic regression, Gaussian process (GP) regression, and Neural ODEs often require complex training pipelines and substantial machine learning expertise, or they depend strongly on system-specific prior knowledge. We propose FIM-ODE, a pretrained Foundation Inference Model that *amortises* ODE inference by predicting the vector field directly from noisy trajectory data *in a single forward pass*. We pretrain FIM-ODE on a prior distribution over ODEs with low-degree polynomial vector fields and represent the target field with neural operators. FIM-ODE achieves strong *zero-shot* performance, matching and often improving upon ODEFormer, a recent pretrained symbolic baseline, across a range of regimes despite using a simpler training prior. Pretraining also provides a strong initialisation for finetuning, enabling fast and stable adaptation that o

utperforms modern neural and GP baselines without requiring machine learning exp
ertise. Our pretrained model, code repository, and tutorials are available onlin
e.

Learning to Perceive the World Through Control: Empowerment-Based Representation
 Learning

Mahsa Bastankhah, Sophie Broderick, Benjamin Eysenbach

In many practical reinforcement learning (RL) environments, observations are far
 higher-dimensional than the variables that matter for control.
In this work, we ask: can we learn representations that capture only control-rel
evant features of the environment?
We study this question through the \emph{empowerment} objective, which maximizes
 an agent’s influence over the environment and is widely used for unsupervised s
kill learning.
We show that empowerment agents induce two distinct representations --- forward
 and backward --- that capture complementary aspects of the state, and both of wh
ich are invariant to control-irrelevant features. Thus, empowerment maximization
 leads agents to learn an implicit, \emph{control-centric} model of the world.
Our analysis highlights the importance of learning representations through inter
action rather than from passive datasets: interaction aimed at maximizing contro
l is essential for learning useful invariance properties, a perspective that ali
gns closely with the causal learning literature.

DLM-Scope: Mechanistic Interpretability of Diffusion Language Models via Sparse
Autoencoders

Xu Wang, Bingqing Jiang, Yu Wan, Baosong Yang, Lingpeng Kong, Difan Zou

Sparse autoencoders (SAEs) have become a standard tool for mechanistic interpret
ability in autoregressive large language models (LLMs), enabling researchers to
extract sparse, human-interpretable features and intervene on model behavior. Re
cently, as diffusion language models (DLMs) have become an increasingly powerful
 and promising alternative to autoregressive LLMs, it is essential to develop ta
ilored mechanistic interpretability tools for this emerging class of models. In
this work, we present **DLM-Scope**, the first SAE-based interpretability framew
ork for DLMs, and demonstrate that trained Top-K SAEs can faithfully extract spa
rse, interpretable features. Notably, we find that inserting SAEs affects DLMs d
ifferently from autoregressive LLMs: while SAE insertion in LLMs typically incur
s a loss penalty, in DLMs it can reduce cross-entropy loss when applied to early
 layers, a phenomenon absent or markedly weaker in LLMs. Additionally, SAE featu
res in DLMs enable more effective diffusion-time interventions, often outperform
ing LLM steering. Moreover, we pioneer new SAE-based research directions for DLM
s: we show that SAEs provide useful signals for DLM decoding order, and that SAE
 features remain stable during DLM post-training. Overall, our work establishes
a foundation for mechanistic interpretability in DLMs and highlights the potenti
al of applying SAEs to DLM-related tasks and algorithms.

RAG without Forgetting: Continual Query-Infused Key Memory

Yuntong Hu, Sha Li, Naren Ramakrishnan, Liang Zhao

Retrieval-augmented generation (RAG) systems commonly improve robustness via que
ry-time adaptations such as query expansion and iterative retrieval. While effec
tive, these approaches are inherently stateless: adaptations are recomputed for
each query and discarded thereafter, precluding cumulative learning and repeated
ly incurring inference-time cost. Index-side approaches like key expansion intro
duce persistence but rely on offline preprocessing or heuristic updates that are
 weakly aligned with downstream task utility, leading to semantic drift and nois
e accumulation. We propose Evolving Retrieval Memory (ERM), a training-free fram
ework that transforms transient query-time gains into persistent retrieval impro
vements. ERM updates the retrieval index through correctness-gated feedback, sel
ectively attributes atomic expansion signals to the document keys they benefit,
and progressively evolves keys via stable, norm-bounded updates. We show that qu
ery and key expansion are theoretically equivalent under standard similarity fun

ctions and prove convergence of ERM’s selective updates, amortizing optimal quer
y expansion into a stable index with zero inference-time overhead. Experiments o
n BEIR and BRIGHT across 13 domains demonstrate consistent gains in retrieval an
d generation, particularly on reasoning-intensive tasks, at native retrieval spe
ed.

DF-LoGiT: Data-Free Logic-Gated Backdoor Attacks in Vision Transformers
Xiaozuo Shen, Yifei Cai, Rui Ning, Chunsheng Xin, Hongyi Wu
The widespread adoption of Vision Transformers (ViTs) elevates supply-chain risk
 on third-party model hubs, where an adversary can implant backdoors into releas
ed checkpoints. Existing ViT backdoor attacks largely rely on poisoned-data trai
ning, while prior data-free attempts typically require synthetic-data fine-tunin
g or extra model components. This paper introduces Data-Free Logic-Gated Backdoo
r Attacks (DF-LoGiT), a truly data-free backdoor attack on ViTs via direct weigh
t editing. DF-LoGiT exploits ViT’s native multi-head architecture to realize a l
ogic-gated compositional trigger, enabling a stealthy and effective backdoor. We
 validate its effectiveness through theoretical analysis and extensive experimen
ts, showing that DF-LoGiT achieves near-100% attack success with negligible degr
adation in benign accuracy and remains robust against representative classical a
nd ViT-specific defenses.

Training Diffusion Language Models for Black-Box Optimization
Zipeng Sun, Can Chen, Ye Yuan, Haolun Wu, Jiayao Gu, Christopher Pal, Xue Liu
We study offline black-box optimization (BBO), aiming to discover improved desig
ns from an offline dataset of designs and labels, a problem common in robotics,
DNA, and materials science with limited labeled samples. While recent work appli
es autoregressive LLMs to BBO by formatting tasks as natural-language prompts, t
heir left-to-right design generation struggles to capture the strong bidirection
al dependencies inherent in design problems. To address this, we propose adaptin
g diffusion LLMs to offline BBO to leverage their bidirectional modeling capabil
ities. However, a domain gap exists between the natural text pre-training of dif
fusion LLMs and the heterogeneous signals in BBO (prompts, designs, and labels).
 To bridge this gap, we construct a unified prompt–-response corpus and introduc
e delimiter tokens to explicitly mark field boundaries for domain adaptation. We
 further propose a two-stage post-training framework to align the diffusion LLM
generation with high-label designs. The first stage performs supervised fine-tun
ing on the unified dataset via masked-response prediction, and the second stage
adopts reinforcement learning with rewards defined by label improvements. Our me
thod achieves state-of-the-art results on Design-Bench under small-data settings
. Code for our work is available here: https://github.com/zpointS/DiBO.
****

Deep Flow Networks
Ozan Candogan, Ayoub Foussoul
We introduce Deep Flow Networks (DFNs), a new class of discrete function approxi
mators. DFNs are inspired by and generalize minimum-cost flow value functions th
at map node imbalances on a subset of nodes to the optimal flow cost. Such funct
ions are known to be M-convex (Murota2003) and admit efficient optimization.
On the theoretical side, we prove that DFNs are universal approximators for disc
rete functions on $\mathbb{Z}^d$ that admit convex extensions to $\mathbb{R}^d$,
 and characterize their optimization complexity in terms of their deviation from
 the M-convex regime. Guided by these results, we develop a practical DFN implem
entation for learning from data. Finally, we evaluate our implementation empiric
ally on data from different ground-truth functions, showing that DFNs achieve st
rong approximation accuracy while being substantially faster to optimize than be
nchmark approaches.

PersistBench: When Should Long-Term Memories Be Forgotten by LLMs?
Sidharth Pulipaka, Oliver Chen, Manas Sharma, Taaha Saleem Bajwa, Vyas Raina, Iv
axi Sheth
Conversational assistants are increasingly integrating long-term memory with lar

ge language models (LLMs). This persistence of memories, e.g., the user is veget arian, can enhance personalization in future conversations. However, the same pe rsistence can also introduce safety risks that have been largely overlooked. Hen ce, we introduce \textbf{PersistBench} to measure the extent of these safety ris ks. We identify two long-term memory-specific risks: \textit{cross-domain leakag e}, where LLMs inappropriately inject context from the long-term memories; and \ textit{memory-induced sycophancy}, where stored long-term memories insidiously r einforce user biases. We evaluate 18 frontier and open-source LLMs on our benchm ark. Our results reveal a surprisingly high failure rate across these LLMs - a m edian failure rate of 53% on cross-domain samples and 97% on sycophancy sa mples. To address this, our benchmark encourages the development of more robust and safer long-term memory usage in frontier conversational systems.
****

Mechanistic Interpretability as Statistical Estimation: A Variance Analysis
Maxime Méloux, François Portet, Maxime Peyrard
Mechanistic Interpretability (MI) aims to reverse-engineer model behaviors by id entifying functional sub-networks. Yet, the scientific validity of these finding s depends on their stability. In this work, we argue that circuit discovery is n ot a standalone task but a statistical estimation problem built upon causal medi ation analysis (CMA). We uncover a fundamental instability at this base layer: e xact, single-input CMA scores exhibit high intrinsic variance, implying that the causal effect of a component is a volatile random variable rather than a fixed property. We then demonstrate that circuit discovery pipelines inherit this vari ance and further amplify it. Fast approximation methods, such as Edge Attributio n Patching and its successors, introduce additional estimation noise, while aggr egating these noisy scores over datasets leads to fragile structural estimates. Consequently, small perturbations in input data or hyperparameters yield vastly different circuits. We systematically decompose these sources of variance and ad vocate for more rigorous MI practices, prioritizing statistical robustness and r outine reporting of stability metrics.

Trainable Nonexpansive Denoisers for Contractive Image Reconstruction
Arghya Sinha, Aditya Banerjee, Trishit Mukherjee, Kunal N. Chaudhury
Trainable denoisers with Lipschitz control have become central to convergent ima ge reconstruction. However, training neural networks that simultaneously offer s trong denoising performance and global Lipschitz guarantees is challenging. Exis ting approaches enforce Lipschitz control only empirically, providing no guarant ees beyond the training data. In this work, we show that by exploiting the actio n of permutations on the image lattice, we can constrain a neural architecture t hat is globally nonexpansive (Lipschitz bound $\leqslant 1$). We integrate the p roposed denoiser with forward imaging operators to develop a reconstruction mech anism that is provably contractive and therefore globally convergent. Experiment s on standard inverse problems, such as superresolution and deblurring, demonstr ate that our reconstruction performance is competitive with softly constrained b aselines while providing Lipschitz guarantees.
****

PDFBench: A Benchmark for De Novo Protein Design from Function
Jiahao Kuang, Nuowei Liu, Changzhi Sun, Jie Wang, Tao Ji, Yuanbin Wu
Function-guided protein design is a crucial task with significant applications i n drug discovery and enzyme engineering. However, the field lacks a unified and comprehensive evaluation framework. Current models are assessed using inconsiste nt and limited subsets of metrics, which prevents fair comparison and a clear un derstanding of the relationships between different evaluation criteria. To addre ss this gap, we introduce **PDFBench**, the first comprehensive benchmark for fu nction-guided de novo protein design. Our benchmark systematically evaluates eig ht state-of-the-art models on 16 metrics across two key settings: description-gu ided design, for which we repurpose the Mol-Instructions dataset, originally lac king quantitative benchmarking, and keyword-guided design, for which we introduc e a new test set, SwissTest, created with a strict datetime cutoff to ensure dat a integrity. By benchmarking across a wide array of metrics and analyzing their

correlations, **PDFBench** enables more reliable model comparisons and provides key insights to guide future research.

The Double-Edged Nature of the Rashomon Set for Trustworthy Machine Learning
Ethan Hsu, Harry Chen, Chudi Zhong, Lesia Semenova
Real-world machine learning (ML) pipelines rarely produce a single model; instead, they produce a Rashomon set of many near-optimal ones. We show that this multiplicity reshapes key aspects of trustworthiness. At the individual-model level, sparse interpretable models tend to preserve privacy but are fragile to adversarial attacks. In contrast, the diversity within a large Rashomon set enables reactive robustness: even when an attack compromises one model, a practitioner can switch to a different near-optimal model that remains accurate, without retraining. However, the same diversity increases information leakage, as disclosing more near-optimal models provides an attacker with progressively richer views of the training data. This produces a robustness–privacy trade-off governed by diversity, which we analyze theoretically and empirically. Beyond this trade-off, Rashomon sets are stable under small distribution shifts, so a set computed once remains valid under such shifts without re-computation. Our results highlight the dual role of Rashomon sets as both a resource and a risk for trustworthy ML.

DP-KFC: Data-Free Preconditioning for Privacy-Preserving Deep Learning
Marc Molina Van den bosch, Riccardo Taiello, Albert Sund Aillet, Andrea Protani, Miguel Angel Gonzalez Ballester, Luigi Serio
Differentially private optimization suffers from a fundamental geometric mismatch: deep networks have highly anisotropic loss landscapes, yet DP-SGD injects isotropic noise. Second-order preconditioning can resolve this, but estimating curvature typically requires private data (consuming privacy budget) or public data (introducing distribution shift). We show that the Fisher Information Matrix decouples into *architectural sensitivity*, recoverable via synthetic noise, and *input correlations*, approximable from modality-specific frequency statistics. We propose DP-KFC, which constructs KFAC preconditioners by probing networks with structured synthetic noise, requiring neither private nor public data. Empirically, DP-KFC consistently outperforms DP-SGD and adaptive baselines across diverse modalities in strong privacy regimes ($\varepsilon \leq 3$). DP-KFC matches private-data preconditioners while public-data variants degrade by up to 4.8 %, showing that curvature can be estimated without consuming privacy budget or introducing distribution shift. This enables privacy-preserving learning in specialized domains (e.g., medical applications) where regulatory constraints make data scarce.

What LLMs Explain Is Not What They Believe: Evaluating Explanation Sufficiency Under Models' Own Input Beliefs
Nhi Nguyen, Shauli Ravfogel, Rajesh Ranganath
Large language models (LLMs) are increasingly deployed in high-stakes domains, where free-text explanations such as chain-of-thought and post-hoc rationales are used to justify model outputs. Yet it remains unclear whether these explanations are _sufficient_, i.e., if they contain enough information to explain the model’s output-generating process. We generalize classical sufficiency from feature attributions to arbitrary explanations and prove that explanation sufficiency can change depending on the input distribution, which must be explicitly defined for LLM explanations. We propose using the LLM itself to generate alternative inputs conditioned on an explanation, capturing its beliefs about possible inputs. We formalize _self-consistent sufficiency_ as a goal for free-text explanations and introduce an information-theoretic metric, SCSuff, that enables evaluation of free-text explanations without relying on predefined biases or shortcuts. Our experiments show that SCSuff agrees with targeted perturbation tests where applicable and demonstrate that explanation sufficiency can vary with the input distribution. We find LLM explanations are generally insufficient and weakly correlated with model size, accuracy, or output entropy. Analysis of final-token hidden states shows that top and bottom SCSuff scores can be predicted from internal re

presentations, suggesting that SCSuff can guide detection and improvement of suf
ficient LLM explanations. The code for this paper is available at https://github
.com/rajesh-lab/self-consistent-sufficiency.

Convergent World Representations and Divergent Tasks
Core Francisco Park
While neural representations are central to modern deep learning, the conditions
 governing their geometry and their roles in downstream adaptability remain poor
ly understood. We develop a framework clearly separating the underlying world, t
he data generation process and the resulting model representations to study thes
e questions in a controlled setup: 5,075 city coordinates define the world and 7
 geometric tasks generate the training data for autoregressive Transformer train
ing. We find that different tasks give rise to qualitatively and quantitatively
distinct world representation geometries. However, multi-task training drives co
nvergence of world representations: models trained on non-overlapping tasks deve
lop aligned geometric representations, providing controlled evidence for the Mul
titask Scaling Hypothesis of the Platonic Representation Hypothesis. To study ad
aptation, we pretrain models on all tasks and all cities, then test whether new
entities can be consistently integrated into the representation space via fine-t
uning. Surprisingly, we find that despite multi-task pretraining, some tasks, wh
ich we call divergent, actively harm the representational integration of new ent
ities. Our results show that training on multiple relational tasks reliably prod
uces convergent world representations, but some lurking divergent tasks can cata
strophically harm new entity integration via fine-tuning.

SimGFM: Simplifying Discrete Flow Matching for Graph Generation
Chunyu Luo, Yuankai Luo, Xiao-Ming Wu, Lei Shi
Discrete Flow Matching (DFM) presents a promising approach for graph generation;
 however, existing adaptations often introduce substantial complexity by incorpo
rating task-specific heuristics, compromising the continuity equation and signif
icantly expanding the hyperparameter space. Moreover, their sampling efficiency
remains limited, as the required number of steps is often comparable to diffusio
n models, diminishing DFM’s practical advantages. To address these limitations,
we propose SimGFM, a simplified graph DFM for graph generation. Leveraging chara
cteristic patterns in graph-generation trajectories, SimGFM relies only on the s
cheduler and rate matrix, eliminating heavy heuristics and hyperparameter tuning
, and achieves large step reductions while preserving SOTA results. SimGFM achie
ves strong empirical results: on QM9, it matches prior models requiring 500–1000
 steps with only 10 steps, and on most datasets, its performance at 50 steps mat
ches or surpasses these baselines, demonstrating both efficiency and competitive
ness. Our source code is available at https://github.com/LUOyk1999/SimGFM.

Orchestrating Spatial Semantics via a Zone-Graph Paradigm for Intricate Indoor S
cene Generation
Meisheng Zhang, Shizhao Sun, Yang Zhao, Ziyuan Liu, Zhijun Gao, Jiang Bian
Autonomous 3D indoor scene synthesis breaks down in non-convex rooms with tightl
y coupled spatial constraints. Data-driven generators lack topological priors fo
r long-horizon planning, while iterative agents fragment semantics and become ge
ometrically brittle. We present \textbf{ZoneMaestro}, a unified framework that s
hifts the paradigm from object-centric synthesis to Zone-Graph Orchestration. By
 internalizing a novel zone-based logic, ZoneMaestro translates high-level seman
tic intent into functional zones and topological constraints, enabling robust ad
aptation to diverse architectural forms. To support this, we construct \textit{Z
one-Scene-10K}, a large-scale dataset enriched with explicit Zone-Graph annotati
ons. We further introduce an \textit{Alternating Alignment Strategy} that cycles
 between reasoning internalization and Zone-Aware Group Relative Policy Optimiza
tion (\textit{Z-GRPO}), effectively reconciling the tension between semantic ric
hness and geometric validity without relying on external physics engines. To rig
orously evaluate spatial intelligence beyond convex primitives, we formally defi
ne the task of \textbf{Intricate Spatial Orchestration} and release SCALE, a str

ess-test benchmark for irregular indoor scenarios with complex, dense spatial re
lations. Extensive experiments demonstrate that ZoneMaestro resolves the density
-safety dichotomy, significantly outperforming state-of-the-art baselines in bot
h structural coherence and intent adherence.

MA^{3}S: Model-Agnostic Active Annotation Strategy for Crowdsourcing
Wenjun Zhang, Liangxiao Jiang, Chaoqun Li, Shanshan Si
In crowdsourcing scenarios, to mitigate the impact of noisy labels assigned by n
on-expert workers, each instance is typically annotated multiple times by differ
ent workers. However, repeated annotation can introduce instance- or label-level
 redundancy, thereby inflating annotation costs. Despite its practical importanc
e, research on repeated annotation strategies remains limited, and no existing s
trategy simultaneously avoids being offline, instance-unaware, and model-centric
. In this paper, we propose a model-agnostic active annotation strategy, MA^{3}S
, that addresses these limitations: (1) To reduce label redundancy caused by off
line procedure, MA^{3}S estimates instance uncertainties with a margin-Beta dist
ribution and updates them online as new labels arrive. (2) To prevent instance r
edundancy induced by instance-unaware designs, MA^{3}S constructs a nearest-neig
hbor graph to propagate instance uncertainties, reducing repeated annotations of
 similar instances. (3) To avoid being model-centric, MA^{3}S actively selects i
nstances for annotation based solely on the estimated uncertainties, without rel
ying on model feedback. Extensive experiments on synthetic and real-world datase
ts demonstrate that MA^{3}S consistently outperforms existing annotation strateg
ies.

Learning Rewrite-Invariant Reasoning with Targeted Alternation Training
Mousa Arraf, Ido Guy, Kira Radinsky
Large language models (LLMs) often fail in systematic, model-specific ways under
 meaning-preserving question rewrites (paraphrases, format changes, benign distr
actors). In this work, we address this instability by identifying where the mode
l's reasoning process diverges across semantically-equivalent inputs. For each t
arget LLM, we sample multiple solution traces under rewrites and aggregate them
into a graph of recurring intermediate steps, which pinpoints where incorrect tr
aces diverge from correct ones. We then generate a small set of semantics-preser
ving examples that mirror the rewrite patterns most responsible for these diverg
ences, and use them to steer the model (\emph{targeted alternation training}), e
ither via fine-tuning or via in-context learning. Across MMLU-Pro, Big-MATH, and
 DROP, this yields consistent gains and cross-dataset generalization. On Humanit
y’s Last Exam, using 200 in-context examples, it improves GPT-5.2 (xhigh) from 3
5.4\% to 38.1\%, demonstrating that targeted alternation training can materially
 improve a frontier, API-accessible closed model under realistic access constrai
nts.

FairRARI: A Plug and Play Framework for Fairness-Aware PageRank
Emmanouil Kariotakis, Aritra Konar
PageRank (PR) is a fundamental algorithm in graph machine learning tasks. Owing
to the increasing importance of algorithmic fairness, we consider the problem of
 computing PR vectors subject to various group-fairness criteria based on sensit
ive attributes of the vertices. At present, principled algorithms for this probl
em are lacking - some cannot guarantee that a target fairness level is achieved,
 while others do not feature optimality guarantees. In order to overcome these s
hortcomings, we put forth a unified in-processing convex optimization framework,
 termed FairRARI, for tackling different group-fairness criteria in a ``plug and
 play'' fashion. Leveraging a variational formulation of PR, the framework compu
tes fair PR vectors by solving a strongly convex optimization problem with fairn
ess constraints, thereby ensuring that a target fairness level is achieved. We f
urther introduce three different fairness criteria which can be efficiently tack
led using FairRARI to compute fair PR vectors with the same asymptotic time-comp
lexity as the original PR algorithm. Extensive experiments on real-world dataset
s showcase that FairRARI outperforms existing methods in terms of utility, while

achieving the desired fairness levels across multiple vertex groups; thereby hi
ghlighting its effectiveness.

BFTS: Thompson Sampling with Bayesian Additive Regression Trees
Ruizhe Deng, Bibhas Chakraborty, Ran Chen, Yan Shuo Tan
We propose Bayesian Forest Thompson Sampling (BFTS), which performs Thompson sam
pling using arm-wise Bayesian Additive Regression Trees (BART) to model each act
ion's mean reward and generate MCMC-based posterior draws for decision-making. W
e derive an information-theoretic Bayesian regret bound of order $\widetilde{\ma
thcal O}(K\sqrt{T})$ for ideal posterior sampling under a correctly specified Ba
yesian design. Empirically, BFTS achieves competitive regret on nonlinear synthe
tic benchmarks with near-nominal uncertainty calibration, attains the best avera
ge rank across nine OpenML contextual bandit benchmarks, and yields higher estim
ated policy values than linear, neural, and tree-ensemble baselines in a Drink L
ess micro-randomized trial case study. Across OpenML benchmarks, BFTS is robust
to hyperparameter choices.

Dustin: Draft-Augmented Sparse Verification for Efficient Long-Context Generatio
n with Speculative Decoding
WenHung Lee, Jian-Jia Chen, Xiaolin Lin, Pei-Shuo Wang, Chi-Chih Chang, Chun-Che
Yang, Wei-Chen Wang, Hanrui Wang, Ning-Chi Huang, Grace Li Zhang, Kai-Chiang Wu
While speculative decoding improves inference throughput for multi-batch long-co
ntext Large Language Models (LLMs), its efficiency is often limited by a verific
ation bottleneck where Key-Value (KV) cache loading dominates latency. Existing
compression methods fail in this regime: static eviction incurs accuracy loss du
e to saliency shift, while dynamic selection introduces prohibitive computationa
l overhead during the verification path. We propose Dustin, a sparse verificatio
n framework designed for long-context speculative decoding. Dustin integrates lo
okahead signals from the draft model with historical attention from the target m
odel to identify critical tokens with high fidelity across multi-step verificati
on windows. To reduce recomputation latency, this approach further employs a spa
rse estimation scheme that restricts importance scoring to a minimal subset of a
ttention heads. Evaluations on PG-19 and LongBench with Qwen2.5-72B demonstrate
that Dustin achieves a 27.85× speedup in self-attention and a 9.17× end-to-end d
ecoding speedup at a 32k sequence length, all with negligible accuracy degradati
on.

Breaking the Synthetic-Real Domain Shortcut for Training-Free Generative Replay-
based Class Incremental Learning
Tao Zhang, Qixuan Fan, Yiyuan Liang, Yanjie Wang, Song Yan, Tian Tian, Jiahuan Z
hou, Luxin Yan, Sheng Zhong, Xu Zou
Class-incremental learning (CIL) requires models to continuously acquire new kno
wledge while avoiding catastrophic forgetting. While exemplar replay is effectiv
e, it raises concerns regarding privacy and storage. Thus, generative replay has
emerged as a viable alternative, synthesizing old data using frozen pretrained
text-to-image (T2I) models without any extra training. However, we observe that
directly mixing synthetic old-class data with real new-class data during increme
ntal training leads to significant performance degradation. This issue stems fro
m a ‘’domain shortcut'', where models rely on domain-discriminative features ins
tead of semantic class cues. To address this, we propose DREAM (Domain-Regulariz
ed Exemplar-free Alignment Model), which uses a training-free generator to synth
esize old-class data and eliminates domain shortcut via subspace rectification a
nd orthogonal projection, while reinforcing semantic alignment through real-anch
ored prototype regularization. Extensive experiments on 4 datasets demonstrate t
hat DREAM outperforms existing exemplar-free CIL methods and achieves state-of-t
he-art performance.

Learning the Best Under Constraints: A Duality-Based Framework
Mingjie Hu, Enlu Zhou, Jianqiang Hu
This paper studies a constrained linear best arm identification problem with cov

ariate selection in the fixed-confidence setting, where each arm is evaluated ac ross multiple performance metrics. The mean performance of each metric depends l inearly on the feature vectors of both arms and covariates. The goal is to ident ify the arm with the highest expected value of one targeted metric while ensurin g that the means of the remaining metrics stay below specified thresholds for ea ch covariate. We first establish an instance-dependent lower bound on the sample complexity, formulated as a multi-level optimization problem that captures both feasibility and optimality. We then prove that this bound is tight by designing an algorithm that asymptotically matches it. Since the original algorithm is co mputationally intensive, we develop a relaxed version of the bound through a sur rogate optimization problem and derive its convex dual. Using this bound, we pro pose a duality-based decomposition algorithm that is computationally efficient, updating only two coordinates and performing a single gradient step per iteratio n. We further show that the algorithm achieves the relaxed bound in theory and d emonstrates its practical effectiveness through numerical experiments.

How Should Transformers Encode Numeric Values in Electronic Health Records?

Maria Elkjær Montgomery, Christian Igel, Mikkel Fruelund Odgaard, Martin Sillese n, Mads Nielsen

How do we encode numeric values in transformer-based sequence processing, partic ularly in electronic health record (EHR) data? We systematically compare discret e, continuous, and hybrid value encoding strategies using synthetic arithmetic t asks embedded within real-world EHR data, as well as real-world clinical predict ion tasks. Our study reveals trade-offs between numeric precision, optimisation stability, and architectural flexibility. We find that approaches that explicitl y model value-concept interactions perform best on precision-sensitive arithmeti c tasks when architectural constraints permit. Hybrid token-based approaches tha t retain numeric values but apply binning prior to projection provide a more rob ust and broadly applicable alternative, with the optimal number of bins followin g a simple empirically derived power-law in dataset size. Across tasks, models c onsistently exhibit reliable “good enough” numeric computation rather than exact arithmetic, while clinical gains from incorporating laboratory values are task- dependent. This suggests that robustness and deployability often outweigh maxima l numeric precision in practice, motivating hybrid token-based approaches as a p ractical default.

Online Continual Learning with Dynamic Label Hierarchies

Xinrui Wang, Bart■omiej Twardowski, Alexandra Gomez-Villa, Shao-Yuan Li, Songcan Chen

Online Continual Learning (OCL) aims to learn from endless non\text{-}stationary data streams, yet most existing methods assume a flat label space and overlook the hierarchical organization of real\text{-}world concepts that evolves both ho rizontally (sibling classes) and vertically (coarse or fine categories). To bett er reflect this context, we introduce a new problem setting, DHOCL (Online Conti nual Learning from Dynamic Hierarchies), where taxonomies evolve across granular ities and each sample provides supervision at a single hierarchical level. In th is setting, we find two fundamental issues: (i) partial supervision under mixed granularities provides only point-wise signals over an evolving path-wise hierar chy, which constrains plasticity and undermines cross-level semantic consistency , and (ii) the dynamically evolving hierarchies induce granularity-dependent int erference, destabilizing popular replay and regularization mechanisms and thereb y exacerbating catastrophic forgetting. To tackle these issues, we propose HALO (Hierarchical Adaptive Learning with Organized Prototypes), which adaptively com bines complementary classification heads, regularized by organized learnable hie rarchical prototypes, enabling rapid adaptation, hierarchical consistency, and s tructured knowledge consolidation as the taxonomy evolves. Extensive experiments on multiple benchmarks demonstrate that HALO consistently outperforms existing methods across hierarchical accuracy, mistake severity, and continual performanc e.

Learning Treatment Representations for Downstream Instrumental Variable Regressi
on
Shiangyi Lin, Hui Lan, Vasilis Syrgkanis
Traditional instrumental variable (IV) estimators cannot accommodate more treatm
ents than instruments, a limitation that is critical for high-dimensional, unstr
uctured data like clinical treatment pathways. Current practice—applying unsuper
vised dimension reduction before IV estimation—suffers from substantial omitted
treatment bias because the representation learning step ignores the instrument.
We propose a novel framework that constructs treatment representations by explic
itly incorporating instrumental variables. We prove that this instrument-guided
approach ensures the identification of optimal outcome-prediction directions eve
n with limited instruments. Validation on large-scale, semi-synthetic clinical d
ata derived from a major hospital, along with other simulations, shows that our
approach significantly outperforms conventional two-stage methods.

Asking What Matters: Reward-Driven Clarification for Software Engineering Tasks
Sanidhya Vijayvargiya, Vijay Viswanathan, Graham Neubig
Humans often specify tasks incompletely, so assistants must know when and how to
ask clarifying questions. However, effective clarification remains challenging
in software engineering tasks as not all missing information is equally valuable
, and questions must target information users can realistically provide. We stud
y clarification in real software engineering tasks by quantifying which types of
information most affect task success and which questions elicit useful response
s from simulated users. Using Shapley attribution and distributional comparisons
, we identify two key properties of effective clarification: task relevance (whi
ch information predicts success) and user answerability (what users can realisti
cally provide). We operationalize these properties as multi-stage reinforcement
learning rewards to train CLARITI, an 8B-parameter clarification module, that ma
tches GPT-5’s resolution rate on underspecified issues while generating 41% fewe
r questions. Our results suggest that grounding reward design in empirical analy
sis of information impact and user answerability improves clarification efficien
cy.

Radial Scaling Voxelization for Accurate Small Object 3D Detection
Hao Liu, Yi Zhou, Yanni Ma
Voxel-based 3D object detectors typically discretize the spatial domain using a
uniform Cartesian grid, which allocates the same voxel size to both near-range a
nd far-range regions. However, this uniform discretization is suboptimal for sma
ll objects such as pedestrians and cyclists, as they occupy only a few voxels an
d thus struggle to capture fine-grained geometric details. Although increasing t
he global voxel resolution can alleviate this problem, it inevitably increases s
ubstantial memory consumption and computational cost. In this paper, we propose
Radial Scaling Voxelization (RSV), a simple yet effective non-uniform discretiza
tion strategy that adaptively modulates the effective voxel size based on the ra
dial distance from the LiDAR sensor. Unlike previous cylindrical or polar discre
tization schemes, RSV preserves the Cartesian grid topology by applying a contin
uous radial scaling function to the input coordinates before standard voxelizati
on. This operation yields a near-high, far-unchanged resolution pattern, i.e., t
he effective voxel size becomes finer in near regions, where the geometric struc
tures of small objects are difficult to capture, while remaining nearly unchange
d in far regions to avoid unnecessary computational cost. Importantly, RSV is ar
chitecture-agnostic and can directly replace the discretization module in any vo
xel-based detector without modifying the backbone, network design, or training p
ipeline. Extensive experiments on the KITTI and nuScenes datasets demonstrate th
at integrating our RSV into several voxel-based baselines consistently enhances
small-object detection performance, especially for the Pedestrian and Cyclist ca
tegories, while incurring only marginal additional computational overhead. Code
is available at https://github.com/Zeoy2020/RadialScalingVoxelization.

Optimizing Diversity and Quality through Base-Aligned Model Collaboration

Yichen Wang, Chenghao Yang, Tenghao Huang, Muhao Chen, Jonathan May, Mina Lee
Alignment has greatly improved large language models (LLMs)' output quality at t he cost of diversity, yielding highly similar outputs across generations, especi ally in open-ended generation tasks. We propose Base-Aligned Model Collaboration (BACo), an inference-time token-level model collaboration framework that dynami cally combines a base LLM with its aligned counterpart to optimize diversity and quality. Using uncertainty and content-based signals, BACo employs routing stra tegies to determine, at each token, which model to decode from. Prior diversity-promoting methods often improve diversity at the expense of quality or require e xpensive decoding or post-training. In contrast, BACo achieves both high diversi ty and quality post hoc within a single pass, while offering strong controllabil ity. We introduce a family of effective routing strategies and evaluate them acr oss three open-ended generation tasks with 13 diversity and quality metrics. BAC o consistently surpasses state-of-the-art inference-time baselines. With our bes t router, BACo achieves a 21.3% joint improvement in diversity and quality, whic h is further supported by human evaluations. Overall, our results demonstrate th at collaboration between base and aligned models provides an effective and contr ollable mechanism for optimizing the diversity-quality trade-off.

Stabilizing Reinforcement Learning for Diffusion Language Models
Jianyuan Zhong, Kaibo Wang, Ding Ding, Zijin Feng, Haoli Bai, Yang Xiang, Jiache ng Sun, Qiang Xu
Diffusion Large Language Models (dLLMs) often exhibit severe instability during Group Relative Policy Optimization (GRPO) training, limiting the effectiveness o f reinforcement learning for improving reasoning capabilities. In dLLMs, the imp ortance ratios used by GRPO are derived from finite-sample estimates rather than exact likelihoods, making them inherently noisy. In this paper, we show that GR PO is highly sensitive to this noise, which drives training instability. Through theoretical analysis and empirical evidence, we identify a self-reinforcing ins tability loop in which noisy importance ratios induce gradient spikes and policy drift, further amplifying future importance ratio estimation variance. To addre ss this issue, we propose StableDRL, a novel reinforcement learning framework fo r dLLMs. StableDRL stabilizes training via (i) unconditional clipping to suppres s outlier-induced gradient spikes, and (ii) self-normalization to constrain grad ients within the convex hull of per-sample updates. We further extend StableDRL to block-wise diffusion models via a staircase attention mechanism. StableDRL is the first method that enables stable, full-parameter reinforcement learning for dLLMs. It achieves the state-of-the-art performance, outperforming prior best f ull-attention baselines by 6% on MATH500 and block-diffusion baselines by 25.6% on AIME.
****

Robustness of Mixtures of Experts to Feature Noise
Dong Sun, Rahul Nittala, Rebekka Burkholz
Despite their practical success, it remains unclear why Mixture of Experts (MoE)

models can outperform dense networks beyond sheer parameter scaling. We study a n iso-parameter regime where inputs exhibit latent modular structure but are cor rupted by feature noise, a proxy for noisy internal activations. We show that sp arse expert activation acts as a noise filter: compared to a dense estimator, Mo Es achieve lower generalization error under feature noise, improved robustness t o perturbations, and faster convergence speed. Empirical results on synthetic da ta and real-world language tasks corroborate the theoretical insights, demonstra ting consistent robustness and efficiency gains from sparse modular computation.

Learning Attribute–Affordance Hierarchies in Hyperbolic Space for Open-Vocabular y 3D Object Affordance Grounding
Yuxuan Wang, Tong Li, Yihang Zhu, Guangtao Lyu, Yukuan Min, Chenghao Xu, Jiexi Y an, Xu Yang, Cheng Deng
This paper pays attention to open-vocabulary 3D object affordance grounding (OVA G), which aims to localize affordance regions on 3D objects by leveraging intera ction images or textual instructions. Most existing methods treat interaction im ages as sources of external affordance knowledge and align them with 3D visual r epresentations, while overlooking the intrinsic relationship between local objec t attributes and affordances, which limits localization accuracy and generalizat ion. For instance, a cup handle affords grasping due to its curved shape and app ropriate thickness, indicating that affordances emerge from specific attribute c ompositions rather than global object appearance.

Motivated by this, we propose Attribute-Affordance Hierarchies (AAH) learning framework that explicitly models the hierarchical relationships between object-r egion attributes and affordances. Our approach first captures local region relat ionships using hypergraph, and then projects these region-level concepts into a hyperbolic space to encode their hierarchical organization. Furthermore, we intr oduce counterfactual attribute samples to encourage robust learning of attribute –affordance dependencies under varying conditions. By jointly modeling visual st ructure and hierarchical concept information, our method achieves more accurate affordance localization. Extensive experiments and qualitative analyses demonstr ate the effectiveness of our approach.

OSNIP: Balancing the Privacy-Utility-Efficiency Trilemma in LLM Inference via Ob fuscated Semantic Null Space
Zhiyuan Cao, Zeyu Ma, Chenhao Yang, HAN ZHENG, Mingang Chen
We propose Obfuscated Semantic Null Space Injection for Privacy (OSNIP), a light weight client-side encryption framework for privacy-preserving LLM inference. Ge neralizing the geometric intuition of linear kernels to the high-dimensional lat ent space of LLMs, we formally define the ``Obfuscated Semantic Null Space'', a high-dimensional regime that preserves semantic fidelity while enforcing near-or thogonality to the original embedding. By injecting perturbations that project t

he original embedding into this space, OSNIP ensures privacy without any post-pr
ocessing. Furthermore, OSNIP employs a key-dependent stochastic mapping that gen
erates distinct perturbations under fresh keys.
Evaluations on generative and classification benchmarks show that OSNIP achieves
 state-of-the-art performance, sharply reducing attack success rates while maint
aining strong model utility under strict security constraints.

Beyond the Bellman Recursion: A Pontryagin-Guided Framework for Non-Exponential
Discounting
Hojin Ko, Jeonggyu Huh
Most value-based and actor-critic reinforcement learning methods rely on Bellman
-style recursions, yet these recursions collapse under non-exponential discounti
ng common in human preferences and survival processes. We show the breakdown is
structural: exponential discounting sits at a fragile intersection of multiplica
tivity and time homogeneity, and violating either property breaks standard dynam
ic programming. To overcome this, we propose **Pontryagin-Guided Direct Policy O
ptimization (PG-DPO)**, a variational framework that abandons recursion and coup
les the Pontryagin Maximum Principle with Monte Carlo rollouts via an *Adjoint-M
C projection* enforcing pointwise Hamiltonian maximization. Across multidimensio
nal hyperbolic and survival-discount benchmarks, PG-DPO improves accuracy and st
ability where equation-driven solvers and critic-based baselines diverge.

ANCHOR: Automated Alignment Auditing for CLI Agents on Real-World Harm
Kefan Song, Yanjun Qi
Autonomous CLI agents can now execute hundreds of actions across multi-hour sess
ions: writing code, executing shell commands, browsing the web, and managing clo
ud infrastructure, all with minimal human oversight. Does greater autonomy invit
e greater risk? We introduce ANCHOR, an automated auditing framework that stress
-tests CLI agents on illegal tasks grounded in public US court cases. ANCHOR dep
loys an auditor agent fine-tuned on dark personality data using supervised and r
einforcement fine tuning. This auditor roleplays persistent malicious users who
decompose tasks, reframe requests upon refusal, and adapt strategies across mult
i-turn interactions. Evaluating frontier CLI agents, we find that while they oft
en refuse illegal tasks when prompted directly, compliance reaches 100\% under p
ersistent malicious interaction. When agents comply, they frequently exceed user
 requests, autonomously building infrastructure for large-scale harm, including
catastrophic risk scenarios such as large-scale financial fraud and bioweapon de
velopment. These findings demonstrate that current alignment techniques are insu
fficient for autonomous agents and underscore the need for safety evaluations ag
ainst persistent, adaptive malicious users.
****

OSCS: Online Selection with Provable FAR Control for LLM Safety
Zirui Hu, Zheng Zhang, Yingjie Wang, Dacheng Tao
Large language models (LLMs) are vulnerable to malicious inputs, posing serious
risks in high-stakes applications. Although existing detection-based defenses ac
hieve strong empirical performance, they generally lack explicit control over th
e false acceptance rate (FAR), a critical safety requirement in sensitive deploy
ment scenarios. This challenge is further complicated by two practical constrain
ts: the lack of malicious calibration samples and the streaming nature of real-w
orld inputs. To address these challenges, we propose \textit{OSCS}, a novel fram
ework for online FAR control without requiring malicious calibration data. OSCS
leverages detection scores produced by existing defenses and employs recursive d
ensity estimation to estimate benign probability from the test stream. Based on
these estimates, OSCS performs real-time accept/reject decisions while provably
satisfying a user-specified FAR target. Theoretically, we show that OSCS control
s the FAR up to a vanishing excess term under mild assumptions. Extensive experi
ments on backdoor and jailbreak attack tasks further demonstrate the effectivene
ss of OSCS, showing that it consistently achieves robust FAR control across dive
rse attack settings while outperforming existing baselines.

Can LLMs Reason Like Automated Theorem Provers for Rust Verification? VCoT-Bench : Evaluating via Verification Chain of Thought
Zichen Xie, Wenxi Wang
As Large Language Models (LLMs) increasingly assist secure software development, their ability to meet the rigorous demands of Rust program verification remains unclear. Existing evaluations treat Rust verification as a black box, assessing models only by binary pass or fail outcomes for proof hints. This obscures whether models can systematically reconstruct the explicit deductive steps required for verifying nontrivial Rust code. To bridge this gap, we introduce VCoT-Lift, a framework that lifts low-level solver reasoning into high-level, human-readable verification steps. By exposing solver-level reasoning as an explicit Verification Chain-of-Thought, VCoT-Lift provides a concrete ground truth for fine-grained evaluation. Leveraging VCoT-Lift, we introduce VCoT-Bench, a comprehensive benchmark of 1,988 VCoT completion tasks for rigorously evaluating LLMs' ability to reconstruct the entire verification process. VCoT-Bench measures performance along three orthogonal dimensions: robustness to varying degrees of missing proofs, competence across different proof types, and sensitivity to proof locations. Evaluation of ten state-of-the-art models reveals severe fragility, indicating that current LLMs fall well short of the reasoning capabilities exhibited by automated theorem provers.
****
LaRI: Layered Ray Intersections for Single-view 3D Geometric Reasoning
Rui Li, Biao Zhang, Zhenyu Li, Federico Tombari, Peter Wonka
We present Layered Ray Intersections (LaRI), a fully supervised method for occluded geometry reasoning from a single image. Unlike conventional depth estimation, which is limited to visible surfaces, LaRI predicts multiple surfaces intersected by the camera rays using layered point maps. Compared to the existing approaches that leverage neural implicit representations or iterative refinement, LaRI achieves complete scene reconstruction in one feed-forward pass, enabling efficient and view-aligned geometric reasoning to underpin both object-level and scene-level tasks. We further propose to predict the ray stopping index, which identifies valid intersecting pixels and layers from LaRI's output. To better underpin and evaluate this task, we build an annotation pipeline using rendering engines, construct annotations for five public datasets, including synthetic and real-world data covering 3D objects and scenes. As a generic method, LaRI's performance is validated in object-level and scene-level reconstruction tasks.

Simple Algorithms for Bad Triangle Transversals with Applications to Correlation Clustering
Florian Adriaens, Nikolaj Tatti
The Bad Triangle Transversal (BTT) problem asks for the smallest set of edges that need to be removed from a given signed graph, so that the resulting graph does not have a bad triangle. Here, a bad triangle is a triangle with exactly one negative edge.
Several 2-approximations for BTT are proposed in this paper. On the hardness side, we show that BTT is NP-hard to approximate with factor better than $\frac{2137}{2136}$ on complete graphs. Our reduction also works for Correlation Clustering (CC), the Cluster Deletion problem (CD) and the Minimum Strong Triadic Closure problem (MinSTC). Lastly, we show that the BTT and CC optima are within a factor of 3/2 in complete graphs, by describing a pivot procedure that transforms transversals into clusters.

Logit Distance Bounds Representational Similarity
Beatrix Miranda Ginn Nielsen, Emanuele Marconato, Luigi Gresele, Andrea Dittadi, Simon Buchholz
For a broad family of discriminative models that includes autoregressive language models, identifiability results imply that if two models induce the same conditional distributions, then their internal representations are equal up to an invertible linear transformation. We ask whether an analogous conclusion holds approximately when the distributions are close instead of equal.

Building on the observation of Nielsen et al. (2025) that closeness in KL diverg
ence need not imply high linear representational similarity, we study a distribu
tional distance based on logit differences and show that closeness in this dista
nce does yield linear similarity guarantees.
Specifically, we define a representational dissimilarity measure based on the mo
dels' identifiability class and prove that it is bounded by the logit distance.
We further show that, when model probabilities are bounded away from zero, KL di
vergence upper-bounds logit distance; yet the resulting bound fails to provide n
ontrivial control in practice.
As a consequence, KL-based distillation can match a teacher’s predictions while
failing to preserve linear representational properties, such as linear-probe rec
overability of human-interpretable concepts.
In distillation experiments on synthetic and image datasets, logit-distance dist
illation yields students with higher linear representational similarity and bett
er preservation of the teacher’s linearly recoverable concepts.

f-Divergence Self-Play for Tabular Anomaly Detection via Large Language Models
Hoang Tran Vuong, Linh Ngo Van, Dang Nguyen, Thin Nguyen, Phuoc Nguyen, Mehrtash
Harandi, Trung Le
Anomaly detection in tabular data poses significant challenges due to heterogene
ous feature types—mixing numerical, categorical, and textual attributes, which c
omplicate learning meaningful representations of normality. Recent work has appl
ied large language models (LLMs) to this problem by serializing table rows as te
xt sequences, yet these approaches rely on one-shot supervised fine-tuning that
offers limited signal to tighten the model's description of normality. We propos
e DiSPaT, a self-play fine-tuning framework that strengthens the model's underst
anding of normal data. Building on the theoretical foundation of f-divergence
minimization, we derive a tight approximation connecting our training objective
to reducing the distributional gap between real normal data and model-generated
samples. DiSPaT operates through an alternating optimization: at each iteration,
the current policy generates synthetic samples that serve as pseudo-anomalies,
while a critic discriminator learns to distinguish these from real normal sample
s; this signal drives policy updates that progressively align the model distribu
tion with the true normal-data distribution. Extensive experiments on diverse be
nchmarks demonstrate that DiSPaT consistently outperforms prior LLM-based method
s, deep learning approaches, and classical unsupervised detectors for tabular an
omaly detection.

The Accumulation of Score Estimation Error in Diffusion Models
Baoxiang He, Valentio Iverson, Shuai Li, Cheng Chen, Bo Jiang
Diffusion models are widely used for high-quality generation, but their performa
nce is sensitive to the accuracy of the estimated score.
We first derive a stepwise Wasserstein error bound in a Gaussian-mixture setting
, where the score admits a closed-form structure, and the score Hessian can be c
ontrolled explicitly, leading to sharp Wasserstein estimates.
We then extend the analysis to general data distributions, which yields a more g
eneral but typically looser upper bound.
This general bound can be sharpened under mild regularity: when the initial dist
ribution has a globally Lipschitz score, the curvature contribution at small tim
es is uniformly bounded, avoiding the worst-case blow-up.
The results hold for both variance-preserving (VP) and variance-exploding (VE) d
iffusions, and apply to both the reverse-time SDE and the associated probability
-flow ODE.

Visual Implicit Autoregressive Modeling
Pengfei Jiang, Jixiang Luo, Luxi Lin, Zhaohong Huang, Xuelong Li
Visual Autoregressive Modeling (VAR) based on next-scale prediction achieves str
ong generation quality, but their explicit deep stacks fix the amount of computa
tion per scale and inflate memory at high resolutions. We introduce Visual Impli
cit Autoregressive Modeling (VIAR), a next-scale autoregressive generator that e

mbeds an implicit equilibrium layer between shallow pre/post blocks. The implicit layer is trained with Jacobian■Free Backpropagation, yielding constant training memory, while inference exposes a per■scale iteration knob that enables compute control. On ImageNet 256 × 256 benchmark, VIAR attains FID 2.16, and sFID 8.07 with only 38.4\% parameters of VAR, matching or surpassing strong AR baselines and remaining competitive with large diffusion models. By controlling the per-scale knob, VIAR can reduce peak memory from 19.24 GB to 8.53 GB and doubles throughput from 15.16 to 32.08 images/s on a single RTX 4090, without retraining. Ablations show that fewer steps are sufficient for fixed-point iterations to converge and that VIAR consistently dominates VAR across quality efficiency operating points. In zero shot in-painting and class■conditional editing, VIAR produces sharper details and smoother boundaries while preserving global structure, validating the benefits of implicit equilibria and per■scale compute control for practical, deployable visual generation.

Revealing Scaling Paradox in Large-scale Time Series Models: Implications for More Efficient and Accurate Forecasting

Xin Qiu, Junlong Tong, Yirong Sun, Yunpu Ma, Xiaoyu Shen

Large-scale models are at the forefront of time series (TS) forecasting, dominated by two paradigms: fine-tuning text-based Large Language Models for TS (LLM4TS) and training Time Series Foundation Models (TSFMs) from scratch. Both approaches share a foundational assumption that scaling up model capacity and data volume leads to improved performance. However, we observe a scaling paradox in TS models, revealing a puzzling phenomenon that larger models do NOT always achieve better performance. Through extensive experiments on two model families across four scales (100M to 1.7B parameters) and diverse data (up to 6B observations), we rigorously confirm that the scaling paradox is a pervasive issue. We then diagnose its root cause by analyzing internal representations, identifying a phenomenon we call few-layer dominance: only a small subset of layers are functionally important, while the majority are redundant, under-utilized, and can even distract training. Based on this discovery, we propose a practical method to automatically identify and retain only these dominant layers. In our models, retaining only 21% of the parameters achieves up to a 12% accuracy improvement and a 2.7x inference speedup. We validate the universality of our method on 8 prominent SOTA models (LLM4TS and TSFMs, 90M to 6B), showing that retaining less than 30% layers achieves superior accuracy in over 95% tasks.

Dream-MPC: Gradient-Based Model Predictive Control with Latent Imagination

Jonathan Spieler, Sven Behnke

State-of-the-art model-based Reinforcement Learning (RL) approaches either use gradient-free, population-based methods for planning, learned policy networks, or a combination of policy networks and planning. Hybrid approaches that combine Model Predictive Control (MPC) with a learned model and a policy prior to leverage the advantages of both paradigms have shown promising results. However, these approaches typically rely on gradient-free optimization methods, which can be computationally expensive for high-dimensional control tasks. While gradient-based methods are a promising alternative, recent works have empirically shown that gradient-based methods often perform worse than their gradient-free counterparts. We propose Dream-MPC, a novel approach that generates few candidate trajectories from a rolled-out policy and optimizes each trajectory by gradient ascent using a learned world model, uncertainty regularization and amortization of optimization iterations over time by reusing previously optimized actions. Our results on 24 continuous control tasks show that Dream-MPC can significantly improve the performance of the underlying policy and can outperform gradient-free MPC and state-of-the-art baselines. Code and videos are available at https://dream-mpc.github.io.

How Does Reasoning Flow? Tracing Attention-Induced Information Flow for Targeted RL in LLMs

Zhichen Dong, Yang Li, Yuhan Sun, Weixun Wang, Yijia Luo, Zinian Peng, Wenbo Su,

Cheng Yu, Bo Zheng, Junchi Yan
Token-level credit assignment remains a key obstacle for reinforcement learning (RL) in large language models (LLMs), where RL recipes typically treat all tokens equally, failing to distinguish decisive reasoning steps from routine formatting or fluent filler. Recent attempts leverage model-internal signals to assign finer-grained credit, but these are often point-wise heuristics that ignore the global structure of information propagation. We propose FlowTracer, an RL framework that traces answer-targeted reasoning flow on an attention-induced directed acyclic graph in which nodes correspond to tokens and edge capacities come from aggregated attention weights and derives token credit from this global structure. The edge capacities are reweighted to retain only the influence that can reach the answer region, while enforcing local flow conservation so intermediate tokens neither lose nor gain effective mass due to path length or irrelevant branches. On this graph, FlowTracer extracts an information-flow backbone connecting the question to the answer and scores tokens by flow throughput, revealing high-impact hubs and aggregation checkpoints that mediate long-range dependencies. These derived importances are used to shape token-level rewards, enabling learning signals to focus precisely on the tokens that route information toward (or away from) correct answers and delivering consistent performance gains across a range of reasoning tasks.

Block-wise Codeword Embedding for Reliable Multi-bit Text Watermarking
Joeun Kim, HoEun Kim, Dongsup Jin, Young-Sik Kim
Recent multi-bit watermarking methods for large language models (LLMs) prioritize capacity over reliability, often conflating decoding with detection. Our analysis reveals that existing ECC-based extractors suffer from catastrophic false positive rates (FPR), and applying rejection thresholds merely collapses detection sensitivity (TPR) to random guessing. To resolve this structural limitation, we propose **BREW** (Block-wise Reliable Embedding for Watermarking), a framework shifting the paradigm to *designated verification*. BREW employs a two-stage mechanism: (i) **blind message estimation** via independent block voting, followed by (ii) **window-shifting verification** that rigorously validates the payload against local edits. Experiments demonstrate that BREW achieves a TPR of 0.965 with an FPR of 0.02 under 10\% synonym substitution, demonstrating that the high-FPR issue is not an inherent trade-off of multi-bit watermarking, but a solvable structural flaw of prior decoding-centric designs. Our framework is model-agnostic and theoretically grounded, providing a scalable solution for reliable forensic deployment.

Flow Sampling : Learning to Sample from Unnormalized Densities via Denoising Conditional Processes
Aaron J Havens, Brian Karrer, Neta Shaul
Sampling from unnormalized densities is analogous to the generative modeling problem, but the target distribution is defined by a known energy function instead of data samples. Because evaluating the energy function is often costly, a primary challenge is to learn an efficient sampler. We introduce Flow Sampling, a framework built on diffusion models and flow matching for the data-free setting. Our training objective is conditioned on a noise sample and regresses onto a denoising diffusion drift constructed from the energy function. In contrast, diffusion models' objective is conditioned on a data sample and regresses onto a noising diffusion drift. We utilize the interpolant process to minimize the number of energy function evaluations during training, resulting in an efficient and scalable method for sampling unnormalized densities. Furthermore, our formulation naturally extends to Riemannian manifolds, enabling diffusion-based sampling in geometries beyond Euclidean space. We derive a closed-form formula for the conditional drift on constant curvature manifolds, including hyperspheres and hyperbolic spaces. We evaluate Flow Sampling on synthetic energy benchmarks, small peptides, large-scale amortized molecular conformer generation, and distributions supported on the sphere, demonstrating strong empirical performance.

Long-term Fairness with Selective Labels
Giovani Valdrighi, Isabel Valera, Marcos M. Raimundo
Long-term fairness algorithms aim to satisfy fairness beyond static and short-te rm notions by accounting for the dynamics between decision-making policies and p opulation behavior. Most previous approaches evaluate performance and fairness m easures from observable features and a label, which is assumed to be fully obser ved. However, in scenarios such as hiring or lending, the labels (e.g., ability to repay the loan) are _selective labels_ as they are only revealed based on pos itive decisions (e.g., when a loan is granted). In this paper, we study long-ter m fairness in the selective labels setting and analytically show that naive solu tions do not guarantee fairness. To address this gap, we then introduce a novel framework that leverages both the observed data and a label predictor model to e stimate the true fairness measure value by decomposing it into the observed fair ness and bias from label predictions. This allows us to derive sufficient condi tions to satisfy true fairness from observable quantities by using the confidenc e in the predictor model. Finally, we rely on our theoretical results to propo se a novel reinforcement learning algorithm for effective long-term fair decisio n-making with selective labels. In semisynthetic environments, the proposed algo rithm reached comparable fairness and performance to an agent with oracle access to the true labels.

Revisiting Positive Samples in Graph Contrastive Learning: From the Perspective of Message Passing
Lianze Shan, Ningchong Wang, Jitao Zhao, Di Jin, Dongxiao He
Graph Contrastive Learning (GCL), which trains graph encoders by maximizing simi larity between positive samples and minimizing it between negative ones, has eme rged as a mainstream graph pre-training paradigm. It is widely recognized that p ositive samples are essential in GCLs. Ideally, maximizing the similarity of pos itive samples enables graph encoders to capture intrinsic semantic and patterns of graph data. However, we discover an interesting phenomenon: GCLs can achieve competitive performance even without positive samples. This motivates us to revi sit the fundamental mechanism of positive samples in GCLs. From the perspective of Dirichlet energy, we theoretically finds that message passing, a key mechanis m in graph encoders, trivializes the maximization of positive samples, preventin g GCLs from effectively learning from positive samples. To address this, we prop ose SPGCL to mitigate the trivialization caused by message passing and restore t he learning efficacy of positive samples. Specifically, we find that high Dirich let energy features help positive samples provide effective learning signals whi le low Dirichlet energy features contribute little to positive learning signal b ut is useful for positive sampling. Based on this, SPGCL propagates only high Di richlet energy features and uses low energy features to construct a probability matrix for reliable positive sampling. Extensive experiments demonstrate the eff ectiveness of SPGCL.

Decompose and Recompose: Reasoning New Skills from Existing Abilities for Cross-Task Robotic Manipulation
Xitie Zhang, Aming WU, Yahong Han
Cross-task generalization is a core challenge in open-world robotic manipulation , and the key lies in extracting transferable manipulation knowledge from seen t asks. Recent in-context learning approaches leverage seen task demonstrations to generate actions for unseen tasks without parameter updates. However, existing methods provide only low-level continuous action sequences as context, failing t o capture composable skill knowledge and causing models to degenerate into super ficial trajectory imitation. We propose Decompose and Recompose, a skill reasoni ng framework using atomic skill-action pairs as intermediate representations. Ou r approach decomposes seen demonstrations into interpretable skill--action align ments, enabling the model to recompose these skills for unseen tasks through com positional reasoning. Specifically, we construct a task-adaptive dynamic demonst ration library via visual-semantic retrieval combined with skill sequences from a planning agent, complemented by a coverage-aware static library to fill missin

g skill patterns. Together, these yield skill-comprehensive demonstrations that explicitly elicit compositional reasoning for skill composition and execution ordering. Experiments on the AGNOSTOS benchmark and real-world environments validate our method's zero-shot cross-task generalization capability.

LimiX-2M: Mitigating Low-Rank Collapse and Attention Bottlenecks in Tabular Foundation Models
Yuanrui Wang, Xingxuan Zhang, Han Yu, Mingchao Hao, Gang Ren, Hao Yuan, Li Mao, Yunjia Zhang, Chun Yuan, Peng Cui
Tabular foundation models (TFMs) increasingly rival tree ensembles, but their performance is often compute-inefficient: with standard affine scalar tokenization, each feature injects value variation through an essentially one-dimensional channel, and feature IDs/positional signals cannot increase within-feature value degrees of freedom, yielding weak early-layer value sensitivity and redundant hidden states.
We present a unified tokenize-and-route framework for strong TFMs: RaBEL expands each scalar into compact localized RBF features (optionally exponent-gated) to improve conditioning and shallow-layer effective rank, while a reordered bidirectional block $\textbf{S$\rightarrow$N$\rightarrow$F}$ aligns computation with the readout by aggregating cross-sample context before feature mixing and using attention pooling.
Together, these changes yield $\textbf{LimiX-2M}$, a 2M-parameter model that outperforms larger TabPFN-v2 and TabICL baselines on widely used tabular benchmarks while reducing training and inference costs. These results highlight value-aware tokenization and readout-aligned routing as key levers for improving the accuracy--efficiency trade-off in TFMs. Model checkpoints and inference code are available at https://github.com/limix-ldm-ai/LimiX.

Unveiling Prior-Data Fitted Networks on Causal Effect Estimation: Pre-Training or Fine-Tuning?
Haotian Wang, Xinpeng Lv, Hao Zou, Yanghao Xiao, Shanzhi Gu, Yang Shi, Yunxin Mao, Yuanxing Zhang, Mingyang Geng, Shaowu Yang, Haoxuan Li, Wenjing Yang, Peng Cui, Zhouchen Lin
Amortized causal inference via Prior-data Fitted Networks (PFNs) has emerged as a promising paradigm, enabling zero-shot estimation of causal effects without the need for dataset-specific model tuning. However, the principled effectiveness of unified pre-training across general interventional regimes remains an underexplored question. In this paper, we investigate interventions on subsets of variables within Structural Causal Models (SCMs) and identify a fundamental theoretical limitation of current pre-training approaches. Theoretically, we prove that a single observational SCM induces an exponentially large space of interventional distributions, resulting in a phenomenon we term prior uncoverage. Consequently, this uncoverage yields a mismatch between the learned meta-prior and the true grounding prior, leading to unavoidable posterior inconsistency and estimation bias. To address this, we posit that fine-tuning is a fundamental necessity and propose a target-specific strategy named Point-Wise Interventional Fine-tuning (PWF), enabling the local generalization property. We further scale this approach via Meta-Sampling Fine-tuning (MSF) from a budgeted active learning perspective, thereby achieving uniform generalization on any interventional distribution.
****
Replay Failures as Successes: Sample-Efficient Reinforcement Learning for Instruction Following
Kongcheng Zhang, QI YAO, Shunyu Liu, Wenjian Zhang, Min Cen, Yang Zhou, Wenkai Fang, Yiru Zhao, Baisheng Lai, Mingli Song
Reinforcement Learning (RL) has shown promise for aligning Large Language Models (LLMs) to follow instructions with various constraints. Despite the encouraging results, RL improvement inevitably relies on sampling successful, high-quality responses; however, the initial model often struggles to generate responses that satisfy all constraints due to its limited capabilities, yielding sparse or indistinguishable rewards that impede learning. In this work, we propose ***H**inds

ight **i**nstruction **R**eplay* (HiR), a novel sample-efficient RL framework fo r complex instruction following tasks, which employs a *select*-then-*rewrite* s trategy to *replay failed attempts as successes* based on the constraints that h ave been satisfied in hindsight. We perform RL on these replayed samples as well as the original ones, theoretically framing the objective as dual-preference le arning at both the instruction- and response-level to enable efficient optimizat ion using only a binary reward signal. Extensive experiments demonstrate that th e proposed HiR yields promising results across different instruction following t asks, while requiring less computational budget. Our code and dataset are availa ble at https://github.com/sastpg/HIR.

Automata-Conditioned Cooperative Multi-Agent Reinforcement Learning
Beyazit Yalcinkaya, Marcell Vazquez-Chanlatte, Ameesh Shah, Hanna Krasowski, San jit A. Seshia
We study learning multi-task, multi-agent policies for cooperative, temporal obj ectives, under centralized training, decentralized execution. In this setting, u sing automata to represent tasks assigned to agents enables breaking down a team -level objective into simpler, smaller sub-tasks. However, existing approaches r emain sample-inefficient and are limited to the single-task case, requiring retr aining policies for each new task. In this work, we present Automata-Conditioned Cooperative Multi-Agent Reinforcement Learning (ACC-MARL), a framework for lear ning task-conditioned, decentralized team policies. We identify challenges to th e feasibility of ACC-MARL, propose solutions, and prove that our approach is opt imal. We further show that learned value functions can be used to assign tasks o ptimally at test time. Experiments demonstrate emergent task-aware, multi-step c oordination among agents, such as pressing a button to unlock a door, holding th e door, and short-circuiting tasks.
