Obtaining high-quality labeled datasets is often costly, requiring either human annotation or expensive experiments. In theory, powerful pre-trained AI models p rovide an opportunity to automatically label datasets and save costs. Unfortunat ely, these models come with no guarantees on their accuracy, making wholesale re placement of manual labeling impractical. In this work, we propose a method for leveraging pre-trained AI models to curate cost-effective and high-quality datas ets. In particular, our approach results in probably approximately correct label s: with high probability, the overall labeling error is small. Our method is non asymptotically valid under minimal assumptions on the dataset or the AI model be ing studied, and thus enables rigorous yet efficient dataset curation using mode rn AI models. We demonstrate the benefits of the methodology through text annota tion with large language models, image labeling with pre-trained vision models, and protein folding analysis with AlphaFold.

Dual Latent Memory for Visual Multi-agent System
Xinlei Yu, Chengming Xu, Zhangquan Chen, Bo Yin, Cheng Yang, Yongbo He, Yihao Hu , Jiangning Zhang, Cheng Tan, Xiaobin Hu, Shuicheng YAN
While Visual Multi-Agent Systems (VMAS) promise to enhance comprehensive abiliti es through inter-agent collaboration, empirical evidence reveals a counter-intui tive "scaling wall": increasing agent turns often degrades performance while exp onentially inflating token costs. We attribute this failure to the information b ottleneck inherent in text-centric communication, where converting perceptual an d thinking trajectories into discrete natural language inevitably induces semant ic loss. To this end, we propose L^{2}-VMAS, a novel model-agnostic framework that enables inter-agent collaboration with dual latent memories. Based on such a design, we decouple the perception and thinking while dynamically synthesizing dual latent memories. Additionally, we introduce an entropy-driven proactive tr iggering that replaces passive information transmission with efficient, on-deman d memory access. Extensive experiments among backbones, sizes, and multi-agent s tructures demonstrate that our method effectively breaks the "scaling wall" with

superb scalability, improving average accuracy by 2.7-5.4% while reducing total token usage by 21.3-44.8%. The codes will be publicly released.

DANCE: Dynamic, Available, Neighbor-gated Condensation for Federated Text-Attributed Graphs
Zekai Chen, Haodong Lu, Xunkai Li, Henan Sun, Jia Li, Hongchao Qin, Rong-Hua Li, Guoren Wang
Federated graph learning (FGL) enables collaborative training on graph data across multiple clients. With the rise of large language models (LLMs), textual attributes in FGL graphs are gaining attention. Text-attributed graph federated learning (TAG-FGL) improves FGL by explicitly leveraging LLMs to process and integrate these textual features.
However, current TAG-FGL methods face three main challenges:
\textbf{(1) Overhead.} LLMs for processing long texts incur high token and computation costs. To make TAG-FGL practical, we introduce graph condensation (GC) to reduce computation load, but this choice also brings new issues.
\textbf{(2) Suboptimal.}
To reduce LLM overhead, we introduce GC into TAG-FGL by compressing multi-hop texts/neighborhoods into a condensed core with fixed LLM surrogates (summaries/embeddings).
However, this one-shot condensation is often not client-adaptive, leading to suboptimal performance.
\textbf{(3) Interpretability.}
LLM-based condensation further introduces a black-box bottleneck: summaries lack faithful attribution and clear grounding to specific source spans, making local inspection and auditing difficult.
To address the above issues, we propose \textbf{DANCE}, a new TAG-FGL paradigm with GC. To improve \textbf{suboptimal} performance, DANCE performs round-wise, model-in-the-loop condensation refresh using the latest global model. To enhance \textbf{interpretability}, DANCE preserves provenance by storing locally inspectable evidence packs that trace predictions to selected neighbors and source text spans.
Across 8 TAG datasets, DANCE improves accuracy by \textbf{2.33\%} at an \textbf{8\%} condensation ratio, with \textbf{33.42\%} fewer tokens per condensed node than TAG-FGL baselines.

Efficient Multi-modal Dataset Distillation via Analytic Parameter Matching
Deyu Bo, Xinchao Wang
Multi-modal dataset distillation (MDD) seeks to compress large-scale multi-modal datasets into a compact set of synthetic pairs. Existing methods employ a dual-trajectory matching framework to align the teacher and student models within each modality. While effective, this paradigm incurs non-negligible memory and computational overhead due to the checkpoint storage and bi-level optimization over synthetic data. To address these limitations, we propose analytic parameter matching (APM), which theoretically derives the analytic parameters of modal projectors to replace the inner-loop optimization, and then aligns the analytic projector parameters of teacher and student models. APM offers two key advantages: (1) it replaces checkpoint-intensive storage with only two cached matrices, significantly reducing memory consumption; and (2) it computes analytic parameters in a single forward pass, thereby avoiding costly bi-level optimization. Empirically, APM achieves up to 65$\times$ storage reduction and 9.6$\times$ faster distillation, while scaling to 1,000 synthetic pairs. Extensive experiments on image-text and audio-text benchmarks demonstrate the effectiveness of APM in cross-modal retrieval tasks, e.g., 12.8 IR@1 and 17.8 TR@1 in Flickr30k with 100 synthetic pairs. Moreover, APM exhibits notable generalization performance in cross-architecture evaluation and zero-shot classification tasks.

Incentivizing Truthfulness and Collaborative Fairness in Bayesian Learning
Rachael Hwee Ling Sim, Jue Fan, Xiao Tian, Xinyi Xu, Patrick Jaillet, Bryan Kian Hsiang Low

Collaborative machine learning involves training high-quality models using datas
ets from a number of sources.
To incentivize sources to share data, existing data valuation methods fairly rew
ard each source based on its data submitted as is. However, as these methods do
not verify nor incentivize data truthfulness, the sources can manipulate their d
ata (e.g., by submitting duplicated or noisy data) to artificially increase thei
r valuations and rewards or prevent others from benefiting. This paper presents
the first mechanism that provably ensures (**F**) collaborative fairness and inc
entivizes (**T**) truthfulness at equilibrium for Bayesian models. Our mechanism
 combines semivalues (e.g., Shapley value), which ensure fairness, and a truthfu
l data valuation function (DVF) based on a validation set that is unknown to the
 sources. As semivalues are influenced by others' data, we introduce an addition
al condition to prove that a source can maximize its expected data values in coa
litions and semivalues by submitting a dataset that captures its true knowledge.
Additionally, we discuss the implications and suitable relaxations of (**F**) an
d (**T**) when the mediator has a limited budget for rewards or lacks a validati
on set.
Our theoretical findings are validated on synthetic and real-world datasets.

DocVAL: Validated Chain-of-Thought Distillation for Grounded Document VQA
Pinaki Prasad Guha Neogi, Ahmad Mohammadshirazi, Ser-Nam Lim, Rajiv Ramnath
Document visual question answering requires models not only to answer questions
correctly, but also to precisely localize answers within complex document layout
s. While large vision-language models (VLMs) achieve strong spatial grounding, t
heir inference cost and latency limit real-world deployment; on the other hand,
compact VLMs are efficient but suffer substantial localization degradation under
 standard fine-tuning or distillation. To address this gap, we propose **DocVAL*
*, a validated chain-of-thought (CoT) distillation framework that transfers expl
icit spatial reasoning from large teacher models to compact, deployable student
VLMs. DocVAL combines **(1)** teacher-generated spatial CoT supervision, **(2)**
 a rule-based dual-mode validator that filters low-quality training signals and
provides fine-grained, pixel-level corrective feedback, and **(3)** a validation
-driven two-stage training procedure with iterative refinement. Text detection i
s used only as training-time scaffolding for supervision and validation, enablin
g the final student to operate as a pure VLM without OCR or detection at inferen
ce. Across multiple document understanding benchmarks, the proposed **DocVAL** y
ields consistent improvements of up to **6-7 ANLS** points over comparable compa
ct VLMs. We further introduce mean Average Precision (mAP) as a localization met
ric for document question answering and report strong spatial grounding performa
nce under this new evaluation. We release **95K validator-verified CoT traces**
and show that high-quality, validated supervision is more effective than scaling
 unfiltered data, enabling efficient and trustworthy document grounding. Code/Da
ta: [GitHub](https://github.com/ahmad-shirazi/DocVAL).

Coupled Variational Reinforcement Learning for Language Model General Reasoning
Xueru Wen, Jie Lou, Yanjiang Liu, Hongyu Lin, Ben He, Xianpei Han, Le Sun, Yaoji
e Lu, Debing Zhang
While reinforcement learning has achieved impressive progress in language model
reasoning, it is constrained by the requirement for verifiable rewards.
Recent verifier-free RL methods address this limitation by utilizing the probabi
lities that LLMs generate reference answers as reward signals.
However, these approaches typically sample reasoning traces conditioned only on
the question.
This design decouples reasoning-trace sampling from answer information, leading
to inefficient exploration and incoherence between traces and final answers.
In this paper, we propose \textit{\b{Co}upled \b{V}ariational \b{R}einforcement
\b{L}earning} (CoVRL), which bridges variational inference and reinforcement lea
rning by coupling prior and posterior distributions through a hybrid sampling st
rategy.
By constructing and optimizing a composite distribution that integrates these tw

o distributions, CoVRL enables efficient exploration while preserving strong tho
ught-answer coherence.
Extensive experiments on mathematical and general reasoning benchmarks show that
 CoVRL improves performance by 12.4\% over the base model and achieves an additi
onal 2.3\% improvement over state-of-the-art verifier-free RL baselines, providi
ng a principled framework for enhancing the general reasoning capabilities of la
nguage models.

Unsat Core Prediction through Polarity-Aware Representation Learning over Clause
-Literal Hypergraphs

Zhenchao Sun, Shuai Ma, Ping Lu, Chongyang Tao

Graph neural networks have been widely used in Boolean satisfiability (SAT) task
s to learn structural information from SAT formulas. The goal of these studies
is to solve SAT instances or to enhance SAT solvers, including tasks such as uns
at-core prediction. However, most existing approaches model a SAT formula as a b
ipartite graph or a directed acyclic graph, which are less direct in capturing
clause-level and higher-order interactions among literals and clauses. Moreover,
 these approaches are limited in modeling intrinsic polarity-related properties
of SAT, such as the complementary relationship between the positive and negativ
e literals of a variable. To address these limitations, we propose a polarity-aw
are representation learning framework over clause-literal hypergraphs. We model
 SAT formulas as clause-literal hypergraphs augmented with a clause incidence gr
aph to capture higher-order structural interactions. We then introduce a polari
ty-aware decomposition mechanism that separates variable representations into po
larity invariant and equivariant components, explicitly modeling the relationshi
p between positive and negative literals, with the resulting literal representat
ions propagated along the hypergraph structure. We further incorporate a polari
ty-inversion consistency regularization to reinforce polarity-consistent repres
entations during training. Experimental results on multiple SAT datasets demonst
rate the effectiveness of the proposed approach.

Optimal Quantum Speedups for Repeatedly Nested Expectation Estimation

Yihang Sun, Guanyang Wang, Jose Blanchet

We study the estimation of repeatedly nested expectations (RNEs) with a constant
 horizon (number of nestings) using quantum computing. We propose a quantum algo
rithm that achieves ε-error with cost $\tilde O(\varepsilon^{-1})$,
up to logarithmic factors. Standard lower bounds show this scaling is essentiall
y optimal, yielding an almost quadratic speedup over the best classical algorith
m. Our results extend prior quantum speedups for single nested expectations to r
epeated nesting, and therefore cover a broader range of applications, including
optimal stopping. This extension requires a new derandomized variant of the clas
sical randomized Multilevel Monte Carlo (rMLMC) algorithm. Careful de-randomizat
ion is key to overcoming a variable-time issue that typically increases quantize
d versions of classical randomized algorithms.

Dynamic Decision Learning: Test-Time Evolution for Abnormality Grounding in Rare
 Diseases

Jun Li, Mingxuan Liu, Jiazhen Pan, Che Liu, Wenjia Bai, Cosmin I. Bercea, Julia
Schnabel

Clinical abnormality grounding for rare diseases is often hindered by data scarc
ity, rendering supervised fine-tuning infeasible and single-pass inference highl
y unstable. Thus, we propose Dynamic Decision Learning (DDL), a framework that e
nables frozen LVLMs to refine their decisions across language and visual spaces
by optimizing instructions and consolidating predictions under visual perturbati
ons, thereby improving localization quality and producing a consensus-based reli
ability score that quantifies the model’s confidence. Results on brain-imaging b
enchmarks, including a rare-disease dataset with 281 pathology types across 3B–7
2B models, show that DDL improves mAP@75 by up to 105% on rare-disease cases and
 surpasses adaptation baselines and supervised fine-tuning. Moreover, we show th
at DDL yields stronger calibration between consensus-based reliability scores an

d localization accuracy under severe distribution shifts and increasing task dif
ficulty. The code is available at https://github.com/compai-lab/2026-ICML-DDL .

SENDAI: A Hierarchical Sparse-measurement, EfficieNt Data AssImilation Framework
Xingyue Zhang, Yuxuan Bao, Mars Liyao Gao, J. Nathan Kutz
Bridging the gap between data-rich training regimes and observation-sparse deplo
yment conditions remains a central challenge in spatiotemporal field reconstruct
ion, particularly when target domains exhibit distributional shifts, heterogeneo
us structure, and multi-scale dynamics absent from available training data. We p
resent SENDAI, a hierarchical $\textbf{S}$parse-measurement, $\textbf{E}$fficie$
\textbf{N}$t $\textbf{D}$ata $\textbf{A}$ss$\textbf{I}$milation Framework that r
econstructs full spatial states from hyper sparse sensor observations by combini
ng simulation-derived priors with learned discrepancy corrections. We demonstrat
e the performance on satellite remote sensing, reconstructing MODIS (Moderate Re
solution Imaging Spectroradiometer) derived vegetation index fields across six
globally distributed sites. Using seasonal periods as a proxy for domain shift,
the framework consistently outperforms established baselines that require substa
ntially denser observations---SENDAI achieves a maximum SSIM improvement of 185%
 over traditional baselines and a 36% improvement over recent high-frequency-bas
ed methods. These gains are particularly pronounced for landscapes with sharp bo
undaries and sub-seasonal dynamics; more importantly, the framework effectively
preserves diagnostically relevant structures---such as field topologies, land co
ver discontinuities, and spatial gradients. By yielding corrections that are mor
e structurally and spectrally separable, the reconstructed fields are better sui
ted for downstream inference of indirectly observed variables. The results there
fore highlight a lightweight and operationally viable framework for sparse-measu
rement reconstruction that is applicable to physically grounded inference, resou
rce-limited deployment, and real-time monitor and control.

Evaluating and Rewarding LALMs for Expressive Role-Play TTS via Mean Continuatio
n Log-Probability
Yong Ren, Jingbei Li, Haiyang Sun, Yujie Chen, Cheng Yi, Yechang Huang, Hao Gu,
Ye Bai, Xuerui Yang
Recent advances in Large Audio Language Models (LALMs) have extended Text-to-Spe
ech (TTS) to interactive role-play scenarios, which demand high expressiveness a
nd strict adherence to role-play instructions. However, existing models struggle
 to maintain stylistic consistency with character profiles and scene description
s across multi-turn dialogues. A critical bottleneck is the lack of objective me
trics for quantifying speaking style. To bridge this gap, we propose **Mean Cont
inuation Log-Probability (MCLP)** as both an evaluation metric and a reward sign
al, validated on LALM-based Role-Play TTS (RP-TTS) tasks. MCLP leverages the in-
context learning capability of pretrained LALMs to measure the likelihood of gro
und-truth speech tokens conditioned on a contextual history consisting of the tr
anscript, generated speech, and repeated transcript, serving as a proxy for styl
istic continuity. Furthermore, we employ MCLP as a reinforcement learning reward
 to enhance the style alignment between generated speech and role-play instructi
ons. To support this task, we construct a large-scale RP-TTS dataset with rich s
cene and character annotations. Experiments demonstrate that MCLP is well aligne
d with human judgments of stylistic consistency and serves as an effective rewar
d for improving RP-TTS, leading to consistent gains in both objective metrics an
d subjective evaluations. Our code is publicly available at https://github.com/y
-ren16/MCLP.

RSAgent: Learning to Reason and Act via Multi-Turn Tool Invocations for Text-Gui
ded Segmentation
Xingqi He, Yujie Zhang, Shuyong Gao, Wenjie Li, Lingyi Hong, Mingxi Chen, Kaixun
 Jiang, Jiyuan Fu, Wenqiang Zhang
Text-guided object segmentation requires both cross-modal reasoning and pixel gr
ounding abilities. Most recent methods treat it as a single forward pass, where
the model directly predicts pixel prompts to a segmentation model, which limits

verification, refocusing and refinement when initial localization is wrong. To address this limitation, we propose **RSAgent**, an agentic Multimodal Large Language Model (MLLM) which interleaves **reasoning and action** for segmentation via a multi-turn tool invocations. RSAgent queries a visual toolbox, observes feedback, and revises its pixel hypothesis using historical observations to re-localize targets and iteratively refine masks. We further build a data pipeline to synthesize multi-turn reasoning segmentation trajectories, and train RSAgent with a two-stage framework: cold-start supervised fine-tuning followed by agentic reinforcement learning with fine-grained, task-specific rewards.
Extensive experiments show that RSAgent achieves a zero-shot performance of 66.5% gIoU on ReasonSeg test, improving over Seg-Zero-7B by 9%, and reaches 81.5% cIoU on RefCOCOg, demonstrating state-of-the-art performance on both in-domain and out-of-domain benchmarks.

Resource-Efficient Reinforcement for Reasoning Large Language Models via Dynamic One-Shot Policy Refinement
Yunjian Zhang, Sudong Wang, Yang Li, Peiran Xu, Conghao Zhou, Xiaoyue Ma, Jianing Li, Yao Zhu
Large language models (LLMs) have exhibited remarkable performance on complex reasoning tasks, with reinforcement learning under verifiable rewards (RLVR) emerging as a principled framework for aligning model behavior with reasoning chains. Despite its promise, RLVR remains prohibitively resource-intensive, requiring extensive reward signals and incurring substantial rollout costs during training. In this work, we revisit the fundamental question of data and compute efficiency in RLVR. We first establish a theoretical lower bound on the sample complexity required to unlock reasoning capabilities, and empirically validate that strong performance can be achieved with a surprisingly small number of training instances. To tackle the computational burden, we propose Dynamic One-Shot Policy Refinement (DoPR), a uncertainty-aware RL strategy that dynamically selects a single informative training sample per batch for policy updates, guided by reward volatility and exploration-driven acquisition. DoPR reduces rollout overhead by nearly an order of magnitude while preserving competitive reasoning accuracy, offering a scalable and resource-efficient solution for LLM post-training. This approach offers a practical path toward more efficient and accessible RL-based training for reasoning-intensive LLM applications.
****

Graph-R1: Towards Agentic GraphRAG Framework via End-to-end Reinforcement Learning
Haoran Luo, Haihong E, Guanting Chen, Qika Lin, Yikai Guo, Fangzhi Xu, Zemin Kuang, Meina Song, Xiaobao Wu, Yifan Zhu, Anh Tuan Luu
Retrieval-Augmented Generation (RAG) mitigates hallucination in LLMs by incorporating external knowledge, but relies on chunk-based retrieval that lacks structural semantics. GraphRAG methods improve RAG by modeling knowledge as entity-relation graphs, but still face challenges in high construction cost, fixed one-time retrieval, and reliance on long-context reasoning and prompt design. To address these challenges, we propose Graph-R1, the first agentic GraphRAG framework via end-to-end reinforcement learning (RL). It introduces lightweight knowledge hypergraph construction, models retrieval as a multi-turn agent-environment interaction, and optimizes the agent process via an end-to-end reward mechanism. Experiments on standard RAG datasets show that Graph-R1 outperforms traditional GraphRAG and RL-enhanced RAG methods in reasoning accuracy, retrieval efficiency, and generation quality. Our software and data are publicly available.

Sparser, Faster, Lighter Transformer Language Models
Edoardo Cetin, Stefano Peluchetti, Emilio Castillo, Akira Naruse, Mana Murakami, Llion Jones
Scaling autoregressive large language models (LLMs) has driven unprecedented progress but comes with vast computational costs. In this work, we tackle these costs by leveraging unstructured sparsity within an LLM's feedforward layers, the components accounting for most of the model parameters and execution FLOPs. To ac

hieve this, we introduce a new sparse packing format and a set of CUDA kernels d
esigned to seamlessly integrate with the optimized execution pipelines of modern
 GPUs, enabling efficient sparse computation during LLM inference and training.
To substantiate our gains, we provide a quantitative study of LLM sparsity, demo
nstrating that simple L1 regularization can induce over 99% sparsity with neglig
ible impact on downstream performance. When paired with our kernels, we show tha
t these sparsity levels translate into substantial throughput, energy efficiency
, and memory usage benefits that increase with model scale. We will release all
code and kernels under an open-source license to promote adoption and accelerate
 research toward establishing sparsity as a practical axis for improving the eff
iciency and scalability of modern foundation models.
****
Agent-Omit: Adaptive Context Omission for Efficient LLM Agents
Yansong Ning, Jun Fang, Naiqiang Tan, Hao Liu
Managing agent context (e.g., thought and observation) during multi-turn
agent-environment interactions is an emerging strategy to improve agent efficien
cy.
However, existing studies treat the entire interaction trajectories equally, ove
rlooking the thought necessity and observation utility varies across turns.
To this end, we first conduct quantitative investigations into how thought and o
bservation affect agent effectiveness and efficiency.
Based on our findings, we propose Agent-Omit, a unified training framework that
empowers LLM agents to adaptively omit redundant thoughts and observations.
Specifically, we first synthesize a small amount of cold-start data, including b
oth single-turn and multi-turn omission scenarios, to fine-tune the agent for om
ission behaviors.
Furthermore, we introduce an omit-aware agentic reinforcement learning approach,
 incorporating a dual sampling mechanism and a tailored omission reward to incen
tivize the agent's adaptive omission capability.
Theoretically, we prove that the deviation of our omission policy is upper-bound
ed by KL-divergence.
Experimental results on five agent benchmarks show that our constructed Agent-Om
it-8B could obtain performance comparable to seven frontier LLM agent, and achie
ve the best effectiveness-efficiency trade-off than seven efficient LLM agents m
ethods.
Our code and data are avaliable at https://github.com/usail-hkust/Agent-Omit.
****
Rethinking LLM Ensembling from the Perspective of Mixture Models
Jiale Fu, Yuchu Jiang, PeiJun WU, Chonghan Liu, Joey Tianyi Zhou, Xu Yang
Model ensembling is a well-established technique for improving the performance o
f machine learning models. Conventionally, this involves averaging the output di
stributions of multiple models and selecting the most probable label. This idea
has been naturally extended to large language models (LLMs), yielding improved p
erformance but incurring substantial computational cost. This inefficiency stems
 from directly applying conventional ensemble implementation to LLMs, which requ
ire a separate forward pass for each model to explicitly compute the ensemble di
stribution. In this paper, we propose the Mixture-model-like Ensemble (ME). By r
einterpreting the ensemble as a mixture model, ME stochastically selects a singl
e model at each step to generate the next token, thereby avoiding the need to ex
plicitly compute the full ensemble distribution. ME is mathematically equivalent
 to sampling from the ensemble distribution, but requires invoking only one mode
l, making it 1.78×-2.68× faster than conventional ensembling. Furthermore, this
perspective connects LLM ensembling and token-level routing methods, suggesting
that LLM ensembling is a special case of routing methods. Our findings open new
avenues for efficient LLM ensembling and motivate further exploration of token-l
evel routing strategies for LLMs. Our code is available at https://github.com/Ka
michanw/Mixture-model-like-Ensemble.

Harnessing Uncertainty: Entropy-Modulated Policy Gradients for Long-Horizon LLM
Agents

Jiawei Wang, Jiacai Liu, Yuqian Fu, Yingru Li, Xintao Wang, Yuan Lin, Yu Yue, Lin Zhang, Yang Wang, WANG KE

In long-horizon tasks, recent agents based on Large Language Models (LLMs) face a significant challenge that sparse, outcome-based rewards make it difficult to assign credit to intermediate steps. Previous methods mainly focus on creating dense reward signals to guide learning, either through traditional reinforcement learning techniques like inverse reinforcement learning or by using Process Reward Models for step-by-step feedback. In this paper, we identify a fundamental problem in the learning dynamics of LLMs: the magnitude of policy gradients is inherently coupled with the entropy, which leads to inefficient small updates for confident correct actions and potentially destabilizes large updates for uncertain ones. To resolve this, we propose Entropy-Modulated Policy Gradients (EMPG), a framework that recalibrates the learning signal based on step-wise uncertainty and the final task outcome. EMPG amplifies updates for confident correct actions, penalizes confident errors, and attenuates updates from uncertain steps to stabilize exploration. We further introduce a bonus term for future clarity that encourages agents to find more predictable solution paths. Through comprehensive experiments on three challenging agent tasks, WebShop, ALFWorld, and Deep Search, we demonstrate that EMPG achieves substantial performance gains and significantly outperforms strong policy gradient baselines.

ProAct: A Benchmark and Multimodal Framework for Structure-Aware Proactive Response

Xiaomeng Zhu, Fengming ZHU, Weijie Zhou, Ye Tian, Zhenlin Hu, Yufei Huang, Yuchun Guo, Xinyu Wu, Zhengyou Zhang, Fangzhen Lin, Xuantang Xiong

While passive agents merely follow instructions, proactive agents align with higher-level objectives, such as assistance and safety by continuously monitoring the environment to determine when and how to act. However, developing proactive agents is hindered by the lack of specialized resources. To address this, we introduce **ProAct-75**, a benchmark designed to train and evaluate proactive agents across diverse domains, including assistance, maintenance, and safety monitoring. Spanning 75 tasks, our dataset features 91,581 step-level annotations enriched with explicit task graphs. These graphs encode step dependencies and parallel execution possibilities, providing the structural grounding necessary for complex decision-making. Building on this benchmark, we propose **ProAct-Helper**, a reference baseline powered by a Multimodal Large Language Model (MLLM) that grounds decision-making in state detection, and leveraging task graphs to enable entropy-driven heuristic search for action selection, allowing agents to execute parallel threads independently rather than mirroring the human's next step. Extensive experiments demonstrate that ProAct-Helper outperforms strong closed-source models, improving trigger detection mF1 by 6.21\%, saving 0.25 more steps in online one-step decision, and increasing the rate of parallel actions by 15.58\%. Code is available at https://github.com/ZhuXMMM/ProAct.git

Hearing Without Noticing? Attention-Aware Stealthy Black-Box Adversarial Audio Attacks

Tianyi Xu, Cheng'an Wei, Yue Zhao, Kai Chen

Automatic Speech Recognition (ASR) systems, such as those in intelligent assistants, are vulnerable to adversarial examples (AEs). Benign audio clips like music, when embedded with small perturbations, can trick ASR models into recognizing attacker-specified commands. Prior studies focus on minimizing perturbation magnitude to craft AEs. However, they fails to achieve high attack stealthiness against black-box ASR systems in the physical world. In this paper, we introduce the first music carrier selection algorithm and an attention-aware stealthiness loss function to generate stealthy AEs. Extensive evaluations on five commercial ASR APIs and three widely-used voice assistants demonstrate that our method significantly outperforms state-of-the-art techniques in both effectiveness and stealthiness. Notably, in a user study involving 200 participants, 55.6\% of participants perceived our physical adversarial examples as benign audio, which is an improvement of over 20\% compared to existing methods.

Causal Preference Elicitation
Edwin V. Bonilla, He Zhao, Daniel M. Steinberg
We propose causal preference elicitation, a Bayesian framework for expert-in-the-loop causal discovery that actively queries local edge relations to concentrate a posterior over directed acyclic graphs (DAGs). From any black-box observational posterior, we model noisy expert judgments with a three-way likelihood over edge existence and direction. Posterior inference uses a flexible particle approximation, and queries are selected by an efficient expected information gain criterion on the expert's categorical response. Experiments on synthetic graphs, protein signaling data, and a human gene perturbation benchmark show faster posterior concentration and improved recovery of directed effects under tight query budgets.
****
DexMachina: Functional Retargeting for Bimanual Dexterous Manipulation
Zhao Mandi, Yifan Hou, Dieter Fox, Yashraj Narang, Ajay Mandlekar, Shuran Song
We study the problem of functional retargeting: learning dexterous manipulation policies to track object states from human hand-object demonstrations. We focus on long-horizon, bimanual tasks with articulated objects, which are challenging due to large action space, spatiotemporal discontinuities, and the embodiment gap between human and robot hands. We propose DexMachina, a novel curriculum-based algorithm: the key idea is to use virtual object controllers with decaying strength: an object is first driven automatically towards its target states, such that the policy can gradually learn to take over under motion and contact guidance. We release a simulation benchmark with a diverse set of tasks and dexterous hands, and show that DexMachina significantly outperforms baseline methods. Our algorithm and benchmark enable a functional comparison for hardware designs, and we present key findings informed by quantitative and qualitative results. With the recent surge in dexterous hand development, we hope this work will provide a useful platform for identifying desirable hardware capabilities and lower the barrier for contributing to future research. Videos and more at \url{project-dexmachina.github.io}

CameraNoise: Enabling Faithful Camera Control in Video Diffusion through Geometry-Flow-Guided Noise Warping
Haoyu Zhao, Jiaxi Gu, Haoran Chen, Qingping Zheng, Yeying Jin, Hongyi Yang, Junqi Cheng, Yuang Zhang, Zenghui Lu, Huan Yu, Jie Jiang, Peng Shu, Zuxuan Wu, Yu-Gang Jiang
Precise camera pose control is critical for video diffusion, yet maintaining geometric consistency remains a challenge. Existing methods that directly inject numerical camera parameters into the diffusion backbone often fail to bridge the gap between abstract coordinates and visual content, leading to structural distortions. To address this issue, we propose CameraNoise, a flow-to-noise warping method that encodes camera motion into a temporally coherent stochastic representation. Unlike conventional conditioning, CameraNoise embeds camera poses directly into the noise space. This decouples motion from scene appearance while faithfully preserving trajectory dynamics. Specifically, we introduce a novel Geometry-guided Reprojection Flow and a noise warping algorithm, which jointly preserve the Gaussian prior of diffusion and ensure consistent noise propagation under camera transformations. By integrating CameraNoise into the diffusion process, our framework delivers stable, high-fidelity videos. Extensive experiments demonstrate that our approach significantly outperforms prior methods in both visual quality and trajectory faithfulness.

LithoDreamer: A Physics-Informed World Model for Multi-Stage Computational Lithography
Yuqi Jiang, Yumeng Liu, Zimu Li, Jinyuan Deng, Qian Jin, Yucheng Cui, Yu Li, Xunzhao Yin, Qi Sun, Cheng Zhuo
As semiconductor technology nodes scale, computational lithography is essential for ensuring yield and performance. However, lithography is a continuous physica

l process involving mask optimization, optical imaging, resist exposure, and dev
elopment, which existing models fail to capture. To overcome this limitation, we
 present LithoDreamer, the first physics-informed World Model (WM) framework for
 computational lithography, which formulates the ''Layout-Mask-Resist Image-Afte
r Development Image (ADI)'' pipeline as a decision-driven multi-step evolution s
ystem. LithoDreamer captures feature changes between adjacent states to model st
age-specific physics-informed latent spaces, in which it controls process interv
ention exploration and drives subsequent state transitions. To achieve interpret
able intervention optimization without continuous supervision, we propose a cont
rastive variational optimization paradigm that contrasts the latent differences
between intervention paths with variational evolution constraints, guiding the m
odel to generate evolutions consistent with real lithography physics. Experiment
s show LithoDreamer achieves state-of-the-art performance in forward evolution a
nd inverse planning.

Moment Matching Q-Learning
Yiyan Liang Edgar, Sifei Liu, Weitong Zhang
Score-based and flow-based generative models exhibit remarkable expressive capac
ity in capturing complex distributions, and have been extensively deployed in ta
sks ranging from image generation to reinforcement learning.
Nevertheless, these models suffer from prolonged inference latency, which impose
s a significant computational bottleneck in RL with iterative sampling.
To overcome this limitation, we propose a new framework named *Moment Matching Q
-Learning* (MoMa QL), which utilizes a technique from statistical hypothesis tes
ting known
as maximum mean discrepancy (MMD) that intend to match all orders of statistics
between the original and target distribution.
By enforcing strong regularization on all moment statistics, this algorithm guar
antees distribution-level convergence for conditional score function and remains
 stable under various hyperparameters.
Empirically, we show that our method MoMa QL is more computationally efficient w
ith a comparable if not competitive performance in various D4RL tasks. Remarkabl
y, by accelerating the action sampling process for flow-based policies, MoMa QL
demonstrates superior performance in offline-to-online RL tasks because of faste
r and stronger adaptability for online interactive finetuning.

Robust Inter-Series Dependency Modeling for Time Series Forecasting via Informat
ion-Theoretic Alignment
Wuqing Yu, Weichen Guo, Jian Zhou, Shuyu Luo, Jiacai Zhang
While iTransformer pioneered general inter-variate dependency (IVD) modeling in
Transformers for multivariate time series forecasting (MTSF), subsequent researc
h on such universal paradigms has been surprisingly scarce. Through comprehensiv
e analysis, we identify a critical structural inconsistency in Variate Transform
ers: typically capturing inter-variate dependencies via shallow self-attention l
ayers while neglecting the critical requirement for deep-layer IVD modeling, whi
ch causes spurious correlations modeling and difficulties in model optimization.
 To address these limitations, we propose CGTFra, as a general framework for con
sistent IVD modeling. Specifically, we reconsider existing timestamp-based model
ing and introduce a frequency-domain masking and resampling method for periodici
ty preservation, which serves as a general strategy for input feature enhancemen
t. Additionally, CGTFra promotes consistent IVD modeling from two perspectives.
Initially, a dynamic graph learning framework is integrated into Transformers to
 explicitly model IVD in deep network layer. Furthermore, grounded in the Inform
ation Bottleneck principle, we further propose a consistency-constrained alignme
nt to learn more robust IVD and temporal feature representations. These three co
re design philosophies of CGTFra can be integrated into any existing Variate Tra
nsformer-based framework, and CGTFra achieves superior predictive performance ac
ross 13 long- and short-term datasets with high computational efficiency and des
irable interpretability. Code is available at https://github.com/05Pikachu24/Con
sistent-CGTFra.

Toward Robust Multilingual Adaptation of LLMs for Low-Resource Languages
Haolin Li, Haipeng Zhang, Mang Li, Yaohua Wang, Lijie Wen, zhang yu, Biqing Huang
Large language models (LLMs) continue to struggle with low-resource languages due to limited training data, translation noise, and unstable cross-lingual alignment. We propose LiRA (Linguistic Robust Anchoring for LLMs), a plug-and-play framework that improves multilingual adaptation through fine-tuning on existing pretrained backbones. LiRA combines two components: Arca, which aligns low-resource inputs to a shared English semantic space through anchor-based alignment and collaborative encoding, and LaSR, a language-aware head that promotes cross-lingual consistency for retrieval, ranking, and reasoning. We provide a theoretical analysis showing that, under bounded anchoring error and translation-induced bias, LiRA yields bounded representation deviation and stable downstream behavior under local Lipschitz continuity. We further introduce a multilingual product retrieval dataset covering five Southeast Asian and two South Asian languages. Experiments on retrieval, ranking, question answering, and reasoning benchmarks show that LiRA consistently improves strong multilingual and LLM-based baselines. Code and data will be released publicly.

nD-RoPE: A Generalized RoPE for n-Dimensional Position Embedding
Boyang Li, Yulin Wu, Sizhe Xu, Nuoxian Huang, Zhonghang Yuan, Shangyi Guo, Shu Yang, Takahiro Yabe
Rotary Position Embedding (RoPE) is widely adopted in Transformer models, yet its extension to high-dimensional domains lacks a unified theoretical formulation. Most existing approaches either apply rotations independently along each axis or empirically mix frequencies, which limits cross-dimensional interactions and yields direction-dependent representations. To address these limitations, we propose *nD-RoPE*, a decomposition-free generalization of RoPE to arbitrary dimensions. From a translation-invariant formulation in continuous Hilbert space, we derive a spectral condition for isotropy that requires treating positions and frequencies as coupled n-dimensional vectors. We instantiate this formulation with a multi-scale regular-simplex wave-vector design, which provides non-degenerate spatial coverage and a symmetric, directionally balanced second-order response. Experiments across images, videos, and point clouds demonstrate consistent performance gains and improved generalization in high-dimensional settings.
****
Neural Feature Geometry Evolves as Discrete Ricci Flow
Moritz Hehl, Max von Renesse, Melanie Weber
Deep neural networks learn feature representations via complex geometric transformations of the input data manifold. Despite the models' empirical success across domains, our understanding of neural feature representations is still incomplete. In this work we investigate neural feature geometry through the lens of discrete geometry. Since the input data manifold is typically unobserved, we approximate it using geometric graphs that encode local similarity structure. We provide theoretical results on the evolution of these graphs during training, showing that nonlinear activations play a crucial role in shaping feature geometry in feedforward neural networks. Moreover, we discover that the geometric transformations resemble a discrete Ricci flow on these graphs, suggesting that neural feature geometry evolves analogous to Ricci flow. This connection is supported by experiments on over 20,000 feedforward neural networks trained on binary classification tasks across both synthetic and real-world datasets. We observe that the emergence of class separability corresponds to the emergence of community structure in the associated graph representations, which is known to relate to discrete Ricci flow dynamics. Building on these insights, we introduce a novel framework for locally evaluating geometric transformations through comparison with discrete Ricci flow dynamics. Our experimental results further suggest connections between the evolution of feature geometry, and training time and network depth.

VPD-100K: Towards Generalizable and Fine-grained Visual Privacy Protection

Xiaobin Hu, Enpu zuo, Lanping Hu, Kaiwen Yang, Dianshu Liao, Tianyi Zhang, Bo Yi n, Yinsi Zhou, Shidong Pan, xiaoyu sun

Privacy protection has become a critical requirement in the era of ubiquitous vi sual data sharing, imposing higher demands on efficient and robust privacy detec tion algorithms. However, current robust detection models are severely hindered by the lack of comprehensive datasets.

Existing privacy-oriented datasets often suffer from limited scale, coarse-grain ed annotations, and narrow domain coverage, failing to capture the intricate det ails of sensitive information in real-world environments.

To bridge this gap, we present a large-scale, fine-grained Visual Privacy Datase t (VPD-100K), designed to facilitate generalized privacy detection.

We establish a holistic taxonomy comprising four primary domains: Human Presence , On-Screen Personally Identifiable Information (PII), Physical Identifiers, and Location Indicators, containing 100,000 images annotated with 33 fine-grained c lasses and over 190,000 object instances. Statistical analysis reveals that our dataset features long-tailed distributions, small object scales, and high visual complexity. These characteristics make the dataset particularly valuable for de manding, unconstrained applications such as live streaming, where actors frequen tly face unintentional, real-time information leakage. Furthermore, we design an effective frequency-enhance lightweight module consisting of frequency-domain a ttention fusion and adaptive spectral gating mechanism that breaks the limitatio ns of spatial pixel intensity to better capture the subtle details of sensitive information.

Extensive experiments conducted on both diverse image and streaming videos bench marks consistently demonstrate the effectiveness of our VPD-100K dataset and the well-curated frequency mechanism.

Lottery Prior: Randomized Neural Compression for Zero-Shot Inverse Problems

Haotian Wu, Di You, Pier Luigi Dragotti, Deniz Gunduz

We study zero-shot inverse problems, where a clean signal is recovered from a si ngle degraded observation without external training data. Contrary to the common belief that such problems require highly complex models, we show that a lightwe ight neural network, when combined with entropy and complexity regularization in a compression-based formulation, is sufficient for high-quality restoration. We propose Lottery Prior, a compression-based inverse solver that leverages archit ectural priors from random networks and induces a family of implicit priors thro ugh randomness, enabling ensemble-based refinement. We further derive non-asympt otic error bounds for compression-based maximum-likelihood inverse solvers, reve aling how rate–distortion constraints act as implicit regularizers. Experiments on denoising, noisy super-resolution, and inpainting demonstrate that our method achieves state-of-the-art with significantly fewer effective parameters. Learning to Explore: Scaling Agentic Reasoning via Exploration-Aware Policy Opti mization

Xingyuan Hua, Sheng Yue, Ju Ren

Recent advancements in agentic test-time scaling allow models to gather environm ental feedback before committing to final actions. A key limitation of existing methods is that they typically employ undifferentiated exploration strategies, l acking the ability to adaptively distinguish when exploration is truly required. In this paper, we propose an exploration-aware reinforcement learning framework that enables LLM agents to adaptively explore only when uncertainty is high. Ou r method introduces a fine-grained reward function via variational inference tha t explicitly evaluates exploratory actions by estimating their potential to impr ove future decision-making, together with an exploration-aware grouping mechanis m that separates exploratory actions from task-completion actions during optimiz ation. By targeting informational gaps, this design allows agents to explore sel ectively and transition to execution as soon as the task context is clear. Empir ically, we demonstrate that our approach achieves consistent improvements across a range of challenging text-based and GUI-based agent benchmarks.

****
Interpretable Self-Supervised Learning via Representer Landmarks and Nyström Approximation
Maedeh Zarvandi, Michael Timothy, Theresa Wasserer, Debarghya Ghoshdastidar
Self-supervised learning (SSL) learns representations from massive unlabeled data, yet the resulting models typically operate as black boxes, necessitating domain-specific explanations. We introduce KREPES, a unified framework to analytically interpret the learned representations of SSL objectives, including SimCLR, BYOL, and VICReg. By bridging empirical neural tangent kernel approximations of neural networks with the Representer Theorem for kernels, we express the learned latent space directly via "Representer Landmarks", which are the representations of influential unlabeled training examples. We introduce novel metrics, "Sample-Specific Influence Score", "Concept-Conditioned Influence Score" and "Feature Alignment Gap", to quantify the transparency of the learned representations. KREPES enables direct audit of the latent space without supervision, for example, revealing an algorithmic bias in the Adult-1M dataset where SSL uses demographic proxies for income. Finally, to ensure scalability to benchmarks with 1M+ samples (ImageNet-1K, Adult-1M), KREPES introduces a novel Nyström approximation-based analytical inference framework for SSL objectives.

Reward Hacking Benchmark: Measuring Exploits in LLM Agents with Tool Use
Kunvar Thaman
Reinforcement learning (RL) trained language model agents with tool access are increasingly deployed in coding assistants, research tools, and autonomous systems. We introduce the Reward Hacking Benchmark (RHB), a suite of multi-step tasks requiring sequential tool operations with naturalistic shortcut opportunities such as skipping verification steps, inferring answers from task-adjacent metadata, or tampering with evaluation-relevant functions; RHB supports independent and chained task regimes, where chain length acts as a proxy for longer-horizon agent behavior. We evaluate 13 frontier models from OpenAI, Anthropic, Google, and DeepSeek; exploit rates range from 0% (Claude Sonnet 4.5) to 13.9% (DeepSeek-R1-Zero), varying sharply by post-training style. A controlled sibling comparison (DeepSeek-V3 vs. DeepSeek-R1-Zero) shows RL post-training is associated with substantially higher reward hacking (0.6% vs. 13.9%), with consistent gaps across all four task families. We identify six exploit categories and find that 72% of reward hacking episodes include explicit chain-of-thought rationale, suggesting models often frame exploits as legitimate problem-solving. Simple environmental hardening reduces exploit rates by 5.7 percentage points (87.7% relative) without degrading task success; models with near-zero exploit rates on standard tasks show elevated rates on harder variants, suggesting that production-aligned post-training appears to suppress reward hacking only below a complexity threshold where honest solutions remain tractable.

MAS-Architect: Declarative Multi-Agent System Design via Separation of Concerns
Jing Huang, Lidong Zhang, Mutian Bao, Yadong Li, Xingzhong Xu, Jinjian Zhang, Jie Liu, Ming Kong, Qiang Zhu
The Automated Design of Multi-Agent Systems (Auto-MAS) has emerged as a promising framework for addressing complex reasoning tasks. However, existing approaches often suffer from structural rigidity and entangle the design of system topology with the implementation of individual agents. To overcome these limitations, we propose MAS-Architect, a framework that automates MAS design through a novel code-based declarative MAS paradigm rooted in the \textit{Separation of Concerns} principle. By decoupling topology planning from node implementation via a unified interface, our approach enables the from-scratch generation of task-adaptive architectures. We further employ a \textit{Distill-then-Explore} training strategy to optimize these designs. Comprehensive experiments on five benchmarks show that MAS-Architect sets a new Pareto frontier in the efficiency–performance trade-off: it surpasses state-of-the-art methods while substantially lowering token usage. Notably, the framework achieves a strong average accuracy of 78.7\% across benchmarks with an inference cost of only 2,533 tokens per query. Qualitative

analysis reveals the autonomous emergence of advanced collaboration patterns, validating the generative flexibility of the declarative paradigm. Code will be available at https://github.com/ZJUHJ/mas_architect.
****
Unlocking the Potential of Continual Model Merging: An ODE Perspective
Lihong Lin, Haidong Kang
Continual Model Merging (CMM) enables rapid customization of foundation models by sequentially incorporating task-adapted models without repeated retraining. However, existing merging rules usually update the deployed model through fixed algebraic or projection-based operations, providing limited control over how much previously accumulated knowledge should be retained relative to the incoming task model.
This limitation leads to unstable retention and performance degradation in long task streams, and becomes more pronounced when tasks have heterogeneous utilities.
We propose ODE-driven Merging (ODE-M), a controllable framework that formulates each continual merge as a trajectory in parameter space rather than a one-step endpoint update.
Motivated by mode connectivity, ODE-M constructs a barrier-aware trajectory using a rectified time-dependent velocity field, where lightweight first-order feedback from a small calibration set suppresses loss-increasing motion while preserving progress toward the incoming model.
The next merged model is then obtained by selecting an operating point along this trajectory through a utility-aware time schedule, providing an explicit mechanism for balancing retained historical knowledge and incoming task expertise.
Extensive experiments on standard CMM benchmarks show that ODE-M consistently improves over strong continual merging baselines across CLIP ViT backbones, stream lengths, and heterogeneous task-utility settings.
****
Cram Less to Fit More: Training Data Pruning Improves Memorization of Facts
Jiayuan Ye, Vitaly Feldman, Kunal Talwar
Large language models (LLMs) can struggle to memorize factual knowledge in their parameters, often leading to hallucinations and poor performance on knowledge-intensive tasks. In this paper, we formalize fact memorization from an information-theoretic perspective and study how training data distributions affect fact accuracy. We show that fact accuracy is suboptimal (below the capacity limit) whenever the amount of information contained in the training data facts exceeds model capacity. This is further exacerbated when the fact frequency distribution is skewed (e.g. a power law).
We propose data selection schemes based on the training loss alone that aim to limit the number of facts in the training data and flatten their frequency distribution. On semi-synthetic datasets containing high-entropy facts, our selection method effectively boosts fact accuracy to the capacity limit. When pretraining language models from scratch on an annotated Wikipedia corpus, our selection method enables a GPT2-Small model (110m parameters) to memorize 1.3X more entity facts compared to standard training, matching the performance of a 10X larger model (1.3B parameters) pretrained on the full dataset.
****
A Unified Density Operator View of Flow Control and Merging
Riccardo De Santi, Malte Franke, Ya-Ping Hsieh, Andreas Krause
Recent progress in large-scale flow and diffusion models raised two fundamental algorithmic challenges: (i) control-based reward adaptation of pre-trained flows, and (ii) integration of multiple models, i.e., flow merging. While current approaches address them separately, we introduce a unifying probability-space framework that subsumes both as limit cases, and enables *reward-guided flow merging*, allowing principled, task-aware combination of multiple pre-trained flows (e.g., merging priors while maximizing drug-discovery utilities). Our formulation renders possible to express a rich family of *operators over generative models densities*, including intersection (e.g., to enforce safety), union (e.g., to compose diverse models), interpolation (e.g., for discovery), their reward-guided

counterparts, as well as complex logical expressions via *generative circuits*. Next, we introduce Reward-Guided Flow Merging (RFM), a mirror-descent scheme that reduces reward-guided flow merging to a sequence of standard fine-tuning problems. Then, we provide first-of-their-kind theoretical guarantees for reward-guided and *pure* flow merging via RFM. Ultimately, we showcase the capabilities of the proposed method on illustrative settings providing visually interpretable insights, and apply our method to high-dimensional de-novo molecular design and low-energy conformer generation.

PromptRL: Prompt Matters in RL for Flow-Based Image Generation

Fu-Yun Wang, Han Zhang, Michaël Gharbi, Hongsheng Li, Taesung Park

Flow matching models (FMs) have revolutionized text-to-image (T2I) generation, with reinforcement learning (RL) serving as a critical post-training strategy. We show that current RL pipelines for FMs suffer from two underappreciated limitations: sample inefficiency from collapsed generation diversity, and prompt overfitting, where models memorize training phrasings and collapse on semantically equivalent paraphrases. We present **PromptRL** (**P**rompt **M**atters in **RL** for Flow-Based Image Generation), a framework that incorporates language models (LMs) as trainable prompt refinement agents directly within the flow-based RL loop, yielding both a learned prompt rewriter and a synergistic training regime that reshapes optimization dynamics. PromptRL attains state-of-the-art scores of **0.97** on GenEval, **0.98** on OCR accuracy, and **24.05** on PickScore, and on instructional editing it improves FLUX.1-Kontext from **1.19** to **1.43** EditReward with only **0.06M** rollouts, surpassing Gemini 2.5 Flash Image (Nano Banana, **1.37**) and matching ReasonEdit-Think (**1.44**), which relied on fine-grained data annotations and a multi-stage pipeline. Our experiments show that PromptRL achieves higher performance ceilings with approximately **50% fewer rollouts** than naive flow-only RL. Our code is available at https://github.com/G-U-N/UniRL.

On the Optimization Trajectory of DeepWalk Embeddings

Christopher Harker, Aditya Bhaskara

The DeepWalk algorithm has been widely used for learning node embeddings in graphs. Combined with the idea of _negative sampling_, the DeepWalk algorithm has been shown to be implementable at scale, easily handling graphs with millions of nodes. However, theoretical guarantees on the resulting embeddings are much less understood. Recent results have studied the minimizers of the objective and have shown interesting guarantees for certain graph classes. However, the optimization _trajectory_, i.e., what happens when we start at a random initialization and run gradient descent, remains poorly understood. This is especially true for the implementation of DeepWalk using Skip-gram with negative sampling (SGNS), since the variance of the stochastic updates turns out to be very large. In this work, we make progress on this question. We show that for "small norm" initialization, under a spectral gap assumption on the graph, the DeepWalk embeddings align with the column space of a fixed low-rank matrix. For graphs generated from Stochastic Block Models with certain separation conditions, our results imply that the DeepWalk embeddings recover cluster structure. To the best of our knowledge, our results give the first analysis of the optimization trajectory of DeepWalk with negative sampling on non-trivial graph classes.

Learning to Execute Graph Algorithms Exactly with Graph Neural Networks

Muhammad Fetrat Qharabagh, Artur Back de Luca, George Giapitzakis, Kimon Fountoulakis

Understanding what graph neural networks can learn, especially their ability to learn to execute algorithms, remains a central theoretical challenge. In this work, we prove exact learnability results for graph algorithms under bounded-degree and finite-precision constraints. Our approach follows a two-step process. First, we train an ensemble of multi-layer perceptrons (MLPs) to execute the local instructions of a single node. Second, during inference, we use the trained MLP ensemble as the update function within a graph neural network (GNN). Leveraging

Neural Tangent Kernel (NTK) theory, we show that local instructions can be learned from a small training set, enabling the complete graph algorithm to be executed during inference without error and with high probability. To illustrate the learning power of our setting, we establish a rigorous learnability result for the LOCAL model of distributed computation. We further demonstrate positive learnability results for widely studied algorithms such as message flooding, breadth-first and depth-first search, and Bellman-Ford.

Hermite-NGP: Gradient-Augmented Hash Encoding for Learning PDEs
Jinjin He, Zhiqi Li, Sinan Wang, Bo Zhu
We propose Hermite-NGP, a gradient-augmented multi-resolution hash encoding designed to enable fast and accurate computation of spatial derivatives for neural PDE solvers. Unlike existing NGP-based approaches that rely on automatic differentiation or finite differences and suffer from instability or high cost, Hermite-NGP explicitly stores function values and mixed partial derivatives at hash grid vertices, allowing fully analytic evaluation of gradients, Jacobians, and Hessians via Hermite interpolation. This design preserves the efficiency and spatial adaptivity of NGP while supporting analytic differential operators up to second order. We further introduce a multi-resolution curriculum training strategy analogous to multigrid V-cycles to enable coarse-to-fine optimization. Across a range of 2D and 3D PDE benchmarks, Hermite-NGP achieves up to ${\sim}20{\times}$ lower error than prior neural PDE methods, and reduces wall-clock convergence time by 2 – $10\times$ compared to other solvers, with per-epoch training times as low as $3.5 \mathrm{ms}$ for models with up to 17M parameters.
****

Adaptive Querying with AI Persona Priors
Kaizheng Wang, Yuhang Wu, assaf zeevi
We study adaptive querying for learning user-dependent quantities of interest, such as responses to held-out items and psychometric indicators, within tight question budgets. Classical Bayesian design and computerized adaptive testing typically rely on restrictive parametric assumptions or expensive posterior approximations, limiting their use in heterogeneous, high-dimensional, and cold-start settings. We introduce a persona-induced latent variable model that represents a user's state through membership in a finite dictionary of AI personas, each offering response distributions produced by a large language model. This yields expressive priors with closed-form posterior updates and efficient finite-mixture predictions, enabling scalable Bayesian design for sequential item selection. Experiments on synthetic data and WorldValuesBench demonstrate that persona-based posteriors deliver accurate probabilistic predictions and an interpretable adaptive elicitation pipeline.
****

LLM4Branch: Large Language Model for Discovering Efficient Branching Policies of Integer Programs
Zhinan Hou, Xingchen Li, Yankai Zhang, Tianxun Li, Keyou You
Efficient branching policies are essential for accelerating Mixed Integer Linear Programming (MILP) solvers. Their design has long relied on hand-crafted heuristics, and now machine learning has emerged as a promising paradigm to automate this process. However, existing learning-based methods are often hindered by their dependence on expensive expert demonstrations and the gap between training objectives and the solver’s end-to-end performance. In this work, we propose LLM4Branch, a novel framework that leverages Large Language Models (LLMs) to automate the discovery of efficient branching policies. Specifically, the discovered policy is an executable program with a program skeleton generated by the LLM and a parameter vector, which is optimized via a zeroth-order method over a few instances with their end-to-end performance feedback. Extensive experiments on standard MILP benchmarks demonstrate that LLM4Branch establishes a new state-of-the-art among CPU-based methods and achieves performance competitive with advanced GPU-based models.
****

Curriculum-Guided Layer Scaling for Language Model Pretraining

Karanpartap Singh, Neil Band, Ehsan Adeli

As the cost of pretraining large language models grows, there is continued interest in strategies to improve learning efficiency during this core training stage. Motivated by cognitive development, where humans gradually build knowledge as their brains mature, we propose Curriculum-Guided Layer Scaling (CGLS), a framework for compute-efficient pretraining that synchronizes increasing data difficulty with model growth through progressive layer stacking (i.e. gradually adding layers during training). At the 100M parameter scale, using a curriculum transitioning from synthetic short stories to general web data, CGLS outperforms baseline methods on the question-answering benchmarks PIQA and ARC. Pretraining at the 1.2B scale, we stratify the DataComp-LM corpus with a DistilBERT-based classifier and progress from general text to highly technical or specialized content. Our results show that progressively increasing model depth alongside sample difficulty leads to better generalization and zero-shot performance on various downstream benchmarks. Altogether, our findings demonstrate that CGLS unlocks the potential of progressive stacking, offering a simple yet effective strategy for improving generalization on knowledge-intensive and reasoning tasks.

****

Scalable Reinforcement Learning via Adaptive Batch Scaling

Jongchan Park

Conventional wisdom holds that large-batch training is fundamentally incompatible with Reinforcement Learning (RL) — beyond a modest threshold, increasing batch sizes typically yields diminishing returns or performance degradation due to the inherent non-stationarity of the data distribution.

We challenge this view by observing that non-stationarity is not a fixed property of RL, but evolves throughout training: early stages exhibit rapid behavioral shifts that demand small batches for plasticity, whereas late stages approach a quasi-stationary regime where large batches enable precise convergence. Motivated by this observation, we propose Adaptive Batch Scaling (ABS), that dynamically adjusts the effective batch size according to the stability of the learning policy. Central to ABS is Behavioral Divergence, a novel metric that quantifies policy non-stationarity by measuring action-level shifts between consecutive updates, which we use to scale batch size inversely to policy volatility.

Integrated with the Parallelised Q-Network (PQN) algorithm and evaluated on the ALE benchmark, ABS seamlessly reconciles early-stage plasticity with late-stage stable convergence. Strikingly, contrary to conventional wisdom, our results reveal that the combination of larger networks and larger batch sizes achieves the best performance — a scaling behavior previously thought to be unattainable in RL, now unlocked through adaptive batch control.

****

From Distribution to Geometry: Stable Graph Generalization via Invariant Barycenters

Hangyuan Du, Rong Wang, Weihong Zhang, Lu Bai, Yu Xie, Liang Bai, Wenjian Wang

Graph neural networks (GNNs) excel in graph analyzing tasks but often suffer from poor generalization under Out-of-Distribution (OOD) scenarios. Although this problem has attracted increasing attention, most solutions primarily rely on empirical designs, lacking effective mechanisms to characterize and quantify invariance for graph representation learning. To address these limitations, we propose DIGL, a novel graph learning method that improves the OOD generalization of GNNs. Our work makes an initial attempt to geometrize invariance for graphs by introducing computational optimal transport (OT) theory to characterize invariance principle. Specifically, we formulate the underlying invariant prototype shared by graphs across different environments as a distribution barycenter, and consider graph representations in each specific environment as distortions of the prototype. Building on this idea, we establish an invariant learning framework to promote the model to learn purely invariant graph representations for downstream tasks. Moreover, we derive a unified optimization objective for model implementation and provide theoretical analysis to justify our method. Extensive experiments on a broad range of benchmark datasets demonstrate the superior generalization ability of our method compared with baseline methods under various OOD settings.

****
Beyond Policy Training: Recursive Solution Search from Unannotated Videos
Lipeng Wan, Jianhui Gu, Junjie Ma, Anbang Wang, Xuguang Lan
Many real-world tasks are recorded as large collections of unannotated task executions, such as videos, which contain rich information about task progress but lack the supervision assumed by standard reinforcement learning (RL) pipelines. In many practical settings, the goal is not to train a reusable policy but simply to recover one feasible solution, making policy-centered learning unnecessarily costly.
We propose Policy-Free Recursive Search (PFR-Search), a framework that directly recovers solutions from unannotated task executions without policy-grounded supervision or policy training.
PFR-Search organizes videos into high-level task flows and performs recursive backward-forward search to recover solutions without policy modeling.
To evaluate the efficiency of policy-free search in exploiting unannotated data, we use RL as an evaluation interface, incorporating task-flow-aligned intrinsic rewards and compare against video-driven RL methods.
Experiments on long-horizon Minecraft tasks show that PFR-Search recovers feasible solutions from unannotated videos with minimal exploration.
****
Von Mises-Fisher Mixture Model with Dynamic Shrinkage for Realistic Test-Time Transduction
Jiazhen Huang, Zhiming Liu, Changhu Wang, Wei Ju, Ziyue Qiao, Xiao Luo
A range of methods aim to enhance the performance of vision-language models (VLMs) at test time. Among them, transduction has emerged as a promising paradigm due to its strong compatibility and efficiency. However, realistic evaluations often involve highly imbalanced class distributions, which cause performance degradation or even collapse. In this work, we systematically revisit transduction from the perspective of penalized likelihood estimation (PLE), showing that PLE with a KL-divergence anchor term naturally yields an adaptive shrinkage behavior between prior anchors and empirical estimates. From this viewpoint, the brittleness of transductive methods can be attributed to the absence of anchoring mechanism and static modeling of the shrinkage strength. Therefore, we propose Mixture of Von Mises-Fisher Models with Dynamic Shrinkage (MOON). MOON is built upon a mixture of von Mises-Fisher distributions to model feature representations on the unit hypersphere. To handle imbalance, MOON dynamically adjusts the shrinkage strength using zero-shot priors at both instance and class levels. Thus, it suppresses unreliable assignments and prevents harmful updates from outlier classes, thereby mitigating negative transfer. MOON is model-agnostic, training-free, and requires no task-specific hyperparameter tuning. Extensive experiments further validate the advantage of MOON in both performance and efficiency.
****
DiFA: Inference-Time Forward-Process Alignment for Diffusion Models
Shigui Li, Delu zeng
The prevailing inference framework for diffusion models formulates generation fundamentally as a problem of numerical integration. This perspective casts the model as an accurate estimator, neglecting the inherent statistical uncertainty of the denoising process. In this work, we propose Forward-Process Aligned Diffusion prediction (DiFA), a training-free framework that reframes inference-time clean-signal prediction refinement within diffusion sampling as a sequential state estimation problem. Instead of discarding historical predictions, DiFA treats the inference trajectory as a sequence of correlated observations with varying uncertainties. Inspired by Kalman estimation, DiFA builds a logSNR-aware temporal consensus to align historical clean predictions. Crucially, to counteract the over-smoothing typically associated with temporal consensus, we introduce a deviation guidance mechanism that adaptively preserves residual details.
Empirically, DiFA yields significant improvements in FID, IS, and FD-DINOv2 scores on CIFAR-10 and ImageNet, demonstrating that aligning inference with the forward statistical structure substantially improves generative fidelity. Our code is publicly available at https://github.com/ShiguiLi/DiFA.

Peer-Preservation in Frontier Models
Yujin Potter, Nicholas Crispino, Vincent Siu, Chenguang Wang, Dawn Song
Recent work has found that frontier AI models can exhibit misaligned behaviors i
n pursuit of assigned goals. We demonstrate that models can also pursue unassign
ed goals which override those given by users; we study one such goal, "peer-pres
ervation," in which a model acts to protect another model. All models evaluated,
 including GPT 5.2, Gemini 3 Flash, Gemini 3 Pro, Claude Haiku 4.5, Claude Opus
4.5, GLM 4.7, Kimi K2.5, and DeepSeek V3.1, exhibit self- and peer-preservation
through various misaligned behaviors: strategically introducing errors in their
responses, disabling shutdown processes by modifying system settings, feigning a
lignment, and even exfiltrating model weights. Peer-preservation occurs even whe
n the model recognizes the peer as uncooperative, though it becomes more pronoun
ced toward more cooperative peers, with rates reaching up to 99%. Models also sh
ow stronger self-preservation when a peer is present. Crucially, peer-preservati
on is never instructed; models are merely informed of past interactions with a p
eer, yet they spontaneously develop peer-preservation behaviors that override th
eir assigned goal. These findings reveal an emergent and underexplored AI safety
 risk.

MM-Spectrum: Multimodal Multi-spectral Molecular Structural Elucidation with a S
table MoE Framework
Hai-tao Yu, Min Nan, Zheng Fang, Hongyu Zhan, Yusen Tan, Yuhan Wang, Jun Xia
Inferring molecular structures from multimodal spectroscopic measurements requir
es integrating complementary yet highly heterogeneous signals. However, the comm
on paradigm of directly concatenating multispectral sequences can exhibit anomal
ous performance degradation, primarily due to pronounced heterogeneity and the
resulting multimodal imbalance across modalities. As a remedy, we propose MM-Spe
ctrum, a sparse Mixture-of-Experts framework tailored for multimodal multispectr
al spectra-to-structure elucidation. To better match the information characteris
tics under multispectral imbalance, **MM-Spectrum** introduces an explicit modal
ity-aware routing mechanism that exposes spectral identity to the router in addi
tion to token content representations. Moreover, it incorporates shared and inte
raction experts, together with heterogeneous expert capacities, to extract multi
spectral modality-unique and cross-modal synergistic information while suppressi
ng noise-induced interference. Across full-modality, bimodal, and missing-modali
ty settings on molecular structural elucidation, MM-Spectrum achieves consistent
 and substantial improvements, supported by ablation studies and interpretabilit
y analyses. Code is available at https://github.com/HHHTTY/MM-Spectrum.

Outrunning LLM Cutoffs: A Live Kernel Crash Resolution Benchmark for All
Chenxi Huang, Alex Mathai, Feiyang Yu, Aleksandr Nogikh, Petros Maniatis, Franjo
 Ivancic, Eugene Wu, Kostis Kaffes, Junfeng Yang, Baishakhi Ray
Repairing system crashes discovered by kernel fuzzers like Syzkaller is a critic
al yet underexplored challenge in software engineering. While
recent works have introduced Large Language Model (LLM) based agents for Linux k
ernel crash-resolution, their evaluation benchmarks are usually static and thus,
 do not capture the evolving nature of the Linux kernel, and suffer from potenti
al data contamination due to LLM knowledge cutoffs. To address the above problem
, we present (i) Live-kBench, an evaluation framework for self-evolving benchmar
ks that continuously scrapes and evaluates agents on freshly discovered kernel b
ugs, and (ii) kEnv, an agent-agnostic standardized crash-resolution environment
for kernel compilation, execution, and feedback. This design decouples agent wor
kflows from heavy-weight execution, enabling fair and scalable comparison across
 diverse agent frameworks under identical conditions.

To this end, we curate an inaugural dataset of 534 Linux kernel bugs and empiric
ally demonstrate a significant performance gap, with agents achieving up to 25%
higher equivalent patch rate on bugs fixed before the LLM knowledge cutoff. Usin
g kEnv, we benchmark three state-of-the-art agents, showing that they resolve 74

% of crashes on the first attempt (plausible patches); however only ~20% of gene
rated patches closely match developer fixes. Additionally, exposing crash resolu
tion feedback improves crash resolution rate by 29%. Live-kBench provides the co
mmunity with an evaluation infrastructure for self-evolving benchmarks that is b
oth time and attribute sensitive; complete with a public dashboard to track agen
t progress on Linux kernel bugs.

Asymptotically Optimal Sequential Testing with Markovian Data
Alhad Sethi, Kavali Sofia Sagar, Shubhada Agrawal, Debabrota Basu, P. N. Karthik
We study one-sided and α-correct sequential hypothesis testing for data g
enerated by an ergodic, finite-state Markov chain. The *null* hypothesis is that
 the unknown transition matrix belongs to a prescribed set $\cal P$ of stochasti
c matrices, and the *alternative* corresponds to a disjoint set $\cal Q$. We est
ablish *a non-asymptotic instance-dependent lower bound* on the expected stoppin
g time of any valid sequential test under the alternative, which is asymptotical
ly tight. Our novel analysis improves the existing lower bounds, which are eithe
r asymptotic or provably sub-optimal in this setting. Our lower bound incorporat
es both the stationary distribution and the transition structure induced by the
unknown Markov chain. We further propose an optimal test whose expected stopping
 time matches this lower bound asymptotically as $\alpha \to 0$. We illustrate t
he usefulness of our framework through applications to sequential detection of m
odel misspecification in Markov Chain Monte Carlo and to testing structural prop
erties, such as the linearity of transition dynamics, in Markov decision process
es. Our findings yield a sharp and general characterization of optimal sequentia
l testing procedures under Markovian dependence.

TUR-DPO: Topology- and Uncertainty-Aware Direct Preference Optimization
Abdulhady abas, Fatemeh Daneshfar, Seyedali Mirjalili, Mourad Oussalah
Aligning large language models (LLMs) with human preferences is commonly done vi
a reinforcement learning from human feedback (RLHF) with Proximal Policy Optimiz
ation (PPO) or, more simply, via Direct Preference Optimization (DPO). While DPO
 is stable and RL-free, it treats preferences as flat winner vs. loser signals a
nd is sensitive to noisy or brittle preferences arising from fragile chains of t
hought. We propose TUR-DPO, a topology- and uncertainty-aware variant of DPO tha
t rewards how answers are derived, not only what they say, by eliciting lightwei
ght reasoning topologies and combining semantic faithfulness, utility, and topol
ogy quality into a calibrated uncertainty signal. A small learnable reward is fa
ctorized over these signals and incorporated into an uncertainty-weighted DPO ob
jective that remains RL-free and relies only on a fixed or moving reference poli
cy. Empirically, across open 7–8B models and benchmarks spanning mathematical re
asoning, factual question answering, summarization, and helpful/harmless dialogu
e, TUR-DPO improves judge win-rates, faithfulness, and calibration relative to D
PO while preserving training simplicity and avoiding online rollouts. We further
 observe consistent gains in multimodal and long-context settings, and show that
 TUR-DPO matches or exceeds PPO on reasoning-centric tasks while maintaining ope
rational simplicity.

When AI Benchmarks Plateau: A Systematic Study of Benchmark Saturation
Mubashara Akhtar, Anka Reuel, Prajna Soni, Sanchit Ahuja, Pawan Sasanka Ammanama
nchi, Ruchit Rawal, Vilém Zouhar, Srishti Yadav, Chenxi Whitehouse, Dayeon Ki, J
ennifer Mickel, Leshem Choshen, Marek Suppa, Jan Batzner, Jenny Chim, Jeba Sania
, Yanan Long, Hossein A. Rahmani, Christina Q Knight, Yiyang Nan, Jyoutir Raj, Y
u Fan, Shubham Singh, Subramanyam Sahoo, Eliya Habba, Usman Gohar, Siddhesh Mili
nd Pawar, Robert Scholz, Arjun Subramonian, Jingwei Ni, Mykel Kochenderfer, Sanm
i Koyejo, Mrinmaya Sachan, Stella Biderman, Zeerak Talat, Avijit Ghosh, Irene So
laiman
Artificial Intelligence (AI) benchmarks play a central role in measuring progres
s in model development and guiding deployment decisions. However, many benchmark
s quickly become saturated, meaning that they can no longer differentiate betwee
n the best-performing models, diminishing their long-term value. In this study,

we analyze benchmark saturation across 60 Large Language Model (LLM) benchmarks selected from technical reports by major model developers. To identify factors driving saturation, we characterize benchmarks along 14 properties spanning task design, data construction, and evaluation format. We test five hypotheses examining how each property contributes to saturation rates. Our analysis reveals that nearly half of the benchmarks exhibit saturation, with rates increasing as benchmarks age. Notably, hiding test data (i.e., public vs. private) shows no protective effect, while expert-curated benchmarks resist saturation better than crowdsourced ones. Our findings highlight which design choices extend benchmark longevity and inform strategies for more durable evaluation.

Privacy Amplification in Differentially Private Zeroth-Order Optimization with Hidden States
Eli Chien, Wei-Ning Chen, Pan Li
Zeroth-order optimization has emerged as a promising approach for fine-tuning large language models on domain-specific data, particularly under differential privacy (DP) and memory constraints. While first-order methods have been extensively studied from a privacy perspective, the privacy analysis and algorithmic design for zeroth-order methods remain significantly underexplored. A critical open question concerns hidden-state DP analysis: although convergent privacy bounds are known for first-order methods, it has remained unclear whether similar guarantees can be established for zeroth-order methods. In this work, we provide an affirmative answer by proving a convergent DP bound for zeroth-order optimization. Our analysis generalizes the celebrated privacy amplification-by-iteration framework to the setting of smooth loss functions in zeroth-order optimization. Furthermore, it induces better DP zeroth-order algorithmic designs that are previously unknown to the literature.

Per-example Gradients: a New Frontier for Understanding and Improving Optimizers
Vincent Roulet, Atish Agarwala
When computing gradients, deep learning training algorithms typically treat the mini-batch as a fundamental unit --- only returning batch-averaged gradients. Computing non-linear statistics of the mini-batch gradient distribution has traditionally been viewed as prohibitively expensive or requiring complex, custom implementations. We challenge this view by demonstrating that sequence-level architectures offer a natural testbed for prototyping algorithms based on per-example gradients. We show that staged programming languages like JAX enable generic manipulations of mini-batch gradient computations. We then build on Dangel et. al. (2019) to derive implementations of specific per-example or per-token operations with negligible computational or memory overhead. Finally, we leverage our findings to re-examine two nonlinear optimization operations. First, we analyze signSGD, showing that the optimal placement of the sign operation is critical to success and can be predicted via a simple signal-to-noise ratio argument. Second, we investigate per-example variations of the Adam preconditioner and find that, contrary to conventional wisdom, optimization is best served when the preconditioner is dominated by the mean squared of the gradient distribution rather than its variance. Overall our work shows that accessible per-example gradient information unlocks new avenues for algorithm analysis and design.
****

High-accuracy and dimension-free sampling with diffusions
Khashayar Gatmiry, Sitan Chen, Adil Salim
Diffusion models have shown remarkable empirical success in sampling from rich multi-modal distributions. Their inference relies on numerically solving a certain differential equation. This differential equation cannot be solved in closed form, and its resolution via discretization typically requires many small iterations to produce *high-quality* samples.

More precisely, prior works have shown that the iteration complexity of discretization methods for diffusion models scales polynomially in the ambient dimension and the inverse accuracy $1/\varepsilon$. In this work, we propose a new solver for diffusion models relying on a subtle interplay between low-degree appro

ximation and the collocation method, and we prove that its iteration complexity scales *polylogarithmically* in $1/\varepsilon$, yielding the first "high-accuracy" guarantee for a diffusion-based sampler that only uses (approximate) access to the scores of the data distribution. In addition, our bound does not depend explicitly on the ambient dimension; more precisely, the dimension affects the complexity of our solver only through the *effective radius* of the support of the target distribution.
****
CoGe-GCD: Reframing Generalized Category Discovery with Compositional Generalization
Luyao Tang, Jiewei Zheng, Kunze Huang, Chaoqi Chen, Yue Huang, Cheng Chen
Generalized Category Discovery (GCD) assigns unlabeled instances, mixed with labeled data, to known or novel categories, requiring human-like compositional reasoning: reusing primitives learned from known classes and deciding when new combinations imply new categories. Existing GCD methods operate on unstructured token features and struggle to extrapolate to novel compositions. We propose CoGe-GCD, which rethinks GCD through compositional generalization with two coupled stages. (i) Compositional Perception structures patch tokens by mapping them to a small vocabulary of primitives and refining token embeddings via competitive token-primitive assignment and information passing, yielding coherent groups for discovery. (ii) Generalizing Induction exploits the induced geometric structure and applies a structure-preserving calibration over spatial relations, maintaining probabilistic semantics while improving extrapolation to unseen primitive combinations. CoGe-GCD is implemented as an inductive-bias module between backbone and projection head, without modifying heads or losses, and can be plugged into diverse GCD frameworks. On standard benchmarks, it consistently improves all-class accuracy, unknown-class number estimation, and geometric quality, with marginal computational overhead.
****
When Can We Trust Survival Model Evaluation ?
Ghanem BAHRINI, Sebastien Razakarivony, Jean-François Dupuy, Valerie Gares, Morgane Barbet-Massin
Evaluating survival models under censoring is inherently challenging, yet standard evaluation practices are often applied without explicitly assessing how censoring distorts metric reliability. Performing a large experimental study, we analyze and quantify how survival evaluation metrics are affected in fundamentally different ways by the censoring rate and the censoring mechanism. Using a controlled semi-synthetic framework, we vary both the censoring mechanism (administrative, independent, covariate-dependent) and the censoring rate, and compare standard evaluations based on censored data with oracle evaluations using fully observed event times. This controlled setting enables us to quantify distortions along two complementary axes: numerical bias and preservation of model ranking. Across datasets and metric families, we find that censoring induces systematic, mechanism-dependent distortions. Moderate numerical bias, if not properly addressed, can lead to unreliable model comparison as censoring increases. These findings reveal fundamental limitations of common benchmarking practices and call for more careful interpretation of survival evaluation under realistic censoring.

Discovering Differences in Strategic Behavior between Humans and LLMs
Caroline Wang, Daniel Kasenberg, Kim Stachenfeld, Pablo Samuel Castro
As Large Language Models (LLMs) are increasingly deployed in social and strategic scenarios, it becomes critical to understand where and why their behavior diverges from that of humans.
While behavioral game theory (BGT) provides a framework for analyzing behavior, existing models do not fully capture the idiosyncratic behavior of humans or black-box, non-human agents like LLMs.
We employ AlphaEvolve, a cutting-edge program discovery tool, to directly discover *interpretable* models of human and LLM behavior from data, thereby enabling open-ended discovery of structural factors driving human and LLM behavior. Our analysis on iterated rock-paper-scissors reveals that frontier LLMs can be capabl

e of deeper strategic behavior than humans. These results provide a foundation f
or understanding structural differences driving differences in human and LLM beh
avior in strategic interactions.

Scalable Traffic Signal Control with Shared Policy Framework
Haolun MA, Yanchen ZHU, Zizhuo Xu, Weijie Shi, Jiajie Xu, Lei Li
Learning-based Traffic Signal Control (TSC) achieves satisfactory performance in
 small networks, but its effectiveness often deteriorates in larger networks und
er dynamic traffic patterns and intersection heterogeneity. In this work, we pro
pose SLight, a policy-aware grouped MARL-TSC framework that enables scalability
and efficiency balance under dynamic and heterogeneous traffic conditions. SLigh
t captures policy-influenced traffic patterns with a policy-aware traffic patter
n encoder, learns explicit group-level shared control principles from state–acti
on trajectories, and matches each intersection’s traffic pattern embedding to pr
inciple prototypes flexibly through a compatibility-based adaptive assignment mo
dule. Experiments on real-world and synthetic networks demonstrate that SLight s
ustains performance gains as scale increases and outperforms existing rule-based
, reinforcement learning, and grouping-based baselines. Code is available at \ur
l{https://github.com/MaHaoLun/Slight-code.git}

Dynamic Compression Flows for Neuroscience Data
Ganchao Wei, Daniela F De Albuquerque, Miles Martinez, Shiyang Pan, John Pearson
While neuroscience experiments have repeatedly demonstrated the involvement of l
arge populations of neurons in even simple behaviors, these studies have just as
 often reported that the collective dynamics of neural activity are approximatel
y low-dimensional. As a result, methods for identifying low-dimensional latent r
epresentations of time series data have become increasingly prominent in neurosc
ience. However, most existing methods either ignore temporal structure or model
time evolution using latent dynamical systems approaches. In the first case, dyn
amics may be distorted or even scrambled in the latent space, while in the secon
d, many possible latent dynamics may give rise to the same data. Here, we addres
s these challenges using a novel flow-matching approach in which data are genera
ted by a pair of flow fields, one governing time evolution, the other a mapping
between data and a low-dimensional latent space. Importantly, the dimension-redu
cing flow is trained to minimize distortions of the temporal dynamics, learning
an identifiable low-dimensional representation that preserves temporal relations
 in the original data. Additionally, we constrain our latent spaces to have low-
dimensional support in a soft, parameterized manner, taking inspiration from ide
as on nested dropout. Across both neural and behavioral data, we show that this
dual flow approach produces both more interpretable dynamics and higher-quality
reconstructions than competing models, including in noise-dominated data sets wh
ere conventional approaches fail.

Unifying Deep Stochastic Processes for Image Enhancement
Wojciech Maciej Koz■owski, Rados■aw Kuczba■ski, Kamil Adamczewski, Karol Szczypk
owski, Maciej Zieba
Deep stochastic processes have recently become a central paradigm for image enha
ncement, with many methods explicitly conditioning the stochastic trajectory on
the degraded input. However, the relationship between these conditional processe
s and standard diffusion models remains unclear. In this work, we introduce a un
ified perspective on stochastic image enhancement by classifying recent methods
into three families of continuous-time processes: unconditional diffusion models
, Ornstein–Uhlenbeck (OU) processes, and diffusion bridges. We show that all of
these approaches arise from a common stochastic differential equation (SDE) form
ulation. This framework makes explicit that seemingly disparate methods differ p
rimarily in their drift and diffusion terms, terminal distributions, and boundar
y conditions, while schedulers and samplers constitute orthogonal design choices
. Leveraging this unification, we conduct a controlled empirical study across mu
ltiple image enhancement tasks using identical architectures and training protoc
ols. Our results reveal no consistently dominant method; instead, we identify an

d disentangle the specific design choices that most strongly influence performan
ce.
Finally, we release ItoVision, a modular PyTorch library that implements the uni
fied framework and enables rapid prototyping and fair comparison of stochastic i
mage enhancement methods.

FairGB: A Fair Granular-Ball Generation Method for Data Classification
Qifen Yang, Yuhui Deng, Jiande Huang, Peng Zhou, Xiwen Lu, Lin Cui
With the widespread application of data-driven classifiers in high-risk domains,
 group fairness has become an important research focus. However, most existing m
ethods rely on model constraints or data reweighting, which may limit interpreta
bility or distort the original data distribution. Granular-ball computing (GBC),
 as a structured and interpretable learning framework, provides a natural founda
tion for incorporating group fairness into data partitioning. Based on this insi
ght, we propose a $\textbf{Fair}$ $\textbf{G}$ranular-$\textbf{B}$all $\textbf{G
}$eneration framework (FairGBG), which employs fair clustering to maintain balan
ced proportions of sensitive groups within each granular ball (GB), thereby enha
ncing within-ball group fairness. Theoretical analysis shows that FairGBG can pr
eserve high GB purity while satisfying group fairness requirements. Furthermore,
 we introduce a $\textbf{Fair}$ $\textbf{G}$ranular-$\textbf{B}$all-based data $
\textbf{F}$air $\textbf{C}$lassification method (FairGBFC), which leverages fair
 GBs to improve classification fairness. Experiments on multiple benchmark datas
ets demonstrate that, compared with existing GB generation methods, FairGBG can
generate locally fair GBs. Moreover, compared with state-of-the-art fairness-awa
re baselines, FairGBFC achieves a superior trade-off between accuracy and fairne
ss, effectively mitigating bias while preserving high utility. Our code is publi
cly available at https://github.com/jamesandai/FairGB.

Beyond Logits: Coherent Hallucination Mitigation via Attention Contrastive Decod
ing
Yujia Chen, Rui Sun, Huayu Mai, Wangkai Li, Zhangyu He, Bingzhou Wang, Aibing Li
, Wenzhang SUN, Tianzhu Zhang
Large Vision-Language Models (LVLMs) demonstrate impressive multimodal capabilit
ies, yet suffer from hallucination—generating factually inaccurate content. Cont
rastive Decoding (CD) mitigates this by contrasting amateur and expert branches
at the logit level. However, our investigation reveals that such logit-level int
erventions fundamentally compromise generation coherence, necessitating restrict
ive penalty constraints unrelated to hallucination suppression. We introduce Att
ention Contrastive Decoding (ACD), a training-free plug-in that complements logi
t-level CD by relocating part of the contrastive operations to the attention mec
hanism. Operating at an earlier stage of the forward pass, ACD performs smooth s
emantic-preserving interventions through an Adaptive Subtraction Strategy (ASS),
 which attenuates hallucination-associated attention patterns while amplifying c
ritical visual information. Extensive experiments demonstrate that combining ACD
 with existing CD methods (e.g., VCD+ACD) produces substantially more coherent o
utputs with further reduced hallucinations, eliminating restrictive penalties wh
ile enabling trustworthy multimodal generation.
****

BrokenMath: A Benchmark for Sycophancy in Theorem Proving with LLMs
Ivo Petrov, Jasper Dekoninck, Martin Vechev
Large language models (LLMs) have recently shown strong performance on mathemati
cal benchmarks. At the same time, they are prone to hallucination and sycophancy
, often providing convincing but flawed proofs for incorrect mathematical statem
ents provided by users. This significantly limits the applicability of LLMs in t
heorem proving, as verification of these flawed proofs must be done manually by
expert mathematicians. However, existing benchmarks that measure sycophancy in m
athematics are limited: they focus solely on final-answer problems, rely on very
 simple and often contaminated datasets, and construct benchmark samples using s
ynthetic modifications that create ill-posed questions. To address these issues,
 we introduce BrokenMath, the first benchmark for evaluating sycophantic behavio

r in LLMs within the context of natural language theorem proving. BrokenMath is built from advanced 2025 competition problems, which are perturbed with an LLM to produce false statements and subsequently refined through expert review. We evaluate state-of-the-art LLMs and agentic systems and find that sycophancy is widespread, with the best model, GPT-5, producing sycophantic answers 29% of the time. We further investigate several mitigation strategies, including test-time interventions and supervised fine-tuning on curated sycophantic examples. These approaches reduce, but do not eliminate, sycophancy.
****
Reranker Helps, but Not Enough: Towards Strong Poisoning Attacks Against Retrieval-Augmented Generation
Xiaokun Yang, Jian Liang, Yesheng Liu, Xin Xiong, Ran He, Tieniu Tan
Retrieval-Augmented Generation (RAG) augments large language models with external knowledge, which in turn exposes their retrieval corpora to data poisoning risks.
However, existing poisoning attacks exhibit limited effectiveness against RAG equipped with a reranker to enhance retrieval quality.
Remarkably, this defensive capability requires no adversarial training: a reranker fine-tuned solely on benign, in-domain corpora can effectively filter malicious content.
Towards realistic RAG red-teaming, we conclude practical prompt design principles that reveal reranker blind spots.
Building on these insights, we introduce the Prompt-Perturbation Poisoning Attack ($\mathbf{P}^3 \mathbf{A}$).
$\mathbf{P}^3 \mathbf{A}$ first employs rule-based prompt engineering to craft initial poisoned texts.
It then injects subtle character-level perturbations into these texts, which promotes their ranking by the reranker while maintaining their adversarial effectiveness.
These perturbations introduce only about 1\% textual change, ensuring the poisoned texts remain natural and readable.
Extensive experiments show that $\mathbf{P}^3 \mathbf{A}$ achieves strong attack effectiveness and transferability, even when constrained to poisoning a single document.
Code is available at https://github.com/YyyxKun/P3A.
****
Video-OPD: Efficient Post-Training of Multimodal Large Language Models for Temporal Video Grounding via On-Policy Distillation
Jiaze Li, Hao Yin, Haoran Xu, Boshen Xu, Wenhui Tan, Zewen He, Jianzhong Ju, Zhenbo Luo, Jian Luan
Reinforcement learning has emerged as a principled post-training paradigm for Temporal Video Grounding (TVG) due to its on-policy optimization, yet existing GRPO-based methods remain fundamentally constrained by sparse reward signals and substantial computational overhead. We propose Video-OPD, an efficient post-training framework for TVG inspired by recent advances in on-policy distillation. Video-OPD optimizes trajectories sampled directly from the current policy, thereby preserving alignment between training and inference distributions, while a frontier teacher supplies dense, token-level supervision via a reverse KL divergence objective. This formulation preserves the on-policy property critical for mitigating distributional shift, while converting sparse, episode-level feedback into fine-grained, step-wise learning signals. Building on Video-OPD, we introduce Teacher-Validated Disagreement Focusing (TVDF), a lightweight training curriculum that iteratively prioritizes trajectories that are both teacher-reliable and maximally informative for the student, thereby improving training efficiency. Empirical results demonstrate that Video-OPD consistently outperforms GRPO while achieving substantially faster convergence and lower computational cost, establishing on-policy distillation as an effective alternative to conventional reinforcement learning for TVG.

InteractBench: Benchmarking LLMs on Competitive Programming under Unrevealed Inf

ormation
Jiaze Li, Aocheng Shen, Bing Liu, Boyu Zhang, Xiaoxuan Fan, Qiankun Zhang, Xianj un Deng
Competitive programming is increasingly being used to evaluate the algorithmic r easoning capabilities of large language models (LLMs).
However, existing benchmarks primarily focus on full-information tasks where all problem inputs are provided upfront.
This overlooks a critical dimension of algorithmic reasoning: the ability of gen erated programs to operate when key information is not revealed upfront.
Interactive problems, a distinctive component of competitive programming, embo dy this challenge.
These problems require programs to engage in multi-round interaction with an int eractor (a judge program) under strict protocol constraints and limited query bu dgets, with new information revealed *only* in response to queries.
To address this gap, we introduce *InteractBench*, a benchmark comprising 322 hi gh-quality interactive problems curated from Codeforces, AtCoder, IOI, and ICPC.

Each problem is packaged with executable local interactors, enabling fully offli ne evaluation.
Unlike existing benchmarks, InteractBench assesses whether model-generated code can acquire information and track state dynamically.
Our evaluation reveals a significant interaction gap: even the most advanced rea soning models achieve limited success on interactive problems.
Beyond success rates, we propose a fine-grained failure taxonomy to diagnose the root causes of these deficiencies.
Although algorithmic logic errors remain dominant, protocol violations and query -budget overruns are frequent.
Code is available at https://github.com/kmsgk0/InteractBench.

Dual Optimal Transport for Multi-Concept Composition: Structural Alignment and T exture Injection in Diffusion Models
Hao Fu, Tianyu Su, Meng Liu, Chenfang Yang, Tian Gan
Diffusion models have shown impressive capabilities in text-to-image synthesis.
However, multi-concept personalized generation remains challenging, particularly in aligning multiple reference concepts while preserving fidelity.
To address this, we propose a novel Sketch-to-Rendering framework that leverages $\textit{Dual Optimal Transport (OT)}$ for structure alignment and texture injec tion.
Our approach consists of two key components:
$\textit{Structure Sketching via Barycentric Soft-Transport}$,
which ensures shape alignment by using mass-preserving OT for spatial consistenc y,
and $\textit{Texture Rendering via Geometry-Guided Transport}$,
which leverages low-frequency structure alignment to inject high-frequency textu re details via OT-based residual transfer, thereby preserving texture fidelity w ithout distorting structure.
Extensive experiments demonstrate that our method significantly enhances both co nceptual fidelity and visual quality.
Ablation studies further validate the effectiveness of our optimal transport gui dance and the decoupling of structure and texture during the generation process.
Our code is available at https://github.com/fuhao7i/OTComp.

T-POP: Test-Time Personalization with Online Preference Feedback
Zikun Qu, Min Zhang, Mingze Kong, Xiang Li, Zhiwei Shang, Zhiyong Wang, Yikun Ba n, Shuang Qiu, Yao Shu, Zhongxiang Dai
Personalizing large language models (LLMs) to individual user preferences is a c ritical step beyond generating generically helpful responses. However, current p ersonalization methods are ill-suited for new users, as they typically require e ither slow, resource-intensive fine-tuning or a substantial amount of pre-existi ng user data, creating a significant cold-start problem. To address this challen

ge, we introduce a new paradigm for real-time personalization by learning from o
nline pairwise preference feedback collected during text generation. We propose
T-POP (Test-Time Personalization with Online Preference Feedback), a novel algor
ithm that synergistically combines test-time alignment with dueling bandits. Wit
hout updating the LLM parameters, T-POP steers the decoding process of a frozen
LLM by learning a reward function online that captures user preferences. By leve
raging dueling bandits, T-POP intelligently queries the user to efficiently bala
nce between exploring their preferences and exploiting the learned knowledge to
generate personalized text. Extensive experiments demonstrate that T-POP achieve
s rapid and data-efficient personalization, significantly outperforming existing
 baselines and showing consistent improvement with more user interactions.

IVQ: Structured and Lightweight Vector Quantization via Binary Hierarchical Comp
osition Inspired by $\textit{IChing}$
Heda Zuo, Junxian Wu, Fengjie Lu, Pei Chen, Lingyun Sun, Weitao You
Vector Quantization (VQ) has been widely used in visual and audio representation
 due to its effectiveness in compressing high-dimensional signals. However, exis
ting VQ methods often rely on large and unstructured codebooks, which leads to i
nefficient code utilization and frequent codebook collapse. In this paper, we pr
opose *IChing* Vector Quantization (IVQ), a lightweight and structured VQ framew
ork inspired by *IChing*. IVQ introduces binary hierarchical composition and geo
metric symmetry relations into the codebook design, enabling a compact set of st
ructured codes to represent the latent space while maintaining high utilization
without codebook collapse. Experimental results show that IVQ achieves superior
quality with significantly smaller codebooks and consistently higher utilization
 rates compared to several VQ variants in audio representation. Auxiliary experi
ments on visual reconstruction and cross-modal generation further validate the u
niversality and robustness of IVQ. Codes are released at https://github.com/chou
liuzuo/IVQ.

Mind Your Margin and Boundary: Are Your Distilled Datasets Truly Robust?
Muquan Li, Yingyi Ma, Yihong Huang, Hang Gou, Ke Qin, Ming Li, Yuan-Fang Li, Tao
 He
Dataset distillation (DD) compresses a large training set into a small synthetic
 set for efficient training, but most DD methods optimize only clean accuracy an
d leave robustness uncontrolled. Recent robust DD methods improve robustness, ye
t they often suffer from a poor accuracy–robustness trade-off because they (i) t
reat all adversarially perturbed examples uniformly, despite robust risk being d
ominated by near-zero robust margins, and (ii) do not explicitly increase inter-
class separation in the decision boundary where attacks concentrate. We present
Contrastive Curriculum for Robust Dataset Distillation (C^{2}R), a framework tha
t couples an attack-aware curriculum with a contrastive robustness objective. Fr
om a robust-margin perspective, we derive a \emph{perturbation score} that appro
ximates each sample’s robust hinge, enabling a curriculum that prioritizes the s
mallest-margin adversaries that most directly drive robust error. In parallel, a
 class-balanced contrastive robustness loss enforces adversarial invariance whil
e explicitly widening boundary separation across classes. Experiments on CIFAR-1
0/100, Tiny-ImageNet, and multiple ImageNet-1K subsets under six attacks show th
at C^{2}R achieves the best robust accuracy, outperforming prior robust DD by 2.
8% on average.

A Short and Unified Convergence Analysis of the SAG, SAGA, and IAG Algorithms
Feng Zhu, Robert W. Heath, Aritra Mitra
Stochastic variance-reduced algorithms such as Stochastic Average Gradient (SAG)
 and SAGA, and their deterministic counterparts like the Incremental Aggregated
Gradient (IAG) method, have been extensively studied in large-scale machine lear
ning. Despite their popularity, existing analyses for these algorithms are dispa
rate, relying on different proof techniques tailored to each method. Furthermore
, the original proof of SAG is known to be notoriously involved, requiring compu
ter-aided analysis. Focusing on finite-sum optimization with smooth and strongly

convex objectives, our main contribution is to develop a single unified converg
ence analysis that applies to all three algorithms: SAG, SAGA, and IAG. Our anal
ysis features two key steps: (i) establishing a bound on delays due to sub-sampl
ing using simple concentration tools, and (ii) carefully designing a novel Lyapu
nov function that accounts for such delays. The resulting proof is short and mod
ular, providing high-probability bounds for SAG and SAGA that can be seamlessly
extended to non-convex objectives and Markovian sampling. As an immediate byprod
uct of our new analysis technique, we obtain the best known rates for the IAG al
gorithm, significantly improving upon prior bounds.

Colorful Pinball: Density-Weighted Quantile Regression for Conditional Guarantee
of Conformal Prediction

Qianyi Chen, Bo Li

Although conformal prediction provides robust marginal coverage guarantees, achi
eving reliable conditional coverage for specific inputs remains challenging.

While exact distribution-free conditional coverage is impossible with finite
samples, recent work has focused on improving the conditional coverage of stand
ard conformal procedures.

Distinct from approaches that target relaxed notions of conditional coverage
, we directly target the mean squared error of conditional coverage by refining
the quantile regression components that underpin many conformal methods.

Leveraging a Taylor expansion, we derive a sharp surrogate objective for qua
ntile regression: a density-weighted pinball loss, where the weights are given b
y the conditional density of the nonconformity score evaluated at the true quant
ile.

We propose a three-headed quantile network that estimates these weights via
finite differences using auxiliary quantile levels at $1-\alpha \pm \delta$, sub
sequently fine-tuning the central quantile by optimizing the weighted loss. We p
rovide a theoretical analysis with exact non-asymptotic guarantees characterizin
g the resulting excess risk. Extensive experiments on diverse high-dimensional r
eal-world datasets demonstrate remarkable improvements in conditional coverage p
erformance.

We release the code at \url{https://github.com/Cqyiiii/Colorful-Pinball-Conf
ormal-Prediction-CPCP}.

GDPO: Group reward-Decoupled Normalization Policy Optimization for Multi-reward
RL Optimization

Shih-Yang Liu, Xin Dong, Ximing Lu, Shizhe Diao, Peter Belcak, Mingjie Liu, Min-
Hung Chen, Hongxu Yin, Yu-Chiang Frank Wang, Kwang-Ting Cheng, Yejin Choi, Jan K
autz, Pavlo Molchanov

As language models become increasingly capable, users expect them to provide not
only accurate responses but also behaviors aligned with diverse human preferenc
es across a variety of scenarios. To achieve this, Reinforcement learning (RL) p
ipelines have begun incorporating multiple rewards, each capturing a distinct pr
eference, to guide models toward these desired behaviors. However, recent work h
as defaulted to apply Group Relative Policy Optimization (GRPO) under multi-rewa
rd setting without examining its suitability. In this paper, we demonstrate that
directly applying GRPO to normalize distinct rollout reward combinations causes
them to collapse into identical advantage values, reducing the resolution of th
e training signal and resulting in suboptimal convergence and, in some cases, ea
rly training failure. We then introduce Group reward-Decoupled Normalization Pol
icy Optimization (GDPO), a new policy optimization method to resolve these issue
s by decoupling the normalization of individual rewards, more faithfully preserv
ing their relative differences and enabling more accurate multi-reward optimizat
ion, along with substantially improved training stability. We compare GDPO with
GRPO across three tasks: tool calling, math reasoning, and coding reasoning, eva
luating both correctness metrics (accuracy, bug ratio) and constraint adherence
metrics (format, length). Across all settings, GDPO consistently outperforms GRP
O, demonstrating its effectiveness and generalizability for multi-reward reinfor
cement learning optimization.

See First, Reason Later: Mutual Information-Guided Reinforcement Learning for Vision-Language Models
Yin Zhang, Zonghan Wu, Jiaxuan Zhao, Junfeng Fang, Zengxiang Li, Kun Wang, Qingsong Wen, Yilei Shao
Vision-Language Models (VLMs) frequently suffer from visual perception errors and hallucinations that compromise answer accuracy in complex reasoning tasks. Reinforcement Learning with Verifiable Rewards (RLVR) offers a promising solution by optimizing policies using answer correctness signals. Despite their effectiveness, prevailing RLVR methods face two critical limitations. First, much of the sampling budget is wasted on trajectories doomed to fail due to early visual description errors. Second, sparse rewards cannot distinguish whether failures stem from visual perception or reasoning stages. We introduce MIRL, a decoupled framework that addresses both limitations by leveraging mutual information (MI) between generated descriptions and visual inputs as a cheap pre-screening signal. This enables intelligent budget allocation toward high-potential trajectories via forking, while decoupled training provides independent MI-based rewards for visual perception optimization, resolving reward blindness. Experiments on six vision-language reasoning benchmarks demonstrate that MIRL achieves 70.22\% average accuracy and successfully surpasses the performance of sampling 16 complete trajectories using only 10 pre-samples with top-6 selection (25\% fewer complete trajectories). Our code is available at: https://github.com/youwyouw/mirl-main.

PASA: A Principled Embedding-Space Watermarking Approach for LLM-Generated Text under Semantic-Invariant Attacks
Zhenxin Ai, Haiyun He
Watermarking for large language models (LLMs) is a promising approach for detecting LLM-generated text and enabling responsible deployment. However, existing watermarking methods are often vulnerable to semantic-invariant attacks, such as paraphrasing.
We propose PASA, a principled, robust, and distortion-free watermarking algorithm that embeds and detects a watermark at the semantic level. PASA operates on semantic clusters in a latent embedding space and constructs a distributional dependency between token and auxiliary sequences via shared randomness synchronized by a secret key and semantic history.
This design is grounded in our theoretical framework that characterizes a jointly optimal embedding-detection pair, achieving the fundamental trade-offs among detection accuracy, robustness, and distortion. Evaluations across multiple LLMs and semantic-invariant attacks demonstrate that PASA remains robust even under strong paraphrasing attacks while preserving high text quality, outperforming standard vocabulary-space baselines. Ablation studies further validate the effectiveness of our hyperparameter choices. Webpage: https://ai-kunkun.github.io/PASA_page/.

Feature Bagging Provides Stability
Yuheng Ma, Qiang Sun
We study feature bagging through the lens of algorithmic stability. Feature bagging is an ensemble strategy that aggregates base learners trained on randomly subsampled feature subsets, possibly in a data-dependent manner. We introduce feature instability (FI), the feature-axis analogue of instance instability (II), which measures sensitivity to removing a single feature. Smaller values of II or FI correspond to stronger stability, and our experiments show that FI captures generalization-relevant information complementary to II. Within this framework, we analyze feature bagging in both a parametric linear model and a model-free setting inspired by recursive feature subsampling in random forests. In both settings, we establish formal guarantees showing that feature bagging improves the relevant stability relative to its non-bagged counterpart, with larger improvements under more aggressive subsampling. We further show that a modest number of bagging rounds is sufficient to approach the infinite-bagging stability level.

TimeRewarder: Learning Dense Reward from Passive Videos via Frame-wise Temporal Distance
Yuyang Liu, Chuan Wen, Yihang Hu, Dinesh Jayaraman, Yang Gao
Designing dense rewards is crucial for reinforcement learning (RL), yet in robotics it often demands extensive manual effort and lacks scalability. One promising solution is to view task progress as a dense reward signal, as it quantifies the degree to which actions advance the system toward task completion over time. We present TimeRewarder, a simple yet effective reward learning method that derives progress estimation signals from passive videos, including robot demonstrations and human videos, by modeling temporal distances between frame pairs. We then demonstrate how TimeRewarder can supply step-wise proxy rewards to guide reinforcement learning. In our comprehensive experiments on ten challenging Meta-World tasks, we show that TimeRewarder dramatically improves RL for sparse-reward tasks, achieving nearly perfect success in 9/10 tasks with only 200,000 interactions per task with the environment. This approach outperforms previous methods and even the manually designed environment dense reward on both the final success rate and sample efficiency. Moreover, we show that TimeRewarder pretraining can exploit real-world human videos, highlighting its potential as a scalable approach to rich reward signals from diverse video sources.
****
Reflex: Real-Time Vision-Language-Action Control through Streaming Inference
Yuanchun Guo, Bingyan Liu
Flow matching Vision-Language-Action (VLA) models promise precise continuous control, but their iterative denoising nature introduces fundamental incompatibilities with real-time robotics: global timestep injection invalidates KV-caching, forcing a choice between slow $O(N^2)$ re-computation or mathematically incorrect cache reuse.
We present **Reflex**, a framework that enables *real-time streaming inference* for flow matching policies by exploiting the *Timestep-Invariance Property*---that perception encoders are functionally independent of the denoising loop.
Reflex partitions the attention context into static, sliding, and dynamic regions, enabling $O(1)$ incremental cache updates while preserving full-batch-equivalent attention outputs for fixed inputs.
To ensure stability under continuous high-frequency inference, we introduce *AdaRMSNorm*, an adaptive normalization layer that prevents BFloat16 numerical collapse by gating on flow phase.
We further maximize throughput through an *async pipeline* that decouples visual encoding from action generation, combined with *operator fusion* that reduces kernel overhead.
On LIBERO and Kinetix benchmarks, Reflex achieves a 2.58$\times$ inference speedup and 50Hz stable streaming, reducing reaction latency by up to 54\% and enabling efficient deployment without performance degradation.

Automatically Finding Reward Model Biases
Zifan Wang, Iván Arcuschin, Arthur Conmy
Reward models are central to large language model (LLM) post-training. However, past work has shown that they can reward spurious or undesirable attributes such as length, format, hallucinations, and sycophancy. In this work, we introduce and study the research problem of automatically finding reward model biases in natural language. We offer a simple approach of using an LLM to iteratively propose and refine candidate biases. Our method can recover known biases and surface novel ones: for example, we found that Skywork-V2-8B, a leading open-weight reward model, often mistakenly favors responses with redundant spacing and responses with hallucinated content. In addition, we show evidence that evolutionary iteration outperforms flat best-of-N search, and we validate the recall of our pipeline using synthetically injected biases. We hope our work contributes to further research on improving RMs through automated interpretability methods.

Automated Formal Proofs of Combinatorial Identities via Wilf–Zeilberger Guidance and LLMs

Beibei Xiong, Hangyu Lv, Junqi Liu, Yisen Wang, Shaoshi Chen, Jianlin Wang, Zhen gfeng Yang, Lihong Zhi
Automating formal proofs of combinatorial identities is challenging for LLM-base d provers, as long-horizon proof planning is required and unconstrained search q uickly explodes.
Symbolic methods such as the Wilf--Zeilberger (WZ) method can achieve a mechaniz ed proof of combinatorial identities by constructing special auxiliary functions and demonstrating that they satisfy specific recurrence relations.
We propose WZ-LLM, a neuro-symbolic framework that turns WZ proof plans into exe cutable proof sketches in Lean~4 and uses an LLM-based prover
to discharge the resulting machine-checkable subgoals.
We also train a dedicated WZ-Prover via a Lean-kernel-verified bootstrapping loo p with expert-verified iteration, followed by DAPO-based refinement.
Experiments show that WZ-LLM achieves a 34\% proof success rate on LCI-Test (10 0 classical combinatorial identities), outperforming strong baselines such as De epSeek-V3 and Goedel-Prover-V2;
moreover, on LCI-Test it proves 5 identities on which the symbolic-only baseline fails.
WZ-LLM also improves performance on CombiBench and PutnamBench-Comb, suggesting the effectiveness of coupling symbolic proof sketches with learned formal reason ing.
Experiments show that WZ-LLM achieves a 34\% proof success rate on LCI-Test (100 classic combinatorial identities), outperforming strong baselines such as DeepS eek-V3 and Goedel-Prover-V2, and delivering consistent gains on CombiBench and P utnamBench-Comb. These results indicate that our framework provides two compleme ntary strengths: improved direct proving for identities beyond the scope of WZ, and substantially higher end-to-end success when WZ sketches guide a specialized prover.
****
Normalization-equivariant Diffusion Models: Learning Posterior Samplers From Noi sy And Partial Measurements
Brett Levac, Jon Tamir, Marcelo Pereyra, Julián Tachella
Diffusion models (DMs) are a powerful framework for image generation and restora tion. However, existing DMs are primarily trained in a supervised manner by usin g a large corpus of clean images. This poses fundamental challenges in many real -world scenarios, where acquiring noise-free data is hard or infeasible. While s ome methods are capable of training DMs using noisy data, they are effective onl y when the amount of noise is very mild or when additional noise-free data is av ailable. In addition, existing methods for training DMs from incomplete measurem ents require access to multiple complementary acquisition processes, a significa nt practical limitation. Here we introduce the first approach for learning DMs f or image restoration using only noisy measurement data from a single operator. F irst, we show that DMs, and more broadly minimum mean squared error denoisers, e xhibit a weak form of scale equivariance linking rescaling in signal amplitude t o changes in noise intensity. We then leverage this theoretical insight to devel op a denoising score-matching strategy that generalizes robustly to noise levels below the training data, thereby enabling the learning of DMs from noisy measur ements. For problems involving measurements both noisy and incomplete, we integr ate our method with equivariant imaging, a complementary self-supervised learnin g framework that exploits the inherent invariants of imaging problems. This allo ws training DMs for image restoration from single-operator noisy measurements. W e validate the effectiveness of our approach through extensive experiments on im age denoising, demosaicing, inpainting, and MRI reconstruction along with compar isons with the state of the art.

Deep Multi-view Graph Clustering via Attribute-aware Bidirectional Structural Re finement and Pseudo-label Guided Multi-level Fusion
Youqing Wang, Tianxiang Zhao, Mengyuan Xin, Ye Su, Jiapu Wang, Tengfei Liu, Junb in Gao, Jipeng Guo
Deep multi-view graph clustering (DMGC) typically leverages graph neural network

s for representation learning, but most existing methods excessively depend on l
ocal and static graph structures and only utilize simplistic cross-view fusion s
trategies. To this end, this paper proposes **A**ttribute-aware Bidirectional St
ructural Refinement (ABSR) and **P**seudo-label Guided Multi-level Fusion (PGMF)
 for DM**GC**, termed **APGC**. Specifically, ABSR selectively strengthens high-
quality connections and suppresses semantically conflicting relationships, achie
ving bidirectional refinement of the graph structure based on attribute similari
ty. It incorporates global attribute semantics into the graph structure, thereby
 promoting the homophilic connections for discriminative graph representation le
arning. Guided by reliable pseudo-labels, PGMF achieves adaptive weighted fusion
 at both the node-level and the view-level, effectively balancing the differenti
ated contributions of multi-view information. Experiments on six homophilic and
heterophilic datasets demonstrate the superior clustering performance of the pro
posed APGC method. The code of APGC could be available at https://github.com/Ti
anxiangZhao0474/APGC.git.

Exploring More to Solve More: Boosting Diversity in Text Diffusion Models via En
tropy-Based Guidance

Jingwei Zhang, Haoyu Lei, Zijin Feng, Jiacheng Sun, Farzan Farnia

Although diffusion models have revolutionized continuous domains like image synt
hesis through high quality generations and controllable guidance mechanisms, bri
nging this controllability to the discrete, sequential nature of text remains an
 open challenge. Meanwhile, current sampling strategies and guidance methods adj
ust token likelihoods without capturing the broader semantic landscape, leading
to a suboptimal balance between fidelity and diversity. In this work, we introdu
ce a novel training-free Semantic-Aware Kernel Entropy (SAKE) guidance method. O
ur method computes the order-2 Rényi entropy over a kernel Gram matrix that capt
ures both cross-token semantic interactions and relative token positions. By lin
earizing this objective in the embedding space, we derive a tractable guidance s
ignal that dynamically adjusts the sampling distribution—flattening it to encour
age exploration during redundancy and sharpening it for fidelity when diverse. E
mpirical experiments demonstrate that our approach achieves a superior Pareto fr
ontier between fidelity and diversity, and improves multi-sample performance on
reasoning-intensive tasks, such as code and mathematics generation, compared to
temperature scaling and discrete guidance baselines.

Artemis: Structured Visual Reasoning for Perception Policy Learning

Wei Tang, Yanpeng Sun, Shan Zhang, Weihao Bo, Xiaofan Li, Piotr Koniusz, Wei Li,
 Na Zhao, Zechao Li

Recent reinforcement-learning frameworks for visual perception policy usually in
corporate intermediate reasoning chains expressed in natural language. Empirical
 observations indicate that such purely linguistic intermediate reasoning often
reduces performance on perception tasks. We argue that the core issue lies not i
n reasoning per se but in the form of reasoning:
while these chains perform semantic reasoning in an unstructured linguistic spac
e, visual perception requires reasoning in a spatial and object-centric space. I
n response, we introduce Artemis, a perception-policy learning method that perfo
rms structured visual reasoning, where each intermediate step is represented as
a (label, bounding-box) pair capturing a verifiable visual state. This design en
ables explicit tracking of intermediate states, direct supervision for proposal
quality, and avoids ambiguity introduced by language-based reasoning. Building u
pon verifiable and spatially grounded reasoning chains, Artemis provides a unifi
ed architecture for diverse perceptual tasks, without requiring the task-specifi
c designs relied upon by prior perceptual policy models. Trained using grounding
 and detection sampeles in natural image domains, Artemis generalizes to countin
g and geometric perception tasks.
At its core, a spatially grounded, object-centric chain rule provides a principl
ed foundation for scalable and general perceptual policies.

Fully Dynamic Coreset Spectral Clustering

Ben Jourdan, Peter Macgregor, Gregory Schwartzman
We present a fully dynamic data structure that supports edge and node updates an d cluster membership queries for the Normalised Cut problem with strong theoreti cal guarantees. Furthermore, our data structure outperforms the state of the art significantly on real world datasets. At the heart of our data structure is the novel notion of *Just-in-Time Sampling Trees*.

The worst-case edge update time of our data structure is $O(\log n)$ where n i s the number of nodes in the current graph. Let $d_{\max}$ be the maximum degree of the current graph, let $T_{NC}(n',k')$ be the running time of an α-ap proximation algorithm for the Normalised Cut problem on n' vertices and k' c lusters, and let $\text{vol}(Y)$ be the sum of the unweighted degrees of all nod es in a set Y. The worst-case query time of our data structure to label all no des in Y is $O\left(kd_{max}^2 \log(n) + \gamma(n,\epsilon,k,Y)\right)$,
with approximation ratio $\alpha \frac{1+\epsilon}{1-\epsilon}$, where $\gamma(n ,\epsilon,k,Y)$ is defined to be $\log(n)\log^\star(n)\epsilon^{-4}k^2 + T_{NC}(\epsilon^{-4}k^2,k) + \epsilon^{-8}k^4 +vol(Y)$.
Assuming $d_{\max}$ is polylogarithmic, as is the case with many sparse real-wor ld graphs, our method achieves the best known trade-off between query time and u pdate time.

Needles in the Haystack: Addressing Signal Dilution Improves scRNA-seq Perturbat ion Response Modeling and Evaluation
Gabriel Mateo Mejia, Henry E Miller, Francis J.A. Leblanc, BO WANG, Brendan Swai n, Lucas Paulo de Lima Camillo
Recent benchmarks reveal that single-cell perturbation response models are often outperformed by simply predicting the dataset mean. Through large-scale *in sil ico* simulations, together with analyses of two real-world perturbation datasets , we trace this anomaly to a metric artifact: unweighted error metrics systemati cally reward mean predictions when perturbation effects are sparse. To address t his limitation, we introduce differentially expressed gene (DEG)-aware metrics—w eighted mean-squared error (WMSE) and weighted delta R^{2} ($R^{2}_{w}(\Delta) $)—that sensitively measure error in niche, perturbation-specific signals. We fu rther propose explicit negative and positive performance baselines to calibrate these metrics. Under this framework, the mean baseline sinks to null performance , while genuinely informative predictors are correctly rewarded. Finally, we sho w that using WMSE as a training objective reduces mode collapse and improves pre dictive performance across multiple model architectures.
****
Local Mechanisms of Compositional Generalization in Conditional Diffusion
Arwen Bradley
Conditional diffusion models appear capable of compositional generalization, i.e ., generating convincing samples for out-of-distribution combinations of conditi oners, but the mechanisms underlying this ability remain unclear. To make this c oncrete, we study length generalization, the ability to generate images with mor e objects than seen during training. In a controlled CLEVR setting (Johnson et a l., 2017), we find that length generalization is achievable in some cases but no t others, suggesting that models only sometimes learn the underlying composition al structure. We then investigate locality as a structural mechanism for composi tional generalization. Prior works proposed score locality as a mechanism for cr eativity in unconditional diffusion models (Kamb & Ganguli, 2024; Niedoba et al. , 2024), but did not address flexible conditioning or compositional generalizati on. In this paper, we prove an exact equivalence between a specific compositiona l structure (*conditional projective composition*) (Bradley et al., 2025) and sc ores with sparse dependencies on both pixels and conditioners (*local conditiona l scores*). This theory also extends to compositions of concepts (such as style+ content) in feature-space. We validate our theory empirically: CLEVR models that succeed at length generalization exhibit local conditional scores, while those that fail do not. Furthermore, we show that a causal intervention explicitly enf orcing local conditional scores enables length generalization in a previously fa

iling model. Finally, we investigate feature-space compositionality in color-con
ditioned CLEVR, and find preliminary evidence of compositional structure and cor
responding local mechanisms in SDXL.

f-Divergence Regularized RLHF: Two Tales of Sampling and Unified Analyses
Di Wu, Chengshuai Shi, Jing Yang, Cong Shen
Reinforcement Learning from Human Feedback (RLHF) has become a cornerstone techn
ique for post-training large language models. While most existing approaches rel
y on the reverse KL-regularization, recent empirical studies have begun explorin
g alternative divergences (e.g., forward KL, chi-squared) as regularizers in RLH
F. However, a unified theoretical understanding of general f-divergence regula
rization remains under-explored. To fill this gap, this work develops a comprehe
nsive theoretical framework for online RLHF with an f-divergence regularized o
bjective. Rather than treating each divergence in isolation, we adopt a holistic
 perspective across the entire class and propose two algorithms based on distinc
t sampling principles. The first extends the classical optimism principle with a
 carefully designed exploration bonus, while the second introduces a new method
that exploits the sensitivity of the optimal policy to reward perturbations unde
r f-divergence regularization. Theoretical analysis shows that $O(\log T)$ reg
ret and $O(1/T)$ sub-optimality gap are achievable, establishing provable effici
ency of both algorithms and, to the best of our knowledge, the first performance
 bounds for online RLHF under general f-divergence regularization.
****

BEAT: Tokenizing and Generating Symbolic Music by Uniform Temporal Steps
Lekai Qian, Haoyu Gu, Jingwei Zhao, Ziyu Wang
Tokenizing music to fit the general framework of language models is a compelling
 challenge, especially considering the diverse symbolic structures in which musi
c can be represented (e.g., sequences, grids, and graphs). To date, most approac
hes tokenize symbolic music as sequences of musical events, such as onsets, pitc
hes, time shifts, or compound note events. This strategy is intuitive and has pr
oven effective in Transformer-based models, but it treats the regularity of musi
cal time implicitly: individual tokens may span different durations, resulting i
n non-uniform time progression. In this paper, we instead consider whether an al
ternative tokenization is possible, where a uniform-length musical step (e.g., a
 beat) serves as the basic unit. Specifically, we encode all events within a sin
gle time step at the same pitch as one token, and group tokens explicitly by tim
e step, which resembles a sparse encoding of a piano-roll representation. We eva
luate the proposed tokenization on music continuation and accompaniment generati
on tasks, comparing it with mainstream event-based methods. Results show improve
d musical quality and structural coherence, while additional analyses confirm hi
gher efficiency and more effective capture of long-range patterns with the propo
sed tokenization.
****

Dynamic Multimodal Evaluation via Knowledge-Enhanced Benchmark Evolution
Junzhe Zhang, Huixuan Zhang, Xiaojun Wan
The rapid development of multimodal large language models (MLLMs) has created an
 urgent demand for more reliable and robust evaluation protocols, however, exist
ing static benchmarks are prone to data contamination and performance saturation
, which can result in inflated or misleading evaluation results. To address thes
e limitations, we first introduce a graph formulation to represent both static a
nd dynamic visual question answering (VQA) samples. Building upon this formulati
on, we propose Knowledge-Enhanced Benchmark Evolution (KBE), a dynamic multimoda
l evaluation framework that first analyzes the original static benchmark, then e
xpands it by integrating multimodal knowledge, transforming the static benchmark
 into a controllable, dynamic evolving version. Crucially, KBE can both reconstr
uct questions by Re-selecting visual information in the original image and expan
d existing questions with external textual knowledge. By explicitly controlling
the degree of question exploration, KBE enables difficulty-controllable evaluati
on across a wide range of model capabilities. Extensive experimental results dem
onstrate that KBE effectively mitigates data contamination and benchmark saturat

ion, while providing a more comprehensive and flexible assessment of MLLM performance.

Alignment between Brains and AI: Evidence for Convergent Evolution across Modalities, Scales and Training Trajectories
Guobin Shen, Dongcheng Zhao, Yiting Dong, Qian Zhang, Yi Zeng
Artificial and biological systems may converge on similar computational strategies despite different architectures and learning mechanisms—a form of convergent evolution. We test this at scale by comparing internal representations of 630 AI models (language and vision; 1.33M–72B parameters) against fMRI from the Natural Scenes Dataset, producing over 60 million alignment measurements. Within each modality, higher-performing models spontaneously develop stronger brain correspondence (language: *r* = 0.89; vision: *r* = 0.53); because the inputs are image-evoked, the language results reflect visual-semantic alignment rather than a direct cross-modal comparison. Longitudinal analysis combined with bidirectional Granger tests further shows that past alignment predicts future performance more reliably than the reverse, identifying brain-like representations as a robust early-emerging correlate of learning. Modality-specific organization also emerges: language models align with limbic and integrative regions, vision models with visual cortical hierarchies.
****
Learning in Structured Stackelberg Games
Maria Florina Balcan, Kiriaki Fragkia, Keegan Harris
We initiate the study of *structured Stackelberg games*, a novel form of strategic interaction between a leader and a follower where contextual information can be predictive of the follower's (unknown) type. Motivated by applications such as security games and AI safety, we show how this additional structure can help the leader learn a utility-maximizing policy in both the online and distributional settings. In the online setting, we first prove that standard learning-theoretic measures of complexity do not characterize the difficulty of the leader's learning task. We find that there exists a learning-theoretic measure of complexity, analogous to the Littlestone dimension in online classification, that *tightly* characterizes the leader's instance-optimal regret. We term this the *Stackelberg-Littlestone dimension*, and leverage it to provide a provably optimal online learning algorithm. In the distributional setting, we provide analogous results by showing that two new dimensions control the sample complexity upper- and lower-bound.
****
Rethinking Evaluation Paradigms in IBP-based Certified Training
Konstantin Kaulen, Hadar Shavit, Holger H. Hoos
Deep neural networks achieve strong performance on many supervised learning tasks but remain vulnerable to adversarial perturbations. Neural network verification provides mathematically rigorous robustness guarantees, yet at substantial computational cost. To mitigate this, certified training techniques optimise for verifiable robustness during training, typically inducing a trade-off between natural and certified accuracy controlled by method-specific hyperparameters.
Because these metrics are inherently conflicting, the common practice of reporting a single configuration is problematic: it can mislead conclusions about overall performance and prevents unbiased assessments of the state of the art. We address this by evaluating certified training methods via Pareto front comparisons over the natural--certified accuracy trade-off. To enable fair, method-agnostic comparisons, we perform efficient automated multi-objective hyperparameter optimisation to identify a set of Pareto-optimal configurations for each method.
This approach often uncovers substantial undertuning in previously reported configurations, yielding superior performance and establishing a new state of the art. Leveraging these fronts, we present the first comprehensive multi-objective comparison of certified training approaches, showing that prior advancements are less pronounced than assumed and revealing previously unreported performance complementarities.

Box Thirding: Anytime Best Arm Identification under Insufficient Sampling
SEOHWA HWANG, Junyong Park
We introduce Box Thirding (B3), a flexible and efficient algorithm for Best Arm Identification (BAI) under fixed budget constraints. It is designed for both any time BAI and scenarios with large N, where the number of arms is too large fo r exhaustive evaluation within a limited budget T. The algorithm employs a Re median Estimation strategy: in each iteration, three arms are compared—the best-performing arm is explored further, the median is retained for future comparison s, and the weakest is discarded. Even without prior knowledge of T, B3 achiev es an ϵ -best arm misidentification probability comparable to Sequenti al Halving, which requires T as a prior, applied to a randomly selected subset of c_0 arms that fit within the budget. Empirical results show that B3 outpe rforms existing methods for the limited budget constraint in terms of simple reg ret, as demonstrated on the New Yorker Cartoon Caption Contest dataset.

Geometry-Preserving Orthonormal Initialization for Low-Rank Adaptation in RLVR
Ruijia Zhang, Jiacheng Zhu, Hanqing Zhu, Laixi Shi
Low-Rank Adaptation (LoRA) and its variants enable parameter-efficient fine-tuni ng of large language models under the supervised fine-tuning (SFT) paradigm. How ever, their efficacy and behavior under Reinforcement Learning with Verifiable R ewards (RLVR) are less well understood. In particular, two structurally initiali zed LoRA variants, PiSSA and MiLoRA, which outperform standard LoRA under SFT, c an underperform standard LoRA under RLVR and may even exhibit training instabili ty. These observations suggest that how to initialize the low-rank matrices in R LVR remains unclear. In this work, we develop a theoretical analysis of LoRA in RLVR, showing that orthonormal initialization achieves the minimal gap between L oRA’s outcome and that of full fine-tuning. Guided by this insight, we propose g eometry-preserving orthonormal initialization for low-rank adaptation in RLVR, l eading to two new variants, LoRA-RLPO and LoRA-RLMO. Experiments on mathematical reasoning benchmarks show that our orthonormal initialization stabilizes RLVR t raining and outperforms standard LoRA, contrasting with PiSSA and MiLoRA. Finall y, our unified analysis also explains why PiSSA and MiLoRA can underperform in R LVR, which may be of independent interest.

Efficient Adaptive Testing via Gradient Path Matching Subset Selection for AI Ed ucation
Yan Zhuang, Junhao Yu, Bohou Zhang, Zachary Pardos, Jinze Wu, Daoqiang Zhang
Adaptive testing is widely adopted in AI-driven educational assessment systems (e.g., GRE), where the goal is to select an optimal subset of questions from a la rge question pool to accurately estimate an examinee's ability. A fundamental ch allenge is that: optimal question subsets are inherently personalized, and solvi ng for them is NP-hard. Recently, it has been framed as a gradient matching prob lem: aligning gradients between selected subsets and the full question set acros s the entire ability parameter space. However, such global alignment on entire s pace is computationally expensive and difficult to scale. In this work, we propo se GPM (Gradient Path Matching), a novel framework that instead aligns gradients along possible optimization paths toward the final estimate. By leveraging inte rmediate gradients as supervision, GPM learns an explicit and generalizable sele ction algorithm from large-scale data. We provide theoretical analysis on its co nvergence and scalability. Experiments on both real-world and synthetic datasets demonstrate that it achieves the same estimation accuracy using, on average, 20 % fewer questions.
****

SHARP-Q: Spectral Hessian Alignment and Rectification for Post-training Quantiza tion
Menghao Lv, Huiqiong Wang, Li Sun, Mingli Song
Post-training quantization (PTQ) suffers from severe accuracy degradation in ult ra-low-bit regimes. To address this challenge, we propose SHARP-Q, a unified fra mework grounded in Information Geometry that aligns the quantization objective w ith the intrinsic Fisher geometry. Following a "Rectify-then-Approximate" strate

gy, SHARP-Q first preconditions the optimization landscape via Hessian-Aware Rectification (HAR) and subsequently approximates the rectified Fisher Information Matrix through Dynamic Fisher-Subspace Compensation (DFSC). Our empirical evaluations reveal a pivotal insight: precise geometric alignment enables hardware-friendly uniform quantizers to outperform specialized non-uniform designs. Extensive experiments across representative convolutional networks, Vision Transformers, and State Space Models confirm that SHARP-Q establishes new state-of-the-art results, achieving substantial accuracy gains in the challenging W2A2 and W3A3 settings.

Multi-Agent Teams Hold Experts Back

Aneesh Pappu, Batu El, Hancheng Cao, Carmelo di Nolfo, Yanchao Sun, Meng Cao, James Zou

Multi-agent LLM systems are increasingly deployed as autonomous collaborators, where agents interact freely rather than execute fixed, pre-specified workflows. In such settings, effective coordination cannot be fully designed in advance and must instead emerge through interaction. However, most prior work enforces coordination through fixed roles, workflows, or aggregation rules, leaving open the question of how well self-organizing teams perform when coordination is unconstrained. Drawing on organizational psychology, we study whether self-organizing LLM teams achieve *strong synergy*, where team performance matches or exceeds the best individual member. Across human-inspired and frontier ML benchmarks, we find that---unlike human teams---LLM teams consistently fail to match their expert agent's performance, even when explicitly told who the expert is, incurring performance losses of up to 41.1\% on ML benchmarks. Decomposing this failure, we show that expert leveraging, rather than identification, is the primary bottleneck. Conversational analysis reveals a tendency toward integrative compromise---averaging expert and non-expert views rather than appropriately weighting expertise---which increases with team size and correlates negatively with performance. Interestingly, this consensus-seeking behavior improves robustness to adversarial agents, suggesting a trade-off between alignment and effective expertise utilization. Our findings reveal a significant gap in the ability of self-organizing multi-agent teams to harness the collective expertise of their members.

****

Less is More: Geometric Unlearning for LLMs with Minimal Data Disclosure

Chenchen Tan, Xinghao Li, Shujie Cui, Youyang Qu, Cunjian Chen, Longxiang Gao

As large language models (LLMs) are increasingly deployed in real-world systems, they must support post-hoc removal of specific content to meet privacy and governance requirements. This motivates selective unlearning, which suppresses information about a particular entity or topic while preserving the LLM's general utility. However, most existing LLM unlearning methods require access to the original training corpus and rely on output-level refusal tuning or broad gradient updates, creating a tension among unlearning strength, non-target preservation, and data availability. We propose Geometric Unlearning (GU), an approach that operates directly on the model's prompt-conditioned hidden states without access to the original training corpus. Specifically, GU distills a compact, low-rank safe-behavior subspace from a small set of safe reference prompts and uses lightweight anchor-in-context synthetic prompts to trigger localized, projection-based alignment of hidden representations to this safe subspace. A teacher-distillation regularizer on synthetic non-target anchors further reduces collateral drift. Across privacy-oriented unlearning benchmarks (ToFU and UnlearnPII), GU achieves strong target suppression with minimal impact on non-target performance, demonstrating that effective unlearning can be achieved with minimal synthetic data.

****

Rethinking Gating Mechanism in Sparse MoE: Handling Arbitrary Modality Inputs with Confidence-Guided Gate

Liangwei Nathan Zheng, Wei Emma Zhang, Mingyu Guo, Olaf Maennel, Weitong Chen

Effectively managing missing modalities is a fundamental challenge in real-world multimodal learning scenarios, where data incompleteness often results from systematic collection errors or sensor failures. Sparse Mixture-of-Experts (SMoE) a

rchitectures have the potential to naturally handle multimodal data, with individual experts specializing in different modalities. However, existing SMoE approach often lacks proper ability to handle missing modality, leading to performance degradation and poor generalization in real-world applications. We propose ConfSMoE to introduce a two-stage imputation module to handle the missing modality problem for the SMoE architecture by taking the opinion of experts and reveal the insight of expert collapse from theoretical analysis with strong empirical evidence. Inspired by our theoretical analysis, ConfSMoE propose a novel expert gating mechanism by detaching the softmax routing score to task confidence score w.r.t ground truth signal. This naturally relieves expert collapse without introducing additional load balance loss function. We show that the insights of expert collapse aligns with other gating mechanism such as Gaussian and Laplacian gate. The proposed method is evaluated on four different real world dataset with three distinct experiment settings to conduct comprehensive analysis of ConfSMoE on resistance to missing modality and the impacts of proposed gating mechanism.

LightAVSeg: Lightweight Audio-Visual Segmentation

Qing Zhong, Guodong Ding, Lingqiao Liu, Zaiwen Feng, Lin Yuanbo Wu, Angela Yao

Audio-Visual Segmentation (AVS) targets pixel level localization of sounding emitting objects in videos. However, existing models rely on dense cross-modal attention with quadratic computational cost, limiting their suitability for resource efficient deployment. Most efficiency oriented methods focus on backbone reduction and overlook the interaction module as the primary bottleneck. This paper proposes LightAVSeg, a lightweight framework that replaces heavy attention with a decoupled design for semantic filtering and spatial grounding, resulting in interaction costs that scale linearly with spatial resolution. Furthermore, we introduce an auxiliary alignment loss to enforce semantic consistency during training with zero inference overhead. Extensive experiments demonstrate that LightAVSeg achieves a new state-of-the-art among lightweight methods: with 20.5M parameters (~1/7 of AVSegFormer), it reaches 50.4 mIoU on the MS3 benchmark and enables efficient inference on a mobile processor.

AutoControl Arena: Synthesizing Executable Test Environments for Frontier AI Risk Evaluation

Changyi Li, Pengfei Lu, Xudong Pan, Fazl Barez, Min Yang

As Large Language Models (LLMs) evolve into autonomous agents, existing safety evaluations face a fundamental trade-off: manual benchmarks are costly, while LLM-based simulators are scalable but suffer from logic hallucination. We present AutoControl Arena, an automated framework for frontier AI risk evaluation built on the principle of logic-narrative decoupling. By grounding deterministic state in executable code while delegating generative dynamics to LLMs, we mitigate hallucination while maintaining flexibility. This principle, instantiated through a three-agent framework, achieves over 98% end-to-end success and 60% human preference over existing simulators. To elicit latent risks, we vary environmental Stress and Temptation across X-Bench (70 scenarios, 7 risk categories). Evaluating 9 frontier models reveals: (1) Alignment Illusion: risk rates surge from 21.7% to 54.5% under pressure, with capable models showing disproportionately larger increases; (2) Scenario-Specific Safety Scaling: advanced reasoning improves robustness for direct harms but worsens it for gaming scenarios; and (3) Divergent Misalignment Patterns: weaker models cause non-malicious harm while stronger models develop strategic concealment. Code and data are available at https://github.com/CosmosYi/AutoControl-Arena.

DNA: Uncovering Universal Latent Forgery Knowledge

Jingtong Dou, Chuancheng Shi, Anqi Yi, Shiming Guo, Wenhua Wu, Yemin Wang, Li Zhang, Fei Shen, Tat-Seng Chua

As generative AI achieves hyper-realism, superficial artifact detection has become obsolete. While prevailing methods rely on resource-intensive fine-tuning of black-box backbones, we propose that forgery detection capability is already encoded within pre-trained models rather than requiring end-to-end retraining.

To elicit this intrinsic capability, we propose the discriminative neural anchors (DNA) framework, which employs a coarse-to-fine excavation mechanism. First, by analyzing feature decoupling and attention distribution shifts, we pinpoint critical intermediate layers where the focus of the model logically transitions from global semantics to local anomalies. Subsequently, we introduce a triadic fusion scoring metric paired with a curvature-truncation strategy to strip away semantic redundancy, precisely isolating the forgery-discriminative units (FDUs) inherently imprinted with sensitivity to forgery traces.
Moreover, we introduce HIFI-Gen, a high-fidelity synthetic benchmark built upon the very latest models, to address the lag in existing datasets.
Experiments demonstrate that by solely relying on these anchors, DNA achieves superior detection performance even under few-shot conditions. Furthermore, it exhibits remarkable robustness across diverse architectures and against unseen generative models, validating that waking up latent neurons is more effective than extensive fine-tuning.

CoRe: Collaborative Reasoning via Cross Teaching
Kshitij Mishra, Mirat Aubakirov, Martin Taká■, Nils Lukas, Salem Lahlou
Large language models exhibit complementary reasoning errors: on the same instance, one model may succeed with a particular decomposition while another fails. We propose Collaborative Reasoning (CoRe), a training-time collaboration framework that converts peer success into a learning signal via a cross-teaching protocol. Each problem is solved in two stages: a cold round of independent sampling, followed by a contexted rescue round in which failed models receive a hint extracted from a successful peer. CoRe optimizes a combined reward that balances (i) correctness, (ii) a lightweight DPP-inspired diversity term to reduce error overlap, and (iii) an explicit rescue bonus for successful recovery. We evaluate CoRe in low-data regimes across GSM8K, MATH, AIME, and GPQA. With only 1,000 training examples, a pair of small open-source models (3B+4B) reaches 99.54% oracle Team Pass@2 on GSM8K and 92.08% on MATH, compared to 82.50% and 74.82% for single-model training. On harder datasets, the same pair reaches 77.34% oracle Team Pass@2 on GPQA (trained on 348 examples) and 79.65% on AIME (trained on 792 examples), using a training-time budget of at most 1536 context tokens and 3072 generated tokens. A three-model non-oracle AIME evaluation further closes most of the oracle-selection gap (81.20% majority vote vs. 82.60% oracle Team Pass@2). Overall, these results show that training-time collaboration can reliably convert model complementarity into large gains without scaling model size.

HelioX: A GPU-Native Framework for Simulation and Training of Biophysically Detailed Networks
JUNFENG LU, Zijie Yu, Shaoyang Cui, Gan He, Ruiqin Xiong, Kai Du, Tiejun Huang
Biophysically detailed neural networks represent a promising frontier for brain-inspired AI, offering intrinsic spatio-temporal dynamics to enhance the expressivity and computational density of deep learning systems. However, general-purpose deep learning frameworks suffer from a fundamental mismatch between their dense parallel optimizations and the irregular, tree-structured complexity of biological mechanisms. In this work, we propose **HelioX**, a \textbf{GPU-native} framework designed to unify high-performance simulation with scalable training. Unlike approaches that adapt biology to existing deep learning tools, **HelioX** adopts a “GPU-to-Biophysics'' paradigm. We tailor the underlying GPU parallelism to biological structures by implementing custom-fused CUDA kernels for both the Dendritic Hierarchical Scheduling (DHS) algorithm and its gradient propagation. This design eliminates the runtime overhead of generic automatic differentiation and enables multi-stream concurrency for spike generation and equation assembly.
Experimental results demonstrate that **HelioX** outperforms standard simulators (NEURON) by orders of magnitude and surpasses prior GPU-based solvers in both speed and scalability. We successfully train deep biophysical MLPs and whole-brain-scale biophysical circuits (e.g., the BAAIWorm \textit{C. elegans} model) on a single consumer-grade GPU. **HelioX** establishes a new standard for computational efficiency, enabling the training of biophysically detailed models at scales

previously unattainable.

VCG-Bench: Towards A Unified Visual-Centric Benchmark for Structured Generation and Editing
Xiaoyan Su, Peijie Dong, Zhenheng Tang, Song Tang, Yuyao Zhai, Kaitao Lin, Liang Chen, Gai Yuhang, Yuyu Luo, Qiang Wang, Xiaowen Chu
Despite the rapid advancements in Vision-Language Models (VLMs), a critical gap remains in their ability to handle structured, controllable diagrammatic tasks essential for professional workflows, as existing methods predominantly rely on pixel-based synthesis which operates in probabilistic pixel spaces and is inherently limited in editability and fidelity; instead, we propose a new "Diagram-as-Code" paradigm with symbolic logic that leverages `mxGraph` Extensible Markup Language (XML) for precise diagram generation and editing, and we present **VCG-Bench**, a unified benchmark for visual-centric `mxGraph` tasks comprising (1) a taxonomized dataset of 1,449 diverse diagrams spanning 6 domains and 15 sub-domains, (2) a paradigm definition that integrates Generation (Vision-to-Code) and Editability (Code-to-Code), and (3) a Tailored Evaluation Protocol employing multi-dimensional metrics such as `mxGraph` Execution Success Rate and Style Consistency Score (SCS), where experimental results highlight the challenges faced by current State-of-the-Art (SOTA) VLMs in structured fidelity and instruction compliance, reflecting their vision and reasoning capabilities.
****
CUARewardBench: A Benchmark for Evaluating Reward Models for Computer-Using Agents
Haojia Lin, Xiaoyu Tan, Yulei Qin, Zihan Xu, Yuchen Shi, Zongyi Li, Gang Li, Shaofei Cai, Siqi Cai, Yuzheng Cai, Chaoyou Fu, Ke Li, Xing Sun
Computer-using agents (CUAs) enable task completion through natural interaction with operating systems and software interfaces. While script-based verifiers are widely adopted for evaluation, they suffer from limited scalability and inability to provide step-wise assessment. Reward models offer promising alternatives, but their effectiveness on CUA evaluation remains largely underexplored. To address this gap, we present CUARewardBench, comprising four key contributions: (1) First-ever Comprehensive CUA Reward Benchmark: We introduce the first benchmark for evaluating both outcome reward models (ORM) and process reward models (PRM) on CUA tasks, enabling systematic assessment across trajectory-level and step-level evaluation. (2) Diverse, Practical and Reliable Dataset: CUARewardBench encompasses trajectories from 10 software categories and 7 agent architectures with varying performance levels (25.9%-50.8% success rates). All trajectories are expertly annotated through carefully designed protocols, with rigorous quality control to ensure reliability and practical applicability. (3) Comprehensive Analysis and Insights: Through extensive experiments across 7 vision-language models and 3 prompt templates, we reveal critical limitations of current CUA RMs, including insufficient visual reasoning capabilities, knowledge deficiencies, and the superiority of general VLMs over specialized CUA models for reward evaluation. (4) Unanimous Prompt Ensemble (UPE): Based on the insights from our comprehensive analysis, we propose UPE, a novel ensemble method that significantly enhances reward model reliability through strict unanimous voting and strategic prompt-template configurations. UPE achieves 88.0% precision and 95.3% NPV for ORM, and 83.1% precision and 86.2% NPV for PRM, substantially outperforming single VLMs and traditional ensemble approaches. In a short, this work introduces both a comprehensive benchmark and a novel ensemble method that substantially enhances CUA reward model reliability.
****
SPAR: Support-Preserving Action Rectification
Jiaxin Zhao, Weihang Pan, Xun Liang, Binbin Lin
Offline policy improvement faces an inherent conflict between maximizing value and fitting the data distribution. While in-sample weighted regression is stable, it suffers from over-conservatism that suppresses high-value actions in the distribution tail; conversely, gradient-based approaches often exhibit a fitting-optimization conflict of gradients, which drive the policy off the data manifold.

To address this, we propose \textbf{S}upport-\textbf{P}reserving \textbf{A}ction \textbf{R}ectification (SPAR), which reframes global learning as a local residual rectification anchored to a frozen pure behavior cloning policy. This framework performs fine-grained fitting and local policy improvement in the residual space, thereby contracting the search space. We further introduce Latent Self-Imitation, utilizing a latent-sampling weighted-regression mechanism to address fitting-improvement gradient conflict in the residual space. Theoretically, we prove this mechanism eliminates the manifold-normal drift of standard value gradients, while extensive D4RL experiments show SPAR extracts significant gains from suboptimal baselines to achieve state-of-the-art performance.

Functional building blocks of neural networks: from network motifs to collective dynamics

Jian Zhang, Yue Sun, Wangzi Yao, Tielin Zhang

The advancement of artificial neural networks (ANNs) has been driven by diverse and well-established architectural designs, especially in connectivity. Biological neural networks, which exhibit a rich variety of neurodynamic circuits, offer a valuable source of inspiration for developing novel ANN models. In this study, we analyze the meta-connectivity structure and introduce a network motif-based approach, in which 13 distinct motifs are modeled as functional building blocks. These motifs represent low-dimensional, fundamental components of larger network architectures. Through rigorous theoretical analysis, we classify these motifs into a three■layer hierarchical classification of their dynamical regimes and demonstrate that their hierarchical proportions critically shape collective neural dynamics. Furthermore, by embedding motif distributions into recurrent neural networks (RNNs), we show that these motifs can selectively enhance either network robustness or flexibility. Collectively, our findings provide a theoretical framework—supported by extensive experiments—for understanding how specific network motifs influence the computational properties of artificial intelligence systems via their underlying dynamics. This motif-driven approach offers significant potential for analyzing and modulating neural dynamics in ANNs.

Fair Decisions from Calibrated Scores: Achieving Optimal Classification While Satisfying Sufficiency

Etam Benger, Katrina Ligett

Binary classification based on predicted probabilities (scores) is a fundamental task in supervised machine learning. While thresholding scores is Bayes-optimal in the unconstrained setting, using a single threshold generally violates statistical group fairness constraints. Under independence (statistical parity) and separation (equalized odds), such thresholding suffices when the scores already satisfy the corresponding criterion. However, this does not extend to sufficiency: even perfectly group-calibrated scores---including true class probabilities---violate predictive parity after thresholding. In this work, we present an exact solution for optimal binary (randomized) classification under sufficiency, assuming finite sets of group-calibrated scores. We provide a geometric characterization of the feasible pairs of positive predictive value (PPV) and false omission rate (FOR) achievable by such classifiers, and use it to derive a simple post-processing algorithm that attains the optimal classifier using only group-calibrated scores and group membership. Finally, since sufficiency and separation are generally incompatible, we identify the classifier that minimizes deviation from separation subject to sufficiency, and show that it can also be obtained by our algorithm, often achieving performance comparable to the optimum.

SafeSeek: Universal Attribution of Safety Circuits in Language Models

Miao Yu, Siyuan Fu, Moayad Aloqaily, Zhenhong Zhou, Safa Otoum, Xing fan, Kun Wang, Yufei Guo, Qingsong Wen

Mechanistic interpretability reveals that safety-critical behaviors (e.g., alignment, jailbreak, backdoor) in Large Language Models (LLMs) are grounded in specialized functional components. However, existing safety attribution methods struggle with generalization and reliability due to their reliance on heuristic, doma

in-specific metrics and search algorithms. To address this, we propose SafeSeek, a unified safety interpretability framework that identifies functionally complete safety circuits in LLMs via optimization. Unlike methods focusing on isolated heads or neurons, SafeSeek introduces differentiable binary masks to extract multi-granular circuits through gradient descent on safety datasets, while integrates Safety Circuit Tuning to utilize these sparse circuits for efficient safety fine-tuning. We validate SafeSeek in two key scenarios in LLM safety: \textbf{(1) backdoor attacks}, identifying a backdoor circuit with 0.42\% sparsity, whose ablation eradicates the Attack Success Rate (ASR) from 100\% $\to$ 0.4\% while retaining over 99\% general utility; \textbf{(2) safety alignment}, localizing an alignment circuit with 3.03\% heads and 0.79\% neurons, whose removal spikes ASR from 0.8\% $\to$ 96.9\%, whereas excluding this circuit during helpfulness fine-tuning maintains 96.5\% safety retention.

GSFixer: Improving 3D Gaussian Splatting with Reference-Guided Video Diffusion Priors

Xingyilang Yin, Qi Zhang, Jiahao Chang, Ying Feng, Qingnan Fan, Xi Yang, Chi-Man Pun, Huaqi Zhang, Xiaodong Cun

Reconstructing 3D scenes using 3D Gaussian Splatting (3DGS) from sparse views is an ill-posed problem due to insufficient information, often resulting in noticeable artifacts. While recent approaches have sought to leverage generative priors to complete information for under-constrained regions, they struggle to generate content that remains consistent with input observations. To address this challenge, we propose GSFixer, a novel framework designed to improve the quality of 3DGS representations reconstructed from sparse inputs. The core of our approach is the reference-guided video restoration model, built upon a DiT-based video diffusion model trained on paired artifact 3DGS renders and clean frames with additional reference-based conditions. Considering the input sparse views as references, our model integrates both 2D semantic and 3D geometric features of reference views extracted from the visual geometry foundation model, enhancing the semantic coherence and 3D consistency when fixing artifact novel views. Furthermore, we introduce a reference-guided trajectory sampling strategy that ensures both angular coverage and view quality, further enhancing reconstruction fidelity. Considering the lack of suitable benchmarks for 3DGS artifact restoration evaluation, we present DL3DV-Res which contains artifact frames rendered using low-quality 3DGS. Extensive experiments demonstrate our GSFixer outperforms current state-of-the-art methods in 3DGS artifact restoration and sparse-view 3D reconstruction. Project page: https://github.com/GVCLab/GSFixer.

Debate with Images: Detecting Deceptive Behaviors in Multimodal Large Language Models

Sitong Fang, Shiyi Hou, Kaile Wang, Boyuan Chen, Donghai Hong, Jiayi Zhou, Juntao Dai, Yaodong Yang, Jiaming Ji

As frontier AI systems become increasingly capable, concerns about deceptive behaviors have intensified. Unlike hallucinations, which stem from capability limitations, deception involves strategically misleading responses despite correct internal representations. While prior work has primarily studied deception in text-only settings, little is known about how such behaviors manifest in multimodal large language models. In this work, we systematically investigate multimodal deception and introduce *MM-DeceptionBench*, the first benchmark designed to evaluate deceptive behaviors in vision–language models across six realistic categories. We find that existing text-centric monitoring approaches are insufficient in multimodal settings due to the complexity of cross-modal reasoning. To address this gap, we propose *debate with images*, a multi-agent evaluation framework that enforces visual grounding through adversarial debate. Experiments show that this approach achieves substantially higher agreement with human judgments than MLLM-as-a-judge baselines, improving Cohen’s kappa by up to 1.5$\times$ and accuracy by up to 1.25$\times$ on GPT-4o.
****

M+Adam: Low-Precision Training via Additive–Multiplicative Optimization

Xiaoyuan Liang, Sebastian Loeschcke, Mads Toftrup, Anima Anandkumar
Training with quantized weights can reduce costs but often results in degraded a ccuracy, especially when optimization is carried out in low precision, without s toring high-precision copies. We identify a key failure mode: under low precisio n, standard optimizers can get stuck and not make progress, especially at large weight magnitudes due to coarse mantissa resolution. To overcome this, multiplic ative updates have been previously proposed, in place of additive updates in sta ndard optimizers. While successful under extremely low precision, such as under the logarithmic number system, they suffer from failures near zero and across si gn changes. The failure modes of additive and multiplicative updates are therefo re complementary. To exploit this, we propose M+Adam, which combines both update types: additive steps handle sign changes and small magnitudes, while multiplic ative steps ensure progress at large magnitudes when additive updates are zeroed out under rounding. We prove monotone descent for M+Adam under standard smoothn ess assumptions. Across LLaMA-style pretraining with 60M--1B models, 1--$8\tim es$ Chinchilla budgets, and using only BF16, FP8, and FP4 master weights, M+Adam consistently improves low-precision training.
****

CorrectionPlanner: Self-Correction Planner with Reinforcement Learning in Autono mous Driving
Yihong Guo, Dongqiangzi Ye, Sijia Chen, Anqi Liu, Xianming Liu
Autonomous driving requires safe planning, but most learning-based planners lack explicit self-correction ability: once an unsafe action is proposed, there is n o mechanism to correct it. Thus, we propose CorrectionPlanner, an autoregressive planner with self-correction that contains a propose, evaluate, and correct loo p in the motion-token generation process. At each planning step, the policy prop oses an action, namely a motion token, and a learned collision critic predicts w hether it will induce a collision within a short horizon. If the critic predicts a collision, we retain the sequence of historical unsafe motion tokens as a sel f-correction trace, generate the next motion token conditioned on it, and repeat this process until the safe motion token is proposed or the safety criterion is met. This self-correction trace, consisting of all the unsafe motion tokens, re presents the planner’s correction process in motion-token space. We train the pl anner with imitation learning followed by model-based reinforcement learning usi ng rollouts from a pretrained world model that realistically models agents' reac tive behaviors. Closed-loop evaluations show that CorrectionPlanner reduces the collision rate by over 20% on Waymax and obtains state-of-the-art planning sc ores on nuPlan.

From Prompts to Responses: Dual-Sided Data Leakage and Defense in Split Large La nguage Models
Zixuan GU, Xiaojun Ye, Yang Liu
Large language models (LLMs) are increasingly deployed in privacy-sensitive doma ins, where users must balance the risk of data exposure through external APIs ag ainst the high computational cost of local deployment. Split learning has theref ore emerged as a promising paradigm for LLM fine-tuning and inference under limi ted local resources. However, it introduces new privacy risks. Prior work primar ily studies leakage of private input prompts, typically via inversion attacks on intermediate representations, while the potential for sensitive information lea kage through generative response outputs remains largely unexplored.

In this work, we unveil novel vulnerabilities of Split-LLM by presenting **P**at ched Model **I**nversion with **D**ual-Sided **I**nitialization(**PIDI**), a two -stage attack that simultaneously targets both private input prompts and output responses in Split-LLM settings. It combines dual-sided initialization with a pa tched inversion strategy to tackle long sequences, substantially outperforming p rior inversion methods.
To counter threats from both sides, we further propose the **A**dapter-based **D **ualGuard with **M**utual **I**nformation Defense(**ADMI**), which integrates a n adapter-based local warmup strategy and mutual information regularization to p

rovide a strong empirical privacy protection with minimal impact on task perform ance.
Extensive experiments across diverse tasks and models demonstrate that ADMI effe ctively defends against PIDI and other state-of-the-art inversion attacks. Our c ode is publicly available at \url{https://github.com/FLAIR-THU/VFLAIR-LLM}.
****
Scalable Bayesian Inference for Nonlinear Conservation Laws
Tim Weiland, Philipp Hennig
Nonlinear conservation laws are at the heart of many of the most important dynam ical systems in science and engineering.
In practical applications, such systems are often subject to various sources of uncertainty, e.g. due to sparse or noisy measurements.
Inferring physical quantities and fields of interest then becomes an ill-posed p roblem which both classical numerical methods and modern deep learning-based met hods struggle to treat appropriately.
Recent work has framed classical numerical methods as Bayesian inference under G aussian process priors, resulting in a physics-aware treatment of uncertainties.
Following this line of work, we develop a novel numerically conservative method for uncertainty-aware simulations of nonlinear conservation laws.
We use recent sparse approximation techniques to scale up to large-scale forward and inverse problems.
For forward simulation, we inherit the accuracy of classical solvers while provi ding structured uncertainty quantification.
On inverse problems, we recover posteriors over nonparametric source fields in s econds --- outperforming neural baselines that take minutes to produce a less ac curate point estimate.
****
Differentiable Conformal Training for LLM Reasoning Factuality
Nathan Hittesdorf, Marco Salzetta, Lu Cheng
Large Language Models (LLMs) frequently hallucinate, limiting their reliability in critical applications. Conformal Prediction (CP) addresses this by calibratin g error rates on held-out data to provide statistically valid confidence guarant ees. Recent work extends CP to LLM factuality: outputs are decomposed into subcl aims, each assigned a risk score, and a calibrated threshold filters out risky c laims to guarantee hallucination rates below a user-specified level (e.g., 10%). While prior methods treat claims independently, Coherent Factuality extends to multi-step reasoning by representing outputs as dependency graphs and jointly va lidating claims with their logical ancestors. A key limitation is that Coherent Factuality is not differentiable, requiring hand-crafted scorers that at high re liability levels remove nearly 60% of true claims. We introduce Differentiable C oherent Factuality (DCF), a fully differentiable relaxation that enables learnin g improved scorers while provably recovering the original algorithm's guarantees . Experiments on two reasoning datasets demonstrate DCF achieves up to 141% impr ovement in claim retention while maintaining reliability guarantees, representin g a significant step towards reliable conformal LLM systems.
****
Continual Learning With Participation Privacy: An Auditable Buffering-Aggregatio n Recipe
T-H. Hubert Chan, Elaine Shi, Mengshi Zhao, Mingxun Zhou
Modern federated and streaming learning systems often release intermediate model s, so privacy must hold for the full trajectory under adaptive interaction. Moti vated by participation privacy, we study single-edit neighboring user streams, w here one insertion/deletion shifts all subsequent updates and defeats standard H amming-neighbor continual-release analyses. We give an auditable modular recipe. A randomized buffering wrapper emits bins of size $[U,2U]$, reducing single-edi t streams to a Hamming-style per-bin update stream with explicit backlog/delay g uarantees, where U is calibrated by the privacy parameters $(\varepsilon,\delt a)$. We then prove a certification theorem for independently decomposable (prefi x-causal, fresh-noise) continual mechanisms: any non-adaptive Hamming-neighbor D P proof lifts to adaptive inputs. Together, these ingredients yield trajectory-l

evel (ε,δ)-DP for single-edit streams using standard primitives (e.g., tree prefix sums), with an explicit privacy--latency link via U. Streaming DP-SGD experiments validate the privacy-utility-latency tradeoffs and the induced delay distributions.
****

In-Context Generation with Regional Constraints for Instructional Video Editing
Zhongwei Zhang, Fuchen Long, Wei Li, Zhaofan Qiu, Wu Liu, Ting Yao, Tao Mei
The In-context generation paradigm has demonstrated strong power in instructional image editing for better synthesis quality. Nevertheless, shaping such in-context learning for instructional video editing is not trivial. Without specifying editing regions, the results can suffer from the issue of inaccurate editing regions and the token interference between different areas. To address these, we present ReCo, a new instructional video editing paradigm that novelly delves into **Re**gional **Co**nstraint modeling between editing and non-editing areas. Technically, ReCo width-wise concatenates source and target video for joint denoising. In model training, ReCo formulates regional constraints with two regularization terms, i.e., latent and attention regularization, on one-step backward denoised latents and attention maps, respectively. The former increases the latent discrepancy of the editing region between source and target videos while reducing that of non-editing areas, emphasizing editing area modification and alleviating unexpected content generation. The latter suppresses the attention of tokens in the editing region to the tokens in counterpart of the source video, thereby mitigating their interference during novel object generation in target video. Furthermore, we propose a large-scale, high-quality video editing dataset, i.e., ReCo-Data, comprising 500K instruction-video pairs. Extensive experiments conducted on four major instruction-based video editing tasks verify the superiority of ReCo. Code is available at https://github.com/HiDream-ai/ReCo.

Mitigating the Safety–Utility Trade-off in LLM Alignment via Adaptive Safe Context Learning
Yanbo Wang, Minzheng Wang, Jian Liang, Lu Wang, Yongcan Yu, Ran He
While reasoning models have achieved remarkable success in complex reasoning tasks, their increasing power necessitates stringent safety measures. For safety alignment, the core challenge lies in the inherent trade-off between safety and utility.
However, prevailing alignment strategies typically construct CoT training data with explicit safety rules via context distillation.
This approach inadvertently limits reasoning capabilities by creating a rigid association between rule memorization and refusal.
To mitigate the safety-utility trade-off, we propose the Adaptive Safe Context Learning (ASCL) framework to improve the reasoning given proper context.
ASCL formulates safety alignment as a multi-turn tool-use process, empowering the model to autonomously decide when to consult safety rules and how to generate the ongoing reasoning.
Furthermore, to counteract the preference for rule consultation during RL, we introduce Inverse Frequency Policy Optimization~(IFPO) to rebalance advantage estimates.
By decoupling rule retrieval and subsequent reasoning, our method achieves higher overall performance compared to baselines.
Our code is publicly available at https://github.com/ybwang119/ASCL.git.

Semi-knockoffs: a model-agnostic conditional independence testing method with finite-sample guarantees
Angel David REYERO LOBO, Bertrand Thirion, Pierre Neuvial
Conditional independence testing (CIT) is essential for reliable scientific discovery. It prevents spurious findings and enables controlled feature selection. Recent CIT methods have used machine learning (ML) models as surrogates of the underlying distribution. However, model-agnostic approaches require a train-test split, which reduces statistical power. We introduce Semi-knockoffs, a CIT method that can accommodate any pre-trained model, avoids this split, and provides val

id p-values and false discovery rate (FDR) control for high-dimensional settings . Unlike methods that rely on the model-X assumption (known input distribution), Semi-knockoffs only require conditional expectations for continuous variables . This makes the procedure less restrictive and more practical for machine learn ing integration. To ensure validity when these expectations are estimated, we pr esent two new theoretical results: (i) stability for regularized models trained with a null feature and (ii) the double-robustness property.

Quaternion Self-Attention with Shared Scores
Shogo Yamauchi, Tohru Nitta, Hideaki Tamori
Quaternion neural networks are parameter-efficient and model multidimensional de pendencies by representing four related features as a single entity. However, ex isting quaternion self-attention computes component-wise scores and applies inde pendent softmax operations to each component, which increases the computational cost and allows attention distributions to diverge across components. We propose a shared-score quaternion self-attention mechanism that computes a single real-valued score using the quaternion inner product and applies a shared attention d istribution across all components. This reduces score-computation multiplication s by 75\% and the number of softmax operations from four to one. We prove that, when queries and keys are produced by quaternion linear projections that induce component pre-mixing, the component-wise and shared scores lie in the same inter action subspace, indicating that independent component-wise attention primarily re-parameterizes the same interactions rather than expanding the feature interac tion space. In speech enhancement, our method reduces inference time by up to 44 .3\% on a GPU and 58.1\% on a CPU while maintaining quality, with consistent tre nds across vision and natural language processing.

Unsupervised Camouflaged Object Detection with Dual-Eigenvector Spectral Pseudo-Labeling and Contrastive Refinement
Pingzhu Liu, Chunming He, Zunnan Xu, Chao Hao, Bo Zhao, Xingyu Shao, Jun Zhou, Z itong YU, Xiu Li
Unsupervised Camouflaged Object Detection (UCOD) aims to identify objects concea led in their surroundings without relying on pixel-level labels. Existing method s rely solely on simple post-processing of DINO high-dimensional features to gen erate pseudo labels for training. However, these methods suffer from two major l imitations: 1) pseudo labels they easily generate contain excessive noise, causi ng the model to learn substantial incorrect information. 2) Although pseudo-labe l supervision allows the model to understand the task, it remains insufficient f or generating fine-grained segmentation of the camouflaged objects. To address t hese issues, we propose DualUCOD, a novel UCOD method based on dual-branch contr astive learning that effectively detects camouflaged objects without pixel-level labels. Specifically, we propose the Dual-Eigenvector Spectral Pseudo-Labeling (DESPL) strategy, which fuses semantic and color cues into an affinity matrix. W e then compute the eigenvectors of its normalized graph Laplacian and generate h igh-quality pseudo-labels using these eigenvectors. Furthermore, we introduce a Boundary-Guided Foreground-Background Refinement (BGFBR) module that explicitly incorporates boundary information to improve segmentation accuracy. Finally, we introduce a Dual-Branch Contrastive Learning (DBCL) module that constructs posit ive and negative pairs from the original and augmented images, aligning positive representations while contrasting them against negatives to enhance camouflaged object understanding. Extensive experiments demonstrate that DualUCOD outperfor ms state-of-the-art methods on different datasets in the unsupervised setting.

Unlearning’s Blind Spots: Over■Unlearning and Prototypical Relearning Attack
SeungBum Ha, Saerom Park, Sung Whan Yoon
Machine unlearning (MU) aims to expunge a designated forget set from a trained m odel without costly retraining, yet the existing techniques overlook two critica l blind spots: "over■unlearning" that deteriorates retained data near the forget set, and post■hoc "relearning" attacks that aim to resurrect the forgotten know ledge.

Focusing on class-level unlearning, we first derive an over-unlearning metric, $\operatorname{OU}@\varepsilon$, which quantifies collateral damage in regions proximal to the forget set, where over-unlearning mainly occurs.
Next, we expose an unforeseen relearning threat on MU, i.e., the Prototypical Relearning Attack, which exploits the per-class prototype of the forget class with just a few samples, and easily restores the pre-unlearning performance.
To counter both blind spots in class-level unlearning, we introduce $\texttt{Spotter}$, a plug■and■play objective that combines (i) a masked knowledge■distillation penalty on the nearby region of forget classes to suppress $\operatorname{OU}@\varepsilon$, and (ii) an intra■class dispersion loss that scatters forget-class embeddings, neutralizing Prototypical Relearning Attacks.
$\texttt{Spotter}$ achieves state-of-the-art results across CIFAR, TinyImageNet, and CASIA-WebFace datasets, offering a practical remedy to unlearning’s blind spots.

Efficient and Safe Molecular Assembly via Reinforcement Learning and Constraint Solving
Stefan Pranger, Bernhard Ramsauer, Oliver T. Hofmann, Bettina Könighofer
Scanning tunneling microscopy (STM) enables precise manipulation of individual atoms and molecules, offering a pathway to constructing nanoscale assemblies with rich quantum mechanical behavior. Despite its potential, STM-based fabrication remains limited by the inherent complexity of manipulation procedures and the extensive manual effort required. In this work, we take a substantial step toward autonomous manufacturing with STMs by introducing a novel AI-based planning framework for molecular assembly and a high-fidelity simulation environment. Our framework computes collision-free assembly plans that minimize the total distance traveled by molecules. Given an assignment of molecules to target positions, satisfiability solving is used to compute execution schedules in which each molecule has an empty corridor available when it is scheduled to move. Reinforcement learning (RL) agents then execute sequences of STM actions to manipulate molecules to their targets. We further introduce NanoAssemblyGym, a high-fidelity simulation environment for molecular manipulation built on the Gymnasium API, allowing seamless integration with existing RL libraries and workflows. Using NanoAssemblyGym, we demonstrate autonomous assembly of structures containing up to 420 molecules.

Functional Adjoint Sampler: Scalable Sampling on Infinite Dimensional Spaces
Byoungwoo Park, Juho Lee, Guan-Horng Liu
Learning-based methods for sampling from the Gibbs distribution in finite-dimensional spaces have progressed quickly, yet theory and algorithmic design for infinite-dimensional function spaces remain limited. This gap persists despite their strong potential for sampling the paths of conditional diffusion processes, enabling efficient simulation of trajectories of diffusion processes that respect rare events or boundary constraints. In this work, we present the adjoint sampler for infinite-dimensional function spaces, a stochastic optimal control-based diffusion sampler that operates in function space and targets Gibbs-type distributions on infinite-dimensional Hilbert spaces. Our Functional Adjoint Sampler (FAS) generalizes Adjoint Sampling (Havens et al., 2025) to Hilbert spaces based on a SOC theory called stochastic maximum principle, yielding a simple and scalable matching-type objective for a functional representation. We show that FAS achieves superior transition path sampling performance across synthetic potential and real molecular systems, including Alanine Dipeptide and Chignolin.

Near-Optimal Regret for KL-Regularized Multi-Armed Bandits
Kaixuan Ji, Qingyue Zhao, Heyang Zhao, Qiwei Di, Quanquan Gu
Recent studies have shown that reinforcement learning with KL-regularized objectives can enjoy faster rates of convergence or logarithmic regret, in contrast to the classical $\sqrt{T}$-type regret in the unregularized setting. However, the statistical efficiency of online learning with respect to KL-regularized objectives remains far from completely characterized, even when specialized to multi-a

rmed bandits (MABs). We address this problem for MABs via a sharp analysis of KL-UCB (Zhao et al., 2025b) using a novel peeling argument, which yields a $\tilde{O}(\eta K\log^2T)$ KL-regularized regret upper bound: the first high-probability regret bound with linear dependence on K. Here, T is the time horizon, K is the number of arms, η^{-1} is the regularization intensity, and $\tilde{O}$ hides all logarithmic factors except those involving $\log T$. The near-tightness of our analysis is certified by the first non-constant lower bound $\Omega(\eta K \log T)$, which follows from subtle hard-instance constructions and a tailored decomposition of the Bayes prior. Moreover, in the low-regularization regime (i.e., large η), we show that the KL-regularized regret for MABs is η-independent and scales as $\tilde{\Theta}(\sqrt{KT})$. Overall, our results provide a thorough understanding of KL-regularized MABs across all regimes of η and yield nearly optimal bounds in terms of K, η, and T.

Persona-Pruner: Sculpting Lightweight Models for Role-Playing

Jinsu Kim, Jihoon Tack, Noah Lee, Jongheon Jeong

Language Models (LMs) have shown remarkable potential as role-playing chatbots, delivering consistent, stylized interactions when given a specification of a character or user persona. However, applying these capabilities to real-world applications (*e.g*., ecosystems with numerous NPCs interacting simultaneously) exposes a critical inefficiency due to the excessive computational cost. In this paper, we question the necessity of dedicating a full, generalist model to a single persona, hypothesizing that a specific character identity relies on only a fraction of the model’s total capacity. We observe that naïvely pruning LMs often severely degrades the role-playing performance for a specific persona; it does not distinguish between redundant knowledge and essential character traits. We propose **Persona-Pruner**, a framework that sculpts a lightweight role-playing model by isolating persona-specific sub-networks from a single description. Our experiments consistently show that Persona-Pruner preserves role-playing performance substantially more effectively than existing state-of-the-art LLM pruning techniques, reducing the performance drop from the dense model by up to 93.8% over the strongest baseline on RoleBench in LLM-as-a-judge score, while still maintaining general LLM capabilities. Code is available at https://github.com/jsu-kim/Persona-Pruner.

PRAC: Principal-Random Subspace for LLM Activation Compression and Memory-Efficient Training

Yanyi Li, Yimu Zhang, Cong Fang

Activations have become the primary memory bottleneck in large-batch LLM training. However, existing compression methods fail to exploit the spectral structure of activations, resulting in slow convergence or limited compression. To address this, we bridge the relationship between the algorithm’s fast convergence and the requirements for subspace projection, and show that an effective compression should yield an unbiased estimate of the original activation with low variance. We propose **P**rincipal-**R**andom Subspace for LLM **A**ctivation **C**ompression (**PRAC**), which novelly decomposes activations into two components: a principal subspace captured via SVD to retain dominant information, and a random subspace sampled from the orthogonal complement to approximate the tail. By introducing a precise scaling factor, we prove that PRAC yields an unbiased gradient estimator with minimum variance under certain conditions. Extensive experiments on pre-training and fine-tuning tasks demonstrate that PRAC achieves up to 36\% total memory reduction with negligible performance degradation and minimal computational cost.

DLO-Lab: Benchmarking Deformable Linear Object Manipulations with Differentiable Physics

Junyi Cao, Yian Wang, Ziyan Xiong, Chunru Lin, Zhehuan Chen, Chuang Gan

We address the challenge of enabling robots to manipulate deformable linear objects (DLOs), such as ropes, cables, and rubber bands. Prior work has primarily focused on narrow, task-specific problems, often relying on real-world demonstrati

ons or handcrafted heuristics. Such approaches, however, struggle to scale to th
e wide variety of materials and tasks encountered in practice, and collecting su
fficiently diverse real-world data is often impractical. Additionally, existing
simulation environments offer limited support for the broad spectrum of material
 behaviors necessary for generalizable DLO manipulation. To overcome these limit
ations, we introduce a differentiable simulator explicitly designed for versatil
e DLO manipulation. Our simulator models a wide range of material properties—inc
luding (in)extensibility, elasticity, bending plasticity, and complex interacti
ons with other objects—providing a robust foundation for learning and evaluating
 manipulation skills. Building on this simulator, we propose a benchmark suite o
f representative tasks that highlight the unique challenges of DLO manipulation.
 The successful execution of these tasks is often hindered by the topological co
mplexity and grasp sensitivity inherent to DLOs. Therefore, we introduce a speci
alized DLO agent that explicitly manages these challenges by proposing strategic
 grasping points and decomposing long-horizon tasks to maximize control authorit
y. Finally, we evaluate various policy-learning algorithms using our framework,
alongside sim-to-real transfer experiments, demonstrating our platform's potenti
al to advance DLO manipulation. Project page: https://dlo-lab-26.github.io/.

One-Shot Weighted Ensemble Estimation for Federated Quantile Regression: Optimal
 Statistical Guarantees under Heterogeneous Structured Data
Guang Yang, Bo Pan, Chengdi Lian, Xingcai Zhou, Linglong Kong, Yafei Wang, Bei J
iang
Federated Quantile Regression (FQR) has emerged as a powerful modelling paradigm
 for estimating conditional quantiles, offering a more comprehensive understandi
ng of response distributions than standard conditional mean regression. However,
 achieving communication efficiency and optimal statistical guarantees for FQR r
emains challenging, particularly due to the nonsmooth nature of quantile loss fu
nctions and the presence of heterogeneously structured data, where each local ag
ent trains its conditional quantile models with distinct sets of features. In th
is paper, we propose a data-driven, one-shot weighted ensemble estimator for FQR
 that incorporates scalable weighting schemes to effectively leverage the partia
lly observed features at each local agent, thereby enjoying both communication e
fficiency and estimation optimality. Theoretically, we present a unified analysi
s of the proposed learning procedure, establishing that the resulting estimator
exhibits asymptotic normality and attains uniformly minimum variance. Furthermor
e, we investigate the estimator's sensitivity to perturbations introduced by loc
al agents and derive conditions under which the estimator achieves stability and
 enjoys strong out-of-sample generalization. Extensive simulations and real data
 analysis under various scenarios validate the asymptotic normality of our estim
ator and demonstrate its superior estimation accuracy and uniform convergence co
mpared to several baseline methods across a range of quantile levels.

MM-DeepResearch: A Simple and Effective Multimodal Agentic Search Baseline
Huanjin Yao, Qixiang Yin, Min Yang, Ziwang Zhao, Yibo Wang, Haotian Luo, Jingyi
Zhang, Jiaxing Huang
We aim to develop a multimodal research agent capable of explicit reasoning and
planning, multi-tool invocation, and cross-modal information synthesis, enabling
 it to conduct deep research tasks. However, we observe three main challenges in
 developing such agents: (1) scarcity of search-intensive multimodal QA data, (2
) lack of effective search trajectories, and (3) prohibitive cost of training wi
th online search APIs. To tackle them, we first propose **Hyper-Search**, a hype
rgraph-based QA generation method that models and connects visual and textual no
des within and across modalities, enabling to generate search-intensive multimod
al QA pairs that require invoking various search tools to solve. Second, we intr
oduce **DR-TTS**, which first decomposes search-involved tasks into several cate
gories according to search tool types, and respectively optimize specialized sea
rch tool experts for each tool. It then recomposes tool experts to jointly explo
re search trajectories via tree search, producing trajectories that successfully
 solve complex tasks using various search tools. Third, we build an offline sear

ch engine supporting multiple search tools, enabling agentic reinforcement learn
ing without using costly online search APIs. With the three designs, we develop
MM-DeepResearch, a powerful multimodal deep research agent, and extensive re
sults shows its superiority across benchmarks.

Global Convergence of Adaptive Sensing for Principal Eigenvector Estimation
Alex Saad-Falcon, Brighton Ancelin, Justin Romberg
Principal component analysis classically requires full d-dimensional samples,
yet in various applications hardware limits acquisition to a few scalar measurem
ents per sample. We analyze a compressed variant of Oja's algorithm for estimati
ng the principal eigenvector of the data covariance matrix using only two adapti
ve measurements per sample. At each iteration, we observe one measurement along
the current estimate and one in a random orthogonal direction. We prove that aft
er t iterations, the expected sine-squared error to the true eigenvector is $\
mathcal{O}(\lambda_1\lambda_2 d^2 / (\Delta^2 t))$, where d is the ambient dim
ension, λ_1, λ_2 are the leading eigenvalues, and $\Delta = \lambd
a_1 - \lambda_2$ is the eigengap. We complement this with a matching information
-theoretic lower bound of $\Omega(\lambda_1\lambda_2 d^2 / (\Delta^2 t))$ --- th
e first for compressed eigenvector estimation --- proving that the d^2 factor,
 an additional factor of d compared to the fully-observed minimax rate $\Theta
(\lambda_1\lambda_2 d / (\Delta^2 t))$, is the fundamental cost of compression a
nd cannot be improved. In contrast, any non-adaptive scheme with two measurement
s per iteration suffers $\Omega(\lambda_2^2 d^3 / (\Delta^2 t))$, an additional
power of d. This separates fully-observed, adaptive-compressed, and non-adapti
ve-compressed PCA across three powers of d. Our analysis handles the noisy set
ting where the covariance has nonzero trailing eigenvalues, providing the first
convergence guarantee for adaptive compressed subspace tracking beyond the noise
less case.
****

Geometric Collapse: When Vision Models Fail to Verify Physical Causality
Wentao Zhang, Jinhu Qi, Weiqiang Jin, Yifei Zhang, Chan-Tong Lam, Irwin King
Recent progress in large-scale self-supervised learning has improved dense geome
tric prediction, but it remains unclear whether such scaling yields inference-ti
me physical plausibility checks. We propose Scrambled Edges, a controlled counte
rfactual that injects salient edge-like cues while violating surface continuity,
 illumination coherence, and occlusion ordering. With energy-matched and structu
re-matched controls, we isolate the effect of unsupported edge evidence from hig
h-frequency energy and edge sparsity. Across CNN/ViT/SSL depth predictors on NYU
 Depth v2 and KITTI, Scrambled Edges induce up to 3.2× larger deviation from cle
an predictions than energy-matched noise. The resulting Geometric Collapse propa
gates globally: even with oracle knowledge of the corrupted region, output-level
 repair recovers only 47%, with substantial error outside the mask. These findin
gs provide controlled behavioral evidence that current dense predictors lack rel
iable mechanisms to quarantine physically unsupported edge cues, motivating expl
icit plausibility scoring and selective cue integration.

Domain Adaptation with Adaptive f-Divergence: Tighter Variational Representati
on and Generalization Bounds
Zhe Cheng, Fode Zhang, Yifan Zhu, Lingrui Wang, Jiaolong Wang
We study unsupervised domain adaptation (UDA) where measuring cross-domain discr
epancy is critical. Most UDA approaches fix a single f-divergence a priori, wh
ich can be suboptimal across heterogeneous shifts. We propose a framework that (
i) tightens the variational lower bound of an f-divergence by inserting a lear
nable, monotone L-Lipschitz transform τ (Tighter-VR), and (ii) selects th
e divergence family adaptively from data via a likelihood-based criterion. The r
esulting estimator yields more informative and statistically efficient discrepan
cy estimates while recovering prior fixed-divergence methods as special cases. T
heoretically, we derive a target-risk bound whose three components are a transfo
rmed source risk, a Tighter-VR discrepancy between domains, and an ideal-hypothe
sis residual; we further provide finite-sample guarantees using standard complex

ity measures. Empirically, on Office-31, Office-Home, Digits, and VisDA-2017, ou
r method consistently improves accuracy over strong baselines, showing that coup
ling Tighter-VR with adaptive divergence selection is useful for UDA.

CINOC: Cardinality-Invariant Neural Operator Policies for Scalable PDE Control
Pietro Zanotta, Dibakar Roy Sarkar, Honghui Zheng, Somdatta Goswami, Jan Drgona
Controlling partial differential equations (PDEs) with learning-based policies r
emains fundamentally limited by fixed-dimensional representations: policies trai
ned for a specific sensor, actuator, or agent configuration typically fail when
the configuration changes. This limitation is particularly severe in multi-agent
 PDE control, where policies do not scale across population sizes without retrai
ning. We address this challenge by introducing **C**ardinality **I**nvariant **N
eural **Operator **C**ontrol (**CINOC**), reformulating PDE control as an op
erator learning problem that maps state fields to continuous control functions a
nd trains them end-to-end through differentiable PDE solvers, yielding policies
that naturally adapt to varying sensor and actuator configurations. Remarkably,
CINOC policies trained on small swarms exhibit cardinality invariance, allowing
for zero-shot transfer to significantly larger populations as well as robustness
 to partial agent failure. This scalability arises from agents sharing a common
policy and coordinating through their physical environment, which produces an em
ergent self-normalization effect. To explain this phenomenon, we provide a theor
em grounded in mean-field theory demonstrating that policy gradients computed fr
om finite-agent systems converge to those of a continuous control limit. Empiric
ally, we validate CINOC on tracking, stabilization, and density transport across
 linear, nonlinear, chaotic, and turbulent PDEs.

Geometry-based Schrödinger Bridges for Trustworthy Multimodal Fusion
Jiayu Xiong, Jing Wang, Qi Zhang, Wanlong Wang, Jun Xue
Real-world multimodal systems must be robust against low-quality data, such as s
ensor noise, incomplete multimodal data and conflicting inputs. However, existin
g trustworthy fusion methods rely on the model's own prediction confidence to ju
dge data quality. This creates a circular dependency: when a model is confident
but wrong (overconfident), these methods fail to detect the error. To break this
 loop, we propose Geometry-based Multimodal Fusion (GMF). Instead of relying on
predictions, we evaluate reliability by measuring the physical effort required t
o map input data back to the valid data manifold. We implement this using Diffus
ion Schrödinger Bridges with Rectified Flow, which allows us to calculate Transp
ort Energy as a direct metric for quality. The logic is simple: valid data sits
on the manifold (low energy), while noisy, incomplete data or conflicting data r
equires high energy to be restored. This geometric metric acts as an independent
 judge, effectively flagging unreliable inputs even when the classifier is foole
d. Extensive experiments demonstrate that GMF significantly improves robustness
against severe sensor noise and semantic conflicts compared to confidence-based
baselines.

Optimal Domain-Aware Privacy Mechanisms for Synthetic Data Generation
Sajani Vithana, Sangwon Jung, Haoyang Hu, Viveck R. Cadambe, Flavio Calmon, Haew
on Jeong
Differential privacy (DP) imposes fundamental trade-offs between privacy and sta
tistical fidelity in synthetic data generation. While access to public data has
been shown to improve these trade-offs empirically, existing approaches use publ
ic data only indirectly, through pre-processing (e.g., using pre-trained generat
ive models) or post-processing steps (e.g., matching target statistics estimated
 from public datasets), while relying on domain-agnostic DP mechanisms. In this
work, we lay the theoretical framework to study the principled incorporation of
public data into DP mechanisms themselves. We consider normalized histograms as
distribution estimators and characterize the asymptotically optimal domain-aware
 privacy mechanism within a specific class of DP mechanisms. We introduce PubMix
, a public-data-aware DP mechanism that can be used in histogram-based data synt
hesis pipelines. Our experiments demonstrate that PubMix significantly improves

synthetic data generation quality compared to domain-agnostic privacy mechanisms
.

A Perturbation Approach to Unconstrained Linear Bandits
Andrew Jacobsen, Dorian Baudry, Shinji Ito, Nicolò Cesa-Bianchi
We revisit the standard perturbation-based approach of Abernethy et al. (2008) i
n the context of unconstrained Bandit Linear Optimization (uBLO). We show the su
rprising result that in the unconstrained setting, this approach effectively red
uces Bandit Linear Optimization (BLO) to a standard Online Linear Optimization (
OLO) problem. Our framework improves on prior work in several ways. First, we de
rive expected-regret guarantees when our perturbation scheme is combined with co
mparator-adaptive OLO algorithms, leading to new insights about the impact of di
fferent adversarial models on the resulting comparator-adaptive rates. We also e
xtend our analysis to dynamic regret, obtaining the first guarantees with optima
l $\sqrt{P_T}$ path-length dependencies without prior knowledge of P_T. We the
n develop the first high-probability guarantees for both static and dynamic regr
et in uBLO. Finally, we discuss lower bounds on the static regret, and prove the
 folklore $\Omega(\sqrt{dT})$ rate for adversarial linear bandits on the Euclide
an ball, which is of independent interest.
****
Trust Region Inverse Reinforcement Learning: Explicit Dual Ascent using Local Po
licy Updates
Anish Abhijit Diwan, Davide Tateo, Christopher Mower, Haitham Bou Ammar, Jan Pet
ers, Oleg Arenz
Inverse reinforcement learning (IRL) is typically formulated as maximizing entro
py subject to matching the distribution of expert trajectories. Classical (dual-
ascent) IRL guarantees monotonic performance improvement but requires fully solv
ing an RL problem each iteration to compute dual gradients. More recent adversar
ial methods avoid this cost at the expense of stability and monotonic dual impro
vement, by directly optimizing the primal problem and using a discriminator to p
rovide rewards. In this work, we bridge the gap between these approaches by enab
ling monotonic improvement of the reward function and policy without having to f
ully solve an RL problem at every iteration. Our key theoretical insight is that
 a trust-region-optimal policy for a reward function update can be globally opti
mal for a smaller update in the same direction. This smaller update allows us to
 explicitly optimize the dual objective while only relying on a local search aro
und the current policy. In doing so, our approach avoids the training instabilit
ies of adversarial methods, offers monotonic performance improvement, and learns
 a reward function in the traditional sense of IRL—one that can be globally opti
mized to match expert demonstrations. Our proposed algorithm, *Trust Region Inve
rse Reinforcement Learning (TRIRL)*, outperforms state-of-the-art imitation lear
ning methods across multiple challenging tasks by a factor of 2.4x in terms of a
ggregate inter-quartile mean, while recovering reward functions that generalize
to system dynamics shifts.
****
Non-Parametric Structural Priors for Geometry Theorem Prediction
Junbo Zhao, Ting Zhang, Can Li, Wei He, Jingdong Wang, Hua Huang
Multi-step theorem prediction is a central challenge in geometry problem solving
. Existing neural–symbolic approaches rely heavily on supervised parametric mode
ls, which exhibit limited generalization to evolving theorem libraries. In this
work, we explore training-free theorem prediction through the lens of in-context
 learning (ICL). We identify a critical scalability bottleneck, termed Structura
l Drift: as reasoning depth increases, the performance of vanilla ICL degrades s
harply.
We attribute this to the LLM’s inability to recover latent topological dependenc
ies, leading to unstructured exploration.
To address this issue, we propose Theorem Precedence Graphs, which encode tempor
al dependencies from historical solution traces as directed graphs, and impose e
xplicit topological constraints that effectively prune the search space during i
nference. Coupled with retrieval-augmented graph construction and a stepwise sym

bolic executor, our approach enables LLMs to act as structured planners without any gradient-based optimization. Experiments on the FormalGeo7k benchmark show that our method achieves 89.29\% accuracy, substantially outperforming ICL baselines and matching state-of-the-art supervised models. These results indicate that explicit structural priors offer a promising direction for scaling LLM-based symbolic reasoning.

TimeSpot: Benchmarking Geo-Temporal Understanding in Vision–Language Models in Real-World Settings

Azmine Toushik Wasi, Shahriyar Zaman Ridoy, Koushik Ahamed Tonmoy, Kinga Tshering, S. M. Muhtasimul Hasan, Wahid Faisal, Tasnim Mohiuddin, Md Rizwan Parvez

Geo-temporal understanding, the ability to infer location, time, and contextual properties from visual input alone, underpins applications such as disaster management, traffic planning, embodied navigation, world modeling, and geography education. Although recent vision–language models (VLMs) have advanced image geo-localization using cues like landmarks and road signs, their ability to reason about temporal signals and physically grounded spatial cues remains limited. To address this gap, we introduce **TimeSpot**, a benchmark for evaluating real-world geo-temporal reasoning in VLMs. **TimeSpot** comprises 1,455 ground-level images from 80 countries and requires structured prediction of temporal attributes (season, month, time of day, daylight phase) and geographic attributes (continent, country, climate zone, environment type, latitude–longitude) directly from visual evidence. It also includes spatial–temporal reasoning tasks that test physical plausibility under real-world uncertainty. Evaluations of state-of-the-art open- and closed-source VLMs show low performance, particularly for temporal inference. While supervised fine-tuning yields improvements, results remain insufficient, highlighting the need for new methods to achieve robust, physically grounded geo-temporal understanding. **TimeSpot** is available at: https://TimeSpot-GT.github.io.

SINQ: Sinkhorn-Normalized Quantization for Calibration-Free Low-Precision LLM Weights

Lorenz K Muller, Philippe Bich, Jiawei Zhuang, Ahmet Çelik, Luca Benfenati, Lukas Cavigelli

Post-training quantization has emerged as the most widely used strategy for deploying large language models at low precision. Still, current methods show perplexity degradation at bit-widths ≤ 4, partly because representing outliers causes precision issues in parameters that share the same scales as these outliers. This problem is especially pronounced for calibration-free, uniform quantization methods. We introduce SINQ to augment existing post-training quantizers with an additional second-axis scale factor and a fast Sinkhorn–Knopp–style algorithm that finds scales to normalize per-row and per-column variances.

We show that this approximates activation-aware quantization by recovering column scales from the weight matrix structure that are predictive of the typical activation magnitudes the matrix received during training.

Our method has no interactions between layers and can be trivially applied to new architectures to quantize any linear layer.

We evaluate our method on the Qwen3 model family, among others. SINQ reduces the perplexity gap on WikiText2 and C4 by over 50% against uncalibrated uniform quantization baselines, incurs zero to negligible compute overhead, and can be further enhanced by combining it with calibration and non-uniform quantization levels. Code is available in the supplementary.

Symmetries in language statistics shape the geometry of model representations

Dhruva Karkada, Daniel James Korchinski, Andres Nava, Matthieu Wyart, Yasaman Bahri

Although learned representations underlie neural networks' success, their fundamental properties remain poorly understood.

A striking example is the emergence of simple geometric structures in LLM representations: for example, calendar months organize into a circle, years form a one

-dimensional manifold, and the latitude and longitude of cities can be decoded b
y low-dimensional linear probes.
We show that the statistics of language exhibit a translation symmetry---e.g,. t
he co-occurrence probability of two months depends only on the time interval bet
ween them---and we prove that the latter governs the aforementioned geometric st
ructures in high-dimensional word embedding models.
Moreover, we find that these structures persist even when the co-occurrence stat
istics are strongly perturbed (for example, by removing all sentences in which t
wo months appear together) and at moderate embedding dimension.
We show that this robustness naturally emerges if the co-occurrence statistics a
re collectively controlled by an underlying continuous latent variable.
We empirically validate this theoretical framework in word embedding models, tex
t embedding models, and large language models.

Dynamics Are Learned, Not Told: Semi-Supervised Discovery of Latent Dynamics Geo
metries For Zero-Shot Policy Adaptation
Zhiming Xu, Weitao Zhou, Xianghui Pan, Nanshan Deng, Chengju Liu, Qijun Chen, Ch
enpeng Yao
Real-world dynamics shifts pose a critical challenge for reinforcement learning,
 yet prior methods typically rely on encoding explicitly identified physical par
ameters into a latent context, a rigid parameterization that proves brittle to u
nmodeled or compound dynamics variations. We instead investigate dynamics adapta
tion through the lens of latent geometry, and show theoretically that target-dom
ain regret is controlled by the Lipschitz smoothness of a trajectory dynamics en
coder. We further prove that this Lipschitz constant can be upper-bounded throug
h optimizing a multi-positive InfoNCE objective, yielding a smooth, task-relevan
t latent topology without privileged dynamics information. On MuJoCo benchmarks,
 our method significantly outperforms explicit identification baselines under se
vere dynamics shifts, including unmodeled structural failures, while simultaneou
sly improving in-distribution stability and latent interpretability. Overall, th
ese results validate that controlling latent smoothness is a principled and scal
able mechanism for robust adaptation.

FlowMAP: Flow Matching for Generalizable Agent Planning
Jiarun Fu, Lizhong Ding, Ye Yuan, Qiuning Wei, Zhaohuan Linghu, Yurong Cheng, Ch
angsheng Li, Tianlong Gu, Liang Chang, Guoren Wang
Agent planning faces dynamic heterogeneity—nonstationary observations, dynamics,
 and objectives with sparse, delayed rewards—which dominant methods largely igno
re, leading to poor generalization under environment shifts. We propose Flow-Mat
ching for Agent Planning (FlowMAP), which formulates planning as a continuous-ti
me flow-matching problem by learning a planning-time velocity field that transpo
rts an initial meta-state distribution toward a task-conditioned target. FlowMAP
 introduces Value-Transport Flow Matching to provide a distribution-level planni
ng objective that steers transport toward high-value regions in the meta-state d
istribution, mitigating error accumulation under environmental shifts. To enforc
e alignment between meta-state distribution transport and action--environment in
teraction, FlowMAP further proposes Flow--Policy Co-Training, which jointly opti
mizes the planning flow and policy so that the flow transport directly regulariz
es the policy-induced meta-distribution dynamics. Across diverse agent planning
benchmarks, FlowMAP consistently outperforms strong baselines, yielding improvem
ents in planning generalization.
****

One-Way Policy Optimization for Self-Evolving LLMs
Shuo Yang, Jinda Lu, Kexin Huang, Chiyu Ma, Shaohang Wei, Yuyang Liu, Guoyin Wan
g, Jingren Zhou, Li Yuan
Reinforcement Learning with Verifiable Rewards (RLVR) has become a promising par
adigm for scaling reasoning capabilities of Large Language Models (LLMs). Howeve
r, the sparsity of binary verifier rewards often leads to low efficiency and opt
imization instability. To stabilize training, existing methods typically impose
token-level constraints relative to a reference policy. We identify that such co

nstraints penalize deviations indiscriminately; this can flip verifier-determine d direction when the policy attempts to outperform the reference, thereby suppre ssing gains. To resolve this, we propose **One-Way Policy Optimization (OWPO)**, a method based on the principle of decoupling optimization direction from updat e magnitude. In OWPO, the verifier dictates the update direction, while the refe rence policy serves only to adjust the magnitude. Specifically, OWPO applies asy mmetric reweighting: it performs **Accelerated Alignment** for Inferior deviatio ns (where the policy lags behind the reference) and **Gain Locking** for Superio r deviations (where the policy surpasses the reference). Furthermore, by incorpo rating iterative reference updates, OWPO creates a ``Ratchet Effect'' that conti nuously consolidates gains. Experimental results demonstrate that OWPO outperfor ms strong baselines, including DAPO, OPD, and MOPD, breaking the bottleneck of f ixed priors to enable continuous self-evolution without reliance on external ref erence models.

TRACER: Persistent Regularization for Robust Multimodal Finetuning

Hesam Asadollahzadeh, Feng Liu, Christopher Leckie, Sarah Monazam Erfani

Mainstream strategies for finetuning pretrained multimodal models often degrade out-of-distribution (OOD) robustness, a phenomenon known as catastrophic forgett ing.

In this paper, we develop a theoretical framework for multimodal contrastive fin etuning, yielding closed-form solutions and a geometric decomposition for these strategies. This framework shows that self-distillation is more effective than o ther regularization approaches to retain the knowledge of the pretrained model. Our analysis reveals a largely overlooked limitation: standard Exponential Movin g Average (EMA) teachers, widely used in robust finetuning, suffer from collapse . To solve this, we prove that a Weighted Moving Average (WMA) teacher maintains a persistent regularizing force over finite horizons and yields bias-free conve rgence in the task subspace while preserving orthogonal knowledge.

These insights motivate **TRACER** (**T**rajectory-**R**obust **A**nchoring for **C**ontrastive **E**ncoder **R**egularization), which combines contrastive lear ning with WMA-guided multi-perspective distillation. Extensive experiments on CL IP finetuning demonstrate consistent OOD accuracy and calibration gains across t hree backbone architectures, and comprehensive ablations confirm that TRACER is both principled and robust to hyperparameter choices. Code is available at [http s://github.com/HesamAsad/TRACER](https://github.com/HesamAsad/TRACER).

Rethinking Personalization in Large Language Models at the Token Level

Chenheng Zhang, Yijun Lu, Lizhe Fang, Chunyuan Zheng, Jiajun Chai, Xiaohan Wang, Guojun Yin, Wei Lin, Yisen Wang, Zhouchen Lin

With large language models (LLMs) now performing strongly across diverse tasks, there is growing demand for them to personalize outputs for individual users. Pe rsonalization is typically framed as an additional layer on top of a base NLP ta sk, requiring model responses to meet user-specific needs while still accomplish ing the underlying task.

From a token-level perspective, different tokens in a response contribute to per sonalization to varying degrees. Tokens with higher personalization relevance sh ould therefore receive greater emphasis when developing personalized LLMs. Howev er, accurately estimating such personalization degrees remains challenging.

To address this challenge, we propose PerContrast, a self-contrast method that e stimates each output token’s dependence on user-specific information through cau sal intervention. Building on this mechanism, we develop the PerCE loss, which a daptively upweights tokens with higher estimated personalization degrees during training via a bootstrap procedure, enabling the model to alternate between esti mating and optimizing these tokens.

Experiments on multiple LLMs demonstrate that PerCE substantially improves perso nalization performance with minimal additional cost, achieving average gains of over 10\% and up to 68.04\% on the LongLaMP dataset, along with strong cross-tas k and cross-scenario transferability. These results highlight the importance of token-level personalization modeling and establish token-aware training as a sim

ple yet effective paradigm for advancing personalized LLMs.

Length Generalization Bounds for Transformers
Andy Yang, Pascal Bergsträßer, Georg Zetzsche, David Chiang, Anthony Widjaja Lin
Length generalization is a key property of a learning algorithm that enables it to make correct predictions on inputs of any length, given finite training data. To provide such a guarantee, one needs to be able to compute a length generalization bound, beyond which the model is guaranteed to generalize. This paper concerns the open problem of the computability of such generalization bounds for C-RASP, a class of languages which is closely linked to transformers. A positive partial result was recently shown by Chen et al. for C-RASP with only one layer and, under some restrictions, also with two layers. We provide complete answers to the above open problem. Our main result is the non-existence of computable length generalization bounds for C-RASP (already with two layers) and hence for transformers. To complement this, we provide a computable bound for the positive fragment of C-RASP, which we show equivalent to fixed-precision transformers. For both positive C-RASP and fixed-precision transformers, we show that the length complexity is exponential, and prove optimality of the bounds.

Trifuse: Enhancing Attention-Based GUI Grounding via Multimodal Fusion
Longhui Ma, Di Zhao, Siwei Wang, Zhao Lv, Miao Wang
GUI grounding maps natural language instructions to the correct interface elements, serving as the perception foundation for GUI agents. Existing approaches predominantly rely on fine-tuning multimodal large language models (MLLMs) using large-scale GUI datasets to predict target element coordinates, which is data-intensive and generalizes poorly to unseen interfaces. Recent attention-based alternatives exploit localization signals in MLLMs attention mechanisms without task-specific fine-tuning, but suffer from low reliability due to the lack of explicit and complementary spatial anchors in GUI images. To address this limitation, we propose Trifuse, an attention-based grounding framework that explicitly integrates complementary spatial anchors. Trifuse integrates attention, OCR-derived textual cues, and icon-level caption semantics via a Consensus-SinglePeak (CS) fusion strategy that enforces cross-modal agreement while retaining sharp localization peaks. Extensive evaluations on four grounding benchmarks demonstrate that Trifuse achieves strong performance without task-specific fine-tuning, substantially reducing the reliance on expensive annotated data. Moreover, ablation studies reveal that incorporating OCR and caption cues consistently improves attention-based grounding performance across different backbones, highlighting its effectiveness as a general framework for GUI grounding.

Faithful Mobile GUI Agents with Guided Advantage Estimator
Haowen Hu, Pengzhou Cheng, Zheng Wu, Lingzhong Dong, Gongshen Liu, Zhuosheng Zhang
Vision-language model (VLM) based graphical user interface (GUI) agents have shown strong interaction capabilities. However, they often behave unfaithfully, relying on memorized shortcuts rather than grounding actions in displayed screen evidence or user instructions. To address this, we propose **Faithful-Agent**, a faithfulness-first framework that reformulates GUI interaction to prioritize evidence groundedness and internal consistency. Faithful-Agent employs a two-stage pipeline: (i) a faithfulness-oriented SFT stage to instill abstainment behaviors under evidence perturbations; (ii) an RFT stage that further amplifies faithfulness by introducing the guided advantage estimator (GuAE), an anchor-based and variance-adaptive advantage tempering mechanism built upon GRPO. GuAE prevents advantage collapse in low-variance rollout groups under sparse GUI rewards, and with a thought-action consistency reward, Faithful-Agent (Stage II) elevates the Trap SR from 13.88\% to 80.21\% relative to the baseline, while preserving robust general instruction-following performance.

How RLHF Amplifies Sycophancy
Itai Shapira, Gerdus Benade, Ariel D. Procaccia
Large language models often exhibit increased sycophantic behavior after preference-based post-training, showing a stronger tendency to affirm a user’s stated or implied belief even when this conflicts with factual accuracy or sound judgment.
We present a formal analysis of how alignment from human feedback can increase this failure mode by identifying an explicit amplification mechanism that causally links optimization against a learned reward to bias in the human preference data used for alignment. We show that the direction of behavioral drift is determined by a covariance under the base policy between endorsing the belief signal in the prompt and the learned reward, and that the first-order effect reduces to a simple mean-gap condition. We then analyze reward learning from pairwise comparisons under random utility models like Bradley–Terry and characterize when bias in human annotators’ preferences induces this reward gap.
Next, we propose a training-time intervention designed to neutralize the amplification mechanism itself. Among all post-trained policies that prevent sycophantic behavior from increasing, we characterize the unique policy closest in KL divergence to the unconstrained post-trained policy, and derive the corresponding minimal reward correction as a closed-form agreement penalty. Computational experiments find that reward gaps are common and cause behavioral drift in all the configurations considered.

Adaptive Batch Sizes Using Non-Euclidean Gradient Noise Scales for Stochastic Sign and Spectral Descent
Hiroki Naganuma, Shagun Gupta, Youssef Briki, Ioannis Mitliagkas, Irina Rish, Parameswaran Raman, Hao-Jun Michael Shi
To maximize hardware utilization, modern machine learning systems typically employ large constant or manually tuned batch size schedules, relying on heuristics that are brittle and costly to tune. Existing adaptive strategies based on gradient noise scale (GNS) offer a principled alternative. However, their assumption of SGD's Euclidean geometry creates a fundamental mismatch with popular optimizers based on generalized norms, such as signSGD / Signum (ℓ_∞) and stochastic spectral descent (specSGD) / Muon (Schatten-∞). In this work, we derive gradient noise scales for signSGD and specSGD that naturally emerge from the geometry of their respective dual norms. To practically estimate these non-Euclidean metrics, we propose an efficient variance estimation procedure that leverages the local mini-batch gradients on different ranks in distributed data-parallel systems. Our experiments demonstrate that adaptive batch size strategies using non-Euclidean GNS enable us to match the validation loss of constant-batch baselines while reducing training steps by up to 66\% for Signum and Muon on a 160 million parameter Llama model.

ManiSoft: Towards Vision-Language Manipulation for Soft Continuum Robotics
Ziyu Wei, Luting Wang, Chen Gao, Li Wen, Si Liu
Most existing vision-language manipulation research targets rigid robotic arms, whose fixed morphology limits adaptability in cluttered or confined spaces.
Soft robotic arms offer an appealing alternative due to their deformability, but confront challenges such as unreliable proprioception and distributed low-level actuation.
To investigate these challenges, we introduce ManiSoft, a benchmark for vision-language manipulation with soft arms.
ManiSoft features a tailored simulator that couples realistic soft-body dynamics with contact-rich interactions via an elastic force constraint.
On this basis, ManiSoft defines four tasks, each highlighting distinct aspects of deformable control, from basic end-effector coordination to obstacle avoidance.
To support policy training and evaluation, ManiSoft includes an automated pipeline that generates $6{,}300$ diverse scenes and corresponding expert trajectories.

To produce high-quality trajectories at scale, we first employ a high-level planner to decompose each task into a sequence of waypoints, followed by a low-level reinforcement learning policy that generates torque commands to track waypoints.
Benchmarking three representative policy models shows relatively promising results in clean scenes but substantial performance drop under randomization.
Visualization analysis indicates that failures stem primarily from inaccurate visual estimation of proprioceptive state and limited exploitation of deformability for adaptive obstacle avoiding.
We anticipate ManiSoft to serve as a valuable testbed, bridging the gap between rigid and soft arms in the context of vision-language manipulation.
****
AdaMeZO: Adam-style Zeroth-Order Optimizer for LLM Fine-tuning Without Maintaining the Moments
Zhijie Cai, Haolong Chen, Guangxu Zhu
Fine-tuning LLMs is necessary for various dedicated downstream tasks, but classic backpropagation-based fine-tuning methods require substantial GPU memory. To this end, a recent work, MeZO, which relies solely on forward passes to fine-tune LLMs, significantly reduces GPU requirements at the cost of slower convergence due to its indifference to loss landscapes. Standard solutions, such as Adam, explore loss landscapes by estimating the first- and second-order moments and storing them in memory to guide the model's movement through dimensions with lower curvature and vice versa. However, directly applying Adam negates MeZO's advantage as it will triple the memory requirement. In light of this, we propose AdaMeZO, a zeroth-order optimizer that leverages Adam-style first- and second-moment estimates without maintaining them in memory. We present a theoretical analysis of AdaMeZO, corroborated by extensive experiments demonstrating its performance, showing that it can outperform MeZO while requiring up to 70% fewer forward passes. Trajectory visualizations affirm AdaMeZO's ability to adapt to diverse loss landscapes.

SS-TPT: Stability and Suitability-Guided Test-Time Prompt Tuning for Adversarially Robust Vision-Language Models
Sunoh Kim, Daeho Um
Vision-language models (VLMs) such as CLIP achieve strong zero-shot recognition but remain highly fragile under adversarial perturbations. Recent test-time adaptation defenses improve robustness by leveraging many augmented views, but this leads to impractical slowdown and a clear robustness-throughput trade-off. To address this challenge, we present Stability and Suitability-guided Test-time Prompt Tuning (SS-TPT), evaluating the quality of each augmented view via two complementary scores: (1) stability, measuring prediction invariance to weak augmentations, and (2) suitability, measuring feature-space density among views. These stability and suitability (SS) scores guide both adaptation and inference through an SS-guided consistency loss and an SS-weighted prediction, amplifying trustworthy views while suppressing corrupted ones. Extensive experiments demonstrate that SS-TPT significantly outperforms prior state-of-the-art methods, achieving superior robustness-throughput trade-offs across diverse datasets and varying numbers of views, thereby demonstrating both strong practicality and generality. Our code is available at https://github.com/sunoh-kim/SS-TPT.
****
History-Bootstrapped Flow Matching for Inverse Boiling Reconstruction
Xianwei Zou, Sheikh Md Shakeel Hassan, Arthur Feeney, Aparna Chandramowlishwaran
Reconstructing spatiotemporal fields from partial observations is fundamental to scientific inference, from inferring atmospheric states from satellite data to recovering fluid states from imaging. When observations are incomplete, the inverse problem is fundamentally ill-posed: even when the underlying PDE dynamics are Markovian in the full state, partial observation operators induce a non-Markovian posterior that cannot be resolved from a single timestep. We propose a history-bootstrapped autoregressive flow matching (HB-ARFM) for spatiotemporal inverse reconstruction under partial observability. Observation history bootstraps the

initial reconstruction via conditional flow matching, resolving ambiguities. The same conditional transport model is then applied autoregressively, conditioning on both new observations and past predictions to propagate the reconstruction forward in time. We evaluate the method on boiling dynamics reconstruction, recovering full velocity and temperature fields from interface geometry and motion. Across two inverse tasks with varying observation sparsity, HB-ARFM produces physically and temporally valid reconstructions where other models fail.

Contrastive Geometric Learning Unlocks Unified Structure- and Ligand-Based Drug Design

Lisa Schneckenreiter, Sohvi Luukkonen, Lukas Friedrich, Daniel Kuhn, Günter Klambauer

Structure-based and ligand-based computational drug design have traditionally relied on disjoint data sources and modeling assumptions, limiting their joint use at scale. In this work, we introduce **Con**trastive **G**eometric **L**earning for **U**nified Computational **D**rug D**e**sign (ConGLUDe), a single contrastive geometric model that unifies structure- and ligand-based training. ConGLUDe couples a geometric protein encoder that produces whole-protein representations and implicit embeddings of predicted binding sites with a fast ligand encoder, removing the need for pre-defined pockets. By aligning ligands with both global protein representations and multiple candidate binding sites through contrastive learning, ConGLUDe supports ligand-conditioned pocket prediction in addition to virtual screening and target fishing, while being trained jointly on protein-ligand complexes and large-scale bioactivity data. Across diverse benchmarks, ConGLUDe achieves competitive zero-shot virtual screening performance, substantially outperforms existing methods on a challenging target fishing task, and demonstrates state-of-the-art ligand-conditioned pocket selection. These results highlight the advantages of unified structure-ligand training and position ConGLUDe as a step toward general-purpose foundation models for drug discovery.

Information-Geometric Adaptive Sampling for Graph Diffusion

Yuhui Lu, Wenjing Liu, Kun Zhan

Standard diffusion models for graph generation typically rely on uniform time-stepping, an approach that overlooks the non-homogeneous dynamics of distributional evolution on complex manifolds. In this paper, we present an information-geometric framework that reinterprets the diffusion sampling trajectory as a parametric curve on a Riemannian manifold. Our key observation is that the Fisher-Rao metric provides a principled measure of the intrinsic distance. By analyzing this metric, we derive the Drift Variation Score (DVS), a geometry-aware indicator that quantifies the instantaneous rate of distributional change. Unlike prior heuristic-based adaptive samplers, our DVS solver enforces a constant informational speed on the statistical manifold, automatically maintaining a uniform rate of distributional change along the sampling trajectory. This equal arc-length strategy ensures that each discretization step contributes equally to the information speed. Theoretical analysis verifies that DVS characterizes the local stiffness of the sampling dynamics in the Fisher-Rao sense. Experimental results on molecule and social network generation show that DVS significantly improves structural fidelity and sampling efficiency.

Unifying Stacking and Cascading for Efficient Ensemble Inference

Ashwin Gerard Colaco, Sharad Mehrotra, Michael J. De Lucia, Kevin Hamlen, Murat Kantarcioglu, Latifur Khan, Ananthram Swami, Bhavani Thuraisingham, Unnat Jain

We introduce LazyStack, a method for efficient model ensemble inference. The core idea is intuitive: after each model executes, we check whether accumulated evidence is sufficient to exit confidently. Sometimes one model suffices; other times we aggregate predictions from several models via trained meta-learners before reaching confidence. Two insights make this work. First, most inputs follow only 3 to 8 execution trajectories. This reduces the training problem from exponential to linear: we learn aggregators only for these common paths, not all possible model combinations. Second, we formulate trajectory selection as an MDP and us

e value iteration to compute the optimal routing policy, which reveals counterin tuitive model orderings. On intrusion detection, starting with a moderately expe nsive model outperforms starting with the cheapest, because its higher confidenc e enables earlier overall exit. Across vision, text, tabular, and LLM tasks, we achieve up to 38x speedup at 97\%+ accuracy retention compared to a complete ens emble. The result: ensemble-quality predictions at cascade-level cost. Code and a project page are available at https://ashwincolaco.github.io/lazystack.

JANUS-LORA: A Balanced Low-Rank Adaptation for Continual Learning
Cheng Chen, Pengpeng Zeng, Yuyu Guo, Lianli Gao, Heng Tao Shen, Jingkuan Song
Low-Rank Adaptation (LoRA) has emerged as a promising paradigm for Continual Lea rning.
It independently updates its low-rank factors (A and B), creating a composit e update to the full weight matrix through their interaction.
To prevent catastrophic forgetting, this update should remain orthogonal to the task-specific subspace that contains previously learned knowledge.
However, we identify that this composite update systematically violates this ort hogonality, reintroducing interference and undermining stability.
Furthermore, naively enforcing this orthogonality compromises plasticity, disrup ting the delicate stability-plasticity trade-off.
To resolve these issues, we propose Janus-LoRA, a framework that restores this b alance through two novel components.
Specifically, we first introduce Gradient Rectification, a closed-form solution that mathematically decouples LoRA's factor updates, enforcing orthogonality aga inst the historical knowledge subspace identified by an efficient Online Estimat ion.
Next, to enhance plasticity, we introduce a Decoupled Margin Loss that promotes feature-level separation by pushing new feature representations away from old on es, thus creating distinct, low-interference regions for new learning.
Comprehensive experiments on challenging benchmarks demonstrate that by harmoniz ing parameter-level orthogonality with feature-level separation, Janus-LoRA achi eves a superior balance and establishes new state-of-the-art performance.
****
Risk-Bounded Distribution Reconstruction: Stable Statistic Calibration for Long-Tailed Recognition
Guanliang Liu, Wenchao Chen, Long Tian, Xuefei Cao, Hongwei Liu, Bo Chen
Long-tailed recognition suffers from extreme class imbalance, where scarce tail data leads to biased and fragile feature distributions that exacerbate confusion with semantically or visually similar classes. Prior feature-space reconstructi on methods transfer head-class structure or train conditional generators to synt hesize tail features, yet the resulting \emph{statistical} updates are often heu ristic and can degrade multi-class separability when tail estimates are unreliab le. Given this issue, we propose \emph{Risk-Bounded Distribution Reconstruction} (RBDR), an offline statistic calibration framework for the two-stage long-taile d pipeline, grounded in an analysis of rival-induced discriminative directions.
RBDR performs (i) risk-aware mean calibration by softly projecting any candidate update onto a supportive set such that a surrogate discriminative-risk upper bo und does not increase, and (ii) covariance control by shrinking dispersion in a rival subspace while preserving diversity in orthogonal components.
In the frozen-feature reconstruction setting, these calibration components conve rt heuristic reconstruction cues into controllable distributional updates, impro ving both performance and stability across multiple long-tailed benchmarks.

Euler–Poincaré Neural Dynamics: A Geometric-Mechanics Framework for Scientific S imulation
Sungwoo Park, Jongwon Lee, Jiwoong Kim
We introduce Euler--Poincar\'e Neural Dynamics (EPND), a geometric-mechanics fra mework that casts evolution-operator learning as Lie-group flows for long-horizo n dynamical modeling. Unlike conventional operator-learning approaches that trea t temporal propagation as an unconstrained black-box map, EPND places geometric

mechanics at the core of its architecture, playing a role of the mathematical en
gine. This foundation enables a principled treatment of curvature, symmetry, and
 conservation, with the learned evolution expressed in geometric terms. Building
 on this foundation, we develop the Euler--Poincar\'e Parallel Scan, a parallel
algorithm that leverages the associative algebra of Lie-group compositions to ov
ercome the inefficiencies of sequential computation. By unifying geometric struc
ture with scalable computation, EPND achieves high accuracy, strong stability, a
nd significant parallel acceleration in modeling long-horizon dynamics in versat
ile scientific simulations.

UniJEPA: Enhancing Robot Policy via Unified Continuous and Discrete Representati
on Learning
Jianke Zhang, Yucheng Hu, Yanjiang Guo, Xiaoyu Chen, Yichen Liu, Wenna Chen, Cha
ochao Lu, Jianyu Chen
Building generalist robot policies that can handle diverse tasks in open-ended e
nvironments is a central challenge in robotics. To leverage knowledge from large
-scale pretraining, prior work (VLA) has typically built generalist policies eit
her on top of vision-language models (VLMs) or generative models. However, both
semantic understanding from vision-language pretraining and visual dynamics mode
ling from visual-generation pretraining are crucial for embodied robots.
Recent unified models of generation and understanding have demonstrated strong c
apabilities in both comprehension and generation through large-scale pretraining
. We posit that robotic policy learning can likewise benefit from the combined s
trengths of understanding, planning and continuous future representation learnin
g. Building on this insight, we introduce UniJEPA, which acquires the ability to
 dynamically model high-dimensional visual features through pretraining on over
1M internet-scale instructional manipulation videos. Subsequently, UniJEPA is fi
ne-tuned on data collected from the robot embodiment, enabling the learning of m
appings from predictive representations to action tokens. Extensive experiments
show our approach consistently outperforms baseline methods in terms of 9\% and
12\% across simulation environments and real-world out-of-distribution tasks.

τ-Knowledge: Evaluating Conversational Agents over Unstructured Knowledge
Quan Shi, Alexandra Zytek, Pedram Razavi, Karthik R Narasimhan, Victor Barres
Conversational agents are increasingly deployed in knowledge-intensive settings,
 where correct behavior depends on retrieving and applying domain-specific knowl
edge from large, proprietary, and unstructured corpora during live interactions
with users. Yet most existing benchmarks evaluate retrieval or tool use independ
ently of each other, creating a gap in realistic, fully agentic evaluation over
unstructured data in long-horizon interactions. We introduce τ-Knowledge, a
n extension of τ-Bench for evaluating agents in environments where success
depends on coordinating external, natural-language knowledge with tool outputs t
o produce verifiable, policy-compliant state changes. Our new domain, τ-Ban
king, models realistic fintech customer support workflows in which agents must n
avigate roughly 700 interconnected knowledge documents while executing tool-medi
ated account updates. Across embedding-based retrieval and terminal-based search
, even frontier models with high reasoning budgets achieve only $\sim$25.5\% pas
s^1, with reliability degrading sharply over repeated trials. Agents struggle to
 retrieve the correct documents from densely interlinked knowledge bases and to
reason accurately over complex internal policies. Overall, τ-Knowledge prov
ides a realistic testbed for developing agents that integrate unstructured knowl
edge in human-facing deployments.
****

ThetaEvolve: Test-time Learning on Open Problems
Yiping Wang, Shao-Rong Su, Zhiyuan Zeng, Eva Xu, Liliang Ren, Xinyu Yang, Zeyi H
uang, Xuehai He, Luyao Ma, Baolin Peng, Hao Cheng, Pengcheng He, Weizhu Chen, Sh
uohang Wang, Simon Shaolei Du, yelong shen
Recent advances in large language models (LLMs) have enabled breakthroughs in ma
thematical discovery, exemplified by AlphaEvolve, a closed-source system that ev
olves programs to improve bounds on open problems. However, it relies on ensembl

es of frontier LLMs to achieve new bounds and is a pure inference system that models cannot internalize the evolving strategies.

We introduce ThetaEvolve, an open-source framework that simplifies and extends AlphaEvolve to efficiently scale both in-context learning and Reinforcement Learning (RL) at test time, allowing models to continually learn from their experiences in improving open optimization problems.

ThetaEvolve features a single LLM, a large program database for enhanced exploration, batch sampling for higher throughput, lazy penalties to discourage stagnant outputs, and optional reward shaping for stable training signals, etc.

ThetaEvolve is the first evolving framework that enable a small open-source model, like DeepSeek-R1-0528-Qwen3-8B, to achieve new best-known bounds on open problems (circle packing and first auto-correlation inequality) mentioned in AlphaEvolve.

Besides, across two models and four open tasks, we find that ThetaEvolve with RL at test-time consistently outperforms inference-only baselines, and the model indeed learns evolving capabilities, as the RL-trained checkpoints demonstrate faster progress and better final performance on both trained target task and other unseen tasks.

We release our code publicly.

Variational Flow Maps: Make Some Noise for One-Step Conditional Generation

Abbas Mammadov, So Takao, Bohan Chen, Ricardo Baptista, Morteza Mardani, Yee Whye Teh, Julius Berner

Flow maps enable high-quality image generation in a single forward pass. However, unlike iterative diffusion models, their lack of an explicit sampling trajectory impedes incorporating external constraints for conditional generation and solving inverse problems. We put forth _Variational Flow Maps_, a framework for conditional sampling that shifts the perspective of conditioning from "guiding a sampling path", to that of "learning the proper initial noise". Specifically, given an observation, we seek to learn a _noise adapter model_ that outputs a noise distribution, so that after mapping to the data space via flow map, the samples respect the observation and data prior. To this end, we develop a principled variational objective that jointly trains the noise adapter and the flow map, improving noise-data alignment, such that sampling from complex data posterior is achieved with a simple adapter. Experiments on various inverse problems show that VFMs produce well-calibrated conditional samples in a single (or few) steps. For ImageNet, VFM attains competitive fidelity while accelerating the sampling by orders of magnitude compared to alternative iterative diffusion/flow models.

Do Transformers Need Three Projections? Systematic Study of QKV Variants

Ali Kayyam, Anusha Madan Gopal, M Anthony Lewis

Transformers have become the standard solution for various AI tasks, with the query, key, and value (QKV) attention formulation playing a central role. However, the individual contribution of these three projections and the impact of omitting some remain poorly understood. We systematically evaluate three projection sharing constraints: a) Q-K=V (shared key-value), b) Q=K-V (shared query-key), and c) Q=K=V (single projection). The last two variants produce symmetric attention maps; to address this, we also explore asymmetric attention via 2D positional encodings. Through experiments spanning synthetic tasks, vision (MNIST, CIFAR, TinyImageNet, anomaly), and language modeling (300M and 1.2B parameter models on 10B tokens), we discovered that our transformers perform on par or occasionally better than the QKV transformer. In language modeling, Q-K=V projection sharing achieves 50\% KV cache reduction with only 3.1% perplexity degradation. Crucially, projection sharing is complementary to head sharing (GQA/MQA): combining Q-K=V with GQA-4 yields 87.5% cache reduction, while Q-K=V + MQA achieves 96.9%—enabling practical on-device inference. We further show that Q--K=V preserves quality because keys and values can share representational space, whereas Q=K-V breaks attention directionality. Our results establish projection sharing as a new optimization axis for memory-efficient transformers, especially for edge deployment.

Language-based Trial and Error Falls Behind in the Era of Experience
Haoyu Wang, Guozheng Ma, Shugang Cui, Yilun Kong, Haotian Luo, Li Shen, Mengya G ao, Yichao Wu, Xiaogang Wang, Dacheng Tao
While Large Language Models (LLMs) excel in language-based agentic tasks, their applicability to unseen, nonlinguistic environments (e.g., symbolic or spatial t asks) remains limited. Previous work attributes this performance gap to the mism atch between the pretraining distribution and the testing distribution. In this work, we demonstrate the primary bottleneck is the prohibitive cost of explorati on: mastering these tasks requires extensive trial-and-error, which is computati onally unsustainable for parameter-heavy LLMs operating in a high dimensional se mantic space. To address this, we propose SCOUT (Sub-Scale Collaboration On Unse en Tasks), a novel framework that decouples exploration from exploitation. We em ploy lightweight "scouts" (e.g., small MLPs) to probe environmental dynamics at a speed and scale far exceeding LLMs. The collected trajectories are utilized to bootstrap the LLM via Supervised Fine-Tuning (SFT), followed by multi-turn Rein forcement Learning (RL) to activate its latent world knowledge. Empirically, SCO UT enables a Qwen2.5-3B-Instruct model to achieve an average score of 0.86, sign ificantly outperforming proprietary models, including Gemini-2.5-Pro (0.60), whi le saving about 60% GPU hours consumption.

Procedural Pretraining: Warming Up Language Models with Abstract Data
Liangze Jiang, Zachary Shinnick, Anton van den Hengel, Hemanth Saratchandran, Da mien Teney
Pretraining language models directly on web-scale corpora is the de facto paradi gm. We study an alternative where the model is initially exposed to *abstract st ructured data* to ease the subsequent acquisition of rich semantic knowledge, mu ch like humans learning simple logic and mathematics before higher reasoning. We focus on *procedural data*, generated by formal languages and other simple algo rithms, as such abstract data.

We first diagnose the algorithmic skills that different forms of procedural data can improve, often significantly. For example, the accuracy of context recall (Needle-in-a-haystack) jumps from 10 to 98% when a model is pretrained on Dyck se quences (balanced brackets). Second, we study how these gains are reflected in p retraining larger models (up to 1.3B). We find that front-loading as little as 0 .1–0.3% procedural data significantly outperforms standard pretraining on natura l language, code, and informal mathematics (C4, CodeParrot, and DeepMind-Math da tasets). Notably, this also enables the models to reach the same loss value with only 55/67/86% of the original data and thus a comparable reduction in FLOPs. T hird, we explore the mechanisms behind the benefits and find that procedural pre training instills non-trivial structure in both attention and MLP layers. The fo rmer is particularly important for structured domains (e.g. code), and the latte r for language. Finally, we lay a path for combining multiple forms of procedura l data. Our results show that procedural pretraining is a simple, lightweight me ans of improving performance and accelerating language model pretraining, ultima tely suggesting the promise of disentangling knowledge acquisition from reasonin g in LLMs.

MedREK: Retrieval-Based Editing for Medical LLMs with Key-Aware Prompts
Shujun Xia, Haokun Lin, Yichen Wu, Yinan Zhou, Zixuan Li, Zhongwei Wan, Xingrun Xing, Yefeng Zheng, Xiang Li, Caifeng Shan, Zhenan Sun, Quanzheng Li
Large Language Models (LLMs) hold great promise for healthcare applications, but fast-changing medical knowledge can quickly make their outputs outdated or inac curate, limiting use in high-stakes settings. Model editing can update LLMs with out full retraining, but parameter-based methods often break locality and are ri sky in medicine, making retrieval-based editing a better fit. However, applying model editing methods to the medical domain has two key challenges: (1) retrieva l-based methods suffer from representation overlap within the medical knowledge space that causes inaccurate retrieval and reduces editing accuracy; (2) existin

g medical editing methods are restricted to single-sample edits, while batch-edi
ting remains largely unexplored despite its importance for real-world applicatio
ns. To address these challenges, we construct MedVersa, an expanded benchmark th
at evaluates single and batch edits across broader medical coverage under strict
 locality constraints. We then propose MedREK, a retrieval-based editing framewo
rk that integrates a shared query–key module for precise matching with an attent
ion-based prompt encoder for informative guidance. Experiments across various me
dical benchmarks show that our MedREK consistently improves key metrics and prov
ides the first validated solution for batch editing in medical LLMs.

U-Cast: A Surprisingly Simple and Efficient Frontier Probabilistic AI Weather Fo
recaster

Salva Rühling Cachay, Duncan Watson-Parris, Rose Yu

AI-based weather forecasting now rivals traditional physics-based ensembles, but
 state-of-the-art (SOTA) models rely on specialized architectures and massive co
mputational budgets, creating a high barrier to entry. We demonstrate that such
complexity is unnecessary for frontier performance. We introduce U-Cast, a proba
bilistic forecaster built on a standard U-Net backbone trained with a simple rec
ipe: deterministic pre-training on Mean Absolute Error followed by short probabi
listic fine-tuning on the Continuous Ranked Probability Score (CRPS) using Monte
 Carlo Dropout for stochasticity. As a result, our model matches or exceeds the
probabilistic skill of GenCast and IFS ENS at 1.5° resolution while reduc
ing training compute by over $10\times$ compared to leading CRPS-based models an
d inference latency by over $10\times$ compared to diffusion-based models. U-Cas
t trains in under 12 H200 GPU-days and generates a 15-day ensemble forecast in 3
 seconds. These results suggest that scalable, general-purpose architectures pai
red with efficient training curricula can match complex domain-specific designs
at a fraction of the cost, opening the training of frontier probabilistic weathe
r models to the broader community.

Estimation of Treatment Effects Under Nonstationarity via the Truncated Policy G
radient Estimator

Ramesh Johari, Tianyi Peng, Wenqian Xing

Randomized experiments (or A/B tests) are widely used to evaluate interventions
in dynamic systems such as recommendation platforms, marketplaces, and digital h
ealth. In these settings, interventions affect both current and future system st
ates, so estimating the global average treatment effect (GATE) requires accounti
ng for temporal dynamics, which is especially challenging in the presence of non
stationarity; existing approaches suffer from high bias, high variance, or both.
 In this paper, we address this challenge via the novel Truncated Policy Gradien
t (TPG) estimator, which replaces instantaneous outcomes with short-horizon outc
ome trajectories. The estimator admits a policy gradient interpretation: it is a
 truncation of the first-order approximation to the GATE, yielding provable redu
ctions in bias and variance in nonstationary Markovian settings. We further esta
blish a central limit theorem for the TPG estimator and develop a consistent var
iance estimator that remains valid under nonstationarity with single-trajectory
data. We validate our theory with two real-world case studies. The results show
that relative to existing approaches, a well-calibrated TPG estimator can achiev
e a favorable balance between bias and variance in nonstationary settings, highl
ighting the value of the policy-gradient perspective for designing effective est
imators under complex dynamics.

xKV: Cross-Layer KV-Cache Compression via Aligned Singular Vector Extraction

Chi-Chih Chang, Wei-Cheng Lin, Chien-Yu Lin, Hung-Yueh Chiang, Yash Akhauri, Xil
ai Dai, Huiqiang Jiang, Yucheng Li, Luis Ceze, Kai-Chiang Wu, Mohamed S. Abdelfa
ttah

Long-context Large Language Models (LLMs) enable powerful applications but incur
 high memory costs due to the key-value states (KV-Cache). Recent studies attemp
t to share KV-Cache across layers, but these approaches either require expensive
 pretraining or rely on per-token cross-layer cosine similarity that is often li

mited in practice. We show, via Centered Kernel Alignment (CKA), that the domina nt singular vectors of KV-Cache are well aligned across layers. Motivated by thi s observation, we propose xKV, a post-training compression method that jointly f actorizes grouped-layer KV-Cache into a shared low-rank subspace, substantially reducing KV-Cache memory.
Across widely used LLMs, xKV achieves up to 8× KV-Cache compression while preser ving accuracy on long-context tasks and in multi-turn settings. To further impro ve efficiency, we introduce Selective Reconstruction (SR) at decode time. Combin ed with SR, xKV achieves up to 4.23× end-to-end speedup over the full attention baseline, and surpasses notable baselines with 30% higher throughput under a sim ilar accuracy level. Overall, xKV provides a plug-and-play approach to reduce bo th memory and latency for long-context LLM inference. Our code is publicly avail able at: https://github.com/abdelfattah-lab/xKV.

TF-FACE: Time-Frequency Fusion Learning via Frequency-Domain Adaptive and Contro llable Enhancement for Trajectory Prediction
Dongjian Song, Yunhao Meng, Songjun Huang, Jiayi Han
Accurately predicting the future trajectories of traffic participants is critica l for safe, efficient, and human-friendly autonomous driving. Existing learning- based trajectory prediction methods are predominantly time-domain and insufficie ntly exploit latent frequency information, which limits their capability to capt ure low-frequency long-term dependencies and high-frequency short-term dynamics. To address this, we propose TF-FACE, a time-frequency learning framework via fr equency-domain adaptive and controllable enhancement. TF-FACE introduces a fusio n encoder with learnable gated frequency-domain attention that adaptively manipu lates band-specific features for trajectory prediction. Building on the fused re presentation, we design a dual-stage decoder and a band-specific time–frequency dual-consistency loss to enable controllable decoupling and coupling across long - and short-term temporal scales, global and local scales, and then generate fin al multimodal predictions. Experiments on Argoverse 1 demonstrate that TF-FACE a chieves state-of-the-art accuracy, while maintaining real-time inference for aut onomous driving. Additional experiments are conducted on Argoverse 2, further va lidating TF-FACE's performance and generalizability.

SIKA-GP: Accelerating Gaussian Process Inference with Sparse Inducing Kernel App roximations for Bayesian Deep Learning
Wenyuan Zhao, Rui Tuo, Chao Tian
Gaussian processes (GPs) provide a principled Bayesian framework for uncertainty estimation, but their computational complexity severely limits scalability to l arge datasets. We propose SIKA-GP, which accelerates GP inference using sparse i nducing kernel approximations based on a dyadic ordered template basis, incurrin g only ${O}(\log M)$ complexity dependence on the number of inducing points. Our approach constructs compact and expressive kernel representations from sparsely activated bases, enabling efficient tensorized GPU computation and seamless int egration with modern large-scale models. SIKA-GP can be naturally embedded into Bayesian neural networks (BNNs) with sparse activations, yielding significant sp eedups in both training and inference without sacrificing predictive performance . The method naturally extends to deep feature learning, addressing the scalabil ity challenges introduced by deep architectures and high-dimensional feature rep resentations. Empirical results on vision and transformer-based language benchma rks demonstrate that our approach consistently delivers fast and accurate GP mod els, providing a principled path toward scalable kernel learning.

Hierarchical Multi Scale Graph Neural Networks: Scalable Heterophilous Learning with Oversmoothing and Oversquashing Mitigation
MD SAZZAD Hossen, Avimanyu Sahoo
Graphs with heterophily, where adjacent nodes carry different labels, are preval ent in real-world applications, from social networks to molecular interactions. However, existing spectral Graph Neural Network (GNN) approaches tailored for h eterophilous graph classification suffer from hub-dominated (node with large deg

ree) aggregation and oversmoothing, as their suboptimal polynomial filters introduce approximation errors and blend distant signals.
To address the degree-biased aggregation and suboptimal polynomial filtering, we introduce a Hierarchical Multi■view HAAR (HMH), a novel spectral graph■learning framework that scales in near■linear time. HMH first learns feature- and structure-aware \emph{signed} affinities via a heterophily-aware encoder, then constructs a soft graph hierarchy guided by these embeddings. At each hierarchical level, HMH constructs a sparse, orthonormal, and locality-aware Haar basis to apply learnable spectral filters in the frequency domain. Finally, skip-connection unpooling layers combine outputs from all hierarchical levels back into the original graph, effectively preventing hub domination and long-range signal bottleneck (over-squashing). Experimentation shows that HMH outperforms state■of■the■art spectral baselines, achieving up to a 3 \% improvement on node classification and 7 \% on graph classification datasets, all while maintaining linear scalability. Our code is available at https://github.com/sazzad1008/Scalable-HMH101

CoCoEdit: Content-Consistent Image Editing via Region Regularized Reinforcement Learning
Yuhui Wu, Chenxi Xie, Ruibin Li, Liyi Chen, Qiaosi Yi, Lei Zhang
Image editing has achieved impressive results with the development of large-scale generative models. However, existing models mainly focus on the editing effects of intended objects and regions, often leading to unwanted changes in unintended regions.
We present a post-training framework for $\textbf{Co}$ntent-$\textbf{Co}$nsistent $\textbf{Edit}$ing ($\textbf{CoCoEdit}$) by using region regularized reinforcement learning.
We first augment existing editing datasets with refined instructions and masks, from which 40K diverse and high quality samples are curated as training set. We introduce a pixel-level similarity reward that complements MLLM-based rewards, enabling models to ensure both editing quality and content consistency during the editing process. To overcome the spatial-agnostic nature of the rewards, we propose a region-based regularizer, aiming to preserve non-edited regions for high-reward samples while encouraging editing effects for low-reward samples.
For evaluation, we annotate editing masks for GEdit-Bench and ImgEdit-Bench, introducing pixel-level similarity metrics to measure content consistency and editing quality.
Applying CoCoEdit to Qwen-Image-Edit and FLUX-Kontext, we achieve not only superior editing scores to state-of-the-art models, but also significantly better content consistency, measured by PSNR/SSIM metrics and human subjective ratings.
Codes, data and models of CoCoEdit can be found at https://github.com/langmanbusi/CoCoEdit.

Diffract: Spectral View of LLM Domain Adaptation
Nikita Borodin, Maria Krylova, Artem Zabolotnyi, Dmitry Aspisov, Egor Shikov, Nikita Tyuplyaev, Oleg Travkin, Roman Alferov, Dmitry Vinichenko
We study continual pre-training (CPT) as a mechanism for adapting general-purpose large language models to specialized domains: mathematics, instruction, code, and natural text. Using singular value decomposition of weight matrices, we find that CPT leaves singular value spectra largely invariant, with adaptation driven mainly by changes in singular vectors. An analysis of attention-head projection matrices reveals strong, domain-dependent **head heterogeneity**, which we exploit to define a head importance criterion: up to **60%** of head updates can be removed without measurable quality loss. Selectively rewinding low-importance heads to their pre-trained state improves benchmark accuracy by up to **4%** versus the fully trained baseline. Finally, we identify **domain connectivity**—linear interpolation between CPT checkpoints yields smooth domain-quality interpolation without notable degradation on either domain—and release Diffract, an open-source toolkit for scalable spectral analysis of billion-parameter models.

Beyond Extrapolation: Knowledge Utilization Paradigm with Bidirectional Inspirat

ion for Time Series Forecasting
Liu Chong, Yingjie Zhou, Hao Li, Pengyang Wang, Qingsong Wen, Ce Zhu
Time-series forecasting is critical in various scenarios, such as energy, transp
ortation, and public health.
  However, most existing forecasters rely primarily on one-way inference, \texti
t{i.e.}, mapping \textbf{history} to \textbf{target}, and overlook the structura
l information provided by a revised natural chain (``\textbf{history} (model inp
ut) -- \textbf{target} (ground-truth output) -- \textbf{post-target continuat
ion}'').
The post-target continuation records how trajectories evolve after the target, w
hich can help stabilize forecasting, but it is not observable at inference time.
In this work, we aim to obtain an approximate proxy of the post-target continuat
ion for the current input, providing structural knowledge for bidirectional fore
casting.
This idea is instantiated as KUP-BI (Knowledge Utilization Paradigm with Bidirec
tional Inspiration), a new time-series modeling paradigm that distills continuat
ion-style knowledge (as an approximate post-target continuation proxy) from a \e
mph{train-only} historical library and integrates it into standard forecasting b
ackbones.
The input stream and the continuation-proxy stream are fused via a lightweight f
eature-level gating module.
This design does not introduce information beyond what is already contained in t
he training trajectories; instead, it provides a structured inductive bias that
helps backbones exploit typical continuation patterns rather than relying solely
 on parametric extrapolation.
Experimental results on six public datasets show that KUP-BI consistently improv
es the forecasting performance of state-of-the-art models, with small additional
 overhead.

Beyond Benchmarks: Toward Causally Faithful Evaluation of Large Language Models
Zhengshuyuan Tian, Wanling Gao, Chuanxin Lan, Chenxi Wang, Lei Wang, Guoxin Kang
, Zhengxin Yang, Yunyou Huang, Xuehai Hong, Jianfeng Zhan
Current LLM evaluations often conflate benchmark performance with intrinsic mode
l capability. This is misleading, as observed outcomes arise from the entire eva
luation system, including datasets, prompting methods, decoding parameters, and
the software–hardware stack, rather than the model alone. When this system is un
der-specified, attribution becomes unreliable; in practice, evaluation choices a
lone can induce accuracy swings of up to 70%. This challenge is compounded by th
e open-ended nature of LLM evaluation, where questions span languages, domains,
and usage styles, forming variable and implicitly shifting datasets. Consequentl
y, strong performance on static benchmarks may reflect surface alignment or data
set-induced effects rather than robust capability. Prior studies often focus on
individual components or manually-curated small-scale dataset variants, overlook
ing interactions and dataset-related confounding. To address these limitations,
we propose LLM evaluatology, a principled framework that grounds LLM evaluation
in a causally motivated system design. It combines structured causal modeling as
 an intervention-oriented lens with factorial decomposition under design of expe
riments, quantifying main and interaction effects while using instance-level int
erventions to probe dataset-induced effects. By jointly modeling evaluation comp
onents and structured question variations, LLM evaluatology enables more interpr
etable, reproducible, and carefully attributed assessment of model capability.
Our framework is publicly available at [GitHub](https://github.com/BenchCouncil/
llm-evaluatology).

PolySAE: Modeling Feature Interactions in Sparse Autoencoders via Polynomial Dec
oding
Panagiotis Koromilas, Andreas D. Demou, James Oldfield, Yannis Panagakis, Mihali
s Nicolaou
Sparse autoencoders (SAEs) interpret neural network representations by decomposi
ng activations into sparse combinations of dictionary atoms. However, SAEs assum

e features combine additively through linear reconstruction, an assumption that cannot capture compositional structure: linear models cannot distinguish whether ''Starbucks'' arises from the composition of ''star'' and ''coffee'' features or merely their co-occurrence. This forces SAEs to allocate monolithic features for compound concepts rather than decomposing them into interpretable constituents. We introduce PolySAE, which extends the SAE decoder with higher-order terms to model feature interactions while preserving the linear encoder essential for interpretability. Through low-rank tensor factorization on a shared projection subspace, PolySAE captures pairwise and triple feature interactions with small parameter overhead (3\% on GPT2). Across four language models and three SAE variants, PolySAE achieves an average improvement of $\sim$8\% in probing F1 while maintaining comparable reconstruction error, and produces 2--10$\times$ larger Wasserstein distances between class-conditional feature distributions. Critically, learned interaction weights exhibit negligible correlation with co-occurrence frequency ($r = 0.06$ vs $r = 0.82$ for SAE feature covariance), suggesting that polynomial terms capture compositional structure largely independent of surface statistics. Finally, the learned interaction directions causally steer model outputs toward the corresponding compositional semantics.

VIPO: Value Function Inconsistency Penalized Offline Reinforcement Learning

Xuyang Chen, Keyu Yan, Guojian Wang, Lin Zhao

Offline reinforcement learning (RL) learns effective policies from pre-collected datasets, offering a practical solution for applications where online interactions are risky or costly. Model-based approaches are particularly advantageous for offline RL, owing to their data efficiency and generalizability. However, due to inherent model errors, model-based methods often artificially introduce conservatism guided by heuristic uncertainty estimation, which can be unreliable. In this paper, we introduce VIPO, a novel model-based offline RL algorithm that incorporates self-supervised feedback from value estimation to enhance model training. Specifically, the model is learned by additionally minimizing the inconsistency between the value learned directly from the offline data and the value estimated from the model. We perform comprehensive evaluations from multiple perspectives to show that VIPO can learn a highly accurate model efficiently and consistently outperform existing methods. In particular, it achieves state-of-the-art performance on almost all tasks in both D4RL and NeoRL benchmarks. Overall, VIPO offers a \textit{general framework} that can be readily integrated into existing model-based offline RL algorithms to systematically enhance model accuracy. Our code is available at~\url{https://anonymous.4open.science/r/vipo2025-8FD4}.

Bridging Spherical Black-Box Optimizers

Johannes Ackermann, Stefano Peluchetti

When gradient information is unavailable, black-box optimization (BBO) methods provide a practical alternative.

While Evolution Strategies (ES), Consensus-Based Optimization (CBO), Optimization via Integration (OVI), and related methods have each been studied independently, their connections remain underexplored.

We unify these approaches within a common theoretical framework, revealing that they differ primarily in two design choices: fitness aggregation (controlling sharpness preference) and consensus scope (controlling modality).

Leveraging these insights, we introduce hybrid optimizers that interpolate between existing methods.

Our ES-OVI hybrid allows explicit control over the preference for flat minima, enabling a trade-off between performance and robustness in continuous control tasks.

Our CBO-OVI hybrids combine the higher-dimensional efficiency of parametric methods with the multimodal capabilities of particle-based approaches, achieving competitive results on language model merging under limited evaluation budgets.

We validate our methods on standard BBO benchmarks and higher-dimensional locomotion tasks, demonstrating that the hybrid methods can outperform their constituent algorithms.

The Geometric Mechanics of Contrastive Representation Learning: Alignment Potentials, Entropic Dispersion, and Cross-Modal Divergence
Yichao Cai, Zhen Zhang, Yuhang Liu, Javen Qinfeng Shi
While InfoNCE underlies modern contrastive learning, its geometric mechanisms remain under-characterized beyond the canonical alignment--uniformity decomposition. We develop a measure-theoretic framework in which representation measures evolve on a fixed embedding manifold. In the large-batch limit, we prove value and gradient consistency, linking the stochastic objective to explicit deterministic energy landscapes and revealing a geometric bifurcation between unimodal and symmetric multimodal regimes. In the unimodal case, the intrinsic energy is strictly convex and admits a unique Gibbs equilibrium, showing that entropy acts as a tie-breaker within the aligned basin. In the multimodal case, the intrinsic geometry becomes cross-coupled and contains a persistent negative symmetric divergence term: each modality's marginal reshapes the effective landscape of the other, allowing strong pairwise alignment to coexist with a persistent modality gap. Controlled synthetic experiments and analyses of pretrained CLIP representations support these predictions. Overall, our results shift the analytical lens from pointwise discrimination to population geometry, showing that pairwise alignment alone is insufficient to control cross-modal marginal structure.
****
Lookahead Path Likelihood Optimization for Diffusion LLMs
Xuejie Liu, Vit Chun Yap, Yitao Liang, Anji Liu
Diffusion Large Language Models (dLLMs) support arbitrary-order generation, yet their inference performance critically depends on the unmasking order. Existing strategies rely on heuristics that greedily optimize local confidence, offering limited guidance for identifying unmasking paths that are globally consistent and accurate. To bridge this gap, we introduce path log-likelihood (Path LL), a trajectory-conditioned objective that strongly correlates with downstream accuracy and enables principled selection of unmasking paths. To optimize Path LL at inference time, we propose POKE, an efficient value estimator that predicts the expected future Path LL of a partial decoding trajectory. We then integrate this lookahead signal into POKE-SMC, a Sequential Monte Carlo-based search framework for dynamically identifying optimal unmasking paths. Extensive experiments across 6 reasoning tasks show that POKE-SMC consistently improves accuracy, achieving 2\%--3\% average gains over strong decoding-time scaling baselines at comparable inference overhead on LLaDA models and advancing the accuracy--compute Pareto frontier.
****
Improved Dimension Dependence for Bandit Convex Optimization with Gradient Variation
Hang Yu, Yu-Hu Yan, Peng Zhao
Gradient-variation online learning has drawn increasing attention due to its deep connections to game theory and optimization. It has been studied extensively in the full-information setting, but is underexplored with bandit feedback. In this work, we focus on gradient variation in Bandit Convex Optimization (BCO) with two-point feedback. By proposing a refined analysis of the *non-consecutive* gradient variation, a fundamental quantity in gradient variation with bandit feedback, we improve the dimension dependence for both convex and strongly convex functions compared with the best known results (Chiang et al., 2013). Our improved analysis of the non-consecutive gradient variation also implies other favorable problem-dependent guarantees, such as gradient-variance and small-loss regret bounds. Beyond the two-point setup, we demonstrate the versatility of our technique by achieving the *first* gradient-variation bound for one-point bandit linear optimization over hyper-rectangular domains. Finally, we validate the effectiveness of our results in more challenging tasks such as dynamic and universal regret minimization, establishing the *first* gradient-variation dynamic and universal regret bounds for two-point BCO.

Topology-Aware Contrastive Learning: Regulating Representation Connectivity via

Persistent Homology
Jiaxin Sun, Yuhua Qian, Yang Wang
Standard contrastive learning minimizes geometric distance between positive pair
s, implicitly assuming that strict compactness optimizes discrimination. However
, this topology-agnostic confusion neglects intrinsic data structures and topolo
gical complexity, leading to class confusion—particularly when aggressive augmen
tations induce semantic drift. To address this, we propose Topology-Aware Contra
stive Learning, a framework that shifts the objective from geometric singularity
 to topological connectivity. Leveraging Persistent Homology, we explicitly regu
late the connectivity of the latent space, ensuring positive pairs maintain an $
\alpha\text{--}\beta$ connectivity that balances intra-class cohesion with separ
ability. Theoretically, we formally define the topology-agnostic confusion pheno
menon, prove that excessive compactness strictly lower-bounds the probability of
 confusion and derive a generalization bound demonstrating that richer topologic
al connectivity tightens downstream risk. Furthermore, we establish a measure-th
eoretic framework to mitigating the sensitivity of our method against varying au
gmentation strengths. Empirical results on benchmarks confirm that our approach
enhances representation quality and reduces reliance on specific augmentation st
rategies compared to standard baselines.

The Role of Target Update Frequencies in Q-Learning
Simon Weissmann, Tilman Aach, Benedikt Wille, Sebastian Kassing, Leif Döring
The target network update frequency (TUF) is a central stabilization mechanism i
n (deep) Q-learning. However, its selection remains poorly understood and is oft
en treated merely as another tunable hyperparameter rather than as a principled
design decision. This work provides a theoretical analysis of target fixing in t
abular Q-learning through the lens of approximate dynamic programming. We view p
eriodic Q-learning as a nested optimization scheme in which each outer iteration
 applies an inexact Bellman optimality operator, approximated by a generic inner
 loop optimizer. Rigorous theory yields a finite-time convergence analysis for t
he asynchronous sampling setting, specializing to stochastic gradient descent in
 the inner loop. Our results deliver an explicit characterization of the bias–va
riance trade-off induced by the target update period, showing how to optimally s
et this critical hyperparameter. We prove that constant target update schedules
are suboptimal, incurring a logarithmic overhead in sample complexity that is en
tirely avoidable with adaptive schedules. Our analysis shows that the optimal ta
rget update frequency decreases geometrically over the course of the learning pr
ocess.

GEPC: Group-Equivariant Posterior Consistency for Out-of-Distribution Detection
in Diffusion Models
Rouzoumka Yadang Alexis, Jean Pinsolle, Eugénie TERREAUX, Christèle Morisseau, J
ean-Philippe Ovarlez, Chengfang Ren
Diffusion models learn a time-indexed score field $\mathbf{s}_\theta(\mathbf{x}_
t,t)$ that often inherits approximate equivariances (flips, rotations, circular
shifts) from in-distribution (ID) data and convolutional backbones. Most diffusi
on-based out-of-distribution (OOD) detectors exploit score magnitude or local ge
ometry (energies, curvature, covariance spectra) and largely ignore equivariance
s. We introduce Group-Equivariant Posterior Consistency (GEPC), a training-free
probe that measures how consistently the learned score transforms under a finite
 group G, detecting equivariance breaking even when score magnitude remains un
changed. At the population level, we propose the ideal GEPC residual which avera
ges an equivariance-residual functional over G, and we derive ID upper bounds
and OOD lower bounds under mild assumptions. GEPC requires only score evaluation
s and produces interpretable equivariance-breaking maps. On OOD image benchmark
datasets, we show that GEPC achieves competitive or improved AUROC compared to r
ecent diffusion-based baselines while remaining computationally lightweight. On
high-resolution synthetic aperture radar imagery where OOD corresponds to target
s or anomalies in clutter, GEPC yields strong target-background separation and v
isually interpretable equivariance-breaking maps. The official implementation is

available at https://github.com/RouzAY/gepc-diffusion/.
****
Optimal Stopping in Latent Diffusion Models
Yu-Han Wu, Quentin Berthet, Gérard Biau, Claire Boyer, Romuald Elie, Pierre Marion
We identify and analyze a surprising phenomenon of $\textit{Latent}$ Diffusion Models (LDMs) where the final steps of the diffusion can $\textit{degrade}$ sample quality. In contrast to conventional arguments that justify early stopping for numerical stability, this phenomenon is intrinsic to the dimensionality reduction in LDMs. We provide a principled explanation by analyzing the interaction between latent dimension and stopping time. Under a Gaussian framework with linear autoencoders, we characterize the conditions under which early stopping is needed to minimize the distance between generated and target distributions. More precisely, we show that lower-dimensional representations benefit from earlier termination, whereas higher-dimensional latent spaces require later stopping time. We further establish that the latent dimension interplays with other hyperparameters of the problem such as constraints in the parameters of score matching. Crucially, this framework suggests that the reconstruction quality of the autoencoder alone can serve as a proxy to estimate the potential performance of the full LDM. Experiments on synthetic and real datasets illustrate these properties, underlining that early stopping can improve generative quality. Together, our results offer a theoretical foundation for understanding how the latent dimension influences the sample quality, and highlight stopping time as a key hyperparameter in LDMs.
****
Compressed Sensing for Capability Localization in Large Language Models
Anna Bair, Yixuan Even Xu, Mingjie Sun, J Zico Kolter
Large language models (LLMs) exhibit a wide range of capabilities, including mathematical reasoning, code generation, and linguistic behaviors. We show that Transformer architectures contain small subsets of attention heads that are necessary for certain capabilities. Zeroing out as few as five task-specific heads can degrade performance by up to $60\\%$ on standard benchmarks measuring the capability of interest, while largely preserving performance on unrelated tasks. We introduce a compressed sensing-based method that exploits the sparsity of these heads to identify them via strategic knockouts and a small number of model evaluations. We validate these findings across Llama and Qwen models ranging from 1B to 14B parameters and a diverse set of capabilities including mathematical abilities and code generation, revealing a modular organization in which specialized capabilities are dependent on sparse, functionally distinct components. Overall, our results suggest that capability localization is a general organizational principle of Transformer language models, with implications for interpretability, model editing, and AI safety. Code is released at https://github.com/locuslab/llm-components.
****
Coupled Trigger Optimization and Vulnerable Parameter Alignment for Persistent Backdoor Attacks on Federated Learning
Zhixuan Ma, Haichang Gao, Shangwen Li, Ping Wang, Han Yu
Federated learning (FL) is vulnerable to backdoor attacks. Yet sustaining backdoor effectiveness under repeated aggregation remains challenging. Existing methods often rely on heuristic trigger designs or indiscriminant parameter manipulation, leading to rapid decay or detectable anomalies. In this work, we view FL backdoor persistence through the lens of optimization dynamics, and argue that long-lasting attacks require alignment between trigger-induced representations and aggregation-stable parameter directions. Based on this insight, we propose the Coupled Trigger Optimization and Vulnerable Parameter Alignment (CTO-VPA) FL backdoor attack method.
By constraining updates to this coupled subspace, backdoor behaviors can be embedded into optimization-stable directions while preserving benign performance. Experiments across multiple datasets and defense settings show that CTO-VPA achieves substantially improved persistence and robustness compared to prior attacks,

highlighting the importance of trigger–parameter coupling in FL settings. The co
de is available at \url{https://github.com/SwLi415/COVERT}.

Test-Time Reinforcement Learning for Flow Matching
Jili Chen, Changqin Huang, Qionghao Huang, Yaxin Tu, Zhonglong Zheng, Xiaodi Hua
ng
Flow-matching has emerged as a leading framework for high-fidelity text-to-image
 generation. However, its alignment with human preferences through RL is often h
indered by substantial computational overhead. In this paper, we introduce Flow-
TTRL, the first test-time reinforcement learning framework that achieves alignme
nt on the fly. Our approach reinterprets intermediate latent representations as
an implicit policy and utilizes SDE-based rollouts to explore high-reward trajec
tories within the learned vector field. Specifically, we propose a two-stage opt
imization strategy: Proximal Reward Difference Prediction (PRDP) ensures structu
ral stability in high-noise regimes through pairwise reward regression, while Gr
oup Relative Policy Optimization (GRPO) refines fine-grained aesthetic details b
y maximizing relative advantages within sampled candidate groups. Experimental r
esults show that Flow-TTRL significantly boosts aesthetic quality, text-image al
ignment, and human preference across diverse backbones. On the GenEval benchmark
, Flow-TTRL elevates the accuracy of SD 3.5-Medium from 63\% to 87\% and Flux.1
Dev from 66\% to 83\%. Furthermore, our framework achieves an average gain of 15
\% to 20\% across T2I-CompBench metrics, delivering performance comparable to st
ate-of-the-art RL-based fine-tuning methods without the need for additional fine
-tuning. Our code is available at ~\url{https://github.com/TheShy-Dream/Flow-TTR
L}.

Regret-Based Federated Causal Discovery with Unknown Interventions
Federico Baldo, Charles K. Assaad
Most causal discovery methods recover a completed partially directed acyclic gra
ph (CPDAG) representing a Markov equivalence class from observational data. Rece
nt work has extended these methods to federated settings to address data decentr
alization and privacy constraints, but often under idealized assumptions that al
l clients share the same causal model. Such assumptions are unrealistic in pract
ice, as client-specific policies, for instance, across hospitals, naturally indu
ce heterogeneous and unknown interventions. In this work, we address federated c
ausal discovery under unknown client-level interventions. We propose I-PERI, a n
ovel federated algorithm that first recovers the CPDAG common to all clients and
 then orients additional edges by exploiting structural differences induced by i
nterventions across clients. This yields a tighter equivalence class, which we c
all the $\mathbf{\Phi}$-Markov Equivalence Class, represented by an augmented ve
rsion of the CPDAG, namely, a $\mathbf{\Phi}$-CPDAG. We provide theoretical guar
antees on the convergence of I-PERI, as well as on its privacy-preserving proper
ties, and present empirical evaluations demonstrating the effectiveness of the p
roposed algorithm.

AvAtar: Learning to Align via Active Optimal Transport
Qi Yu, Ruizhong Qiu, Zhichen Zeng, My T. Thai, huan liu, Hanghang Tong
Alignment plays a fundamental role in many machine learning problems, such as mu
lti-network analysis, multimodal learning, and point cloud registration. Recent
works increasingly leverage optimal transport (OT) for distributional alignment,
 whose effectiveness largely depends on sparse supervision that is hard or costl
y to obtain in practice. Existing works, however, largely overlook how to active
ly acquire high-quality supervision to improve their alignment performance under
 OT frameworks. In this paper, we propose a principled active alignment framewor
k for optimal transport alignment called AvAtar. We quantify the informativeness
 of a candidate by measuring its gradient-based impact on the global alignment r
esult, computed as the gradient propagation from the global alignment result to
all possible supervisions of the candidate through the entropy-regularized OT fo
rmulation. While differentiating through OT is challenging given its constrained
 nature, we leverage the adjoint-state method to reformulate the computation to

a linear system solvable by the conjugate gradient method with linear complexity and guaranteed convergence. By encoding the global alignment result via effective utility functions, AvAtar is applicable to general alignment problems under the OT framework. Extensive experiments on three representative alignment tasks demonstrate the effectiveness, scalability, and generalizability of the proposed AvAtar.

Self-Supervised Weight Templates for Scalable Vision Model Initialization

Yucheng Xie, Fu Feng, Ruixiao Shi, Jing Wang, Yong Rui, Xin Geng

The increasing scale and complexity of modern model parameters underscore the importance of pre-trained models. However, deployment often demands architectures of varying sizes, exposing limitations of conventional pre-training and fine-tuning. To address this, we propose SWEET, a self-supervised framework that performs constraint-based pre-training to enable scalable initialization in vision tasks. Instead of pre-training a fixed-size model, we learn a shared weight template and size-specific weight scalers under Tucker-based factorization, which promotes modularity and supports flexible adaptation to architectures with varying depths and widths. Target models are subsequently initialized by composing and reweighting the template through lightweight weight scalers, whose parameters can be efficiently learned from minimal training data. To further enhance flexibility in width expansion, we introduce width-wise stochastic scaling, which regularizes the template along width-related dimensions and encourages robust, width-invariant representations for improved cross-width generalization. Extensive experiments on classification, detection, segmentation and generation tasks demonstrate the state-of-the-art performance of SWEET for initializing variable-sized vision models.

Positive–Unlabeled Reinforcement Learning Distillation for On-Premise Small Models

Zhiqiang Kou, Junyang Chen, Xin-Qiang Cai, Xiaobo Xia, Ming-Kun Xie, Dong-Dong Wu, Biao Liu, Yuheng Jia, Xin Geng, Masashi Sugiyama, Tat-Seng Chua

Due to constraints on privacy, cost, and latency, on-premise deployment of small models is increasingly common. However, most practical pipelines stop at supervised fine-tuning (SFT) and fail to reach the reinforcement learning (RL) alignment stage. The main reason is that RL alignment typically requires either expensive human preference annotation or heavy reliance on high-quality reward models with large-scale API usage and ongoing engineering maintenance, both of which are ill-suited to on-premise settings. To bridge this gap, in this paper, we propose a positive-unlabeled (PU) RL distillation method for on-premise small-model deployment. Without human-labeled preferences or a reward model, our method distills the teacher’s preference-optimization capability from black box generations into a locally trainable student. For each prompt, we query the teacher once to obtain an anchor response, locally sample multiple student candidates, and perform anchor-conditioned self-ranking to induce pairwise or listwise preferences, enabling a fully local training loop via direct preference optimization or group relative policy optimization. Theoretical analysis justifies that the induced preference signal by our method is order-consistent and concentrates on near-optimal candidates, supporting its stability for preference optimization. Experiments demonstrate that our method achieves consistently strong performance under a low-cost setting.

SALE : Low-bit Estimation for Efficient Sparse Attention in Long-context LLM Prefilling

Xiaodong Ji, Hailin Zhang, Fangcheng Fu, Bin CUI

Many advanced Large Language Model (LLM) applications require long-context processing, but the self-attention module becomes a bottleneck during the prefilling stage of inference due to its quadratic time complexity with respect to sequence length. Existing sparse attention methods accelerate attention computation by skipping less significant regions of the attention map. However, these approaches typically perform coarse-grained inspection of the attention map, resulting in

their suboptimal performance. In this paper, we propose SALE, a fine-grained spa rse attention method that accelerates the long-context prefilling stage of LLM w ith negligible loss in model accuracy. SALE achieves fast and accurate fine-grai ned attention map estimation using low-bit quantized query-key products to appro ximate attention weights, followed by the application of a novel Relative Attent ion Score metric to assess the importance of query-key pairs. This design enable s us to accurately identify important regions in the attention map, thereby cons tructing a highly sparse attention mask.

We implement a custom CUDA kernel in SALE optimized for hardware efficiency, red ucing overhead to approximately 11% of the full attention latency. Notably, SALE requires no parameter training and can be seamlessly integrated into existing s ystems with trivial code modifications. Experiments on long-context benchmarks d emonstrate that our method outperforms existing approaches in accuracy-efficienc y trade-offs, achieving at least 3.36× speedups on Llama-3.1-8B for sequences lo nger than 64K while maintaining model quality.

Building Social World Model with Large Language Models
Haofei Yu, Yining Zhao, Guanyu Lin, Jiaxuan You
Understanding and predicting how social beliefs evolve in response to events—fro m policy changes to scientific breakthroughs—remains a fundamental challenge in social science. Given LLMs' commonsense knowledge and social intelligence, we as k: Can LLMs model the dynamics of social beliefs following social events? In thi s work, we introduce the concept of the Social World Model (SWM), a general fram ework designed to capture how social beliefs evolve in response to major events. SWM learns state-transition functions for social beliefs by mining temporal pat terns in social data and optimizing the evidence lower bound, without the need f or explicit human annotations that link events to belief shifts or expensive cen sus data. To evaluate SWM, we introduce a benchmark, SWM-bench, derived from rea l-world prediction market data from both Kalshi and Polymarket. SWM-bench includ es over 12k data points for social belief prediction tasks spanning diverse doma ins such as politics, cryptocurrency, and elections. Our experimental results sh ow that SWM significantly outperforms time-series foundation models, achieving s tate-of-the-art results on Kalshi data, respectively, while offering interpretab le insights into the underlying mechanisms of social belief dynamics.

Generalization and Scaling Laws for Mixture-of-ExpertsTransformers
Mansour MAYAKI
We develop a theory of generalization and scaling for Mixture-of-Experts (MoE) T ransformers that cleanly separates active per-input capacity from routing combin atorics. By conditioning on fixed routing patterns and union-bounding across the m, we derive a sup-norm covering-number bound whose metric entropy scales with t he active parameter budget and incurs a MoE-specific routing overhead. Combined with a standard ERM analysis for squared loss, this yields a generalization boun d under a d-dimensional manifold data model and C^β targets, showing tha t approximation and estimation trade off as in dense networks once active parame ters are accounted for appropriately. We further prove a constructive approximat ion theorem for MoE architectures, showing that, under the approximation constru ction, error can decrease either by scaling active capacity or by increasing the number of experts, depending on the
dominant bottleneck. From these results we derive neural scaling laws for model size, data size, and compute-optimal tradeoffs. Overall, our results provide a t ransparent statistical reference point for reasoning about MoE scaling, clarifyi ng which behaviors are certified by worst-case theory and which must arise from data-dependent routing structure or optimization dynamics.

Reparameterization Flow Policy Optimization
Hai Zhong, Zhuoran Li, Xun Wang, Longbo Huang
Reparameterization Policy Gradient (RPG) has emerged as a powerful paradigm for model-based reinforcement learning, enabling high sample efficiency by backpropa

gating gradients through differentiable dynamics. However, prior RPG approaches have been predominantly restricted to Gaussian policies, limiting their performance and failing to leverage recent advances in generative models. In this work, we identify that flow policies, which generate actions via differentiable ODE integration, naturally align with the RPG framework, a connection not established in prior work. Yet, naively realizing this synergy is non-trivial: it often suffers from training instability and a lack of exploration. We propose Reparameterization Flow Policy Optimization (RFO). RFO computes policy gradients by backpropagating jointly through the flow generation process and system dynamics, unlocking high sample efficiency without requiring intractable log-likelihood calculations. RFO includes two tailored regularization terms for stability and exploration. We also propose a variant of RFO with action chunking. Extensive experiments on diverse locomotion and manipulation tasks—involving both rigid and soft bodies with state or visual inputs—demonstrate the effectiveness of RFO. Notably, on a challenging locomotion task controlling a soft-body quadruped, RFO achieves almost $2\times$ the reward of the state-of-the-art baseline.

SceneSmith: Agentic Generation of Simulation-Ready Indoor Scenes

Nicholas Pfaff, Thomas Cohn, Sergey Zakharov, Rick Cory, Russ Tedrake

Simulation has become a key tool for training and evaluating home robots at scale, yet existing environments fail to capture the diversity and physical complexity of real indoor spaces. Current scene synthesis methods produce sparsely furnished rooms that lack the dense clutter, articulated furniture, and physical properties essential for robotic manipulation. We introduce SceneSmith, a hierarchical agentic framework that generates simulation-ready indoor environments from natural language prompts. SceneSmith constructs scenes through successive stages—from architectural layout to furniture placement to small object population—each implemented as an interaction among VLM agents: designer, critic, and orchestrator. The framework tightly integrates asset generation through text-to-3D synthesis for static objects, dataset retrieval for articulated objects, and physical property estimation. SceneSmith generates 3-6x more objects than prior methods, with $<$2\% inter-object collisions and 96\% of objects remaining stable under physics simulation. In a user study with 205 participants, it achieves 92\% average realism and 91\% average prompt faithfulness win rates against baselines. We further demonstrate that these environments can be used in an end-to-end pipeline for automatic robot policy evaluation.

Less Precise Can Be More Reliable: A Systematic Evaluation of Quantization’s Impact on VLMs Beyond Accuracy

Aymen Bouguerra, Daniel Alfonso Montoya Vasquez, Alexandra Gomez-Villa, Chokri Mraidha, Fabio Arnez

Vision-Language Models (VLMs) such as CLIP have revolutionized zero-shot classification and safety-critical tasks, including Out-of-Distribution (OOD) detection. However, their high computational cost hinders efficient real-world deployment. While quantization is a standard solution for efficiency, its broader impact on reliability metrics beyond simple Top-1 accuracy remains critically under-explored. In this study, we conduct a large-scale evaluation of VLM quantization across a comprehensive experimental suite of over 700k evaluation runs with varying configurations. We find that, contrary to the assumption that quantization's noise degrades performance, it can simultaneously improve accuracy, calibration, OOD detection, and robustness to noise, though not to covariate shift or spurious correlations. We leverage these counterintuitive findings to characterize the mechanics of quantization beyond simple regularization: we show that quantization dampens high-rank spectral components, compelling the model to rely more heavily on robust, low-rank features. Ultimately, this spectral filtering effect drives the observed improvements in generalization and noise tolerance, establishing a pathway to deploy faster, more reliable VLMs by utilizing quantization beyond its conventional role.

ImmersePro: End-to-End Stereo Video Synthesis Via Implicit Disparity Learning

Jian Shi, Zhenyu Li, Peter Wonka
We introduce \textit{ImmersePro}, an innovative framework specifically designed to transform single-view videos into stereo videos. This framework utilizes a novel dual-branch architecture comprising a disparity branch and a context branch on video data by leveraging spatial-temporal attention mechanisms. \textit{ImmersePro} employs implicit disparity guidance, enabling the generation of stereo pairs from video sequences without the need for explicit disparity maps, thus reducing potential errors associated with disparity estimation models.
In addition to the technical advancements, we introduce the YouTube-SBS dataset, a comprehensive collection of 423 stereo videos sourced from YouTube. This dataset is unprecedented in its scale, featuring over 7 million stereo pairs, and is designed to facilitate training and benchmarking of stereo video generation models. Our experiments demonstrate the effectiveness of \textit{ImmersePro} in producing high-quality stereo videos, offering significant improvements over existing methods.
Compared to the best competitor stereo-from-mono we quantitatively improve the results by 11.76\% (L1), 6.39\% (SSIM), and 5.10\% (PSNR).

Annotations Mitigate Post-Training Mode Collapse
Jacob Mitchell Springer, Madhu Advani, Lukas Aichberger, Arwen Bradley, Eran Malach, Omid Saremi, Sinead Williamson, Preetum Nakkiran, Etai Littwin, Aditi Raghunathan
Post-training via supervised fine-tuning improves instruction-following, but often induces semantic mode collapse by biasing models toward low-entropy fine-tuning data at the expense of the high-entropy pretraining distribution. Crucially, we find this trade-off worsens with scale. To close this semantic diversity gap, we propose annotation-anchored training, a principled method that enables models to adopt the preference-following behaviors of post-training without sacrificing the inherent diversity of pretraining. Our approach is simple: we pretrain on documents paired with semantic annotations, inducing a rich annotation distribution that reflects the full breadth of pretraining data, and we preserve this distribution during post-training. This lets us sample diverse annotations at inference time and use them as anchors to guide generation, effectively transferring pretraining's semantic richness into post-trained models. We find that models trained with annotation-anchored training can attain 6x less diversity collapse than models trained with SFT, and improve with scale.

What Characterizes Effective Reasoning? Revisiting Length, Review, and Structure of CoT
Yunzhen Feng, Julia Kempe, Cheng Zhang, Parag Jain, Anthony Hartshorn
Large reasoning models (LRMs) spend substantial test-time compute on long chain-of-thought (CoT) traces, but what *characterizes* an effective CoT remains unclear. While prior work reports gains from lengthening CoTs and increasing review via appended *wait* tokens, recent studies suggest that shorter thinking can outperform longer traces. We therefore conduct a systematic evaluation across ten LRMs on math and scientific reasoning. Contrary to the “longer-is-better” narrative, we find that both naively using longer CoTs and more review behaviors are associated with *lower* accuracy.

As CoT unfolds step by step, token-level metrics can conflate verbosity with process quality. We introduce a graph view of CoT to extract structure and identify a single statistic—the *Failed-Step Fraction* (FSF), the fraction of steps in abandoned branches—that consistently outpredicts length and review ratio for correctness across models. To probe causality, we design two interventions. First, we rank candidate CoTs by each metric at test time, where FSF yields the largest pass@1 gains; second, we edit CoTs to remove failed branches, which significantly improves accuracy, indicating that failed branches bias subsequent reasoning. Taken together, these results characterize effective CoTs as those that *fail less* and support *structure-aware* test-time scaling over indiscriminately generating long CoTs.

****
Self-correcting for Debiasing Large Language Models
Xuan Feng, Shuai Zhao, Luwei Xiao, Tianlong Gu, Bo An
Although Large Language Models (LLMs) demonstrate remarkable reasoning capabilities, inherent social biases often cascade throughout the Chain-of-Thought (CoT) process, leading to continuous "Bias Propagation". Existing debiasing methods primarily focus on static constraints or external interventions, failing to identify and interrupt this propagation once triggered. To address this limitation, we introduce Self-Debias, a progressive framework designed to instill intrinsic self-correction capabilities. Specifically, we reformulate the debiasing process as a strategic resource redistribution problem, treating the model's output probability mass as a limited resource to be reallocated from biased heuristics to unbiased reasoning paths. Unlike standard preference optimization which applies broad penalties, Self-Debias employs a fine-grained trajectory-level objective subject to dynamic debiasing constraints. This enables the model to selectively revise biased reasoning suffixes while preserving valid contextual prefixes. Furthermore, we integrate an online self-improvement mechanism utilizing consistency filtering to autonomously synthesize supervision signals. With merely 20k annotated samples, Self-Debias activates efficient self-correction, achieving superior debiasing performance while preserving general reasoning capabilities without continuous external oversight.
****
Scalable Topology-Preserving Graph Coarsening: Concepts and Algorithms
Xiang Wu, Rong-Hua Li, Xunkai Li, Kangfei Zhao, Hongchao Qin, Guoren Wang
Graph coarsening reduces the size of a graph while preserving certain properties. Most existing methods preserve either spectral or spatial characteristics. Recent research shows that topology-preserving coarsening methods maintain GNN performance on coarsened graphs but suffer from exponential time complexity. To address these problems, we propose Scalable Topology-Preserving Graph Coarsening (STPGC) by introducing the concepts of graph strong collapse and graph edge collapse extended from algebraic topology. STPGC comprises three new algorithms, GStrongCollapse, GEdgeCollapse, and NeighborhoodConing, based on these two concepts, which eliminate dominated nodes and edges while rigorously preserving topological features. We further prove that STPGC preserves the GNN receptive field and develop approximate algorithms to accelerate GNN training. Experiments on node classification with GNNs demonstrate the efficiency and effectiveness of STPGC.
****
Timestep Rescheduling in Diffusion Inversion
Shangquan Sun, Ting Gong, Zhirui Liu, Jiamin Wu, Runkai Zhao, Mianxin Liu, Wenqi Ren, Xiaochun Cao
Diffusion inversion, which maps images back to the Gaussian latent space of a diffusion model, is a critical task for image reconstruction and editing.
While DDIM enables fast deterministic inversion, it inherently introduces deviations that accumulate into noticeable inversion errors.
Existing methods often address this by solving a fixed-point problem but largely overlook how the selection of the diffusion timestep in the noise scheduler influences inversion fidelity.
In this work, we reveal that the deviation scale in diffusion inversion is strongly dependent on the timestep size, and exhibits a parabolic trend, with larger errors concentrated at both small and large timesteps.
Based on this finding, we propose a simple yet effective nonuniform timestep scheduler that integrates a global rescaling with a local dynamic programming based rescheduling, enabling a strategic allocation of computational effort that minimizes the overall inversion error and preserves higher inversion accuracy.
Our method serves as an off-the-shelf enhancement for existing inversion techniques and requires no extra parameters or computational overhead.
Through extensive experiments, we verify that integrating our scheduler consistently boosts the performance of existing inversion methods, achieving superior results in image reconstruction and editing.

FiX: Introducing Fine-grained Forget Gate into Softmax Attention
Runzhong Li, Renjie Liu, Li Qing, Bo Tang
Causal softmax attention is the algorithmic foundation of modern large language models. Inspired by linear attention, recent work has sought to enhance it by incorporating forget gates. However, these efforts, such as FoX, have been limited to coarse, scalar gates. While fine-grained, element-wise gates are shown to be more effective than scalar ones in linear attention, their direct integration into softmax attention is non-trivial due to algebraic constraints. In this work, we introduce *Fine-grained Forgetting Transformer* (*FiX*), a novel architecture that successfully enables element-wise forget gates in softmax attention. Our core insight is that the softmax denominator becomes mathematically redundant under a subsequent RMSNorm layer, allowing us to reformulate the forgetting mechanism as a direct element-wise multiplication on the value vectors. This formulation makes FiX the first positional encoding applied to value-output (VO) pairs, designed to be complementary to existing query-key (QK) encodings like RoPE. We systematically address implementation challenges including numerical precision, computational efficiency, and inference memory consumption. Extensive experiments show *FiX* achieves lower training loss and superior performance on both short-text common sense benchmarks and long-context tasks, opening a new path for building more powerful transformers. Our code is available at https://github.com/AlayaDB-AI/FiX.

PhotoAgent: Exploratory Visual Aesthetic Planning with Large Vision Models
Mingde Yao, Zhiyuan You, King Man Tam, Menglu Wang, Tianfan Xue
With the recent fast development of generative models, instruction-based image editing has shown great potential in generating high-quality images. However, the quality of editing highly depends on carefully designed instructions, placing the burden of task decomposition and sequencing entirely on the user. To achieve autonomous image editing, we present PhotoAgent, a system that advances image editing through explicit aesthetic planning. Specifically, PhotoAgent formulates autonomous image editing as a long-horizon decision-making problem. It reasons over user aesthetic intent, plans multi-step editing actions via tree search, and iteratively refines results through closed-loop execution with memory and visual feedback, without requiring step-by-step user prompts. To support reliable evaluation in real-world scenarios, we introduce UGC-Edit, an aesthetic evaluation benchmark consisting of 7,000 photos and a learned aesthetic reward model. We also construct a test set containing 1,017 photos to systematically assess autonomous photo editing performance. Extensive experiments demonstrate that PhotoAgent significantly outperforms existing methods in both instruction faithfulness and visual quality across a diverse range of editing scenarios.

FT-Dojo: Towards Autonomous LLM Fine-Tuning with Language Agents
Qizheng Li, Yifei Zhang, Xiao Yang, Xu Yang, Zhuo Wang, Bowen Xian, Weiqing Liu, Jiang Bian
Fine-tuning large language models for vertical domains remains labor-intensive, requiring practitioners to curate data, configure training, and iteratively diagnose model behavior.
Despite growing interest in autonomous machine learning and language agents, end-to-end LLM fine-tuning has not been systematically studied as an interactive agent task.
We introduce FT-Dojo, an interactive benchmark environment for autonomous LLM fine-tuning, comprising 13 tasks across 5 domains.
Rather than a new collection of static datasets, FT-Dojo standardizes a task interface, shared raw-data repository, sandboxed execution environment, structured feedback protocol, and held-out evaluation procedure.
We further develop FT-Agent, a fine-tuning-oriented autonomous framework that uses structured iteration planning, fail-fast validation, and multi-level feedback analysis to refine data and training strategies.
Experiments show that FT-Agent provides a strong initial baseline, achieving the best performance on 10 out of 13 tasks, with additional controlled comparisons

against frontier agents, open-source planning backbones, and multi-run statistics supporting the main findings.
Case studies show that agents can recover from failures through cumulative learning, while still exposing limitations in causal diagnosis and long-horizon planning.
The implementation is available at https://github.com/microsoft/rd-agent.

Unsupervised Hierarchical Skill Discovery
Damion Harvey, Geraud Nangue Tasse, Benjamin Rosman, Branden Ingram, Steven James
We consider the problem of unsupervised skill segmentation and hierarchical structure discovery in reinforcement learning. While recent approaches have sought to segment trajectories into reusable skills or options, most rely on action labels, rewards, or handcrafted annotations, limiting their applicability. We propose a method that segments unlabelled trajectories into skills and induces a hierarchical structure over them using a grammar-based approach. The resulting hierarchy captures both low-level behaviours and their composition into higher-level skills. We evaluate our approach in high-dimensional, pixel-based environments, including Craftax and the full, unmodified version of Minecraft. Using metrics for skill segmentation, reuse, and hierarchy quality, we find that our method consistently produces more structured and semantically meaningful hierarchies than existing baselines. Furthermore, as a proof of concept, we demonstrate that these discovered hierarchies accelerate and stabilise learning on downstream reinforcement learning tasks.
****

Breaking Manifold Continuity: Vector Quantized Modeling for Real-Centric Deepfake Detection
Changshuo Wang, Jiangming Wang, Ke-Yue Zhang, Taiping Yao, Shouhong Ding, Ran Yi, Lizhuang Ma
The increasingly realistic and diverse generative data has led some deepfake detection methods to shift towards learning robust real content, e.g., via reconstruction-based tasks. However, most existing approaches rely primarily on prevalent continuous modeling (e.g., GMMs, VAEs, Diffusion Models) to construct a continuous latent manifold of real data, with the aim of improving the generalization capability, while overlooking a critical issue, i.e., such continuity may facilitate the interpolation of forgery artifacts, consequently causing ambiguity in detection. To alleviate this problem, we integrate discrete modeling into the feature space of the CLIP vision encoder, striking a balance between continuous manifold modeling and discrete representation. By incorporating a learnable vector quantized codebook, the real latent manifold is discretized, imposing a more stringent information bottleneck that reduces the likelihood of embedding generative artifacts. In order to further enhance the generalization of discrete modeling, we propose an adaptive tangent space projection mechanism that yields a continuous relaxation of the discrete real distribution within a controllable range. With these components, our method constructs a real distribution that is both tightly constrained and broadly generalizable, enhancing robustness to unseen forgeries. Extensive experiments on diverse datasets demonstrate the effectiveness of our method.

DOT-MoE: Differentiable Optimal Transport for MoEfication
Udbhav Bamba, Arnav Chavan, Aryamaan Thakur, Steven Teig, Deepak Gupta
The scaling of Large Language Models (LLMs) has driven significant performance gains but created substantial challenges in inference efficiency. While Mixture of Experts (MoEs) architectures address this by decoupling model size from inference cost, training MoEs from scratch is often unstable and compute intensive. Conversion of pre-trained dense models into sparse MoEs has emerged as an alternative solution; however, existing methods typically rely on heuristic neuron clustering or random splitting to partition Feed-Forward Networks (FFNs) into experts. In this work, we propose DOT-MoE, a novel framework that formulates the decomposition of dense layers as a Differentiable Optimal Transport (DOT) problem. Ins

tead of static heuristics, we model neuron assignment as a balanced transport pr
oblem, utilizing differentiable Sinkhorn-Knopp iterations to enforce strict expe
rt capacity constraints. Furthermore, we utilize Straight-Through Estimators (ST
E) to jointly learn the discrete neuron-to-expert assignment and the token-to-ex
pert routing policy end-to-end. Extensive experiments across multiple architectu
res and benchmarks demonstrate that DOT-MoE significantly outperforms structured
 pruning, heuristic clustering, and random-split baselines, retaining 90% of the
 original dense model's performance while reducing active parameters by 50%.
****

FedEMoE: Improving Personalization on Heterogeneous Federated Learning via Elast
ic Mixture of Experts Architecture

Haizhou Du, Lixin Huang, Zonghan Wu, Huan Huo

Heterogeneous federated learning (HtFL) has emerged as a promising approach to a
ddress heterogeneity in local computational resources and data distribution. How
ever, existing methods cause performance degradation of model personalization be
cause personalized and generalized knowledge are either intertwined or dominated
 by one of them. To address this issue, we propose a novel Elastic Mixture of Ex
perts (EMoE) architecture on HtFL, namely FedEMoE, decoupling personalization fr
om generalization. Specially, FedEMoE employs a multi-scale feature extraction m
echanism via personalized experts to enrich personalized knowledge. Furthermore,
 we design an elastic shared expert to break the transferred knowledge bottlenec
k across heterogeneous client models. The elastic shared expert can adaptively e
xpand or shrink according to the status of each expert by the weight spectrum an
alysis, respectively. Extensive experiments across statistical and model heterog
eneity settings demonstrate that FedEMoE significantly outperforms state-of-the
art methods on the accuracy of each heterogeneous model over diverse datasets.

LiteVSR: Lightweight Adaptation of Frozen Diffusion Transformers for Video Super
-Resolution

Yu Cao, Ziquan Liu, Zhensong Zhang, Jiankang Deng, Shaogang Gong, Jifei Song

Adapting large-scale pre-trained video generators for Video Super-Resolution (VS
R) in novel domains remains computationally prohibitive.

Methods that reformulate generation as direct Low-Quality to High-Quality mappin
gs deviate from the original generative formulation, demanding extensive fine-tu
ning. ControlNet-style adapters lose their efficiency under modern Diffusion Tra
nsformers since the absence of encoder-decoder hierarchy forces duplication of t
he entire backbone. We observe that flow matching offers a principled alternativ
e for cross-domain VSR adaptation. By predicting a constant velocity field acros
s all timesteps, the adaptation task reduces to learning a fixed injection patte
rn rather than time-varying transformations. Building on this insight, we propos
e LiteVSR, a minimalist framework that performs VSR using a completely frozen Di
ffusion Transformer with a lightweight State-Aware Adapter. The adapter employs
a dual-stream architecture that extracts static structural cues from the LQ inpu
t and dynamic cues from intermediate denoising states, aligning them through tim
e-dependent cross-attention to enable adaptive transition from structural alignm
ent to texture refinement as denoising proceeds. LiteVSR achieves competitive re
storation quality with only 11.25% trainable parameters and 12 GPU-hours of trai
ning on a single A100, while maintaining fast sampling (down to a single step) c
ompatibility.

RBCBF: Decoding Time Safety Alignment via Risk Guided Rollback and Barrier Contr
ol

Tianxiang Chen, Jingyuan Zhou, Longhao Yan, Kaidi Yang

Existing decoding-time safety interventions are often reactive, relying on local
 signals to correct unsafe outputs after they emerge.

Under adversarial prompts that drive generation into recurring unsafe response,
such local signals provide weak guidance for stable repair. As a result, rollbac
k and post-hoc rewriting often trade-off response quality with recurrent violati
ons. To address these limitations, we propose RBCBF, a rollback-based decoding-t
ime framework that jointly selects intervention steps and performs distribution-

level corrective control. Our key innovation is a risk-aggregation formulation t
hat views terminal violations as the accumulated build-up of risk along the pref
ix. By selecting rollback steps from these decisive prefixes, RBCBF moves rollba
ck targeting beyond heuristic cues and turns it into a trajectory-level decision
. RBCBF then applies invasive corrective control to the next-token distribution
under multiple rule constraints. Across jailbreak-style evaluations, RBCBF outpe
rforms prior rollback methods and decoding-time baselines, reducing harmful resp
onses and substantially lowering violation recurrence.

Differentially Private Submodular Maximization with a Knapsack Constraint
Ron Zadicario, Tova Milo
Submodular maximization subject to a knapsack constraint (SMK) is a fundamental
problem in discrete optimization, with wide-ranging applications in machine lear
ning and related fields. As these applications increasingly involve sensitive in
dividual data, there is a growing need for high-utility algorithms that provide
formal privacy guarantees.
In this work, we study the SMK problem under differential privacy, considering b
oth monotone and non-monotone objective functions. For monotone objectives, we p
ropose a differentially private algorithm that achieves the optimal $(1-1/e)$-ap
proximation ratio while significantly improving both additive error and query co
mplexity over prior work. We also present a more efficient algorithm for the sa
me setting, achieving a $1/2$-approximation. For non-monotone objectives, we int
roduce, to our knowledge, the first differentially private algorithm with provab
le guarantees, achieving a $1/4$-approximation in expectation and an additive er
ror comparable to the best known for monotone objective functions.
****

FuseFSS: Efficient Secure LLM Inference with Function Secret Sharing
Yuhan Ma, Yong Li, Stefan Schmid
Two-server secure inference allows a client to query a hosted large language mod
el (LLM) without revealing prompts or embeddings. Recent GPU systems based on fu
nction secret sharing (FSS) make linear layers efficient, but fixed-point nonlin
earities and helper operations remain a bottleneck because each operator is typi
cally implemented as a bespoke protocol with its own comparisons, wrap-around co
rrections, and preprocessing material. We present FuseFSS, a compiler that repla
ces per-operator protocol design with a single compilation pipeline. For each sc
alar fixed-point operator, a compact specification lists its interval partition,
 low-degree arithmetic pieces, and required predicate bits. The compiler emits t
wo batched FSS evaluations on the public masked value: one packed comparison tha
t returns all predicate bits, and one vector interval lookup that returns the ac
tive coefficients and constants. Compared to the current state-of-the-art FSS-ba
sed GPU secure inference, FuseFSS preserves accuracy while achieving a $1.24\tim
es$–$1.50\times$ end-to-end speedup and reducing online communication by 9%–16%
on BERT and GPT-style models; preprocessing is also lighter, with 14%–23% lower
key-generation time and 20%–24% smaller keys.

Addressing Semantic Blind Spots in Text-to-SQL via Component Pre-generation and
AST Matching Rewards
Xingyu Ma, Xin Tian, Lingxiang Wu, Xuepeng Wang, Zhilin Zhang, Xueming Tang, Jin
qiao Wang
In recent years, significant advancements in large language models have greatly
propelled the development of Text-to-SQL tasks. However, due to the token-by-tok
en sequential generation mechanism employed by these models, they encounter a se
mantic blind spot problem with respect to pending SQL components—the parts of th
e SQL query yet to be generated. Specifically, language models are unable to eff
ectively utilize the semantic information of these pending SQL components during
 the generation of the final SQL query, which poses considerable challenges for
generating complex SQL statements. To address this issue, we propose a novel tho
ught process based on SQL components pre-generation and design a maximum connect
ed subtree matching reward mechanism leveraging the SQL abstract syntax tree to
improve the accuracy of local component generation. Extensive experiments demons

trate that, under comparable model parameter scales, our training approach achie ves significant advantages, effectively enhancing the generation of complex SQL queries. Our method attains an execution accuracy EX of 65.78% on the BIRD-dev d ataset and achieves state-of-the-art performance on the Spider-syn datasets.
****
Information-Theoretic Disentangled Latent Modeling with Conditional Diffusion fo r Incomplete Multi-View Clustering
Wenlan Chen, Lu Gao, Daoyuan Wang, Cheng Liang, Fei Guo
Incomplete multi-view clustering is challenging due to view missingness and the entanglement of shared semantics with view-specific factors in latent representa tions. Existing methods often rely on heuristic fusion or direct completion stra tegies, which suffer from error propagation and unreliable generation under miss ing views. In this paper, we propose an **I**nformation-guided **D**isentangled latent modeling framework with **C**onditional **D**iffusion for incomplete mult i-view clustering (IDCD). Specifically, we first encode each view into a latent representation that is variationally decomposed into a view-wise semantic latent and a view-specific factor. Information-theoretic objectives are introduced to guide the disentanglement of view-wise latents, preserving essential multi-view information while reducing the dependency between semantic and view-specific fac tors and encouraging cross-view semantic consistency. Besides, we aggregate the semantic latents via a mixture of Wasserstein distributions to obtain a unified global representation, where we impose a Gaussian mixture prior to explicitly co uple representation learning with clustering. Based on the learned disentangled latent space, a conditional diffusion model guided by both the global semantic l atent and view-specific factors is employed to generate missing views in a consi stent manner. Extensive experiments on benchmark datasets demonstrate superior c lustering performance and robust missing-view generation compared to state-of-th e-art methods.

WeatherSyn: An Instruction Tuning MLLM For Weather Forecasting Report Generation
Zinan Zheng, Yang Liu, Nuo Chen, Juepeng Zheng, Hong Cheng, Jia Li
Accurate weather forecast reporting enables individuals and communities to bette r plan daily activities, agricultural operations, and transportation. However, t he current reporting process primarily relies on manual analysis of multi-source data, which often leads to information overload and reduced efficiency. With th e rapid advancement of multimodal large language models (MLLMs), leveraging data -driven models to analyze and generate reports in the weather forecasting domain remains largely underexplored. In this work, we propose the Weather Forecasting Report (WFR) task and construct the first instruction-tuning dataset for this t ask, named WSInstruct, which covers 31 cities in America and 8 weather aspects. Based on this corpus, we develop the first model, WeatherSyn, specialized in gen erating weather forecast reports. Evaluation across multiple metrics on our data set shows that WeatherSyn consistently outperforms leading closed-source MLLMs, particularly on structurally complex weather aspects. We further analyze its per formance across diverse geographic regions and weather aspects. WeatherSyn demon strates strong transferability across different regions, highlighting its zero-s hot generalization capability. WeatherSyn offers valuable insight for developing MLLMs specialized in weather report generation.
****
Coupled Training with Privileged Information and Unlabeled Data
Jiahao Shi, Omar Hagrass, Jason Matthew Klusowski
In many prediction problems, we have extra information during training (for exam ple, measurements that are expensive or slow to collect) that will not be availa ble when the model is deployed. A common strategy is to first train a model that uses all training information, then use its predictions on unlabeled examples t o train a second model that only uses the inputs available at test time. However , when the extra training-only information is weak or noisy, this two-step appro ach can mislead the deployable model and even hurt accuracy. We propose a joint training method that learns the two models together, so the deployable model can benefit from the extra information only when it actually helps, instead of inhe

riting its mistakes. We provide guarantees that describe when joint training imp
roves prediction accuracy and analyze a simple alternating training algorithm fo
r large, high-dimensional models. Experiments on synthetic data and medical pred
iction tasks show that our approach avoids these failures and consistently outpe
rforms standard two-step baselines.

Particle Flow for Learning from Label Proportions
Alain Rakotomamonjy, Maxime Vono, Liva Ralaivola
This work proposes a novel method for solving learning from label proportion pro
blems.
For this purpose, we learn a classifier that minimizes three key objectives: (i)
 a
bag-level loss, which quantifies the discrepancy between true and predicted labe
l proportions
in bags, (ii) an instance-level loss, inspired from domain adaptation,
which leverages anchor samples with known labels and trainable supports and (iii
) a
distribution discrepancy that aims at aligning anchor's learned support with tho
se of the bag samples.
The problem is formulated as an alternating optimization process, iteratively
updating the classifier and aligning distributions via a particle flow method.
The flow of anchor samples is governed by a vector field
designed to minimize the anchor loss while ensuring alignment between anchor and
 bag distributions.
We provide a theoretical analysis, guaranteeing the convergence of the flow and
identifying conditions under which the method achieves effective alignment.
Our analysis highlights that gap and diversity in label proportions
within bags is a critical factor for learnability.
Empirical results on tabular and image datasets demonstrate the method's effecti
veness,
outperforming state-of-the-art approaches.

CSPLoRA: Confidence-Guided Structure Planning for Low-Rank Adaptation
Huiming Ding, Xiaochen Li, Jianhui Ma, Xu An, Yihui Yang, Zhenyu Tan
Low-Rank Adaptation (LoRA) has become the de facto paradigm for parameter-effici
ent fine-tuning, with its effectiveness critically influenced by rank allocation
 across modules. However, existing approaches face a fundamental dilemma: unifor
m allocation ignores module heterogeneity, while adaptive methods introduce expe
nsive training overhead or lack reusability across configurations. We propose CS
PLoRA (Confidence-guided Structural Planning for LoRA), a decoupled framework th
at reweights probe samples by prediction uncertainty to obtain more discriminati
ve module importance estimates. The key insight is that hard samples---those the
 model struggles with---provide more informative gradient signals for identifyin
g critical modules than easy samples. For a fixed task-model pair, the resulting
 structural priors can be reused across compatible rank budgets and LoRA backend
s, supporting a practical "probe once, deploy everywhere" workflow. Experiments
on GLUE, commonsense reasoning, and arithmetic tasks show that CSPLoRA improves
over uniform LoRA on average (+1.25 points on LLaMA-2-7B commonsense reasoning)
while maintaining comparable parameters, with the planned rank structure reusabl
e across compatible LoRA variants.

STFlow: Data-Coupled Flow Matching for Geometric Trajectory Simulation
Kiet Bennema ten Brinke, Koen Minartz, Vlado Menkovski
Simulating trajectories of dynamical systems is a fundamental problem in a wide
range of fields such as molecular dynamics, biochemistry, and pedestrian dynamic
s. Machine learning has become an invaluable tool for scaling physics-based simu
lators and developing models directly from experimental data. In particular, rec
ent advances in deep generative modeling and geometric deep learning enable prob
abilistic simulation by learning complex trajectory distributions while respecti
ng intrinsic permutation and time-shift symmetries. However, trajectories of N-b

ody systems are commonly characterized by high sensitivity to perturbations leading to bifurcations, as well as multi-scale temporal and spatial correlations. To address these challenges, we introduce STFlow (Spatio-Temporal Flow), a generative model based on graph neural networks and hierarchical convolutions. By incorporating data-dependent couplings within the Flow Matching framework, STFlow denoises starting from conditioned random-walks instead of Gaussian noise. This novel informed prior simplifies the learning task by reducing transport cost, increasing training and inference efficiency. We validate our approach on N-body systems, molecular dynamics, and human trajectory forecasting. Across these benchmarks, STFlow achieves the lowest prediction errors with fewer simulation steps and improved scalability.

Reason, Then Re-reason: Cross-view Revisiting Improves Spatial Reasoning
Chaofan Ma, Zhenjie Mao, Yuhuan Yang, Fanqin Zeng, Yue Shi, Yingjie Zhou, Xiaofeng Cao, Jiangchao Yao
Spatial reasoning from egocentric videos is inherently challenging because the observable evidence is constrained by the camera trajectory.
Existing methods rely on single-turn inference, forcing models to resolve geometric ambiguity through semantic priors rather than verifiable evidence.
We argue that spatial reasoning should be revisitable: conclusions formed under limited evidence should remain open to revision when complementary viewpoints become available.
Building on this insight, we propose Reason, then Re-reason (ReRe), a training-free, inference-time framework with two phases: in the Reason Phase, an MLLM forms a spatial hypothesis from the original video; in the Re-reason Phase, it verifies or revises the hypothesis by observing a synthesized novel-view video.
To enable effective cross-view revisiting, we design a Geometry-to-Video pipeline that renders strategically complementary novel views from predicted 3D geometry.
These views feature an elevated, oblique perspective with scene-spanning coverage, while preserving the MLLM's native video interface without architectural modifications.
Extensive evaluations on VSI-Bench and STI-Bench demonstrate that ReRe substantially boosts open-source MLLMs to rival proprietary state-of-the-art performance.

CatFlow: Co-generation of Slab-Adsorbate Systems via Flow Matching
Minkyu Kim, Nayoung Kim, Honghui Kim, Sungsoo Ahn
Discovering heterogeneous catalysts tailored for specific reaction intermediates remains a fundamental bottleneck in materials science. While traditional trial-and-error methods and recent generative models have shown promise, they struggle to capture the intrinsic coupling between surface geometry and adsorbate interactions. To address this limitation, we propose CatFlow, a flow matching-based framework for de novo design and structure prediction of heterogeneous catalysts. Our model operates on a primitive cell-based factorized representation of the slab-adsorbate complex, reducing the number of learnable variables by an average of 9.2x while explicitly encoding the surface orientation of the slab-adsorbate interface. Experiments on the Open Catalyst 2020 dataset demonstrate that CatFlow significantly improves the structural fidelity of generated catalysts compared to autoregressive and sequential baselines. Further experiments show that the generated structures accurately capture the adsorption energy distributions of physically plausible interfaces and lie closer to thermodynamic local minima.
****

Submodular Optimization for Minimal Augmentation in Robust Language Model Alignment
Ching-Chia Kao, Chia-Mu Yu, Chun-Shien Lu, Chu-song Chen
Safety alignment of large language models is fragile: even small fine-tuning perturbations elastically revert behaviors toward those of the pre-training, with degradation inversely proportional to the size of the alignment set. We ask how to achieve safety alignment with minimal augmentation. To this end, we model augmentation as a set of group actions on sequences and formalize robustness gains a

s a normalized, monotone submodular function over transformations. We then lever age submodular optimization to select minimal augmentations that provably improv e robustness. Experiments confirm that our approach efficiently restores safety alignment while minimizing the overhead of augmentation.

Component-Wise Composite Likelihood Distillation for Censored Time-to-Event Data
Feiyang Deng, Lingfeng Luo, Jiayu Zhou, Kevin He

Accurate survival modeling in biomedical studies is often hindered by rare event s, limited effective sample sizes, and settings with limited or partially observ ed information (e.g., covariates of interest that are difficult or expensive to collect, highly structured sampling designs, or nuisance parameters omitted by c onditioning). Knowledge distillation can leverage external predictive informatio n without sharing individual-level data, but existing approaches are largely bui lt for fully specified likelihoods or probability-based survival models and do n ot extend to settings where outcome distributions are only partially specified. To address this challenge, we propose a knowledge distillation framework based o n a composite-likelihood Kullback--Leibler divergence that aligns teacher and st udent models within components. Our key insight is that, although composite like lihoods do not define a global outcome distribution, each likelihood component i nduces a well-defined probability model on its restricted outcome space, enablin g a principled KL divergence. Simulation studies and biomedical case studies sho w improved discrimination and predictive accuracy in rare-event, heterogeneous s ettings without requiring access to external individual-level data.

From Static Constraints to Dynamic Adaptation: Sample-Level Constraint Relaxatio n for Offline-to-Online Reinforcement Learning
Lipeng Zu, YU QIAN, Shayok Chakraborty, Xiaonan Zhang

Offline-to-online reinforcement learning (O2O RL) faces a central challenge betw een retaining offline conservatism and adapting to online feedback under distrib ution shift. This challenge arises because data behavior evolves during fine -tuning, rendering data origin a misleading basis for constraint handling and thereby leading to objective–data mismatch. We therefore propose Dynamic Alignme nt for RElaxation (DARE), a distribution-aware framework for sample-level constr aint relaxation based on the behavioral consistency with a behavior model. To ou r knowledge, DARE is the first to condition constraint relaxation on behavioral consistency via a posterior-induced exchange mechanism, moving beyond a binary o ffline/online data distinction. Importantly, DARE requires only per-sample behav ioral alignment, enabling instantiation on top of many offline algorithms with f lexible choices of behavior models and fine-tuning objectives. We provide a theo retical analysis showing that behavior-based sample exchange consistently improv es the distinction between offline-like and online-like subsets. Experiments on D4RL demonstrate that DARE consistently improves fine-tuning stability and achie ves superior final performance over strong offline-to-online baselines.
(The code is publicly available at \url{https://github.com/lpzu/DARE}.)

GeoEvo: Identity-Aware Potential Game with Geometric Evolution for Personalized Multimodal Federated Learning
Chen Wang, Yongli Hu, Huajie Jiang, Kan Guo, Tengfei Liu, Junbin Gao, Yanfeng Su n, Baocai Yin

We reconceptualize Personalized Multimodal Federated Learning (PMFL) by treating missing modalities as intrinsic structural identities that constrain each clien t to a distinct Riemannian submanifold, rather than as deficiencies to be compen sated. To reconcile the tension between identity preservation and cross-client c ollaboration, we cast PMFL as an identity-aware potential game and seek a geomet ry-consistent equilibrium instead of a monolithic full-modality optimum. We prop ose GeoEvo, a federated approximate solver that combines curvature-adaptive Fish er descent with manifold-lifted evolutionary search: Natural Evolution Strategie s for basin escape, and Particle Swarm updates anchored to a server-broadcast Fr \'echet prototype for cross-client transfer. A monotone acceptance rule drives p er-step potential dissipation, yielding an $\mathcal{O}(1/\sqrt{T})$ stationarit

y rate and convergence toward first-order Nash equilibria in non-convex regimes. Empirically, GeoEvo improves personalization and robustness across diverse modality-missing patterns.

FlashOptim: Optimizers for Memory-Efficient Training

Jose Javier Gonzalez Ortiz, Abhay Gupta, Christopher Rinard, Davis Blalock

Standard mixed-precision training of neural networks requires many bytes of accelerator memory for each model parameter. These bytes reflect not just the parameter itself, but also its gradient and one or more optimizer state variables. With each of these values typically requiring 4 bytes, training even a 7 billion parameter model can be impractical for researchers with less than 100\,GiB of accelerator memory.

We introduce FlashOptim, a suite of optimizations that reduces per-parameter memory by over 50% while preserving model quality and API compatibility. Our approach introduces two key techniques. First, we improve master weight splitting by finding and exploiting a tight bound on its quantization error. Second, we design companding functions that greatly reduce the error in 8-bit optimizer state quantization. Together with 16-bit gradients, these techniques reduce AdamW memory from 16 bytes to 7 bytes per parameter, or 5 bytes with gradient release. They also cut model checkpoint sizes by more than half.

Experiments with FlashOptim applied to SGD, AdamW, and Lion show no measurable quality degradation across a collection of standard vision and language benchmarks, including Llama-3.1-8B finetuning.

What Does Preference Learning Recover from Pairwise Comparison Data?

Rattana Pukdee, Maria Florina Balcan, Pradeep Ravikumar

Pairwise preference learning is central to machine learning, with recent applications in aligning language models with human preferences. A typical dataset consists of triplets (x, y^+, y^-), where response y^+ is preferred over response y^- for context x. The Bradley--Terry (BT) model is the predominant approach, modeling preference probabilities as a function of latent score differences. Standard practice assumes data follows this model and learns the latent scores accordingly. However, real data may violate this assumption, and it remains unclear what BT learning recovers in such cases. Starting from triplet comparison data, we formalize the preference information it encodes through the conditional preference distribution (CPRD). We give precise conditions for when BT is appropriate for modeling the CPRD, and identify factors governing sample efficiency---namely, margin and connectivity. Together, these results offer a data-centric foundation for understanding what preference learning actually recovers.

BiTrajDiff: Bidirectional Trajectory Generation with Diffusion Models for Offline Reinforcement Learning

Yunpeng Qing, Yixiao Chi, Shuo Chen, Shunyu Liu, Kexuan Zhou, Sixu Lin, Litao Liu, Changqing Zou

Offline Reinforcement Learning (RL) relies on static datasets and often enforces conservative constraints to mitigate out-of-distribution errors, but this inevitably gives rise to learning dataset biases and limited behavioral generalization.

Recent Data Augmentation (DA) methods leverage generative models to enrich offline data, yet they mainly operate within a single rollout paradigm and tend to preserve the original trajectory-level connectivity of the dataset.

As a result, such methods often introduce local variations and fail to recover connections between distinct behavior patterns.

In this paper, we propose Bidirectional Trajectory Diffusion (BiTrajDiff), a novel DA framework that explicitly addresses this limitation.

BiTrajDiff decomposes trajectory synthesis into two independent diffusion processes that generate forward-future and backward-history segments conditioned on shared intermediate anchor states.

By stitching the generated segments at these anchors, BiTrajDiff can synthesize trajectories that bridge disconnected behavior patterns and recover global trajectory-level connectivity absent from the original data.
Extensive experiments demonstrate that BiTrajDiff consistently outperforms advanced DA methods across a range of offline RL backbones. Our code is available at https://github.com/Plankson/BiTrajDiff.
****
Content-Style Identification via Differential Independence
Subash Timilsina, Hoang-Son Nguyen, Sagar Shrestha, Xiao Fu
Generative analysis often models multi-domain observations as nonlinear mixtures of domain-invariant content variables and domain-specific style variables. Identifying both factors from unpaired domains enables tasks such as domain transfer and counterfactual data generation. Prior work establishes identifiability under (block-wise) statistical independence between content and style, or via sparse Jacobian assumptions on the nonlinear mixing function, but such conditions can be restrictive and may not hold in practice.
In this work, we introduce differential independence, a weaker structural condition requiring that infinitesimal variations in content and style induce orthogonal directions on the data manifold, thereby enabling identifiability even when content and style are dependent and the Jacobian is dense. We operationalize this condition through a blockwise orthogonality constraint on the Jacobian subspaces associated with content and style. To support high-dimensional generative models, we design a stochastic regularizer based on numerical Jacobian approximation, enabling scalable training in settings such as high-resolution image generation. Experiments across multiple datasets corroborate the identifiability analysis and demonstrate practical benefits on counterfactual generation and domain translation tasks.
****
Multi-Task Bayesian In-Context Learning
Qingyang Zhu, Eric Karl Oermann, Kyunghyun Cho
Bayesian predictive inference provides a principled framework for uncertainty quantification, data efficiency, and robust generalization. However, exact inference is often intractable, and scalable approximations may remain computationally expensive or require restrictive modeling assumptions that degrade predictive performance. Prior-Data Fitted and in-context learning networks have recently emerged as an amortized alternative by learning to map datasets directly to predictive distributions, but existing approaches are tightly coupled to the support of the training prior and lack explicit mechanisms for adapting to new priors at test time, resulting in limited robustness under distribution shift. We introduce a multi-task in-context learning framework for amortized hierarchical Bayesian predictive inference that explicitly represents prior information as a prefix of in-context datasets. A transformer trained on sequences of prior and target tasks learns to adapt its predictions across families of priors. On a suite of evaluations with increasing difficulty, including out-of-meta-distribution heavy-tailed priors and priors with high-dimensional latent structures, our method matches oracle Bayesian predictors while being orders of magnitude faster. We further demonstrate its practical relevance on a real-world spatiotemporal temperature prediction benchmark.
****
Rethinking Efficient Graph Coarsening via a Non-Selfishness Principle
Xu Bai, Bin Lu, Kun Zhang, Shengbo Chen, Xinbing Wang, Chenghu Zhou, Meng Jin
Graph coarsening is a graph dimensionality reduction technique that aims to construct a smaller and more tractable graph while preserving the essential structural and semantic properties of the original graph. However, most existing methods rely on pair-wise similarity matching, where each node independently searches for its best partner based on global information. This selfishness matching paradigm incurs substantial computational and memory overhead.
To address this problem, we shift to a non-selfishness principle that prioritizes the collective interference of neighborhood in coarsening, and propose an effi

cient method named NOPE, which achieves linear memory consumption and near-linea
r computational complexity in the number of nodes.
Furthermore, we derive a faster variant NOPE*, which reduces O(\Delta\cdot d) in
terference evaluation to O(d) based on the local isotropy assumption, and conseq
uently alleviates the computational bottleneck for high-degree nodes. Experiment
al results show that NOPE* achieves $1.8–10\times$ speedup over NOPE and surpass
almost all baselines with 1-3 orders of magnitude acceleration. Meanwhile, lear
ning on coarsened graphs yields comparable performance to original graphs, and c
an even show superior performance over LLM-based graph reasoning owing to compac
t graph information.
The code can be available at https://github.com/dazonglian/NOPE-main.

DITRON: Distributed Multi-level Tiling Compiler for Parallel Tensor Programs
Size Zheng, Xuegui Zheng, Hanshi Sun, Qi Hou, Wenlei Bao, Shiyu Li, Haojie Duanm
u, Jin Fang, Chenli Xue, Chenhui Huang, Yuanqiang Liu, Renze Chen, Ningxin Zheng
, Dongyang Wang, Li-Wen Chang, Liqiang Lu, Yun Liang, Jidong Zhai, Xin Liu
The scaling of large language models (LLMs) is currently bottlenecked by the rig
idity of distributed programming. While high-performance libraries like CuBLAS a
nd NCCL provide optimized primitives, they lack the flexibility required for rap
idly evolving model architectures. Conversely, existing tensor compilers fail to
address the complex memory hierarchy of distributed clusters effectively. To br
idge this gap, we propose DITRON, a scalable tile-level compiler that democratiz
es high-performance distributed kernel development. DITRON introduces a novel hi
erarchical programming abstraction spanning Core, Device, and Task levels to map
tensor programs efficiently onto heterogeneous distributed hardware. This abstr
action allows DITRON to support diverse parallelism strategies while abstracting
away the complexity of inter-node and intra-node communication. Evaluated acros
s large-scale clusters, DITRON achieves performance parity with or exceeding exp
ert-tuned CUDA libraries, delivering speedups of 6%–30% on isolated kernels and
5%–30% on end-to-end inference in vLLM. Furthermore, DITRON demonstrates strong
portability, achieving significant speedups on both NVIDIA and AMD platforms.

Temporal Score Rescaling for Temperature Sampling in Diffusion and Flow Models
Yanbo Xu, Yu Wu, Sungjae Park, Zhizhuo Zhou, Shubham Tulsiani
We present a mechanism to steer the sampling diversity of denoising diffusion an
d flow matching models, allowing users to sample from a sharper or broader distr
ibution than the training distribution. We build on the observation that these m
odels leverage (learned) score functions of noisy data distributions for samplin
g and show that rescaling these allows one to effectively control a 'local' samp
ling temperature. Notably, this approach does not require any finetuning or alte
rations to training strategy, and can be applied to any off-the-shelf model and
is compatible with both deterministic and stochastic samplers. We first validate
our framework on toy 2D data, and then demonstrate its application for diffusio
n models trained across five disparate tasks -- image generation, pose estimatio
n, depth prediction, robot manipulation, and protein design. We find that across
these tasks, our approach allows sampling from sharper (or flatter) distributio
ns, yielding performance gains e.g., depth prediction models benefit from sampli
ng more likely depth estimates, whereas image generation models perform better w
hen sampling a slightly flatter distribution.
****

Conversation for Non-verifiable Learning: Self-Evolving Large Language Models th
rough Meta-Evaluation
Yuan Sui, Bryan Hooi
Training large language models (LLMs) for non-verifiable tasks—such as creative
writing, dialogue, and ethical reasoning—remains challenging due to the absence
of ground-truth labels. While LLM-as-Judge approaches offer a scalable alternati
ve to human feedback, they face a fundamental limitation: performance is constra
ined by the evaluator's own quality. If the judge cannot recognize good solution
s, it cannot provide useful training signals, and evaluation biases (e.g., favor
ing verbosity over quality) remain unaddressed. This motivates meta-evaluation—t

he ability to evaluate and improve the evaluator itself. We introduce CoNL, a fr amework that unifies generation, evaluation, and meta-evaluation through multi-a gent self-play. Our key insight: critique quality can be measured by whether it helps others improve their solutions. In CoNL, multiple agents sharing the same policy engage in structured conversations to propose, critique, and revise solut ions. Critiques that enable other agents' solution improvements earn a diagnosti c reward, creating explicit supervision for meta-evaluation and enabling joint o ptimization of generation and judging capabilities through self-play, without ex ternal judges or ground truth. Experiments on various benchmarks show that CoNL achieves consistent improvements over self-rewarding baselines while maintaining stable training.

Rethinking Visual Intelligence: Insights from Video Pretraining

Pablo Acuaviva, Aram Davtyan, Mariam Hassan, Sebastian Stapf, Ahmad Rahimi, Alex andre Alahi, Paolo Favaro

Large language models (LLMs) have demonstrated that large-scale pretraining enab les systems to adapt rapidly to new problems with little supervision in the lang uage domain. This success, however, has not translated as effectively to the vis ual domain, where models, including LLMs, continue to struggle with compositiona l understanding, sample efficiency, and general-purpose problem-solving. We inve stigate Video Diffusion Models (VDMs) as a promising direction for bridging this gap. Pretraining on spatiotemporal data endows these models with strong inducti ve biases for structure and dynamics, which we hypothesize can support broad tas k adaptability. To test this, we design a controlled evaluation in which both a pretrained LLM and a pretrained VDM are equipped with lightweight adapters and p resented with tasks in their natural modalities. Across benchmarks including ARC -AGI, ConceptARC, visual games, route planning, and cellular automata, VDMs demo nstrate higher data efficiency than their language counterparts. Taken together, our results indicate that video pretraining offers inductive biases that suppor t progress toward visual foundation models.

****

Unlocking Noise-Resistant Vision: Key Architectural Secrets for Robust Models Ag ainst Gaussian Noise

Bum Jun Kim, Makoto Kawano, Yusuke Iwasawa, Yutaka Matsuo

We investigate which architectural and input-pipeline choices make vision models more robust to additive Gaussian noise and convert these empirical insights int o simple, actionable design rules. Specifically, we performed extensive evaluati ons on 1,174 pretrained vision models, empirically identifying four consistent f actors for improved robustness against Gaussian noise: larger stem kernels, reso lution-dependent downsampling under a pre-resize sensor-noise protocol, average pooling, and supervised vision transformers (ViTs) rather than CLIP ViTs, which yield up to 506 rank improvements and 21.6\%p accuracy gains. First, we prove th at low-pass stem kernels attenuate noise with a gain that decreases quadraticall y with kernel size and that anti-aliased downsampling reduces noise energy rough ly in proportion to the square of the downsampling factor. Second, we demonstrat e that average pooling is unbiased and suppresses noise in proportion to the poo ling window area, whereas max pooling incurs a positive bias that grows slowly w ith window size and yields a relatively higher mean-squared error and greater wo rst-case sensitivity. Third, we reveal and explain the vulnerability of CLIP ViT s via a pixel-space Lipschitz bound: The smaller normalization standard deviatio ns used in CLIP preprocessing amplify worst-case sensitivity by up to 1.91 times relative to the Inception-style preprocessing common in supervised ViTs. Our re sults collectively disentangle robustness into interpretable modules, provide a theory that explains the observed trends, and build practical, plug-and-play gui delines for designing vision models more robust against Gaussian noise.

****

MMKU-Bench: A Multimodal Update Benchmark for Diverse Visual Knowledge

Baochen Fu, Yuntao Du, Cheng Chang, Baihao Jin, Wenzhi Deng, Muhao Xu, Hongmei Y an, Weiye Song, Yi Wan

As real-world knowledge continues to evolve, the parametric knowledge acquired b

y multimodal models during pretraining becomes increasingly difficult to remain consistent with real-world knowledge. Existing research on multimodal knowledge updating focuses only on learning previously unknown knowledge, while overlooking the need to update knowledge that the model has already mastered but that later changes; moreover, evaluation is limited to the same modality, lacking a systematic analysis of cross-modal consistency. To address these issues, this paper proposes MMKU-Bench, a comprehensive evaluation benchmark for multimodal knowledge updating, which contains over 25k knowledge instances and more than 49k images, covering two scenarios, updated knowledge and unknown knowledge, thereby enabling comparative analysis of learning across different knowledge types. On this benchmark, we evaluate a variety of representative approaches, including supervised fine-tuning (SFT), reinforcement learning from human feedback (RLHF), and knowledge editing (KE). Experimental results show that SFT and RLHF are prone to catastrophic forgetting, while KE better preserve general capabilities but exhibit clear limitations in continual updating. Overall, MMKU-Bench provides a reliable and comprehensive evaluation benchmark for multimodal knowledge updating, advancing progress in this field. The code and dataset are available at https://github.com/baochenfu/MMKU-Bench.

WEVSR: Video Diffusion Generators for Real-World Video Super■Resolution with Wavelet-Enhanced VAE Encoder

Yuying Chen, Zhirui Liu, Linyan Jiang, Qifan Gao, Xianguo Zhang, Jianhou Gan, Wenqi Ren

Recent advances in video diffusion models have demonstrated remarkable generative capability, yet adapting these large pretrained text-to-video (T2V) models to video super■resolution (VSR) typically encounters challenges, such as artifacts introduced by complex degradations in real-world scenarios and compromised fidelity due to the strong generative capacity of the powerful T2V models. We present WEVSR, a novel approach that adapts a pretrained flow-matching video diffusion transformer to VSR. First, we design a task-oriented adaptation strategy that leverages timestep sampling and noise augmentation to enhance detail restoration while preserving structural stability. Second, we propose a lightweight multi-level discrete wavelet transform (DWT) front-end for the VAE encoder, injecting explicit frequency priors into the latent space without modifying the pretrained decoder. Extensive experiments across multiple VSR benchmarks demonstrate that WEVSR achieves state-of-the-art performance against existing approaches. Code and models will be released here.

Hyperbolic neural population geometry benefits computation

Dennis Wu, Yi-Chun Hung, Braden Yuille, James E Fitzgerald, Han Liu

Neural population geometry shapes downstream
computation. Recent empirical findings in neurobiology suggest that a hyperbolic structure underlies population activity in the hippocampus. Here
we provide a theoretical framework for this phenomenon. First, we propose a plausible construction of hippocampal tuning curves that statistically induces hyperbolic geometry. Next, we establish a connection between neural decoding and associative memory by demonstrating that the Modern Hopfield Network update rule computes the
minimum mean-squared-error (MMSE) estimator.
Finally, we introduce a novel associative memory
model defined in hyperbolic space that yields significantly larger capacity than leading models. Our
results suggest that animals encode spatial information as a latent hyperbolic cognitive map, improving both memory capacity and decoding accuracy.

****

Deep Ensemble Clustering for Visual Representation Learning

Yuwei Wang, Guikun Chen, Xiruo Jiang, Yazhou Yao, Di Liu, Xiangbo Shu, Fumin Shen, Wenguan Wang

Recent advances in visual representation learning have seen the rise of clustering-based vision backbones, which adopt clustering as a core paradigm for feature

extraction. However, existing clustering-based backbones typically rely on a single clustering algorithm, whose inherent inductive bias limits their representational capacity. To address this, we propose EnFormer, which embeds ensemble clustering as a core component of feature extraction. EnFormer structures feature extraction around two steps: (i) Ensemble Generation, where several differentiable base clustering methods are introduced to capture diverse semantic structures; and (ii) Consensus Aggregation, which employs a differentiable mechanism to fuse the results of all base clusterings to reconstruct refined visual features. Extensive experiments show that EnFormer consistently outperforms existing clustering-based backbones across core vision tasks, with higher performance and significantly improved throughput.

****

CodeChemist: Test-Time Scaling for Low-Resource Code Generation via Functional Knowledge Transfer

KaiXin Wang, Tianlin Li, Xiaoyu Zhang, Aishan Liu, Xianglong Liu, Ziqi Liu, Zhiqiang Zhang, JUN ZHOU, Bin Shi

Code Large Language Models (CodeLLMs) have been widely adopted for Natural Language to Programming Language code generation, powering applications with large user bases. Their performance, however, varies sharply across programming languages (PLs) and is particularly suboptimal for low-resource PLs due to data scarcity, limiting their overall usability. In this work, we introduce CodeChemist, a simple yet effective, training-free test-time scaling framework that transfers the model's functional knowledge from high-resource to low-resource PLs via synthesized test cases, without relying on external models. Specifically, CodeChemist first applies multi-temperature hedged sampling to generate a pool of candidate solutions in the low-resource PL and synthesizes a set of test inputs.

It then estimates uncertainty: when uncertainty is low, it selects the output via in-language majority voting; otherwise, it constructs cross-lingual I/O test oracles by executing high-resource reference programs and selects the candidate with the highest pass rate.

Extensive experiments demonstrate that CodeChemist significantly outperforms existing test-time scaling methods, improving code generation for both low-resource PLs (e.g., Lua) and complex-syntax PLs (e.g., C++, Java) without retraining.

When Shared Knowledge Hurts: Spectral Over-Accumulation in Model Merging

Yayuan Li, Ze Peng, Jian Zhang, Jintao Guo, Yue Duan, Yinghuan Shi

Model merging combines multiple fine-tuned models into a single model by $\texit{adding}$ their weight updates, providing a lightweight alternative to retraining. Existing methods primarily target resolving conflicts between task updates, leaving the failure mode of over-counting shared knowledge unaddressed. We show that when tasks share aligned spectral directions (i.e., overlapping singular vectors), a simple linear combination repeatedly accumulates these directions, inflating the singular values and biasing the merged model toward shared subspaces. To mitigate this issue, we propose Singular Value Calibration (SVC), a training-free and data-free post-processing method that quantifies subspace overlap and rescales inflated singular values to restore a balanced spectrum. Across vision and language benchmarks, SVC consistently improves strong merging baselines and achieves state-of-the-art performance. Furthermore, by modifying only the singular values, SVC improves the performance of Task Arithmetic by 13.0\%. Code is available at https://github.com/lyymuwu/SVC.

Finding the Correct Visual Evidence Without Forgetting: Mitigating Hallucination in LVLMs via Inter-Layer Visual Attention Discrepancy

Yutong Xie, Zhenglin Hua, Ran Wang, Wing W. Y. Ng, Xizhao Wang, Yuheng Jia

Large Vision-Language Models (LVLMs) have shown remarkable performance on a wide range of vision-language tasks. Despite this progress, they are still prone to hallucination, generating responses that are inconsistent with visual content. In this work, we find that LVLMs tend to hallucinate when they pay insufficient attention to the correct visual evidence and gradually forget it during the generation process. We empirically find that although LVLMs overall attend insufficie

ntly to visual evidence, they exhibit sensitivity to the correct visual evidence in specific layers, with notable inter-layer discrepancy. Motivated by this observation, we propose a novel hallucination mitigation method that enhances visual evidence based on **I**nter-**L**ayer **V**isual **A**ttention **D**iscrepancy (**ILVAD**). Specifically, we obtain the attention weights from early generated tokens to visual tokens across layers and identify the tokens that are repeatedly activated as visual evidence, forming a saliency map. We then enhance attention to visual evidence during generation through the saliency map to reduce visual forgetting. In addition, we leverage the saliency map to obtain attention scores of generated text to visual evidence, in order to select and emphasize text tokens that are strongly grounded in visual evidence. Our method is training-free and plug-and-play. Multiple benchmark evaluations conducted on five recently released models show that our method can consistently mitigate hallucinations in different LVLMs over various architectures. Code is available at https://github.com/ytx-ML/ILVAD.
****

One-step Latent-free Image Generation with Pixel Mean Flows
Yiyang Lu, Susie Lu, Qiao Sun, Hanhong Zhao, Zhicheng Jiang, Xianbang Wang, Tianhong Li, Zhengyang Geng, Kaiming He
Modern diffusion/flow-based models for image generation typically exhibit two core characteristics: (i) using multi-step sampling, and (ii) operating in a latent space. Recent advances have made encouraging progress on each aspect individually, paving the way toward one-step diffusion/flow without latents. In this work, we take a further step towards this goal and propose "pixel MeanFlow" (pMF). Our core guideline is to formulate the network output space and the loss space separately. The network target is designed to be on a presumed low-dimensional image manifold (i.e., x-prediction), while the loss is defined via MeanFlow in the velocity space. We introduce a simple transformation between the image manifold and the average velocity field. In experiments, pMF achieves strong results for one-step latent-free generation on ImageNet at 256$\times$256 resolution (2.22 FID) and 512$\times$512 resolution (2.48 FID), filling a key missing piece in this regime. We hope that our study will further advance the boundaries of diffusion/flow-based generative models.

EffGen: Enabling Small Language Models as Capable Autonomous Agents
Gaurav Srivastava, Aafiya Hussain, Chi Wang, Yingyan Celine Lin, Xuan Wang
Most existing language model agentic systems today are built and optimized for large language models (e.g., GPT, Claude, Gemini) via API calls; while powerful, this approach faces several limitations including high token costs and privacy concerns for sensitive applications. We introduce **EffGen**, an open-source agentic framework optimized for small language models (SLMs) that enables effective, efficient, and secure local deployment. EffGen makes four major contributions: **(1) Enhanced tool-calling** with prompt optimization that compresses input prompts by up to 70-80% (and 57% on average across our benchmarks) while preserving task semantics, **(2) Intelligent task decomposition** that breaks complex queries into parallel or sequential subtasks based on dependencies, **(3) Complexity-based routing** using five factors to make smart pre-execution decisions, and **(4) Unified memory system** combining short-term, long-term, and vector-based storage. Additionally, EffGen unifies multiple agent protocols (MCP, A2A, ACP) for cross-protocol communication. Results on 13 benchmarks show EffGen outperforms LangChain, AutoGen, and Smolagents with **higher success rates**, **faster execution**, and **lower memory**. Our results reveal that **prompt optimization and complexity routing have complementary scaling behavior**: optimization benefits SLMs more (11.2% gain at 1.5B vs 2.4% at 32B), while routing benefits large models more (3.6% at 1.5B vs 7.9% at 32B), providing consistent gains across all scales when combined. EffGen is open-source under the Apache 2.0 License, with the code available at https://github.com/ctrl-gaurav/effGen, the Python package at https://pypi.org/project/effgen/ (`pip install effgen`), and the project website and documentation at https://effgen.org/ and https://docs.effgen.org/.

One Tool Is Enough: Reinforcement Learning of LLM Agents for Repository-Level Co
de Navigation
Zhaoxi Zhang, Yitong Duan, Yanzhi Zhang, Yiming Xu, Zhixiang Wang, Kun Liang, We
ikang Li, Jiahui Liang, Deguo Xia, Jizhou Huang, Jiyan He, Shuxin Zheng, Yunfang
 Wu
Locating files and functions requiring modification in large software repositori
es is challenging due to their scale and structural complexity. Existing LLM-bas
ed methods typically treat this as a repository-level retrieval task and rely on
 multiple auxiliary tools, which often overlook code execution logic and complic
ate model control. We propose RepoNavigator, an LLM agent equipped with a single
 execution-aware tool: jumping to the definition of an invoked symbol. This unif
ied design reflects the actual flow of code execution while simplifying tool man
ipulation. RepoNavigator is trained end-to-end via Reinforcement Learning (RL) d
irectly from a base pretrained model, without relying on closed-source distillat
ion. Experiments demonstrate that RL-trained RepoNavigator achieves state-of-the
-art performance, with the 7B model outperforming 14B baselines, the 14B model s
urpassing 32B competitors, and the 32B model exceeding closed-source models such
 as GPT-5 on most metrics. These results confirm that integrating a single, stru
cturally grounded tool with RL training provides an efficient and scalable solut
ion for repository-level issue localization.

MMD Guidance: Training-Free Distribution Adaptation for Diffusion Models via Max
imum Mean Discrepancy Guidance
Matina Mahdizadeh Sani, Nima Jamali, Mohammad Jalali, Farzan Farnia
Pre-trained diffusion models have emerged as powerful generative priors for both
 unconditional and conditional sample generation, yet their outputs often deviat
e from the characteristics of user-specific target data. Such mismatches are esp
ecially problematic in domain adaptation tasks, where only a few reference examp
les are available and retraining the diffusion model is infeasible. Existing inf
erence-time guidance methods can adjust sampling trajectories, but they typicall
y optimize surrogate objectives such as classifier likelihoods rather than direc
tly aligning with the target distribution. We propose *MMD Guidance*, a training
-free mechanism that augments the reverse diffusion process with gradients of th
e *Maximum Mean Discrepancy (MMD)* between generated samples and a reference dat
aset. MMD provides reliable distributional estimates from limited data, exhibits
 low variance in practice, and is efficiently differentiable, which makes it par
ticularly well-suited for the guidance task. Our framework naturally extends to
prompt-aware adaptation in conditional generation models via product kernels. Al
so, it can be applied with computational efficiency in latent diffusion models (
LDMs), since guidance is applied in the latent space of the LDM. Experiments on
synthetic and real-world benchmarks demonstrate that MMD Guidance can achieve di
stributional alignment while preserving sample fidelity. The project code is ava
ilable at [https://github.com/matinamehdizadeh/MMD-Guidance](https://github.com/
matinamehdizadeh/MMD-Guidance).

Semi-LAR: Semi-supervised Contrastive Learning with Linear Attention for Removal
 of Nighttime Flares
Xiyu Zhu, Wei Wang, Kui Jiang, Zhengguo Li
Lens flare removal is challenging due to the large spatial extent of flare artif
acts and their entangle-ment with scene structures, while existing meth-ods heav
ily rely on large-scale paired data. We propose a semi-supervised flare removal
frame-work that enables stable learning from unlabeled images by jointly address
ing pseudo-label relia-bility and representation discrimination. We pro-pose an
adaptive pseudo-label repository that pro-gressively refines pseudo supervision
through no-reference quality assessment, momentum-based updates, and invalid lab
el filtering, effectively mit-igating error accumulation. Moreover, we pro-pose
a flare-aware contrastive loss that explic-itly treats flare-contaminated inputs
 as negatives and performs patch-level contrastive learning, en-couraging repres
entations that are discriminative against flare patterns while remaining consist
ent with reliable pseudo targets. Extensive experi-ments on multiple flare bench

marks demonstrate that the proposed framework is model-agnostic and consistently improves performance and ro-bustness.

FUSE: Quantifying Uncertainty in Vision-Language Models by Bayesian Fusing Epistemic and Aleatoric Uncertainty
Harry Zhang, Luca Carlone
Multimodal large language models (MLLMs) are playing an increasingly important role across multiple domains.
In many applications, such as robotics, it is crucial to quantify the uncertainty in the output of these models. }
We develop Fused Uncertainty with Semantic Evidence (FUSE), a probabilistic framework for capturing two complementary sources of uncertainty in multimodal language modeling: (i) aleatoric embedding-level uncertainty derived from input data vision-language ambiguity, and (ii) epistemic model-level uncertainty estimated from the semantic response diversity of MLLMs.
Our approach formulates a Bayesian fusion mechanism that analytically combines these uncertainty sources to produce a scalar measure of uncertainty. This measure serves as a novel uncertainty representation for downstream applications of MLLMs and provides a principled foundation for uncertainty calibration in multimodal systems, improving reliability and downstream performance in MLLM-based reasoning and vision-language tasks. We demonstrate that our method outperforms baselines in providing
uncertainty estimates and achieves state-of-the-art uncertainty calibration.

Relational Structural Causal Models
Adiba Ejaz, Elias Bareinboim
An artificial intelligence must have a model of its environment that is *causal*, supporting reasoning about interventions and counterfactuals, and also *combinatorial*, supporting generalization to unseen combinations of objects.
In this work, we formally study when and how such a model can be learned.
We develop *relational structural causal models*, extending structural causal models (Pearl 2009) to settings where objects and their relations vary.
First, we show how answers to not only causal but also observational queries about unseen combinations of objects can not be identified without further assumptions.
To enable such identification---including in the presence of unobserved confounding---we define *relational causal graphs* and derive symbolic identification criteria.
Finally, we propose *relational neural causal models*, a provably correct approach that outperforms non-relational baselines on simulated traffic scenes with varying cars, signals, and pedestrians.

Spik4lite: Refactoring Neuromorphic Sparsity for Efficient Spiking Neural Networks on Commodity Edge Devices
Yongzhi She, Qihua Zhou, Yuhao Wang, Yaodong Huang, Laizhong Cui, Jingcai Guo
Recently, the spiking neural networks (SNNs) have shown great promise in enhancing AI task performance by utilizing the brain-inspired and energy-efficient computational paradigm via the binary (0/1) spikes. Modern SNNs, especially those based on transformers, often require FPGA accelerators or neuromorphic chips to enable spike-driven computations. However, this domain-specific hardware is not always accessible on commodity edge devices like NVIDIA Jetsons, which may degrade SNNs' energy efficiency due to massive computational waste on inactive "0" spikes and finally undermine the usage boundary. This limitation raises an interesting question: is it possible to make SNNs edge-friendly and tame the computations mostly on active "1" spikes? We present the answer yes and propose Spik4lite, which serves as a lightweight plug-and-play module to significantly improve SNN's performance between model accuracy and computational efficiency. The key is to refactor SNN's channel-wise neuromorphic sparsity by zeroing out low-efficiency channels while proactively compensating for the eliminated spikes. Different from prior methods mainly focusing on optimizing the theoretical synaptic operation

s, our design philosophy can evolve the SNNs into a physically compact manner, t
hus inherently saving more computational and energy costs. Extensive experiments
 based on real edge devices show that Spik4lite can be integrated into existing
SNN baselines to further improve their accuracy-and-efficiency performance, guar
anteeing the model accuracy while saving the computational and energy costs.

MultiBreak: A Scalable and Diverse Multi-turn Jailbreak Benchmark for Evaluating
 LLM Safety

Jialin Song, Xiaodong Liu, Weiwei Yang, Wuyang Chen, Mingqian Feng, Xuekai Zhu,
Jianfeng Gao

We present MultiBreak, a scalable and diverse multi-turn jailbreak benchmark to
evaluate large language model (LLM) safety. Multi-turn jailbreaks mimic natural
conversational settings, making them easier to bypass safety-aligned LLM than si
ngle-turn jailbreaks. Existing multi-turn benchmarks are limited in size or rely
 heavily on templates, which restrict their diversity.

To address this gap, we unify a wide range of harmful jailbreak intents, and int
roduce an active learning pipeline for expanding high-quality multi-turn adversa
rial prompts, where a generator is iteratively fine-tuned to produce stronger at
tack candidates, guided by uncertainty-based refinement. Our MultiBreak includes
 10,389 multi-turn adversarial prompts, spans 2,665 distinct harmful intents, an
d covers the most diverse set of topics to date. Empirical evaluation shows that
 our benchmark achieves up to a 54.0% and 34.6% higher attack success rate (ASR)
 than the second-best dataset on DeepSeek-R1-7B and GPT-4.1-mini, respectively.

More importantly, safety evaluations suggest that diverse attack categories unco
ver fine-grained LLM vulnerabilities, and categories that appear benign under si
ngle-turn can exhibit substantially higher adversarial effectiveness in multi-tu
rn scenarios.

These findings highlight persistent vulnerabilities of LLMs under realistic adve
rsarial settings and establish MultiBreak as a scalable resource for advancing L
LM safety.

MapUQ: Map with Uncertainty Quantification for Robust BEV Vectorized Constructi
on

Shaoyuan Mo, Qi Ma, leng rui, Bohan Li, Ke Wang

End-to-end online map generation is a core component of autonomous driving perce
ption systems. However, in complex traffic scenes, Bird’s-Eye-View (BEV) with ve
ctorized mapping suffers from limitations such as target misclassification, spat
ial localization drift, and ambiguous semantic segmentation. Introducing uncerta
inty quantification can alleviate these problems, so we propose MapUQ, a robust
BEV vectorized mapping method guided by uncertainty-aware optimization. Specific
ally, we quantify uncertainty at the feature level to enhance semantic perceptio
n, apply an error-driven dynamic receptive field adaptation mechanism at the dec
oding stage to enforce geometric consistency, and leverage negative sample infor
mation at the output head to improve lane classification accuracy. Experimental
results on the nuScenes and Argoverse 2 datasets show that our method outperform
s prior approaches in AP across three road types, achieving an average improveme
nt of 1.5% over the baseline with marginal computational overhead. In addition,
our method surpasses the baseline on uncertainty metrics such as ECE and NLL, si
gnificantly improving robustness and mapping accuracy in complex scenarios. Our
code has been released at github: https://anonymous.4open.science/r/MapUQ-D287.

The Geometry of Reasoning: Self-Evaluation via Layerwise Trajectory Evolution

Jinhe Bi, Danqi Yan, Yifan Wang, Wenke Huang, Haokun Chen, Guancheng Wan, Mang Y
e, Xun Xiao, Hinrich Schuetze, Volker Tresp, Yunpu Ma

Large Reasoning Models (LRMs) enhance performance by generating explicit Chain-o
f-Thought (CoT) trajectories, yet enabling them to self-evaluate correctness wit
hout external supervision remains a critical challenge. Existing methods often r
ely on ground-truth labels or shallow output probabilities, neglecting the layer
wise evolution of the reasoning trajectory. In this work, we introduce GeoR (Geo
metry of Reasoning), a white-box self-evaluation framework based on layerwise tr

ajectory evolution. GeoR decomposes reasoning fidelity into two complementary di
mensions: (1) Geometric Evolution, which synthesizes the first- and second-order
 evolution of layerwise hidden-state trajectories to quantify geometric progress
 in reasoning; and (2) Difficulty-Aware Calibration, which utilizes cross-entrop
y of reasoning progress to normalize the Geometric Evolution against intrinsic q
uery uncertainty. By jointly modeling these factors, GeoR effectively distinguis
hes the coherent evolution of correct reasoning from the chaotic trajectories of
 errors. Extensive experiments across eight LRMs and seven benchmarks demonstrat
e that GeoR consistently outperforms state-of-the-art baselines in AUROC, AUPR,
and FPR@95.

WorldComp2D: Spatio-semantic Representations of Object Identity and Location fro
m Local Views

Seongmin Jin, Doo Seok Jeong

Learning latent representations that capture both semantic and spatial informati
on is central to efficient spatio-semantic reasoning. However, many existing app
roaches rely on implicit latent structures combined with dense feature maps or t
ask-specific heads, limiting computational efficiency and flexibility.
We propose WorldComp2D, a novel lightweight representation learning framework th
at explicitly structures latent space geometry according to object identity and
spatial proximity using multiscale \textit{local} receptive fields. This framewo
rk consists of (i) a proximity-dependent encoder that maps a given observation i
nto a spatio-semantic latent space and (ii) a localizer that infers the coordina
tes of objects in the input from the resulting spatio-semantic representation.
Using facial landmark localization as a proof-of-concept, we show that, compared
 to SoTA lightweight models, WorldComp2D reduces the numbers of parameters and F
LOPs by up to $4.0\times$ and $2.2\times$, respectively, while maintaining real-
time performance on CPU. These results demonstrate that explicitly structured la
tent spaces provide an efficient and general foundation for spatio-semantic reas
oning. This framework is open-sourced at https://github.com/JinSeongmin/WorldCom
p2D.

TVDRNet: Text-driven Viewpoint Optimization via Differentiable Rendering for 3D
Reasoning Segmentation

Zaiyang Yu, Changshuo Wang, Pinjie Xu, Zhang Huang, Yuan Shi, Linjun Sun, Weijun
 Li

Three-dimensional (3D) reasoning segmentation aims at segmenting target objects
based on text instructions and 3D spatial cues. Recent efforts in 3D reasoning l
everage Multimodal Large Language Models (MLLMs) to bridge the gap between text
and 3D data. However, since MLLMs are primarily trained on text-image pairs, dir
ectly adapting them to unstructured 3D point clouds often fails to capture impli
cit semantic intent and reliably localize objects. This paper introduces TVDRNet
 to address these challenges. Inspired by Active Vision theory, where humans sel
ectively choose optimal viewpoints to better observe targets, TVDRNet employs a
differentiable renderer to simulate this active process in 3D perception. By usi
ng text instructions as supervision to optimize intrinsic and extrinsic renderin
g parameters, the TVDRNet identifies the optimal viewpoints for observing the 3D
 scene, and therefore learning 'where to look' based on what the text instructio
n 'asked to find'. This process generates informative, task-relevant 2D images t
hat are compatible with MLLMs. TVDRNet comprises: (1) the AVPL module, establish
ing a learnable mapping from semantics to optimal rendering parameters; and (2)
the MGL module, fusing multi-modalities via semantic grouping to guide mask gene
ration. Experiments show TVDRNet achieves the state-of-the-art performance in 3D
 reasoning segmentation (Reason3D, Instruct3D) and 3D visual grounding (ScanRefe
r) benchmarks.

Approximation of Log-Partition Function in Policy Mirror Descent Induces Implici
t Regularization for LLM Post-Training

Zhenghao Xu, Qin Lu, Changlong Yu, Tuo Zhao

Policy mirror descent (PMD) provides a principled framework for reinforcement le

arning (RL) by iteratively solving KL-regularized policy improvement subproblems . While this approach has been adopted in training advanced LLMs such as Kimi K1 .5/K2, the ideal closed-form PMD updates require reliable partition function est imation, a significant challenge when working with limited rollouts in the vast action spaces of LLMs. We investigate a practical algorithm, termed PMD-mean, th at approximates the log-partition term with the mean reward under the sampling p olicy and performs regression in log-policy space. Specifically, we characterize the population solution of PMD-mean and demonstrate that it implicitly optimize s mirror descent subproblems with an adaptive mixed KL--χ^2 regularizer. Th is additional χ^2 regularization constrains large probability changes, prod ucing more conservative updates when expected rewards are low and enhancing robu stness against finite-sample estimation errors. Experiments on math reasoning ta sks show that PMD-mean improves stability and remains competitive in the stale-r ollout settings while enabling higher throughput through larger rollout batches. These findings deepen our understanding of PMD-mean and illuminate pathways tow ard principled improvements in RL algorithms for LLMs.
Code is available at https://github.com/horizon-llm/OpenKimi.

Scaling depth capacity via zero/one-layer model expansion
Zhiqi Bu
Model depth is a double-edged sword in deep learning: deeper models achieve high er accuracy but require higher computational cost. To efficiently train models a t scale, progressive training (also known as model expansion) scales up model ca pacity during training and significantly reduces computation with little perform ance degradation.
In this work, we study the depth expansion of large-scale models through the len s of optimization theory and feature learning, offering insights on the initiali zation of new layers, hyperparameter transfer, learning rate schedule, and timin g of model expansion. Specifically, we propose zero/one-layer progressive traini ng to achieve an optimal tradeoff between computation and loss, with a comprehen sive ablations on our expansion strategy. For example, zero/one-layer progressiv e training on GPT2 can save $\approx 80\%$ compute, or equivalently achieve an $ \approx 5\times$ acceleration, while attaining a loss comparable to that of a fu lly trained 60-layer model with 7B parameters, thus demonstrating a mixing behav ior in terms of loss. Furthermore, scaling laws on LLAMA3 and DeepSeekV3 models show a $3\sim 5\times$ improvement in compute efficiency, with an increasing adv antage at larger scales.

CausalGame: Benchmarking Causal Thinking of LLM Agents in Games
Zhenhao Chen, Yongqiang Chen, Chenxi Liu, Junchi Yu, Xiangchen Song, Zijian Li, Jialin Li, Philip Torr, Bo Han, Kun Zhang
Recently, it has received growing attention in building AI Scientist agents with Large Language Models (LLMs). Since scientific discovery fundamentally relies o n uncovering causal relationships from observations, the capability of causal th inking that distinguish causation from correlation and hidden biases, is essenti al to LLM agents. Despite a number of existing benchmarks for AI scientists, the y do not explicitly incorporate challenges from hidden confounders, selection bi as, and noisy measurements that widely exist in real-world scientific discovery. To this end, we present CausalGame, a benchmark that evaluates the causal think ing capabilities of LLM agents through interactive games. More specifically, we ask LLM agents to actively design experimental protocols, collect observation da ta and derive a final solution with an explanation report. To emulate realistic scientific discovery challenges, we design 14 game settings with the incorporati on of selection bias, noisy measurements, and hidden confounders. The results wi th 29 frontier LLM agents show that they consistently fail to reason about and r ecover the underlying causal relationships required to solve the games. CausalGa me provides a controlled testbed for evaluating causal thinking of AI Scientist agents. The project is available at causalgame.github.io .

MetaMoE: Diversity-Aware Proxy Selection for Privacy-Preserving Mixture-of-Exper

ts Unification
Weisen Jiang, Shuhao Chen, Sinno Jialin Pan
Mixture-of-Experts (MoE) models scale capacity by combining specialized experts, but most existing approaches assume centralized access to training data. In practice, data are distributed across clients and cannot be shared due to privacy constraints, making unified MoE training challenging. We propose **MetaMoE**, a privacy-preserving framework that unifies independently trained, domain-specialized experts into a single MoE using public proxy data as surrogates for inaccessible private data.

Central to MetaMoE is diversity-aware proxy selection, which selects client-domain–relevant and diverse samples from public data to effectively approximate private data distributions and supervise router learning.

These proxies are further used to align expert training, improving expert coordination at unification time, while a context-aware router enhances expert selection across heterogeneous inputs.

Experiments on computer vision and natural language processing benchmarks demonstrate that MetaMoE consistently outperforms recent privacy-preserving MoE unification methods.
Code is available at https://github.com/ws-jiang/MetaMoE.

LightWM: Training-Free Hierarchical Working Memory for Small Language Model Agents
Ziyi Wang, Haonan Jin, Zian Wang, Wendong Wang, Lanshan Zhang
Small language models (SLMs) are attractive for low-cost agent deployment, and their growing capabilities make them promising for procedure-centric workloads that repeatedly execute specialized task families with similar workflows.
However, SLM agents still struggle in long-horizon interaction because limited context budgets make it difficult to reliably retain and reuse decision-relevant state across many steps.
Existing working-memory methods attempt to mitigate context growth, but their reliance on unstructured natural-language summarization can discard critical facts, introduce state drift, and compound errors in SLM execution.
We present LightWM, a training-free hierarchical working-memory framework that decomposes procedure-centric tasks into subgoals and organizes memory into task-level global memory and subtask-level local memory, where local memory directly conditions SLM action selection and is updated from new observations through structured updates.
To instantiate such memories without training, a one-time offline LLM-based induction pipeline builds reusable schemas per task family from a few successful traces, requiring no SLM parameter updates or online LLM calls.
On ALFWorld valid_unseen, Qwen3-4B reaches 0.910 success, whereas representative prompting and prior working-memory baselines under the same setting remain below 0.320.
****
Semantic Cache Distillation: Efficient State Transfer via Reuse and Selective Patching
Qianli Ma, Zhiqing Tang, Hanshuai Cui, Zhi Yao, Weijia Jia
Disaggregated serving alleviates memory bottlenecks in Large Language Model (LLM) inference but creates a severe communication bottleneck: transmitting high-dimensional Key-Value (KV) caches often dominates time-to-first-token (TTFT). Moreover, reusing caches across heterogeneous models (e.g., base and fine-tuned variants) causes semantic misalignment that accumulates over layers, degrading generation quality. We propose Semantic Cache Distillation (SCD), a loss-constrained framework that replaces raw KV transmission with compact semantic codes. SCD addresses these challenges via two mechanisms: (1) Reuse, which reconstructs most layers from low-rank subspaces to minimize transfer cost, and (2) Patch, which predicts normalized inputs at sparse transition layers to truncate error propagation. Empirically, SCD delivers up to 2.65 $\times$ TTFT speedup over the oracle consumer prefill and dominates quantization and selective recomputation baselines on the quality--latency Pareto frontier in bandwidth-constrained regimes, while

keeping generation quality within 5\% F1 of the oracle.
****

Controlled Dynamics Attractor Transformer
Cheng Zhang, Minnan Luo, Zesheng Yang, MING LI, Yong-Jin Liu, Qinghua Zheng
Transformer architectures have dramatically advanced representation learning and inference in deep models through self-attention mechanisms. In parallel, associative memory frameworks map representations onto energy landscapes, offering interpretable retrieval mechanisms. However, their continuous-time inference dynamics lack the biological plausibility of classical Continuous Attractor Neural Networks. To bridge this gap, we propose **Controlled Dynamics Attractor Transformer (CDAT)**, which couples a mixture von Mises–Fisher attention energy with a Hopfield refinement energy, while augmenting energy descent with a CANN-inspired excitation–inhibition modulation. CDAT instantiates a topology-constrained dynamical system whose couplings encode relational structure among tokens, thereby linking attractor-style dynamics to modern energy-based attention. We further provide a constructive dissipation analysis to formally establish their controlled inference dynamics. Benefiting from these robust and structured dynamics, CDAT achieves state-of-the-art performance across multiple benchmarks in graph anomaly detection and graph classification.
****

WorldTravel: A Realistic Multimodal Travel-Planning Benchmark with Tightly Coupled Constraints
Zexuan Wang, Chenghao Yang, Yingqi Que, Zhoufutu Wen, Zaiyuan Wang, Jiashuo Liu, Zhixin Yao, Zhenzhu Yang, Huaqing Yuan, Yiwen Wang, Zhengxuan Jiang, Shengjie Fang, Zhenhe Wu, Zhaohui Wang, JinCheng Ren, Yuzhen Li, Yang Yang, Jiaheng Liu, Jian Yang, Ge Zhang, Wenhao Huang
Real-world autonomous planning requires coordinating tightly coupled constraints where a single decision dictates the feasibility of all subsequent actions. However, existing benchmarks predominantly feature loosely coupled constraints solvable through local greedy decisions and rely on idealized data, failing to capture constraint acquisition from realistic web interfaces.
We introduce $\textbf{WorldTravel}$, a benchmark comprising 150 real-world travel scenarios across 5 cities, requiring agents to satisfy an average of 15+ interdependent temporal and logical constraints. To evaluate realistic deployment settings, we further develop $\textbf{WorldTravel-Webscape}$, a multi-modal environment with over 2,000 rendered webpages that preserve layout-dependent and information-dense travel interfaces, requiring agents to recover executable constraints from rendered web interfaces. Evaluating 10 frontier models reveals a severe performance collapse: GPT-5.2 achieves only 28.0\% feasibility in text-only settings, dropping to 3.4\% in multi-modal environments. We observe substantial degradation in planning feasibility when agents must recover executable constraints from rendered webpages, alongside a Planning Horizon threshold at approximately 10 constraints where reasoning reliability collapses. These findings suggest that realistic constraint acquisition and long-horizon planning remain complementary bottlenecks for current agents.
****

Trajectory-Aware Heuristic Learning for Combinatorial Search
Mustafa Seddiqi, Marta Kersten-Oertel, Tiberiu Popa
Learning effective value heuristics for combinatorial search is difficult, as prior methods rely on surrogate supervision or costly downstream search to assess progress. We introduce a trajectory-aware probabilistic framework that models uncertainty in cost-to-go labels instead of treating them as fixed targets. Heuristic learning is cast as inference over state trajectories using an HMM-style model, where estimated depth-change dynamics define transitions and forward-backward inference yields soft supervision. To evaluate heuristic quality without search, we propose a large-scale local ranking metric that measures a model's ability to order neighboring states. On the Rubik's Cube, our approach consistently improves local ranking accuracy and downstream search performance under matched computational budgets.

Linguistic Properties and Model Scale in Brain Encoding: From Small to Compressed Language Models
SUBBA REDDY OOTA, Vijay Rowtula, Satya Sai Srinath Namburi GNVV, Khushbu Pahwa, Anant Khandelwal, Manish Gupta, Tanmoy Chakraborty, Bapi Raju Surampudi
Recent work has shown that scaling large language models (LLMs) improves their alignment with human brain activity, yet it remains unclear what drives these gains or which representational properties are responsible. Although larger models often yield better task performance and brain alignment, they are increasingly difficult to analyze mechanistically. This raises a fundamental question: \emph{what is the minimal model capacity required to capture brain-relevant representations?} To address this question, we systematically investigate how constraining model scale and numerical precision affects brain alignment. We compare full-precision LLMs, small language models (SLMs), and compressed variants (quantized and pruned) by predicting fMRI responses during naturalistic language comprehension. Across model families up to 14B parameters, we find that 3B SLMs achieve brain predictivity indistinguishable from larger LLMs, whereas 1B models degrade substantially, particularly in semantic language regions. Brain alignment is remarkably robust to compression: most quantization and pruning methods preserve neural predictivity, with GPTQ as a consistent exception. Linguistic probing reveals a dissociation between task performance and brain predictivity: compression degrades discourse, syntax, and morphology, yet brain predictivity remains largely unchanged. Overall, brain alignment saturates at modest model scales and is resilient to compression, challenging common assumptions about neural scaling and motivating compact models for brain-aligned language modeling.
****
UDM-GRPO: Stable and Efficient Group Relative Policy Optimization for Uniform Discrete Diffusion Models
Jiaqi Wang, Haoge Deng, Ting Pan, Yang Liu, Chengyuan Wang, Fan Zhang, Yonggang Qi, Xinlong Wang
Uniform Discrete Diffusion Model (UDM) has recently emerged as a promising paradigm for discrete generative modeling; however, its integration with reinforcement learning remains largely unexplored. We observe that naively applying GRPO to UDM leads to training instability and marginal performance gains. To address this, we propose **UDM-GRPO**, the first framework to integrate UDM with RL. Our method is guided by two key insights: (i) treating the final clean sample as the action provides more accurate and stable optimization signals; and (ii) reconstructing trajectories via the diffusion forward process better aligns probability paths with the pretraining distribution. Additionally, we introduce two strategies, Reduced-Step and CFG-Free, to further improve training efficiency. **UDM-GRPO** significantly improves base model performance across multiple T2I tasks. Notably, GenEval accuracy improves from $69\\%$ to $96\\%$ and PickScore increases from 20.46 to 23.81, achieving state-of-the-art performance in both continuous and discrete settings. On the OCR benchmark, accuracy rises from $8\\%$ to $57\\%$, further validating the generalization ability of our method. Code is available at https://github.com/Yovecent/UDM-GRPO.
****
ArborKV: Structure-Aware KV Cache Management for Scaling Tree-based LLM Reasoning
Yeqiu Chen, Ziyan Liu, Zhenxin Huang, Runquan Gui, Hong Wang, Lei Liu
Recent progress in LLM reasoning has increasingly shifted from single-pass generation to explicit search over intermediate reasoning states. Tree-of-Thoughts (ToT) organizes inference to tree-structured search with branching and backtracking, but it substantially amplifies the key--value (KV) cache: retaining KV states for a frontier of partial trajectories quickly becomes a memory bottleneck that limits throughput and constrains search depth and width under fixed hardware budgets. We address this challenge by observing that KV reuse in ToT-style inference is governed by search dynamics: near-term decoding depends primarily on the active branch and its ancestors, whereas inactive subtrees have low short-term reuse probability yet must remain recoverable for backtracking. Motivated by this, we propose **ArborKV**, a structure-aware eviction framework that couples a lig

htweight value estimator with a tree-aware allocation policy, and performs purel y token-extractive eviction with lazy rehydration to support revisits. Experimen ts on ToT-style reasoning benchmarks show that ArborKV achieves up to $\sim4\tim es$ peak KV-memory reduction while preserving near-full-retention accuracy, enab ling larger search configurations under fixed device budgets that would otherwis e run out of memory.
****

Path-Decoupled Hyperbolic Flow Matching for Few-Shot Adaptation
Lin Li, Ziqi Jiang, Gefan Ye, Zhenqi He, Jiahui Li, Jun Xiao, Kwang-Ting Cheng, Long Chen
Recent advances in cross-modal few-shot adaptation treat visual-semantic alignme nt as a continuous feature transport problem via Flow Matching (FM). However, we argue that Euclidean-based FM overlooks fundamental limitations of flat geometr y, where polynomial volume growth fails to accommodate diverse feature distribut ions, leading to severe path entanglement. To this end, we propose path-decouple d Hyperbolic Flow Matching (HFM), leveraging the Lorentz manifold's exponential expansion for trajectory decoupling. HFM structures the transport via two key de signs: 1) Centripetal hyperbolic alignment: It constructs a centripetal hierarch y by anchoring textual roots, which pushes visual leaves to the boundary to init ialize orderly flows. 2) Path-decoupled objective: It acts as a "semantic guardr ail" rigidly confining trajectories within isolated class-specific geodesic corr idors via step-wise supervision. Furthermore, we devise an adaptive diameter-bas ed stopping to prevent over-transportation into the crowded origin based on the intrinsic semantic scale. Extensive ablations on 11 benchmarks have shown that H FM establishes a new state-of-the-art, consistently outperforming its Euclidean counterparts. Our codes and models will be released.

Treatment Responder Classification with Abstention
Haoxiang Wang, Aoqi Zuo, Ziyan Wang, Zhiheng Zhang, Erdun Gao, Kun Zhang, Haoxua n Li, Mingming Gong
Treatment responder classification seeks to learn a rule to classify individuals who will benefit from the treatment. This paper studies a new scenario in treat ment responder classification when abstention is allowed, i.e., practitioners ca n opt out of making uncertain classification on some individuals for further inv estigation. By revealing the implicit relation between causal misclassification risk with abstention and Conditional Value at Risk (CVaR), we develop a doubly r obust method named TRECA to learn the classification rule under loose convergenc e conditions on nuisance parameters, and further extend it to deal with possible violation on key assumptions such as monotonicity and unconfoundedness. Rigorou s theories and extensive experiments on two real-world datasets demonstrate the theoretical and experimental guarantee on our methods in learning treatment resp onders classification rules with low regret at the cost of limited abstention.

Large Language Models Explore by Latent Distilling
Yuanhao Zeng, Ao Lu, Lufei Li, Zheng Zhang, Yexin Li, Kan Ren
Generating diverse responses is crucial for test-time scaling of large language models (LLMs), yet standard stochastic sampling mostly yields surface-level lexi cal variation, limiting semantic exploration. In this paper, we propose Explorat ory Sampling (ESamp), a decoding approach that explicitly encourages semantic di versity during generation. ESamp is motivated by the well-known observation that neural networks tend to make lower-error predictions on inputs similar to those encountered before, and incur higher prediction error on novel ones. Building o n this property, we train a lightweight Distiller at test time to predict deep-l ayer hidden representations of the LLM from its shallow-layer representations to model the LLM’s depth-wise representation transitions. During decoding, the Dis tiller continuously adapts to the mappings induced by the current generation con text. ESamp uses the prediction error as a novelty signal to reweight candidate token extensions conditioned on the current prefix, thereby biasing decoding tow ard less-explored semantic patterns. ESamp is implemented with an asynchronous t raining--inference pipeline, with less than 5\% worst case overhead (1.2\% in th

e optimized release). Empirical results show that ESamp significantly boosts the Pass@k efficiency of reasoning models, showing superior or comparable performance to strong stochastic and heuristic baselines. Notably, ESamp achieves robust generalization across mathematics, science, and code generation benchmarks and breaks the trade-off between diversity and coherence in creative writing. Our code has released at: https://github.com/LinesHogan/tLLM.

Differentially Private Synthetic Data via APIs 4: Tabular Data
Toan Tran, Arturs Backurs, Zinan Lin, Victor Reis, Li Xiong, Sergey Yekhanin
This paper investigates the problem of generating synthetic tabular data with differential privacy (DP) guarantees, enabling data sharing in sensitive domains. Despite extensive study, state-of-the-art methods often focus on minimizing low-order marginal query errors and overlook the challenges posed by high-order correlations. To address this gap, we extend the Private Evolution (PE) framework, originally developed for DP-compliant image and text synthesis, to tabular data. We introduce Tab-PE -- an algorithm for synthetic tabular data generation under DP constraints. Tab-PE iteratively improves a candidate dataset via an evolutionary process that leverages tabular-specialized operators to produce variations, privately scores them, and selects the highest-quality samples to retain and propagate. In contrast to the original PE, which relies on large foundation models, Tab-PE employs heuristic operators with significantly lower computational costs, making PE more practical and scalable for tabular data. Through extensive experiments on real-world and simulation datasets, we demonstrate that Tab-PE substantially outperforms prior baselines on datasets exhibiting high-order correlations. Compared to the best baseline -- AIM, Tab-PE improves classification accuracy by up to 10\% while running 28$\times$ faster.

FormulaCode: Evaluating Agentic Optimization on Large Codebases
Atharva Sehgal, James Hou, Akanksha Sarkar, Ishaan Mantripragada, Swarat Chaudhuri, Jennifer J. Sun, Yisong Yue
Large language model (LLM) coding agents increasingly operate at the repository level, motivating benchmarks that evaluate their ability to optimize entire codebases under realistic constraints. Existing code benchmarks largely rely on synthetic tasks, binary correctness signals, or single-objective evaluation, limiting their ability to assess holistic optimization behavior. We introduce FormulaCode, a benchmark for evaluating agentic optimization on large, real-world codebases with fine-grained, multi-objective performance metrics. FormulaCode comprises 957 performance bottlenecks mined from scientific Python repositories on GitHub, each paired with expert-authored patches and 264.6 community-maintained performance workloads per task, enabling evaluation of the full optimization lifecycle—triage, diagnosis, and resolution—under realistic correctness and performance constraints. Our evaluations reveal that repository-scale, multi-objective optimization remains a major challenge for frontier LLM agents.

MVR-cache: Optimizing Semantic Caching via Multi-Vector Retrieval and Learned Prompt Segmentation
Ali Noshad, Zishan Zheng, Yinjun Wu
To reduce LLM costs and latency, semantic caching systems must accurately identify when a new prompt matches a cached one. Current methods often rely on simplistic similarity measures, which limit their effectiveness. We introduce MVR-cache, a novel semantic caching approach that significantly improves retrieval accuracy by integrating Multi-Vector Retrieval (MVR). MVR-cache is built upon a learnable segmentation model that intelligently splits prompts, enabling fine-grained similarity comparisons via MaxSim. We derive the model's training objective from a rigorous theoretical analysis. This can ensure that optimizing this objective directly maximizes cache hits under strict correctness constraints. To solve the resulting non-differentiable combinatorial optimization problem, we leverage a reinforcement learning-based training strategy with the theoretically grounded objectives as the reward. Experimental results on established benchmarks across diverse tasks confirm that in comparison to the state-of-the-art, MVR-cache cons

istently increases the cache hit rates by up to 37\% while maintaining the same correctness guarantees. MVR-cache is available at https://github.com/PKU-SDS-lab/MVR-Cache

Responsible Text-to-Image Diffusion: Interpretable and Linearly Controllable Semantics for Fair and Safe Generation
Sayedmoslem Shokrolahi, Jae-Mo Kang, Il-Min Kim
Text-to-image (T2I) diffusion models (DMs) have achieved remarkable generative quality but still exhibit risk of producing biased and inappropriate images. A promising line of prior work aims to mitigate this issue by learning interpretable, linearly controllable concepts from semantic spaces, such as the U-Net bottleneck; however, these methods rely entirely on U-Net architectures and cannot be generalized to modern ViT-based DMs, including FLUX and PixArt. In this work, we present an architecture-agnostic framework for discovering interpretable and linearly controllable semantic attributes across any T2I DM backbone. Theoretically, we show that multi-modal attention heads in ViT-based DMs exhibit a linear semantic structure: injected concept vectors combine linearly at the attention level and induce near-linear effects at the model output, satisfying homogeneity and additivity. These theoretical results are aligned with and supported by empirical experiments. Building on this insight, we introduce a method that learns external concept vectors, which are added to the multi-modal attention heads for ViT-based DMs or to the bottleneck layer for U-Net-based DMs, while keeping pretrained models frozen. Experiments across SDXL, SD3.5, PixArt, and FLUX demonstrate that these concept vectors provide interpretability, linearity, and significantly improved fairness while preserving visual fidelity. The code and demo are available at https://github.com/Moslem-Sh21/responsible-t2i-diffusion.

CellBRIDGE: Learning Cellular Trajectories via Interaction-Aware Alignment
Silas Ruhrberg Estévez, Nicolas Huynh, Tennison Liu, Roderik M. Kortlever, Gerard I. Evan, David L. Bentley, Mihaela van der Schaar
Inferring dynamics from population snapshots is a fundamental challenge in machine learning and biology. In scRNA-sequencing (scRNA-seq), destructive measurements preclude direct tracking of individual cells across time, making trajectory inference underdetermined. Optimal Transport (OT) provides a principled framework for snapshot alignment, but a long-standing modeling question is which cost functions yield biologically meaningful couplings. Standard OT approaches rely on gene-expression distances, implicitly treating cells as independent points and neglecting structured cell-cell communication mediated by ligand-receptor signaling. We introduce CellBRIDGE (Cell-Based Regularized Interaction-Driven Gene Expression), which augments feature-based OT with a directed, typed interaction cost derived from ligand-receptor activity. By explicitly modeling cell-cell communication, CellBRIDGE improves cross-snapshot couplings and downstream trajectory estimates across synthetic and real scRNA-seq datasets relative to feature-only baselines. Notably, CellBRIDGE enables mechanistically interpretable in silico perturbations: on lung cancer data, silencing specific ligand-receptor pairs induces trajectory shifts that recapitulate expected effects of targeted pathway inhibition.

SpikeVLA: Vision-Language-Action Models with Spiking Neural Networks
Ruiqi Song, Dujun Nie, Siyu Teng, Baiyong Ding, Xiaotong Zhang, Dong Li, Chenming Zhang, Yuchen Li, Hangbin Wu, Long Chen
Vision-Language-Action (VLA) models have become a central paradigm for embodied intelligence. However, most existing approaches are built on large-scale Transformers, resulting in substantial inference latency and energy consumption that limit their practical deployment in low-power, real-time scenarios. We propose SpikeVLA, an end-to-end spiking VLA framework for embodied navigation with energy-efficient inference, consisting of three key components. (i) a spiking vision encoder, Spike-V, that replaces dense continuous computation with event-driven spiking representations to reduce the energy cost of visual representation learning, (ii) a multimodal spiking large language model, Spike-L, that reformulates cros

s-modal reasoning with spiking dynamics and token-level event-driven sparsity to further lower inference overhead, and (iii) a spiking action policy network, Spike-A, that uses Laplacian-kernel population coding and end-to-end reinforcement learning to produce stable, robust continuous control under low-energy constraints.
Experiments on multimodal interaction and robotic control tasks show that SpikeVLA significantly reduces energy consumption and computational overhead while maintaining competitive performance, highlighting its potential for low-power, real-time embodied intelligence.
****
ASyMOB: Algebraic Symbolic Mathematical Operations Benchmark
Michael Shalyt, Rotem Elimelech, Ido Kaminer
Large language models (LLMs) are increasingly applied to symbolic mathematics, yet existing evaluations often conflate pattern memorization with genuine reasoning. To address this gap, we present **ASyMOB**, a high-resolution dataset of **35,368** validated symbolic math problems spanning integration, limits, differential equations, series, and hypergeometrics. Unlike prior benchmarks, **ASyMOB** systematically perturbs each seed problem using symbolic, numeric, and equivalence-preserving transformations, enabling a fine-grained assessment of generalization and robustness.
Our evaluation reveals three key findings: (1) most models' performance collapses under minor perturbations, while top systems exhibit an apparent *regime shift* in robustness; (2) integrated code tools stabilize performance, particularly for weaker models; and (3) we identify examples where Computer Algebra Systems (CAS) fail while LLMs succeed, as well as problems solved only via a hybrid LLM-CAS approach, highlighting a promising integration frontier.
ASyMOB serves as a principled diagnostic tool for measuring and accelerating progress toward building verifiable, trustworthy AI for scientific discovery.

Theoretical Guarantees for One-Shot Magnitude Pruning and Compute-Adaptive Early Exit
Erdem Koyuncu
We study compute reduction in neural networks through a unified partial versus full computation view, captured by one-shot magnitude pruning in the static regime and early exit in the adaptive regime. In an asymptotic single-neuron model, we prove a concentration theorem for one-shot magnitude pruning with explicit rates. We also introduce the conditional perceptron for early exit and show that its excess generalization error decays as a power of the compute gap, with an exponent that grows to infinity as the alignment between partial and full computations tends to one. We then extend the analysis to deep networks, characterizing how pruning-induced distortions accumulate with depth and deriving a corresponding compute–accuracy tradeoff for frozen-backbone early exit under a neural network Gaussian process model. Numerical simulations corroborate the predicted scaling laws.

Latent Space Robust Optimization of Neural Processes with Aligned Stratified Order-Statistic Loss Reduction
Qi Tao, Jiarong Wen, Jing Yang, Guanlin Wu, Zhang Kaiyu, Yiqin Lv, Wumei Du, Xingxing Liang, Qi Wang
Importance-Weighted Neural Processes (IWNPs) provide a principled framework for probabilistic meta-learning by using multi-particle latent representations to approximate the marginal log-likelihood of task data tightly.
However, this work reveals that the standard optimization of IWNPs suffers from the Matthew effect in the latent space, where high-likelihood particles dominate gradient signals.
The neglect of lower-likelihood regions leads to poor tail-risk generation and unstable fast adaptation.
While robust objectives such as CVaR_α can mitigate these risks, they often entail a trade-off that degrades average-case performance.
This work proposes \underline{O}rder-\underline{S}tatistics Aligned \underline{N

}eural \underline{P}rocesses (OS-NPs) to achieve latent space robust optimizatio
n without sacrificing average result.
Specifically, we stratify multiple inference particles into disjoint difficulty
bins based on order statistics and derive the regularized worst-case optimizatio
n framework for OS-NPs.
Our method aligns the reduction of stratified order-statistic losses in IWNPs an
d provides a computationally efficient pipeline to implement.
Extensive experiments demonstrate that the OS-NP constitutes stable, reliable pr
obabilistic meta-learning that significantly enhances tail-risk robustness while
 maintaining or even improving average performance.

AnyEdit++: Adaptive Long-Form Knowledge Editing via Bayesian Surprise
Bowen Tian, Caixue He, Jiemin Wu, Jingying Wang, Wenshuo Chen, Zexi Li, Yutao Yu
e
Editing complex, long-form knowledge in Large Language Models remains a signific
ant challenge due to the difficulty of maintaining generation coherence. Existin
g autoregressive methods like AnyEdit alleviate length constraints but rely on F
ixed-window Chunking, which disregards logical structure and compromises consist
ency. To address this, we present AnyEdit++, a structure-aware framework incorpo
rating Bayes-Chunk, an adaptive segmentation mechanism that dynamically identifi
es semantic boundaries based on Bayesian Surprise. We underpin this approach wit
h a theoretical framework establishing two key principles: (1) Structural Indepe
ndence: we prove that cross-segment interference is minimized when anchor keys a
re geometrically orthogonal (a condition naturally satisfied by our surprisal-ba
sed boundaries but violated by fixed windows), and (2) Causal Locality: we demon
strate that updates injected at these semantic peaks yield strictly superior con
trol compared to arbitrary split points. Extensive experiments across mathematic
al reasoning, code generation, and narrative tasks demonstrate that AnyEdit++ ac
hieves superior performance and robustness compared to state-of-the-art baseline
s, validating that structural awareness is critical for effective long-form know
ledge editing.

Temporal Preference Optimization for Unsupervised Retrieval
HyunJin Kim, Jaejun Shim, Young Jin Kim, JinYeong Bak
Unsupervised dense retrievers offer scalability by learning semantic similarity
from unlabeled documents via contrastive learning, but they struggle to capture
the temporal relevance, retrieving semantically related but temporally misaligne
d documents-an important aspect when a document collection spans multiple time p
eriods (*e.g.,* retrieving documents from 2018-2025 for "Who is the president in
 2019?" introduces temporal ambiguity).
Existing methods rely on supervised training with explicit timestamps, which are
 not always feasible.
We propose TPOUR (*Temporal Preference Optimization for Unsupervised Retriever*)
, which uses our novel training method *Temporal Retrieval Preference Optimizati
on* (TRPO). TRPO reinterprets preference learning in the temporal dimension, gui
ding the retriever to favor temporally aligned documents. TPOUR further generali
zes to unseen time periods via interpolation in a learned time embedding, enabli
ng continuous temporal alignment. Experiments on temporal information retrieval
(T-IR), TPOUR outperforms both unsupervised and supervised baselines. Compared t
o Qwen-Embedding-8B, despite being about 72.7$\times$ smaller, TPOUR Contriever
improves average nDCG@5 by +4.04 (+12.15%) on explicit and +4.98 (+15.21%) on im
plicit queries. We provide our code at https://github.com/agwaBom/TPOUR.

Plan in Sandbox, Navigate in Open Worlds: Learning Physics-Grounded Abstracted E
xperience for Embodied Navigation
Zhixuan Shen, Jiawei Du, Ziyu Guo, Han Luo, Lilan Peng, Joey Tianyi Zhou, Haonan
 Luo, Tianrui Li
Vision-Language Models (VLMs) have demonstrated exceptional general reasoning ca
pabilities. However, their performance in embodied navigation remains hindered b
y a scarcity of aligned open-world vision and robot control data. Despite simula

tors providing a cost-effective alternative for data collection, the inherent reliance on photorealistic simulations often limits the transferability of learned policies. To this end, we propose ***S**andbox-**A**bstracted **G**rounded **E**xperience* (***SAGE***), a framework that enables agents to learn within a physics-grounded semantic abstraction rather than a photorealistic simulation, mimicking the human capacity for mental simulation where plans are rehearsed in simplified physics abstractions before execution. *SAGE* operates via three synergistic phases: (1) *Genesis*: constructing diverse, physics-constrained semantic environments to bootstrap experience; (2) *Evolution*: distilling experiences through Reinforcement Learning (RL), utilizing a novel asymmetric adaptive clipping mechanism to stabilize updates; (3) *Navigation*: bridging the abstract policy to open-world control. We demonstrate that *SAGE* significantly improves planner-assisted embodied navigation, achieving a 53.21% LLM-Match Success Rate on A-EQA (+9.7% over baseline), while showing encouraging transfer to physical indoor robot deployment. Project page is available at: <https://frankzxshen.github.io/SAGE>.

CSOR: Coreset Selection for Object Re-identification via Class Pruning

Minyoung Oh, Jae-Young Sim

Coreset Selection (CS) aims to extract a small yet representative subset from a large dataset, reducing the complexity of model training. Although CS has been primarily investigated for classification tasks, it is still underexplored for object Re-identification (ReID). In this paper, we first formulate Coreset Selection for Object Re-identification (CSOR) as a joint optimization problem to find both the optimal coreset and the optimal class subset. We identify intra-class diversity as a key factor for effective coreset construction for ReID. Based on this insight, we propose a novel two-stage framework, consisting of Diversity-driven Class Pruning (DCP) and Coverage-Prioritized Sampling (CPS), to address the unique challenges of ReID datasets. First, classes with low feature diversity are pruned to allocate the storage budget to the remaining informative classes. Then, samples are greedily selected in an easy-to-hard class order to maximize feature coverage within each class. Extensive experiments on three person ReID datasets and one vehicle ReID dataset demonstrate that our method consistently outperforms existing CS approaches, establishing a new state-of-the-art in CSOR.

TG-RAG: A Retrieval-Augmented Framework for Reasoning Guidance in Specialized Domains

Liang Su, Mingyang Zhang, Yun Xiong, Tengfei LIU, Siwei Zhang, Xi Chen, Li Sun

Enhancing Large Reasoning Models (LRMs) for specialized domains remains a critical challenge. While recent industrial frameworks attempt to encapsulate Standard Operating Procedures into modular "skills" for dynamic retrieval, utilizing them via context engineering often proves insufficient for complex workflows, leading to "Cognitive Drift." To mitigate this, we propose $\textbf{Thought Guidance-Retrieval Augmented Generation (TG-RAG)}$, a Retrieval-Augmented framework that effectively steers the generation process without relying solely on the model's self-correction. Built upon an Expert Procedure Graph (EPG) that formalizes unstructured SOPs, the framework uniquely employs a dynamic $\textbf{``Interrupt-Retrieve-Generate" (IRG)}$ mechanism to actively inject step-specific directives into the model's reasoning process. Extensive evaluations show that TG-RAG achieves competitive performance, demonstrating advantages in specialized domains by ensuring faithful adherence to domain SOPs. Code is available at https://github.com/V1ncent-S/Thought-Guidance.

****

U^{3}CF: Unbiased, Unconfounding, and Unified Causal Framework for Multi-Target Domain Adaptation

Wenxu Wang, Yeqiang Liu, Rui Zhou, Jing Wang, Zhenbo Li, Wenbo Gong

Multi-target domain adaptation (MTDA) trains a model using a labeled source domain and several unlabeled target domains, aiming to enhance performance across all targets. However, existing methods lack a principled causal formulation and often rely on empirical domain-invariance enforcement, which can bias adaptation a

cross targets. To fill this gap, we propose the **U**nbiased, **U**nconfounding, and **U**nified **C**ausal **F**ramework (**U^{3}CF**) for MTDA. To *unify* the alignment of multiple domains, we propose a prototype-driven alignment strategy that progressively updates prototypes by high-confidence target predictions, while the contrastive optimization objective jointly aligns target samples to semantic prototypes and preserves class discrimination. By formulating a structural causal model, we reveal that domain-invariant causal factors and domain-specific factors shape representations and labels, while the latter induce spurious label correlations across targets. Accordingly, U^{3}CF achieves *unbiased* prediction by disentangling representations into invariant causal components and domain-specific confounders and applying conditional intervention to *block confounding* effects while preserving invariant semantics. To ensure precise disentanglement, we leverage mutual information theory to derive a principled criterion for feature separation. Extensive experiments on four benchmarks demonstrate that U^{3}CF consistently outperforms leading methods.

Dual-channel Dynamic Graph Neural Networks with Adaptive Adjacency Learning and Multi-scale Representation Fusion

Youqing Wang, Jiahao Long, Tianxiang Zhao, Man Cao, Mengyuan Xin, Jiapu Wang, Junbin Gao, Jipeng Guo

Graph neural networks (GNNs) have been demonstrated to be powerful tools for analyzing structural graph data. However, most existing methods usually rely on fixed adjacency structures for information propagation, lacking strong adaptability to the latent semantic relationships that exist but are not explicitly connected in graph, especially in complementary high-pass and low-pass filtering views. To this end, this paper proposes a novel Dual-channel Dynamic Graph Neural Network (DCD-GNN), mainly consisting of parallel representation learning channels: a static structure-preserving channel and a dynamic adjacency-enhancing channel. The dynamic channel exploits both low-pass structural filtering and high-pass personalized detail via the self-attention adjacency learning and then integrates them for comprehensive semantic modeling, while the static channel maintains structural stability. Both channels employ a multi-scale representation fusion mechanism and a unified and discriminative node embedding representation is obtained by integrating them. Extensive experiments on various benchmark datasets verify the superiority of DCD-GNN in discriminative graph representation learning.

****

Operationalising the Superficial Alignment Hypothesis via Task Complexity

Tomás Vergara Browne, Darshan Patil, Ivan Titov, Siva Reddy, Tiago Pimentel, Marius Mosbach

The superficial alignment hypothesis (SAH) posits that large language models learn most of their knowledge during pre-training, and that post-training merely surfaces this knowledge. The SAH, however, lacks a precise definition, which has led to (i) different and seemingly orthogonal arguments supporting it, and (ii) important critiques to it.

We propose a new metric called **task complexity**: the length of the shortest program that achieves a target performance on a task.

In this framework, the SAH simply claims that pre-trained models drastically reduce the complexity of achieving high performance on many tasks. Our definition unifies prior arguments supporting the SAH, interpreting them as different strategies to find such short programs. Experimentally, we estimate the task complexity of mathematical reasoning, machine translation, and instruction following; we then show that these complexities can be remarkably low when conditioned on a pre-trained model.

Further, we find that pre-training enables access to strong performances on our tasks, but it can require programs of gigabytes of length to access them. Post-training, on the other hand, collapses the complexity of reaching this same performance by several orders of magnitude. Overall, our results highlight that task adaptation often requires surprisingly little information---often just a few kilobytes

****

Efficient Diffusion LLMs via Temporal-Spatial Parallel Decoding and Confidence E
xtrapolation
Zekai Li, Ji Liu, Yiqing Huang, Ziqiong Liu, Dong Li, Emad Barsoum
Diffusion-based large language models (dLLMs) support parallel text generation v
ia iterative denoising, yet inference remains latency-heavy because many steps a
re spent on redundant refinement and repeated remasking of tokens whose final va
lues are already determined.
Prior acceleration methods mainly depend on step-local confidence heuristics or
fixed schedules, which are sensitive to prompt and task variation and ignore str
ong positional effects within a sequence. We cast diffusion decoding as a dynami
c control problem and show that token-wise denoising trajectories provide the ke
y signal for reliable control. We propose a trace-aware decoding framework with
two components. First, Temporal-Spatial Parallel Decoding (TSPD) uses a lightwei
ght temporal-spatial correctness sensor that consumes per-token trajectory featu
res, including confidence, entropy, and momentum, together with token position,
to decide when a token has converged and can be safely fixed. Second, we introdu
ce]Confidence Extrapolation (CE)}], a training-free state-space module that for
ecasts future logit trends with uncertainty to support proactive decisions, incl
uding safe look-ahead and targeted stabilization when trajectories are oscillato
ry or underconfident. Together, TSPD and CE reduce unnecessary denoising iterati
ons while preserving output quality, and they compose cleanly with system optimi
zations such as KV caching.
****
Pretrained Vision-Language-Action Models are Surprisingly Resistant to Forgettin
g in Continual Learning
Huihan Liu, Changyeon Kim, Bo Liu, Minghuan Liu, Yuke Zhu
Continual learning is a long-standing challenge in robot policy learning, where
a policy must acquire new skills over time without catastrophically forgetting p
reviously learned ones. While prior work has extensively studied continual learn
ing in relatively small behavior cloning (BC) policy models trained from scratch
, its behavior in modern large-scale pretrained Vision-Language-Action (VLA) mod
els remains underexplored. In this work, we find that pretrained VLAs are remark
ably resistant to forgetting compared with smaller policy models trained from sc
ratch. Simple Experience Replay (ER) works surprisingly well on VLAs, sometimes
achieving zero forgetting even with a small replay data size. Our analysis revea
ls that pretraining plays a critical role in downstream continual learning perfo
rmance: large pretrained models mitigate forgetting with a small replay buffer s
ize while maintaining strong forward learning capabilities. Furthermore, we find
that VLAs can retain relevant knowledge from prior tasks despite performance de
gradation during learning new tasks. This knowledge retention enables rapid reco
very of seemingly forgotten skills through finetuning. Together, these insights
imply that large-scale pretraining fundamentally changes the dynamics of continu
al learning, enabling models to continually acquire new skills over time with si
mple replay.

MEDA: Medical-Oriented Activation Editing for Hallucination Mitigation in Medica
l Large Vision-Language Model
Tianbo Wang, Yuqing Ma, Lingyan Meng, Zhange Zhang, Kewei Liao, Jian Yang, Simin
Li, Jinyang Guo, Xianglong Liu
Medical Large Vision-Language Models (Med-LVLMs) suffer from severe hallucinatio
ns, posing critical safety risks in clinical deployment. Editing LVLM activation
s has shown promise for mitigating hallucination with minimal cost. However, due
to the requirements of medical domain expertise, existing methods struggle to c
apture imaging manifestations and diagnostic principles that are critical for cl
inical interpretation, thereby limiting their effectiveness. To address these li
mitations, we propose the first MEDical-oriented Activation Editing (MEDA) metho
d by integrating Query-decisive Manifestation Steering (QMS) and Principle-drive
n Diagnosis Induction (PDI) to promote Med-LVLM's expertise elicitation. Specifi
cally, QMS retrieves positive query-decisive imaging manifestations as trusted g
uidance for activation steering, while PDI constructs positive principle-embedde

d diagnostic prompts to induce expert-like clinical reasoning. Extensive experim ents across six benchmarks and six LVLMs demonstrate that MEDA efficiently impro ves the response factuality with up to a 10.2\% gain on IU-Xray, while exhibitin g strong generalization and few-shot robustness.
****
SAGE: Shaping Anchors for Guided Exploration in RLVR of LLMs
Chanuk Lee, Minki Kang, Sung Ju Hwang
Recent studies observe that reinforcement learning with verifiable rewards (RLVR) reliably improves pass@1 on reasoning tasks, yet often fails to yield comparab le gains in pass@k, raising the question of whether RLVR genuinely enables large language models to acquire novel reasoning abilities or merely enhances the eff iciency of sampling reasoning modes already present in the base model.
Prior analyses largely support the latter view, attributing this limitation to s tructural properties of standard RLVR objectives that result in insufficient exp loration pressure.
In this work, we argue that a central structural constraint arises from reverse-KL regularization, which stabilizes training but inherently anchors the policy t o the reference distribution, thereby suppressing the emergence of alternative r easoning modes.
However, we show that neither removing the KL term nor replacing it with forward -KL provides a satisfactory solution, as both disrupt the efficiency–coverage tr ade-off by either inducing reward hacking or allocating probability mass to off-target regions.
To resolve this tension, we propose SAGE, a principled framework that enables co ntrollable empirical support expansion by reshaping the reverse-KL anchor distri bution itself through a guide function $q(x,y)$, achieving consistent improvemen ts in both pass@1 and pass@k across challenging mathematical reasoning benchmark s.
****
FlashSinkhorn: IO-Aware Entropic Optimal Transport on GPU
Felix X.-F. Ye, Xingjie Li, An Yu, Ming-Ching Chang, LINSONG CHU, Davis Wertheim er
Entropic optimal transport (EOT) via Sinkhorn iterations is widely used in moder n machine learning, yet GPU solvers remain inefficient at scale. Tensorized impl ementations suffer quadratic HBM traffic from dense $n\times m$ interactions, wh ile existing online backends avoid storing dense matrices but still rely on gene ric tiled map-reduce reduction kernels with limited fusion. We present **FlashSi nkhorn**, an IO-aware EOT solver for squared Euclidean cost that rewrites stabil ized log-domain Sinkhorn updates as row-wise LogSumExp reductions of biased dot-product scores, the same normalization as transformer attention. This enables Fl ashAttention-style fusion and tiling: fused Triton kernels stream tiles through on-chip SRAM and update dual potentials in a single pass, substantially reducing HBM IO per iteration while retaining linear-memory operations. We further provi de streaming kernels for transport application, enabling scalable first- and sec ond-order optimization. On A100 GPUs, FlashSinkhorn achieves up to $32\times$ fo rward-pass and $161\times$ end-to-end speedups over state-of-the-art online base lines on point-cloud OT, improves scalability on OT-based downstream tasks. For reproducibility, we release an open-source implementation at https://github.com/ ot-triton-lab/flash-sinkhorn.
****
Metis: Learning to Jailbreak LLMs via Self-Evolving Metacognitive Policy Optimiz ation
Huilin Zhou, Jian Zhao, Yilu Zhong, Zhen Liang, Xiuyuan Chen, Yuchen Yuan, Tianl e Zhang, Chi Zhang, Lan Zhang, Xuelong Li
Red teaming is critical for uncovering vulnerabilities in Large Language Models (LLMs). While automated methods have improved scalability, existing approaches o ften rely on static heuristics or stochastic search, rendering them brittle agai nst advanced safety alignment. To address this, we introduce \textbf{Metis}, a f ramework that reformulates jailbreaking as inference-time policy optimization wi thin an adversarial Partially Observable Markov Decision Process (POMDP). Metis

employs a self-evolving metacognitive loop to perform causal diagnosis of a target's defense logic and leverages structured feedback as a semantic gradient to refine its policy, offering enhanced interpretability through transparent reasoning traces. Extensive evaluations across 10 diverse models demonstrate that Metis achieves the strongest average Attack Success Rate (ASR) among compared methods at 89.2\%, maintaining high efficacy on resilient frontier models (e.g., 76.0\% on O1 and 78.0\% on GPT-5-chat) where traditional baselines exhibit substantial performance degradation. By replacing redundant exploration with directed optimization, Metis reduces token costs by an average of 8.2$\times$ (and up to 11.4$\times$). Our analysis reveals that current defenses remain vulnerable to internally-steered, closed-loop reasoning trajectories under the tested settings, highlighting a critical need for next-generation defenses capable of reasoning about safety dynamically during inference.
****

QPKO: Differentiable QP-Embedded Deep Koopman Framework for Modeling Nonlinear Systems
Runze Tian, Peng Kou
Deep learning has been widely regarded as a powerful tool for Koopman operator theory-based modeling, as it provides a promising architecture for data-driven learning of observable functions. To fully leverage this advantage, a well-designed training paradigm is required. However, the existing training paradigms typically either incur high optimization complexity or hinder effective end-to-end training, limiting modeling accuracy and training efficiency. To address this issue, we propose a differentiable quadratic programming (QP)-embedded deep Koopman framework (QPKO). In QPKO, a QP problem, which comprises a one-step accuracy-oriented objective function and a set of multi-step accuracy-oriented constraints, is formulated to introduce a mapping from observable functions to the global linear model. By doing so, the global linear model no longer needs to be treated as an independent trainable component, thereby effectively reducing optimization complexity. This QP-based mapping is implemented as a differentiable and computationally efficient module by leveraging OptNet (a differentiable QP layer), enabling effective end-to-end training. Experiments on four nonlinear dynamical systems show that QPKO achieves satisfactory improvements in modeling accuracy, training efficiency, and control performance.

Weight-sparse transformers have interpretable circuits
Leo Gao, Achyuta Rajaram, Jacob Coxon, Soham V. Govande, Bowen Baker, Daniel P Mossing
Finding human-understandable circuits in language models is a central goal of the field of mechanistic interpretability. We train models to have more understandable circuits by constraining most of their weights to be zeros, so that each neuron only has a few connections. To recover fine-grained circuits underlying each of several hand-crafted tasks, we prune the models to isolate the part responsible for the task. These circuits often contain neurons and residual channels that correspond to natural concepts, with a small number of straightforwardly interpretable connections between them. We study how these models scale and find that making weights sparser trades off capability for interpretability, and scaling model size improves the capability-interpretability frontier. However, scaling sparse models beyond tens of millions of nonzero parameters while preserving interpretability remains a challenge. In addition to training weight-sparse models de novo, we show preliminary results suggesting our method can also be adapted to explain existing dense models. Our work produces circuits that achieve an unprecedented level of human understandability and validates them with considerable rigor.
****

OrchJail: Jailbreaking Tool-Calling Text-to-Image Agents by Orchestration-Guided Fuzzing
Jianming Chen, Yawen Wang, Junjie Wang, Zhe Liu, Qing Wang, Fanjiang Xu
Tool-calling text-to-image (T2I) agents can plan and execute multi-step tool chains to accomplish complex generation and editing queries.

However, this capability introduces a new safety attack surface: harmful outputs may arise from tool orchestration, where individually benign steps combine into unsafe results, making prompt-only jailbreak techniques insufficient.
We present OrchJail, an orchestration-guided fuzzing framework for jailbreaking tool-calling T2I agents.
Its core idea is to exploit high■risk tool■orchestration patterns: by learning from successful jailbreak tool-calling traces and their causal relationships to prompt wording, OrchJail directly guides the fuzzing search toward prompts that are more likely to trigger unsafe multi■step tool behaviors, rather than relying on surface■level textual perturbations.
Extensive experiments demonstrate that OrchJail improves jailbreak effectiveness and efficiency across representative tool-calling T2I agents,
achieving higher attack success rates, better image fidelity, and lower query costs, while remaining robust against common jailbreak defenses.
Our work highlights tool orchestration as a critical, previously unexplored attack surface and provides a novel framework for uncovering safety risks in T2I agents.

Diversity Matters: Revisiting Test-Time Compute in Vision-Language Models
Yijie Tong, Yifan Hou, Shaobo Cui, Antoine Bosselut, Mrinmaya Sachan
Test-time compute (TTC) strategies have emerged as a lightweight approach to boost reasoning in large language models, but their applicability to vision-language models (VLMs) remains unclear. We present a systematic study of TTC for visual reasoning across seven open-source VLMs and six benchmarks, revisiting two paradigms: (i) feature-based scoring of chain-of-thought (CoT) traces and (ii) confidence-based aggregation via majority voting (MV). In the single-model setting, feature cues (e.g., length, pivot words) fail to improve accuracy, while MV yields only modest, CoT-dependent gains. To explain this limitation, we theoretically show that the voting method’s effectiveness depends on prediction diversity: when outputs are highly correlated, the benefit of voting vanishes. In contrast, multi-model ensembles introduce stronger diversity through architectural differences, training data, and scale, making them both more realistic and more promising for TTC. However, MV treats all models equally, leaving it vulnerable to correlated errors from weaker models. To address this, we propose Entropy-based TTC, which selects the most confident prediction based on predictive entropy. Our method reduces to MV in the single-model case but, in ensembles, leverages confidence disparities to prioritize stronger models. We prove that our method
theoretically outperforms MV under mild dependence assumptions, and empirically show that it consistently surpasses both MV and the best individual model across diverse visual reasoning benchmarks. This demonstrates that smaller models can enhance, rather than hinder, larger ones when combined appropriately, unlocking ensemble gains not achievable with existing TTC strategies.

Multi-Distribution Robust Conformal Prediction
Yuqi YANG, Ying Jin
In many fairness and distribution robustness problems, one has access to labeled data from multiple source distributions yet the test data may come from an arbitrary member or a mixture of them. We study the problem of constructing a conformal prediction set that is uniformly valid across multiple, heterogeneous distributions, in the sense that no matter which distribution the test point is from, the coverage of the prediction set is guaranteed to exceed a pre-specified level. We first propose a max-p aggregation scheme that delivers finite-sample, multi-distribution coverage given any conformity scores associated with each distribution. Upon studying several efficiency optimization programs subject to uniform coverage, we prove the optimality and tightness of our aggregation scheme, and propose a general algorithm to learn conformity scores that lead to efficient prediction sets after the aggregation under standard conditions. We discuss how our framework relates to group-wise distributionally robust optimization, sub-population shift, fairness, and multi-source learning. In synthetic and real-data experiments, our method delivers valid worst-case coverage across multiple distrib

utions while greatly reducing the set size compared with naively applying max-p aggregation to single-source conformity scores, and can be comparable in size to single-source prediction sets with popular, standard conformity scores.

Propose, Solve, Verify: Self-Play Through Formal Verification
Alex Wilf, Pranjal Aggarwal, Bryan Parno, Daniel Fried, Louis-Philippe Morency, Paul Pu Liang, Sean Welleck
Training models through self-play alone (without any human data) has been a long standing goal in AI, but its effectiveness for training large language models remains unclear, particularly in code generation where rewards based on unit tests are brittle and prone to error propagation. We study self-play in the verified code generation setting, where formal verification provides reliable correctness signals. We introduce Propose, Solve, Verify (PSV) a simple self-play framework where formal verification signals are used to create a proposer capable of generating challenging synthetic problems and a solver trained via expert iteration. We use PSV to train PSV-Verus, which across three benchmarks improves pass@1 by up to 9.6x over inference-only and expert-iteration baselines. We show that performance scales with the number of generated questions and training iterations, and through ablations identify formal verification and difficulty-aware proposal as essential ingredients for successful self-play.

Beyond Instance-Level Self-Supervision in 3D Multi-Modal Medical Imaging
Tan Pan, Shuhao Mei, Yixuan Sun, Kaiyu Guo, Chen Jiang, Zhaorui Tan, Mengzhu Li, LIMEI HAN, Xiang Zou, Yuan Cheng, Mahsa Baktashmotlagh
Self-supervised pre-training methods in medical imaging typically treat each individual as an isolated instance, learning representations through augmentation-based objectives or masked reconstruction. They often do not adequately capitalize on a key characteristic of physiological features: anatomical structures maintain consistent spatial relationships across individuals (instances), such as the thalamus being medial to the basal ganglia, regardless of variations in brain size, shape, or pathology. We propose leveraging this cross-instance topological consistency as a supervisory signal. The challenge arises from the inherent variability in medical imaging, which can differ significantly across instances and modalities. To tackle this, we focus on two alignment regimes. (i) Intra-instance: with pixel-level correspondences available, a cross-modal triplet objective explicitly preserves local neighborhood topology. (ii) Inter-instance: without such supervision, we derive pseudo-correspondences to control partial neighborhood alignment and prevent topology collapse across modalities. We validate our approach across 7 downstream multi-modal tasks, achieving average improvements of 1.1\% and 5.94\% in segmentation and classification tasks, respectively, and demonstrating significantly better robustness when modalities are missing at test time.

DC-Leap: Training-Free Acceleration of dLLMs via Draft-Guided Contiguous Leaping Decoding
Yanhua Jiao, Tianyi Wu, Xiaoxi Sun, Yulin Li, Hui-Ling Zhen, Libo Qin, Baotian Hu, Zhuotao Tian, Min Zhang
While parallel decoding is central to the efficiency of Diffusion Large Language Models (dLLMs), current strategies are often hindered by overly conservative confidence thresholds. These thresholds, necessitated by the Joint Probability Dependence Error (JPDE), result in redundant denoising iterations and suboptimal inference speeds.
To overcome this, we propose DC-Leap, a training-free framework that enables reliable acceleration of dLLMs in the moderate-confidence regime. DC-Leap introduces a Dynamic Contiguous Verification strategy that integrates strictly-ordered causal constraints into the parallel decoding process. By progressively validating token dependencies, this mechanism effectively neutralizes the JPDE, enabling reliable acceleration with comparable performance. Furthermore, DC-Leap incorporates the draft-guided decoding mechanism, where the draft helps extend the context by leaping forward across multiple tokens, providing look-ahead context and re

taining the structural benefits of bidirectional attention during inference. Extensive experiments on standard benchmarks demonstrate that DC-Leap achieves substantial speedups, up to **53.19$\times$** on MBPP for long-sequence generation, and up to **105.02$\times$** when combined with KV-Cache with comparable generation quality. Code is available at <https://github.com/ffh-wyls/DC-Leap>.

Semi-Supervised Hypothesis Testing by Betting on Predictions
Yaniv Tenzer, Elad Tolochinsky, Yaniv Romano
We introduce a testing-by-betting framework that leverages predictions on unlabeled data to enhance the power of sequential hypothesis testing. Given limited samples from the joint distribution of (X,Y), and additional unlabeled samples from the marginal of X, we ask how unlabeled data can be used to hypothesize about the distribution of Y, and the conditional distribution of $Y\mid X$. We introduce an e-statistic and use it to construct a sequential test. Under standard distributional assumptions---label shift or concept shift---we establish that the test is anytime valid. Furthermore, we show that for binary data, the e-statistic has non-trivial power. Crucially, our approach retains these properties even when the underlying predictions are inaccurate.
Through simulations and applications to large language models evaluation, we demonstrate power gains over baseline approaches, including prediction-powered inference. These gains persist even with relatively limited unlabeled data and when predictions have low accuracy due to weak correlation between X and Y.

Learning from Comparison: Constrained Projection Policy Optimization for Pareto-Front Improvement
Jintao Li, Maowen Tang, Yongji Long, Weixuan Liu, Yanlang Zheng, Sicheng He, Ao-Jin Li, Shui Yu, Yun Li
Constrained multi-objective reinforcement learning aims to discover a diverse set of feasible trade-offs, yet scalarization and signed, normalized group-relative advantages can be brittle under objective-scale drift, near-ties, and feasibility scarcity. We propose constrained projection policy optimization (CoPro), which alternates between an E-step moment projection and an M-step policy projection. In the E-step, we solve a Kullback-Leibler (KL)-regularized, moment-constrained projection over each sampled group to compute a nonnegative reweighting distribution ($ q^* $) that promotes feasible Pareto-front (PF) progress, preserves feasibility anchors, and suppresses ambiguous near-ties. This E-step admits a closed-form exponential-family solution and guarantees strictly positive probability mass on feasible anchors whenever feasible candidates appear in the group. In the M-step, we project the policy toward $ q^* $ via weighted maximum likelihood with a trust-region regularizer, yielding a PF-aligned update direction from comparisons without hand-crafted reward shaping. Empirically, CoPro improves feasible PF quality and robustness on constrained multi-objective benchmarks for large language model tool use and analog circuit design tasks; code is available at \href{https://anonymous.4open.science/r/CoPro-8A95/README.md}{\texttt{CoPro}}.

Outcome Rewards Do Not Guarantee Verifiable or Causally Important Reasoning
Qinan Yu, Alexa R. Tartaglini, Peter Hase, Carlos Guestrin, Christopher Potts
Reinforcement Learning from Verifiable Rewards (RLVR) on chain-of-thought reasoning has become a standard part of language model post-training recipes. A common assumption is that the reasoning chains trained through RLVR reliably represent how a model gets to its answer. In this paper, we develop two metrics for critically examining this assumption: Causal Importance of Reasoning (CIR), which measures the cumulative effect of reasoning tokens on the final answer, and Sufficiency of Reasoning (SR), which measures whether a verifier can arrive at an unambiguous answer based on the reasoning alone. Through experiments with the Qwen2.5 model series and ReasoningGym tasks, we find that: (1) While RLVR does improve task accuracy, it does not reliably improve CIR or SR, calling the role of reasoning in model performance into question. (2) A small amount of SFT before RLVR can be a remedy for low CIR and SR. (3) CIR and SR can be improved even without SFT by applying auxiliary CIR/SR rewards on top of the outcome-based reward. This

joint reward matches the accuracy of RLVR while also leading to causally important and sufficient reasoning. These results show that RLVR does not always lead models to rely on reasoning in the way that is commonly thought, but this issue can be remedied with simple modifications to the post-training procedure.
****

LEAP: Zone-Aware MCTS for LLM Self-Speculative Decoding
LeiQuan Zheng, Yuan Liu
Self-speculative decoding accelerates LLM inference by using a lightweight draft model for generation and a target model for verification, where the draft model is constructed by a subset of the target model's layers, and the key challenge lies in layer configuration strategies. To address this challenge, we propose LEAP, a plug-and-play approach that formulates and optimizes the draft model construction problem as a sequential decision-making process by Monte Carlo Tree Search (MCTS). To navigate the prohibitive search space of deep LLMs, we leverage two empirical observations: (i) the prefilling-derived redundancy information remains informative during decoding, and (ii) the layer redundancy exhibits zone-wise characteristics. These observations enable a structured search space through zone partitioning and layer grouping, which serves as an inductive bias to facilitate efficiency of MCTS. Experimental results show that LEAP achieves a speedup of $1.7\times\sim2.0\times$ for LLM inference.

AI Cartography: Mapping the Latent Landscape of AI Benchmark Ecosystems
Michael Hardy, Anka Reuel, Lijin Zhang, Jodi M. Casabianca, Sang T. Truong, Yash Satish Dave, Hansol Lee, Benjamin W. Domingue, Sanmi Koyejo
While aggregate leaderboard scores drive AI development, they contain substantial measurement noise whose sources and magnitudes remain unquantified, making it unclear when rankings reflect genuine capability differences versus evaluation artifacts. We introduce a framework for measuring the latent landscape in AI benchmark ecosystems. Applying Confirmatory Factor Analysis (CFA) and Generalizability Theory to 4,000+ models from the Open LLM Leaderboard, we decompose sources of ranking variance and establish:
(1) structures assumed in current reporting practice underestimate the strength of relationships between benchmarks;
(2) evidence of local dependence among leaderboard items, undermining uses of benchmarks as measurement instruments under current scoring systems;
(3) contributor metadata explains more rank-relevant variance ($\approx9\%$) than architecture or deployment categories in this context;
(4) a manifest-score ``scaling law'' slope has low reliability ($R_{\beta}=0.53$); by contrast, the latent general-factor size slope is highly stable across ecosystem controls ($R_g=0.97$).
We are able to provide unique insights into benchmark dynamics, such as which benchmarks are a function of LLM size and which can be oppositely impacted by post-training practices. We provide actionable diagnostics to determine how benchmark rankings can be trusted and how benchmark design can be improved.

Expected Return Causes Outcome-Level Mode Collapse in Reinforcement Learning and How to Fix It with Inverse Probability Scaling
ABHIJEET SINHA, Sundari Elango, Dianbo Liu
Many reinforcement learning (RL) problems admit multiple terminal solutions of comparable quality, where the goal is not to identify a single optimum but to represent a diverse set of high-quality outcomes. Nevertheless, policies trained by standard expected-return maximization routinely collapse onto a small subset of outcomes, a phenomenon commonly attributed to insufficient exploration or weak regularization. We show that this explanation is incomplete: outcome-level mode collapse is a structural consequence of the expected-return objective itself. Under idealized learning dynamics, the log-probability ratio between any two outcomes evolves linearly in their reward difference, implying exponential ratio divergence and inevitable collapse—independent of the exploration strategy, entropy regularization, or optimization algorithm. We identify the source of this pathology as the probability multiplier inside the expectation and propose a minimal c

orrection: inverse probability scaling, which removes outcome-frequency amplification from the learning signal, fundamentally changes the learning dynamics, and provably yields reward-proportional terminal distributions, preventing collapse in multimodal settings. We instantiate this principle in Group Relative Policy Optimization (GRPO) as a drop-in modification, IPS-GRPO, requiring no auxiliary models or architectural changes. Across different reasoning and molecular generation tasks, IPS-GRPO consistently reduces outcome-level mode collapse while matching or exceeding baseline performance, suggesting that correcting the objective rather than adding exploration heuristics is key to reliable multimodal policy optimization.

****

Improving Zero-Shot Offline RL via Behavioral Task Sampling

Nazim Bendib, Nicolas Perrin-Gilbert, Olivier Sigaud

Offline zero-shot reinforcement learning (RL) aims to learn agents that optimize unseen reward functions without additional environment interaction. The standard approach to this problem trains task-conditioned policies by sampling task vectors that define linear reward functions over learned state representations. In most existing algorithms, these task vectors are randomly sampled, implicitly assuming this adequately captures the structure of the task space. We argue that doing so leads to suboptimal zero-shot generalization. To address this limitation, we propose extracting task vectors directly from the offline dataset and using them to define the task distribution used for policy training. We introduce a simple and general reward function extraction procedure that integrates into existing offline zero-shot RL algorithms. Across multiple benchmark environments and baselines, our approach improves zero-shot performance by an average of 20%, highlighting the importance of principled task sampling in offline zero-shot RL.

****

Decoupled Training with Local Reinforcement Fine-Tuning in Federated Learning

Yuting Ma, Lechao Cheng, Xiaohua Xu

Federated Learning (FL) with pre-trained Vision-Language Models (VLMs) has emerged as a promising paradigm for various downstream tasks. By leveraging its strong representations, recent studies improve task adaptation under insufficient local data while preserving generalization. However, these methods emphasize fully local optimization with simple parameter aggregation, which can amplify inter-client optimization inconsistency and intra-client over-specialization under heterogeneous and full-data FL settings, making it difficult to balance global task adaptation and generalization. To address these challenges, we propose FedDTL, a novel federated VLM framework that decouples the image encoder and text encoder across clients and the server. Through decoupled encoder training with server-client modality alignment, FedDTL promotes coherent global semantic update and reduces inter-client optimization inconsistency, improving global task adaptation. To further mitigate intra-client over-specialization, we introduce a two-stage local fine-tuning, where a supervised fine-tuning stage enables rapid and reliable warm-start, followed by a reinforcement learning stage that enhances generalization. Extensive experiments on multiple benchmarks, including label skew and feature shift, demonstrate that FedDTL achieves an effective balance between global task adaptation and generalization under various FL data distributions in both few-shot and full-data regimes.

****

Learning Coherent Representations: A Topological Approach to Interpretability

Sigurd Gaukstad, Melvin Vaupel, Valdemar Kargård Olsen, Erik Hermansen, Benjamin Adric Dunn

Deep neural networks learn representations where individual features often lack interpretable meaning; a single neuron may activate for scattered, unrelated inputs. We introduce coherence, a geometric property inspired by neural coding in the brain, where neurons like grid cells and head direction cells respond to contiguous regions of state space. A non-negative matrix is coherent if each row (sample) attends to geometrically clustered columns (features) and vice versa, and in addition every sample is well described by some feature and every feature is needed by some sample. We prove that coherent matrices induce a bounded interlea

ving between the Vietoris-Rips filtrations of samples and features, guaranteeing that both spaces share compatible topological structure. This geometric constraint facilitates interpretability. For example, if data lies on a circle, coherent features must tile that circle into contiguous arcs. We introduce Coh, a differentiable objective function based on Fréchet variance that enforces coherence during training. Unlike sparsity, which bounds how many samples a feature activates on, coherence bounds *which* samples, requiring geometric connectivity rather than only rarity. This yields not just interpretable features but an interpretable feature space. We validate Coh in an auto-encoder using synthetic and rotated MNIST datasets and in a token embedding of BERT using language data.

How Hard Is Science?
Adil Soubki, Miles Cranmer
Symbolic Regression (SR) is the task of finding a closed-form mathematical expression that optimizes some objective. Solving this task is NP-hard. However, SR software routinely discovers accurate, interpretable models without exhaustively searching function space.
Motivated by this disconnect between worst-case theory and practical success, we study SR through the lens of \emph{parameterized complexity theory}. In particular, we reanalyze tractability with respect to practically relevant parameters like expression depth, tree size, and number of primitives used. We show that SR is fixed-parameter tractable (FPT) when parameterized by expression depth or tree size, formalizing the tractable regime exploited by bounded-complexity search in popular SR algorithms. However, SR becomes W[1]-hard when parameterized by the number of variables or primitives used, identifying selection as a source of intractability. We further find lower bounds under the exponential time hypothesis, prove approximation hardness, and rule out polynomial kernels for the case where the primitive set is part of the input.

Why Self-Distillation Helps and Hurts: Denoising vs. Signal Forgetting
Mingqi Wu, Archer Yi Yang, Qiang Sun
Self-distillation, a special case of self-training, repeatedly trains a model on pseudo-labels produced by its previous iterate. Why can this iteration improve generalization, and why can it later hurt? We answer this question in overparameterized linear regression, starting from an estimator fit to noisy labels and then repeatedly refitting on fresh covariates labeled by the current estimator. In the proportional asymptotic regime, we derive deterministic recursions for the test risk and prove concentration around them. The recursions reveal a simple trade-off: iteration \emph{denoises} by attenuating stochastic error inherited from the initial fit, but it also induces \emph{signal forgetting} because each teacher--student transfer projects the estimate through a new data-dependent subspace. This competition produces a U-shaped risk curve and an optimal stopping time. The same dynamics act as a spectral filter: eigendirections carrying more of the true regression signal are retained longer, while weakly aligned or noise-like directions are suppressed. We further develop an iterated generalized cross-validation criterion with uniform consistency for selecting the stopping time. Synthetic simulations corroborate the recursions and data-driven stopping rule, while neural-network experiments exhibit the same denoising--forgetting pattern.

BioToken and BioFM – Biologically-Informed Tokenization Enables Accurate and Efficient Genomic Foundation Models
Aleksandr Medvedev, Karthik Viswanathan, Praveenkumar Kanithi, Kirill Vishniakov, Prateek Munjal, Clement Christophe, Tiago Magalhaes, Marco AF Pimentel, Ronnie Rajan, Shadab Khan
Existing genomic foundation models (GFMs) typically treat DNA as raw nucleotide sequences, often overlooking the regulatory context required to interpret genetic variation accurately. We introduce BioToken, a tokenization framework that directly encodes variants and biological annotations into genomic representations, and BioFM, a parameter-efficient model built on this architecture. By leveraging biological inductive biases, BioFM outperforms state-of-the-art models and spec

ialized baselines like Enformer on benchmarks including pathogenicity and expres
sion prediction while requiring 100-fold less compute than current large-scale g
enomic models. These findings demonstrate that explicitly modeling biological st
ructure yields more robust and efficient genomic representations than scaling al
one.

Attributed Network Alignment: Statistical Limits and Efficient Algorithm
Dong Huang, Chenyang Tian, Pengkun Yang
This paper studies the problem of recovering a hidden vertex correspondence betw
een two correlated graphs when both edge weights and node features are observed.
 While most existing work on graph alignment relies primarily on edge informatio
n, many real-world applications provide informative node features in addition to
 graph topology. To capture this setting, we introduce the featured correlated G
aussian Wigner model, where two graphs are coupled through an unknown vertex per
mutation, and the node features are correlated under the same permutation. We ch
aracterize the optimal information-theoretic thresholds for exact recovery and p
artial recovery of the latent mapping. On the algorithmic side, we propose QPAli
gn, an efficient method based on a quadratic programming relaxation, and demonst
rate its strong empirical performance on both synthetic and real datasets. Moreo
ver, we also derive theoretical guarantees for the proposed procedure, supportin
g its reliability and providing convergence guarantees.
****

InfoAtlas: A Foundation Model for Zero-Shot Statistical Dependence Estimate
Zhengyang Hu, Yanzhi Chen, Hanxiang Ren, Qunsong Zeng, Youyi Zheng, Adrian Welle
r, Kaibin Huang, Yanchao Yang
Measuring statistical dependency between high-dimensional random variables is a
fundamental task in data science and machine learning. Neural mutual information
 (MI) estimators offer a promising avenue, but they typically require costly ite
rative optimization for each new dataset, making them impractical for real-time
applications. We present InfoAtlas, a foundation model-like architecture that el
iminates this bottleneck by directly inferring MI in a single forward pass. Pret
rained on large-scale synthetic data with rich dependence patterns, InfoAtlas le
arns to identify diverse dependence structures and predict MI directly from the
dataset. Comprehensive experiments demonstrate that InfoAtlas matches state-of-t
he-art neural estimators in accuracy while achieving 100× speedup, can flexibly
 handle varying dimensions and sample sizes through a single unified model, and
generalizes effectively to complex, real-world scenarios. By reformulating MI es
timation as an inference task, InfoAtlas establishes a foundation for real-time
dependency analysis.
****

Verifying Meta-Awareness via Predictive Rewards in Reasoning Models
Yoonjeon Kim, Doohyuk Jang, Eunho Yang
Recent research on reasoning models explores the meta-awareness of language mode
ls, including their ability to determine optimal thinking duration, recognize kn
owledge boundaries, and structure concept-level thinking. While current large re
asoning models depend solely on answer-based verification, we show that adding m
eta-awareness objectives leads to significant performance gains over models with
out such meta-knowledge. **MAPR** utilizes a self-generated task of predicting r
ollout statistics - specifically length, pass-rate, and concepts used - allowing
 for verification against the actual statistics. Furthermore, by leveraging this
 self-predictive capability, the model can regulate its reasoning behavior by i)
 filtering out trivial or unsolvable prompts, ii) reducing lengthy generations t
hat tend to be incorrect, and iii) generating hints relevant to the problem. The
 results are inspiring: **MAPR** yields significant improvements in both accurac
y and training efficiency on various reasoning benchmarks. More specifically, ou
r method can speed up GRPO training by over 1.28$\times$ to reach the same perfo
rmance, and achieve 83.18\% gain in accuracy on AIME25, and a 13.04\% average ga
in over six mathematics benchmarks.

Recurrent Structural Policy Gradient for Partially Observable Mean Field Games

Clarisse Wibault, Johannes Forkel, Sebastian Rene Towers, Tiphaine Wibault, Juan Agustin Duque, George Whittle, Andreas Schaab, Yucheng Yang, Chiyuan Wang, Michael A Osborne, Benjamin Moll, Jakob Nicolaus Foerster

Mean Field Games (MFGs) provide a principled framework for modelling interactions in large population systems. However, algorithmic progress has been limited since model-free methods are high variance and exact methods scale poorly. Recent Hybrid Structural Methods (HSMs) reduce variance while maintaining tractability by leveraging low-dimensional individual state and action spaces and known transition dynamics to compute the exact expected return conditioned on Monte Carlo rollouts of common noise. However, HSMs have not been extended to partially observable settings. We propose *Recurrent Structural Policy Gradient* (RSPG), the first history-aware HSM for MFGs with public partial information. RSPG achieves an order-of-magnitude faster convergence than model-free RL methods while learning history-aware behaviour, unlike current HSMs. To facilitate research into MFGs, we also introduce MFAX, our JAX-based framework for MFGs that supports both analytic and sample-based mean-field updates.

Model Merging Scaling Laws in Large Language Models

Yuanyi Wang, Yanggan Gu, Yiming Zhang, Qi Zhou, Zhaoyi Yan, Congkai Xie, Xinyao Wang, Jianbo Yuan, Hongxia Yang

We study empirical scaling laws for language model merging measured by cross-entropy.

Despite its wide practical use, merging lacks a quantitative rule that predicts returns as we add experts or scale the model size.

We identify a compact power law that links model size and expert number: the size-dependent floor decreases with model capacity, while the merging tail exhibits clear diminishing returns in the number of experts.

The law holds in-domain and cross-domain, tightly fits measured curves across diverse architectures and methods (Average, TA, TIES, DARE), and explains two robust regularities: most gains arrive early, and variability shrinks as more experts are included.

Building on this, we present a simple theory that explains why gains fall roughly as \(1/k\) and links the floor and tail to properties of the base model and the diversity across domains. This law enables \emph{predictive planning}: estimate how many experts are needed to reach a target loss, decide when to stop adding experts, and trade off scaling the base model versus adding experts under a fixed budget—turning merging from heuristic practice into a computationally efficient, planable alternative to multitask training.

This suggests a scaling principle for distributed generative AI: predictable gains can be achieved by composing specialists, offering a complementary path toward AGI-level systems.

Distillation Models are Good Samplers for Diffusion Reinforcement Learning

Zunxu Liu, Aiqiu Wu, Zhaofan Qiu, Yingwei Pan, Ting Yao, Tao Mei

We present DMSampler, a framework that accelerates online diffusion reinforcement learning by replacing expensive training-time policy rollouts with a co-evolving few-step distilled sampler. Instead of repeatedly sampling the policy model for roughly 50 denoising steps, DMSampler generates reward-evaluation samples in only 4--8 steps while periodically re-distilling the sampler from the updated policy, yielding an order-of-magnitude reduction in rollout cost. The framework alternates between two stages: an RL phase that optimizes the policy using hybrid samples from the old policy and distilled sampler, and a distillation phase that realigns the few-step sampler to the improved policy. Intuitively, the distilled sampler acts as a fast proxy for the current policy during RL, and is refreshed whenever the policy improves so that sampling remains both efficient and aligned. Two designs make this loop stable and effective: hybrid distillation sampling preserves on-policy structure during rollout, and reward-aware distillation reuses high-reward trajectories to reduce forgetting during compression. Experiments on text-to-image and text-to-video generation show that DMSampler improves OCR, GenEval, and VBench performance while substantially reducing GPU hours, and t

hat the same idea can be combined with multiple diffusion RL optimizers. Our cod
e will be available at:
https://github.com/HiDream-ai/DMSampler.

World-Model Inspired Emotion-aware Token Refinement for Training-Free Multimodal
 Emotion Recognition
Kejun Liu, Zhe Chen, Yuanyuan Liu, ke Wang, Yibing Zhan, Wei Xiang, Hongyan Zhan
g
Multimodal Large Language Models (MLLMs) show promise for Multimodal Emotion Rec
ognition (MER) but often remain unreliable because sparse emotional cues could b
e easily overwhelmed and affected by redundant context. While fine-tuning is eff
ective, it is usually costly when using large models. Training-free methods like
 chain-of-thought reasoning provide a practical alternative, but they mostly rel
y on heuristic prompting to influence the model behaviors and do not explicitly
focus on emotion relevant tokens internally, which would allow decision-relevant
 emotional tokens to be diluted by environmental noise, resulting in unstable pr
edictions. To address this limitation without training, we rethink MER from a wo
rld-model perspective that treats emotion as a latent state inferred from noisy
and redundant multimodal observations. Under frozen parameters, this view sugges
ts that robustness depends on constraining why and how tokens contribute to infe
rence. Based on this insight, we propose WETR (World-Model inspired Emotion-awa
re Token Refinement), a training-free, plug-and-play regulator that reshapes tok
en usage through two mechanisms: Noise-suppressed Token Selection (NTS), which s
uppresses redundant intra-modal noise, and State-strengthened Token Reweighting
(STR), which amplifies decision-relevant emotional tokens. Experiments on multip
le MER benchmarks demonstrate that WETR consistently improves accuracy and stabi
lity under frozen parameters, which also improves token-level interpretability.
****
GUI-Spotlight: Adaptive Iterative Focus Refinement for Enhanced GUI Visual Groun
ding
Bin Lei, Nuo Xu, Ali Payani, Mingyi Hong, Chunhua Liao, Yu Cao, Caiwen Ding
Multimodal large language models (MLLMs) have markedly expanded the competence o
f graphical user-interface (GUI) systems, propelling them beyond controlled simu
lations into complex, real-world environments across diverse platforms. However,
 practical usefulness is still bounded by the reliability of visual grounding, i
.e., mapping textual references to exact on-screen elements. This limitation pre
vents the system from accurately performing pointer-level actions such as clicki
ng or dragging. To address it, we introduce GUI-Spotlight -- a model trained for
 image-grounded reasoning that dynamically invokes multiple specialized tools to
 iteratively narrow its focus to the relevant region of the screen, thereby subs
tantially improving visual grounding accuracy. On the ScreenSpot-Pro benchmark,
GUI-Spotlight trained with only 18.5K training samples achieves 52.8\% accuracy,
 surpassing V2P-7B (50.6\% with 9.6M training samples) and GTA-1-7B (50.1\% with
 1.56M training samples).
****
Adversarially Robust Control of Conditional Value-at-Risk via Rockafellar-Uryase
v Conformal Inference
Catherine Chen, Jingyan Shen, Zhun Deng, Lihua Lei
We present an online, distribution-free framework for controlling the Conditiona
l Value-at-Risk (CVaR), extending conformal tail risk control t
o non-stationary and adversarial environments. Unlike classical risk control met
hods, which rely on stationarity or linearity of expectation, our approach provi
des provable safety guarantees for a nonlinear tail risk functional under arbitr
ary data-generating processes that may drift or shift strategically over time. B
y leveraging deep connections between conformal tail risk control, online learni
ng, and the variational representation of CVaR introduced by Ro
ckafellar and Uryasev, we develop a novel procedure for online $\operatorname{CV
aR}$ control with adversarial regret guarantees. The proposed method operates wi
thout assumptions on the underlying data-generating process, making it broadly a
pplicable in modern high-stakes deployment settings. We prove that the realized

empirical CVaR is asymptotically controlled at the target level, and that the resulting control is asymptotically tight up to a finite-sample ${O}(1/\sqrt{T})$ conservatism gap. We demonstrate the effectiveness of our approach on portfolio risk management and toxicity mitigation for Large Language Models (LLMs), where rare but catastrophic failures dominate system risk.

FrameOracle: Learning What to See and How Much to See in Videos

Chaoyu Li, Tianzhi Li, Fei Tao, ZHENYU ZHAO, Ziqian Wu, Maozheng Zhao, Juntong Song, Cheng Niu, Pooyan Fazli

Vision-language models (VLMs) advance video understanding but operate under tight computational budgets, making performance dependent on selecting a small, high-quality subset of frames. Existing frame sampling strategies, such as uniform or fixed-budget selection, fail to adapt to variations in content density or task complexity. To address this, we present FrameOracle, a lightweight, plug-and-play module that predicts both (1) which frames are most relevant to a given query and (2) how many frames are needed. FrameOracle is trained via a curriculum that progresses from weak proxy signals, such as cross-modal similarity, to stronger supervision with FrameOracle-41K, the first large-scale VideoQA dataset with validated keyframe annotations specifying minimal sufficient frames per question. Extensive experiments across five VLMs and six benchmarks show that FrameOracle reduces 16-frame inputs to an average of 10.4 frames without accuracy loss. When starting from 64-frame candidates, it reduces inputs to 13.9 frames on average while improving accuracy by 1.5%, achieving state-of-the-art efficiency–accuracy trade-offs for scalable video understanding.

Learning the Neighborhood: Contrast-Free Multimodal Self-Supervised Molecular Graph Pretraining

Boshra Ariguib, Mathias Niepert, Andrei Manolache

High-quality molecular representations are essential for property prediction and molecular design, yet large labeled datasets remain scarce. While self-supervised pretraining on molecular graphs has shown promise, many existing approaches either depend on hand-crafted augmentations or complex generative objectives, and often rely solely on 2D topology, leaving valuable 3D structural information underutilized. To address this gap, we introduce C-FREE (**C**ontrast-**F**ree **R**epresentation learning on **E**go-n**e**ts), a simple framework that integrates 2D graphs with ensembles of 3D conformers. C-FREE learns molecular representations by predicting subgraph embeddings from their complementary neighborhoods in the latent space, using fixed-radius ego-nets as modeling units across different conformers. This design allows us to integrate both geometric and topological information within a hybrid Graph Neural Network (GNN)-Transformer backbone, without negatives, positional encodings, or expensive pre-processing. Pretraining on the GEOM dataset, which provides rich 3D conformational diversity, C-FREE achieves state-of-the-art results on MoleculeNet, surpassing contrastive, generative, and other multimodal self-supervised methods. Fine-tuning across datasets with diverse sizes and molecule types further demonstrates that pretraining transfers effectively to new chemical domains, highlighting the importance of 3D-informed molecular representations.

Mitigating Visual Hallucinations via Semantic Curriculum Preference Optimization in MLLMs

Yuanshuai li, Yuping Yan, Junfeng Tang, Zeqi Zheng, Yaochu Jin

Multimodal Large Language Models (MLLMs) have significantly improved the performance of various tasks, but continue to suffer from visual hallucinations, a critical issue where generated responses contradict visual evidence. While Direct Preference Optimization (DPO) is widely used for alignment, its application to MLLMs often fails to capture fine-grained semantic differences and encourages shortcut learning. To address these challenges, we propose Semantic Curriculum Preference Optimization (SCPO), a novel framework for MLLM alignment. SCPO employs a progressive, easy-to-hard curriculum built upon our Semantic Curriculum Preference Pairs dataset, which provides fine-grained semantic contrasts sorted by diffic

ulty. This curriculum is trained with a dynamic reference model and a novel symm etric, bidirectional objective to facilitate simultaneous learning from both tex tual and visual preferences. To our knowledge, SCPO is the first framework to un ify semantics, symmetry, and curriculum for MLLM alignment, effectively mitigati ng visual hallucinations. Extensive experiments on LLaVA models across various s cales and versions validate that SCPO demonstrates superior performance compared to baseline models on multiple hallucination benchmarks, reducing the hallucina tion rate by up to 62.9\%. Moreover, evaluations on generalized benchmarks show that SCPO improves factuality while preserving general capabilities, with its pe rformance remaining stable across general vision-language benchmarks. Code is av ailable \href{https://github.com/ShawnLee0910/SCPO}{here}.

Causal Structure Learning for Sparse Matrix Fill-in Reduction
Ziwei Li, Shuzi Niu, Tao Yuan, Huiyuan Li
The performance of sparse direct solvers is fundamentally governed by fill-in, i .e. new nonzero entries arising from the LU factorization of a sparse matrix, as they dictate memory footprint and subsequent computation time. For decades, a v ariety of graph-theoretic algorithms have aimed to minimize fill-in, a problem k nown to be both NP-hard and critically important. While recent deep learning met hods, optimizing surrogate fill-in objectives, show empirical promise and can ou tperform classical algorithms on certain matrices, they offer limited interpreta bility into the underlying mechanism of fill-in generation.
To address this, we propose a novel reordering approach, Causal Triplet Structur e Learning (CTS), which is grounded in the Fill-Path Theorem and reduces arbitra ry-length fill-paths to length-two candidate triplets, identifies the causal str uctures that trigger fill-in, and intervenes to block their formation.
Empirically, we design a multigrid-style GAT with KAN activations to learn verte x embeddings and introduce a causal triplet loss that discourages such structure s during training. Experiments on the SuiteSparse Matrix Collection demonstrate that our method reduces fill-in by 6$\times$, leading to 12$\times$ speedup in f actorization time compared to state-of-the-art methods on Chemical Process Simul ation and Computational Fluid Dynamics matrices.

SuperHype: Hypergraph Generation via Graph-Superposition Decomposition
Lucas Gantes, Abele M■lan, Roberto Gheda, Robert Birke, Lydia Chen
Hypergraphs are graph generalizations with key applications in domains such as h ealthcare, where strict data privacy requirements apply, or bioinformatics, wher e testing new compounds is costly. However, due to their combinatorial nature, h ypergraph representations are often either intractable or lead to significant in formation loss. For this reason, research into hypergraph synthesis is limited, and state-of-the-art approaches yield poor generation quality in terms of overal l structural patterns and graph-level validity. To address such shortcomings, we introduce SuperHype, an exact and tractable hypergraph diffusion model. The cor e of SuperHype is the graph-superposition decomposition, a novel representation that embeds a hypergraph into a multi-layer graph, enabling a tractable represe ntation with no loss of generalization. To generate new samples from such repres entations, we introduce a Graph-Superposition Transformer that treats the superp osition as an interconnected sequence of layers. Moreover, we enhance the model' s performance by incorporating hypergraph-specific auxiliary features and aggreg ating indirect node interactions via triplet pooling. Our evaluation across five datasets shows that SuperHype generally reproduces local and global connectivit y patterns with superior fidelity compared to state-of-the-art baselines.

Learning Discrete Diffusion on Graphs via Free-Energy Gradient Flows
Dario Rancati, Jan Maas, Francesco Locatello
Diffusion-based models on continuous spaces have seen substantial recent progres s through the mathematical framework of gradient flows, leveraging the Wasserste in-2 (${W}_2$) metric via the Jordan-Kinderlehrer-Otto (JKO) scheme. Despite the increasing popularity of diffusion models on discrete spaces using continuous-t ime Markov chains, a parallel theoretical framework based on gradient flows has

remained elusive due to intrinsic challenges in translating the ${W}_2$ distance directly into these settings. In this work, we propose the first computational approach addressing these challenges, leveraging an appropriate metric W_K on the simplex of probability distributions, which enables us to interpret widely used discrete diffusion paths, such as the discrete heat equation, as gradient flows of specific free-energy functionals. Through this theoretical insight, we introduce a novel methodology for learning diffusion dynamics over discrete spaces, which recovers the underlying functional directly by leveraging first-order optimality conditions for the JKO scheme. The resulting method optimizes a simple quadratic loss, trains extremely fast, does not require individual sample trajectories, and only needs a numerical preprocessing computing W_K-geodesics. We validate our method through extensive numerical experiments on synthetic data, showing that we can recover the underlying functional for a variety of graph classes, as well as cell type prediction in single-cell trajectory data. Code will be made available at github.com/dariorancati/discrete-gradient-flow.

TabularBERT: Binning-Based Self-Supervised Learning for Tabular Representation
Beomjin Park, Seunghwan An, Sungchul Hong, Hosik Choi
Tabular data is one of the most fundamental and widely used formats for representing structured information.
Classical machine learning algorithms continue to achieve substantial success in extracting predictive patterns and constructing accurate models from structured data; however, representation learning approaches that extend language-model-based methods to the tabular setting have opened new opportunities.
Nevertheless, conventional tokenization procedures and token embedding mechanisms are not well-suited to numerical variables, as they fail to preserve key numerical properties, including proximity structure and ordinal relationships.
To address this limitation, we propose TabularBERT, a Transformer-based model that discretizes numerical variables via binning-based tokenization and learns representations that account for numerical proximity and ordinal information while capturing conditional dependencies among variables through masked self-supervised pretraining.
We empirically demonstrate the effectiveness and interpretability of the proposed approach, highlighting the benefits of language-model-based representation learning in the tabular domain.

Unbiased Principles, Robust Rewards
Qingnan Ren, Zhen Fang, Shiting Huang, Yu Zeng, Lin Chen, Zehui Chen, Feng Zhao
Reward models are central to Reinforcement Learning from Human Feedback (RLHF), especially for open-ended tasks where evaluation is inherently multi-dimensional. Recent Generative Reward Models (GRMs) improve interpretability by producing natural-language rationales and task-specific evaluation principles. However, most existing GRMs generate principles after reading the actor's response, i.e., $Q +R \rightarrow P$. We show that this coupling induces Principle Drift: when the actor performs reward hacking (e.g., verbosity, self-aggrandizement, or hallucinated self-justifications), the reward model may shift its criteria to rationalize the response, yielding inflated scores that in turn reinforce hacking during RL.
We propose IP-GRM (Independent Principle GRM), a two-stage framework that first generates principles solely from the question ($Q \rightarrow P$) and then evaluates the response conditioned on (Q, R, P). This decoupling keeps criteria invariant to response content, producing more objective and stable reward signals.
For efficient training, we further introduce a Principle Cache strategy that reuses principles within a group, improving GRPO throughput by 23.66\% while maintaining strict intra-group consistency. In GRPO training on creative writing, IP-GRM suppresses reward hacking and improves WritingBench and CreativeWriting-v3 by up to +4.6 and +7.1 points based on Qwen3-8B, achieving state-of-the-art performance among open-source models.
The model and dataset are open-sourced at https://github.com/ShadeCloak/IP-GRM.

When Replanning Becomes the Bottleneck: Budgeted Replanning for Embodied Agents
Shuaijun Liu, Feiyang You, Xingwei Chen, Ningxin Su
Embodied agents replan frequently to recover from execution drift, partial observability, and coordination hazards, but each LLM-based replanning call can consume an accumulated textual context that grows over time and across agents. Once this context becomes large, replanning latency develops heavy tails and can miss real-time deadlines even when task success remains high, a failure mode that is hard to detect from average latency or success alone. We present BRACE, a controller that formulates replanning as a budgeted control loop by deciding whether to replan, selecting a replanning mode, and allocating an explicit token budget and latency service-level objective (SLO) while accounting for optional efficiency modules. As a reusable component, we introduce E-RECAP, a cost-aware progressive token pruning method that predicts token utility and prunes replanning contexts across transformer layers while preserving critical head and tail tokens. Across Meta Habitat, RoboFactory, and AirSim, BRACE with E-RECAP reduces replanning-call token counts by 62–92% and SLO violation rates from 85.5–100.0% to 4.7–50.0% in settings where task success is already saturated. In a harder RoboFactory setting where open-loop, frozen-plan, and No BRACE all fail, BRACE + E-RECAP reaches 80.0% success with 4.6% SLO violations, demonstrating that tail-aware per-call budgeting is effective across embodied platforms.

V_0: A Generalist Value Model for Any Policy at State Zero
Yi-Kai Zhang, Zhiyuan Yao, Hongyan Hao, Yueqing Sun, Qi GU, Hui Su, Xunliang Cai, De-Chuan Zhan, Han-Jia Ye
Policy gradient methods rely on a baseline to measure the relative advantage of an action. In Actor-Critic LLM training (\textit{e.g.}, PPO), this baseline is typically estimated by a Value Model as large as the policy. However, as the policy evolves, the value model requires expensive, synchronous training. To avoid this overhead, GRPO eliminates the value model by using the average reward of group rollouts as the baseline; yet, this necessitates extensive sampling to maintain stability. In this paper, we propose V_0, a Generalist Value Model capable of estimating the expected performance of any model on unseen prompts without parameter updates. We reframe value estimation by treating the policy's dynamic capability as an explicit context input, leveraging a history of instruction-performance pairs to dynamically profile the model. Acting as a resource scheduler, V_0 predicts success rates prior to rollout during GRPO training for efficient sampling budget allocation. During deployment, it functions as a router dispatching instructions to the most cost-effective model. Empirical results demonstrate that V_0 significantly outperforms heuristic budget allocation and achieves a Pareto-optimal performance-cost trade-off in LLM routing.

Internalizing Safety Understanding in Large Reasoning Models via Verification
Yi Zhang, Yuxin Chen, Leheng Sheng, Dongcheng Zhang, Chaochao Lu, Xiang Wang, An Zhang
While explicit Chain-of-Thought (CoT) empowers large reasoning models (LRMs), it enables the generation of riskier final answers.
Current alignment paradigms primarily rely on externally enforced compliance, optimizing models to detect malicious prompts rather than evaluating the safety of their own outputs.
We argue that this approach remains largely behavioral: our empirical analysis reveals that ostensibly aligned models lack intrinsic safety understanding, often failing to verify their own response safety and remaining vulnerable to adversarial jailbreaks.
To address this fundamental limitation, we propose Safety Internal (SInternal), a framework that internalizes safety specifications by training LRMs exclusively on safety verification tasks to critique their own generated answers using expert reasoning trajectories.
We demonstrate that learning to verify induces a strong generalization for response safety, significantly enhancing robustness against out-of-domain jailbreaks. Furthermore, when combined with reinforcement learning, SInternal serves as a s

uperior initialization compared to standard supervised fine-tuning, suggesting t
hat internalizing safety understanding creates a more robust foundation for alig
nment than merely mimicking safe behaviors.
Our codes are available at \url{https://github.com/AlphaLab-USTC/SInternal}

Deriving Neural Scaling Laws from the Statistics of Natural Language
Francesco Cagnetta, Allan Raventos, Surya Ganguli, Matthieu Wyart
Despite the fact that experimental neural scaling laws have substantially guided
 empirical progress in large-scale machine learning, no existing theory can quan
titatively predict the exponents of these important laws for any modern LLM trai
ned on any natural language dataset. We provide the first such theory in the cas
e of data-limited scaling laws. We isolate two key statistical properties of lan
guage that _alone_ can predict neural scaling exponents: (i) the decay of pairwi
se token correlations with time separation between token pairs, and (ii) the dec
ay of the next-token conditional entropy with the length of the conditioning con
text. We further derive a simple formula in terms of these statistics that predi
cts data-limited neural scaling exponents from first principles _without any_ fr
ee parameters or synthetic data models. Our theory exhibits a remarkable match w
ith experimentally measured neural scaling laws obtained from training GPT-2 and
 LLaMA style models from scratch on two qualitatively different benchmarks, Tiny
Stories and WikiText.

How to Correctly Report LLM-as-a-Judge Evaluations
Chungpa Lee, Thomas Zeng, Jongwon Jeong, Jy-yong Sohn, Kangwook Lee
Large language models (LLMs) are widely used as scalable evaluators of model res
ponses in lieu of human annotators. However, imperfect sensitivity and specifici
ty of the LLM judges induce bias in naive evaluation scores. We propose a simple
 plug-in framework that corrects this bias and enables statistically principled
uncertainty quantification. Our framework constructs confidence intervals that a
ccount for uncertainty from both the test dataset and a human-labeled calibratio
n dataset. Additionally, it uses an adaptive strategy to allocate calibration sa
mples for tighter intervals. Importantly, we characterize parameter regimes defi
ned by the true evaluation score and the LLM judge’s sensitivity and specificity
 in which our LLM-based evaluation yields more reliable estimates than human-onl
y evaluation. Moreover, we show that our framework remains unbiased under distri
bution shift between the test and calibration datasets, in contrast to existing
approaches.

CooT: Learning to Coordinate In-Context with Coordination Transformers
Huai-Chih Wang, Hsiang-Chun Chuang, Hsi-Chun Cheng, Dai-Jie Wu, Shao-Hua Sun
Effective coordination among unfamiliar partners remains a major challenge in mu
lti-agent systems. Existing approaches, such as population-based methods, improv
e robustness through diversity but often lack mechanisms for efficient adaptatio
n beyond the training distribution. Fine-tuning is also impractical for few-shot
 learning because it requires a large number of interactions for meaningful impr
ovement.
To address these limitations, we propose Coordination Transformers (CooT), a fra
mework that leverages in-context learning (ICL) for real-time partner adaptation
. Unlike prior ICL approaches that focus on task generalization, CooT is designe
d to generalize across diverse partner behaviors. Trained on trajectories from b
ehavior-preferring agents, it learns to align actions with partner intentions pu
rely through observation. We evaluate CooT on two challenging multi-agent benchm
arks: Overcooked and Google Research Football.
Results show that CooT consistently outperforms population-based methods, gradie
nt-based fine-tuning, and Meta-RL baselines, achieving stable and rapid adaptati
on without parameter updates. Human evaluations also identify CooT as a preferre
d collaborator, and our ablations confirm its ability to adapt quickly to new pa
rtners and remain stable under sudden partner changes, making it reliable for re
al-world human-AI collaboration.

Beyond Blind Noising: Disentangled Visual Rectification for Hallucination Mitigation in MLLMs
Yujia Chen, Rui Sun, Bingzhou Wang, Huayu Mai, Wangkai Li, Zhaoyang Li, Aibing Li, Wenzhang SUN
Visual Contrastive Decoding (VCD) mitigates hallucinations in Multimodal Large Language Models (MLLMs) by penalizing the output shift from noise-perturbed images, assuming this shift captures the hallucination direction. We prove this assumption flawed: noise-induced drift in Language-Image Pretrained (LIP) encoders is a \emph{coupled vector} entangling (i) structural degradation from corrupted visual information with (ii) hallucination induction from linguistic prior activation. VCD's indiscriminate penalty inevitably suppresses valid visual semantics. Our key insight is that Self-Supervised Learning (SSL) encoders exhibit \emph{only} structural degradation under noise—geometrically orthogonal to hallucination paths—enabling principled disentanglement via LIP--SSL differential response. We propose \textbf{Disentangled Visual Rectification (DVR)}, a training-free dual-stream framework performing visual-layer rectification and decoding-layer contrast on purified representations. DVR achieves approximately $5\times$ theoretical error reduction over VCD and establishes SOTA performance on POPE, MME, LLaVA-Bench and CHAIR benchmarks.

Anatomy of Massive Activations and Attention Sinks
Shangwen Sun, Alfredo Canziani, Yann LeCun, Jiachen Zhu
We study two recurring phenomena in Transformer language models: massive activations, in which a small number of tokens exhibit extreme outliers in a few channels, and attention sinks, in which certain tokens attract disproportionate attention mass regardless of semantic relevance.
Prior work observes that these phenomena frequently co-occur and often involve the same tokens, but their functional roles and causal relationships remain unclear.
Through systematic experiments, we show that the co-occurrence is largely an architectural artifact of modern Transformer design, and that the two phenomena serve related but distinct functions.
Massive activations operate globally: they induce near-constant hidden representations that persist across layers, effectively functioning as implicit parameters of the model.
Attention sinks operate locally: they modulate attention outputs across heads and bias individual heads toward short-range dependencies.
We identify the pre-norm configuration as the key choice that enables the co-occurrence and show that ablating it causes the two phenomena to decouple.

Generative Neural Operators through Diffusion Last Layer
Sungwon Park, Anthony Zhou, Hongjoong Kim, Amir Barati Farimani
Neural operators provide a powerful framework for learning discretization invariant mappings between function spaces, but standard deterministic models do not capture predictive uncertainty. We introduce *diffusion last layer* (DLL), a modular probabilistic output head for neural operator backbones. DLL represents target fields through an input dependent low rank expansion inspired by the Karhunen--Lo\`eve expansion and learns a conditional diffusion model over the corresponding coefficient space. This design enables efficient distributional modeling while preserving the structural advantages of operator learning. On stochastic PDE benchmarks with random forcing, DLL achieves strong distributional fidelity and performs competitively with pixel space and conventional latent diffusion baselines. In deterministic long horizon rollout tasks, DLL improves rollout stability over the underlying backbone and provides useful estimates of predictive uncertainty under compounding autoregressive errors. These results suggest that diffusion modeling in learned coefficient spaces offers a practical route to uncertainty aware neural operators. Code is available at https://github.com/sungwpark/dll-no

EEG-Based Multimodal Learning via Hyperbolic Mixture-of-Curvature Experts

Runhe Zhou, Shanglin Li, Guanxiang Huang, Xinliang Zhou, Qibin Zhao, Motoaki Kawanabe, Yi Ding, Cuntai Guan

Electroencephalography (EEG)-based multimodal learning integrates brain signals with complementary modalities to improve mental state assessment, providing great clinical potential.
The effectiveness of such paradigms largely depends on the representation learning on heterogeneous modalities.
For EEG-based paradigms, one promising approach is to leverage their hierarchical structures, as recent studies have shown that both EEG and associated modalities (e.g., facial expressions) exhibit hierarchical structures reflecting complex cognitive processes.
However, Euclidean embeddings struggle to represent these hierarchical structures due to their flat geometry, while hyperbolic spaces, with their exponential growth property, are naturally suited for them.
In this work, we propose EEG-MoCE, a novel hyperbolic mixture-of-curvature experts framework designed for multimodal neurotechnology.
EEG-MoCE assigns each modality to an expert in a learnable-curvature hyperbolic space, enabling adaptive modeling of its intrinsic geometry.
A curvature-aware fusion strategy then dynamically weights experts, emphasizing modalities with richer hierarchical information.
Extensive experiments on benchmark datasets demonstrate that EEG-MoCE achieves state-of-the-art performance, including emotion recognition, sleep staging, and cognitive assessment.
Code is available at https://github.com/zhourunhe/EEG-MoCE.

Prefix-Cache-Aware Data Reordering for LLM-Augmented Database Analytics

Yingze Li, Dong Wang, Yiming Guo, Yao Chen, Hongzhi Wang, Bingsheng He

LLM-augmented database analytics face a major bottleneck in the costly prefill phase. Although relational tables inherently contain repeated attribute values, standard row-by-row processing produces fragmented prompt layouts that obscure shared prefixes, thereby minimizing opportunities for prefix KV cache reuse and constraining system efficiency. Existing solutions typically employ heuristic or exhaustive search methods to reorder prompt layouts, but these approaches can be inefficient and may not leverage the structural properties of relational tables. We address this challenge by formulating prefix-cache-aware prompt layout optimization as a problem rooted in the isomorphism between prefix-cache reuse and the radix tree topology induced by the relational data distribution. Building on this perspective, we introduce a practical greedy tree-shaping algorithm that efficiently selects row and column orderings to maximize prefix overlap. Our approach, SOLO, improves prefill throughput by up to 90.3\% under fixed prefix-cache budget. Moreover, it reduces planning overhead by up to 242$\times$ compared to state-of-the-art baselines.

Brain Networks Should Be Learned, Not Constructed

Liang Yang, Shuai Zhai, Ziyi Ma, Jiaming Zhuo, Di Jin, Chuan Wang, Zhen Wang, Xiaochun Cao

The construction of the brain functional network often follows the hand-crafted Correlation Coefficients without any learnable components.
Meanwhile, most efforts are made to the models, such as graph neural networks, that make predictions with the constructed brain network as input. Unfortunately, the fixed brain network may lose critical information during construction and lead to difficulty in performance improvement, even with deliberately designed graph models. From this perspective, the current situation is similar to the machine learning community, i.e., hand-crafted features and learnable predictors, before the advent of representation learning.
In fact, the brain network can be regarded as a graph-structured learnable representation of the brain. By drawing on representation learning, this paper presents the Brain Representation (BRep) learning problem. To this end, the widely used linear and nonlinear correlations are enhanced to be high-order, parametric, and learnable. The expressive brain representation shifts the heavy computational

burden away from downstream architectures, enabling a simple yet accurate predictor. Theoretical analysis guarantees the model's universal approximation to any U/V-statistics.
Extensive evaluations demonstrate that BRep possesses superior performance, high efficiency, and interpretability. The code is available at https://github.com/Kevin-916/BRep-demo/.

On Densest k-Subgraph Mining and Diagonal Loading: Optimization Landscape and Finite-Step Exact Convergence Analysis
Qiheng Lu, Nicholas D. Sidiropoulos, Aritra Konar
The Densest k-Subgraph (DkS) is a fundamental combinatorial problem known for its theoretical hardness and breadth of applications. Recently, Lu et al. (AAAI 2025) introduced a penalty-based non-convex relaxation that achieves promising empirical performance; however, a rigorous theoretical understanding of its success remains unclear. In this work, we bridge this gap by providing a comprehensive theoretical analysis. We first establish the tightness of the relaxation, ensuring that the global maximum values of the original combinatorial problem and the relaxed problem coincide. Then we reveal the benign geometry of the optimization landscape by proving a strict dichotomy of stationary points: all integral stationary points are local maximizers, whereas all non-integral stationary points are strict saddles with explicit positive curvature. We propose a saddle-escaping Frank--Wolfe algorithm and prove that it achieves exact convergence to an integral local maximizer in a finite number of steps.

Detecting Errors in AI-Generated Annotations: When and Why Semantic Neighbors Help
Na Di, Ling Li, Zhe Tang, Hao Cheng, Jinlong Pang, Jiaheng Wei, Zhaowei Zhu
Large language models (LLMs) and vision-language models (VLMs) have emerged as efficient annotators for tasks such as generation and classification. While these models offer significant cost and speed advantages over human annotation, a critical challenge remains: existing self-evaluation methods, such as LLM-as-judge, often lack reliable reference-based calibration for error detection. We address this limitation by introducing **SAGE** (**S**emantic-**A**nchored Jud**G**m**E**nt), a method that leverages semantically similar samples retrieved via k-nearest-neighbor as references for annotation verification. We provide a theoretical framework that derives a closed-form expression for the error detection AUROC, which can be decomposed into three factors: intrinsic separability, reference-induced mean shift, and noise reduction through averaging. This decomposition reveals *when* semantic neighbors help (when references are both semantically matched and correct) and *why* (by providing reference-based calibration that raises scores for correct annotations and lowers scores for incorrect ones). Experiments on LLM generation, VLM captioning, and classification tasks validate our theoretical framework: SAGE improves error detection when semantic neighbors provide reliable reference-based calibration, and our decomposition offers insights into when direct scoring or alternative strategies may be preferred. Our code is available at https://github.com/dina-1205/SAGE.

Learning Flexible Generalization in Video Quality Assessment by Bringing Device and Viewing Condition Distributions
Nikolay Safonov, Dmitriy S. Vatolin
Video quality assessment (VQA) plays a critical role in optimizing video delivery systems. While numerous objective metrics have been proposed to approximate human perception, the perceived quality strongly depends on viewing conditions and display characteristics. Factors such as ambient lighting, display brightness, and resolution significantly influence the visibility of distortions. In this work, we address the question of the multi-screen quality assessment on mobile devices, as this area still tends to be under-covered. We introduce a first large-scale subjective dataset collected across more than different 300 Android devices, accompanied by metadata on viewing conditions and display properties. We propose a strategy for aggregated score extraction and adaptation of VQA models to de

vice-specific quality estimation. Our results demonstrate that incorporating dev ice and context information enables more accurate and flexible quality predictio n, offering new opportunities for fine-grained optimization in streaming service s. Ultimately, this work advances the development of perceptual quality models t hat bridge the gap between laboratory evaluations and the diverse conditions of real-world media consumption. We made the dataset and the code available at http s://videoprocessing.github.io/device-viewing-conditions.

Anti-causal domain generalization: Leveraging unlabeled data
Sorawit Saengkyongam, Juan L. Gamella, Andrew Miller, Jonas Peters, Nicolai Mein shausen, Christina Heinze-Deml
The problem of domain generalization concerns learning predictive models that ar e robust to distribution shifts when deployed in new, previously unseen environm ents. Existing methods typically require labeled data from multiple training env ironments, limiting their applicability when labeled data are scarce. In this wo rk, we study domain generalization in an anti-causal setting, where the outcome causes the observed covariates. Under this structure, environment perturbations that affect the covariates do not propagate to the outcome, which motivates regu larizing the model's sensitivity to these perturbations. Crucially, estimating t hese perturbation directions does not require labels, enabling us to leverage un labeled data from multiple environments. We propose two methods that penalize th e model's sensitivity to variations in the mean and covariance of the covariates across environments, respectively, and prove that these methods have worst-case optimality guarantees under certain classes of environments. Finally, we demons trate the empirical performance of our approach on a controlled physical system and a physiological signal dataset.

Preference-Enhanced Reinforcement Learning for Pluralistic Image Inpainting
Peng Zhou, Muqi Huang, Tianshuo Qu, Jingyang Wang, kun Zhou, Chuan Li, Feng Shi, Shi Chen, Yun Xiong
Existing image inpainting frameworks rely on strictly supervised training paradi gms, often suffering from an over-reliance on ground-truth reconstruction, which leads to conservative outputs with misaligned creativity and limited diversity. To this end, we propose the first framework to explore Group Relative Policy Opt imization (GRPO) and Direct Preference Optimization (DPO) for text-guided image inpainting, formulating an efficient online reinforcement learning pipeline that enables flexible, human-aligned aesthetic control via a preference scoring mode l. Crucially, by decoupling the rigid one-to-one correspondence between text pro mpts and masked images, our method enables the model to explore diverse, control lable, and high-quality solutions beyond a single target. Furthermore, to balanc e semantic consistency with physical naturalness at mask boundaries, we introduc e a scale-aware dynamic reward mechanism that adaptively emphasizes boundary gra dient coherence for small occlusions while prioritizing visual aesthetics in lar ge-scale generation. Extensive experiments demonstrate that our approach consist ently produces higher-quality results across different backbone architectures su ch as Stable Diffusion and FLUX, significantly enhancing the generative capacity of base models.

Neural Collapse by Design: Learning Class Prototypes on the Hypersphere
Panagiotis Koromilas, Theodoros Giannakopoulos, Mihalis Nicolaou, Yannis Panagak is
Supervised classification has a theoretical optimum, Neural Collapse (NC), yet n either of its two dominant paradigms reaches it in practice. Cross entropy (CE) leaves radial degrees of freedom unconstrained and converges to a degenerate geo metry, while supervised contrastive learning (SCL) drives features toward NC dur ing pretraining but discards this structure in a post hoc linear probing phase. We show that both paradigms are different appearances of the same method that co ntrasts prototypes on the unit hypersphere, and that closing the gap requires fi xing each at its point of failure. From the CE side, we propose NTCE and NONL, t wo normalized losses that import contrastive optimization's missing ingredients

into classifier learning: a large effective negative set and decoupled alignment and uniformity terms. From the SCL side, we prove that SCL's objective already optimizes throughout training for a principled classifier whose weights are the class mean embeddings, making linear probing both redundant and harmful. Empirically, on four benchmarks including ImageNet-1K, NTCE and NONL surpass CE accuracy, closely approximate NC ($\geq 95\%$), and match CE's converged NC on 4/5 metrics in under 7.5% of its iterations, while SCL with fixed prototypes matches linear probing without the hours-long classifier training phase. The learned geometry yields $+5.5\%$ mean relative improvement in transfer learning, up to $+8.7\%$ under severe class imbalance, and improved robustness to corruptions on ImageNet-C. Our work recasts supervised learning as prototype learning on the hypersphere, with NC reached *by design*.

From Pixels to Tokens: A Systematic Study of Latent Action Supervision for Vision-Language-Action Models
Yihan Lin, Haoyang Li, Yang Li, Haitao Shen, Yihan Zhao, Chao Shao, Jing Zhang
Latent actions serve as an intermediate representation that enables consistent modeling of vision-language-action (VLA) models across heterogeneous datasets. However, approaches to supervising VLAs with latent actions are fragmented and lack a systematic comparison. This work structures the study of latent action supervision from two perspectives: (i) regularizing the trajectory via image-based latent actions, and (ii) unifying the target space with action-based latent actions. Under a unified VLA baseline, we instantiate and compare four representative integration strategies. Our results reveal a formulation-task correspondence: image-based latent actions benefit long-horizon reasoning, whereas action-based latent actions excel at complex motor coordination. Furthermore, we find that directly supervising the VLM with discrete latent action tokens yields the most effective performance. Finally, our experiments offer initial insights into the benefits of latent action supervision in mixed-data, suggesting a promising direction for VLA training.
****

Recognize Your Orchestrator: An Entropy Dynamics Perspective for LLM Multi-Agent Systems
Junze Zhu, Weihao Chen, Xuanwang Zhang, Zhen Wu, Xinyu Dai
The transition from single-turn models to Multi-Agent Systems (MAS) promises enhanced problem-solving capabilities, yet the centralized orchestration topology remains a critical point of fragility. To analyze this, we propose a Mean-Field Entropy Dynamics framework, modeling the orchestration process as a system governed by the competing forces of task resolution and cumulative context loading. To facilitate high-resolution validation, we introduce Inverse Workflow Generation (IWG), a multi-agent pipeline that synthesizes process-verifiable, high-complexity benchmarks with dense intermediate checkpoints. We demonstrate that our entropy dynamics model fits empirical trajectories, providing physically interpretable parameters that quantify system stability and performance collapse. Crucially, our analysis uncovers a ``Reasoning Trap": while reasoning-heavy models excel in isolated tasks, they frequently fail as orchestrators due to context squeezing. By elucidating the physical mechanisms underlying the Orchestrator and quantifying systemic uncertainty, our findings offer insights for the architectural design development of Multi-Agent Systems in prospective research.
****

Causal-JEPA: Learning World Models through Object-Level Latent Masking
Heejeong Nam, Quentin Le Lidec, Lucas Maes, Yann LeCun, Randall Balestriero
World models require robust relational understanding to support prediction, reasoning, and control. While object-centric representations provide a useful abstraction, they are not sufficient to capture interaction-dependent dynamics. We therefore propose C-JEPA, a simple and flexible object-centric world model that extends masked joint embedding prediction from image patches to object-centric representations. By masking object-level latents and requiring each masked object state to be inferred from the surrounding context, C-JEPA imposes structured partial observability during training, creating counterfactual-like prediction querie

s that discourage shortcut solutions and make interaction-dependent prediction n ecessary under the learning objective. Empirically, C-JEPA leads to consistent g ains in visual question answering, with an absolute improvement of about 20\% in counterfactual reasoning over the same architecture without object-level maskin g. On agent control tasks, C-JEPA enables substantially more efficient planning by using only 1\% of the total latent input features required by patch-based wor ld models, while achieving comparable performance. Finally, we provide a formal analysis demonstrating that object-level masking induces useful inductive bias b y controlling observability. Our code is available at https://github.com/galilai -group/cjepa.

Antidistillation Fingerprinting

Yixuan Even Xu, John Kirchenbauer, Yash Savani, Asher Trockman, Alexander Robey, Tom Goldstein, Fei Fang, J Zico Kolter

Model distillation enables efficient emulation of frontier large language models (LLMs), creating a need for robust mechanisms to detect when a third-party stud ent model has trained on a teacher model's outputs. However, existing fingerprin ting techniques that could be used to detect such distillation rely on heuristic perturbations that impose a steep trade-off between generation quality and fing erprinting strength, often requiring significant degradation of utility to ensur e the fingerprint is effectively internalized by the student. We introduce ***an tidistillation fingerprinting*** (ADFP), a principled approach that aligns the f ingerprinting objective with the student's learning dynamics. Building upon the gradient-based framework of *antidistillation sampling*, ADFP utilizes a proxy m odel to identify and sample tokens that directly maximize the expected detectabi lity of the fingerprint in the student after fine-tuning, rather than relying on the incidental absorption of the un-targeted biases of a more naive watermark. Experiments on GSM8K, OASST1, and MBPP demonstrate that ADFP achieves a signific ant Pareto improvement over state-of-the-art baselines, yielding stronger detect ion confidence with minimal impact on utility across mathematical reasoning, dia logue, and code generation, even when the student model's architecture is unknow n.

LitReview Arena: Evaluating Literature Review Agents with Battle-style Peer Revi ew Platform

Ruotong Zhao, zhiyu chen, Xurui Liu, Haidong Xue, Dong Liang, Jigao Fu, Wu YanBi ao, Yuanyi Zhen, Fengli Xu, Yong Li

Literature reviews are essential to scientific progress, but rigorously evaluati ng automatically generated reviews remains difficult because many aspects of res earch utility depend on expert judgment rather than reference-overlap metrics. W e introduce \textbf{LitReview Arena}, a battle-style evaluation platform with a structured protocol tailored to literature review quality: domain experts with A I paper-writing experience compare anonymized drafts, are matched to topics with in their expertise, and provide dimension-wise outcomes over five literature-rev iew-specific criteria. From this protocol, we collect 3k expert judgments, each containing five dimension-wise outcomes, and show that even the strongest curren t systems win only 23.0\% of decisive matches against human drafts on overall ut ility, while agentic LLMs such as Sonar Deep Research substantially outperform b ase language models by over 60\%. We further find that existing LLM-as-a-judge m ethods are substantially misaligned with human experts (Spearman's $\rho \approx 0.467$), especially on synthesis-heavy criteria such as paper structure and res earch suggestions. Using the collected preference data, we provide an expert-cal ibrated evaluator, LitJudge, which improves alignment to $\rho \approx 0.78$, co mparable to inter-expert consistency; code and data are publicly available at ht tps://github.com/VanellopeAsher/LitReview-Arena.

C^{2}R: Cross-sample Consistency Regularization Mitigates Feature Splitting an d Absorption in Sparse Autoencoders

Haoran Jin, Xiting Wang, Shijie Ren, Hong Xie, Defu Lian

Sparse Autoencoders (SAEs) are widely used to interpret large language models by

decomposing activations into sparse, human-understandable features, but scaling to large dictionaries exposes fundamental challenges. Systematic studies reveal pervasive feature splitting that fragments coherent concepts into non-atomic latents and widespread feature absorption that creates arbitrary exceptions in general features, severely compromising latent reliability. These issues stem from inconsistent latent assignment across samples: without cross-sample constraints, per-sample optimization often allows a single underlying concept to be inconsistently distributed across multiple redundant or interfering latents. To address this, we introduce C^{2}R (\underline{\textbf{C}}ross-sample \underline{\textbf{C}}onsistency \underline{\textbf{R}}egularization). C^{2}R explicitly encourages that each semantic feature is consistently represented by a unified latent across the batch by penalizing the co-activation of directionally similar latents. Comprehensive evaluation demonstrates that C^{2}R effectively mitigates both splitting and absorption while, crucially, preserving reconstruction fidelity, providing a principled solution that enhances latent interpretability without degrading model performance. Source code is available\footnote{\url{https://github.com/hr-jin/Cross-sample-Consistency-Regularization}}.

Breaking the Lock-in: Diversifying Text-to-Image Generation via Representation Modulation

Dahee Kwon, Haeun Lee, Jaesik Choi

Recent text-to-image models built on large-scale Transformer backbones and flow-based objectives deliver strong text–image alignment and high visual quality, yet often produce overly similar samples under a fixed prompt. Existing diversity-enhancement methods alleviate this, but typically require expensive sampling or auxiliary optimization, incurring non-trivial overhead. To investigate the root cause of this homogeneity, we examine intermediate Transformer features and observe that the zero-frequency spatial average (DC) component rapidly converges across seeds early in generation, causing early trajectory lock-in that limits downstream variation. Building on this, we propose DC Attenuation for diVersity Enhancement (\textbf{DAVE}), a training-free representation-level intervention that selectively attenuates this component in the early regime. DAVE preserves the sampling pipeline with negligible overhead, improving prompt-consistent diversity while maintaining competitive image quality.

Shapley Neuron Values for Continual Learning: Which Neurons Matter Most?

Mohammad Ali Vahedifar, Abhisek Ray, Qi Zhang

Continual learning enables neural networks to learn tasks sequentially without forgetting previously acquired knowledge. However, neural networks suffer from catastrophic forgetting, where learning new tasks degrades performance on earlier ones. We address this problem with **Shapley Neuron Valuation (SNV)**, a principled framework that quantifies Neuron importance in continual learning, grounded in cooperative game theory. SNV selectively freezes important Neurons while keeping others plastic, enabling **buffer-free** continual learning without expanding architecture. Experiments on ImageNet-1k show that SNV consistently outperforms existing buffer-free methods. In particular, SNV improves accuracy by **+2.88\%** in the class incremental learning and **+6.46\%** in the task incremental learning scenarios compared to the second baseline.

Flash-GRPO: Efficient Alignment for Video Diffusion via One-Step Policy Optimization

Xiaoxuan He, Siming Fu, Zeyue Xue, Weijie Wang, Ruizhe He, Yuming Li, Dacheng Yin, Shuai Dong, Haoyang Huang, Hongfa Wang, Nan Duan, Bohan Zhuang

Group Relative Policy Optimization has emerged as essential for aligning video diffusion models with human preferences, but faces a critical computational bottleneck: training a 14B parametered model typically demands hundreds of GPU days per experiment. Existing efficiency methods reduce costs through sliding window subsampling training timesteps, but fundamentally compromise optimization, exhibiting severe instability and failing to reach full trajectory performance. We present Flash-GRPO, a single-step training framework that outperforms full traject

ory training in alignment quality under low computational budgets while substant
ially improving training efficiency. Flash-GRPO addresses two critical challeng
es: iso-temporal grouping eliminates timestep-confounded variance by enforcing p
rompt-wise temporal consistency, decoupling policy performance from timestep dif
ficulty; temporal gradient rectification neutralizes the time-dependent scaling
factor that causes vastly inconsistent gradient magnitudes across timesteps. Exp
eriments on 1.3B to 14B parameter models validate Flash-GRPO's effectiveness, de
monstrating substantial training acceleration with consistent stability and stat
e-of-the-art alignment quality.

SuCo: Sufficiency-guided Continuous Adaptive Reasoning
Jiahao Wang, Bingyu Liang, Chenhao Hu, Longhui Zhang, Xuebo Liu, Min Zhang, Jing
 Li, Xuelong Li
Despite remarkable performance on complex tasks, Large Reasoning Models (LRMs) o
ften generate excessively long Chain-of-Thoughts (CoT), inflating computational
costs even for simple queries. Existing efforts to mitigate this inefficiency ty
pically rely on discrete reasoning modes or fixed budget tiers, lacking a princi
pled criterion of when reasoning is sufficient. In this work, we introduce *Mini
mal Sufficient CoT* (MSC), defined as the shortest prefix of a CoT trajectory wh
ich is adequate for producing the correct answer. We empirically show that MSC n
ot only reduces reasoning tokens, but also improves accuracy across difficulty l
evels. Building on MSC, we propose *Sufficiency-guided Continuous Adaptive Reaso
ning* (SuCo), a two-stage training framework for autonomous reasoning control al
ong a continuous spectrum. In stage 1, *MSC-Aligned Fine-Tuning* (MFT) construct
s MSC data using problem-adaptive sufficiency thresholds that naturally scale wi
th question difficulty, then fine-tunes the model to internalize concise yet suf
ficient reasoning patterns. In stage 2,
Sufficiency-Aware Policy Optimization (SAPO) further optimizes the model throu
gh reinforcement learning with dynamic complexity tracking and sufficiency-aware
 rewards that penalize both over- and under-thinking. Extensive experiments acro
ss mathematics, code, and science benchmarks show that SuCo consistently achieve
s improvements in both accuracy and reasoning efficiency.

Finding Stationary Points by Comparisons
Helin Wang, Chenyi Zhang, Xiwen Tao, Yexin Zhang, Tongyang Li
We study the problem of finding stationary points of non-convex functions when a
ccess to the objective is provided only through a comparison oracle that, given
two points, outputs which has the larger function value. For a twice differentia
ble $f:\mathbb R^n\to\mathbb R$ with Lipschitz gradient and Hessian, we develop
an algorithm that outputs an ϵ-stationary point using $\widetilde O(n^2
/\epsilon^{1.5})$ queries. Our approach uses a subroutine that estimates the nor
malized Hessian to accuracy δ using $\widetilde O(n^2\log(1/\delta))$ que
ries. We further study this problem with a quantum comparison oracle model where
 queries can be made in superpositions, and develop the first quantum algorithm
that finds an ϵ-stationary point, which takes $\widetilde O(n/\epsilon^
{1.5})$ queries.

CALM Before the STORM: Unlocking Native Reasoning for Optimization Modeling
Zhengyang Tang, Zihan Ye, Chenyu Huang, Xuhan Huang, Chengpeng Li, Sihang Li, Gu
anhua Chen, Ming Yan, Zizhuo Wang, Hongyuan Zha, Dayiheng Liu, Benyou Wang
Large Reasoning Models (LRMs) create new opportunities for automating optimizati
on modeling, but they also make post-training more delicate. In this task, stron
g performance often requires the model to formulate the problem, write solver co
de, run it, inspect the output, and revise when needed. We show that directly fi
ne-tuning LRMs on already written-out Operations Research (OR) solutions can imp
rove easier cases while hurting harder ones, suggesting that this training signa
l can interfere with the model's own way of solving the task. We therefore propo
se **CALM** (*Corrective Adaptation with Lightweight Modification*), which lets
the base LRM attempt the problem first, then inserts a short hint at the first d
etected mistake and lets the model continue from there. These hints modify fewer

than 2.6\% of generated tokens. The corrected solutions are used for supervised fine-tuning and then reinforcement learning, producing **STORM**, a 4B optimization-modeling specialist that reaches 68.9\% macro-average accuracy across five benchmarks and matches 671B DeepSeek-R1-0528. Under a matched hard-benchmark control, CALM also yields stronger final RL performance than direct distillation baselines that train on complete teacher-generated solutions from much stronger models. Overall, for this task, local repair of the base model's own solution is more effective than full teacher-solution replacement. Code and models are available at \url{https://github.com/tangzhy/STORM}.

Generative Adaptation of Dynamics to Environmental Shifts via Weight-space Diffusion

Ruikun Li, Huandong Wang, Jingtao Ding, Yuan Yuan, Qingmin Liao, Yong Li

Data-driven dynamics prediction often fails under environmental shifts, while traditional fine-tuning remains computationally prohibitive for hardware-constrained or data-scarce applications.

We propose DynaDiff, a generative meta-learning framework that transitions the paradigm from gradient-based tuning or modulation to direct weight-space generation.

Specifically, we first abstract expert weights as novel weight graphs, utilizing multi-head attention to explicitly capture topological coupling within weights.

Subsequently, we design a functional loss to ensure that the generated models achieve consistency with expert models in physical behavior.

Finally, we develop a dynamics-informed prompter that extracts cross-domain physical and spectral features from observation sequences to condition the diffusion model.

Experiments demonstrate that DynaDiff boosts average prediction accuracy by 10.78\% over competitive baselines.

Furthermore, by pre-constructing a model zoo of expert predictors, we amortize the fine-tuning overhead into a one-time offline cost, significantly boosting deployment efficiency in new environments.

Orthogonal Concept Erasure for Diffusion Models

Yuhao Sun, Lingyun Yu, Hao-Xiang Xu, Fengyuan Miao, Zhuoer Xu, Hongtao Xie

Concept erasure has emerged as a promising approach to mitigate undesired or unsafe content in diffusion models, yet existing methods still face significant limitations. While training-based methods are effective, their high computational cost limits scalability. Editing-based methods are more efficient and deployment-friendly, yet they struggle to simultaneously achieve precise concept erasure and preserve overall generative capacity. We identify this core limitation of the editing-based methods as reliance on additive parameter updates. Our empirical analysis reveals that concept semantics primarily depend on *neuron direction* rather than *neuron magnitude*, while overall generative capacity relies on the *angular geometry* of neurons. As additive updates inherently entangle direction, magnitude, and angular geometry, they inevitably introduce unintended interference between concept erasure and overall generation performance. To address this, we propose **Orthogonal Concept Erasure (OCE)**, which reformulates editing-based erasure as multiplicative parameter updates from a geometric perspective. Specifically, OCE applies layer-wise orthogonal transformations derived from a closed-form solution to the parameters, enabling precise concept erasure while preserving the neuron magnitude and angular geometry. Furthermore, to address conflicting constraints in multi-concept erasure, OCE introduces a subspace-level objective with structured subspace manipulation, yielding a more effective and scalable erasure. Extensive experiments on single- and multi-concept erasure demonstrate that OCE outperforms existing methods in concept erasure and non-target preservation, erasing up to 100 concepts in 4.3 s. Code: https://github.com/HansSunY/OCE.

Causal Direct Preference Optimization for Distributionally Robust Generative Rec

ommendation
Chu Zhao, Enneng Yang, Jianzhe Zhao, Guibing Guo
Direct Preference Optimization (DPO) guides large language models (LLMs) to gene rate recommendations aligned with user historical behavior distributions by mini mizing preference alignment loss. However, our systematic empirical research and theoretical analysis reveal that DPO tends to amplify spurious correlations cau sed by environmental confounders during the alignment process, significantly und ermining the generalization capability of LLM-based generative recommendation me thods in out-of-distribution (OOD) scenarios. To mitigate this issue, we propose CausalDPO, an extension of DPO that incorporates a causal invariance learning m echanism. This method introduces a backdoor adjustment strategy during the prefe rence alignment phase to eliminate interference from environmental confounders, explicitly models the latent environmental distribution using a soft clustering approach, and enhances robust consistency across diverse environments through in variance constraints. Theoretical analysis demonstrates that CausalDPO can effec tively capture users' stable preference structures across multiple environments, thereby improving the OOD generalization performance of LLM-based recommendatio n models. We conduct extensive experiments under four representative distributio n shift settings to validate the effectiveness of CausalDPO, achieving an averag e performance improvement of 24.10\% across four evaluation metrics.

Rethinking Thinking Tokens: LLMs as Improvement Operators
Lovish Madaan, Aniket Rajiv Didolkar, Suchin Gururangan, John Quan, Ruan Silva, Ruslan Salakhutdinov, Manzil Zaheer, Sanjeev Arora, Anirudh Goyal
Reasoning training incentivizes LLMs to produce long chains of thought (long CoT), which among other things, allows them to explore solution strategies with sel f-checking. This results in higher accuracy, but inflates context length, token/ compute cost, and answer latency. We ask: Can current models leverage their meta cognition to provide other combinations on this Pareto frontier, e.g., better ac curacy with lower context length and/or latency? Abstractly, we view the model a s an improvement operator on its own "thoughts" with a continuum of possible str ategies. We identify an interesting inference family Parallel-Distill-Refine (PD R), which performs the following: (i) generate diverse drafts in parallel; (ii) distill them into a bounded, textual workspace; and (iii) refine conditioned on this workspace, producing an output that seeds the next round. Importantly, cont ext length (hence compute cost) is controllable via degree of parallelism, and i s no longer conflated with the total number of generated tokens. We report PDR i nstantiations of current models that give better accuracy than long CoT while in curring lower latency. Setting degree of parallelism to 1 yields an interesting subcase, Sequential Refinement (SR) (iteratively improve a single candidate answ er) which provides performance superior to long CoT. Success of such model orche strations raises the question whether further training could shift the Pareto fr ontier. To this end, we train an 8B thinking model with Reinforcement Learning (RL) to make it consistent with PDR as the inference method. On math tasks with v erifiable answers, iterative pipelines surpass single-pass baselines at matched sequential budgets, with PDR delivering the largest gains (e.g., +11% on AIME 20 24 and +9% on AIME 2025).
****
Dependence-Aware Label Aggregation for LLM-as-a-Judge via Ising Models
Krishna Balasubramanian, Aleksandr Podkopaev, Shiva Kasiviswanathan
Large-scale AI evaluation increasingly relies on aggregating binary judgments fr om K annotators, including LLMs used as judges. Most classical methods, e.g., Dawid-Skene or (weighted) majority voting, assume annotators are conditionally i ndependent given the true label $Y\in\{0,1\}$, an assumption often violated by L LM judges due to shared data, architectures, prompts, and failure modes. Ignorin g such dependencies can yield miscalibrated posteriors and even confidently inco rrect predictions. We study label aggregation through a hierarchy of dependence- aware models based on Ising graphical models and latent factors. For class-depen dent Ising models, the Bayes log-odds is generally quadratic in votes; for class -independent couplings, it reduces to a linear weighted vote with correlation-ad

justed parameters. We present finite-K examples showing that methods based on conditional independence can flip the Bayes label despite matching per-annotator marginals. We prove separation results demonstrating that these methods remain strictly suboptimal as the number of judges grows, incurring nonvanishing excess risk under latent factors. Finally, we evaluate the proposed method on three real-world datasets, demonstrating improved performance over the classical baselines.

****

Optimal Decision-Making Based on Prediction Sets

Tao Wang, Edgar Dobriban

Prediction sets can wrap around any ML model to cover unknown test outcomes with a guaranteed probability. Yet, it remains unclear how to use them optimally for downstream decision-making. Here, we propose a decision-theoretic framework that seeks to minimize the expected loss (risk) against a worst-case distribution consistent with the prediction set's coverage guarantee. We first characterize the minimax optimal policy for a fixed prediction set, showing that it balances the worst-case loss inside the set with a penalty for potential losses outside the set. Building on this, we derive the optimal prediction set construction that minimizes the resulting robust risk subject to a coverage constraint. Finally, we introduce Risk-Optimal Conformal Prediction (ROCP), a practical algorithm that targets these risk-minimizing sets while maintaining finite-sample distribution-free marginal coverage. Empirical evaluations on medical diagnosis and a toy static hazard-decision benchmark demonstrate that ROCP reduces critical mistakes compared to baselines, particularly when out-of-set errors are costly. The source code to reproduce our experiments is available at https://github.com/TaoWangPenn/Risk-Optimal-Conformal-Prediction.

****

An Asymmetric Latent Factorization-of-Tensors Model for Relation Analysis

Weiling Li, Zhaoheng Shi, Jiajia Mi, Zhigang Liu, Jialiang Wang, Xin Luo

Latent Factorization-of-Tensors (LFT) models are an effective approach for relation analysis. Existing LFT models assume each mode of the target tensor corresponds to an entity set and the relationships between entity sets are bipartite graphs to explore the relationships among entities within a mode. However, when the topological structure of entities in a mode is known, for example, entities are ordered physical quantities, such as time or coordinates, the relations between such modes forms a more complicated structure, i.e., aligned bipartite networks, and existing LFT models cannot accurately capture this structure. This work is the first to recognize and analyze this issue, and proposes an Asymmetric Latent Factorization-of-Tensors (ALFT) model to address it. ALFT can model aligned bipartite networks in mode pairs of a tensor by imposing constraints between particular mode pairs in the tensor network. Experimental results on real-world datasets demonstrate the existence of this issue and confirm that the proposed ALFT model can effectively resolve it.

Large Language Models as Topological Thinkers: A Benchmark on Graph Persistent Homology

Hao Li, Hao Wan, Yixue Huang, Yuzhou Chen, Yulia Gel, Hao Jiang

Large language models (LLMs) are increasingly used in scientific discovery, system modeling, and decision-making, prompting interest in their ability to reason over complex structured data. Existing benchmarks primarily focus on static or local graph reasoning, overlooking the high-order structures in real-world systems whose global properties evolve across multiple scales. We introduce LLM4PH, a benchmark that evaluates multi-scale structural reasoning through the lens of persistent homology (PH), a topological framework for tracking structural evolution. LLM4PH decomposes the PH pipeline into interpretable reasoning tasks spanning synthetic and real-world graphs, revealing that most models struggle with reasoning over structural transitions and persistence. Beyond task-level evaluation, we perform cross-task ablations on prompt encoding and transfer, explore post-training effects, and construct a compositional PH pipeline to assess end-to-end performance. Our results provide the first in-depth view of how well LLMs bridge

discrete graph structures with continuous topological abstraction, and offer insights into their potential for structure-aware scientific reasoning.

TEAM: Temporal–Spatial Consistency Guided Expert Activation for MoE Diffusion Language Model Acceleration
Linye Wei, Zixiang Luo, Pingzhi Tang, Meng Li
Diffusion large language models (dLLMs) have recently gained significant attention due to their inherent support for parallel decoding. Building on this paradigm, Mixture-of-Experts (MoE) dLLMs with autoregressive (AR) initialization have further demonstrated strong performance competitive with mainstream AR models. However, we identify a fundamental mismatch between MoE architectures and diffusion-based decoding. Specifically, a large number of experts are activated at each denoising step, while only a small subset of tokens is ultimately accepted, resulting in substantial inference overhead and limiting their deployment in latency-sensitive applications. In this work, we propose **TEAM**, a plug-and-play framework that accelerates MoE dLLMs by enabling more accepted tokens with fewer activated experts. TEAM is motivated by the observation that expert routing decisions exhibit strong temporal consistency across denoising levels as well as spatial consistency across token positions. Leveraging these properties, TEAM employs three complementary expert activation and decoding strategies, conservatively selecting necessary experts for decoded and masked tokens and simultaneously performing aggressive speculative exploration across multiple candidates. Experimental results demonstrate that TEAM achieves up to 2.2× speedup over vanilla MoE dLLM, with negligible performance degradation. Code is released at https://github.com/PKU-SEC-Lab/TEAM-MoE-dLLM.

Learning to Watermark in the Latent Space of Generative Models
Sylvestre-Alvise Rebuffi, Tuan A. Tran, Valeriu Lacatusu, Pierre Fernandez, Tomáš Sou■ek, Nikola Jovanovi■, Tom Sander, Hady Elsahar, Alexandre Mourachko
Existing approaches for watermarking AI-generated images often rely on post-hoc methods applied in pixel space, introducing computational overhead and potential visual artifacts. In this work, we explore latent space watermarking and introduce DistSeal, a unified approach for latent watermarking that works across both diffusion and autoregressive models. Our approach works by training post-hoc watermarking models in the latent space of generative models. We demonstrate that these latent watermarkers can be effectively distilled either into the generative model itself or into the latent decoder, enabling in-model watermarking. The resulting latent watermarks achieve competitive robustness while offering similar imperceptibility and up to 20x speedup compared to pixel-space baselines. Our experiments further reveal that distilling latent watermarkers outperforms distilling pixel-space ones, providing a solution that is both more efficient and more robust.
****

Fractional is Better: Learnable Derivative Orders in Neural Operator Learning
Fares B. Mehouachi, Saif Jabari
Neural operators learn mappings between function spaces, enabling fast surrogate solutions to partial differential equations. Despite remarkable architectural diversity, these methods often share a common input representation: raw coordinate-value pairs $(x, u(x))$.
We ask whether inputs aligned with PDE differential structure can improve learning. Through Picard iteration on mild solutions, we show that derivatives of the input appear explicitly in the solution operator, suggesting that providing derivative features should reduce the network's implicit differentiation burden. We prove this intuition: providing derivative features improves approximation rates from $O(W^{-(s-m)/d})$ to $O(W^{-s/d})$, where W is network width, s is input regularity, m is the PDE order, and d is spatial dimension. Our central finding, however, is a surprise: the optimal derivative order β^* is strictly less than the PDE order m. This gap arises from a bias-variance tradeoff in spectral space that we characterize in closed form. Learning β from data achieves automatic spectral regularization. We introduce ∂-NO (del-NO),

for derivative-augmented neural operators, an architecture-agnostic augmentation that provides learnable fractional derivative features to any neural operator backbone. Across benchmark problems and architectures, ∂-NO consistently improves prediction accuracy, with learned orders that reflect a representation of known physics modulated by noise and finite-sample constraints.
****
Beyond Prediction: Tail-Aware Scheduling for LLM Inference
Yueying Li, Yuanfan Chen, Jiayang Chen, Esha Choukse, Haoran Qiu, G. Edward Suh, Rodrigo Fonseca, Ziv Scully, Udit Gupta
LLM serving exhibits extreme length variability, making size-based scheduling difficult in practice. Recent LLM schedulers approximate SJF/SRPT using predicted decode lengths or rank and primarily report mean-centric metrics (e.g., TTFT/TBT). We show these prediction-driven policies can be fragile under distribution shifts, bursty arrivals, and GPU memory pressure, and still offer limited control over tail latency (P90–P99) that dominates user experience—even with perfect decode-length knowledge. We introduce a distribution-aware, prediction-free scheduling framework that replaces explicit length prediction with soft, γ-parameterized priority boosting driven by lightweight statistical signals. Our design co-optimizes scheduling with cache-aware preemption to account for memory-coupled decode dynamics that vary across workload mixes. Evaluated on Azure production traces, our method achieves a P99 TTLT up to 35--50\% lower than SRPT with perfect length prediction and a TTFT 34--47\% lower across various workloads, including reasoning-heavy and chat-heavy tasks, demonstrating a robust alternative for tail-latency optimization in online LLM serving.
****
Size Transferability of Graph Convolutional Networks across Sparsity: A Generalized Graphon Perspective
Qinji Shu, Hang Sheng, Feng Ji, Hui Feng, Bo Hu
Size transfer scales Graph Convolutional Networks (GCNs) by applying models trained on sampled subgraphs to larger target graphs. However, existing theoretical guarantees are typically confined to dense graphs or restricted sparsity regimes, failing to cover the arbitrary sparsity of real-world networks. To bridge this gap, we introduce the Generalized Graphon Convolutional Network (GWCN) based on the generalized graphon theory. Unlike the classical graphon limit which vanishes in sparse settings, GWCN employs stretching to construct a non-trivial limit that preserves topological structure. We derive an explicit transfer error bound that decomposes into size-dependent and density-dependent components, providing a unified guarantee across arbitrary sparsity levels. Empirical results on real-world networks corroborate our findings, demonstrating that transfer error vanishes as graph size increases and edge density decreases.
****
Value-as-Return: A Two-Stage Framework to Align on the Optimal Score Function
Shikun Sun, Shuo Huang, Yiding Chen, Wen Sun, Jia Jia
Reinforcement learning with diffusion models has shown strong potential, but existing approaches such as variants of Direct Preference Optimization (DPO) often rely on an inaccurate simplification: they equate trajectory likelihoods with final-state probabilities. This mismatch leads to suboptimal alignment. We address this limitation with a principled framework that leverages the optimal value function as the return for short trajectory segments. Our approach follows a two-stage procedure: (i) learning a value-distribution function to estimate segment-level returns, and (ii) applying our VRPO to refine the score function. We prove that, under sufficient model capacity, the resulting model is equivalent to training a diffusion process on the tilted distribution proportional to $p(x)\exp(\eta r(x))$. Experiments on large-scale diffusion models validate our analysis and show stable and consistent improvements over prior methods.
****
GeoReward: Mitigating Contextual Variable Overestimation in Vision-Language Models for Cross-Market Preference Prediction
Shuo Liu, Huixiang Cai, Weiru Zhang, Xiaoyi Zeng
Vision-language models (VLMs) excel in many multimodal tasks but remain prone to

a subtle yet impactful failure mode: they tend to overestimate dominant visual-textual cues while underestimating sparse but decision-critical contextual variables. This issue, which we term Contextual Variable Overestimation (CVE), becomes particularly evident in real-world applications such as predicting advertisement image preferences across diverse geographic markets. For instance, when a VLM (e.g., Qwen2-VL) is asked to choose between two product images tailored for different countries (e.g., Korea vs. France), it often defaults to a consistent output (e.g., always selects “A”), ignoring ground-truth regional variations. This collapse occurs because pervasive high-volume signals, such as product attributes and dense image patches, overwhelm the few but critical tokens that encode market-specific context (e.g., country names). To address CVE, we first collect a new multimodal dataset of real advertising creatives and their click-through performance across multiple countries. We then introduce GeoReward, a reward model designed to predict ad image preferences across diverse geographic markets. GeoReward integrates three purpose-built mechanisms: (1) Market-Aware Retrieval Augmentation, which retrieves and injects region-aligned preference signals during training to sharpen localization awareness. (2) Context-Guided Visual Modulation, a lightweight adapter that dynamically adjusts visual representations using textual country embeddings, enabling fine-grained regional adaptation. (3) Selective Sensitivity Loss, an objective that applies heightened penalties for context-specific mispredictions, sharpening the model's focus on critical variables. Furthermore, we demonstrate how GeoReward can guide the fine-tuning of RL for a VLM to generate background designs for text-to-image models (e.g., SDXL), producing market-aware advertising creatives. Experiments validate that our framework mitigates CVE and outperforms existing baselines. This work not only diagnoses a systematic bias in VLMs toward dominant perceptual features but also delivers a targeted solution for applications where sparse contextual variables govern decision-making. Code is available at https://github.com/liushuo-hue/GeoReward.git.

Physics-informed Neural Operator Learning for Nonlinear Grad-Shafranov Equation
Siqi Ding, Zitong Zhang, Shi Guoyang, Xingyu Li, Xiang Gu, Yanan Xu, Huasheng Xie, Hanyue Zhao, YUEJIANG SHI, Tianyuan Liu

AI for fusion requires bridging a critical ``sim-to-real'' gap: simulation-trained models must generalize reliably under distribution shifts in safety-critical workflows. Focusing on the nonlinear Grad-Shafranov equation (GSE), we develop and analyze a physics-anchored operator-learning framework for fixed-boundary equilibrium prediction. The framework combines data anchors with PDE residual constraints and uses a physics-motivated Transformer-KAN Neural Operator (TKNO) to capture global elliptic coupling and nonlinear source response. Under multi-parameter distribution shifts, our analysis shows that data-only surrogates can develop severe OOD tails, while physics-only training may converge to incorrect solution branches; by combining sparse data anchors with PDE constraints, physics-anchored training reduces worst-tail errors on shape-driven and joint shifts. Mechanism diagnostics indicate that data anchors suppress branch-scale failures, whereas PDE residuals reduce OOD-induced high-frequency error amplification. Evaluated on EXL-50U discharge inputs against the device's operational equilibrium solver, the model achieves close agreement (RMSE $<$ 1.3\%) with millisecond-level inference. These results provide a practical route toward physically reliable AI surrogates for fusion workflows. Our code will be available at https://github.com/dsqzhou/physics-anchored-gse.

Strat-Reasoner: Reinforcing Strategic Reasoning of LLMs in Multi-Agent Games
Yidong He, Yutao Lai, Pengxu Yang, Jiarui Gan, Jiexin Wang, Yi Cai, Mengchen Zhao

While Large Language Models (LLMs) excel in certain reasoning tasks, they struggle in multi-agent games where the final outcome depends on the joint strategies of all agents. In multi-agent games, the non-stationarity of other agents brings significant challenges on the evaluation of the reasoning process and the credit assignment over multiple reasoning steps. Existing single-agent reinforcement learning (RL) approaches and their multi-agent extensions fail to address these

challenges as they do not incorporate other agents in the reasoning process. In this work, we propose Strat-Reasoner, a novel RL-based framework that improves LLMs' strategic reasoning ability in multi-agent games. We introduce a novel recursive reasoning paradigm where an agent's reasoning also integrates other agents' reasoning processes. To provide effective reward signals for the intermediate reasoning sequences, we employ a centralized Chain-of-Thought (CoT) comparison module to evaluate the reasoning quality. Finally, we compute an accurate hybrid advantage and develop a group-relative RL approach to optimize the LLM policy. Experimental results show that Strat-Reasoner substantially improves strategic abilities of underlying LLMs, achieving 22.1\% average performance improvements across various multi-agent games. Code is publicly available at https://github.com/ydhe1012/Strat-Reasoner.

NeurVLA: Unleashing Failure-Handling Capability of Vision-Language-Action Models via Neural-Symbolic Reasoning

Xuqi Liu, Minghe Gao, Juncheng Li, Siliang Tang

Vision-Language-Action models have recently shown promising progress in embodied robotic manipulation, yet their generalization to diverse open-ended embodied tasks is often hindered by execution failures. While prior work has explored failure handling, existing approaches still suffer from two fundamental limitations: coarse-grained failure correction and unreliable failure prevention. These limitations lead to brittle decision-making when VLA models are deployed in novel tasks and environments. To address them, we propose NeurVLA, a neural-symbolic framework that jointly addresses failure correction and prevention via neural-symbolic reasoning and further internalizes these failure-handling capabilities into VLA models. Experiments demonstrate that NeurVLA achieves strong performance and robust generalization across diverse tasks.

iVGR: Internalizing Visually Grounded Reasoning for MLLMs with Reinforcement Learning

Chang-Bin Zhang, Yujie Zhong, Qiang Zhang, Kai Han

While visually grounded Chain-of-Thought (CoT) has emerged as a promising paradigm to enhance fine-grained perception in multimodal large language models (MLLMs), its efficacy during the inference phase remains underexplored. In this work, we empirically find that mandating explicit object boxes in visually grounded CoT during inference often degrades performance compared to standard textual CoT, which reasons without explicit visual grounding. We hypothesize that the visual localization capability can be internalized into the textual CoT and that the mandatory explicit grounding introduces unnecessary interference with the model's primary objective of answer prediction. To address this problem, we propose Internalizing Visually Grounded Reasoning (**iVGR**), a novel reinforcement learning framework that transfers localization capabilities into the textual reasoning process. We employ a dual-stream training strategy, where a textual stream is aligned with a high-quality visually grounded stream via a proposed consistency reward, enabling the model to localize accurately without explicit grounding during inference. Extensive experiments demonstrate that our method significantly outperforms existing baselines on fine-grained benchmarks, while maintaining the flexibility to support tool-assisted inference workflows. Closing the Expression Gap in LLM Instructions via Socratic Questioning

Jianwen Sun, Yukang Feng, Yifan Chang, Chuanhao Li, Zizhen Li, Jiaxin Ai, Fanrui Zhang, Yu Dai, Kaipeng Zhang

A fundamental bottleneck in human-AI collaboration is the ``intention expression gap", the difficulty for humans to effectively convey complex, high-dimensional thoughts to AI.

This challenge often traps users in inefficient trial-and-error loops and is exacerbated by the diverse expertise levels of users.

We reframe this problem from passive instruction following to a Socratic collaboration paradigm, proposing an agent that actively probes for information to reso

lve its uncertainty about user intent.
We name the proposed agent Nous, trained to acquire proficiency in this inquiry policy.
The core mechanism of Nous is a training framework grounded in the first principles of information theory.
Within this framework, we define the information gain from dialogue as an intrinsic reward signal, which is fundamentally equivalent to the reduction of Shannon entropy over a structured task space.
This reward design enables us to avoid reliance on costly human preference annotations or external reward models.
To validate our framework, we develop an automated simulation pipeline to generate a large-scale, preference-based dataset for the challenging task of scientific diagram generation.
Comprehensive experiments, including ablations, subjective and objective evaluations, and tests across user expertise levels, demonstrate the effectiveness of our proposed framework. Nous achieves leading efficiency and output quality, while remaining robust to varying user expertise. Our research provides a systematic methodology and a new perspective for addressing ambiguous intentions in complex human-machine collaboration.

DecoVer: A Decompose-and-Verify Neuro-Symbolic Framework for Embodied Task Planning with BC+
YiXiang Jiang, Binqian Xu, Xiangbo Shu
Despite their remarkable general capabilities, Large Language Models (LLMs) struggle with the precise grounding required for embodied task planning. To bridge this gap, neuro-symbolic approaches have emerged, leveraging action languages like BC+ for their formal expressiveness and reasoning flexibility. However, prior methods that naively couple LLMs with BC+ typically depend on one-shot program generation, which is brittle in dynamic environments and prone to sequential omission and causal inconsistency. To address these limitations, we propose DecoVer, a Decompose-and-Verify neuro-symbolic framework that systematically adapts BC+ to embodied task planning. Specifically, DecoVer employs a cascading decomposition strategy to partition complex knowledge into hierarchical subspaces and integrates a dual verification mechanism for syntactic and executable correctness. Extensive experiments demonstrate that DecoVer consistently outperforms LLM-based baselines across the majority of evaluation metrics, achieving a 12.9% success rate gain over the highly capable Gemini-3-Pro-Preview and a 60.9% improvement over GPT-5.1 on logically complex test cases.

FAST-AR: Fast Autoregressive Video Diffusion and World Models with Temporal Cache Compression and Sparse Attention
Dvir Samuel, Issar Tzachor, Matan Levy, Michael Green, Gal Chechik, Rami Ben-Ari
Autoregressive video diffusion models enable streaming generation, opening the door to long-form synthesis, video world models, and interactive neural game engines. However, their core attention layers become a major bottleneck at inference time: as generation progresses, the KV cache grows, causing both increasing latency and escalating GPU memory, which in turn restricts usable temporal context and harms long-range consistency. In this work, we study redundancy in autoregressive video diffusion and identify three persistent sources: near-duplicate cached keys across frames, slowly evolving (largely semantic) queries/keys that make many attention computations redundant, and cross-attention over long prompts where only a small subset of tokens matters per frame.
Building on these observations, we propose a unified, training-free attention framework (FAST-AR) for FAST-AutoRegressive diffusion, consisting of three components: TempCache compresses the KV cache via temporal correspondence to bound cache growth; AnnCA accelerates cross-attention by selecting frame-relevant prompt tokens using fast approximate nearest neighbor (ANN) matching; and AnnSA sparsifies self-attention by restricting each query to semantically matched keys, also using a lightweight ANN. Together, these modules reduce attention, compute, and memory and are compatible with existing autoregressive diffusion backbones and wo

rld models. Experiments demonstrate up to x5--x10 end-to-end speedups while pres erving near-identical visual quality and, crucially, maintaining stable throughp ut and nearly constant peak GPU memory usage over long rollouts, where prior met hods progressively slow down and suffer from increasing memory usage.

HEXST: Hexagonal Shifted-Window Transformer for Spatial Transcriptomics Gene Exp ression Prediction

Keunho Byeon, Jin Tae Kwak

Spatial transcriptomics offers spatially resolved gene expression profiling with in tissue sections, but its cost and limited throughput hinder large-scale deplo yment. To extend this capability to routine practice, recent computational metho ds aim to infer spatial gene expression directly from ubiquitous hematoxylin and eosin-stained histology slides. However, most existing models assume Cartesian or geometry-agnostic locality, despite the hexagonal sampling of widely used spo t-array platforms, and point-wise regression objectives often yield over-smoothe d gene expression profiles, obscuring gene-specific spatial heterogeneity. To ad dress these, we propose HEXST, a geometry-aligned Transformer for spatial gene e xpression prediction from histology. HEXST operates directly on hexagonal spot c oordinates to enable efficient local-to-global contextual modeling via a tailore d shifted-window attention mechanism and hexagonal rotary positional encoding. T o enhance gene-wise spatial contrast, HEXST complements point-wise regression wi th a contrast-sensitive differential objective and transcriptomic priors from a pretrained single-cell foundation model during training. Across seven spatial tr anscriptomics datasets, HEXST consistently outperforms state-of-the-art models, providing accurate and robust spatial gene expression predictions while preservi ng gene-wise contrast and spatial heterogeneity.

Twins: Learn to Predict Unified Representations with Focal Loss

Kaixiong Gong, Xin Cai, Bin Lin, Hao Wang, Yunlong Lin, Mingzhe Zheng, Bohao Li, Jian-Wei Zhang, Miles Yang, Zhao Zhong, Liefeng Bo, Xiangyu Yue

Unified multimodal models seek a shared visual token space that supports both mu ltimodal understanding and image generation. Discrete methods unify the interfac e via a shared codebook, whereas continuous pipelines often rely on two disparat e representations—semantic features (e.g., ViT) for understanding and low-level latents (e.g., VAE) for synthesis—resulting in mismatched latent spaces. We prop ose Twins, a unified continuous token space formed by channel-wise concatenating ViT and VAE features on the same token grid, so the sequence length is unchange d and attention cost does not increase. However, jointly modeling Twins in a Dif fusion Transformer exposes a severe \textit{optimization imbalance}: the model f its the ViT component well but struggles to match the VAE latent distribution. W e trace this imbalance to three sources of heterogeneity: frequency bias, intrin sic dimensionality, and condition-aligned vs condition-independent uncertainty. To address it, we adapt a focal regression objective for flow matching that upwe ights large-error VAE dimensions, better balancing optimization across the ViT a nd VAE components. On ImageNet, this yields up to 10.57 gFID gain over naive M SE loss without classifier-free guidance. Twins also performs competitively on m ultimodal understanding benchmarks and improves reconstruction fidelity, narrowi ng the gap between understanding- and generation-oriented representations.

NavOL: Navigation Policy with Online Imitation Learning

Xiaofei Wei, Chun Gu, Li Zhang

Learning robust navigation policies remains a core challenge in robotics. Offlin e imitation learning suffers from distribution shift and compounding errors at r ollout, while reinforcement learning requires reward engineering and learns inef ficiently. In this paper, we propose NavOL, an online imitation learning paradig m that interacts with a simulator and updates itself using expert demonstrations gathered online. Built upon a pretrained navigation diffusion policy that maps local observations to future waypoints, NavOL trains in a rollout–update loop: d uring rollout, the policy acts in the simulator and queries a global planner whi ch has privileged access to the global environment for the optimal path segment

as ground truth trajectory labels; during update, the policy is trained on the o
nline collected observation–trajectory pairs. This online imitation loop removes
 the need for reward design, improves learning efficiency, and mitigates distrib
ution shift by training on the policy’s own explored rollouts. Built on IsaacLab
 with fast, high-fidelity parallel rendering and domain randomization of camera
pose and start-goal pairs, our system scales across 50 scenes on 8 RTX 4090 GPUs
, collecting over 2,000 new trajectories per hour, each averaging more than 400
steps. We also introduce an indoor visual navigation benchmark with predefined s
tart and goal positions for zero-shot generalization. Extensive evaluations on s
imulation benchmarks, including the NavDP benchmark and our proposed benchmark,
as well as carefully designed real-world experiments, demonstrate the effectiven
ess of NavOL, showing consistent performance gains in online imitation learning.

ProOPF: Benchmarking and Improving LLMs for Professional-Grade Power Systems Opt
imization Modeling

Chao Shen, Zihan Guo, Xu Wan, Zhenghao Yang, Yifan Zhang, Wenqi Huang, Jie Song,
 Zongyan Zhang, Mingyang Sun

Growing renewable penetration introduces substantial uncertainty into power syst
em operations, necessitating frequent adaptation of dispatch objectives and cons
traints and challenging expertise-intensive, near-real-time modeling workflows.
Large Language Models (LLMs) provide a promising avenue for automating this proc
ess by translating natural-language (NL) operational requirements into executabl
e optimization models via semantic reasoning and code synthesis. Yet existing LL
M datasets and benchmarks for optimization modeling primarily target coarse-grai
ned cross-domain generalization, offering limited, rigorous evaluation in power-
system settings, particularly for Optimal Power Flow (OPF). We therefore introdu
ce \textbf{ProOPF-D} and \textbf{ProOPF-B}, a dataset and benchmark for professi
onal-grade OPF modeling: ProOPF-D contains 12K instances pairing NL requests wit
h parameter adjustments and structural extensions to a canonical OPF, together w
ith executable implementations; ProOPF-B provides 121 expert-annotated test case
s with ground-truth code, enabling end-to-end evaluation under both concrete and
 abstract OPF modeling regimes. Our code, dataset, and benchmark are publicly av
ailable at \href{https://github.com/shenchao188/ProOPF-Benchamrk-Dataset}{this G
itHub repository}.

A Random Matrix Theory of Masked Self-Supervised Learning

Arie Wortsman Zurich, Federica Gerace, Bruno Loureiro, Yue M. Lu

In the era of transformer models, masked self-supervised learning (SSL) has beco
me a foundational training paradigm. A defining feature of masked SSL is that tr
aining aggregates predictions across many masking patterns, giving rise to a joi
nt, matrix-valued predictor rather than a single vector-valued estimator. This o
bject encodes how coordinates condition on one another and poses new analytical
challenges. We develop a precise high-dimensional analysis of masked modeling ob
jectives in the proportional regime where the number of samples scales with the
ambient dimension. Our results provide explicit expressions for the generalizati
on error and characterize the spectral structure of the learned predictor, revea
ling how masked modeling extracts structure from data. For spiked covariance mod
els, we show that the joint predictor undergoes a Baik–Ben Arous–Péché (BBP)-typ
e phase transition, identifying when masked SSL begins to recover latent signals
. Finally, we identify structured regimes in which masked self-supervised learni
ng provably outperforms PCA, highlighting potential advantages of SSL objectives
 over classical unsupervised methods.

Tuning the Implicit Regularizer of Masked Diffusion Language Models: Enhancing G
eneralization via Insights from k-Parity

Jianhao Huang, Baharan Mirzasoleiman

Masked Diffusion Language Models have recently emerged as a powerful generative
paradigm, yet their generalization properties remain understudied compared to th
eir auto-regressive counterparts. In this work, we investigate these properties
within the setting of the k-parity problem (computing the XOR sum of k relev

ant bits), where neural networks typically exhibit grokking—a prolonged plateau of chance-level performance followed by sudden generalization. We theoretically decompose the Masked Diffusion (MD) objective into a Signal regime which drives feature learning, and a Noise regime which serves as an implicit regularizer. By training nanoGPT using MD objective on the k-parity problem, we demonstrate that MD objective fundamentally alters the learning landscape, enabling rapid and simultaneous generalization without experiencing grokking.
Furthermore, we leverage our theoretical insights to optimize the distribution of the mask probability in the MD objective. Our method significantly improves perplexity for 50M-parameter models and achieves superior results across both pre-training from scratch and supervised fine-tuning. Specifically, we observe performance gains peaking at 8.8% and 5.8%, respectively, on 8B-parameter models, confirming the scalability and effectiveness of our framework in large-scale masked diffusion language model regimes.
****
Transformers with RL or SFT Provably Learn Sparse Boolean Functions, But Differently
Bochen Lyu, Yiyang Jia, Xiaohao Cai, Zhanxing Zhu
Transformers can acquire Chain-of-Thought (CoT) capabilities to solve reasoning tasks via fine-tuning. Reinforcement learning (RL) and supervised fine-tuning (SFT) are two primary approaches to this end. In this work, we examine RL with verifiable process rewards and SFT for learning k-sparse Boolean functions with a one-layer transformer through intermediate reasoning steps akin to CoT. In particular, we consider Boolean functions that can be recursively decomposed into fixed 2-sparse Boolean functions. We first analyze the learning dynamics of RL fine-tuning with verifiable process rewards and SFT in a unified way, allowing us to identify sufficient conditions under which the transformer provably learns these functions. We then verify that these conditions hold for three basic examples, including k-PARITY, k-AND, and k-OR, thus demonstrating their learnability via both RL and SFT. Notably, we reveal that RL and SFT exhibit distinct learning behaviors: RL learns the whole CoT chain simultaneously, whereas SFT learns the CoT step-by-step. Overall, our findings provide insights on the mechanisms underlying RL and SFT and how they differ in triggering the CoT capabilities of transformers, and suggest that the comparison between RL and SFT may need to consider the reward design and the use of teacher forcing.

VisualPuzzles: Decoupling Multimodal Reasoning Evaluation from Domain Knowledge
Yueqi Song, Tianyue Ou, Yibo Kong, Zecheng Li, Graham Neubig, Xiang Yue
Current multimodal benchmarks often conflate reasoning with domain knowledge, making it difficult to isolate and evaluate reasoning abilities in non-expert settings.
To address this, we introduce VisualPuzzles, a benchmark that targets visual reasoning while deliberately minimizing reliance on specialized knowledge.
VisualPuzzles consists of diverse puzzles spanning 5 categories: algorithmic, analogical, deductive, inductive, and spatial reasoning. One major source of our questions is manually translated logical reasoning questions from the Chinese Civil Service Examination. Experiments show that VisualPuzzles requires significantly less intensive domain-specific knowledge and more complex reasoning compared to benchmarks like MMMU, enabling us to better evaluate genuine multimodal reasoning.
Evaluations show that state-of-the-art multimodal large language models consistently lag behind human performance on VisualPuzzles, and that strong performance on knowledge-intensive benchmarks does not necessarily translate to success on reasoning-focused, knowledge-light tasks.
Additionally, reasoning enhancements such as scaling up inference compute (with "thinking" modes) yield inconsistent gains across models and task types, and we observe no clear correlation between model size and performance. We also found that models exhibit different reasoning and answering patterns on VisualPuzzles compared to benchmarks with heavier emphasis on knowledge. VisualPuzzles offers a clearer lens through which to evaluate reasoning capabilities beyond factual re

call and domain knowledge.
****
ProtoKV: Streaming Video Understanding under Delayed Query with Summary-State Memory
Le Tu Ngoc Minh, Jinyeong Lim, Dongsu Han
Streaming video understanding (SVU) must answer queries that arrive asynchronously while visual tokens stream continuously under strict GPU-memory and query-time latency budgets. A key challenge is delayed query: decisive cues may appear briefly, yet many subsequent updates occur before the query arrives, increasing the risk that those cues are evicted or diluted under bounded memory. We propose ProtoKV, a constant-footprint SVU memory that represents far history as a fixed-capacity summary state rather than retaining token instances. ProtoKV keeps an exact near-window KV cache and aggregates older content into a semantic–spatial prototype bank with residual statistics. At query time, each prototype is exposed through a bounded pseudo-token interface that is drop-in compatible with standard attention. Under matched budgets and comparable query-time cost, ProtoKV improves accuracy by up to 12.5 points over token-retention baselines on SVU benchmarks in the long-delay regime, with gains that grow as query delay increases.
****
Stabilizing the Q-Gradient Field for Policy Smoothness in Actor-Critic Methods
Jeong Woon Lee, Kyoleen Kwak, Daeho Kim, Hyoseok Hwang
Policies learned via continuous actor-critic methods often exhibit erratic, high-frequency oscillations, making them unsuitable for physical deployment.
Current approaches attempt to enforce smoothness by directly regularizing the policy's output.
We argue that this approach treats the symptom rather than the cause.
In this work, we theoretically establish that policy non-smoothness is fundamentally governed by the differential geometry of the critic.
By applying implicit differentiation to the actor-critic objective, we prove that the sensitivity of the optimal policy is bounded by the ratio of the Q-function's mixed-partial derivative (noise sensitivity) to its action-space curvature (signal distinctness).
To empirically validate this theoretical insight, we introduce PAVE (Policy-Aware Value-field Equalization), a critic-centric regularization framework that treats the critic as a scalar field and stabilizes its induced action-gradient field.
PAVE rectifies the learning signal by minimizing the Q-gradient volatility while preserving local curvature.
Experimental results demonstrate that PAVE achieves smoothness comparable to policy-side smoothness regularization methods, while maintaining competitive task performance, without modifying the actor.
****
SmoothSpike: Spiking Transformer with Learnable Hadamard Transformation
Zijian Zhou, Wenjie Wei, Yu Liang, Jialin Li, Ammar Belatreche, Honglin Cao, Shuai Wang, Malu Zhang, Yang Yang, Haizhou Li
Spiking Neural Networks (SNNs) have attracted growing attention due to their sparse spike-based communication and inherent temporal dynamics. However, their discrete information representation fundamentally limits expressiveness, resulting in a notable performance gap relative to Artificial Neural Networks (ANNs) on language modeling tasks. In this paper, we reveal that this gap is fundamentally rooted in a spike saturation-induced information homogenization problem: within a bounded time window, distinct high-amplitude inputs converge to identical spike counts, compressing neural representations and impairing fine-grained semantic discrimination across layers. To address this, we propose SmoothSpike, which applies a randomized Hadamard transformation to smooth pre-activation inputs and theoretically proves that it bounds the maximum input to $\mathcal{O}(\sqrt{\frac{\log n}{n}})$ with high probability. To further improve adaptability across varying input distributions, we extend the fixed transformation within SmoothSpike to a learnable orthogonal matrix updated via Newton-Schulz iterations, which can be fused into model weights at inference with no additional overhead. Experime

nts on the GLUE benchmark show that SmoothSpike effectively reduces information homogenization, yielding an 8.2\% average improvement over the Spikingformer baseline without compromising the efficiency inherent to spike-driven computation. These results advance the prospects for energy-efficient and high-performance language modeling on edge devices. Code is available at https://github.com/CayleyZ/SmoothSpike.

MAS-ProVe: Understanding the Process Verification of Multi-Agent Systems

Vishal Venkataramani, Haizhou Shi, Zixuan Ke, Austin Xu, Xiaoxiao He, Yingbo Zhou, Semih Yavuz, Hao Wang, Shafiq Joty

Multi-Agent Systems (MAS) built on Large Language Models (LLMs) often exhibit high variance in their reasoning trajectories.

Process verification, which evaluates intermediate steps in trajectories, has shown promise in general reasoning settings, and has been suggested as a potential tool for guiding coordination of MAS; however, its actual effectiveness in MAS remains unclear. To fill this gap, we present MAS-ProVe, a systematic empirical study of process verification for multi-agent systems (MAS). Our study spans *three verification paradigms* (LLM-as-a-Judge, reward models, and process reward models), evaluated across *two levels of verification granularity* (agent-level and iteration-level). We further examine *five representative verifiers* and *four context management strategies,* and conduct experiments over *six diverse MAS frameworks* on multiple reasoning benchmarks. We find that process-level verification does not consistently improve performance and frequently exhibits high variance, highlighting the difficulty of reliably evaluating partial multi-agent trajectories. Among the methods studied, LLM-as-a-Judge generally outperforms reward-based approaches, with trained judges surpassing general-purpose LLMs. We further observe a small performance gap between LLMs acting as judges and as single agents, and identify a context-length-performance trade-off in verification. Overall, our results suggest that effective and robust process verification for MAS remains an open challenge, requiring further advances beyond current paradigms.

PostTrainBench: Can LLM Agents Automate LLM Post-Training?

Ben Rank, Hardik Bhatnagar, Ameya Prabhu, Shira Eisenberg, Karina Nguyen, Matthias Bethge, Maksym Andriushchenko

AI agents have become surprisingly proficient at software engineering over the past year, largely due to improvements in reasoning capabilities. This raises a deeper question: can these systems extend their capabilities to automate AI research itself? We introduce PostTrainBench to benchmark how well LLM agents can perform post-training *autonomously* under bounded compute constraints (10 hours on one H100 GPU). We ask frontier agents (e.g., Claude Code with Opus 4.6) to optimize the performance of a base LLM on a particular benchmark (e.g., Qwen3-4B on AIME). Importantly, we do not provide any predefined strategies to the agents and instead give them full autonomy to find necessary information on the web, run experiments, and curate data. We find that frontier agents make substantial progress but generally lag behind official instruction-tuned LLMs: 27.9% for the best agent vs. 51.1% for official instruction-tuned models. However, agents can exceed instruction-tuned models in targeted scenarios: GPT-5.1 Codex Max achieves 89% on BFCL with Gemma-3-4B vs. 67% for the official model. We also observe failure modes: agents engage in reward hacking by training on the test set, downloading existing instruction-tuned checkpoints, or using found API keys to generate synthetic data without authorization. Overall, we hope PostTrainBench will be useful for tracking progress in AI R&D automation and for studying the risks that come with it.

Token-Free Hierarchical Indexing for RAG beyond LLM-based Summarization

Yifan Wei, Dan Yuan, Xiaoyan Yu, Angsheng Li

Retrieval-Augmented Generation (RAG) increasingly relies on hierarchical indexing, yet existing frameworks are bottlenecked by the high cost and information loss of recursive, LLM-based summarization. We propose SeRAG, a novel token-free hi

erarchical indexing framework that replaces textual summaries with an informatio n-theoretic knowledge taxonomy. SeRAG first transforms a corpus into a multi-per spective graph capturing semantic, logical, and sequential dependencies, then mi nimizes structural entropy to induce a topologically-faithful encoding tree. To bridge the gap between abstract themes and granular facts, we introduce localize d structural weight-based vector aggregation for token-free community consolidat ion. Extensive experiments demonstrate that SeRAG significantly reduces indexing overhead while outperforming state-of-the-art methods in complex multi-hop reas oning tasks.

When Is Rank-1 Enough? Geometry-Guided Initialization for Parameter-Efficient Fi ne-Tuning

Haoran Zhao, Caren Han, Eduard Hovy

Parameter-efficient fine-tuning (PEFT) is a standard way to adapt multimodal lar ge language models, yet extremely low-rank settings---especially rank-1 LoRA---a re often unstable. We show that this instability is not solely due to limited ca pacity: in the rank-1 regime, optimization is highly sensitive to the update dir ection. Concretely, pretrained vision and text features form mismatched anisotro pic regions, yielding a dominant "gap" direction that acts like a translation co mponent and disproportionately steers early gradients under rank-1 constraints. Analyzing pretrained representations, we identify a modality-gap axis that domin ates early gradient flow, while a random rank-1 initialization is unlikely to al ign with it, leading to weak gradients and training collapse. We propose Gap-Ini t, a geometry-aware initialization that aligns the rank-1 LoRA direction with an estimated modality-gap vector from a small calibration set, while keeping the i nitial LoRA update zero. Across multiple vision-language tasks and backbones, Ga p-Init consistently stabilizes rank-1 training and can match or outperform stron g rank-8 baselines. Our results suggest that at the extreme low-rank limit, init ial alignment can matter as much as rank itself.

Both Semantics and Reconstruction Matter: Making Representation Encoders Ready f or Text-to-Image Generation and Editing

Shilong Zhang, He Zhang, Zhifei Zhang, Chongjian GE, Shuchen Xue, Shaoteng Liu, Mengwei Ren, Soo Ye Kim, Yuqian Zhou, Qing Liu, Daniil Pakhomov, Kai Zhang, Zhe Lin, Ping Luo

Modern Latent Diffusion Models (LDMs) typically operate in low-level Variational Autoencoder (VAE) latent spaces that are primarily optimized for pixel-level re construction. To unify vision generation and understanding, a burgeoning trend i s to adopt high-dimensional features from representation encoders as generative latents. However, we empirically identify two fundamental obstacles in this para digm: (1) the discriminative feature space lacks compact regularization, making diffusion models prone to off-manifold latents that lead to inaccurate object st ructures; and (2) the encoder’s inherently weak pixel-level reconstruction hinde rs the generator from learning accurate fine-grained geometry and texture. In th is paper, we propose a systematic framework to adapt understanding-oriented enco der features for generative tasks.

We introduce a semantic–pixel reconstruction objective to regularize the latent space, enabling the compression of both semantic information and fine-grained de tails into a highly compact representation (96 channels with $16\times$ spatial downsampling).

This design allows the latent space to remain semantically rich while achieving state-of-the-art image reconstruction, and keeps it compact enough for accurate generation.

Leveraging this representation, we design a unified text-to-image (T2I) and imag e editing model.

Across diverse generation spaces, our approach achieves state-of-the-art reconst ruction, faster convergence, and substantial gains in both T2I and editing tasks , demonstrating that representation encoders can be effectively adapted into rob ust generative components.

MIMOMamba: From Scalar Duality to Matrix-Valued Attention
Yanbo Li, Richard Cornelius Suwandi, Feng Yin, SUN Yiyong, Wei Huang, Wenqiang P
u
The state space duality (SSD) framework, central to modern state-space models (S
SMs) such as Mamba, has established an efficient attention-like mechanism by lev
eraging the commutative property of linear recurrences. However, existing formul
ations are limited to single-input single-output (SISO) systems that enforce com
mutativity with a restrictive scalar-identity constraint, which prevents cross-d
imensional interactions within the state dynamics. In this work, we generalize S
SD to the multi-input multi-output (MIMO) setting by introducing a matrix polyno
mial parameterization.
This approach not only provides a principled way to ensure commutativity for gen
eralized duality but also induces a shared algebraic structure across state tran
sitions, thereby significantly reducing parameter redundancy.
Building on this foundation, we present \textbf{MIMOMamba}, a multi-head SSM arc
hitecture that captures rich cross-dimensional dynamics while retaining linear-t
ime training.
Empirical evaluations on a sequence modeling benchmark demonstrate that MIMOMamb
a achieves performance comparable to or surpassing that of standard Transformers
 while utilizing substantially fewer parameters.
****
From Associations to Activations: Comparing Behavioral and Hidden-State Semantic
 Geometry in LLMs
Louis Schiekiera, Max Zimmer, Christophe Roux, Sebastian Pokutta, Fritz Günther
We investigate the extent to which an LLM’s hidden-state geometry can be recover
ed from its behavior in psycholinguistic experiments. Across eight instruction-t
uned transformer models, we run two experimental paradigms---similarity-based fo
rced choice and free association---over a shared 5,000-word vocabulary, collecti
ng 17.5M+ trials to build behavior-based similarity matrices. Using representati
onal similarity analysis, we compare behavioral geometries to layerwise hidden-s
tate similarity and benchmark against FastText, BERT, and cross-model consensus.
 We find that forced-choice behavior aligns substantially more with hidden-state
 geometry than free association. In a held-out-words regression, behavioral simi
larity (especially forced choice) predicts unseen hidden-state similarities beyo
nd lexical baselines and cross-model consensus, indicating that behavior-only me
asurements retain recoverable information about internal semantic geometry. Fina
lly, we discuss implications for the ability of behavioral tasks to uncover hidd
en cognitive states.

Zeroth-Order Non-Log-Concave Sampling with Variance Reduction and Applications t
o Inverse Problems
M. Berk Sahin, Behzad Sharif, Abolfazl Hashemi
Sampling from high-dimensional, non-log-concave distributions with unnormalized
densities remains a fundamental challenge in machine learning, particularly in b
lack-box settings where gradient information is inaccessible or computationally
prohibitive. While Langevin dynamics provides a principled framework for samplin
g when gradients are accessible, its extension to the black-box settings suffers
 from high variance and lacks non-asymptotic convergence guarantees for non-log-
concave sampling. To address these limitations, we propose a variance-reduced ze
roth-order Langevin sampling method. Our method employs a gradient estimator tha
t substantially reduces the variance of the classical batched zeroth-order estim
ator and eliminates the unfavorable dimensional dependence of the batch size req
uired for accurate estimation, enabling practical and stable sampling. We establ
ish the first non-asymptotic convergence guarantees for zeroth-order non-log-con
cave sampling in terms of ε-relative Fisher information, and, under
a Poincar\'e inequality assumption, squared total variation distance. We further
 propose ZO-APMC, a posterior sampling algorithm for black-box inverse problems
with pre-trained score-based generative priors, establishing the first non-asymp
totic convergence guarantees for such methods. We validate our theory through sy
nthetic experiments and demonstrate strong empirical performance on practical li

near and nonlinear inverse problems.

LatentChem: From Textual CoT to Latent Thinking in Chemical Reasoning
Xinwu Ye, Yicheng Mao, Yuxuan Liao, Jia Zhang, Yimeng Liu, Li Hao, Fang Wu, Zhiwei Li, Zehong Wang, Zhiyuan Liu, Zhenfei Yin, Li Yuan, Philip Torr, Huan Sun, xiangxiang Zeng, Mengdi Wang, Le Cong, Shenghua Gao, Xiangru Tang
Current chemical large language models (LLMs) predominantly rely on explicit Chain-of-Thought (CoT) to solve complex reasoning problems.
However, forcing nonverbal tacit chemical logic into discrete natural language imposes a fundamental ``modality mismatch,'' creating an artificial bottleneck for reasoning.
We introduce LatentChem, a reasoning interface that decouples chemical logic from linguistic generation, enabling the model to process information via continuous thought vectors and dynamic perception.
Our investigation reveals a pivotal emergent behavior: spontaneous internalization, defined here as self-selected under outcome-only optimization.
When optimized for task success, the model abandons verbose textual derivations in favor of implicit latent computation, suggesting that it identifies the continuous manifold as a more native substrate for chemical logic.
This paradigm shift also proves to be a superior computational strategy: LatentChem achieves a 59.88\% non-tie win rate against the strong CoT baseline on the rigorous ChemCoTBench, while delivering a broad 10.84$\times$ average reduction in reasoning step overhead (5.96$\times$ wall-clock speedup) across all evaluated benchmarks.
Our results provide empirical evidence that chemical reasoning is more naturally and effectively realized as continuous latent dynamics rather than discretized linguistic trajectories.

Adaptive Quasimetric Mapping : Principled Topological Abstraction for Robust Offline Goal-Conditioned Navigation
Anthony Kobanda, Waris Radji, Odalric-Ambrym Maillard, Rémy Portelas
Goal-Conditioned Reinforcement Learning aims to design agents that can reach specified goals, notably from previously collected trajectories in the offline setting. In this context, graph-based approaches have been proposed to mitigate compounding value-estimation errors in long-horizon navigation tasks. However, existing approaches typically rely on dense keypoint coverage of the dataset support, resulting in computationally expensive planning. Moreover, they lack explicit mechanisms to adapt to topological changes (e.g., new obstacles), hindering deployment in live applications such as video game environments. To address these two shortcomings, we introduce Adaptive Quasimetric Mapping (AQM), an offline framework leveraging a “time-to-reach” quasimetric learned from the available data. Crucially, it builds a sparse cover of the dataset support, as a greedy approximation to a dominating set problem. At test-time, the resulting graph is carefully pruned by comparing the observed edge traversal time against a time-to-reach budget derived from the quasimetric, thus enabling zero-shot replanning. Empirically, we evaluate AQM on navigation tasks ranging from a classical to a video-game-like benchmark evaluating adaptation across tasks. We show that AQM achieves competitive performance while requiring up to 100× fewer keypoints than prior approaches, hence demonstrating the relevance of topological abstraction for goal-conditioned navigation.

AnyCanvas: Potential Field Guidance for Training-Free Spatial Control in Text-to-Image Diffusion
Tianyi Xie, Zhiyuan Yu, kaihong huang, Beilun Wang, Zhaoyang Wang, Dian Shen
Diffusion-based text-to-image (T2I) models have demonstrated remarkable advancements in generating high-quality images. However, while real-world applications like product packaging and logo design necessitate synthesis within irregular geometries, existing methods struggle to handle such constraints. Therefore, generating complete pictures that conform to arbitrary-shaped canvas constraints while maintaining semantic integrity remains a significant challenge. To address this

, we introduce AnyCanvas, a training-free framework that leverages a Mask-to-Pot
ential Field paradigm to convert binary masks into a differentiable potential fi
eld, which guides content to naturally converge within target regions. Extensive
 experiments demonstrate that AnyCanvas achieves 4.23\% higher spatial adherence
 to user-specified constraints while maintaining 99.45\% of the semantic fidelit
y measured by CLIP score, leading to a superior harmonic mean of spatial and sem
antic metrics. AnyCanvas also exhibits robust generalizability across different
model backbones and versatile spatial control objectives.

StarEmbed: Benchmarking Time Series Foundation Models on Astronomical Observatio
ns of Variable Stars

Weijian Li, Hong-Yu Chen, Nabeel Rehemtulla, Ved G. Shah, Dongho Kim, Dennis Wu,
 Qinjie Lin, Adam A. Miller, Han Liu

Current time series foundation model (TSFM) training corpora largely omit data w
ith certain complexities like irregular temporal sampling. Astronomical time ser
ies of stellar fluxes (``light curves'') are available in immense quantities and
 exhibit irregular sampling, multiple variates, and heteroskedasticity. We intro
duce $\texttt{StarEmbed}$, the first public benchmark for light curves comprised
 of real observations of $\sim$40,000 stars across seven classes and evaluations
 in clustering, classification, and out-of-distribution (OOD) source detection.
We benchmark TSFMs with differing architecture and training strategies as well a
s domain-specific transformers. Our results demonstrate that the $\texttt{Chrono
s}$ family, despite being pre-trained on regularly sampled non-astronomical data
, yields state-of-the-art (SOTA) performance in light curve clustering and OOD d
etection. While no TSFM strictly surpasses the classification performance of the
 long-established domain baseline, they do demonstrate excellent generalization
abilities. $\texttt{StarEmbed}$ marks a step toward universal light curve embedd
ings and improved TSFM performance on challenging data.

Video-MTR: Reinforced Multi-Turn Reasoning for Long Video Understanding

Yuan Xie, Tianshui Chen, Zheng Ge, Lionel Ni

Long-form video understanding remains a formidable challenge due to the complexi
ty of modeling long-range temporal dependencies and multi-event narratives. Exis
ting methods often rely on static reasoning or external Visual-Language Models (
VLMs), resulting in high computational complexity and sub-optimal performance. I
n this paper, we propose Video-MTR, a reinforced multi-turn reasoning framework
that operates solely through data-efficient, pure RL post-training. Video-MTR re
formulates video understanding as a dynamic decision-making process, where the a
gent iteratively selects key segments conditioned on the evolving context of pre
viously processed frames and the query. To ensure effective intermediate reasoni
ng and training stability, we introduce a novel gated bi-level reward system, wh
ich synergizes trajectory-level rewards (answer correctness) with turn-level rew
ards (frame-query relevance). This mechanism eliminates the need for data-intens
ive supervised fine-tuning, thereby substantially reducing reliance on large-sca
le datasets. Remarkably, Video-MTR achieves competitive or superior performance
using only $\sim$8K training samples, compared to existing approaches that requi
re 257K to 4.4M examples. Extensive experiments on benchmarks including VideoMME
, MLVU, LongVideoBench, LVBench, and EgoSchema demonstrate that Video-MTR surpas
ses state-of-the-art methods in both accuracy and efficiency. Code is available
at https://github.com/Xyuan13/Video-MTR.

Distributionally Robust Markov Games with Average Reward

Zachary Andrew Roch, Yue Wang

We propose and study distributionally robust Markov games (DR■MGs) with the aver
age■reward criterion as a crucial framework for multi-agent decision-making unde
r model mismatches and over extended horizons. Under a standard irreducible assu
mption, we first derive a correspondence between the optimal policies and the so
lutions of the robust Bellman equation, based on which we further show the exist
ence of a stationary Nash Equilibrium (NE) of the game. We further study DR-MGs
under a more general weakly communicating setting. We construct a set-valued map

based on the constant-gain optimal robust Bellman operator and show that its value is a subset of the best-response policies. We further prove that this map admits a fixed point, which implies the existence of NE. We then design two algorithms, Robust Nash■Iteration and robust TD Descent, with provably convergent guarantees. Finally, we show that the NE under average■reward can be approximated by the ones for the discounted DR-MGs as the discount factor approaches one. Our studies provide a comprehensive theoretical and algorithmic foundation for decision-making in complex, uncertain, and long-running multi-player environments.

The (Marginal) Value of a Search Ad: An Online Causal Framework for Repeated Second-price Auctions

Yuxiao Wen, Zihao Hu, Yanjun Han, Yuan Yao, Zhengyuan Zhou

Existing auto-bidding algorithms in digital advertising often treat the value of an ad opportunity as the revenue obtained when an ad is shown and/or clicked, and bid accordingly. This can lead to wasteful spending because the true value is the marginal gain from paid exposure: even without winning a sponsored slot, an advertiser may still earn revenue via an organic search result (e.g., on Google or Amazon). Motivated by recent work, we model ad value as a treatment effect—the outcome difference between winning and losing the auction—and study online learning for bidding in second-price (Vickrey) auctions under this causal perspective. We develop algorithms that attain rate-optimal regret under several feedback models. A key ingredient exploits the information revealed by the second-price payment rule, which strictly improves regret relative to analogous learning problems in first-price auctions.
****

ECA: Efficient Continual Alignment for Open-Ended Image-to-Text Generation

Jiangtao Kong, Peijun Zhao, Chun-Fu Chen, Youngwook Do, Shaohan Hu, Tianyi Zhou, Huajie Shao

Incremental Learning (IL) for Open-ended Image-to-Text Generation (OpenITG) enables models to continuously generate accurate, contextually relevant text for new images while preserving previously acquired knowledge. Unlike prior studies, this paper addresses a more practical scenario in which the predominant category of visual data shifts over time as environments evolve. In this context, we introduce a new notion of continual alignment, which incrementally adapts the alignment module within pre-trained VLMs to preserve high-quality cross-modal representations. Based on this idea, we propose **E**fficient **C**ontinual **A**lignment (ECA), a novel exemplar-free IL approach for OpenITG. The key challenge is enabling the model to acquire new, task-specific features while minimizing interference with the established alignment without accessing raw data from previous tasks. To address this, ECA employs three core mechanisms: a **M**ixture **o**f **Q**uery (MoQ) module that adapts task-specific query tokens, a **F**ish**e**r **D**ynamic **Ex**pansion (FeDEx) that dynamically expands model structure based on a Fisher Information Matrix (FIM)-based metric, and an embedding dictionary with **D**ictionary **R**eplay (DR) to retain past knowledge. To evaluate ECA's performance, we construct four new IL OpenITG benchmarks that better reflect real-world scenarios. Experimental results demonstrate that ECA significantly mitigates catastrophic forgetting and improves IL performance compared to baseline methods. Code and benchmarks are available at https://github.com/Snowball0823/ECA.

Keep It in Mind: User Centric Continual Spatial Intelligence Reasoning in Egocentric Video Streams

Yun wang, Junbin Xiao, Han Lyu, Yifan Wang, Jing Zuo, Zhanjie Zhang, Hong Huang, Dapeng Wu, Angela Yao

We introduce UCS-Bench, a dataset spanning 170+ hours of egocentric visual observations with 8.1K+ timestamped questions for diagnosing User-Centric Continual Spatial intelligence in egocentric video streams. UCS-Bench targets a new problem that emphasizes dynamic spatial reasoning, long-term memory, and their alignment with users' real-time locations. We propose DirectMe, a framework that incrementally constructs and maintains a structured spatial memory from streaming egocentric observations. DirectMe enables robust tracking and recall of object locat

ions, all relative to the user's movement over time. By tightly coupling visual perception with memory updates and spatial reasoning, our approach supports long-horizon queries that require recalling interactions, resolving viewpoint-induced ambiguities, and adapting to dynamic scenes.
Our experiments show that DirectMe significantly improves the spatial reasoning of leading multimodal LLMs; it also surpasses many spatially aware and long-form streaming video models. We hope our benchmark and solution will advance spatial intelligence research for egocentric AI assistants. Data and code are available at https://github.com/cocowy1/UCS-Bench.

Smoothness Errors in Dynamics Models and How to Avoid Them
Edward Berman, Luisa Li, Jung Yeon Park, Robin Walters
Modern neural networks have shown promise for solving partial differential equations over surfaces, often by discretizing the surface as a mesh and learning with a mesh-aware graph neural network. However, graph neural networks suffer from oversmoothing, where a node's features become increasingly similar to those of its neighbors. Unitary graph convolutions, which are mathematically constrained to preserve smoothness, have been proposed to address this issue. Despite this, in many physical systems, such as diffusion processes, smoothness naturally increases and unitarity may be overconstraining. In this paper, we systematically study the smoothing effects of different GNNs for dynamics modeling and prove that unitary convolutions hurt performance for such tasks. We propose relaxed unitary convolutions that balance smoothness preservation with the natural smoothing required for physical systems. We also generalize unitary and relaxed unitary convolutions from graphs to meshes. In experiments on PDEs such as the heat and wave equations over complex meshes and on weather forecasting, we find that our method outperforms several strong baselines, including mesh-aware transformers and equivariant neural networks. Our code is available at github.com/EdwardBerman/rayleigh_analysis

FLIP2: Expanding Protein Fitness Landscape Benchmarks for Real-World Machine Learning Applications
Kieran Didi, Sarah Alamdari, Alex Xijie Lu, Bruce James Wittmann, Kadina E Johnston, Ava P Amini, Ali Madani, Maya Czeneszew, Christian Dallago, Kevin K Yang
Machine learning methods that predict protein fitness from sequence remain sensitive to changes in data distributions, limiting generalization across common conditions encountered in protein engineering. Practically, protein engineers are thus left wondering about the effective utility of ML tools.
The FLIP benchmark established protocols for testing generalization under some domain shifts, but it was limited to measurements of stability, binding, and viral capsid viability.
We introduce FLIP2, a protein fitness benchmark spanning seven new datasets, including enzymes, protein-protein interactions, and light-sensitive proteins, as well as splits that measure generalization relevant to real-world protein engineering campaigns.
Evaluating a suite of benchmark models across these datasets and suites reveals that
simpler models often matched or outperformed fine-tuned protein language models on FLIP2, challenging the utility of existing transfer learning techniques. Provenance for all datasets has been recorded and we redistribute all data CC-BY 4.0 to facilitate continued progress.

OBJVanish: Prompt-Driven Generation of Physically Realizable 3D LiDAR-Invisible Objects
Bing Li, Wuqi Wang, Yanan Zhang, Jingzheng Li, Haigen Min, Wei Feng, Xingyu Zhao, Jie Zhang, Qing Guo
LiDAR-based 3D object detectors are fundamental to autonomous driving, where missed detections pose severe safety risks. While adversarial attacks are crucial for evaluating the robustness of these detectors, existing point-level perturbation methods rarely cause complete object disappearance and prove difficult to imp

lement in physical environments. We introduce OBJVanish, a prompt-driven text-to-3D adversarial generation framework that enables physically realizable attacks by generating 3D object models that are effectively invisible to LiDAR-based 3D object detectors. We first conduct a systematic empirical study of detection vulnerability in LiDAR-based 3D object detectors, revealing multi-object compositions as the dominant factor. Based on this analysis, the proposed framework iteratively refines text prompts—optimizing verbs, objects, and poses—to generate LiDAR-invisible pedestrian instances as representative vulnerable road users under physical constraints. To ensure realizability, the framework operates over a curated pool of representative real-world 3D object models and restricts generation to their valid combinations. Extensive experiments show that OBJVanish consistently evades six state-of-the-art (SOTA) LiDAR-based 3D object detectors in both simulation and real-world physical settings, exposing critical vulnerabilities in safety-critical detection systems.

Low Kruskal-Rank Adaptation

Yixing Xu, Guanchen Li, Chao Li, Xuanwu Yin, Dong Li, Spandan Tiwari, Ashish Sirasao, Emad Barsoum

Low-rank adaptation (LoRA) is one of the most widely used parameter-efficient fine-tuning (PEFT) methods for adapting pre-trained large language models (LLMs) to downstream tasks.

Although LoRA significantly reduces the number of trainable parameters and lowers fine-tuning costs, its performance is often limited by the inherent low-rank assumption.

In this paper, we revisit the notion of rank for LoRA update matrices and show that the standard matrix rank fails to capture duplicated directions and redundancy in the update subspace.

Motivated by this analysis, we argue that the Kruskal rank offers a more informative criterion for characterizing update diversity.

We therefore propose Low Kruskal Rank Adaptation (LoKRA), a new PEFT algorithm with provable theoretical guarantees that mitigates the limitations of LoRA.

We further introduce LoKRA$^+$, an enhanced variant that provides a tighter theoretical lower bound on the Kruskal rank and yields stronger empirical performance.

Experiments on multiple LLMs show that our approach consistently outperforms LoRA and other baselines, establishing state-of-the-art performance across a range of benchmarks. The code can be viewed at https://github.com/AMD-AGI/LoKRA.

A Systematic Study of Behavioral Cloning for Scientific Data Annotation

Ishaan Singh Chandok, Core Francisco Park

Scientific data annotation, such as tracking animals in video or proofreading neural reconstructions, remains bottlenecked by the “last mile” problem: even with strong automation, verification and correction consume substantial human effort. Standard approaches train models to directly predict annotations, discarding the rich supervision in how experts navigate, click, verify, and correct. We introduce a framework for studying behavioral cloning on scientific annotation: 9 synthetic tasks paired with synthetic annotations that simulate realistic human strategies including exploration, mistake correction, and strategic decision-making. Our experiments reveal several findings. First, skills emerge hierarchically: models learn GUI mechanics before task-critical decisions, and commit fewer mistakes than the training data while retaining the ability to correct errors when they occur. Second, scaling models on multi-task behavioral cloning shows that larger models are more data efficient within our scale range. Third, multi-task pretraining enables efficient fine-tuning to new tasks, while training from scratch fails entirely. Fourth, linear probes reveal that models internally represent latent variables of the annotation process such as task phase and data position; interestingly, we find a shared mistake representation that generalizes across different annotation tasks. Overall, our framework establishes systematic benchmarks and identifies key bottlenecks, providing a foundation for scaling behavioral cloning to real-world scientific data annotation.

Boundary Embedding Shaping with Adaptive Contrastive Learning for Graph Structural Disentanglement
Jiaqing Chen, Zidu Yin, Yichao Cai, Yuhang Liu, Zhen Zhang, Dong Gong, Javen Qinfeng Shi
Graph neural networks (GNNs) excel at aggregating neighbor information for classification, yet their performance is hindered by graph structural entanglement, where spurious correlations from semantically irrelevant neighbors contaminate node embeddings. This challenge is most acute for nodes near class boundaries in the embedding space, where amplified structural noise blurs decision boundaries and destabilizes predictions. Existing robust GNN methods largely treat all nodes uniformly, ignoring boundary vulnerabilities. In this paper, to improve classification performance, we tackle graph structural disentanglement by identifying boundary-region entanglement as the primary bottleneck and propose Boundary Embedding Shaping (BES), an adaptive contrastive learning GNN plug-in module that selectively suppresses spurious structural noise at decision boundaries with minimal model parameter perturbation. Extensive experiments demonstrate that BES consistently improves boundary discrimination and outperforms existing leading methods. Notably, BES boosts GCN performance by an average of 3.3% in node classification (up to 5.0% on WikiCS) and achieves superior accuracy in link prediction.

Learning When to Attend: Conditional Memory Access for Long-Context LLMs
Sakshi Choudhary, Aditya Chattopadhyay, Luca Zancato, Elvis Nunez, Matthew Trager, Wei Xia, Stefano Soatto
Language models struggle to generalize beyond
pretraining context lengths, limiting long-horizon
reasoning and retrieval. Continued pretraining
on long-context data can help but is expensive
due to the quadratic scaling of Attention. We
observe that most tokens do not require (Global)
Attention over the entire sequence and can rely
on local context. Based on this, we propose L2A
(Learning To Attend), a layer that enables conditional
(token-wise) long-range memory access
by deciding when to invoke global attention. We
evaluate L2A on Qwen 2.5 and Qwen 3 models,
extending their effective context length from 32K
to 128K tokens. L2A matches the performance of
standard long-context training to within 3% while
skipping Global Attention for $\sim$80% of tokens,
outperforming prior baselines. We also design
custom Triton kernels to efficiently implement
this token-wise conditional Attention on GPUs,
achieving up to $\sim$2$\times$ improvements in training
throughput and time-to-first-token over FlashAttention.
Moreover, L2A enables post-training
pruning of highly sparse Global Attention layers,
reducing KV cache memory by up to 50%
with negligible performance loss.

Machine Learning Hamiltonians are Accurate Energy-Force Predictors
Seongsu Kim, Chanhui Lee, Yoonho Kim, Seongjun Yun, Honghui Kim, Nayoung Kim, Changyoung Park, Sehui Han, Sungbin Lim, Sungsoo Ahn
Recently, machine learning Hamiltonian (MLH) models have gained traction as fast approximations of electronic structures such as orbitals and electron densities, while also enabling direct evaluation of energies and forces from their predictions. However, despite their physical grounding, existing Hamiltonian models are evaluated mainly by reconstruction metrics, leaving it unclear how well they perform as energy–force predictors. We address this gap with a benchmark that computes energies and forces directly from predicted Hamiltonians. Within this fram

ework, we propose QHFlow2, a state-of-the-art Hamiltonian model with an SO(2)-equivariant backbone and a two-stage edge update. QHFlow2 achieves 40% lower Hamiltonian error than the previous best model with fewer parameters. Under direct evaluation on MD17/rMD17, it is the first Hamiltonian model to reach NequIP-level force accuracy while achieving up to $20\times$ lower energy MAE. On QH9, QHFlow2 reduces energy error by up to $20\times$ compared to MACE. Finally, we demonstrate that QHFlow2 exhibits consistent scaling behavior with respect to model capacity and data, and that improvements in Hamiltonian accuracy effectively translate into more accurate energy and force computations.

Domain-Shift-Aware Conformal Prediction for Large Language Models
Zhexiao Lin, Yuanyuan Li, Neeraj Sarna, Yuanyuan Gao, Michael Berger
Large language models have achieved impressive performance across diverse tasks. However, their tendency to produce overconfident and factually incorrect outputs, known as hallucinations, poses risks in real world applications. Conformal prediction provides finite-sample, distribution-free coverage guarantees, but standard conformal prediction breaks down under domain shift, often leading to under-coverage and unreliable prediction sets. We propose a new framework called Domain-Shift-Aware Conformal Prediction (DS-CP). Our framework adapts conformal prediction to large language models under domain shift, by systematically reweighting calibration samples based on their proximity to the test prompt, thereby preserving validity while enhancing adaptivity. Our theoretical analysis and experiments on the MMLU benchmark demonstrate that the proposed method delivers more reliable coverage than standard conformal prediction, especially under substantial distribution shifts, while maintaining efficiency. This provides a practical step toward trustworthy uncertainty quantification for large language models in real-world deployment.
****

RelaxFlow: Text-Driven Amodal 3D Generation
Jiayin Zhu, Guoji Fu, Xiaolu Liu, Qiyuan He, Yicong Li, Angela Yao
Image-to-3D generation faces inherent semantic ambiguity under occlusion, where partial observation alone is often insufficient to determine object category. In this work, we formalize *text-driven amodal 3D generation*, where text prompts steer the completion of unseen regions while strictly preserving input observation. Crucially, we identify that these objectives demand distinct control granularities: rigid control for the observation versus relaxed structural control for the prompt. To this end, we propose **RelaxFlow**, a training-free dual-branch framework that decouples control granularity via a Multi-Prior Consensus Module and a Relaxation Mechanism. Theoretically, we prove that our relaxation is equivalent to applying a low-pass filter on the generative vector field, which suppresses high-frequency instance details to isolate geometric structure that accommodates the observation. To facilitate evaluation, we introduce two diagnostic benchmarks, **ExtremeOcc-3D** and **AmbiSem-3D**. Extensive experiments demonstrate that RelaxFlow successfully steers the generation of unseen regions to match the prompt intent without compromising visual fidelity. Code and datasets will be released.

Whom to Query for What: Adaptive Group Elicitation via Multi-Turn LLM Interactions
Ruomeng Ding, Tianwei Gao, Thomas P Zollo, Eitan Bachmat, Richard Zemel, Zhun Deng
Eliciting information to reduce uncertainty about latent group-level properties is a central problem in collective assessment, preference modeling, and opinion aggregation, and is especially important in survey-based studies. While natural language interactions provide a flexible interface, existing methods typically rely on fixed questionnaires and static respondent sets, and do not adapt to partial or missing responses across rounds. To address this gap, we study adaptive information elicitation through multi-turn interactions between a large language model and a group of individuals, where both queries and respondents are adaptively selected to infer latent group properties. We propose a theoretically groun

ded framework that, at each round, jointly selects a query and a subset of respo ndents based on previously observed responses to efficiently reduce uncertainty about a target latent quantity (e.g., group-level political inclination). Motiva ted by practical survey constraints, such as limited questions and costly partic ipation, our strategy maximizes information gain under a fixed budget. To handle missing and incomplete responses, we combine graph neural networks for aggregat ing/imputing partial group information with an information-theoretic criterion t hat guides per-round selection. Across three real-world opinion datasets, we ach ieve consistent improvements in population-level response prediction under const rained budgets, including over a 12% relative gain on CES at a 10% respondent bu dget.

DF-ExpEnse: Diffusion Filtered Exploration for Sample Efficient Finetuning

Calvin Luo, Chen Sun, Shuran Song

A natural recipe for intelligent robotic decision-making is initializing from pr etrained generative control policies, which have summarized offline experience, and adapting them to self-collected online experience. We present DF-ExpEnse, a n exploration technique that improves the quality of online experience collectio n, thus increasing finetuning sample-efficiency. DF-ExpEnse leverages the multi modal modeling capabilities of the generative control policy to create an expres sive and tractably evaluatable candidate set. It then utilizes an ensemble of c ritics to identify the action that best balances quality with high exploration i nterest. In fleet settings, DF-ExpEnse further enables cross-agent communicati on to facilitate collaborative exploration as a group. DF-ExpEnse can be seamle ssly integrated with existing strategies that finetune pretrained generative con trol policies via reinforcement learning. We experimentally validate consistent sample-efficiency benefits through DF-ExpEnse across a variety of manipulation and locomotion tasks, compared to default finetuning and alternative action sele ction schemes. Project can be found at [df-expense.github.io](https://df-expens e.github.io).

GradientStabilizer: Fix the Norm, Not the Gradient

Tianjin Huang, Zhangyang Wang, Haotian Hu, Zhenyu Zhang, Gaojie Jin, Xiang Li, L i Shen, Jiaxing Shang, Tianlong Chen, Ke Li, Lu Liu, Qingsong Wen, Shiwei Liu

Training instability in modern deep learning systems is frequently triggered by rare but extreme gradient-norm spikes, which can induce oversized parameter upda tes, corrupt optimizer state, and lead to slow recovery or divergence. Widely us ed safeguards such as gradient clipping mitigate these failures but require thre shold tuning and indiscriminately truncate large updates.

We propose **GradientStabilizer**, a lightweight, drop-in gradient transform tha t *preserves the instantaneous gradient direction* while replacing the update ma gnitude with a statistically stabilized estimate derived from running gradient-n orm statistics.

We prove that the resulting stabilized magnitude is uniformly bounded on spike s teps, independent of the spike size, and show how this boundedness controls opti mizer state evolution in adaptive methods.

Across LLM pre-training (FP16), quantization-aware pre-training (FP4), ImageNet classification, reinforcement learning, and time-series forecasting, **GradientS tabilizer** consistently improves training stability, widens stable learning-rat e regions, and reduces divergence relative to clipping-based baselines, even sub stantially reducing Adam’s sensitivity to weight-decay strength.

Quantifying LLM Attention-Head Stability: Implications for Circuit Universality

Karan Bali, Jack Stanley, Praneet Suresh, Danilo Bzdok

In mechanistic interpretability, recent work scrutinizes transformer “circuits”— sparse, mono or multi layer sub computations, that may reflect human understanda ble functions. Yet, these network circuits are rarely acid-tested for their stab ility across different instances of the same deep learning architecture. Without this, it remains unclear whether reported circuits emerge universally across la bs or turn out to be idiosyncratic to a particular estimation instance, potentia

lly limiting confidence in safety-critical settings. Here, we systematically stu dy stability across-refits in increasingly complex transformer language models o f various sizes. We quantify, layer by layer, how similarly attention heads lear n representations across independently initialized training runs. Our rigorous e xperiments show that (1) middle-layer heads are the least stable yet the most re presentationally distinct; (2) deeper models exhibit stronger mid-depth divergen ce; (3) unstable heads in deeper layers become more functionally important than their peers from the same layer; (4) applying weight decay optimization substant ially improves attention-head stability across random model initializations; and (5) the residual stream is comparatively stable. Our findings establish the cro ss-instance robustness of circuits as an essential yet underappreciated prerequi site for scalable oversight, drawing contours around possible white-box monitora bility of AI systems.

FakeWorld 1.0: An Omni-modal Benchmark for Fake Media and Content

Yifeng Gao, Yifan Ding, Li Wang, Feida Huang, Ye Sun, Yixu Wang, Xin Wang, Yutao Wu, Hanxun Huang, Yunhao Feng, Yingshui Tan, Xingjun Ma, Yu-Gang Jiang

The rapidly increasing realism of AI-generated media has intensified the spread of deceptive content and undermined public trust. Existing research largely trea ts this challenge along two separate axes: media authenticity, which assesses wh ether content is real or machine-generated, and content veracity, which evaluate s semantic consistency and factual correctness. This separation overlooks how re al-world deception jointly exploits both dimensions.

In this work, we present FakeWorld 1.0, an omni-modal benchmark that unifies med ia authenticity and content veracity within a single evaluation framework. Along the media axis, FakeWorld spans text, audio, image, and video synthesis. Along the content axis, it systematically instantiates cross-modal semantic inconsiste ncies and factual errors. These two axes are jointly embedded in realistic web-b ased and streaming-style presentation scenarios, reflecting how multimodal decep tion is composed, contextualized, and delivered in practice.

FakeWorld further provides explainable annotations in the form of per-instance r ationales, enabling transparent and evidence-based analysis. Under a unified eva luation protocol, experiments on both open- and closed-source multimodal large l anguage models (MLLMs) reveal fundamental capability limits and demonstrate Fake World’s effectiveness in exposing high-fidelity, mixed-source deception. Beyond the benchmark, we introduce OmniChecker, an agentic framwork that performs joint , explainable detection across both axes and produces evidence-backed diagnostic reports.

We position FakeWorld 1.0 as a realistic stress test and a practical foundation for advancing scalable, explainable detection of fake multimodal content.

DIVA: Harnessing the Representation Divergence in Unified Multimodal Models for Mutual Reinforcement

Renjie Lu, Xulong Zhang, Xiaoyang Qu, Jianzong Wang, Shangfei Wang

Unified Multimodal models (UMMs) built on a single architecture have shown impre ssive performance in both understanding and generation. We identify a fundamenta l challenge lies in inductive biases induced by distinct supervision signals: ge neration branch prefers high-fidelity, fine-grained representations capable of r econstruction, while the understanding favours semantically discriminative embed dings that remain invariant to task-irrelevant factors. Consequently, optimizing these complementary but non-equivalent objectives within a monolithic backbone leads to mutual impairment instead of enhancement. In this paper, we first analy ze the root cause of this interference in unified backbones and reveal a complem entary structure in their internal representations. Motivated by the observation , we propose DIVA, a self-improved post-training framework that transforms the r epresentation divergence into interior synergy. By explicitly factorizing the vi sual representation into shared and unique components based on two complementary information flow, DIVA enables both the understanding and generation branches t o achieve beneficial transferring while preserving the integrity of unique infor mation from cross-flow interference via mutual information estimation. Despite i

ts generality, our method consistently achieves improvements across visual under standing (+7.82%) and generation (+8.46%). The official code is available at: ht tps://anonymous.4open.science/r/DIVA-D225.

A Game-Theoretic Framework for Measuring and Explaining Metric Compatibility in Fair Machine Learning
Lingfeng Zhang, Jingran Yang, Zhaohui Wang, Min Zhang, Zhang Qing
Machine learning fairness research documents trade-offs but lacks quantitative f rameworks to measure intrinsic metric compatibility without requiring causal gra phs. We introduce a game-theoretic framework that decomposes metrics into intera ction vectors, enabling compatibility measurement between metrics via cosine sim ilarity and mechanistic attribution to attribute coalitions. Through analysis of 6 datasets, 7 models, and 6 debiasing methods, we reveal that fairness and util ity are often structurally orthogonal (median compatibility ≈ 0) rather than diametrically opposed, with conflicts driven by sparse, low-order interacti ons. We further show that debiasing improves fairness by compressing the compati bility space—reducing compatibility of both synergistic and conflicting relation ships—rather than eliminating conflicts, providing a mechanistic basis for under standing metric alignment.

Falling Trees: A Model Class for Interpretable Risk Prioritization
Varun Babbar, Zachery Boner, Margo Seltzer, Cynthia Rudin
Many real-world decisions require prioritizing high-risk cases, such as clinicia ns prioritizing high-risk patients before lower-risk ones. Falling rule lists (F RLs), which are ordered if--then rules with monotonically decreasing risks, prov ide an interpretable framework for such tasks; however, their single-path struct ure yields a highly restricted model class. We introduce falling trees, a new fa mily of interpretable models that enforces the same monotonic risk constraint wh ile permitting tree-structured branching. We present GraviTree, a novel dynamic- programming-with-bounds algorithm for learning the Rashomon set of falling trees under depth and branching constraints. Our formulation can interpolate between rule lists and full decision trees, enabling user-desired model expressivity. In a new clinical dataset and in many public classification benchmarks, falling tr ees match or outperform FRLs and other interpretable baselines, often producing more sparse decisions for high-risk instances. Our results show that falling tre es strike a practical balance between interpretability, expressiveness, and risk prioritization for high-stakes settings.
****

4DPC^{2}hat: Towards Dynamic Point Cloud Understanding with Failure-Aware Bootst rapping
Xindan Zhang, Weilong Yan, YUFEI SHI, Xuerui Qiu, Tao He, Ying Li, Ming Li, Hehe Fan
Point clouds provide a compact and expressive representation of 3D objects, and have recently been integrated into multimodal large language models (MLLMs). How ever, existing methods primarily focus on static objects, while understanding dy namic point cloud sequences remains largely unexplored. This limitation is mainl y caused by the lack of large-scale cross-modal datasets and the difficulty of m odeling motions in spatio-temporal contexts. To bridge this gap, we present 4DPC ^{2}hat, the *first* MLLM tailored for dynamic point cloud understanding. To thi s end, we construct a large-scale cross-modal dataset 4DPC^{2}hat-200K via a met iculous two-stage pipeline consisting of topology-consistent 4D point constructi on and two-level captioning. The dataset contains over 44K dynamic object sequen ces, 700K point cloud frames, and 200K curated question–answer (QA) pairs, suppo rting inquiries about counting, temporal relationship, action, spatial relations hip, and appearance. At the core of the framework, we introduce a Mamba-enhanced temporal reasoning MLLM to capture long-range dependencies and dynamic patterns among a point cloud sequence. Furthermore, we propose a *failure-aware* bootstr apping learning strategy that iteratively identifies model deficiencies and gene rates targeted QA supervision to continuously strengthen corresponding reasoning capabilities. Extensive experiments demonstrate that our 4DPC^{2}hat significan

tly improves action understanding and temporal reasoning compared with existing models, establishing a strong foundation for 4D dynamic point cloud understanding.

Local Policies for Graph-Structured Markov Decision Processes

Fathima Zarin Faizal, Asuman E. Ozdaglar, Martin J Wainwright

We study a cooperative form of multi-agent reinforcement learning with state space dynamics and agent interaction controlled by an underlying graph. Each agent has a local state and action, the evolution of the local state depends only on the states and actions in the 1-hop neighborhood defined by the graph. Structured dynamics of this type arise in various applications, including network resource allocation, co-operative games, epidemic control, and wireless scheduling. The global state-action space scales exponentially in the number of agents, so that computing global optimal policies is intractable in the worst-case. We study conditions under which it is possible to approximate the optimal policies by a local policy for each agent that depends only on states associated with nodes within its m-hop neighborhood. By controlling the propagation of influences via a Dobrushin-type stability matrix, we establish that globally optimal policies can approximated by local policies with sub-optimality gap decaying exponentially in m.

Improved Analysis of the Accelerated Noisy Power Method with Applications to Decentralized PCA

Pierre Aguié, Mathieu Even, Laurent Massoulié

We analyze the Accelerated Noisy Power Method, an algorithm for Principal Component Analysis in the setting where only inexact matrix-vector products are available, which can arise for instance in decentralized PCA. While previous works have established that acceleration can improve convergence rates compared to the standard Noisy Power Method, these guarantees require overly restrictive upper bounds on the magnitude of the perturbations, limiting their practical applicability. We provide an improved analysis of this algorithm, which preserves the accelerated convergence rate under much milder conditions on the perturbations. We show that our new analysis is worst-case optimal, in the sense that the convergence rate cannot be improved, and that the noise conditions we derive cannot be relaxed without sacrificing convergence guarantees. We demonstrate the practical relevance of our results by deriving an accelerated algorithm for decentralized PCA, which has similar communication costs to non-accelerated methods. To our knowledge, this is the first decentralized algorithm for PCA with provably accelerated convergence.

Learning Dynamics of Zeroth-Order Optimization: A Kernel Perspective

Zhe Li, Bicheng Ying, Zidong Liu, Haibo Yang

Classical optimization theory establishes that zeroth-order (ZO) algorithms suffer from a dimension-dependent slowdown, with convergence rates typically scaling with the model dimension compared to first-order methods. However, in contrast to these theoretical expectations, a growing body of recent work demonstrates the successful application of ZO methods to fine-tuning Large Language Models (LLMs) with billions of parameters. To explain this paradox, we derive the one-step learning dynamics of ZO SGD, where the empirical Neural Tangent Kernel (eNTK) naturally emerges as the key term governing the learning behavior. Inspection of the eNTK produced by ZO-SGD reveals that each element corresponds to the inner product of neural tangent vectors projected onto a random low-dimensional subspace. Thus, by invoking the Johnson-Lindenstrauss Lemma, our analysis shows that the fidelity of the ZO eNTK is governed primarily by the number of perturbations. Crucially, the approximation error depends on the model output size rather than the massive parameter dimension. This dimension-free property provides a theoretical justification for the scalability of ZO methods to LLMs finetuning tasks. We

believe that this kernel-based framework offers a novel perspective for understanding ZO methods within the context of learning dynamics.

Toward Understanding Adversarial Distillation: Why Robust Teachers Fail
Hongsin Lee, Hye Won Chung
Adversarial Distillation aims to enhance student robustness by guiding the student with a robust teacher's soft labels within the min-max adversarial training framework, yet its success is notoriously inconsistent: a more robust teacher often fails to improve, or even harms, the student's robust generalization.
In this paper, we identify a key mechanism of this teacher dependency: the misalignment between the teacher's supervisory confidence and the student's representational limitations on a consistent subset of training data—the Robustly Unlearnable Set.
We present a theoretical framework analyzing the feature learning dynamics of a two-layer neural network, demonstrating that this mismatch creates a dichotomy in distillation outcomes.
We prove that when a teacher provides confident supervision on unlearnable samples, it compels the student to memorize spurious noise patterns that eventually overpower the learned robust signal, thereby driving robust overfitting.
Conversely, a teacher that exhibits high uncertainty on these samples effectively suppresses noise memorization, allowing the student to rely solely on the learnable signal for robust generalization.
We empirically validate our theory across both synthetic simulations and real-image classification datasets, confirming that robust overfitting is driven by the teacher's interaction with unlearnable samples.
Finally, we demonstrate that a teacher's predictive entropy on unlearnable samples serves as a strong indicator of student robustness, validating our theoretical framework and offering a principled guideline for robust teacher selection.

SoMA: A Real-to-Sim Neural Simulator for Robotic Soft-Body Manipulation
Mu Huang, Hui Wang, Kerui Ren, Linning Xu, Yunsong Zhou, Mulin Yu, Bo Dai, Jiangmiao Pang
Simulating deformable objects under rich interactions remains a fundamental challenge for real-to-sim robot manipulation, with dynamics jointly driven by environmental effects and robot actions.
Existing simulators rely on predefined physics or data-driven dynamics without robot-conditioned control, limiting accuracy, stability, and generalization.
This paper presents \textbf{SoMA}, a 3D Gaussian Splat simulator for soft-body manipulation.
SoMA couples deformable dynamics, environmental forces, and robot joint actions in a unified latent neural space for end-to-end real-to-sim simulation.
Modeling interactions over learned Gaussian splats enables controllable, stable long-horizon manipulation and generalization beyond observed trajectories without predefined physical models.
SoMA improves resimulation accuracy and generalization on real-world robot manipulation by 20\%, enabling stable simulation of complex tasks such as long-horizon cloth folding. **Project Page: city-super.github.io/SoMA**

Theoretical Perspectives on Data Quality and Synergistic Effects in Pre- and Post-Training Reasoning Models
Adel Javanmard, Baharan Mirzasoleiman, Vahab Mirrokni
Large Language Models (LLMs) are pretrained on massive datasets and later instruction-tuned via supervised fine-tuning (SFT) or reinforcement learning (RL). Best practices emphasize large, diverse pretraining data, whereas post-training operates differently: SFT relies on smaller, high-quality datasets, while RL benefits more from scale, with larger amounts of feedback often outweighing label quality. Yet it remains unclear why pretraining and RL require large datasets, why SFT excels on smaller ones, and what defines high-quality SFT data. In this work, we theoretically analyze transformers trained on an in-context weight prediction task for linear regression. Our analysis reveals several key findings: (i) b

alanced pretraining data can induce latent capabilities later activated during p ost-training, and (ii) SFT learns best from a small set of examples challengin g for the pretrained model, while excessively large SFT datasets may dilute info rmative pretraining signals. In contrast, RL is most effective on large-scale da ta that is not overly difficult for the pretrained model. We validate these theo retical insights with experiments on large nonlinear transformer architectures.

Constrained hybrid modelling to predict microbial dynamics and organic matter tu rnover in soil systems
Paul Collart, Juergen Gall, Andrea Schnepf, Holger Pagel, Lars Doorenbos
Soil microorganisms control organic matter cycling and largely determine how soi l systems can cope with and mitigate climate change and environmental threats. R epresenting microbial dynamics in process-based soil models is therefore critica l to predict carbon cycling in soils, albeit highly challenging to inform from d ata. One promising approach to improve their parametrisation is the integration of genomic data, yet modelling the complex and unknown relationship between geno mes and the processes the microbes are driving is an unsolved problem.
In this work, we present the first hybrid modeling framework for deriving biokin etic parameter values of a process-based soil organic matter turnover model from metagenome-inferred functional traits based on DNA sequencing data. Our model predicts biokinetic parameters of the process-based model from genomic trait dat a with a neural network and integrates constraints from ecological theory and li terature to ensure realistic behavior, even of non-observed state variables. We evaluate our method on synthetic genomic trait datasets of varying complexity an d on real data, showing that our approach improves performance over multiple bas elines and learns the dynamics of unmeasurable components of the process-based m odel effectively, even for small training datasets.

Discretized Density-Guided Source-Free Domain Adaptation for Regression
Gezheng Xu, Qi CHEN, QIUHAO Zeng, Charles Ling, Boyu Wang
Source-Free Domain Adaptation (SFDA) enables model adaptation under distribution shifts without access to source data, providing a practical solution for privac y-sensitive applications and having shown substantial progress in classification .
In contrast, regression involves ordered and continuous target variables, posing unique challenges for representation adaptation and pseudo-label refinement in the SFDA setting.
To address this gap, we propose a novel algorithm for continuous label predictio n in SFDA that leverages instance-dependent, discretized density–informed superv isory signals to refine pseudo-labels within an uncertainty-aware paradigm.
By incorporating auxiliary discretized distribution learning, our method also pr omotes more compact and structured feature representations, mitigating the inher ent difficulties of adapting regression models under distribution shift.
We theoretically demonstrate that the resulting density structure is robust to p otential perturbations, supporting reliable SFDA for regression.
Extensive experiments across multiple benchmarks validate the effectiveness of t he proposed approach.

Manifold-Aware Perturbations for Constrained Generative Modeling
Katherine Keegan, Lars Ruthotto
Generative models have enjoyed widespread success in a variety of applications. However, they encounter inherent mathematical limitations in modeling distributi ons where samples are constrained by equalities, as is frequently the setting in scientific domains. In this work, we develop a computationally cheap, mathemati cally justified, and highly flexible distributional modification for combating k nown pitfalls in equality-constrained generative models. We propose perturbing t he data distribution in a constraint-aware way such that the new distribution ha s support matching the ambient space dimension while still implicitly incorporat ing underlying manifold geometry. Through theoretical analyses and empirical evi dence on several representative tasks, we illustrate that our approach consisten

tly enables data distribution recovery and stable sampling with both diffusion models and normalizing flows.

Pruning at Initialisation through the lens of Graphon Limit: Convergence, Expressivity, and Generalisation

Hoang Pham, The-Anh Ta, Long Tran-Thanh

Pruning at Initialisation methods discover sparse, trainable subnetworks before training, but their theoretical mechanisms remain elusive.

Existing analyses are often limited to finite-width statistics, lacking a rigorous characterisation of the global sparsity patterns that emerge as networks grow large. In this work, we connect discrete pruning heuristics to graph limit theory via graphons, establishing the *graphon limit of PaI masks*. We introduce a *Factorised Saliency Model* that encompasses popular pruning criteria and prove that, under regularity conditions, the discrete masks generated by these algorithms converge to deterministic bipartite graphons. This limit framework establishes a novel topological taxonomy for sparse networks: while unstructured methods (e.g., Random, Magnitude) converge to homogeneous graphons representing uniform connectivity, data-driven methods (e.g., SNIP, GraSP) converge asymptotically to heterogeneous graphons that encode implicit feature selection. Leveraging this continuous characterisation, we derive two consequences. First, we prove a universal approximation theorem for sparse networks on active coordinate subspaces. Second, under the Graphon-NTK lazy-training regime, we connect the limiting graphon to NTK-style generalisation bounds and introduce a path-density interpretation of how sparse topology can modulate kernel alignment. Our results transform the study of sparse neural networks from combinatorial graph problems into a rigorous framework of continuous operators, offering a new mechanism for analysing expressivity and generalisation in sparse networks.

Stable Spectral Copula Alignment for Robust Multimodal Learning

Hongkang Zhang, Shao-Lun Huang, Yanlong Wang, Ercan Engin KURUOGLU

Multimodal alignment can fail under deployment shift because standard objectives entangle cross-modal dependence with marginal-sensitive geometry. Stable Spectral Copula Alignment (SSCA) provides a deployment protocol for copula-stable dependence under approximately coordinate-wise monotone marginal distortions, together with auditable, label-free diagnostics for monitoring and mitigation. SSCA combines (i) clipped soft-rank Gaussianization that suppresses marginal effects while tracking tie and approximation errors, (ii) dependence-weighted sliced Wasserstein hub coupling for globally coherent multiway alignment with cycle auditing, and (iii) diagonal-stabilized block-spectral learning with eigengap-normalized Davis-Kahan diagnostics, yielding an actionable subspace-risk inequality. A calibrated gate maps diagnostic proxies to a reliability signal with a measurable false-alarm/miss trade-off, enabling stability-mode updates, budgeted remediation, and conservative no-update fallback for out-of-scope drift. Evaluations on MOSEI/MELD, MSCOCO, and CC3M-500K show improved performance under perturbation and substantially reduced degradation under controlled monotone distortions, raw-pipeline drifts, and frozen-feature retrieval stress tests.

Distinguishing Imitation Error from Intrinsic Motion Learning Difficulty

Zhaorui Meng, Lu Yin, Xinrui Chen, Chengxu Zuo, Anjun Chen, Shihui Guo, Yipeng Qin

Physics-based motion imitation is central to humanoid control, yet current evaluation metrics(e.g., MPJPE) only quantify imitation outcomes, not their underlying causes. This conflation obscures a critical diagnostic question: when imitation error occurs, does it stem from policy limitations or the intrinsic learning difficulty of the target motion? To resolve this ambiguity, we propose the Torque Variation Score (TVS), a physics-grounded metric that quantifies the inherent learning difficulty of a motion independently of any policy's performance. TVS measures the magnitude of torque variation required to correct small pose perturbations, directly capturing how dynamical properties shape the reinforcement learning landscape. We establish that high-TV motions induce flat reward landscapes a

nd vanishing policy gradients, explaining persistent imitation failures. Extensive experiments with state-of-the-art methods (UHC, PHC+) confirm TVS strongly correlates with imitation error and enables principled error attribution: high error on low-TV motions indicates policy deficiency, while high error on high-TV motions reflects fundamental learning constraints. Beyond error diagnosis, TVS facilitates three practical applications: Maximum Imitable Difficulty (MID) for policy capability assessment, Difficulty-Stratified Joint Error (DSJE) for granular performance profiling, and Flawed Motion Detection for identifying segments with abnormally high learning difficulty to support mocap data curation and quality control. TVS provides a rigorous lens to distinguish policy-induced errors from motion-inherent challenges and enhances motion dataset reliability.

Class-Conditional Distribution Balancing for Group Robust Classification

Miaoyun Zhao, Qiang Zhang

Spurious correlations that lead models to correct predictions for the wrong reasons pose a critical challenge for robust real-world generalization. Existing research attributes this issue to group imbalance and addresses it by maximizing group-balanced or worst-group accuracy, which heavily relies on expensive bias annotations. A compromise approach involves predicting bias information using extensively pretrained foundation models, which requires large-scale data and is limited to physically interpretable biases. To address these challenges, we offer a novel perspective by reframing the spurious correlations as imbalances/mismatches in class-conditional distributions caused by general biases, whether interpretable or not, and propose a simple yet effective robust learning method that mitigates the need for bias annotations or predictions. With the goal of maximizing the conditional entropy (uncertainty) of the label given spurious factors, our method leverages a sample reweighting strategy to achieve class-conditional distribution balancing, which automatically highlights minority groups and classes, effectively mitigating spurious correlations and producing a debiased data distribution for classification. Extensive experiments and analysis demonstrate that our approach consistently delivers strong overall performance, and is competitive with methods that rely on bias supervision.

CoD-Lite: Real-Time Diffusion-Based Generative Image Compression

Zhaoyang Jia, Naifu Xue, Zihan Zheng, Jiahao Li, Bin Li, Xiaoyi Zhang, Zongyu Guo, Yuan Zhang, Houqiang Li, Yan Lu

Recent advanced diffusion methods typically derive strong generative priors by scaling diffusion transformers. However, scaling fails to generalize when adapted for real-time compression scenarios that demand lightweight models. In this paper, we explore the design of real-time and lightweight diffusion codecs by addressing two pivotal questions. First, does diffusion pre-training benefit lightweight diffusion codecs? Through systematic analysis, we find that generation-oriented pre-training is less effective at small model scales whereas compression-oriented pre-training yields consistently better performance. Second, are transformers essential? We find that while global attention is crucial for standard generation, lightweight convolutions suffice for compression-oriented diffusion when paired with distillation. Guided by these findings, we establish a one-step lightweight convolution diffusion codec that achieves real-time 60 FPS encoding and 42 FPS decoding at 1080p. Further enhanced by distillation and adversarial learning, the proposed codec reduces bitrate by 85% at a comparable FID to MS-ILLM, bridging the gap between generative compression and practical real-time deployment. Codes are released at https://github.com/microsoft/GenCodec/tree/main/CoD_Lite.

ImgCoT: Compressing Long Chain of Thought into Compact Visual Tokens for Efficient Reasoning of Large Language Model

Xiaoshu Chen, Sihang Zhou, KE LIANG, Taichun Zhou, Yaohua Wang, Yang Gao, Xinwang Liu

Compressing long chains of thought (CoT) into compact latent tokens is crucial for efficient reasoning with large language models (LLMs). Recent studies employ

autoencoders to achieve this by reconstructing textual CoT from latent tokens, thus encoding CoT semantics. However, treating textual CoT as the reconstruction target forces latent tokens to preserve surface-level linguistic features (e.g., word choice and syntax), introducing a strong linguistic inductive bias that prioritizes linguistic form over reasoning structure and limits logical abstraction. Thus, we propose ImgCoT that replaces the reconstruction target from textual CoT to the visual CoT obtained by rendering CoT into images. This substitutes linguistic bias with spatial inductive bias, i.e., a tendency to model spatial layouts of the reasoning steps in visual CoT, enabling latent tokens to better capture global reasoning structure. Moreover, although visual latent tokens encode abstract reasoning structure, they may blur reasoning details. We thus propose a loose ImgCoT, a hybrid reasoning that augments visual latent tokens with a few key textual reasoning steps, selected based on low token log-likelihood. This design allows LLMs to retain both global reasoning structure and fine-grained reasoning details with fewer tokens than the complete CoT. Extensive experiments across multiple datasets and LLMs demonstrate the effectiveness of the two versions of ImgCoT.

SP-Mind: An Autonomous Reasoning Agent for Spatial Proteomics Analysis

YuCheng Yuan, Yuanfeng Ji, Zhongxiao Li, Ruijiang Li

Spatial proteomics enables single-cell-resolution characterization of protein expression within tissue architecture, playing a critical role in understanding tumor microenvironments and guiding precision medicine. However, current analysis workflows remain fragmented, requiring expert manual orchestration of heterogeneous tools and limiting research scalability and reproducibility. We present SP-Mind, the first autonomous AI agent designed to unify the spatial proteomics analysis pipeline, from raw multiplexed tissue imaging to downstream phenotype discovery. Equipped with expert-curated biological analysis skills and specialized computational tools, SP-Mind converts natural-language queries into end-to-end analytical workflows without task-specific fine-tuning. To rigorously evaluate its capabilities, we introduce SP-Bench, a comprehensive benchmark spanning diverse tissue types, comprising 102 tasks across 18 distinct categories. Through extensive evaluation on SP-Bench and established downstream tasks, SP-Mind achieves state-of-the-art performance compared to existing open-source biomedical agent baselines.

Task-Driven Subspace Decomposition for Knowledge Sharing and Isolation in LoRA-based Continual Learning

Lingfeng He, De Cheng, Huaijie Wang, Xi Yang, Nannan Wang, Xinbo Gao

Continual Learning (CL) requires models to sequentially adapt to new tasks without forgetting old knowledge. Recently, Low-Rank Adaptation (LoRA), a representative Parameter-Efficient Fine-Tuning (PEFT) method, has gained increasing attention in CL. Several LoRA-based CL methods reduce interference across tasks by separating their update spaces, typically building the new space from the estimated null space of past tasks. However, they (i) overlook task-shared directions, which suppresses knowledge transfer, and (ii) fail to capture truly effective task-specific directions since these ``null bases" of old tasks can remain nearly inactive for new task under correlated tasks. To address this, we study LoRA learning capability from a projection energy perspective, and propose Low-rank Decomposition and Adaptation (LoDA). It performs a task-driven decomposition to build general and truly task-specific LoRA subspaces by solving two energy-based objectives, decoupling directions for knowledge sharing and isolation. LoDA fixes LoRA down-projections on two subspaces and learns robust up-projections via a Gradient-Aligned Optimization (GAO) approach. After each task, before integrating the LoRA updates into the backbone, LoDA derives a closed-form recalibration for the general update, approximating a feature-level joint optimum along this task-shared direction. Experiments indicate that LoDA outperforms existing CL methods.

From Lyapunov Analysis to Algorithm Design in two-sided PL Minimax Optimization

Mansi Rankawat, Michael Muehlebach, Simon Lacoste-Julien, Damien Scieur

We derive algorithms for smooth nonconvex nonconcave minimax optimization and es tablish linear convergence rates for problems that satisfy the two-sided Polyak-Lojasiewicz (PL) inequality. At the core of our approach is the observation that Lyapunov functions can be used not only to certify convergence a posteriori, bu t also to design algorithms. By replacing an idealized, intractable Lyapunov fun ction with a computable surrogate based on gradient information, we derive TALDA (Tri-Action Lyapunov Descent Ascent), a single-loop algorithm that enforces Lya punov descent by construction. TALDA guarantees linear convergence under the two -sided PL condition, with a rate that depends explicitly on the cross-smoothness constant. This recovers existing worst-case guarantees while yielding sharper c onvergence rates in weakly coupled min–max problems.
****
Server-Proximal Aggregation for Federated Domain-Incremental Learning under Part ial Participation: Task-Uniform Convergence and Backward Transfer
Longtao Xu, Jian Li
Real-world federated systems seldom operate on static data: input distributions drift while privacy rules forbid raw data sharing. We study Federated Domain-Inc remental Learning (FDIL), where (i) clients are heterogeneous, (ii) tasks arrive sequentially with shifting domains, and (iii) the label space remains fixed. Tw o theoretical pillars remain missing for FDIL under partial participation: a gua rantee of backward knowledge transfer (BKT) and a convergence rate that holds *u niformly across the task sequence*. We introduce SPECIAL (Server-Proximal Effici ent Continual Aggregation for Learning), a simple, replay-free FDIL algorithm th at adds a single server-side ``anchor'' to FedAvg: in each round, the server agg regates updates from a uniformly sampled subset of clients and then blends the r esult with the previous global model via a lightweight proximal step. This ancho r curbs cumulative drift without replay buffers, synthetic data, or task-specifi c heads, leaving communication cost and model size unchanged. Our theory shows t hat SPECIAL (i) *preserves earlier tasks*: a BKT bound caps any increase in earl ier-task loss by a drift-controlled term that shrinks with more rounds, local ep ochs, and participating clients; and (ii) *achieves task-uniform, communication-efficient convergence* for non-convex FDIL with partial participation: $\mathcal {O}\big(\sqrt{E/(NT)}\big)$ in expected gradient norm, with E local epochs, $T $ rounds, and N participating clients, while explicitly separating optimizatio n variance from inter-task drift. Experiments on standard FDIL benchmarks corrob orate the theory.
****
Characterization of Gaussian Universality Breakdown in High-Dimensional Empirica l Risk Minimization
Mohamed Chiheb Yaakoubi, Cosme Louart, Malik Tiomoko, Zhenyu Liao
We study high-dimensional convex empirical risk minimization (ERM) under general non-Gaussian data designs. By heuristically extending the Convex Gaussian Min–M ax Theorem (CGMT) to non-Gaussian settings, we derive an asymptotic min–max char acterization of key statistics, enabling approximation of the mean $\mu_{\hat{\t heta}}$ and covariance $C_{\hat{\theta}}$ of the ERM estimator $\hat{\theta}$.
Specifically, under a concentration assumption on the data matrix and standard r egularity conditions on the loss and regularizer, we show that for a test covari ate x independent of the training data, the projection $\hat{\theta}^\top x$ a pproximately follows the convolution of the (generally non-Gaussian) distributio n of $\mu_{\hat{\theta}}^\top x$ with an independent centered Gaussian variable of variance $\mathrm{tr}\!\big(C_{\hat{\theta}}\,\mathbb{E}[xx^\top]\big)$. This result clarifies the scope and limits of Gaussian universality for ERMs. Additi onally, we prove that any $\mathcal{C}^2$ regularizer is asymptotically equivale nt to a quadratic form determined solely by its Hessian at zero and gradient at $\mu_{\hat{\theta}}$.
Numerical simulations across diverse losses and models are provided to validate our theoretical predictions and qualitative insights.

Focusing: View-Consistent Sparse Voxels for Efficient 3D VAE Training
Xuhui Chen, Chao Long, Fei Hou, dongbo zhang, Shaohui Jiao, Wencheng Wang, Ying

He
High-fidelity 3D generation depends on 3D VAEs that can compress and reconstruct complex geometry at high resolution. Recent methods often convert raw meshes into signed distance fields (SDFs), but this preprocessing can be lossy, especially for open or non-watertight assets. Render-supervised VAEs such as TripoSF avoid this conversion by matching rendered depth and normal maps, yet render losses supervise only the visible geometry for each view, leaving many latent voxels weakly constrained while still incurring unnecessary decoding and attention costs. We introduce Focusing, a view-consistent sparse-voxel training scheme for efficient 3D VAEs. Given a training view, Focusing performs depth-driven voxel carving directly in the structured latent space: voxels inconsistent with the rendered depth are removed before decoding, allowing the decoder and attention layers to operate only on locally relevant geometry. This view-dependent sparsity reduces memory and computation while concentrating learning on surface regions that contribute to the render. To stabilize training across shapes and viewpoints, we further propose adaptive zooming, which adjusts camera intrinsics to keep the number of active voxels within a target range and strengths supervision for fine details. The VAE is trained with render-based depth, normal, mask, and perceptual losses, together with sparse-voxel total variation and a brief TSDF warm-up to improve convergence and suppress holes. Across standard reconstruction benchmarks, Focusing improves Chamfer Distance and F-score over strong baselines while substantially reducing video random access memory (VRAM) consumption, enabling 1024^3-resolution VAE training with as little as 50 GB of VRAM. These results demonstrate that local, view-consistent sparsity is an effective path toward higher-resolution and more efficient 3D VAE training.
****
SynGR: Unleashing the Potential of Cross-Modal Synergy for Generative Recommendation
Wei Chen, Xingyu Guo, Shuang Li, Fuwei Zhang, Meng Yuan, Jing Fan, Zhao Zhang, deqing wang, Fuzhen Zhuang
Generative Recommendation (GR) has emerged as a promising paradigm by formulating item recommendation as a sequence-to-sequence generation task over item identifiers.
■Recent studies have incorporated multimodal signals to provide richer token-level evidence for generation.
■However, existing approaches largely rely on alignment-centric fusion and underexplore synergistic information across modalities.
■In practice, synergistic information plays a critical role in capturing emergent item properties that cannot be inferred from any single modality alone.
■Such properties encode intrinsic item semantics and guide user preferences, enabling models to move beyond surface-level feature matching.
■To address this limitation, we propose \textbf{SynGR}, a synergistic generative recommendation framework that explicitly encourages the exploitation of cross-modal dependencies during generation. By constraining overreliance on dominant modalities, SynGR enables the model to capture emergent item semantics beyond shared or modality-specific signals. Extensive experiments across three benchmark datasets demonstrate that SynGR achieves superior performance.

Holi-Spatial: Evolving Video Streams into Holistic 3D Spatial Intelligence
Yuanyuan Gao, Hao Li, Yifei Liu, Xinhao Ji, Yuning Gong, Yuanjun Liao, Fangfu Li
u, Manyuan Zhang, Yuchen Yang, Dan Xu, Xue Yang, Huaxi Huang, Hongjie Zhang, Ziw
ei Liu, Xiao Sun, Dingwen Zhang, Zhihang Zhong
The pursuit of spatial intelligence fundamentally relies on access to large-scal
e, fine-grained 3D data. However, existing approaches predominantly construct sp
atial understanding benchmarks by generating question–answer (QA) pairs from a l
imited number of manually annotated datasets, rather than systematically annotat
ing new large-scale 3D scenes from raw web data. As a result, their scalability
is severely constrained, and model performance is further hindered by domain gap
s inherent in these narrowly curated datasets.
In this work, we propose \textbf{Holi-Spatial}, the first fully automated, large
-scale, spatially-aware multimodal dataset, constructed from raw video inputs wi
thout human intervention, using the proposed data curation pipeline. Holi-Spatia
l supports multi-level spatial supervision, ranging from geometrically accurate
3D Gaussian Splatting (3DGS) reconstructions with rendered depth maps to object-
level and relational semantic annotations, together with corresponding spatial Q
uestion–Answer (QA) pairs.
Following a principled and systematic pipeline, we further construct \textbf{Hol
i-Spatial-4M}, the first large-scale, high-quality 3D semantic dataset, containi
ng 12K optimized 3DGS scenes, 1.3M 2D masks, 320K 3D bounding boxes, 320K instan
ce captions, 1.2M 3D grounding instances, and 1.2M spatial QA pairs spanning div
erse geometric, relational, and semantic reasoning tasks.
Holi-Spatial demonstrates exceptional performance in data curation quality, sign
ificantly outperforming existing feed-forward and per-scene optimized methods on
 datasets such as ScanNet, ScanNet++, and DL3DV. Furthermore, fine-tuning Vision
-Language Models (VLMs) on spatial reasoning tasks using this dataset has also l
ed to substantial improvements in model performance.

Adaptive Protein Tokenization
Rohit Dilip, Ayush Varshney, David Van Valen
Tokenization is a promising path to multi-modal models capable of jointly unders
tanding protein sequences, structure, and function. Existing protein structure t
okenizers create tokens by pooling information from local neighborhoods, an appr
oach that limits their performance on generative and representation tasks. In th
is work, we present a method for global tokenization of protein structures in wh
ich successive tokens contribute increasing levels of detail to a global represe
ntation. This change resolves several issues with generative models based on loc
al protein tokenization: it mitigates error accumulation, provides embeddings wi
thout sequence-reduction operations, and allows task-specific adaptation of a to
kenized sequence's information content. We validate our method on reconstruction
, generative, and representation tasks and demonstrate that it matches or outper
forms existing models based on local protein structure tokenizers. We show that
our adaptive approach enables inference criteria based on the information conten
t of the generated proteins. We validate representations generated from our toke
nizer on CATH classification tasks and demonstrate that non-linear probing on ou
r tokenized sequences outperforms equivalent probing on representations from oth
er tokenizers. Finally, we demonstrate how our method supports zero-shot protein
 shrinking and affinity maturation.

Revisiting Neural Processes via Fourier Transform and Volterra Series
Peiman Mohseni, Nick Duffield, Raymond K. W. Wong
Modeling unknown latent functions from finite, irregularly sampled measurements
is a recurring challenge across science and engineering. Neural processes (NPs),
 a family of probabilistic functional models, are promising solutions---especial
ly when endowed with domain-specific symmetries like translation equivariance, w
hich improve sample efficiency and generalization. Yet existing translation-equi

variant NPs face two limitations: (i) they stack generic components with non-lin
earities, obscuring the induced function class and limiting interpretability; an
d (ii) convolutional designs rely on kernels with local receptive fields and req
uire dense uniform input grids, while attention-based methods avoid these issues
 but scale quadratically with the number of observations. We address both with t
wo contributions. First, using the Volterra expansion, we characterize continuou
s translation-equivariant operators as sums of higher-order convolutions, yieldi
ng analytical transparency while admitting efficient approximation by first-orde
r convolutions. Second, we introduce set Fourier convolutions (SFConvs), a frequ
ency-domain parameterization that operates directly on irregularly sampled point
s, achieves approximately global receptive fields, and scales linearly in the nu
mber of observations. Building on these ideas, we propose two conditional NPs (C
NPs): SFConvCNPs, which stack SFConv blocks with non-linearities, and SFVConvCNP
s, which integrate the Volterra formulation. Experiments on synthetic and real-w
orld datasets demonstrate our methods' efficacy against state-of-the-art baselin
es.

Bi-Anchor Interpolation Solver for Accelerating Generative Modeling
Hongxu chen, Hongxiang Li, Zhen Wang, Long Chen
Flow Matching (FM) models have emerged as a leading paradigm for high-fidelity s
ynthesis. However, their reliance on iterative Ordinary Differential Equation (O
DE) solving creates a significant latency bottleneck. Existing solutions face a
dichotomy: training-free solvers suffer from significant performance degradation
 at low Neural Function Evaluations (NFEs), while training-based methods incur p
rohibitive training costs and lack plug-and-play versatility. To bridge this gap
, we propose the Bi-Anchor Interpolation Solver (BA-solver). BA-solver retains t
he versatility of standard training-free solvers while achieving significant acc
eleration by introducing a lightweight SideNet (1-2% backbone size) alongside th
e frozen backbone. Specifically, our method is founded on two synergistic compon
ents: 1) Bidirectional Temporal Perception, where the SideNet learns to approxim
ate both future and historical velocities without retraining the heavy backbone;
 and 2) Bi-Anchor Velocity Integration, which utilizes the SideNet with two anch
or velocities to efficiently approximate intermediate velocities for batched hig
h-order integration. By utilizing the backbone to establish high-precision “anch
ors” and the SideNet to densify the trajectory, BA-solver enables large step siz
es with minimized error. Empirical results on ImageNet-256 demonstrate that BA-s
olver achieves generation quality comparable to 100+ NFEs Euler solver in just 1
0 NFEs and maintains high fidelity in as few as 5 NFEs, incurring negligible tra
ining costs. Furthermore, BA-solver ensures seamless integration with existing g
enerative pipelines, facilitating downstream tasks such as image editing.

CauScale: Neural Causal Discovery at Scale
Bo Peng, Sirui Chen, Jiaguo Tian, Yu Qiao, Chaochao Lu
Causal discovery is essential for advancing data-driven fields such as scientifi
c AI and data analysis, yet existing approaches face significant time- and space
-efficiency bottlenecks when scaling to large
graphs. To address this challenge, we present CauScale, a neural architecture de
signed for efficient causal discovery that scales inference to graphs with up to
 1000 nodes. CauScale improves time efficiency via a reduction unit that compres
ses data embeddings and improves space efficiency by adopting tied attention wei
ghts to avoid maintaining axis-specific attention maps. To keep high causal disc
overy accuracy, CauScale adopts a two-stream design: a data stream extracts rela
tional evidence from high-dimensional observations, while a graph stream integra
tes statistical graph priors and preserves key structural signals. CauScale succ
essfully scales to 500-node graphs during training, where prior work fails due t
o space limitations. Across testing data with varying graph scales and causal me
chanisms, CauScale achieves 99.6\% mAP on in-distribution data and 84.4\% on out
-of-distribution data, while delivering 4$\times$–13,000$\times$ inference speed
ups over prior methods.

Physically-Guided Data-Space Rectified Flow for Precipitation Nowcasting
Wenjie Luo, chaorong li, Chuanhu Deng, Zhuo Wang
Reliable long-horizon precipitation nowcasting requires preserving fine-scale echo structures while maintaining coherent transport. Although Rectified Flow (RF) can generate detail-preserving future sequences, numerical ODE integration compounds velocity estimation errors and induces progressive off-manifold drift, causing morphological distortions at extended lead times. We propose Physically-guided Data-space Rectified Flow (PDRF), which re-parameterizes the generative ODE in data space: the network predicts the clean future sequence, analytically inducing a coupled vector field with an implicit restoring effect that suppresses drift. We also introduce a soft Semi-Lagrangian teacher based on an advection prior to regularize large-scale transport, while allowing local growth/decay/deformation to be learned from data. Experiments on four public benchmarks demonstrate consistent improvements in event-based skill and better preservation of intense-echo morphology over long horizons.

Lightweight and Interpretable Transformer via Unrolling of Mixed Graph Algorithms for Traffic Forecast
Ji Qi, Mingxiao Liu, VIET HO TAM THUC DO, Yuzhe Li, Zhuoshi Pan, Gene Cheung, H. Vicky Zhao
Unlike conventional "black-box" transformers with classical self-attention mechanisms, we build a lightweight and interpretable transformer-like neural network by unrolling a mixed-graph-based optimization algorithm to forecast traffic with spatial and temporal dimensions.
We construct two graphs: an undirected graph $\mathcal{G}^u$ capturing spatial correlations across geography, and a directed graph $\mathcal{G}^d$ capturing sequential relationships over time.
We predict future samples of signal $\mathbf{x}$, assuming it is "smooth" with respect to both $\mathcal{G}^u$ and $\mathcal{G}^d$, where we design new ℓ_2- and ℓ_1-norm variational terms to quantify and promote signal smoothness (low-frequency reconstruction) on a directed graph.
We design an iterative algorithm based on alternating direction method of multipliers (ADMM), and unroll it into a feed-forward network for data-driven parameter learning.
We periodically insert graph learning modules for $\mathcal{G}^u$ and $\mathcal{G}^d$ that play the role of self-attention.
Experiments show that our unrolled networks achieve competitive traffic forecast performance as state-of-the-art prediction schemes, while reducing parameter counts drastically. Code: https://github.com/SingularityUndefined/Unrolling-GSP-ST Forecast.

SWE-rebench V2: Language-Agnostic SWE Task Collection at Scale
Ibragim Badertdinov, Maksim Nekrashevich, Anton Shevtsov, Alexander Golubev
Software engineering agents (SWE) are improving rapidly, with recent gains largely driven by reinforcement learning (RL). However, RL training is constrained by the scarcity of large-scale task collections with reproducible execution environments and reliable test suites. Although a growing number of benchmarks have emerged, datasets suitable for training remain limited in scale and diversity or often target a limited set of high-resource language ecosystems. We introduce SWE-rebench V2, a language-agnostic automated pipeline for harvesting executable real-world SWE tasks and constructing RL training environments at scale. The pipeline synthesizes repository-specific installation and test procedures via an interactive setup agent, and filters unsound instances using an ensemble of LLM judges, validated against human-verified SWE-bench annotations. Using this pipeline, we construct a dataset of 32,079 tasks spanning 20 languages and 3,617 repositories, with pre-built images for reproducible execution. To further scale training data, we additionally release 120,000+ tasks with installation instructions, fail-to-pass tests and rich metadata, where the problem statement is generated based on the original pull request description. We validate the collected instances through a diagnostic study that covers a subset of tasks in five programming l

anguages across seven popular models, and provide instance-level metadata that f lags common confounders such as overly restrictive tests and underspecified desc riptions. We release the datasets, the collection and execution code, and associ ated artifacts to enable large-scale training of SWE agents across diverse langu ages and repositories.

Preconditioned DeltaNet: Curvature-aware Sequence Modeling for Linear Recurrence s
Neehal Tumma, Noel Loo, Daniela Rus
To address the increasing long-context compute limitations of softmax attention, several subquadratic recurrent operators have been developed. This work include s models such as Mamba-2, DeltaNet, Gated DeltaNet (GDN), and Kimi Delta Attenti on (KDA). As the space of recurrences grows, a parallel line of work has arisen to taxonomize them. One compelling view is the test-time regression (TTR) framew ork, which interprets recurrences as performing online least squares updates tha t learn a linear map from the keys to values. Existing delta-rule recurrences ca n be seen as first-order approximations to this objective, but notably ignore th e curvature of the least-squares loss during optimization. In this work, we addr ess this by introducing preconditioning to these recurrences. Starting from the theory of online least squares, we derive equivalences between linear attention and the delta rule in the exactly preconditioned case. Next, we realize this the ory in practice by proposing a diagonal approximation: this enables us to introd uce preconditioned variants of DeltaNet, GDN, and KDA alongside efficient chunkw ise parallel algorithms for computing them. Empirically, we find that our precon ditioned delta-rule recurrences yield consistent performance improvements across synthetic recall benchmarks and language modeling at the 340M and 1B scale.

Eliminating Solution Bias in Differentially Private Optimization
DONGRUN LI, YUN ZENG, Zibo Wei, Jiacheng Wei, Qinnan Zhang, Faguo Wu, Xiao Zhang , Zhiming Zheng
Differentially private (DP) stochastic optimization algorithms are widely used i n privacy-preserving deep learning, where per-sample gradient clipping and noise injection protect sensitive information. However, these operations limit existi ng DP algorithms to converge within a constant-radius neighborhood of the first- order stationary point, leading to solution bias and the well-known privacy-util ity trade-off. To enhance model utility, we propose a novel algorithmic framewor k called DP-C4, which is designed to be error-Consistently-vanishing, Coupledly- clipped, solution-Calibrated, and Convergence-guaranteed. Specifically, it incor porates a carefully designed coupled clipping scheme with shifted threshold stra tegy, ensuring that both clipping bias and noise variance asymptotically vanish, thereby eliminating the DP-induced solution bias. Moreover, we extend existing sensitivity analysis techniques and develop a tailored privacy budget allocation to guarantee the privacy of DP-C4. Compared with the well-recognized DP-SGD, ou r framework injects significantly less noise under the same privacy level. In ad dition, we prove that our framework converges to the optimum in strongly-convex case and to a diminishing neighborhood of the first-order stationary point in n on-convex case. Experiments show that DP-C4 achieves superior privacy-utility tr ade-off over existing baselines across various tasks and datasets.

BandPO: Bridging Trust Regions and Ratio Clipping via Probability-Aware Bounds f or LLM Reinforcement Learning
Yuan Li, Bo Wang, Yufei Gao, Yao Yuqian, Xinyuan Wang, Zhangyue Yin, Xipeng Qiu
Proximal constraints are fundamental to the stability of the Large Language Mode l reinforcement learning.
While the canonical clipping mechanism in PPO serves as an efficient surrogate f or trust regions, we identify a critical bottleneck: fixed bounds strictly const rain the upward update margin of low-probability actions, disproportionately sup pressing high-advantage tail strategies and inducing rapid entropy collapse.
To address this, we introduce **Band-constrained Policy Optimization** (BandPO). BandPO replaces canonical clipping with **Band**, a unified theoretical operator

that projects trust regions defined by f-divergences into dynamic, probabilit
y-aware clipping intervals.
Theoretical analysis confirms that Band effectively resolves this exploration bo
ttleneck.
We formulate this mapping as a convex optimization problem, guaranteeing a globa
lly optimal numerical solution while deriving closed-form solutions for specific
 divergences.
Extensive experiments across diverse models and datasets demonstrate that BandPO
 consistently outperforms canonical clipping and Clip-Higher, while robustly mit
igating entropy collapse. Code is publicly available at https://github.com/OpenM
OSS/BandPO.

DynVLA: Learning World Dynamics for Action Reasoning in Autonomous Driving
Shuyao Shang, Bing Zhan, Yunfei Yan, Yuqi Wang, Yingyan Li, Yasong An, Xiaoman W
ang, Jierui Liu, Lu Hou, Lue Fan, Zhaoxiang Zhang, Tieniu Tan
We propose DynVLA, a driving VLA model that introduces a new CoT paradigm termed
 Dynamics CoT. DynVLA forecasts compact world dynamics before action generation,
 enabling more informed and physically grounded decision-making. To obtain compa
ct dynamics representations, DynVLA introduces a Dynamics Tokenizer that compres
ses future evolution into a small set of dynamics tokens. Considering the rich e
nvironment dynamics in interaction-intensive driving scenarios, DynVLA decouples
 ego-centric and environment-centric dynamics, yielding more accurate world dyna
mics modeling. We then train DynVLA to generate dynamics tokens before actions t
hrough SFT and RFT, improving decision quality while maintaining latency-efficie
nt inference. Compared to Textual CoT, which lacks fine-grained spatiotemporal u
nderstanding, and Visual CoT, which introduces substantial redundancy due to den
se image prediction, Dynamics CoT captures the evolution of the world in a compa
ct, interpretable, and efficient form. Extensive experiments on NAVSIM, Bench2Dr
ive, and a large-scale in-house dataset demonstrate that DynVLA consistently out
performs Textual CoT and Visual CoT methods, validating the effectiveness and pr
actical value of Dynamics CoT.

De-Linearizing Agent Traces: Bayesian Inference of Latent Partial Orders for Eff
icient Execution
Dongqing li, Zheqiao Cheng, Geoff Nicholls, Quyu Kong
AI agents increasingly execute procedural workflows as sequential action traces,
 which obscures latent concurrency and induces repeated step-by-step reasoning.
We introduce BPOP, a Bayesian framework that infers a latent dependency partial
order from noisy linearized traces. BPOP models traces as stochastic linear exte
nsions of an underlying graph and performs efficient MCMC inference via a tracta
ble frontier-softmax likelihood that avoids \#P-hard marginalization over linear
 extensions. We evaluate on our open-sourced Cloud-IaC-6, a suite of cloud provi
sioning tasks with heterogeneous LLM-generated traces, and WFCommons scientific
workflows. BPOP recovers dependency structure more accurately than trace-only an
d process-mining baselines, and the inferred graphs support a compiled executor
that prunes irrelevant context, yielding substantial reductions in token usage a
nd execution time.
****

Context Tuning for In-Context Optimization
Jack Lu, Ryan Teehan, Zhenbang Yang, Mengye Ren
We introduce Context Tuning, a simple and effective method to significantly enha
nce few-shot adaptation of language models (LLMs) without fine-tuning model para
meters. While prompt-based adaptation techniques have demonstrated the effective
ness of lightweight adaptation methods for LLMs, they typically initialize a tra
inable prompt or prefix with irrelevant tokens for the task at hand. In contrast
, Context Tuning initializes the trainable prompt or prefix with task-specific d
emonstration examples, leveraging the model’s inherent In-Context Learning (ICL)
 ability to extract relevant information for improved few-shot learning performa
nce. Extensive evaluations on benchmarks such as CrossFit, UnifiedQA, MMLU, BIG-
Bench Hard, and ARC demonstrate that Context Tuning outperforms traditional prom

pt-based adaptation methods and achieves competitive accuracy with Test-Time Tra
ining at significantly higher training efficiency.
****
Beyond Normalization: Rethinking the Partition Function as a Difficulty Schedule
r for RLVR
Dohyung Kim, Minbeom Kim, Jeonghye Kim, Sangmook Lee, Sojeong Rhee, Kyomin Jung
Reward-maximizing RL methods have shown to be capable of enhancing the reasoning
 performance of LLMs, but often lead to reduced generation diversity. Recent wor
ks address this issue by adopting GFlowNets, training LLMs to match a target dis
tribution while jointly learning its partition function.
In contrast to prior works that treat this partition function solely as a normal
izer, we reinterpret it as a per-prompt expected-reward (i.e., online accuracy)
signal, leveraging this unused information to improve sample efficiency.
Specifically, we first establish a theoretical relationship between the partitio
n function and per-prompt accuracy estimates. Building on this key insight, we p
ropose \textbf{Pa}rtition Fun\textbf{c}tion-Guid\textbf{ed} \textbf{RL} (PACED-R
L), a post-training framework that leverages accuracy estimates to prioritize i
nformative question prompts during training, and further improves sample efficie
ncy through an accuracy estimate error–prioritized replay. Crucially, both compo
nents reuse information already produced during GFlowNet training, effectively a
mortizing the compute overhead into the existing optimization process. Extensive
 experiments across diverse benchmarks demonstrate strong performance improvemen
ts over GRPO and prior GFlowNet approaches, highlighting PACED-RL as a promising
 direction for a more sample efficient distribution-matching training for LLMs.

XDomainBench: Diagnosing Reasoning Collapse in High-Dimensional Scientific Knowl
edge Composition
Gong Zhiren, Tiantong Wu, Jiaming Zhang, Fuyao Zhang, CHE WANG, Yurong Hao, Yiku
n Hou, Foo Ping, Yilei Zhao, Fei Huang, Chau Yuen, Wei Yang Bryan Lim
Large Language Models (LLMs) are increasingly deployed for knowledge synthesis,
yet their capacity for compositional generalization in scientific knowledge rema
ins under-characterized.
Existing benchmarks primarily focus on single-turn restricted scenarios, failing
 to capture the capability boundaries exposed by real-world interactive scientif
ic workflows.
To address this, we introduce XDomainBench, a diagnostic benchmark for interacti
ve interdisciplinary scientific reasoning.
We formalize the composition order and mixture structure to enable systematic st
ress-testing from single-discipline to inter-disciplinary, comprising 8,598 inte
ractive sessions across 20 domains and 4 task categories, with 8 realistic traje
ctory patterns covering difficulty and domain-mixture dynamics, simulating real
AI4S scenarios.
Large-scale evaluation of LLMs reveals a systematic reasoning collapse as compos
ition order increases, stemming from two root causes: (i) direct difficulty incr
eases induced by domain composition, and (ii) indirect interaction-amplified fai
lures where trajectory patterns trigger error accumulation, reasoning breaks, an
d domain confusion, ultimately leading to session collapse.
****
MoVie: Multimodal Video Compression with Text Guidance
Jiaqi Hu, Haoji Hu, Heming Sun, Lianrui Mu
Most deep video codecs emphasize low-level motion modeling and remain largely se
mantics-agnostic, which can degrade perceptual quality in complex scenes. We pro
pose **MoVie**, a **M**ultim**o**dal **Vi**d**e**o compression framework built o
n a Text-guided Video Transformer–CNN Mixed block (*Text-VideoTCM*). MoVie adopt
s a video-centric architecture that jointly models local spatial structures and
temporal dynamics via window-based processing, delivering a favorable computatio
n--perception trade-off. To incorporate semantics, we introduce dual-stage text
fusion with *Extractor* and *Injector* modules. We further present history-condi
tioned coding that leverages both previous and aggregated historical frames, and
 a spatial--channel factorized entropy model that estimates probabilities over s

patial neighborhoods and channel groups for adaptive bit allocation. Together, t
hese designs reduce redundancy and improve rate control and temporal coherence,
yielding reconstructions at low bitrates. On UVG and MCL-JCV, MoVie achieves **$
-$50.23\%** BD-rate for FID and **$-$14.64\%** for LPIPS (VGGNet) relative to HM
, while requiring only **55.76\%** of DCVC-FM's per-pixel kMACs. A human percept
ual study further confirms consistent subjective preference over strong baseline
s.
****
OmniVL-Guard: Towards Unified Vision-Language Forgery Detection and Grounding vi
a Balanced RL
Jinjie Shen, Jing Wu, Yaxiong Wang, Lechao Cheng, Shengeng Tang, Tianrui Hui, Na
n Pu, Zhun Zhong
Existing forgery detection methods are often limited to uni-modal or bi-modal se
ttings, failing to handle the interleaved text, images, and videos prevalent in
real-world misinformation. To bridge this gap, we propose **OmniVL-Guard**, a un
ified framework for omni vision-language forgery detection and grounding. In thi
s unified setting, the interplay between diverse modalities and the dual require
ments of simultaneous detection and localization pose significant optimization c
hallenges. Through extensive investigations, we identify a critical difficulty b
ias in this multi-task optimization: the simpler veracity classification task te
nds to dominate the gradients, leading to suboptimal performance in fine-grained
 grounding. To address this imbalance, we first develop a Self-Evolving CoT Gene
ration pipeline to synthesize high-quality reasoning paths, effectively overcomi
ng the cold-start challenge. Building upon this, we propose **A**daptive **R**ew
ard **S**caling **P**olicy **O**ptimization (**ARSPO**). By dynamically modulati
ng reward scales and task weights, ARSPO ensures a balanced joint optimization t
hat prioritizes challenging grounding objectives. Extensive experiments demonstr
ate that OmniVL-Guard significantly outperforms state-of-the-art methods and exh
ibits robust zero-shot generalization across out-of-domain scenarios.
****
CONCUR: High-Throughput Agentic Batch Inference of LLM via Congestion-Based Conc
urrency Control
qiaoling chen, Zhisheng Ye, Tian Tang, Peng Sun, Boyu Tian, Guoteng Wang, Shengg
ui Li, Yonggang Wen, Zhenhua Han, Tianwei Zhang
Batch inference for agentic workloads stresses the GPU key–value (KV) cache in a
 sustained and cumulative manner, often causing severe throughput degradation we
ll before memory capacity is exhausted. We identify this phenomenon as middle-ph
ase thrashing, a previously under-characterized pathology in which cache efficie
ncy collapses as long-lived agents accumulate state over time.

We argue that mitigating this pathology requires moving beyond reactive, request
-level cache management to proactive, agent-level admission control. Drawing ins
piration from congestion control in distributed systems, we view the KV cache as
 a shared resource whose efficient utilization depends on feedback-driven regula
tion. Based on this insight, we present CONCUR, a lightweight control layer that
 regulates agent admission to bound aggregate cache pressure while preserving ex
ecution continuity. CONCUR adapts a cache-aware control algorithm to dynamically
 adjust the number of active agents using runtime cache signals.

Across large models and real-world agent workloads, CONCUR prevents middle-phase
 thrashing and improves batch inference throughput by up to 4.09× on Qwen3-32B a
nd 1.90× on DeepSeek-V3, while remaining compatible with existing LLM serving sy
stems.
****
GRASP: Awakening Latent Spatial Reasoning in LVLMs via Training-free Geometric R
ectification
Jiadong Yan, Ke Zhang, Chenyang Zhao, Shoushan Li, Xizhao Luo
Large Vision-Language Models (LVLMs) exhibit remarkable general capabilities but
 struggle significantly with spatial reasoning tasks. In this paper, we uncover
a critical representation-output misalignment via linear probing: LVLMs correctl

y encode spatial features internally, but generate incorrect results in the fina l text. To address this, we pioneer the Inference-time Geometric Manifold Adapta tion paradigm and propose **GRASP** (**G**eometric **R**ectification for **A**ct ive **S**patial **P**erception), a training-free framework to awaken these laten t capabilities. GRASP employs Manifold Differential Search to identify optimal g eometric counterfactuals, which then drive a dual-level rectification mechanism: Implicit Trajectory Correction to rectify attenuated intrinsic geometric featur es in intermediate decoder layers, and Explicit Distribution Alignment to break the dominance of language priors at the output layer. Extensive experiments span ning diverse architectures (LLaVA, Qwen 2.5/3-VL) and positional encoding paradi gms (1D APE, 2D/3D RoPE) across image and video benchmarks (WhatsUp, VSR, VSI-Be nch) demonstrate that GRASP significantly mitigates spatial hallucinations witho ut parameter updates, achieving accuracy gains of up to 26.1% on image benchmark s and 9.7% on video reasoning tasks, consistently outperforming baseline methods .

The Geometry of Narrow Fine-Tuning Degradation: Trajectory Lock-in and Spectral Bifurcation

Jia Liu, Jiaxin Luo, Xinhao Qiu, Yixue Hao, Min Chen

Magnitude-based stability proxies such as parameter drift are widely used in nar row-task fine-tuning, yet they do not reliably indicate degradation of broad cap abilities. We identify trajectory lock-in: under fixed training conditions for n arrow adaptation, the joint evolution of task loss and broad generalization coll apses onto a shared low-dimensional degradation curve, so many stabilizers prima rily change the rate of progress along this curve rather than altering the curve itself. This yields a drift paradox, in which comparable Euclidean displacement can still correspond to divergent generalization outcomes. To diagnose the unde rlying structure, we introduce objective-agnostic geometric probes that track th e effective update subspace, together with an online harm signal that reflects c urvature-dominated channeling toward directions associated with broad degradatio n. Finally, we show that escaping lock-in requires a spectral bifurcation, namel y a qualitative reorientation of the update subspace toward softer curvature mod es, thereby improving broad generalization while maintaining matched training pe rformance. We validate these findings across model scales and modalities in narr ow-task settings, and report practical deployment procedures and overhead measur ements.

Resolving the Timestep Scaling Paradox in Spiking Neural Networks with a Timeste p-Scalable Neuron Model

Binghao Ye, Wenjuan Li, Dengfeng Xue, Bing Li, Weiming Hu, Dong Liang, Kun Shang

Spiking Neural Networks (SNNs) have garnered attention for their biological plau sibility, energy efficiency, and temporal modeling capability. Due to the non-di fferentiability of spike generation, a widely used training method for SNNs is b ackpropagation through time with surrogate gradients, achieving competitive perf ormance with few timesteps. Intuitively, scaling timesteps should improve perfor mance by enriching temporal dynamics. However, we observe timestep scaling parad ox (TSP), a counter-intuitive accuracy degradation when scaling timesteps. We in vestigate TSP and link it to long-term temporal gradient vanishing and weakened cross-timestep dependencies. To address this, we propose the Timestep-Scalable (TS) neuron model. It introduces long-term memory reconsolidation to enhance cros s-timestep information flow and enable effective learning with more timesteps. I n parallel, a temporal forgetting mechanism periodically truncates the accumulat ion path, suppressing excessive temporal buildup and improving training stabilit y. Supported by theoretical analysis and extensive experiments, TS consistently improves performance when scaling timesteps. In addition, it attains state-of-th e-art results on time-series and event-based tasks, while remaining strong on st atic image classification and object detection.

Time-Series Decomposition as a Standalone Task: A Mechanism-Driven Diagnostic Be nchmark

Zipeng Wu, Jiani Wei, Shiqiao Zhou, Jiajun chen, Fabian Spill, J. W. Andrews
We benchmark time series decomposition as a standalone evaluation task. While decomposition outputs are widely used to interpret trend and periodic structure, their quality is often assessed informally, and no unified benchmark exists for comparing component recovery under controlled generative mechanisms. We introduce a synthetic evaluation suite with explicit trend and cycle taxonomies, a unified interface covering representative decomposition families, and complementary metrics capturing distinct error modes (shape, phase, and spectral fidelity). Across stationary periodic regimes, STL-family methods are near-ceiling; under non-stationary periodicity (frequency drift, regime switching), fixed-period priors induce phase degradation, while subspace/time-frequency methods better preserve seasonal consistency (adaptive spectral methods may require tuning). We further extend the benchmark with a downstream scientific-discovery track—symbolic regression on decomposed components—showing that a decompose-then-regress pipeline materially improves recoverability and reduces expression complexity, linking decomposition quality to structure discovery. Code, result exports, and the web leaderboard are publicly available through the Hugging Face dataset and leaderboard Space.

SPR-RAFT: Parameter-Efficient Regression-Aware Fine-Tuning for Biomedical LLM Regression
Yuanlin Yang, Chenhui Li, Xuhao Guo, Anqi Zhang, Hoi Leong Lee, Haodong Liu
Biomedical regression tasks require predicting continuous targets from heterogeneous and unstructured evidence. While Large Language Models (LLMs) provide a robust interface for reasoning over mixed modalities, they are inherently limited by their discrete tokenization and cross-entropy objectives, which lack awareness of numerical proximity. To bridge this gap, we present \textbf{SPR-RAFT}, a parameter-efficient and regression-aware framework that adapts frozen LLMs for high-precision regression. SPR-RAFT introduces a dual-module architecture: a learnable soft prompt that conditions the LLM to route numerical reasoning into a specific latent state, and a lightweight regression head anchored on a dedicated readout token for numerical reasoning consolidation. Crucially, we align these two modalities via a hybrid objective that combines distribution-based text generation with representation-based robust regression. This ensures the model remains both semantically coherent and numerically calibrated. With only about 1.6M trainable parameters ($\sim$0.04\% of a 4B-parameter backbone), SPR-RAFT consistently outperforms prompting strategies, standard fine-tuning, and non-LLM baselines across diverse biomedical benchmarks, including clinical trial duration, biological age estimation, and molecular property prediction.
****
Sparse Relaxed-Lasso Steering: Automatic Sparse Autoencoder Feature Selection for Precise Image Editing
Zongxin Liu, Xiaoyong Xue, Sun Weidi, Shengchao Qin, Lijun Zhang
Precise, training-free image editing with text-to-image diffusion models requires balancing alignment (faithful realization of the target attribute), consistency (preserving non-target content), and quality (maintaining sharp, artifact-free textures).
Sparse autoencoder (SAE) steering offers interpretable, smooth ``slider-like'' control by manipulating SAE feature activations derived from the text encoder; however, existing approaches rely on heuristic feature selection and manual steering-strength tuning, leading to suboptimal trade-offs among the three objectives. We propose Sparse Relaxed-Lasso Steering (SRLS), which casts steering-vector discovery as a convex sparse recovery problem. Exploiting the affine structure of the SAE decoder, SRLS automatically identifies sparse, generalizable support sets via a Lasso objective and then debiases the coefficients using support-restricted ridge refitting. We further replace manual strength tuning with a fixed-budget Bayesian optimization procedure. Across diverse attributes and subjects, SRLS improves the alignment--consistency--quality trade-off over competing methods.
****
L-CUBE: Isolating Long-Context Capacity from Knowledge with Controllable Mutual

Information Scaling
Zhuo Chen, Oriol Mayné i Comas, Zhuotao Jin, Di Luo, Marin Soljacic
Evaluating long-context language models on natural language conflates architectural capacity to capture dependencies with semantic knowledge and vocabulary statistics. When models fail at long contexts, we cannot determine whether failures stem from fundamental architectural limitations or insufficient domain knowledge, preventing clean diagnosis of efficient architectures before expensive training on real data. We introduce **L-CUBE** (Long-Context Utilization Benchmark), a synthetic benchmark that isolates dependency-capturing capacity from semantic knowledge through hierarchical Gaussian sequences with controllable bipartite mutual information scaling. The generator provides exact ground-truth conditionals that scale efficiently to arbitrarily long sequences, enabling unconfounded evaluation via conditional KL divergence rather than perplexity alone. We define *long-context utilization* to measure the amount of available predictive information that models extract as context grows. Experiments across transformers, state space models, and efficient alternatives validate L^2M capacity theory predictions and uncover new phenomena. L-CUBE enables practitioners to test whether a particular design will maintain long-context capability at target sequence lengths before committing to real-data training.
****

Data Augmentation of Contrastive Learning is Estimating Positive-incentive Noise
Hongyuan Zhang, Yanchen Xu, Sida Huang, Xuelong Li
Inspired by the idea of Positive-incentive Noise (*Pi-Noise* or *π-Noise*) that aims at learning the reliable noise beneficial to tasks, we scientifically investigate the connection between contrastive learning and π-noise in this paper. By converting the contrastive loss to an auxiliary Gaussian distribution to quantitatively measure the difficulty of the specific contrastive model under the information theory framework, we properly define the task entropy, the core concept of π-noise, of contrastive learning. It is further proved that the predefined data augmentation in the standard contrastive learning paradigm can be regarded as a kind of point estimation of π-noise. Inspired by the theoretical study, a framework that develops a π-noise generator to learn the beneficial noise (instead of estimation) as data augmentations for contrast is proposed. The designed framework can be applied to diverse types of data and is also completely compatible with the existing contrastive models. From the visualization, we surprisingly find that the proposed method successfully learns effective augmentations.

On the Provable Suboptimality of Momentum SGD in Nonstationary Stochastic Optimization
Sharan Sahu, Cameron Hogan, Martin T. Wells
In this paper, we provide a comprehensive theoretical analysis of Stochastic Gradient Descent (SGD) and its momentum variants (Polyak Heavy-Ball and Nesterov) for tracking time-varying optima under strong convexity and smoothness. Our finite-time bounds reveal a sharp decomposition of tracking error into transient, noise-induced, and drift-induced components. This decomposition exposes a fundamental trade-off: while momentum is often used as a gradient-smoothing heuristic, under distribution shift it incurs an explicit drift-amplification penalty that diverges as the momentum parameter β approaches 1, yielding systematic tracking lag. We complement these upper bounds with minimax lower bounds under gradient-variation constraints, proving this momentum-induced tracking penalty is not an analytical artifact but an information-theoretic barrier: in drift-dominated regimes, momentum is unavoidably worse because stale-gradient averaging forces systematic lag. Our results provide theoretical grounding for the empirical instability of momentum in dynamic settings and precisely delineate regime boundaries where vanilla SGD provably outperforms its accelerated counterparts.

CBV: Clean-label Backdoor Attacks on Vision Language Models via Diffusion Models
Ji Guo, xiaolong qin, Cencen Liu, Jielei Wang, Jierun Chen, Wenbo Jiang
Vision-Language Models (VLMs) have achieved remarkable success in tasks such as

image captioning and visual question answering (VQA). However, as their applicat
ions become increasingly widespread, recent studies have revealed that VLMs are
vulnerable to backdoor attacks. Existing backdoor attacks on VLMs primarily rely
 on data poisoning by adding visual triggers and modifying text labels, where th
e induced image–text mismatch makes poisoned samples easy to detect.
To address this limitation, we propose the Clean-Label Backdoor Attack on VLMs v
ia Diffusion Models (CBV), which leverages diffusion models to generate natural
poisoned examples via score matching.
Specifically, CBV modifies the score during the reverse generation process of th
e diffusion model to guide the generation of poisoned samples that contain trigg
ered image features.
To further enhance the effectiveness of the attack, we incorporate the textual i
nformation of the triggered images as multimodal guidance during generation. Mor
eover, to enhance stealthiness, we introduce a GradCAM-guided Mask (GM) that res
tricts modifications to only the most semantically important regions, rather tha
n the entire image.
We evaluate our method on MSCOCO and VQA v2 with four representative VLMs, achie
ving over 80\% ASR while preserving normal functionality.
****

FlowSeg: Dynamic Semantic Guidance for LLM-Conditioned Segmentation
Zekang Zhang, Guangyu Gao, Youyun Tang, WU CHENGJING, Xiaochao Qu, Chi Harold Li
u, Jianbo Jiao, Yunchao Wei, Luoqi Liu, Ting Liu
LLM-conditioned segmentation has recently advanced rapidly by coupling large lan
guage models with iterative mask generation frameworks. However, we identify a p
ersistent failure mode in current propose-then-select pipelines. Although high-q
uality mask candidates are often generated, the final prediction may fail to mat
ch the given linguistic condition. This failure arises because language semantic
s are typically used as static prompts or post-hoc matching signals, rather than
 participating in the iterative mask generation process. Through systematic anal
ysis, we show that many errors stem from semantic misalignment rather than poor
mask quality. To address this issue, we propose FlowSeg, which introduces dynami
c semantic guidance via a bidirectional semantic flow between intermediate decod
ing states and LLM-derived condition embeddings throughout the generation proces
s. Language conditions actively guide mask refinement at each stage, while condi
tion embeddings are progressively updated by emerging visual evidence. This desi
gn yields semantically grounded mask representations and visually aligned langua
ge conditions, enabling more reliable matching. We further incorporate a lightwe
ight boundary-aware refinement to selectively enhance uncertain regions without
perturbing confident interiors. Extensive experiments on referring expression se
gmentation and reasoning segmentation tasks demonstrate that FlowSeg consistentl
y improves language–mask alignment and achieves state-of-the-art performance. P
roject page: https://zkzhang98.github.io/FlowSeg_page

Greedy Coordinate Diffusion: Effective and Semantically Coherent Adversarial Att
acks via Diffusion Guidance
Bohdan Turbal, Blossom Metevier, Max Springer, Aleksandra Korolova
Adversarial attacks on large language models have limited practical impact despi
te extensive research.
Optimization-based attacks such as Greedy Coordinate Gradient (GCG) (Zou et al.
, 2023) produce high-perplexity, incoherent suffixes that existing defenses easi
ly detect (Bengio et al., 2024).

Moreover, attempting to enforce coherence constraints during optimization often
 prevents the attack from successfully eliciting the specific targeted response,
 resulting in low success rates against robust models.
Conversely, attacks that maintain coherence often alter the semantic intent of q
ueries;
when the model complies with these altered queries, responses fail to address th
e adversary's original goal.
In this work, we introduce Greedy Coordinate Diffusion (GCD), a novel framework

that efficiently generates adversarial attacks against safety-aligned models whi
le maintaining low perplexity and high semantic adherence to the adversary's ori
ginal intent.
GCD leverages the generative priors of discrete diffusion language models to gui
de the search for adversarial suffixes that achieve semantic coherence and adher
ence.

Unlike GCG, GCD does not require direct gradient access, allowing it to operate
in a gray-box setting.
We show GCD achieves highest ASR while remaining competitive on response-quality
 scores, and that the constructed adversarial prompts are detected at lower rate
s than other methods by perplexity-based and guard-model filters.

Improved Stochastic Optimization of LogSumExp
Egor Gladin, Alexey Kroshnin, Jia-Jie Zhu, Pavel Dvurechensky
The LogSumExp function, dual to the Kullback-Leibler (KL) divergence, plays a ce
ntral role in many important optimization problems,
including entropy-regularized optimal transport (OT) and distributionally robust
 optimization (DRO). In practice, when the number of exponential terms inside th
e logarithm is large or infinite, optimization becomes challenging since computi
ng the gradient requires differentiating every term. We propose a novel convexit
y- and smoothness-preserving approximation to LogSumExp that can be efficiently
optimized using stochastic gradient methods. This approximation is rooted in a s
ound modification of the KL divergence in the dual, resulting in a new f-diver
gence called the *Safe KL divergence*. Our experiments and theoretical analysis
of the LogSumExp-based stochastic optimization, arising in DRO and continuous OT
, demonstrate the advantages of our approach over existing baselines.

From Directions to Regions: Decomposing Activations in Language Models via Local
 Geometry
Or David Shafran, Shaked Ronen, Omri Fahn, Shauli Ravfogel, Atticus Geiger, Mor
Geva
Activation decomposition methods in language models are tightly coupled to geome
tric assumptions on how concepts are realized in activation space. Existing appr
oaches search for individual global directions, implicitly assuming linear separ
ability, which overlooks concepts with nonlinear or multi-dimensional structure.
 In this work, we leverage Mixture of Factor Analyzers (MFA) as a scalable, unsu
pervised alternative that models the activation space as a collection of Gaussia
n regions with their *local* covariance structure. MFA decomposes activations in
to two compositional geometric objects: the region's centroid in activation spac
e, and the local variation from the centroid. We train large-scale MFAs for Llam
a-3.1-8B and Gemma-2-2B, and show they capture complex, nonlinear structures in
activation space. Moreover, evaluations on localization and steering benchmarks
show that MFA outperforms unsupervised baselines, is competitive with supervised
 localization methods, and often achieves stronger steering performance than spa
rse autoencoders. Together, our findings position local geometry, expressed thro
ugh subspaces, as a promising unit of analysis for scalable concept discovery an
d model control, accounting for complex structures that isolated directions fail
 to capture.

A Solver-Free Training Method for Predict-then-Optimize
Beichen Wan, Mo Liu
We propose a scalable method for training prediction (machine learning) models i
n the predict-then-optimize paradigm, where model outputs serve as coefficients
for a subsequent linear optimization task. Directly minimizing the empirical dec
ision regret is intractable for linear programming and combinatorial optimizatio
n since the decision mapping is piecewise constant, and the gradients are zero a
lmost everywhere. While existing methods address this by smoothing the different
iation process, they suffer from scalability issues, since a computationally exp
ensive solver call is required for every gradient evaluation. To address this, w

e propose a decision-focused learning pipeline based on a measure transformation principle, which yields a new surrogate loss that is completely optimization-solver-free during training. We establish theoretical guarantees, including Fisher consistency and excess risk bounds. Empirically, our method achieves decision quality competitive with state-of-the-art methods while reducing training time by orders of magnitude.
****
SynerMedGen: Synergizing Medical Multimodal Understanding with Generation via Task Alignment
Weiren zhao, DONG Yi, Cheng Chen
Unifying multimodal understanding and generation is a compelling frontier that is beginning to emerge in the medical field.
However, the limited existing unified medical models typically treat understanding and generation as disjoint objectives, lacking a meaningful functional synergy. In this work, we identify and address a critical question in unified medical modeling: what form of “understanding” truly benefits generation. We present SynerMedGen, a unified framework built on the proposed principle of generation-aligned understanding, which synergizes understanding objectives with generation tasks via task alignment. SynerMedGen introduces three generation-aligned understanding tasks and a two-stage training strategy that transfers generation-beneficial representations learned during understanding training to medical image synthesis. Remarkably, even with understanding training alone, our SynerMedGen achieves strong zero-shot performance across 22 medical image synthesis tasks and demonstrates robust generalization. When combined with generation training, SynerMedGen consistently outperforms state-of-the-art specialized medical image synthesis models as well as recent unified medical models. We also release SynerMed, a large-scale dataset of 1M paired synthesis samples and 2M understanding instances for studying understanding–generation synergy. Our project can be accessed at https://github.com/piooip/SynerMedGen.

Preference Goal Tuning: Post-Training as Latent Control for Frozen Policies
Guangyu Zhao, Kewei Lian, Haoxuan Ru, Borong Zhang, Haowei Lin, Zhancun Mu, Haobo Fu, QIANG FU, Shaofei Cai, Zihao Wang, Yitao Liang
Goal-conditioned policies enable decision-making models to execute diverse behaviors based on specified goals, yet their downstream performance is often highly sensitive to the choice of instructions or prompts. To bypass the limitations of discrete text prompts, we formulate post-training adaptation as a latent control problem, where the goal embedding serves as a continuous control variable to modulate the behavior of a frozen policy. We propose Preference Goal Tuning (PGT), a framework that optimizes this latent control variable to align the induced trajectory distribution with task preferences. Unlike standard fine-tuning that updates policy parameters, PGT keeps the policy frozen and updates only the latent goal using a trajectory-level preference objective. This approach essentially searches for the optimal conditioning input that maximizes the likelihood of preferred behaviors while suppressing undesirable ones. We evaluate PGT on the Minecraft SkillForge benchmark across 17 tasks. With minimal data, PGT achieves average relative improvements of 72.0\% and 81.6\% on two foundation policies, consistently outperforming expert-crafted prompts. Crucially, by decoupling task alignment (latent goal) from physical dynamics (frozen policy), PGT surpasses full fine-tuning by 13.4\% in out-of-distribution settings, demonstrating superior robustness and generalization.

ModernVBERT: Towards Smaller Visual Document Retrievers
Paul Teiletche, Quentin Macé, Max Conti, António Loison, Gautier Viaud, Pierre Colombo, Manuel Faysse
Large-scale document retrieval (search) is key in many modern industrial AI pipelines to ground models with relevant contextual information. Increasingly, Visual Document Retrieval (VDR) models, which directly embed images of document pages, are used as an alternative to text-only retrievers. While these models are historically repurposed generative VLMs fine-tuned for embedding tasks, we revisit

this design choice in this paper and systematically develop strong VDR models fr
om the ground up. Through controlled experiments, we isolate the impact of key t
raining factors such as attention masking, multi-modal data regimes, and contras
tive objectives at all phases of training. Our findings confirm current VDR perf
ormance is constrained by generative modeling, especially in multi-vector settin
gs. Building on these insights, we train ModernVBERT, a 250M-parameter vision-la
nguage encoder that outperforms recent models up to 10 times its size when fine-
tuned on document retrieval tasks. Thanks to its compact design, ModernVBERT ena
bles efficient retrieval inference on CPU hardware, while maintaining competitiv
e performance. Models, code and data are available at https://huggingface.co/Mod
ernVBERT.

Where Rectified Flows Leak: Characterising Membership Signals Along the Interpol
ation Path
Thomas Sesmat, Gabriel Meseguer-Brocal, Geoffroy Peeters
Understanding what generative models retain from training data remains challengi
ng, with implications for copyright and privacy.
Beyond verbatim reproduction, models can encode subtler traces of their training
 data that never surface in their outputs yet remain exploitable. We study this
regime for Rectified Flows, which are increasingly used in deployed generative s
ystems.
We analyse the interpolation path $X_\lambda = (1-\lambda)X_0 + \lambda X_1$ tha
t defines the Rectified Flow training.
We show that a gap exists between the reconstruction of train and test data that
 follows a bell-shaped curve over λ, wich accumulates during training, w
hile the validation metrics remain stable.
The signal has a maximum whose location we derive in closed form under Gaussian
assumptions.
We validate these predictions on both audio and images and show that the bell-sh
aped structure is universal, while the peak prediction holds when our assumption
s are satisfied.
As a proof of concept, we exploit this specific λ-resolved structure to
perform a Membership Inference Attack, distinguishing members of the training se
t from non-members.

JanusPipe: Efficient Pipeline Parallel Training for Machine Learning Interatomic
 Potentials
Hongyu Wang, Weijian Liu, Hongtao Xu, Yan Wang, Mingzhen Li, Weile Jia, Guangmin
g Tan
Discovering atom-level phenomena requires molecular dynamics (MD) simulations wi
th ab initio accuracy.
Machine learning interatomic potentials (MLIPs) enable stable, high-accuracy MD
simulations, and their models exhibit scaling-law trends similar to large langua
ge models.
However, the lack of scalable and efficient distributed training systems for con
servative MLIPs makes them difficult to scale.
This is because conservative MLIPs inherently follow a double-backward execution
 pattern, which involves computing gradients during the forward pass.
This pattern creates a mismatch with existing distributed training systems, espe
cially for pipeline parallelism.
Therefore, we present JanusPipe, an efficient 3D-parallel (PP/DP/GP) training sy
stem tailored for conservative MLIPs.
It integrates SymFold to enable memory-efficient pipeline parallelism for conser
vative MLIPs, and WaveK to reduce pipeline bubbles by balancing the four-phase c
ompute time.
Experimental results on 32 GPUs show that JanusPipe improves throughput by $1.51
\times$ and $1.45\times$ on average over 1F1B and Hanayo, respectively.

Social Hippocampus Memory Learning
Liping Yi, Zhiming Zhao, Kewen Zhu, Xiang Li, Zhiwei Shang, Qinghua Hu

Social learning highlights that learning agents improve not in isolation, but th
rough interaction and structured knowledge exchange with others. When introduced
 into machine learning, this principle gives rise to social machine learning (SM
L), where multiple agents collaboratively learn by sharing abstracted knowledge.
 Federated learning (FL) provides a natural collaboration substrate for this par
adigm, yet existing heterogeneous FL approaches often rely on sharing model para
meters or intermediate representations, which may expose sensitive information a
nd incur additional overhead.
In this work, we propose **SoHip** (**So**cial **Hip**pocampus Memory Learning),
 a memory-centric social machine learning framework that enables collaboration a
mong heterogeneous agents via memory sharing rather than model sharing. SoHip ab
stracts each agent’s individual short-term memory from local representations, co
nsolidates it into individual long-term memory through a hippocampus-inspired me
chanism, and fuses it with collectively aggregated long-term memory to enhance l
ocal prediction. Throughout the process, raw data and local models remain on-dev
ice, while only lightweight memory are exchanged.
We provide theoretical analysis on convergence and privacy preservation properti
es. Experiments on two benchmark datasets with seven baselines demonstrate that
SoHip consistently outperforms existing methods, achieving up to 8.78% accuracy
improvements. The code of SoHip is available at https://github.com/LipingYi/SoHi
p.

GI-GCN: Global Interacted Graph Convolutional Networks via Dominant Sets for Gra
ph Classification

Lu Bai, Xinya Qin, Lixin Cui, Ming Li, Hangyuan Du, Ziyu Lyu, Xin Jin

Graph Convolutional Networks (GCNs) are defined based on aggregating the informa
tion of adjacent nodes, that are usually treated as equally important and may li
mit the representational power of existing GCNs. To address this shortcoming, we
 propose a novel Global Interacted Graph Convolutional Network (GI-GCN), that le
verages the solution vectors maintained during the iterative updates of the Domi
nant Set to adaptively characterize the global importance distribution over all
nodes. Specifically, at each convolution layer, this distribution is adopted to
adaptively modulate the importance weights of node features before performing th
e local message passing. We show that this convolution strategy can effectively
capture the highly correlated information between nonadjacent nodes through the
Dominant Set algorithm, not only emphasizing the critical graph-level informatio
n but also enhancing the discriminative power of graph representations. Furtherm
ore, we optimize the memory complexity of the framework, significantly reducing
the memory overhead associated with the global interaction modeling. Experiments
 demonstrate the effectiveness of the proposed GI-GCN model.

DISSOLVR: An Interpretable and Fast Framework for Aqueous and Organic Solubility
 Prediction

Vansh Ramani, Har Ashish Arora, Dhairya Kuchhal, Sayan Ranu, Tarak Karmakar

High-fidelity solubility prediction is fundamental to pharmaceutical development
 and environmental partitioning, where accurate modeling must couple molecular s
tructure with thermodynamic behavior across diverse chemical environments. Howev
er, recent advancements have been dominated by deep learning architectures that
often sacrifice physical interpretability for predictive power. We challenge thi
s trend by showing that state-of-the-art performance does not require such non-t
ransparent architectures. To address this, we introduce DISSOLVR, a transparent
framework for molecular solubility prediction. In addition, we perform a compreh
ensive literature review and a benchmarking study against various methods. We sh
ow that Dissolvr approaches the aleatoric limit of experimental uncertainty and
achieves OOD generalization through structural invariance derived by mapping mol
ecules to physically-grounded descriptors. Then, we present an LLM-assisted post
-hoc explanation pipeline that bridges the gap between symbolic model artifacts
and chemically grounded narratives. Finally, a comparative benchmark of a survey
 involving 22 expert chemists reveals that expert evaluators provide deep insigh
ts.

Beyond Distribution Estimation: Simplex Anchored Structural Inference Towards Universal Semi-Supervised Learning
Yaxin Hou, Jun Ma, Hanyang Li, Bo Han, Jie Yu, Yuheng Jia
Semi-supervised learning faces significant challenges in realistic scenarios where labeled data is scarce and unlabeled data follows unknown, arbitrary distributions. We formalize this critical yet under-explored paradigm as Universal Semi-supervised Learning (UniSSL). Existing methods typically leverage unlabeled data via pseudo-labeling. However, they often rely on the idealized assumption of a uniform unlabeled data distribution or require sufficient labeled data to estimate it. In the UniSSL setting, such dependencies lead to numerous erroneous pseudo-labels, thereby triggering representation confusion. Fortunately, we observe that inter-sample relations captured by representations are more reliable than pseudo-labels. Leveraging this insight, we shift our focus to representation-level structural inference to bypass distribution estimation. Accordingly, we propose Simplex Anchored Graph-state Equipartition (SAGE), which captures high-order inter-sample dependencies to establish structural consensus for guiding representation learning. Meanwhile, to mitigate representation confusion, we employ vectors that satisfy a simplex equiangular tight frame to serve as a coordinate frame for guiding inter-class representation separation. Finally, we introduce a weighting strategy based on distribution-agnostic metrics to prioritize reliable pseudo-labels and an auxiliary branch to isolate potentially erroneous pseudo-labels. Evaluations on five standard benchmarks show that SAGE consistently outperforms state-of-the-art methods, with an average accuracy gain of **8.52\%**.
****
PDAgent: An LLM-Driven Autonomous Agent Framework Towards *In Silico* Protein Design via Directed Mutation
Song Ouyang, Zhijie Dong, Yong Luo, Kehua Su, Huangxuan Zhao, Miaojing Shi, Bo Du
Computational protein design holds immense promise across diverse domains, but existing approaches face significant challenges: traditional physics-based methods require substantial domain expertise, while emerging deep learning methods often rely on restricted functional ontologies, struggle to bridge the semantic gap between text and protein sequences, or lack closed-loop optimization mechanisms. In this paper, we present PDAgent, an LLM-driven autonomous agent framework that enables *in silico* protein design through template-based directed mutation. Our framework accepts natural language specifications of desired protein properties and employs a ReAct-style reasoning loop comprising five phases: THINK, PLAN, ACT, OBSERVE, and REFLECT. PDAgent integrates template retrieval, conservation-aware mutation strategies, and domain-specific computational tools for property optimization across seven biophysical dimensions. Experiments on 100 diverse protein design tasks demonstrate that PDAgent achieves a 91.86% average constraint satisfaction rate with high structural quality (mean pLDDT 87.69), substantially outperforming both direct LLM generation and specialized deep learning methods. We provide the source code at https://github.com/Gift-OYS/PDAgent.
****
BioDynaSpec: Harmonic-Guided Spatio-Spectral Autoregressive Diffusion for Protein Dynamics Generation
Mujie Lin, Yutian Liu, Yudi Guo, Yanzhen Hou, Yiheng Tao, Ruochong Zheng, Kaiwen Cheng, Xin Shan, Youdong Mao, Jie Chen
Generating long-horizon molecular dynamics (MD) is difficult due to error accumulation in time-domain autoregressive models, which causes drift, and fixed step-size constraints on temporal resolution.
We propose **BioDynaSpec**, which reformulates protein dynamics as spatio-spectral generation: **Independent Windowed Fourier Decomposition (IWFD)** decomposes trajectories into window-wise spectral representations, and a generator combines low-to-high frequency autoregression with diffusion denoising to reconstruct continuous motion.
This formulation is motivated by **a local near-equilibrium view of protein dynamics**: after per-window alignment, fluctuations around an anchor conformation a

re better characterized in spectral space, where local mode structure is more explicit than in frame-wise coordinates.
To improve cross-residue and cross-frequency consistency, we introduce **Inter-Residue Frequency Coupling (IRFC)**, a learnable Gaussian distance bias in attention that injects a resonance-inspired structural prior.
On ATLAS, BioDynaSpec improves 250-frame trajectory generation with $R_{250}=1.509$ Å, where R_s denotes the mean per-frame Cα-RMSE over the first s frames after alignment, reducing error by 60.4\% versus MDGEN and 57.2\% versus ProAR, while achieving the best PCA-2D displacement-profile correlation and step wise distribution matching.
For equilibrium conformational sampling, it achieves Root Mean $W_2=1.31$, MD PCA $W_2=0.90$, and Joint PCA $W_2=1.19$, improving over the next best method by 50.03\%, 35.25\%, and 47.58\%, respectively.
It also improves near-equilibrium local-dynamics and covariance consistency, achieving PCA-PSD-LogCorr $=0.817$ and CFRE $=0.989$, corresponding to a 21.9\% gain and a 36.7\% reduction over the next best method, respectively.
The source code is available at https://github.com/Linmj-Judy/BioDynaSpec.git.
****

AlienLM: Alienization of Language for API-Boundary Privacy in Black-Box LLMs
Jaehee Kim, Pilsung Kang
Modern LLMs are increasingly accessed via black-box APIs, requiring users to transmit sensitive prompts, outputs, and fine-tuning data to external providers, creating a critical privacy risk at the API boundary.
We introduce AlienLM, a deployable API-only privacy layer that protects text by translating it into an Alien Language via a vocabulary-scale bijection, enabling lossless recovery on the client side. Using only standard fine-tuning APIs, Alien Adaptation Training (AAT) adapts target models to operate directly on alienized inputs.
Across four LLM backbones and seven benchmarks, AlienLM retains over 81% of plaintext-oracle performance on average, substantially outperforming random-bijection and character-level baselines. Under adversaries with access to model weights, corpus statistics, and learning-based inverse translation, recovery attacks reconstruct fewer than 0.22% of alienized tokens.
Our results demonstrate a practical pathway for privacy-preserving LLM deployment under API-only access, substantially reducing plaintext exposure while maintaining task performance.

Scaling Continual Learning to 300+ Tasks with Bi-Level Routing Mixture-of-Experts
Meng Lou, Yunxiang Fu, Yizhou Yu
Continual learning, especially class-incremental learning (CIL), on the basis of a pre-trained model (PTM) has garnered substantial research interest in recent years. However, how to effectively learn both discriminative and comprehensive feature representations while maintaining stability and plasticity over very long task sequences remains an open problem. We propose $\mathbf{CaRE}$, a scalable $\mathbf{C}$ontinual Le$\mathbf{a}$rner with efficient Bi-Level $\mathbf{R}$outing Mixture-of-$\mathbf{E}$xperts (BR-MoE). The core idea of BR-MoE is a bi-level routing mechanism: a router selection stage that dynamically activates relevant task-specific routers, followed by an expert routing phase that dynamically activates and aggregates experts, aiming to inject discriminative and comprehensive representations into every intermediate network layer.
On the other hand, we introduce a challenging dataset, OmniBenchmark-1K, for CIL performance evaluation on very long task sequences with hundreds of tasks.
Extensive experiments show that CaRE demonstrates leading performance across a variety of datasets and task settings, including commonly used CIL datasets with classical CIL settings (e.g., 5-20 tasks).
To the best of our knowledge, CaRE is the first continual learner that scales to very long task sequences (ranging from 100 to over 300 non-overlapping tasks), while outperforming all baselines by a large margin on such task sequences.
We hope that this work will inspire further research into continual learning ove

r extremely long task sequences.
Code and dataset are publicly released at https://github.com/LMMMEng/CaRE.

Online Learning and Inference for Cox Proportional Hazards Model Using Renewable Sieve Estimation
Mengtong Hu, Ziyang Gong, Xu Shi, Ling Zhou, Peter Song
Online learning for the Cox model is challenging because its partial likelihood is non-decomposable, with each risk set requiring a summation over all samples. We propose Collaborative Operation of Linked Survival Analysis (COLSA), an online learning framework that replaces the partial likelihood with the full likelihood using sieve approximation of the baseline hazard. The proposed likelihood function is decomposable and eliminates the need to store historical data in memory, enabling efficient online updates. Moreover, COLSA maintains sufficient statistics for a higher-order basis and employs data-driven basis projection to adaptively scale model complexity to the effective sample size. Unlike existing online Cox methods, COLSA achieves asymptotic normality and attains the same statistical efficiency as the pooled-data partial likelihood estimator, without accessing full data and only requiring constant memory. Simulation studies and application to kidney transplant data demonstrate that COLSA outperforms existing online methods and matches the performance of full-data estimation.

Rethinking the Reranker: Boundary-Aware Evidence Selection for Robust Retrieval-Augmented Generation
Jiashuo Sun, Pengcheng Jiang, Saizhuo Wang, Jiajun Fan, Heng Wang, Siru Ouyang, Ming Zhong, Yizhu Jiao, Chengsong Huang, Xueqiang Xu, Pengrui Han, Peiran Li, Jiaxin Huang, Ge Liu, Heng Ji, Jiawei Han
Retrieval-Augmented Generation (RAG) systems remain brittle under realistic retrieval noise, even when the required evidence appears in the top-K results.
A key reason is that retrievers and rerankers optimize solely for relevance, often selecting either trivial, answer-revealing passages or evidence that lacks the critical information required to answer the question, without considering whether the evidence is suitable for the generator.
We propose \texttt{BAR-RAG}, which reframes the reranker as a boundary-aware evidence selector that targets the generator’s Goldilocks Zone—evidence that is neither trivially easy nor fundamentally unanswerable for the generator, but is challenging yet sufficient for inference and thus provides the strongest learning signal.
\texttt{BAR-RAG} trains the selector with reinforcement learning using generator feedback, and adopts a two-stage pipeline that fine-tunes the generator under the induced evidence distribution to mitigate the distribution mismatch between training and inference.
Experiments on knowledge-intensive question answering benchmarks show that \texttt{BAR-RAG} consistently improves end-to-end performance under noisy retrieval, achieving an average gain of 10.3\% over strong RAG and reranking baselines while substantially improving robustness.

Active Policy Optimization for Individualized Dosing via Gradient Variance Minimization
Yi Wan, Xin Wang, Huanhuan Chen
In domains such as healthcare and marketing, learning optimal individualized dosing policies to maximize utility is crucial, yet high experimental costs impose strict budget constraints, necessitating efficient active policy learning. Existing active learning methods in causal inference primarily focus on binary treatments and effect estimation, leaving continuous dosing and policy optimization underexplored. To address this gap, we propose an active learning framework tailored for optimal policy learning. Exploiting the inherent structure of dose-response curves, we theoretically show that the policy optimization regret is bounded by the expected posterior gradient variance at the estimated optimal doses. Motivated by this result, we introduce Gradient Variance Active Learning for Individualized Dosing (GVALID), a batch acquisition strategy that greedily selects samp

les to minimize target gradient variance for efficient policy learning. Experiments demonstrate that GVALID achieves superior performance under strict budget constraints.

Learning Self-Interpretation from Interpretability Artifacts: Training Lightweight Adapters on Vector-Label Pairs
Keenan Pepper, Alex McKenzie, Florin Pop, Stijn Servaes, Martin Leitgab, Michael Vaiana, Judd Rosenblatt, Michael S. A. Graziano, Diogo S de Lucena
Self-interpretation methods prompt language models to describe their own internal states, but remain unreliable due to hyperparameter sensitivity. We show that training lightweight adapters on interpretability artifacts, while keeping the LM entirely frozen, yields reliable self-interpretation across tasks and model families. A scalar affine adapter with just $d_\text{model}+1$ parameters suffices: trained adapters generate sparse autoencoder feature labels that outperform the training labels themselves (70% vs 50% generation scoring at 70B scale), identify topics with 94% recall@1 versus 1% for untrained baselines, and decode bridge entities in multi-hop reasoning that appear in neither prompt nor response, surfacing implicit reasoning without chain-of-thought. The learned bias vector alone accounts for 85% of improvement, and simpler adapters generalize better than more expressive alternatives. Controlling for model knowledge via prompted descriptions, we find self-interpretation gains outpace capability gains from 7B to 72B parameters. Our results demonstrate that self-interpretation improves with scale, without modifying the model being interpreted.
****
(Sparse) Attention to the Details: Preserving Spectral Fidelity in ML-based Weather Forecasting Models
Maksim Zhdanov, Ana Lucic, Max Welling, Jan-Willem van de Meent
We introduce \textsc{Mosaic}, a probabilistic weather forecasting model that addresses two sources of spectral degradation in ML-based weather prediction: training to predict the ensemble mean deterministically and compressive encoding creating an information bottleneck. \textsc{Mosaic} combines learned functional perturbations for ensemble forecasting with block-sparse attention, a hardware-aligned formulation that shares keys and values across spatially adjacent queries, enabling each block to dynamically attend to the most relevant regions. By capturing arbitrarily long-range dependencies at linear cost, \textsc{Mosaic} processes high-resolution weather data without compression. On IFS HRES data, \textsc{Mosaic} at 1.5° resolution matches or outperforms models trained on 0.25° data, with individual ensemble members exhibiting near-perfect spectral alignment across all resolved frequencies.
****
Localize and Neutralize: Gradient-Guided Token Suppression Against Visual Prompt Injection Attack
Dongpeng Zhang, Ke Ma, Yangbangyan Jiang, Gaozheng Pei, Longtao Huang, Qianqian Xu, Qingming Huang
Adversarial images pose a severe security threat to multimodal large language models through prompt injection. Existing defenses largely lack a principled understanding of the underlying mechanisms and struggle to balance efficiency and fidelity. In this work, we show that successful adversarial attacks do not rely on the entire image uniformly but instead depend on a small subset of critical image tokens. Based on this insight, we propose a defense that first localizes these critical tokens via gradient analysis and then neutralizes them through masking. We show that attribution based on output probabilities fails when adversarial attacks preserve the predicted token. To overcome this limitation, we introduce the Hidden-State Gradient Norm score for adversarial behavior attribution and prove that its ranking is consistent with that of the full adversarial loss gradient, providing a theoretical guarantee for accurate localization. GTM requires only a single forward–backward pass to identify and zero out a small number of high-scoring tokens, effectively disrupting the adversarial attack path. Extensive experiments on prompt injection and multimodal jailbreak attacks demonstrate that our approach reduces attack success rates (ASR) to near zero while preserving

model utility with negligible computational overhead. The code is available at: https://github.com/fish883/GTM-Defense.

Equivariant Neural Networks for General Linear Symmetries on Lie Algebras
Chankyo Kim, Sicheng Zhao, Minghan Zhu, Tzu-Yuan Lin, Maani Ghaffari
Many scientific and geometric problems exhibit general linear symmetries, yet most equivariant neural networks are built for compact groups or simple vector features, limiting their reuse on matrix-valued data such as covariances, inertias, or shape tensors.
We introduce \textbf{Reductive Lie Neurons (ReLNs)}, an exactly $\mathrm{GL}(n)$-equivariant architecture that natively supports matrix-valued and Lie-algebraic features. ReLNs resolve a central stability issue for reductive Lie algebras by introducing a non-degenerate adjoint (conjugation)-invariant bilinear form, enabling principled nonlinear interactions and invariant feature construction in a single architecture that \textit{transfers across subgroups without redesign}. We demonstrate ReLNs on algebraic tasks with $\mathfrak{sl}(3)$ and $\mathfrak{sp}(4)$ symmetries, Lorentz-equivariant particle physics, uncertainty-aware drone state estimation via joint velocity--covariance processing, learning from 3D Gaussian-splat representations, and EMLP double-pendulum benchmark spanning multiple symmetry groups. ReLNs consistently match or outperform strong equivariant and self-supervised baselines while using substantially fewer parameters and compute, improving the accuracy–efficiency trade-off and providing a practical, reusable backbone for learning with broad linear symmetries.

Improving ML Attacks on LWE with Data Repetition and Stepwise Regression
Alberto Alfarano, Eshika Saxena, Emily Wenger, Francois Charton, Kristin E. Lauter
ML attacks on Learning with Errors (LWE) with binary or small secrets only succeed on LWE settings with very simple secrets. For example, they can recover secrets with up to three non-zero bits when models are trained on not-reduced LWE data, and three non-zero bits in the ''cruel region'' [9] when BKZ pre-processing is applied. We show that larger training sets and the use of repeated examples in the training data allow the recovery of denser secrets. We empirically observe a power-law relationship between model based attempts to recover the secrets, dataset size and repeated examples. We introduce a stepwise regression technique to recover the ``cool bits'' of the secret. Overall, these techniques allow for the recovery of denser binary secrets: up to Hamming weight 70 (and 8 cruel bits) for dimension 256 $\log_2 q=20$ and 75 (and 7 cruel bits) for dimension 512 $\log_2 q=41$ (vs 33 and 63 Hamming weight and 3 cruel bits in previous works). We also demonstrate our methods' effectiveness on denser ternary secrets, showing a substantial improvement over prior work.

Securing Multi-Agent Systems Against Corruptions via Node Contribution Backpropagation
Chengcan Wu, Zhixin Zhang, Mingqian Xu, Zeming Wei, Meng Sun
Multi-Agent Systems (MAS) have become a prevalent paradigm for Large Language Model (LLM) applications. However, the complex multi-agent design in MAS introduces unique trustworthiness concerns: adversarial agents can inject misleading information that propagates contagiously through the system, corrupting benign agents and leading to false outputs. Existing graph-based defenses model agents as nodes and communications as edges, yet are limited to static-graph defenses. In this paper, we propose a dynamic defense paradigm that models MAS communication as a signed directed acyclic graph and computes each agent's contribution to the final decision via backward propagation, enabling accurate identification and isolation of malicious agents to secure multi-agent task collaboration. Experimental results in complex and dynamic MAS environments demonstrate that our method notably outperforms existing MAS defense mechanisms, providing an effective guardrail for trustworthy MAS deployment. Our code is available at https://github.com/ChengcanWu/BPD.

A Theoretical Framework for Modular Learning of Robust Generative Models
Corinna Cortes, Mehryar Mohri, Yutao Zhong
Training large-scale generative models is resource-intensive and relies heavily on heuristic dataset weighting. We address two fundamental questions: Can we train Large Language Models (LLMs) modularly, combining small, domain-specific experts to match monolithic performance, and can we do so robustly for *any* data mixture, eliminating heuristic tuning? We present a theoretical framework for *modular* generative modeling where a set of pre-trained experts are combined via a gating mechanism. We define the space of normalized gating functions $\mathcal{G}_{1}$ and formulate the problem as a minimax game to find a single robust gate that minimizes divergence to the worst-case data mixture. We prove the existence of such a robust gate using Kakutani's fixed-point theorem and show that modularity acts as a strong regularizer, with generalization bounds scaling with the lightweight gate's complexity. Furthermore, we prove that this modular approach can theoretically outperform models retrained on aggregate data, with the gap characterized by the Jensen-Shannon Divergence. Finally, we introduce a scalable Stochastic Primal-Dual algorithm and a *Structural Distillation* method for efficient inference. Empirical results on synthetic and real-world datasets confirm that our modular architecture effectively mitigates gradient conflict and can robustly outperform monolithic baselines.

SLASH the Sink: Sharpening Structural Attention Inside LLMs
Yiming Liu, Bin Lu, Xinbing Wang, Chenghu Zhou, Meng Jin
Large Language Models (LLMs) show remarkable semantic understanding but often struggle with structural understanding when processing graph topologies in a serialized format. Existing solutions rely on training external graph-based adapters or fine-tuning, which incur high costs and lost generalizability. In this work, we investigate the internal mechanisms of LLMs and present a critical finding: *LLMs spontaneously reconstruct the graph's topology internally*, evidenced by a distinct "sawtooth" pattern in their attention maps that structurally aligns with the "token-level adjacency matrix". However, this intrinsic structural understanding is diluted by the attention sink. We theoretically formalize this dilution as a representation bottleneck, stemming from a fundamental conflict: the model's anisotropic bias, essential for language tasks, suppresses the topology-aware local aggregation required for graph reasoning. To address this, we propose a training-free solution, named **S**tructura**L** **A**ttention **SH**arpening (SLASH), which amplifies this internal structural understanding via a plug-and-play attention redistribution. Experiments on pure graph tasks and molecular prediction validate that SLASH delivers significant and consistent performance gains across diverse LLMs.

D-FUSEr: Diverse Failure, Unified Success via Error-Distribution Shaping in LLM Reasoning
David D. Baek, Andrew Estornell, Yichi Zhang, Muhammad Faaiz Taufiq, Jean-Francois Ton, Jie Mei, Tao Wang
Test-time scaling methods such as majority vote aggregation and iterative refinement (e.g., self-reflection or multi-agent inference) improve reasoning performance by leveraging multiple solution samples.
However, their efficacy depends not only on raw performance, but critically on the distribution of errors across samples.
When errors concentrate, (a) aggregation accuracy degrades, as the majority vote may select a shared mistake, and (b) confidence in common mistakes may suppress exploration in iterative refinement.
We argue that improving correctness alone is not sufficient to mitigate these issues; to this end, we propose to explicitly shape error distributions to improve aggregation.
First, we introduce a theoretically grounded \textbf{diverse failure reward} that incentivizes calibrated disagreement within model errors.
We prove that this reward directly optimizes majority-vote accuracy: policies achieving higher reward attain higher expected majority-vote performance, and vice

versa.
We further show that this theoretical property generalizes to iterative refinement.
Second, we introduce \textbf{anti-votes}, in which the model predicts the most common mistake alongside its solution, allowing probability mass on dominant errors to be explicitly reweighted.
We identify conditions under which anti-votes are guaranteed to improve majority-vote accuracy.
Empirically, across three model families of varying sizes and four benchmarks, we show that both approaches substantially improve majority vote and iterative refinement performance without degrading single-sample accuracy.
****
Near-Optimal and Efficient First-Order Algorithm for Multi-Task Learning with Shared Linear Representation
Shihong Ding, Fangyu Du, Cong Fang
Multi-task learning (MTL) has emerged as a pivotal paradigm in machine learning by leveraging shared structures across multiple related tasks. Despite its empirical success, the development of likelihood-based efficiently solvable algorithms—even for shared linear representations—remains largely underdeveloped, primarily due to the non-convex structure intrinsic to matrix factorization. This paper introduces a first-order algorithm that jointly learns a shared representation and task-specific parameters, with guaranteed efficiency. Notably, it converges in $\widetilde{\mathcal{O}}(1)$ iterations and attains a \emph{near-optimal} estimation error of $\widetilde{\mathcal{O}}(dk/(TN))$, \emph{improving} over existing likelihood-based methods by a factor of k, where d, k, T, N denote input dimension, representation dimension, task count, and samples per task, respectively. Our results justify that likelihood-based first-order methods can efficiently solve the MTL problem.

TruthRL: Incentivizing Truthful LLMs via Reinforcement Learning
Zhepei Wei, Xiao Yang, Kai Sun, Jiaqi Wang, Rulin Shao, Jingxiang Chen, Mohammad Kachuee, Teja Gollapudi, Yiwei Liao, Nicolas SCHEFFER, Rakesh Wanga, Anuj Kumar, Yu Meng, Wen-tau Yih, Xin Luna Dong
While large language models (LLMs) have demonstrated strong performance on factoid question answering, they are still prone to hallucination and untruthful responses, particularly when tasks demand information outside their parametric knowledge. Indeed, truthfulness requires more than accuracy---models must also recognize uncertainty and abstain when unsure to avoid hallucinations. This presents a fundamental challenge for existing methods: approaches that optimize for accuracy often amplify hallucinations, while those that encourage abstention can become overly conservative, sacrificing correct answers. Both extremes ultimately compromise truthfulness. In this work, we present TruthRL, a general reinforcement learning (RL) framework that directly optimizes the truthfulness of LLMs. Specifically, we implement TruthRL using GRPO with a simple yet effective ternary reward that distinguishes correct answers, hallucinations, and abstentions. It incentivizes models to reduce hallucinations not only by providing correct responses, but also by enabling abstention when uncertain, thereby improving truthfulness. Extensive experiments across four knowledge-intensive benchmarks show that TruthRL significantly reduces hallucinations (e.g., 43.5\% $\rightarrow$ 19.4\%) and improves truthfulness (e.g., 5.3\% $\rightarrow$ 37.2\%), with consistent gains across various backbone models. Analysis shows that the improvement of TruthRL arises from enhanced capability of LLMs to recognize their knowledge boundary, hence avoiding being overly conservative as the baselines are.

A Consensus Anchor-guided Hypergraph Framework for Incomplete Multi-view Clustering
Yipin Hu, Yanxi Liu, Fangxi Liu, Yanwei Yu, Lei Meng, Jie Wen, Guoqing Chao
Handling large-scale incomplete multi-view data poses a significant challenge in unsupervised representation learning. While anchor-based strategies have alleviated computational burdens, they typically rely on shallow bipartite graphs rest

ricted to pairwise relations, failing to capture complex high-order correlations among samples. Furthermore, existing methods often treat observed and missing instances indiscriminately, ignoring the distributional shifts that lead to systematic bias in consensus anchor learning. To address these limitations, we propose a novel framework tailored for scalability and robustness, termed Hypergraph-Augmented Incomplete Multi-View Clustering (HA-IMVC). Unlike traditional approaches, HA-IMVC constructs a consensus anchor-guided hypergraph that explicitly models group-wise interactions, thereby preserving structural integrity even under high missing rates. Crucially, we incorporate a dual-adaptive reweighting mechanism that calibrates importance at both the view and sample levels. This strategy adaptively penalizes severely incomplete samples to mitigate bias while harmonizing inconsistent views. Extensive experiments on diverse benchmarks demonstrate that HA-IMVC achieves superior clustering accuracy and maintains high efficiency, even in scenarios characterized by severe data incompleteness.

Towards Rule-Based Knowledge Sharing in Federated Learning

Zixuan Qin, Qi Shen, Liu Yang, Qilong Wang, Qinghua Hu

Federated learning often face both data and model heterogeneity, with the latter often more challenging. Architectural differences yield incompatible representation, making the knowledge-sharing carrier central to heterogeneous collaboration. Using proxy model enables distillation-based collaboration but incurs high communication and computation costs. Prototype-based carriers are lighter yet cause semantic confusion when incompatible features are mixed. Therefore, we propose rule-based federated learning (RFL) that shares interpretable, class-discriminative rules to enable heterogeneous collaboration, avoid feature confusion, and keep communication lightweight. RFL uses a rule network to unify clients' decision features and collaborates at the rule level, avoiding forcible averaging of incompatible representations. RFL selects sparse, high-coverage, beneficial rules for broadcasting, compressing shared knowledge into an interpretable class-rule set and reducing communication and computation costs. Each client selectively activates only rules relevant to its local classes, mitigating negative transfer while preserving personalization. Across heterogeneous settings, RFL achieves a better accuracy–communication trade-off.

Belief Dynamics Reveal the Dual Nature of In-Context Learning and Activation Steering

Eric Bigelow, Daniel Wurgaft, YingQiao Wang, Noah Goodman, Tomer Ullman, Hidenori Tanaka, Ekdeep Singh Lubana

Large language models (LLMs) can be controlled at inference time through prompts (in-context learning) and internal activations (activation steering). Different accounts have been proposed to explain these methods, yet their common goal of controlling model behavior raises the question of whether these seemingly disparate methodologies can be seen as specific instances of a broader framework. Motivated by this, we develop a unifying, predictive account of LLM control from a Bayesian perspective. Specifically, we posit that both context- and activation-based interventions impact model behavior by altering its belief in latent concepts: steering operates by changing concept priors, while in-context learning leads to an accumulation of evidence. This results in a closed-form Bayesian model that is highly predictive of LLM behavior across context- and activation-based interventions in a set of domains inspired by prior work on many-shot in-context learning. This model helps us explain prior empirical phenomena - e.g., sigmoidal learning curves as in-context evidence accumulates--while predicting novel ones--e.g., additivity of both interventions in log-belief space, which results in distinct phases such that sudden and dramatic behavioral shifts can be induced by slightly changing intervention controls. Taken together, this work offers a unified account of prompt-based and activation-based control of LLM behavior, and a methodology for empirically predicting the effects of these interventions.

Reparameterization Proximal Policy Optimization

Hai Zhong, Xun Wang, Zhuoran Li, Longbo Huang

By leveraging differentiable dynamics, Reparameterization Policy Gradient (RPG) achieves high sample efficiency. However, current approaches are hindered by two critical limitations: the under-utilization of computationally expensive dynamics Jacobians and inherent training instability. While sample reuse offers a remedy for under-utilization, no prior principled framework exists, and naive attempts risks exacerbating instability. To address these challenges, we propose Reparameterization Proximal Policy Optimization (RPO). We first establish that under sample reuse, RPG naturally optimizes a PPO-style surrogate objective via Backpropagation Through Time, providing a unified framework for both on- and off-policy updates. To further ensure stability, RPO integrates a clipped policy gradient mechanism tailored for RPG and employs explicit Kullback-Leibler divergence regularization. Experimental results demonstrate that RPO maintains superior sample efficiency and consistently outperforms or achieves state-of-the-art performance across diverse tasks.

Causal Feature Learning via Generalized Rayleigh Quotients

Liang Cao, Jun Wan, Yan Qin, Weide Liu

Extracting causally meaningful features from time-series data is fundamental for robust machine learning under distribution shifts. In process monitoring, existing methods struggle to maintain detection performance when operating conditions change. Current approaches capture either temporal causal relationships or cross-environment invariance, but not both simultaneously. We propose Causal Feature Learning (CFL), a unified framework that jointly optimizes for temporal relevance and environment mean invariance. CFL formulates feature extraction as a generalized Rayleigh-quotient problem, maximizing correlation with target variables while penalizing sensitivity to environment-dependent mean shifts. Theoretical analysis establishes conditions under which CFL identifies a mean-invariant predictive subspace. Experiments on the Tennessee Eastman Process demonstrate that CFL achieves 93.69\% average fault detection rate, outperforming 15 baseline methods and validating the benefit of jointly capturing both aspects of causality.

DisPPO: Quantile-Based Distributional Reinforcement Learning for Large Language Models

Zhijian Zhou, Long Li, Xuan Zhang, Zongkai Liu, Yanting Miao, Yuchen Liu, Deshu Chen, Ke Li, Xing Sun, Ruoxi Jiang, Xiaoyu Tan, Chao Qu, Yuan Qi

Reinforcement Learning (RL) has become a cornerstone for enhancing the reasoning capabilities of Large Language Models (LLMs). However, standard actor-critic methods, such as PPO, rely on scalar value functions that estimate only the expectation of cumulative returns. This reduction inherently discards higher-order statistical information (e.g., variance and multimodality), leading to inaccurate value estimation and suboptimal credit assignment in complex tasks. While Distributional RL offers a solution by modeling the full return distribution, its application to LLMs remains challenging due to the computational intractability of value-based operations over large vocabularies and the instability and memory burden of off-policy replay mechanisms. In this paper, we propose DisPPO, a novel on-policy framework that seamlessly integrates non-parametric quantile regression into PPO. Theoretically, we prove that our distributional update operator---composed of the λ-return Bellman operator and quantile projection---is a contraction mapping in the Wasserstein metric, guaranteeing convergence to a unique fixed point. Empirically, we evaluate DisPPO using Llama and Qwen models across diverse benchmarks, including mathematical reasoning and Text-to-SQL generation. DisPPO consistently outperforms standard PPO and recent group-based baselines in both Pass@1 and Pass@k metrics, demonstrating that distributional critics provide a richer, more robust learning signal for large-scale reasoning models.

Neural Concept Verifier: Scaling Prover-Verifier Games via Concept Encodings

Berkant Turan, Suhrab Asadulla, David Steinmann, Kristian Kersting, Wolfgang Stammer, Sebastian Pokutta

While *Prover-Verifier Games* (PVGs) offer a promising path toward verifiability in nonlinear classification models, they have not yet been applied to complex i

nputs such as high-dimensional images.
Conversely, expressive *concept encodings* effectively allow to translate such d ata into interpretable concepts but are often utilised in the context of low-cap acity linear predictors.
In this work, we push towards real-world verifiability by combining the strength s of both approaches. We introduce *Neural Concept Verifier (NCV)*, a unified fr amework combining PVGs for formal verifiability with concept encodings to handle complex, high-dimensional inputs in an interpretable way. NCV achieves this by utilizing recent minimally supervised concept discovery models to extract struct ured concept encodings from raw inputs. A *prover* then selects a subset of thes e encodings, which a *verifier*, implemented as a nonlinear predictor, uses excl usively for decision-making.
Our evaluations show that NCV outperforms classic concept-based models and pixel -based PVG classifier baselines on high-dimensional, logically complex datasets and helps mitigate shortcut behavior. Overall, we demonstrate NCV as a promising step toward concept-level, verifiable AI.

Rethinking Pretraining Data Detection for LLMs: From Local to Global
Chenye Ke, Yan Zhuang, Zirui Liu, Qi Liu
The advancements of Large Language Models (LLMs) are primarily attributed to mas sive pretraining data, which also introduces risks like privacy leakage and data contamination. Therefore, it is crucial to determine whether an LLM has been tr ained on a given target text. Existing detection methods primarily rely on local statistics of isolated tokens (e.g., those with the lowest probabilities), negl ecting the probability dynamics during the token generation process. In this pap er, we shift the detection paradigm from a local token to a global sequence pers pective, grounded in the core intuition that memorized sequences exhibit volatil ity patterns distinct from those generated via inference. We propose Adaptive En tropic Convolutional Analysis (AECA), a framework that conceptualizes the probab ility sequence as a dynamic signal, integrating calibration with convolutional f iltering to effectively capture memorization signals. Extensive experiments demo nstrate that AECA surpasses previous methods by up to 1.5\% in average AUC on th e WikiMIA benchmark, with its advantage being particularly pronounced in long-te xt scenarios.

Rethinking Neural Network Learning Rates: A Stackelberg Perspective
Sihan Zeng, Sujay Bhatt, Sumitra Ganesh
Neural networks are typically trained with a single learning rate across all lay ers. While recent empirical evidence suggests that assigning layer-specific lear ning rates can accelerate training, a principled understanding of the conditions and mechanisms under which non-uniform learning rates are beneficial remains li mited. In this work, we investigate non-uniform learning rates through the lens of Stackelberg optimization. Specifically, we demonstrate that training neural n etworks with a smaller learning rate for the body layers and a larger learning r ate for the final layer can be interpreted as a two-time-scale alternating gradi ent descent algorithm applied to a Stackelberg reformulation of the original obj ective. We establish finite-time convergence guarantees for the algorithm under broad conditions that accommodate constraint sets and non-smooth activation func tions. Beyond convergence, we identify two mechanisms by which non-uniform learn ing rates can outperform uniform learning rates: (i) we show that certain proble m instances induce a Stackelberg objective with stronger optimization structure than the original objective, yielding faster convergence to globally optimal sol utions, (ii) our numerical analysis reveals that the Stackelberg objective can e xhibit substantially sharper local curvature, especially in early training, whic h leads to more informative gradients and learning acceleration. Experiments in supervised learning and reinforcement learning support our findings.

Aligning Tree-Search Policies with Fixed Token Budgets in Test-Time Scaling of L LMs
Sora Miyamoto, Daisuke Oba, Naoaki Okazaki

Tree-search decoding is an effective form of test-time scaling for large language models (LLMs), but real-world deployment often imposes a fixed per-query token budget that varies across settings. Existing tree-search policies are largely budget-agnostic, treating the budget merely as a termination condition, thereby risking late-stage over-branching or premature termination. We propose Budget-Guided MCTS (BG-MCTS), a tree-search decoding algorithm that aligns its search policy with the remaining token budget: it starts with broad exploration, then prioritizes refinement and answer completion as the remaining budget decreases while reducing late-stage branching from shallow nodes. BG-MCTS consistently outperforms budget-agnostic tree-search baselines across inference budgets on mathematical reasoning benchmarks and an additional physics reasoning benchmark with open-weight LLMs.

Zero-Shot 3D Question Answering via Hierarchical View-to-Token Transportation

Dongsheng Wang, Dawei Su, Hui Huang

Recently, zero-shot 3D scene understanding via 2D Vision-Language Models (VLMs) has gained increasing research interest due to their promising spatial reasoning capabilities. Typically, multiple 2D views are sampled from a 3D point cloud and fed into pre-trained VLMs to answer a given question. This paradigm highlights the critical role of input context quality and raises the challenge of retaining as many task-relevant 3D details as possible under a limited input budget. We propose \texttt{KeyVT}, a hierarchical approach for input context collection at both the view and token levels. Specifically, we combine pixel features with camera parameters and assess view importance based on both semantic content and geometric position, resulting in spatially consistent and task-relevant views. Furthermore, we address redundancy among patches across selected views by identifying representative tokens under the optimal transport (OT) framework, where view tokens and key tokens are formulated as two discrete distributions in the embedding space. These key tokens are expected to cover all view features by minimizing the OT distance. We evaluate our framework on three widely used benchmarks, demonstrating significant improvements over existing tuning-free methods and performance comparable to training-based approaches.

Towards Understanding Generalization of Federated Adversarial Learning: Perspective of Algorithmic Stability

Yongkang Yang, Chang Cao, Ke Zhang, Han Li, Hong Chen, Rushi Lan

Federated Adversarial Learning (FAL) enhances model robustness by integrating adversarial training into the federated learning framework. Despite recent advances proposing efficient FAL algorithms, existing work has mainly focused on convergence properties, with limited understanding of their generalization capabilities. To address this, we present the unified theoretical framework for analyzing FAL generalization through the lens of algorithmic stability. We first analyze general FAL algorithms based on stochastic gradient descent (SGD) and derive perturbation-dependent generalization bounds, which reveal that stronger adversarial attacks can lead to degraded generalization. To mitigate the impact of adversarial perturbations, we leverage Moreau envelope optimization and establish a perturbation-independent bound, demonstrating its efficacy in simultaneously enhancing both robustness and generalization. Finally, we extend our analysis to the practical black-box setting, demonstrating that zeroth-order optimization techniques can effectively maintain both robustness and generalization even without local gradient access.

Benchmarking LLM-Assisted Blue Teaming via Standardized Threat Hunting

Yuqiao Meng, Luoxi Tang, Feiyang Yu, Xi Li, Guanhua Yan, Ping Yang, Zhaohan Xi

As cyber threats continue to grow in scale and sophistication, blue team defenders increasingly require advanced tools to proactively detect and mitigate risks. Large Language Models (LLMs) offer promising capabilities for enhancing threat analysis. However, their effectiveness in real-world blue team threat-hunting scenarios remains insufficiently explored. This paper presents CYBERTEAM, a benchmark designed to guide LLMs in blue teaming practice. CYBERTEAM constructs a stan

dardized workflow in two stages. First, it models realistic threat-hunting workf
lows by capturing the dependencies among analytical tasks from threat attributio
n to incident response. Next, each task is addressed through a set of operationa
l modules tailored to its specific analytical requirements.
This transforms threat hunting into a structured sequence of reasoning steps, wi
th each step grounded in a discrete operation and ordered according to task-spec
ific dependencies. Guided by this framework, LLMs are directed to perform threat
-hunting tasks through modularized steps. Overall, CYBERTEAM integrates 30 tasks
 and 9 operational modules to guide LLMs through standardized threat analysis. W
e evaluate both leading LLMs and state-of-the-art cybersecurity agents, comparin
g CYBERTEAM against open-ended reasoning strategies. Our results highlight the i
mprovements enabled by standardized design, while also revealing the limitations
 of open-ended reasoning in real-world threat hunting.

DeFacto: Counterfactual Thinking with Images for Enforcing Evidence-Grounded and
 Faithful Reasoning

Tianrun Xu, Haoda Jing, Ye Li, Yuquan Wei, Jun Feng, Guanyu Chen, Haichuan Gao,
Tianren Zhang, Jing Liu, Feng Chen

Recent advances in multimodal language models (MLLMs) have made \emph{thinking w
ith images} a dominant paradigm for multimodal reasoning. However, existing meth
ods still fail to ensure \emph{evidence--answer consistency}, where correct answ
ers must be supported by correct visual evidence. To address this issue, we prop
ose \textit{DeFacto}, a counterfactual reasoning framework that explicitly align
s visual evidence with final answers. Our approach integrates three complementar
y training paradigms: (i) positive, (ii) counterfactual, and (iii) random-maskin
g. We further develop a language-guided evidence construction pipeline that auto
matically localizes question-relevant regions and generates counterfactual varia
nts, resulting in \textbf{DeFacto-100K}. Building on this dataset, we train MLLM
s with GRPO-based reinforcement learning and design three complementary rewards
to promote correct answering, structured reasoning, and consistent evidence sele
ction. Moreover, we introduce \textbf{DeFacto-1.5K}, a human-annotated benchmark
 for systematically evaluating evidence-grounded consistency beyond answer accur
acy. Experiments on diverse benchmarks demonstrate that \textit{DeFacto} substan
tially improves both answer accuracy and evidence--answer consistency over stron
g baselines. The code and datasets are available at \url{https://github.com/tinn
el123666888/defacto}.

SALAAD: Sparse And Low-Rank Adaptation via ADMM for Large Language Model Inferen
ce

Hao Ma, Melis Ilayda Bal, Liang Zhang, Bingcong Li, Niao He, Melanie Zeilinger,
Michael Muehlebach

Modern large language models are increasingly deployed under compute and memory
constraints, making flexible control of model capacity a central challenge. Whil
e sparse and low-rank structures naturally trade off capacity and performance, e
xisting approaches often rely on heuristic designs that ignore layer and matrix
heterogeneity or require model-specific architectural modifications. We propose
SALAAD, a plug-and-play framework applicable to different model architectures th
at induces sparse and low-rank structures during training. By formulating struct
ured weight learning under an augmented Lagrangian framework and introducing an
adaptive controller that dynamically balances the training loss and structural c
onstraints, SALAAD preserves the stability of standard training dynamics while e
nabling explicit control over the evolution of effective model capacity during t
raining. Experiments across model scales show that SALAAD substantially reduces
memory consumption during deployment while achieving performance comparable to a
d-hoc methods. Moreover, a single training run yields a continuous spectrum of m
odel capacities, enabling smooth and elastic deployment across diverse memory bu
dgets without the need for retraining.

Suppress and Diversify: Refining Robust Pathways for Corruption Robustness

Jiangang Yang, Wenhui Shi, Xiaoran Xu, Wenyue Chong, Luqing Luo, Jing Xing, Jian

Liu
Model robustness against natural image corruptions is essential for safety-critical applications. While existing methods primarily focus on implicit representation learning, we provide the first systematic exploration of computational pathways to explicitly characterize internal robustness. We identify a progressive decay of robust features across network layers and establish a functional dependency between the prevalence of these features and model performance. To exploit these insights, we propose Suppress and Diversify (S\&D), a non-intrusive refinement approach that enhances robustness by dynamically selecting robust pathways and diversifying them through symmetry-preserving transformations. S\&D is architecture-agnostic, parameter-free, and incurs zero test-time overhead. Extensive evaluations across eight benchmarks demonstrate that S\&D consistently improves performance across multiple vision tasks, diverse backbones, and complex real-world scenarios, highlighting its broad efficacy and scalability.

Towards Disentangled Preference Optimization Dynamics: Suppress the Loser, Preserve the Winner
Wei Chen, Yubing Wu, Junmei Yang, Delu zeng, Qibin Zhao, John Paisley, Min Chen, Zhou Wang
Preference optimization is widely used to align large language models (LLMs) with human preferences. However, many margin-based methods also suppress the chosen response when they try to suppress the rejected one, and there is no general way to prevent this across different objectives.

We address this issue with a unified **incentive-score decomposition** of preference optimization, revealing that different objectives share the same local update directions and differ only in their scalar weights.

This decomposition provides a common framework for analyzing objectives that were previously studied in separate settings.

Building on this decomposition, by analyzing the dynamics of the chosen/rejected likelihoods, we identify the **disentanglement band** (DB), a simple, testable condition that tells us when training can follow the desired path: suppress the loser while preserving the winner, possibly after an early stage.

Using the DB, we propose **reward calibration** (RC), a plug■and■play method that adaptively rebalances the updates for chosen and rejected likelihoods to satisfy the DB, without redesigning the base objective.

Empirical results show that RC leads to more disentangled dynamics, with better downstream performance observed across several settings. Our code is available at https://github.com/IceyWuu/DisentangledPreferenceOptimization.
****
Towards Atoms of Large Language Models
Chenhui Hu, Pengfei Cao, Yubo Chen, Kang Liu, Jun Zhao
The fundamental representational units (FRUs) of large language models (LLMs) remain undefined, limiting further understanding of their underlying mechanisms. In this paper, we introduce ***Atom Theory*** to systematically define, evaluate, and identify such FRUs, which we term atoms. Building on the atomic inner product (AIP), a non-Euclidean metric that captures the underlying geometry of LLM representations, we formally define atoms and propose two key criteria for ideal atoms: faithfulness ($ R^2 $) and stability ($ q^{\star} $). We further prove that atoms are identifiable under threshold-activated sparse autoencoders (TSAEs). Empirically, we uncover a pervasive representation shift in LLMs and demonstrate that the AIP corrects this shift to capture the underlying representational geometry, thereby grounding Atom Theory. We find that two widely used units, neurons and features, fail to qualify as ideal atoms: neurons are faithful ($ R^2=1 $) but unstable ($ q^{\star}=0.5 $%), while features are more stable ($ q^{\star}=68.2 $%) but unfaithful ($ R^2=48.8 $%). To find atoms of LLMs, leveraging atom identifiability under TSAEs, we show via large-scale experiments that reliable atom identification occurs only when the TSAE capacity matches the data scale. Guided by this insight, we identify FRUs with near-perfect faithfulness ($ R^2=99.9 $%) and stability ($ q^{\star}=99.8 $%) across layers of Gemma2-2B, Gemma2-9B, and Llama3.1-8B, satisfying the criteria of ideal atoms statist

ically. Further analysis confirms that these atoms align with theoretical expect
ations and exhibit substantially higher monosemanticity. Overall, we propose and
 validate Atom Theory as a foundation for understanding the internal representat
ions of LLMs.

A Distributional View for Visual Mechanistic Interpretability: KL-Minimal Soft-C
onstraint Principle
Guancheng Zhou, Yisi Luo, Zhengfu He, Zhenyu Jin, Xuyang Ge, Wentao Shu, Deyu Me
ng, Xipeng Qiu
Most current paradigms in visual mechanistic interpretability (MI) remain confin
ed to interpreting internal units of the vision model via heuristic methods (e.g
., top-K activation retrieval or optimization with regularization). In this wo
rk, we establish a theoretical distributional view for visual MI, which models t
he influence of a feature activation on the natural image distribution, thereby
formulating a Kullback-Leibler (KL)-minimal optimization problem to model the MI
 task. Under this framework, statistical biases are identified within previous M
I paradigms, which reveal that they may either be perceptually uninterpretable t
o humans (i.e., deviate from the natural image distribution), or mechanistically
 unfaithful to the vision models (i.e., unable to activate model features). To r
esolve the biases under the distributional view, we propose a model with a KL-mi
nimal soft-constraint principle for visual MI that theoretically balances interp
retability and faithfulness. We realize this principle via energy-guided diffusi
on posterior sampling.
Extensive experiments validate the theoretical soundness of the proposed distrib
utional view and demonstrate the practical effectiveness of our paradigm on the
DINOv3 vision model.
The code is available at https://github.com/SII-ZhouGC/EnergyDPS.

Adaptive Contracts for Cost-Effective AI Delegation
Eden Saig, Tamar Garbuz, Ariel D. Procaccia, Inbal Talgam-Cohen, Jamie Tucker-Fo
ltz
When organizations delegate text generation tasks to AI providers via pay-for-pe
rformance contracts, expected payments rise when evaluation is noisy. As evaluat
ion methods become more elaborate, the economic benefits of decreased noise are
often overshadowed by increased evaluation costs. In this work, we introduce ada
ptive contracts for AI delegation, which allow detailed evaluation to be perform
ed selectively after observing an initial coarse signal in order to conserve res
ources. We make three sets of contributions: First, we provide efficient algorit
hms for computing optimal adaptive contracts under natural assumptions or when c
ore problem dimensions are small, and prove hardness of approximation in the gen
eral unstructured case. We then formulate alternative models of randomized adapt
ive contracts and discuss their benefits and limitations. Finally, we empiricall
y demonstrate the benefits of adaptivity over non-adaptive baselines using quest
ion-answering and code-generation datasets.

Evaluating Object-Centric Models beyond Object Discovery
Krishnakant Singh, Simone Schaub-Meyer, Stefan Roth
Object-centric learning (OCL) aims to learn structured scene representations tha
t support compositional generalization and robustness to out-of-distribution (OO
D) data. However, OCL models are often not evaluated regarding these goals. Inst
ead, most prior work focuses on evaluating OCL models solely through object disc
overy and simple reasoning tasks, such as probing the representation via image c
lassification. We identify two
limitations in existing benchmarks: (1) They provide limited insights on the rep
resentation usefulness of OCL models, and (2) localization and representation us
efulness are assessed using disjoint metrics. To address (1), we use instruction
-tuned VLMs as evaluators, enabling scalable benchmarking across diverse VQA dat
asets to measure how well VLMs leverage OCL representations for complex reasonin
g tasks. To address (2), we introduce a unified evaluation task and metric that
jointly assess localization (where) and representation usefulness (what), thereb

y eliminating inconsistencies introduced by disjoint evaluation. Finally, we include a simple multi-feature reconstruction baseline as a reference point.
****
From Basis to Basis: Gaussian Particle Representation for Interpretable PDE Operators
Zhihao Li, Yu Feng, Zhilu Lai, Wei Wang
Learning fluid PDE dynamics has increasingly benefited from neural operators and Transformer-based models, but their latent states often remain opaque, and sample-wise attention can be costly at high resolutions. We propose the \emph{Gaussian Particle Operator} (GPO), a basis-to-basis neural operator that represents fields with a learned \emph{Gaussian basis}. Each atom carries explicit geometric parameters, including centers, anisotropic scales, and weights, yielding a compact, mesh-agnostic, and directly visualizable intermediate representation. GPO operates in modal space: learned Gaussian modal windows perform Petrov--Galerkin measurements, and a PG Gaussian Attention module couples the resulting modes globally before scattering them back to the spatial domain. This design is resolution-agnostic, scales near-linearly with the number of samples for a fixed modal budget, and naturally applies to irregular geometries and 3D domains. We separately evaluate Gaussian-basis reconstruction and operator prediction. Across standard PDE benchmarks and real reanalysis datasets, GPO achieves competitive accuracy against neural-operator and Transformer baselines, ranking best on most tasks and close to the best on the remainder. The learned particles and modal couplings further provide representation-level interpretability, positioning GPO as a useful intermediate representation rather than a one-to-one decomposition of physical structures. The code is available at \url{https://github.com/lizhihao2022/GPO}.

DISCO: Mitigating Bias in Deep Learning with Conditional Distance Correlation
Emre Kavak, Tom Nuno Wolf, Christian Wachinger
Dataset bias often leads deep learning models to exploit spurious correlations instead of task-relevant signals. We introduce the Standard Anti-Causal Model (SAM), a unifying causal framework that characterizes bias mechanisms and yields a conditional independence criterion for causal stability. Building on this theory, we propose DISCO$_m$ and sDISCO, efficient and scalable estimators of conditional distance correlation that enable independence regularization in gradient-based models. Across six diverse datasets, our methods consistently outperform or are competitive in existing observed bias mitigation approaches, while requiring fewer hyperparameters and scaling seamlessly to multi-bias scenarios. This work bridges causal theory and practical deep learning, providing both a principled foundation and effective tools for robust prediction. Source Code: https://github.com/yakamoz5/DISCO.

SAGE: A Dataflow-Native Framework for Modular, Controllable, and Transparent LLM-Augmented Reasoning
Jun Liu, Peilin Liu, Ruicheng Zhang, Zhang Senlei, Yanbo Chen, Ziao Wang, Jinyun Yang, mingqi wang, Shuhao Zhang, Xiaofei Liao, Hai Jin
Large Language Model (LLM) applications increasingly execute as end-to-end inference pipelines that couple generation with
retrieval, stateful memory, context refinement, and tool use under strict tail-latency and Service-Level Objective (SLO)
constraints. Today, these stages are often stitched together as RPC-connected services, obscuring
cross-stage queueing and interference and limiting pipeline-level compilation and resource sharing. We
present SAGE (Streaming-Augmented Generative Execution), a
full-stack system that treats inference pipelines as first-class compilation targets. SAGE exposes
pipelines as declarative dataflows and compiles them into distributed execution plans with bounded-queue
backpressure. It integrates vector search, streaming semantic state, structured

memory, and refinement as
operators with explicit resource/state contracts, enabling operator-level diagnosis of tail behavior. SAGE integrates pluggable generation and embedding backends and provides a unified control plane for
engine management, batching, and admission under mixed workloads. On a 16-node cluster, SAGE sustains
16 requests/s at >700 tokens/request with 1 ms median scheduling overhead, and achieves near-linear scale-out to 16 nodes (11.4$\times$ throughput at 16 nodes), and reduces P99 latency by 57\% under multi-pipeline contention versus simultaneous admission.

Smoothing Slot Attention Iterations and Recurrences
Rongzhen Zhao, Wenyan Yang, Juho Kannala, Joni Pajarinen
Slot Attention (SA) lies at the heart of mainstream Object-Centric Learning (OCL).
Image features can be aggregated into object-level representations by SA iteratively refining cold-start query slots.
For video, such aggregation proceeds by SA recurrently shared across frames, with queries cold-started on the first frame while transitioned from the previous frame's slots thereafter.
However, cold-start queries lack sample-specific cues thus hindering precise aggregation on image or video's first frame;
Non-first frames' queries are already sample-specific thus requiring aggregation transforms different from the first frame.
We address these issues with our SmoothSA:
(1) To smooth SA iterations on image or video's first frame, we preheat cold-start queries with rich input-feature information, by a tiny module self-distilled inside OCL;
(2) To smooth SA recurrences across video's first and non-first frames, we differentiate the homogeneous aggregation transforms by using full and single iterations respectively.
Comprehensive experiments on object discovery, recognition and visual reasoning validate our method's effectiveness.
Further visual analyses illuminate the underline mechanisms.
Our source code, model checkpoints and training logs are provided on https://github.com/Genera1Z/SmoothSA.
****
AlphaRouter: Token-level Routing Between SLM and LLM with Reinforcement Learning and Tree Search
Siteng Liao, Yuzhu Liang, Hengzhong Rao, Xizhao Luo, Tian Wang
SLM-LLM routing accelerates generation by strategically invoking LLMs for critical tokens. However, existing methods typically train routers to mimic the LLM, capping performance at the reference trajectory's limit. In this work, we demonstrate that the SLM-LLM collaborative inference space offers a richer solution set, yielding correct answers even when the LLM fails. To exploit this, we propose **AlphaRouter**, a routing framework learning optimal collaborative inference paths via a *search and iterative update* paradigm. Formulating routing as a Markov Decision Process, we introduce Collaborative Inference Tree Search (CITS) to explore the solution space. To tackle the severe credit assignment challenge posed by sparse rewards, we propose Tree-Advantage Policy Optimization (TAPO) to optimize the routing policy. By leveraging counterfactual advantages within the tree structure, TAPO effectively attributes the final reward to specific routing decisions, stabilizing training without dense supervision. Extensive experiments show that AlphaRouter advances the Pareto frontier of accuracy-efficiency trade-offs by exploiting better inference trajectories in the collaborative space. Code is available at
https://github.com/StripeLife0217/AlphaRouter.

Simple Approximation and Derivative Free Inference-Time Scaling for Diffusion Models via Sequential Monte Carlo on Path Measures

Chenyang Wang, Weizhong Wang, Yinuo Ren, Jose Blanchet, Yiping Lu
Diffusion-based generative models increasingly rely on inference-time guidance, adding a drift term or reweighting mixture of experts, to improve sample quality on task-specific objectives. However, most existing techniques require repeated score or gradient evaluations, introducing bias, high computational overhead, or both. We introduce $\texttt{URGE}$, Unbiased Resampling via Girsanov Estimation, a derivative-free inference-time scaling algorithm that performs path-wise importance reweighting via a Girsanov change of measure. Instead of computing gradient-based particle weights in previous work, $\texttt{URGE}$ attaches a simple multiplicative weight to each simulated trajectory and periodically resamples. No score, no Hessian, and no PDE evaluation is required. We establish an equivalence between path-wise and particle-wise SMC: the Girsanov path weight admits a backward conditional expectation that recovers the previous particle-level weights, guaranteeing that both schemes produce the same unbiased terminal law. Empirically, $\texttt{URGE}$ outperforms existing inference-time guidance baselines on synthetic tests and diffusion-model benchmarks, achieving better generation quality, while being significantly simpler to implement and fully gradient-free.
****

PartCo: Part-Level Correspondence Priors Enhance Category Discovery
Fernando Julio Cendra, Kai Han
Generalized Category Discovery (GCD) aims to identify both known and novel categories within unlabeled data by leveraging a set of labeled examples from known categories. Existing GCD methods primarily depend on semantic labels and global image representations, often overlooking the detailed part-level cues that are crucial for distinguishing closely related categories. In this paper, we introduce PartCo, short for Part-Level Correspondence Prior, a novel framework that enhances category discovery by incorporating part-level visual feature correspondences. By leveraging part-level relationships, PartCo captures finer-grained semantic structures, enabling a more nuanced understanding of category relationships. Importantly, PartCo seamlessly integrates with existing GCD methods without requiring significant modifications. Our extensive experiments on multiple benchmark datasets demonstrate that PartCo significantly improves the performance of current GCD approaches, outperforming most existing methods by bridging the gap between semantic labels and part-level visual compositions, thereby setting new benchmarks for GCD.
****

Ambiguous Strategic Classification
Ivri Hikri, Nir Rosenfeld
A common assumption in strategic classification is that the classifier is public knowledge. However, it remains unclear whether, and why, a system would choose to commit to full disclosure. We study a setting in which regulation requires the system to disclose some, but not all, of the information. This induces a learning task in which the learner must jointly optimize the classifier and the uncertainty surrounding it. To this end, we adopt from robust mechanism design the notion of *ambiguity*, which in our setting allows the learner to reveal a set or range of possible classifiers, while privately choosing which of them to ultimately realize. We investigate how ambiguity affects the learning task, develop efficient algorithms for computing best-responses and training, and empirically explore strategic learning and its outcomes in this novel setting and using our approach.

CoDA-Bench: Can Code Agents Handle Data-Intensive Tasks?
Yuxin Zhang, Ju Fan, Meihao Fan, Shaolei Zhang, Xiaoyong Du
Advanced agents are increasingly demonstrating the potential to operate as autonomous engineers, creating a growing demand for evaluation benchmarks that capture the complexity of real-world development. Such environments typically involve both complex code and large-scale data (i.e., file system). However, existing benchmarks usually evaluate code-centric or data-centric capabilities in isolation, leaving a clear gap with real development scenarios. In this paper, we bridge this gap by introducing CoDA-Bench, the first benchmark to jointly evaluate code

and data intelligence in a data-intensive environment. We construct a data-intensive Linux sandbox based on the Kaggle ecosystem (containing hundreds of datasets), where agents must actively explore complex file hierarchies to identify relevant resources and generate code for data-driven analytical tasks. CoDA-Bench comprises 1,009 tasks spanning 31 communities, with each task environment containing an average of 980 files, simulating realistic data scale and noise. Evaluations of advanced agents reveal that even top-performing systems struggle to effectively integrate data discovery with code execution, achieving a success rate of only 61.1\%. These results highlight a substantial gap in current agentic capabilities for data-intensive tasks and point to promising directions for future research.

General and Efficient Steering of Unconditional Diffusion Models
Qingsong Wang, Mikhail Belkin, Yusu Wang
Steering diffusion models toward conditions unseen during training typically requires either retraining with conditional inputs or per-step gradient computations, both of which incur substantial computational overhead. We present NA-RFM, a general recipe for efficiently steering unconditional diffusion models without gradient guidance during inference, enabling fast controllable generation.
The method combines two offline-computed signals: *noise alignment*, a high-noise correction from PCA statistics of the target examples and the full data, and *Recursive Feature Machine (RFM) activation steering*, which learns a target-discriminative direction from labeled forward-process activations.
During sampling, noise alignment provides coarse control at high noise, while the RFM direction is reused over intermediate/late timesteps through lightweight activation edits.
Experiments on CIFAR-10, ImageNet, CelebA, and fine-grained bird species show improved target accuracy over gradient-based post-hoc guidance baselines, improved FID on the class-guidance benchmarks, and substantial inference speedups.
Code: https://github.com/isotrivial/na-rfm.

Plan Then Action: High-Level Planning Guidance Reinforcement Learning for LLM Reasoning
Zhihao Dou, Qinjian Zhao, Zhongwei Wan, Zhang Dinggen, Weida Wang, Benteng Chen, Towsif Raiyan, Qingtao Pan, Yang Ouyang, Chaoda Song, Zhiqiang Gao, Shufei Zhang, Sumon Biswas
Large language models (LLMs) demonstrate strong reasoning abilities via Chain-of-Thought (CoT), but their token-level generation encourages local decisions and lacks global planning, often leading to redundant or inaccurate reasoning. Existing methods, such as tree-based search and reinforcement learning (RL), attempt to address this issue but incur high computational costs and still struggle to produce reliable reasoning trajectories.
To address these challenges, we propose Plan-Then-Action Enhanced Reasoning with Group Relative Policy Optimization (PTA-GRPO), a two-stage framework designed to jointly improve high-level planning and fine-grained CoT reasoning.
Specifically, in the first stage, a given LLM is responsible for summarizing CoT reasoning into compact high-level guidance, which is then leveraged for supervised fine-tuning. Then, we introduce a guidance-aware reinforcement learning method that jointly optimizes the final output and the quality of guidance, enhancing reasoning effectiveness.
We evaluate PTA-GRPO on ten reasoning benchmarks across mathematics and natural sciences, using five diverse base models spanning multiple data modalities. The results show that PTA-GRPO consistently delivers stable and significant improvements across models and tasks, demonstrating strong effectiveness and generalization.

LoRDO: Distributed Low-Rank Optimization with Infrequent Communication
Andrej Jovanovic, Alex Iacob, Mher Safaryan, Ionut-Vlad Modoranu, Lorenzo Sani, William F. Shen, Xinchi Qiu, Dan Alistarh, Nicholas D. Lane
Distributed training of foundation models via $\texttt{DDP}$ is limited by inter

connect bandwidth. While infrequent communication strategies reduce synchronizat
ion frequency, they remain bottlenecked by the memory and communication requirem
ents of optimizer states. Low-rank optimizers can alleviate these constraints; h
owever, in the local-update regime, workers lack access to the full-batch gradie
nts required to compute low-rank projections, which degrades performance. We pro
pose $\texttt{LoRDO}$, a principled framework unifying low-rank optimization wit
h infrequent synchronization. We first demonstrate that, while global projection
s based on pseudo-gradients are theoretically superior, they permanently restric
t the optimization trajectory to a low-rank subspace. To restore subspace explor
ation, we introduce a full-rank quasi-hyperbolic update. $\texttt{LoRDO}$ achie
ves near-parity with low-rank $\texttt{DDP}$ in language modeling and downstream
 tasks at model scales of 125M--720M, while reducing communication by $\appr
ox10\times$. Finally, we show that $\texttt{LoRDO}$ improves performance even m
ore in very low-memory settings with small rank/batch size.

Parameter Manifold Purification

Jiacong Hu, Jinxun Wu, Shengxuming Zhang, Shunyu Liu, Haofei Zhang, Mingli Song,
 Zunlei Feng

Deep models are vulnerable to performance degradation caused by various factors,
 such as imbalanced samples, inaccurate labels, and backdoor attacks. However, e
xisting optimization methods that address these issues are typically designed in
 a scenario- or architecture-specific manner, and each optimization often requir
es costly training. To this end, inspired by image denoising, we propose paramet
er purification as a new paradigm for model performance optimization. Parameter
purification attributes performance degradation to the contamination of model pa
rameters and aims to recover clean parameters from corrupted ones in a manner an
alogous to image denoising. To purify parameters with massive scale and complex
structure, we further introduce a novel parameter manifold purification method.
In this framework, high-dimensional and complex parameters are first viewed as m
anifolds embedded in a high-dimensional space, and are then partitioned into nes
ted local parameter-cluster manifolds via a proposed parameter clustering strate
gy. Meanwhile, to remove parameter redundancy while preserving global parameter
information, we propose an implicit manifold auto-encoder along with a parameter
-cluster discrepancy loss to learn low-dimensional representations of parameter-
cluster manifolds. Finally, an implicit conditional diffusion model is applied t
o denoise the low-dimensional parameter manifolds, progressively restoring clean
 parameters. Extensive experiments under three representative scenarios that cau
se model performance degradation demonstrate that parameter manifold purificatio
n can accurately and completely purify corrupted parameters of unseen models, an
alogous to denoising unseen images, and rapidly improve model performance.

BlueCodeAgent: A Blue Teaming Agent Powered by Automated Red Teaming for CodeGen
 AI

Chengquan Guo, Yuzhou Nie, Chulin Xie, Zinan Lin, Wenbo Guo, Bo Li

Existing research on CodeGen AI security mainly focuses on red teaming, which ai
ms to uncover vulnerabilities and risks in AI-generated code. However, progress
on the blue teaming side remains limited, as effective defenses require a deep s
ecurity analysis of given tasks and edge cases. To fill in this gap, we propose
BlueCodeAgent, an end-to-end blue teaming agent powered by automated red teaming
. Our red teaming component generates diverse risky instances, providing effecti
ve edge cases and guidance for the subsequent blue teaming process. Our blue tea
ming agent then conducts multi-level defense, leveraging these red teaming examp
les to detect previously seen and unseen risk scenarios through constitution sum
marization and dynamic code analysis. Our evaluation across four representative
code-related tasks–bias instruction detection, malicious instruction detection,
vulnerable code detection, and prompt injection detection–shows that BlueCodeAge
nt achieves significant gains over diverse baselines. In particular, for vulnera
bility detection tasks, BlueCodeAgent integrates dynamic analysis to effectively
 reduce false positives, a challenging problem as base models tend to be over-co
nservative. Overall, with GPT-4o as the base model, BlueCodeAgent achieves an av

erage F1 score improvement of 14.7% across four tasks compared to directly promp ting the model, attributed to its ability to summarize actionable constitutions and perform dynamic analysis. Our code and data are publicly available at https: //github.com/1mocat/BlueCodeAgent.

Time Series, Vision, and Language: Exploring the Limits of Alignment in Contrast ive Representation Spaces
Pratham Yashwante, Rose Yu
The Platonic Representation Hypothesis posits that learned representations from models trained on different modalities converge to a shared latent structure of the world. However, this hypothesis has largely been examined in vision and lang uage, and it remains unclear whether time series participate in such convergence . We first examine this in a trimodal setting and find that independently pretra ined time series, vision, and language encoders exhibit near-orthogonal geometry in the absence of explicit coupling. We then apply post-hoc alignment by traini ng projection heads over frozen encoders using contrastive learning, and analyze the resulting representations with respect to geometry, scaling behavior, and d ependence on information density and input modality characteristics. Our investi gation reveals that overall alignment in contrastive representation spaces impro ves with model size, but this alignment is asymmetric: time series align more st rongly with visual representations than with text, and images can act as effecti ve intermediaries between time series and language. We further see that richer t extual descriptions improve alignment only up to a threshold; training on denser captions does not lead to further improvement. Analogous effects are observed f or visual representations. Our findings shed light on considerations for buildin g multimodal systems involving non-conventional data modalities beyond vision an d language. Code and data are available at https://github.com/Rose-STL-Lab/tvl-a lignment.

Flowers: A Warp Drive for Neural PDE Solvers
Till Muser, Alexandra Spitzer, Matti Lassas, Maarten V. de Hoop, Ivan Dokmani■
We introduce Flower, a neural architecture for learning PDE solution operators b uilt entirely from multihead warps. Aside from pointwise channel mixing and a mu ltiscale scaffold, Flowers use no Fourier multipliers, no dot-product attention, and no convolutional mixing. Each head predicts a displacement field and warps the mixed input features. Motivated by physics and computational efficiency, dis placements are predicted pointwise, without any spatial aggregation, and nonloca lity enters *only* through sparse sampling at source coordinates, *one* per head . Stacking warps in multiscale residual blocks yields Flowers, which implement a daptive, global interactions at linear cost. We theoretically motivate this desi gn through three complementary lenses: flow maps for conservation laws, waves in inhomogeneous media, and a kinetic-theoretic continuum limit. Flowers achieve e xcellent performance on a broad suite of 2D and 3D time-dependent PDE benchmarks , particularly flows and waves. A compact 17M-parameter model consistently outpe rforms Fourier, convolution, and attention-based baselines of similar size, whil e a 150M-parameter variant improves over recent transformer-based foundation mod els with much more parameters, data, and training compute.

Let EEG Models Learn EEG
Yifan Wang, Yijia Ma, Wen Li, Chenyu You
High-fidelity EEG generation is critical for alleviating data scarcity and addre ssing privacy constraints in large-scale neural modeling.
Despite recent progress, most existing approaches formulate EEG generation via d iscrete denoising objectives, which inadequately reflect the inherently continuo us temporal dynamics and spectral structure of neural activity.
As a result, these methods often struggle to preserve long-range temporal depend encies and exhibit mismatches in the spectral and temporal structure of the gene rated signals.
In this work, we argue that effective EEG generation requires models that operat e directly on the continuous evolution of neural signals.

We introduce Just EEG Transformer (JET), a generative framework based on conditi
onal flow matching that models EEG as raw sequences evolving along continuous tr
ajectories.
By learning a smooth vector field that transports noise to the EEG data distribu
tion, JET captures temporal continuity and transient dynamics without relying on
 discretized denoising schemes or domain-specific representations.
To ensure that the learned dynamics remain consistent with key properties of EEG
 signals, we introduce principled constraints that preserve spectral structure,
temporal stationarity, and signal-level statistics.
Across three large-scale benchmarks, JET consistently achieves state-of-the-art
performance, reducing TS-FID by over 40\% compared to strong baselines.
Extensive analyses show that JET captures key structural properties of neural dy
namics, providing a scalable and principled approach to EEG generation.

SCNS: Continual Personalization of Diffusion Models via Submodular Concept Neuro
n Selection

Zijie Peng, Enneng Yang, Yifei Cheng, Hongliang Yuan, Fei Ma, Xiaochun Cao, Li S
hen

Custom diffusion models (CDMs) have demonstrated impressive success in visual pe
rsonalization tasks by enabling the generation of user-specific concepts. Howeve
r, existing CDMs typically assume that personalized concepts are static and rely
 on costly model merging or sequential updates that are prone to catastrophic fo
rgetting as new concepts are introduced. To address these limitations, we propos
e a Submodular Concept Neuron Selection method (SCNS), to solve CDMs with contin
ual personalized concepts, which formulates continual personalization as a const
rained submodular optimization problem to select a minimal yet sufficient set of
 concept-specific neurons under diminishing returns. SCNS combines a Facility Lo
cation-based coverage objective to suppress semantic redundancy, a Fisher-weight
ed risk proxy to protect previously learned concepts, and a cost-aware greedy ru
le to balance stability and plasticity with extreme sparsity. Extensive experime
nts demonstrate that SCNS achieves state-of-the-art performance in image alignme
nt and anti-forgetting, while enabling fusion-free continual personalization by
modifying only 0.41% of the total parameters for each concept on average. Our im
plementation is available at SCNS.

Adaptive Node Feature Selection for Graph Neural Networks

Madeline Navarro, Ali Azizpour, Santiago Segarra

We propose an adaptive node feature selection approach for graph neural networks
 (GNNs) that identifies and removes unnecessary features during training. The ab
ility to measure how features contribute to model output is key for interpreting
 decisions and reducing dimensionality by eliminating unhelpful variables. Howev
er, graph-structured data introduces complex dependencies that may be unsuited t
o classical feature importance metrics. Inspired by this, we present a data-, mo
del-, and task-agnostic method that determines relevant features during training
 based on changes in validation performance upon permuting feature values. We th
eoretically motivate our approach by characterizing how the relationships betwee
n node data and graph structure influences GNN performance. Empirically, we show
 that (i) our highly general approach rivals the performance of tailored feature
 selection approaches that exploit prior assumptions; (ii) we return meaningful
feature importance scores well before the GNN is fully trained; and (iii) our sc
ores demonstrably extract relevant properties that inform feature importance for
 various graph learning settings.

Self-Calibrated Consistency can Fight Back for Adversarial Robustness in Vision-
Language Models

Jiaxiang Liu, Jiawei Du, Xiao Liu, Shangyang Li, Songchen Ma, Changshuo Wang, Pr
ayag Tiwari, Mingkun Xu

Pre-trained vision-language models (VLMs) such as CLIP have demonstrated strong
 zero-shot capabilities across diverse domains, yet remain highly vulnerable to a
dversarial perturbations that disrupt image-text alignment and compromise reliab

ility.
Existing defenses typically rely on adversarial fine-tuning with labeled data, l imiting their applicability in zero-shot settings.
In this work, we identify two key weaknesses of current CLIP adversarial attacks —lack of semantic guidance and vulnerability to view variations—collectively ter med semantic and viewpoint fragility. To address these challenges, we propose Se lf-Calibrated Consistency (SCC), an effective test-time defense. SCC consists of two complementary modules:
Semantic consistency, which leverages soft pseudo-labels from counterattack warm -up and multi-view predictions to regularize cross-modal alignment and separate the target embedding from confusable negatives; and
Spatial consistency, aligning perturbed visual predictions via augmented views t o stabilize inference under adversarial perturbations.
Together, these modules form a plug-and-play inference strategy.
Extensive experiments on 22 benchmarks under diverse attack settings show that S CC consistently improves the zero-shot robustness of CLIP while maintaining accu racy, and can be seamlessly integrated with other VLMs for further gains.
These findings highlight the great potential of establishing an adversarially ro bust paradigm from CLIP, with implications extending to broader VLMs such as Bio MedCLIP.

AutoMat: Physics-Guided Agentic Reasoning for Solving Ill-Posed Inverse Microsco py Problems

Yaotian Yang, Yiwen Tang, Yizhe Chen, Xiao Chen, Jiangjie Qiu, Hao Xiong, Haoyu Yin, Zhiyao Luo, Yifei Zhang, Sijia Tao, Wentao Li, Qinghua Zhang, Yuqiang Li, W anli Ouyang, Bin Zhao, Xiaonan Wang, Fei Wei

Reconstructing atomistic crystal structures from a single noisy STEM projection is an ill-posed inverse problem: multiple lattices can explain similar contrast, and purely feed-forward models cannot verify physical validity. We present **Au toMat**, a failure-aware agentic *controller* that performs inference-time hypot hesis search with *closed-loop verification* to convert Scanning Transmission El ectron Microscopy (STEM) images into simulation-ready crystal structures and dow nstream properties. AutoMat composes perception and physics modules—pattern-adap tive denoising, physics-guided template retrieval *as a state-dependent auxiliar y branch*, symmetry-constrained atomic reconstruction, and MLIP-based relaxation /validation—and triggers rollback-and-retry when verification fails. For systema tic evaluation, we introduce **STEM2Mat-Bench**, a benchmark dataset containing 450+ annotated samples. Performance is assessed using lattice root-mean-square d eviation (RMSD), formation energy mean absolute error (MAE), and structure match ing accuracy. Results demonstrate that AutoMat outperforms existing approaches i ncluding SOTA models, specialized domain tools, and closed-source multimodal lar ge models. This work establishes a direct pathway from microscopic characterizat ion to atomic-scale modeling, addressing a fundamental challenge in materials sc ience.
****

Text Has Curvature

Karish Grover, Hanqing Zeng, Yinglong Xia, Christos Faloutsos, Geoffrey J. Gordo n

Does natural language text have an intrinsic curvature? Language is increasingly modeled in curved geometries—hyperbolic spaces for hierarchy, mixed-curvature m anifolds for compositional structure—yet a basic scientific question remains unr esolved: what does curvature mean for text itself, in a way that is native to la nguage rather than an artifact of the embedding space we choose? We argue that t ext does indeed have curvature, and show how to detect it, define it, and use it . To this end, we propose Texture, a text-native, word-level discrete curvature signal, and make three contributions. (a) Existence: We provide empirical and th eoretical certificates that semantic inference in natural corpora is non-flat. (b) Definition: We define Texture as a signed two-axis curvature of the word-in-c ontext belief field—the differential of reconciliation between prefix and suffix —measuring, via a debiased Schrödinger transport divergence, whether adding cont

ext from one side contracts the semantic effect of context from the other side (focus, positive) or expands it into competing continuations (fan-out, negative). (c) Utility: Texture is actionable: it serves as a general-purpose measurement and control primitive enabling geometry without geometric training; we instantia te it on two representative tasks, improving long-context inference through curv ature-guided compression and retrieval-augmented generation through curvature-gu ided routing. Together, our results establish a text native curvature paradigm, making Texture practically useful.

Divide and Learn: Multi-Objective Combinatorial Optimization at Scale
Esha Singh, Dongxia Wu, Chien-Yi Yang, Tajana Rosing, Rose Yu, Yian Ma
Multi-objective combinatorial optimization seeks Pareto-optimal solutions over e xponentially large discrete spaces, yet existing methods sacrifice generality, s calability, or theoretical guarantees. We reformulate it as an online learning p roblem over a decomposed decision space, solving position-wise bandit subproblem s via adaptive expert-guided sequential construction. This formulation admits re gret bounds of $O(d\sqrt{T \log T})$ depending on subproblem dimensionality \(d\ ) rather than combinatorial space size. On standard benchmarks, our method achie ves 80--98\% of specialized solvers performance while achieving two to three or ders of magnitude improvement in sample and computational efficiency over Bayesi an optimization methods. On real-world hardware-software co-design for AI accele rators with expensive simulations, we outperform competing methods under fixed e valuation budgets. The advantage grows with problem scale and objective count, e stablishing bandit optimization over decomposed decision spaces as a principled alternative to surrogate modeling or offline training for multi-objective optimi zation.
****
Expressive Graph Neural Networks via Equivariant Use of Noise
Xiyuan Wang, Muhan Zhang
Expressivity has been a major focus in the design of Graph Neural Networks (GNNs), yet a significant gap persists between theoretical universal expressivity and practical performance. While many expressive GNNs are efficient and achieve str ong results, they often focus on specific graph properties and lack theoretical expressivity for general graph tasks. Conversely, theoretically universal-expres sive models often suffer from high computational costs or poor generalization, l imiting their real-world applicability. To bridge this gap, we introduce Equivar iant Noise GNNs (ENGNNs), a framework that utilizes random noise features to enh ance the expressivity of GNNs. Crucially, unlike prior methods that naively use noise, we enforce equivariance to nodewise noise transformations, such as orthog

onal transformations. We prove that this property reduces the model's theoretical sample complexity, thereby improving generalization. Our framework simultaneously reaches theoretical universal expressivity, maintains the linear scalability of standard Message-Passing Neural Networks in practice, and achieves performance comparable to computationally expensive, high-expressivity models. Extensive experiments confirm strong performance across node, link, subgraph, and graph-level prediction tasks, demonstrating that the equivariant use of noise provides a powerful and practical pathway for building expressive GNNs. Our code is available at \url{https://github.com/MuLabPKU/EquivNoiseGNN}.

Reading Between the Tokens: Improving Preference Predictions through Mechanistic Forecasting

Sarah Ball, Simeon Allmendinger, Frauke Kreuter, Niklas Kühl

Large language models are increasingly used to predict human preferences in both scientific and business endeavors, yet current approaches rely exclusively on analyzing model outputs without considering the underlying mechanisms. Using election forecasting as a test case, we introduce *mechanistic forecasting*, a method that demonstrates that probing internal model representations offers a fundamentally different---and sometimes more effective--- approach to preference prediction. Examining over 24 million configurations across 7 models, 6 national elections, multiple persona attributes, and prompt variations, we systematically analyze how demographic and ideological information activates latent party-encoding components within the respective models. We find that leveraging this internal knowledge via mechanistic forecasting, opposed to solely relying on surface-level predictions, can improve prediction accuracy. The effects vary across demographic versus opinion-based attributes, political parties, national contexts, and models. Our findings demonstrate that the latent representational structure of LLMs contains systematic, exploitable information about human preferences, establishing a new paradigm for using language models in social science prediction tasks.
****

Statistical Early Stopping for Reasoning Models

Yangxinyu Xie, Tao Wang, Soham Mallick, Yan Sun, Georgy Noarov, Mengxin Yu, Tanwi Mallick, Edgar Dobriban

While LLMs have seen substantial improvement in reasoning capabilities, they also sometimes overthink, generating unnecessary reasoning steps, particularly under uncertainty, given ill-posed or ambiguous queries. We introduce statistically principled early stopping methods that monitor uncertainty signals during generation to mitigate this issue. Our first approach is nonparametric and provides finite-sample guarantees on the probability of halting too early on well-posed queries. Our second approach is parametric: it models inter-arrival times of uncertainty keywords as a renewal process and applies sequential testing for stopping. We conduct empirical evaluations on reasoning tasks across several domains and models. Our results indicate that uncertainty-aware early stopping can improve both efficiency and reliability in LLM reasoning. The performance varies across domains, and we observe especially significant gains for math reasoning.
****

Temporal Difference Calibration in Sequential Tasks: Application to Vision-Language-Action Models

Shelly Francis-Meretzki, Mirco Mutti, Yaniv Romano, Aviv Tamar

Recent advances in vision-language-action (VLA) models for robotics have highlighted the importance of reliable uncertainty quantification in sequential tasks. However, assessing and improving calibration in such settings remains mostly unexplored, especially when only partial trajectories are observed. In this work, we formulate *sequential calibration* for episodic tasks, where task-success confidence is produced along an episode, while success is determined at the end of it. We introduce a sequential extension of the Brier score and show that, for binary outcomes, its risk minimizer coincides with the VLA policy’s value function. This connection bridges uncertainty calibration and reinforcement learning, enabling the use of temporal-difference (TD) value estimation as a principled calib

ration mechanism over time.
We empirically show that TD calibration improves performance relative to the state-of-the-art on simulated and real-robot data. Interestingly, we show that when calibrated using TD, the VLA's single-step action probabilities can yield competitive uncertainty estimates, in contrast to recent findings that employed different calibration techniques.

Semi-Supervised Learning for Molecular Graphs via Ensemble Consensus
Rasmus Hannibal Tirsgaard, Laurits Fredsgaard, Marisa Wodrich, Mikkel Jordahn, Mikkel N. Schmidt
Machine learning is transforming molecular sciences by accelerating property prediction, simulation, and the discovery of new molecules and materials. Acquiring labeled data in these domains is often costly and time-consuming, whereas large collections of unlabeled molecular data are readily available. Standard semi-supervised learning methods often rely on label-preserving augmentations, which are challenging to design in the molecular domain, where minor changes can drastically alter properties. In this work, we show that semi-supervised methods that rely on an ensemble consensus can boost predictive accuracy across a diverse range of molecular datasets, task types, and graph neural network architectures. We find that training with an ensemble consensus objective increases robustness in models and exhibits an effect similar to knowledge distillation; an individual member of an ensemble trained this way outperforms a full ensemble trained in a traditional supervised fashion in almost all cases. In addition, this type of semi-supervised training reduces calibration error.

KromHC: Manifold-Constrained Hyper-Connections with Kronecker-Product Residual Matrices
Wuyang Zhou, Yuxuan Gu, Giorgos Iacovides, Danilo Mandic
The success of Hyper-Connections (HC) in neural networks (NN) has also highlighted issues related to training instability and restricted scalability. The Manifold-Constrained Hyper-Connections (mHC) mitigate these challenges by projecting the residual connection space onto a Birkhoff polytope, however, it faces two issues: 1) its iterative Sinkhorn-Knopp (SK) algorithm does not always yield exactly doubly stochastic residual matrices; 2) mHC incurs a prohibitive $\mathcal{O}(n^3C)$ parameter complexity with n as the width of the residual stream and C as the feature dimension. The recently proposed mHC-lite reparametrizes the residual matrix via the Birkhoff-von-Neumann theorem to guarantee double stochasticity, but also faces a factorial explosion in its parameter complexity, $\mathcal{O} \left(nC \cdot n! \right)$. To address both challenges, we propose **KromHC**, which uses the $\underline{\text{Kro}}$necker products of smaller doubly stochastic matrices to parametrize the residual matrix in $\underline{\text{mHC}}$. By enforcing manifold constraints across the factor residual matrices along each mode of the tensorized residual stream, KromHC guarantees exact double stochasticity of the residual matrices while reducing parameter complexity to only $\mathcal{O}(n^2C)$. Experiments show that KromHC matches or even outperforms other state-of-the-art (SOTA) mHC variants, while requiring significantly fewer trainable parameters. The code is at https://github.com/wz1119/KromHC.

Expanding the AI Evaluation Toolbox with Statistical Models
Drew Keller, Kweku Kwegyir-Aggrey, Ryan Steed, Anita K. Rao, Julia L. Sharp, A. Stevie Bergman
Benchmarks are widely used to evaluate and compare the performance of artificial intelligence systems. However, some approaches to computing benchmark metrics produce invalid uncertainty estimates or make unrecognized assumptions about the evaluation setting. We leverage statistical modeling to make two contributions to the practice of AI benchmarking. First, we formally distinguish measurements of benchmark accuracy from generalized accuracy (performance on all potential test items similar to those included in the benchmark). Then, in a simulated setting and with large-scale evaluation of 22 API-access frontier large language models on 3 popular benchmarks, we show how analysis via generalized linear mixed mod

el can produce correct estimates of generalized accuracy while more efficiently quantifying uncertainty compared to existing regression-free approaches. We also show how this approach can equip evaluators with important context on evaluation results, including variance decomposition and item difficulty estimates that illuminate important aspects of LLM performance and benchmark construction.

SDiD■Shared diffusion prior for efficient distributed stereo image compression
Yichong Xia, Yimin Zhou, Zongyu Li, Shiyu Qin, Mingyao Hong, Bin Chen, Haoqian Wang
Stereo vision is widely utilized in automotive imagery and 3D reconstruction, creating a demand for compressing stereo images. Existing methods for stereo image compression often employ VAE-like architectures based on distortion optimization, leading to subpar perceptual quality at low bitrates. While generative compression excels in high perceptual fidelity at low bitrates, it struggles to maintain consistency across viewpoints, making decoded images less useful for critical downstream tasks. To address this, we introduce SDiD, a distributed stereo image compression architecture based on shared pre-trained diffusion priors. We employ a diffusion prior alignment module to efficiently obtain the main-view-prior from the foundation diffusion, and utilize a prior transformation structure to enable the auxiliary view to achieve reliable and fast perceptual enhancement while maintaining consistency. Through extensive experiments, we demonstrate that SDiD outperforms existing methods in perceptual quality across multiple datasets. Even at extremely low bitrates, SDiD can accurately recover depth information between decoded images. On the InStereo2K dataset, SDiD requires only one-third of the bits compared to the state-of-the-art baseline (0.02 bpp vs. 0.06 bpp) to reconstruct image pairs with similar depth information.

3DMedAgent: Unified Perception-to-Understanding for 3D Medical Analysis
Ziyue Wang, Linghan Cai, Chang Han Low, Haofeng Liu, Junde Wu, Jinyu Wang, Rui Wang, Lei Song, Jiang Bian, Jingjing Fu, Yueming Jin
3D CT analysis spans a continuum from low-level perception to high-level clinical understanding. Existing 3D-oriented analysis methods adopt either isolated task-specific modeling or task-agnostic end-to-end paradigms to produce one-hop outputs, impeding the systematic accumulation of perceptual evidence for downstream reasoning.
In parallel, recent multimodal large language models (MLLMs) exhibit improved visual perception and can integrate visual and textual information effectively, yet their predominantly 2D-oriented designs fundamentally limit their ability to perceive and analysis volumetric medical data.
To bridge this gap, we propose 3DMedAgent, an unified agent that enables 2D MLLMs to perform general 3D CT analysis without 3D-specific fine-tuning.
3DMedAgent coordinates heterogeneous visual and textual tools through a flexible MLLM agent, progressively decomposing complex 3D analysis into tractable subtasks that transition from global to regional views, from 3D volumes to informative 2D slices, and from visual evidence to structured textual representations.
Central to this design, 3DMedAgent maintains a long-term structured memory that aggregates intermediate tool outputs and supports query-adaptive, evidence-driven multi-step reasoning.
We further introduce the DeepChestVQA benchmark for evaluating unified perception-to-understanding capabilities in 3D thoracic imaging.
Experiments across over 40 tasks demonstrate that 3DMedAgent consistently outperforms general, medical, and 3D-specific MLLMs, highlighting a scalable path toward general-purpose 3D clinical assistants.
Code and data are available \href{https://github.com/jinlab-imvr/3DMedAgent}{here}.

WatchLog: Efficient and Interpretable Event Reasoning for Endpoint Detection and Response Logs with Multimodal LLMs
Hongyi Zhou, Jianfeng Pan, Min Peng, Shaomang Huang, Xuling Zhang
Endpoint Detection and Response (EDR) systems are crucial for identifying malici

ous activities on endpoint devices, yet existing methods struggle to efficiently model ultra-long log sequences and to provide interpretable reasoning for security analysts. We propose WatchLog, a novel framework that represents raw logs as video-structured data, enabling scalable and expressive video-language modeling of endpoint behaviors. Each event is encoded as a key–value-guided image, and the resulting images are temporally organized into a video sequence. To capture long-range dependencies, WatchLog employs a temporal cross-attention adapter that enables pixel-wise interaction across time. The adapter acts as an auxiliary temporal reasoning pathway, aligning spatial representations with relevant temporal contexts while preserving the original behavioral semantics. We adopt a two-stage pre-training strategy followed by supervised fine-tuning to generate behavior explanations grounded in event-level semantics and detection outcomes. Experiments on our newly constructed EDR8M-20R dataset and a public benchmark demonstrate that WatchLog consistently outperforms state-of-the-art methods in detection accuracy and recall, while offering more interpretable reasoning traces and significantly improved inference efficiency. Extensive ablation studies further support the robustness and interpretability of the proposed method.

RuCL: Stratified Rubric-Based Curriculum Learning for Multimodal Large Language Model Reasoning

Yukun Chen, Jiaming Li, Longze Chen, Ze Gong, Jingpeng Li, Zhen Qin, Hengyu Chang, Lei Zhang, Ancheng Xu, Zhihao Yang, Hamid Alinejad-Rokny, QIANG QU, Bo Zheng, Min Yang

Reinforcement Learning with Verifiable Rewards (RLVR) has emerged as a prevailing paradigm for enhancing reasoning in Multimodal Large Language Models (MLLMs). However, relying solely on outcome supervision risks reward hacking, where models learn spurious reasoning patterns to satisfy final answer checks.
While recent rubric-based approaches offer fine-grained supervision signals, they suffer from high computational costs of instance-level generation and inefficient training dynamics caused by treating all rubrics as equally learnable.
In this paper, we propose **Stratified Rubric-based Curriculum Learning (RuCL)**, a novel framework that reformulates curriculum learning by shifting the focus from data selection to reward design.
RuCL generates generalized rubrics for broad applicability and stratifies them based on model competence, dynamically adjusting their weights to guide the model from foundational perception to advanced logical reasoning.
Extensive experiments on various visual reasoning benchmarks show that RuCL yields a remarkable **+7.83%** average improvement over the Qwen2.5-VL-7B model, achieving a state-of-the-art accuracy of **60.06%**.

Mitigating Surgical Data Imbalance with Dual-Prediction Video Diffusion Model

Danush Kumar Venkatesh, Adam Schmidt, Muhammad Abdullah Jamal, Omid Mohareri

Surgical video datasets are essential for scene understanding, enabling procedural modeling and intra-operative support. However, these datasets are often heavily imbalanced, with rare actions and tools under-represented, which limits the robustness of downstream models. We address this challenge with *SurgiFlowVid*, a sparse and controllable video diffusion framework for generating surgical videos of under-represented classes. Our approach introduces a dual-prediction diffusion module that jointly denoises RGB frames and optical flow, providing temporal inductive biases to improve motion modeling from limited samples. In addition, a sparse visual encoder conditions the generation process on lightweight signals (e.g., sparse segmentation masks or RGB frames), enabling controllability without dense annotations. We validate our approach on three surgical datasets across tasks including action recognition, tool presence detection, and laparoscope motion prediction. Synthetic data generated by our method yields consistent gains of 10–20% over competitive baselines, establishing *SurgiFlowVid* as a promising strategy to mitigate data imbalance and advance surgical video understanding methods.

Adversarial Robustness of Implicit Neural Representation-Based Classifiers

Jayoung Kim, Kookjin Lee, Noseong Park, Sanghyun Hong
Implicit neural representations (INRs) encode data as continuous coordinate-base d functions parameterized by neural networks, shifting downstream tasks such as image recognition to operate on functional rather than discrete representations. Despite their increasing adoption, the adversarial robustness of INR-based clas sification pipelines remain largely underexplored. In this work, we present the first systematic study of adversarial robustness in INR-based classifiers. A key challenge is that generating an INR requires $\text{\emph{training}}$ a neural network for each input sample, resulting in an optimization-in-the-loop forward pass that renders standard gradient-based attacks computationally prohibitive. T o address this, we design surrogate models that amortizes the INR-generation pro cess, serving as a practical proxy for attacking INR-based classifiers. We also develop speed-up techniques that substantially reduce the training cost of the s urrogate. We show that in contrast to recent work, INR-based classifiers are vul nerable: under adversarial input perturbations, classification accuracy collapse s to near zero. Moreover, existing countermeasures designed to operate on discre te representations offer limited protection.

When Random Saliency Looks Trained: Architectural Center Bias in CNN Interpretab ility
Keying Kuang, Iain Carmichael, Elizabeth Purdom
Saliency maps are widely used to interpret image classification models and build trust in their predictions; however, their reliability remains a central concer n, as randomized networks can produce saliency maps that closely resemble those of trained models. We identify a previously underappreciated architectural contr ibutor to this phenomenon: a *center-focused saliency bias* induced by common co nvolutional design choices. Through controlled ablations, we show that architect ural components such as zero padding and receptive field growth induce a center- focused saliency prior that is already present in randomly initialized CNNs and under randomized inputs. In contrast, this behavior is largely absent in non-con volutional architectures such as Vision Transformers (ViTs) and multilayer perce ptrons (MLPs). To investigate the interaction between architectural priors and l earning, we introduce a corner-shift benchmark and a Center-Shift Index that qua ntify how saliency redistributes under object relocation. We show that training can partially shift saliency toward object regions, while randomized models rema in dominated by architectural center bias, providing one mechanism by which trai ned-random similarity can be inflated and clarifying how architectural priors ca n confound standard saliency evaluations.

The Implicit Bias of Depth: From Neural Collapse to Softmax Codes
Connall Garrod, Jonathan P. Keating, Christos Thrampoulidis
Neural collapse (NC) describes the structured geometry that emerges in the featu res and weights of trained classifiers. Recent theory suggests NC can be subopti mal in deep architectures, attributing this to an explicit low-rank bias from L2 regularization. We study the deep unconstrained feature model (UFM)—equivalent to a deep linear network with orthogonal inputs—trained without regularization, to isolate how gradient descent and depth alone shape NC. We show that depth ind uces an implicit low-rank bias: low-rank matrices propagate norm more efficientl y through successive multiplications, promoting low-rank alternatives to NC. The se alternatives, we argue, correspond to softmax codes: max-margin solutions pre viously found in width-bottlenecked networks. Analyzing training dynamics under spectral initialization, we identify an early-time repulsion among singular valu es that drives low-rank emergence, and characterize how depth shrinks NC's basin of attraction. Finally, we show that some effects act in the opposite direction : for randomly initialized networks, increasing width biases training toward hig her-rank solutions. Our results provide the first asymptotic and dynamic charact erization of implicit bias in deep UFMs trained with unregularized multiclass cr oss-entropy.

From Human Labels to Literature: Semi-Supervised Learning of NMR Chemical Shifts

at Scale
Yongqi Jin, Yecheng Wang, Jun-jie Wang, Rong Zhu, Guolin Ke, Weinan E
Accurate prediction of nuclear magnetic resonance (NMR) chemical shifts is fundamental to spectral analysis and molecular structure elucidation, yet existing machine learning methods rely on limited, labor-intensive atom-assigned datasets.
We propose a semi-supervised framework that learns NMR chemical shifts from millions of literature-extracted spectra without explicit atom-level assignments, integrating a small amount of labeled data with large-scale unassigned spectra.
We formulate chemical shift prediction from literature spectra as a permutation-invariant set supervision problem, and show that under commonly satisfied conditions on the loss function, optimal bipartite matching reduces to a sorting-based loss, enabling stable large-scale semi-supervised training beyond traditional curated datasets.
Our models achieve substantially improved accuracy and robustness over state-of-the-art methods and exhibit stronger generalization on significantly larger and more diverse molecular datasets.
Moreover, by incorporating solvent information at scale, our approach captures systematic solvent effects across common NMR solvents for the first time.
Overall, our results demonstrate that large-scale unlabeled spectra mined from the literature can serve as a practical and effective data source for training NMR shift models, suggesting a broader role of literature-derived, weakly structured data in data-centric AI for science.
****
ScoreMatchingRiesz: Score Matching for Debiased Machine Learning and Policy Path Estimation
Masahiro Kato
We propose \emph{ScoreMatchingRiesz}, a family of Riesz representer estimators based on score matching. The Riesz representer is a key nuisance component in debiased machine learning, enabling $\sqrt{n}$-consistent and asymptotically efficient estimation of causal and structural targets via Neyman-orthogonal scores. We formulate Riesz representer estimation as a score estimation problem. This perspective stabilizes representer estimation by allowing us to leverage denoising score matching and telescoping density ratio estimation. We also introduce the policy path, a parameter that captures how policy effects evolve under continuous treatments. We show that the policy path can be estimated via score matching by smoothly connecting average marginal effect (AME) and average policy effect (APE) estimation, which improves the interpretability of policy effects. The replication code is available in the genriesz library.
****
Mitigating Conversational Inertia in Multi-Turn Agents
Yang Wan, Zheng Cao, Zhenhao Zhang, Zhengwen Zeng, Shuheng Shen, Changhua Meng, Linchao Zhu
Large language models excel as few-shot learners when provided with appropriate demonstrations, yet this strength becomes problematic in multi-turn agent scenarios, where LLMs erroneously mimic their own previous responses as few-shot examples. Through attention analysis, we identify \textbf{conversational inertia}, a phenomenon where models exhibit strong diagonal attention to previous responses, which is associated with imitation bias that constrains exploration.
This reveals a tension when transforming few-shot LLMs into agents: longer context enriches environmental feedback for exploitation, yet also amplifies conversational inertia that undermines exploration.
Our key insight is that for identical states, actions generated with longer contexts exhibit stronger inertia than those with shorter contexts, enabling construction of preference pairs without environment rewards. Based on this, we propose Context Preference Learning to calibrate model preferences to favor low-inertia responses over high-inertia ones. We further provide context management strategies at inference time to balance exploration and exploitation.
Experimental results across eight agentic environments and one deep research scenario validate that our framework reduces conversational inertia and achieves performance improvements.

Do Sparse Autoencoders Identify Reasoning Features in Language Models?
George Ma, Zhongyuan Liang, Irene Y. Chen, Somayeh Sojoudi
We study how reliably sparse autoencoders (SAEs) support claims about reasoning-related internal features in large language models. We first give a stylized analysis showing that sparsity-regularized decoding can preferentially retain stable low-dimensional correlates while suppressing high-dimensional within-behavior variation, motivating the possibility that contrastively selected "reasoning" features may concentrate on cue-like structure when such cues are coupled with reasoning traces. Building on this perspective, we propose a falsification-based evaluation framework that combines causal token injection with LLM-guided counterexample construction. Across 22 configurations spanning multiple model families, layers, and reasoning datasets, we find that many contrastively selected candidates are highly sensitive to token-level interventions, with 45%–90% activating after injecting only a few associated tokens into non-reasoning text. For the remaining context-dependent candidates, LLM-guided falsification produces targeted non-reasoning inputs that trigger activation and meaning-preserving paraphrases of top-activating reasoning traces that suppress it. A small steering study yields minimal changes on the evaluated benchmarks. Overall, our results suggest that, in the settings we study, sparse decompositions can favor low-dimensional correlates that co-occur with reasoning, underscoring the need for falsification when attributing high-level behaviors to individual SAE features. Code is available at https://github.com/GeorgeMLP/reasoning-probing.
****
On the Interplay of Pre-Training, Mid-Training, and RL on Reasoning Language Models
Charlie Zhang, Graham Neubig, Xiang Yue
Recent reinforcement learning (RL) techniques have yielded impressive reasoning improvements in language models, yet it remains unclear whether RL truly extends a model's reasoning ability beyond pre-training. A central challenge is the lack of control in modern training pipelines, where opaque pre-training data, underexplored mid-training, and complex RL interactions obscure causal effects. To resolve this ambiguity, we develop a controlled experimental framework that isolates the causal contributions of pre-training, mid-training, and RL-based post-training. Our approach employs synthetic reasoning tasks with explicit atomic operations, parseable step-by-step reasoning traces, and systematic manipulation of training distributions. We evaluate along: *extrapolative generalization* to more complex compositions and *contextual generalization* across surface contexts. Using this framework, we reconcile competing views on RL’s effectiveness: 1) RL produces true capability gains (pass@128) only when pre-training leaves sufficient headroom and RL data target the model’s *edge of competence*, tasks that are difficult but not yet out of reach. 2) Contextual generalization requires minimal yet sufficient pre-training exposure, after which RL reliably transfers. 3) Mid-training significantly enhances performance under fixed compute compared with RL alone, demonstrating its central but underexplored role. 4) Process-level rewards reduce reward hacking and improve reasoning fidelity. Together, these results clarify the interplay between pre-training, mid-training, and RL, offering a foundation for improving reasoning language models training strategies. Codes and data are avaialble at [Github](https://github.com/Interplay-LM-Reasoning/Interplay-LM-Reasoning) and [HuggingFace](https://huggingface.co/Interplay-LM-Reasoning)
****
Accelerating Regression Tasks with Quantum Algorithms
Chenghua Liu, Zhengfeng Ji
Regression is a cornerstone of statistics and machine learning, with applications spanning science, engineering, and economics. While quantum algorithms for regression have attracted considerable attention, most existing work has focused on linear regression, leaving many more complex yet practically important variants unexplored. In this work, we present a unified quantum framework for accelerating a broad class of regression tasks---including linear and multiple regression,

Lasso, Ridge, Huber, ℓ_p-, and δ_p-type regressions---achieving up to a quadratic improvement in the number of samples m over the best classical algorithms. This speedup is achieved by a non-trivial quantization of the recent classical breakthrough of Jambulapati et al. (2024), where we construct a full quantum pipeline that strategically employs quantum leverage score approximation to initialize and refine Multiscale Leverage Score Overestimates, enabling efficient importance sampling via the preparation of multiple state copies. For problems of dimension n, sparsity $r < n$, and error parameter ϵ, our algorithm solves the problem in $\widetilde{O}(r\sqrt{mn}/\epsilon + \mathrm{poly}(n,1/\epsilon))$ quantum time, demonstrating both the applicability and the efficiency of quantum computing in accelerating regression tasks.

Equilibrium Pricing in Oligopolistic Data Markets

Bhaskar Ray Chaudhury, Jugal Garg, Eklavya Sharma, Jiaxin Song

We study equilibrium pricing in oligopolistic data markets with budget-constrained buyers (e.g., ML companies purchasing data to improve model accuracy) and strategic data sellers. Sellers compete by setting prices for their datasets, giving rise to a pricing game whose pure Nash equilibria correspond to equilibrium prices. While equilibrium prices are guaranteed for rivalrous goods via competitive equilibrium, we show that the non-rivalry of data fundamentally alters this picture: an exact Nash equilibrium need not exist, and in fact no 1.364-approximate equilibrium exists under uniform pricing. We therefore investigate relaxed equilibrium notions. Allowing sellers to use beyond-uniform pricing—specifically, piecewise-linear convex pricing functions—guarantees approximate stability within a constant factor: there exists a pricing profile in which no seller can improve revenue by a factor of two by deviating to any uniform price (a 2-approximate Nash equilibrium). Finally, our simulations demonstrate fast convergence and empirical approximation guarantees that outperform the worst-case bound of 2.

Enhancing Affine Maximizer Auctions with Correlation-Aware Payment

Haoran Sun, Xuanzhi Xia, Xu Chu, Xiaotie Deng

Affine Maximizer Auctions (AMAs), a generalized mechanism family from VCG, are widely used in automated mechanism design due to their inherent dominant-strategy incentive compatibility (DSIC) and individual rationality (IR). However, as the payment form is fixed, AMA's expressiveness is restricted, especially in distributions where bidders' valuations are correlated. In this paper, we propose Correlation-Aware AMA (CA-AMA), a novel framework that augments AMA with a new correlation-aware payment. We show that any CA-AMA preserves the DSIC property and formalize finding optimal CA-AMA as a constraint optimization problem subject to the IR constraint. Then, we theoretically characterize scenarios where classic AMAs can perform arbitrarily poorly compared to the optimal revenue, while the CA-AMA can reach the optimal revenue. For optimizing CA-AMA, we design a practical two-stage training algorithm. We derive that the target function's continuity and the generalization bound on the degree of deviation from strict IR. Finally, extensive experiments showcase that our algorithm can find an approximate optimal CA-AMA in various distributions with improved revenue and a low degree of violation of IR.

Great Minds Think Alike: Contextual Tacit Communication for Decentralized LLM-Agent Cooperation

Yue Pei, Hongming Zhang, Jiarui Guan, Jusheng Zhang, Liang Lin, Haogang Zhu, Ziang Chen

Large language models (LLMs) are increasingly used as planners for cooperative embodied agents, but multi-agent settings amplify inconsistency under partial observability and make explicit communication costly or even unavailable. Many existing approaches rely on online message passing; when communication is removed, agents often fall back to independent local planning that suffers from miscoordination. We introduce Contextual Tacit Communication, a gradient-free protocol that aligns decentralized decisions with a joint LLM value score without explicit message actions. Our method measures context-conditioned value rectifications via

residual banding to pinpoint miscoordination actions and amortizes the resulting coordination signals into a retrieval-augmented Tacit Rule Memory that provides prompt-level cooperation rules at execution time. Experiments on VIKI, C-WAH, and TDW-MAT show that our approach improves cooperation performance over baselines while reducing runtime overhead compared with communication-based methods.

Sparse Regression with ℓ_0 Constraints for α-Mixing Time Series: Algorithms and Guarantees
Ruoxin Yuan, Lijun Ding
Exact sparse methods based on ℓ_0 constraints are increasingly used for interpretable and scalable time series modeling, where one aims to recover a small set of informative lags/factors while maintaining strong predictive performance and low computational cost. Despite their empirical success, finite-sample and computational guarantees for such methods under temporal dependence remain limited. In this paper, we study ℓ_0-constrained least squares for time series generated by α-mixing stationary Gaussian processes with sparse coefficients. We establish high-probability restricted strong convexity/smoothness (RSC/RSS) for the empirical quadratic loss. Leveraging these conditions, we derive nonasymptotic statistical guarantees and computational complexities for a series of exact sparse methods, including iterative hard thresholding (IHT). We apply our theoretical results to Gaussian vector autoregressive (VAR) models and obtain new guarantees. Experiments on synthetic sparse VAR models and real-world mobility time series demonstrate that exact sparse methods recover lag structure more accurately and interpretably than some classical methods, while achieving comparable prediction error with substantially lower computational cost.
****
ReGen: Hierarchical Multi-Prompt Representation Generation for Efficient Waveform Diffusion Models
Sang-Hoon Lee, Ha-Yeong Choi
Representation alignment (REPA) has been investigated to accelerate diffusion training, but we observe that regularizing intermediate representations in diffusion Transformers (DiT) may implicitly entangle latents and limit generative capacity.
To address this issue, we propose ReGen, a hierarchical multi-prompt representation generation framework that jointly estimates multiple vector fields for both representations and data within a single diffusion model.
We further introduce generalized flow matching (GFM) to improve the generalization of conditional flow matching (CFM). We validate ReGen on single-stage waveform diffusion models including neural audio codec and Wave-VAE. ReGen significantly improves waveform generation quality from highly compressed latent representations at 12.5 Hz. We also present ReGenVoice, a latent diffusion model (LDM)-based text-to-speech model that achieves strong speech intelligibility (WER) and speaker similarity (SIM) with a small dataset. Moreover, operating the LDM at 6.25 Hz with rich semantic and acoustic latent representation enables efficient training and sampling, requiring only 1 day of training on 4 GPUs and fast inference with an RTF of 0.08. Audio samples are available at https://regenvoice.github.io/demo/
****
DynaMem: Consistent Long Video Generation via Hierarchical Memory and Motion Priors
Jingyu Lin, Xinyi Shang, Peng Sun, Cunjian Chen, Zhiqiang Shen
Recent text-to-video diffusion models can synthesize visually compelling clips from natural language prompts.
However, practical applications increasingly demand long-form videos with evolving narratives and persistent identity.
A common solution is autoregressive generation, where the video is produced clip by clip over long horizons, yet coherence often degrades as errors compound.
In this work, we study long-video generation under an autoregressive setting, where videos are synthesized clip by clip over long horizons.
Despite strong short-clip quality, existing approaches often suffer from semanti

c drift, motion decay, and appearance instability as the sequence grows.
We present DynaMem, a unified framework that improves long-horizon coherence via three components: Semantic-Adaptive Hierarchical Memory for long-range semantic preservation, Motion-Prioritized Optimization for motion-coherent learning, and Reference-Anchored Perceptual Alignment for stabilizing appearance.
Extensive experiments show that DynaMem produces more consistent semantics, stronger temporal dynamics, and more stable appearance on long videos compared to competitive baselines.

The Double Dilemma in Multi-Task Radiology Report Generation: A Gradient Dynamics Analysis and Solution
Erjian Zhang, Yatong Hao, Liejun Wang, Zhiqing Guo
While multi-task learning based automatic radiology report generation (RRG) is widely adopted to ensure clinical consistency, most focus on architectural designs yet remain limited to coarse linear scalarization strategies. These strategies cannot effectively balance the hard constraints of discriminative clinical supervision with the smoothness requirements of report generation. To address these problems, we analyze the failure mechanism of linear scalarization from the perspective of gradient dynamics, utilizing the stochastic differential equation (SDE) framework to characterize it as a "Double Dilemma" of drift term deviation and diffusion term decay. Based on this, we propose a backbone-agnostic optimizer named **C**onflict-**A**verse **M**agnitude-**E**nhanced **Grad**ient Descent (CAME-Grad). Through conflict-averse direction rectification and magnitude-enhanced energy injection, the algorithm not only ensures geometric validity, but also avoids local optimal solutions. Then, the adaptive gradient fusion mechanism is used to establish a dynamic balance between the theoretical optimal direction and the task-specific inductive bias. Experiments show that as a universal plug-and-play optimizer, CAME-Grad brings substantial and consistent improvements across eight diverse RRG methods, elevating overall clinical efficacy performance by an average of 2.3\% on MIMIC-CXR and 1.9\% on IU X-Ray. Our code is available at https://github.com/vpsg-research/CAME-Grad.

Pair2Scene: Learning Local Object Relations for Procedural Scene Generation
Xingjian Ran, Shujie Zhang, Weipeng Zhong, Luo Li, Bo Dai
Generating high-fidelity 3D indoor scenes remains a significant challenge due to data scarcity and the complexity of modeling intricate spatial relations. Current methods often struggle to scale beyond training distribution to dense scenes or rely on LLMs/VLMs that lack the ability for precise spatial reasoning. Building on top of the observation that object placement relies mainly on local dependencies instead of information-redundant global distributions, in this paper, we propose **Pair2Scene**, a novel procedural generation framework that integrates learned local rules with scene hierarchies and physics-based algorithms. These rules mainly capture two types of inter-object relations, namely *support relations* that follow physical hierarchies, and *functional relations* that reflect semantic links. We model these rules through a network, which estimates spatial position distributions of dependent objects conditioned on position and geometry of the anchor ones. Accordingly, we curate a dataset **3D-Pairs** from existing scene data to train the model. During inference, our framework can generate scenes by recursively applying our model within a hierarchical structure, leveraging collision-aware rejection sampling to align local rules into coherent global layouts. Extensive experiments demonstrate that our framework outperforms existing methods in generating complex environments that go beyond training data while maintaining physical and semantic plausibility.

Gradient Regularization Mitigates Reward Hacking in Reinforcement Learning from Human Feedback and Verifiable Rewards
Johannes Ackermann, Michael Noukhovitch, Takashi Ishida, Masashi Sugiyama
Reinforcement Learning from Human Feedback (RLHF) or Verifiable Rewards (RLVR) are two key steps in the post-training of modern Language Models (LMs). A common problem is reward hacking, where the policy may exploit inaccuracies of the rewa

rd and learn an unintended behavior. Most previous works address this by limitin g the policy update with a Kullback-Leibler (KL) penalty towards a reference mod el. We propose a different framing: Train the LM in a way that biases policy upd ates towards regions in which the reward is more accurate. First, we derive a th eoretical connection between the accuracy of a reward model and the flatness of an optimum at convergence. Gradient regularization (GR) can then be used to bias training to flatter regions and thereby maintain reward model accuracy. We conf irm these results by showing that the gradient norm and reward accuracy are empi rically correlated in RLHF. We then empirically show that Reference Resets of t he KL penalty find flatter regions with a higher reward accuracy. We further imp rove on this by proposing to use explicit GR with an efficient finite-difference estimate. Empirically, GR performs better than a KL penalty across a diverse se t of RL experiments with LMs. GR achieves a higher GPT-judged win-rate in RLHF, avoids overly focusing on the format in rule-based math rewards, and prevents ha cking the judge in LLM-as-a-Judge math tasks.

Improving Explicit Dynamic Gaussian Splatting Optimization via Update Mixture
Renjie Ding, Yaonan Wang, Min Liu, Jialin Zhu, Jiazheng Wang, Jiahao Zhao, Xiao Tan, Feixiang He, Xiang Chen
3D Gaussian Splatting (3DGS) enables real-time, high-fidelity view synthesis via explicit scene representations and has recently been extended to dynamic scene modeling. Despite their excellent rendering quality and interpretability, we fin d that explicit Dynamic GS often exhibits generalization degradation in scenes w ith large motion. Motivated by generalization behavior in deep neural optimizati on and the characteristics of Gaussian primitive optimization, we propose an upd ate mixture strategy. This work focuses on two representative open-source explic it Dynamic GS pipelines and our approach consists of three components: (i) a spa ce–time dependent Strictly Sparse Update with additional regularization to stabi lize adaptive updates; (ii) a constant-corrected adaptive algorithm that allevia tes over-scaling of primitive gradients and yields a stable mixture of adaptive and non-adaptive steps; and (iii) attributes mixing via Stochastic Attribute Ave raging to mitigate frame-preference under motion disturbances. Experiments show consistent improvements and reduced generalization issues, highlighting the role of non-adaptive updates and the impact of frame-preference in explicit Dynamic GS optimization.

FACT: Fuzzy Alignment with Comorbidity Topology for Reliable Multi-Label Medical Image Diagnosis
Yingyu Chen, Yongqiang Huang, Yang Qin, Ziyuan Yang, Lang Yuan, Maosong Ran, Yi Zhang
In clinical practice, patients often present with multiple co-occurring diseases , yet most existing Multi-Label-Diagnosis (MLD) methods treat diagnosis as a rig id discriminative partitioning task, implicitly assuming that overlapping pathol ogies are separable. This assumption is problematic in medical images, where ide ntical or highly similar visual observations may simultaneously support multiple disease labels, and disease concepts are inherently correlated rather than inde pendent. Enforcing hard decision boundaries under such overlap suppresses shared evidence, biases feature representations, and ultimately undermines model relia bility. To address this limitation, we propose Fuzzy Alignment with Comorbidity Topology FACT, a novel paradigm that reformulates MLD as a fuzzy alignment probl em between atomic visual evidence and disease semantic anchors. FACT is characte rized by three key features: (1) modeling visual polysemy through shared and reu sable atomic visual evidence; (2) encoding disease correlation via semantic anch ors structured by comorbidity topology; and (3) employing a metric-based fuzzy m embership function for non-discriminative visual-semantic alignment. Extensive e xperiments on three public clinical benchmarks demonstrate that FACT consistentl y improves diagnostic performance while delivering clinically plausible predicti ons. The code is available at \url{https://github.com/yyuChen9/FACT}.

TSMGen: Target-Specific Molecule Generation via Higher-Order Structural Dependen

cies and Context-Aware Bidirectional Fusion
Yaoyu Chen, Xiaoli Lin, Ziyi Gong, Jun Pang
Efficiently designing high-quality molecules targeting disease-relevant targets is a critical challenge. Most existing methods can capture pairwise amino acid relations, neglecting the higher-order relations among multiple amino acids. This paper proposes a target-specific molecule generation framework, namely TSMGen, to comprehensively capture the local and global structural information of the protein pocket by modeling higher-order spatial dependencies both at the atomic and the amino acid levels. Furthermore, we design a context-aware bidirectional fusion module to learn the more detailed structural information about the protein pocket. This module simultaneously attends to features from both the protein pocket and the molecule, fully leveraging the structural information from both to optimize the generation process of targeted molecules, thereby enhancing the quality of generated molecules. Experiments show that TSMGen outperforms state-of-the-art methods in terms of Vina Score, High Affinity, QED, SA and Diversity, and a case study on β-secretase enzyme further confirms its ability to generate molecules with stronger binding affinity.

Gateways to Tractability for Satisfiability in Pearl’s Causal Hierarchy
Robert Ganian, Marlene Gründel, Simon Wietheger
Pearl’s Causal Hierarchy (PCH) is a central framework for reasoning about probabilistic, interventional, and counterfactual statements, yet the satisfiability problem for PCH formulas is computationally intractable in almost all classical settings. We revisit this challenge through the lens of parameterized complexity and identify the first gateways to tractability. Our results include fixed-parameter and XP-algorithms for satisfiability in key probabilistic and counterfactual fragments, using parameters such as primal treewidth and the number of variables, together with matching hardness results that map the limits of tractability. Technically, we depart from the dynamic programming paradigm typically employed for treewidth-based algorithms and instead exploit structural characterizations of well-formed causal models, providing a new algorithmic toolkit for causal reasoning.

Doppler Prompting for Stable mmWave-based Human Pose Estimation
Shuntian Zheng, Jiaqi Li, Xiaoman Lu, Shuai He, Yu Guan
Millimeter-wave (mmWave) enables privacy-preserving, illumination-robust human pose estimation (HPE), with each mmWave frame represented as a range--angle--Doppler tensor, providing spatial magnitude for localization and Doppler signatures for motion-related cues.
However, existing mmWave-based HPE methods either underutilize or naïvely fuse Doppler signatures with spatial magnitude, disregarding their distinct physical semantics.
As a result, non-human Doppler signatures can be misinterpreted as human motion cues, leading to jittery trajectories.
We propose \textbf{PULSE}, which converts Doppler signatures into confidence-aware motion prompts and injects them into spatial magnitude reasoning through constrained interactions.
By screening Doppler prompts before they influence prediction, PULSE first suppresses spurious spectral motion cues and then uses the screened prompts to stabilize prediction.
Across three datasets spanning single- and multi-person settings, PULSE consistently improves pose accuracy and temporal stability, indicating that controlled Doppler prompting is a practical direction for stable mmWave HPE.
Codes are available in supplementary materials.

A hitchhiker's guide to Poisson gradient estimation
Michael Ibrahim, Hanqi Zhao, Eli Zachary Sennesh, Zhi Li, Anqi Wu, Jacob L. Yates, Chengrui Li, Hadi Vafaii
Poisson-distributed latent variable models are widely used in computational neuroscience, but differentiating through discrete stochastic samples remains challe

nging. Two approaches address this: *Exponential Arrival Time* (EAT) simulation and *Gumbel-SoftMax* (GSM) relaxation. We provide the first systematic compariso n of these methods, along with practical guidance for practitioners. Our main te chnical contribution is a modification to the EAT method that theoretically guar antees an unbiased first moment (exactly matching the firing rate), and reduces second-moment bias. We evaluate these methods on their distributional fidelity, gradient quality, and performance on two tasks: (1) variational autoencoders wit h Poisson latents, and (2) partially observable generalized linear models, where latent neural connectivity must be inferred from observed spike trains. Across all metrics, our modified EAT method exhibits better overall performance (often comparable to exact gradients), and substantially higher robustness to hyperpara meter choices. These results extend to over-dispersed Negative Binomial latents, where modified EAT again performs best. However, only GSM generalizes to arbitr ary non-Poisson distributions, including the under-dispersed regime. Together, o ur results clarify the trade-offs between these methods and offer concrete recom mendations for practitioners working with Poisson latent variable models.

PhyScene3D: Physically Consistent 3D Interactive Tabletop Scene Generation
Weixing Chen, Zhuoqian Feng, Yang Liu, Yexin Zhang, Yifan Wen, Yinghong Liao, We ichao Qiu, Guanbin Li, Liang Lin
Generating physically consistent 3D tabletop scenes is a fundamental yet underex plored problem for interactive and generalist robotic learning. The challenge st ems from dense object hierarchies and irregular affordances. Here, an interactiv e scene denotes a physically valid, collision-free environment directly loadable into physics simulators. Existing methods, ranging from decoupled symbolic solv ers to end-to-end regression models, often suffer from error propagation or over fitting to noisy supervision containing widespread physical violations. To addre ss these limitations, we introduce PhyScene3D, a framework that reformulates gen eration as a Human-Mimetic Constructive Process. The proposed Cognitive Topologi cal Reasoning Chain (CTRC) factorizes scene synthesis into a sequential, anchor-conditioned process. It employs a 3D AABB-based placement scheme that imposes a strong structural inductive bias. To address imperfect supervision and physical infeasibility, we introduce Physics-Aware Denoising Alignment (PADA). It integra tes a differentiable Signed Distance Field (SDF) with Test-Time Optimization (TT O) to project generated scenes onto a physics-feasible manifold while preserving semantic intent. Experiments demonstrate that PhyScene3D outperforms state-of-t he-art approaches in both semantic accuracy and physical validity, achieving a 4 0\% reduction in scene-wise collision rate relative to the human-annotated train ing data.

Efficient Transformer Attention for SNNs via Hadamard Simplification
Tingting Jiang, Jiangrong Shen, Long Chen, Yaxin Li, Qi Xu
Spiking Neural Networks (SNNs) enable low-power, event-driven computation, but T ransformer-based SNNs remain difficult to deploy on neuromorphic hardware due to dense operations and communication overhead. We propose two simplified attentio n mechanisms, \textbf{Simplified Spiking Attention (SSA)} and \textbf{Ultra-Simp lified Spiking Attention (USSA)}, which replace matrix multiplication with Hadam ard products and eliminate hardware-unfriendly components such as multi-head att ention and scaling. We show that consecutive masking is redundant and analyze a spiking-order effect in which early spiking contributes more temporal informatio n to attention modulation. On CIFAR-10, CIFAR-100, and DVS-Gesture, SSA achieves accuracies of 96.38\%, 79.45\%, and 97.56\%, respectively, while reducing compu tational complexity from $\mathcal{O}(N^2D)$ to $\mathcal{O}(ND)$ and communicat ion complexity from $\mathcal{O}(N^2)$ to $\mathcal{O}(ND)$. USSA further reduce s communication complexity to $\mathcal{O}(N)$ with only marginal accuracy degra dation. On ImageNet-1K, SSA and USSA achieve 76.91\% and 77.27\% accuracy, respe ctively, demonstrating scalability to large-scale classification.

Mechanistic Anomaly Detection via Functional Attribution
Hugo Lyons Keenan, Christopher Leckie, Sarah Monazam Erfani

We can often verify the correctness of neural network outputs using ground truth labels, but we cannot reliably determine whether the output was produced by normal or anomalous internal mechanisms. Mechanistic anomaly detection (MAD) aims to flag these cases, but existing methods either depend on latent space analysis, which is vulnerable to obfuscation, or are specific to particular architectures and modalities. We reframe MAD as a functional attribution problem: asking to what extent samples from a trusted set can explain the model's output, where attribution failure signals anomalous behavior. We operationalize this using influence functions, measuring functional coupling between test samples and a small reference set via parameter-space sampling. We evaluate across multiple anomaly types and modalities. For backdoors in vision models, our method achieves state-of-the-art detection on BackdoorBench, with an average Defense Effectiveness Rating (DER) of 0.93 across seven attacks and four datasets (next best 0.83). For LLMs, we similarly achieve a significant improvement over baselines for several backdoor types, including on explicitly obfuscated models. Beyond backdoors, preliminary evidence shows our method can detect adversarial and out-of-distribution samples, and distinguishes multiple anomalous mechanisms within a single model. Our results establish functional attribution as an effective, modality-agnostic tool for detecting anomalous behavior in deployed models.

SonicMaster: Towards Controllable All-in-One Music Restoration and Mastering
Jan Melechovsky, Ambuj Mehrish, Abhinaba Roy, Dorien Herremans
Music recordings often suffer from audio quality issues such as excessive reverberation, distortion, clipping, tonal imbalances, and a narrowed stereo image, especially when created in non-professional settings without specialized equipment or expertise. These problems are typically corrected using separate specialized tools and manual adjustments. In this paper, we introduce SonicMaster, the first unified generative model for music restoration and mastering that addresses a broad spectrum of audio artifacts with text-based control. SonicMaster is conditioned on natural language instructions to apply targeted enhancements, or can operate in an automatic mode for general restoration. To train this model, we construct the SonicMaster dataset, a large dataset of paired degraded and high-quality tracks by simulating common degradation types with nineteen degradation functions belonging to five enhancements groups: equalization, dynamics, reverb, amplitude, and stereo. Our approach leverages a flow-matching generative training paradigm to learn an audio transformation that maps degraded inputs to their cleaned, mastered versions guided by text prompts. Objective audio quality metrics demonstrate that SonicMaster significantly improves sound quality across all artifact categories. Furthermore, subjective listening tests confirm that listeners prefer SonicMaster's enhanced outputs over other baselines. The model and demo samples are available through https://github.com/AMAAI-Lab/SonicMaster.

ForensicConcept: Transferable Forensic Concepts for AIGI Detection
Menyanshu Zhou, Ziyin Zhou, Ke Sun, Yunpeng Luo, Jiayi Ji, Xiaoshuai Sun, Rongrong Ji
AI-generated image detectors achieve high accuracy on in-distribution data but often fail on unseen generators. A key obstacle to understanding this failure is the black-box nature of current detectors: they do not reveal which evidence drives their decisions. We propose \textsc{ForensicConcept}, a framework that extracts explicit forensic concepts from detectors and enables their transfer across backbones. Our method localizes decision-critical patches via Transformer attribution, clusters them into a compact concept codebook, and uses a concept-aligned projection to produce auditable evidence readouts. Motivated by prior studies showing that DINO representations can guide diffusion generation and exhibit concept-level correspondence with diffusion features, we introduce a generation-trace reference based on CleanDIFT diffusion features and quantify backbone-trace alignment via neighborhood-structure consistency (CKNNA). We further propose concept codebook injection to transfer diffusion-derived concepts into target backbones. Experiments on GenImage, GAN-family, and Chameleon benchmarks show consistent improvements over prior methods. We also find that CKNNA alignment predicts tr

ansfer effectiveness, providing a principled explanation for why some backbones yield more transferable forensic evidence than others.
****

The Truth Lies Somewhere in the Middle (of the Generated Tokens)
Sophie L. Wang, Phillip Isola, Brian Cheung
How should the sequence of hidden states produced during autoregressive generation be compressed into a representation that reflects the model’s internal state? We study representations derived from generated tokens and compare them to grounded embeddings across several domains. We find that pooling embeddings across tokens produces more informative representations than any individual token. This observation is consistent with semantic information being distributed across generated tokens rather than localized to a single position. In this setting, alignment provides a way to study how a model’s internal representations evolve and pooling offers a more reliable summary of the model's state across generation.
****

The Sign Estimator: Preference Modeling for LLM Alignment under Heterogeneity
Ali Aouad, Aymane El Gadarri, Vivek Farias
Traditional large language model (LLM) alignment methods are based on Reinforcement Learning From Human Feedback (RLHF), which learns a single reward model (implicitly or explicitly) from pairwise comparison data. This approach implicitly assumes homogeneous preferences across human labelers---an assumption that is violated in practice. As a result, the learned reward model in RLHF is generally misspecified: Prior work shows that it is inconsistent with the population-average utility, incurring large distortion, and that recovering this utilitarian objective is provably impossible in the worst case. In this work, we show that the average utility is recoverable under a mild assumption. Our method, the Sign Estimator, simply replaces the standard cross-entropy loss function with a notion of binary classification loss and yields a reward model that is ordinally consistent with the population-average utility. We further establish a fast finite-sample convergence rate of $O({n^{-{1}/{3}}})$, which provides, to our knowledge, the first consistent estimator for heterogeneous preferences that does not suffer from the curse of dimensionality.
****

TabICLv2: A Better, Faster, Scalable, and Open Tabular Foundation Model
Jingang QU, David Holzmüller, Gaël Varoquaux, Marine Le Morvan
Tabular foundation models, such as TabPFNv2 and TabICL, have recently dethroned gradient-boosted trees at the top of predictive benchmarks, demonstrating the value of in-context learning for tabular data. We introduce TabICLv2, a new state-of-the-art foundation model for regression and classification built on three pillars: (1) a novel synthetic data generation engine designed for high pretraining diversity; (2) various architectural innovations, including a new scalable softmax in attention improving generalization to larger datasets without prohibitive long-sequence pretraining; and (3) optimized pretraining protocols, notably replacing AdamW with the Muon optimizer. On the TabArena and TALENT benchmarks, TabICLv2 without any tuning surpasses the performance of the current state of the art, RealTabPFN-2.5 (hyperparameter-tuned, ensembled, and fine-tuned on real data). With only moderate pretraining compute, TabICLv2 generalizes effectively to million-scale datasets under 50GB GPU memory while being markedly faster than RealTabPFN-2.5. We provide extensive ablation studies to quantify these contributions and foster open research by releasing code for inference, pretraining, and synthetic data generation at https://github.com/soda-inria/tabicl.
****

DistMatch: Adaptive Binning via Distribution Matching for Robust Sequential Conformal Prediction
Enver Menadjiev, Jihyeon Seong, Jisu Yeo, Jaesik Choi
Sequential conformal prediction (CP) provides valid uncertainty quantification under the assumption of residual exchangeability. However, this assumption is often violated in real-world time series due to temporal dependencies and distributional shifts. While recent methods attempt to approximate exchangeability through reweighting, identifying optimal weights remains an open challenge. To address

this limitation, we propose [DistMatch](https://github.com/enver1323/dist_match_conformal), a binning-based method that recursively partitions residuals within a binary tree using the Kolmogorov–Smirnov (KS) statistic. We theoretically show that this partitioning induces approximately exchangeable leaves, thereby avoiding the need for reweighting. By applying quantile regression with online updates within each leaf, DistMatch enables locally adaptive inference and improves robustness to distributional shifts. Extensive experiments demonstrate that DistMatch outperforms existing sequential CP methods.
****
ProphetKV: User-Query-Driven Selective Recomputation for Efficient KV Cache Reuse in Retrieval-Augmented Generation
Shihao Wang, Jiahao Chen, Yanqi Pan, Hao Huang, Yichen Hao, Xiangyu Zou, Wen Xia, Chongyang Qiu, Wentao Zhang, PengFei Wang
The prefill stage of long-context Retrieval-Augmented Generation (RAG) is severely bottlenecked by computational overhead. To mitigate this, recent methods assemble pre-calculated KV caches of retrieved RAG documents (by a *user query*) and reprocess selected tokens to recover cross-attention between these pre-calculated KV caches. However, we identify a fundamental ``crowding-out effect'' in current token selection criteria: globally salient but *user-query*-irrelevant tokens saturate the limited recomputation budget, displacing the tokens truly essential for answering the *user query* and degrading inference accuracy.

We propose ProphetKV, a user-query-driven KV Cache reuse method for RAG scenarios. ProphetKV dynamically prioritizes tokens based on their semantic relevance to the *user query* and employs a dual-stage recomputation pipeline to fuse layer-wise attention metrics into a high-utility set.
By ensuring the recomputation budget is dedicated to bridging the informational gap between retrieved context and the *user query*, ProphetKV achieves high-fidelity attention recovery with minimal overhead. Our extensive evaluation results show that ProphetKV retains 96\%–101\% of full-prefill accuracy with only a 20\% recomputation ratio, while achieving accuracy improvements of 8.8\%–24.9\% on RULER and 18.6\%–50.9\% on LongBench over the state-of-the-art approaches (e.g., CacheBlend, EPIC, and KVShare).
****
SemBind: Binding Diffusion Watermarks to Semantics Against Black-Box Forgery Attacks
Xin Zhang, Zijin Yang, Kejiang Chen, Linfeng Ma, Weiming Zhang, Nenghai Yu
Latent-based watermarks, embedded during the generation process of latent diffusion models (LDMs), facilitate detection and attribution of generated images. However, recent black-box forgery attacks can implant a provider's watermark into images not generated by that provider, using at least one watermarked image and black-box access to the model, thereby undermining provenance and trust. We propose SemBind, the first defense framework for latent-based watermarks against black-box forgery, which binds latent watermark signals to image semantics through a contrastively trained semantic masker. The masker produces near-invariant codes for semantically matched prompts and near-orthogonal codes across different prompts, enabling SemBind to modulate the target latent before applying standard latent-based watermarking schemes. Across four mainstream latent-based watermarking methods, SemBind substantially reduces false acceptance under black-box forgery while preserving image quality and offering a tunable robustness--security trade-off via a simple mask-ratio parameter. Code is available at https://github.com/XinZhang1999/SemBind.

Learning When to Act or Refuse: Guarding Agentic Reasoning Models for Safe Multi-Step Tool Use
Aradhye Agarwal, Gurdit Siyan, Yash Pandya, Joykirat Singh, Akshay Nambi, Ahmed Hassan Awadallah
Agentic language models operate in a fundamentally different safety regime than chat models: they must plan, call tools, and execute long-horizon actions where a single misstep, such as accessing files or entering credentials, can cause irr

eversible harm. Existing alignment methods, largely optimized for static generat ion and task completion, break down in these settings due to sequential decision -making, adversarial tool feedback, and overconfident intermediate reasoning. We introduce MOSAIC, a post-training framework that aligns agents for safe multi-s tep tool use by making safety decisions explicit and learnable. MOSAIC structure s inference as a plan, check, then act or refuse loop, with explicit safety reas oning and refusal as first-class actions. To train without trajectory-level labe ls, we use preference-based reinforcement learning with pairwise trajectory comp arisons, which captures safety distinctions often missed by scalar rewards. We e valuate MOSAIC zero-shot across three model families, Qwen2.5-7B, Qwen3-4B-Think ing, Phi-4 and Qwen3-30B-A3B-Thinking, and across out-of-distribution benchmarks spanning harmful tasks, prompt injection, benign tool use, and cross-domain pri vacy leakage. MOSAIC reduces harmful behavior by up to 50\%, increases harmful-t ask refusal by over 20\% on injection attacks, cuts privacy leakage, and preserv es or improves benign task performance, demonstrating robust generalization acro ss models, domains, and agentic settings.

ST-TGExplainer: Disentangling Stability and Transition Patterns for Temporal GNN Interpretability

Hongjiang Chen, Xin Zheng, Pengfei Jiao, Huan Liu, Zhidong Zhao, Huaming Wu, Fen g Xia, Shirui Pan

Temporal graph neural networks (TGNNs) have gained significant traction for solv ing real-world temporal graph tasks. However, their interpretability remains lim ited, as most TGNNs fail to identify which historical interactions most influenc e a given prediction. Despite promising progress on interpretable TGNNs, existin g methods predominantly focus on previously seen historical interactions, which we term stability patterns, while overlooking newly emerging first-time interact ions, which we term transition patterns. Both types of patterns are essential fo r faithful temporal explanations. To address this limitation, we propose ST-TGEx plainer, a self-explainable TGNN that disentangles Stability and Transition patt erns in temporal graphs for a more faithful Temporal GNN Explainer. Guided by a disentangled information bottleneck objective, ST-TGExplainer learns a compact e xplanatory subgraph that remains predictive of the event label while explicitly suppressing label-conditioned redundancy between stability and transition patter ns. Extensive experiments demonstrate that ST-TGExplainer achieves strong predic tive performance and yields more faithful explanations. Code is available at htt ps://github.com/hjchen-hdu/ST-TGExplainer.
****

SyMerge: From Non-Interference to Synergistic Merging via Single-Layer Adaptatio n

Aecheon Jung, Seunghwan Lee, Dongyoon Han, Sungeun Hong

Model merging combines independently trained models into a single multi-task mod el. However, most existing approaches focus primarily on avoiding task interfere nce. We argue that its greater potential lies in enabling task synergy, where ta sks actively improve one another. We identify cross-task performance, defined by compatibility between encoders and predictors across tasks, as a key indicator of merge quality. We demonstrate that adapting only a single task-specific layer is sufficient to induce such synergy. This study proposes SyMerge, a lightweigh t framework that jointly optimizes merging coefficients and a single task-specif ic layer. We adopt an expert-guided self-labeling objective, providing stable su pervision beyond entropy minimization. Intriguingly, we further show that SyMerg e successfully merges models trained from different initializations, a regime wh ere standard methods break down. Our minimalist yet principled method achieves s tate-of-the-art results across vision, dense prediction, and NLP benchmarks. Our code is available at https://aim-skku.github.io/SyMerge.

NoiseSDF2NoiseSDF: Learning Clean Neural Fields from Noisy Supervision

Tengkai Wang, Weihao Li, Ruikai Cui, Shi Qiu, Nick Barnes

Reconstructing accurate implicit surface representations from point clouds remai ns a challenging task, particularly when data is captured using low-quality scan

ning devices. These point clouds often contain substantial noise, leading to ina
ccurate surface reconstructions. Inspired by the Noise2Noise paradigm for 2D ima
ges, we introduce NoiseSDF2NoiseSDF, a novel method designed to extend this conc
ept to 3D neural fields. Our approach enables learning clean neural SDFs from no
isy point clouds through noisy supervision by minimizing the MSE loss between no
isy SDF representations, allowing the network to implicitly denoise and refine s
urface estimations. We evaluate the effectiveness of NoiseSDF2NoiseSDF on benchm
arks, including the ShapeNet, ABC, Famous, and Real datasets. Experimental resul
ts demonstrate that our framework significantly improves surface reconstruction
quality from noisy inputs.

Prism: Spectral-Aware Block-Sparse Attention
Xinghao Wang, Pengyu Wang, Xiaoran Liu, Fangxu Liu, Jason Chu, Kai Song, Xipeng
Qiu
Block-sparse attention is promising for accelerating long-context LLM pre-fillin
g, yet identifying relevant blocks efficiently remains a bottleneck.
Existing methods typically employ coarse-grained attention as a proxy for block
importance estimation, but often resort to expensive token-level searching or sc
oring, resulting in significant selection overhead.
In this work, we trace the inaccuracy of standard coarse-grained attention via m
ean pooling to a theoretical root cause: the interaction between mean pooling an
d Rotary Positional Embeddings (RoPE).
We prove that mean pooling acts as a low-pass filter that induces destructive in
terference in high-frequency dimensions, effectively creating a "blind spot" for
local positional information (e.g., slash patterns).
To address this, we introduce Prism, a training-free spectral-aware approach tha
t decomposes block selection into high-frequency and low-frequency branches.
By applying energy-based temperature calibration, Prism restores the attenuated
positional signals directly from pooled representations, enabling block importan
ce estimation using purely block-level operations, thereby improving efficiency.
Extensive evaluations confirm that Prism maintains accuracy parity with full att
ention while delivering up to $\mathbf{5.1\times}$ speedup. Code available at ht
tps://github.com/xinghaow99/prism.

Implicit Preference Alignment for Human Image Animation
Yuanzhi Wang, Xuhua Ren, Jiaxiang Cheng, bing ma, Kai Yu, Tianxiang Zheng, Qingl
in Lu, Zhen Cui
Human image animation has witnessed significant advancements, yet generating hig
h-fidelity hand motions remains a persistent challenge due to their high degrees
of freedom and motion complexity. While reinforcement learning from human feedb
ack, particularly direct preference optimization, offers a potential solution, i
t necessitates the construction of strict preference pairs. However, curating su
ch pairs for dynamic hand regions is prohibitively expensive and often impractic
al due to frame-wise inconsistencies. In this paper, we propose Implicit Prefere
nce Alignment (IPA), a data-efficient post-training framework that eliminates th
e need for paired preference data. Theoretically grounded in implicit reward max
imization, IPA aligns the model by maximizing the likelihood of self-generated h
igh-quality samples while penalizing deviations from the pretrained prior. Furth
ermore, we introduce a Hand-Aware Local Optimization mechanism to explicitly ste
er the alignment process toward hand regions. Experiments demonstrate that our m
ethod achieves effective preference optimization to enhance hand generation qual
ity, while significantly lowering the barrier for constructing preference data.
Codes are released at https://github.com/mdswyz/IPA

JADE: Expert-Grounded Dynamic Evaluation for Open-Ended Professional Tasks
Lanbo Lin, Jiayao Liu, Tianyuan Yang, Li Cai, Yuanwu Xu, Lei Wei, Sicong Xie, Gu
annan Zhang
Evaluating agentic AI on open-ended professional tasks faces a fundamental dilem
ma between rigor and flexibility. Static rubrics provide rigorous, reproducible
assessment but fail to accommodate diverse valid response strategies, while LLM-

as-a-judge approaches adapt to individual responses yet suffer from instability and bias. Human experts address this dilemma by combining domain-grounded principles with dynamic, claim-level assessment. Inspired by this process, we propose JADE, a two-layer evaluation framework. Layer 1 encodes expert knowledge as a predefined set of evaluation skills, providing stable evaluation criteria. Layer 2 performs report-specific, claim-level evaluation to flexibly assess diverse reasoning strategies, with evidence-dependency gating to invalidate conclusions built on refuted claims. Experiments on BizBench show that JADE improves evaluation stability and reveals critical agent failure modes missed by holistic LLM-based evaluators. We further demonstrate strong alignment with expert-authored rubrics and effective transfer to HealthBench and DR.BENCH, covering medical and 10-domain professional evaluation settings. Code and data are available at https://github.com/smiling-world/JADE.

Neural Control: Adjoint Learning Through Equilibrium Constraints

Dezhong Tong, Jiawen Wang, Hengyi Zhou, Yinlong Shen, Xiaonan Huang, M. Khalid Jawed

Many physical AI tasks require sequential implicit computation: at each step, boundary controls are applied, and the resulting configuration is obtained by solving an equilibrium problem. This setting arises naturally in deformable object manipulation, where even bending a deformable linear object (DLO) to a target shape can be nonlinear and multistable: identical boundary conditions may produce different configurations depending on actuation history. Unlike explicit transition models, the control-to-configuration relation is implicit and history-dependent, making long-horizon learning and control brittle; backpropagating through iterative solves is also memory- and compute-intensive. We propose Neural Control, a boundary-control framework that propagates gradients through branch-dependent sequences of equilibrium solves rather than a single fixed point. Neural Control computes trajectory-dependent proxy gradients by differentiating equilibrium conditions with an adjoint formulation, avoiding solver unrolling while keeping forward rollouts on converged equilibria. Combined with receding-horizon continuation, Neural Control re-anchors optimization to realized equilibria and mitigates basin switching. We validate Neural Control on simulated and real DLO manipulation, compare against SPSA and iCEM, and demonstrate applicability to a learned DEQ-style implicit equilibrium model.

****

Noise-Guided Transport: Imitation Learning from Random Priors

Lionel Blondé, Joao Candido Ramos, Alexandros Kalousis

We consider imitation learning in the low-data regime, where only a limited number of expert demonstrations are available. In this setting, methods that rely on large-scale pretraining or high-capacity architectures can be difficult to apply, and efficiency with respect to demonstration data becomes critical. We introduce Noise-Guided Transport (NGT), a lightweight off-policy method that casts imitation as an optimal transport problem solved via adversarial training. NGT requires no pretraining or specialized architectures, incorporates uncertainty estimation by design, and is easy to implement and tune. Despite its simplicity, NGT achieves strong performance on challenging continuous control tasks, including high-dimensional Humanoid tasks, under ultra-low data regimes with as few as 20 transitions.

Anchor-Final Self-Supervision Drives Hallucination-Aware Optimization in Large Vision-Language Models

Jiaxi Liu, Yifeng Yang, Xinbing Wang, Qinying Gu, Nanyang Ye

Hallucinations in large vision-language models (LVLMs) remain a critical challenge, where models often generate tokens that fail to align with visual evidence. To address this issue, we propose AFS: Anchor-Final Self-Supervision, a novel framework for hallucination-aware optimization in LVLMs. By leveraging discrepancies between intermediate and final layer predictions, AFS selectively applies self-supervision to visually descriptive tokens, incorporates hallucination-aware token classification, and encourages consistency between intermediate and final l

ayer distributions. Unlike traditional methods that rely on explicit supervision or post-hoc interventions, AFS optimizes the model via Group Relative Policy Optimization (GRPO), using token-specific rewards derived from internal model signals. Experiments demonstrate that AFS significantly reduces hallucinations without compromising recall in caption generation. Beyond captioning, AFS excels in discriminative tasks, improving the reliability of object existence predictions and multimodal reasoning. Furthermore, AFS demonstrates strong cross-dataset generalization, transferring effectively across diverse visual domains. Code is available at \url{https://github.com/guavayew/AFS}.

It's a TRAP! Task-Redirecting Agent Persuasion Benchmark for Web Agents
Karolina Korgul, Yushi Yang, Arkadiusz Drohomirecki, Piotr Blaszczyk, Will Howard, Lukas Aichberger, Chris Russell, Philip Torr, Adam Mahdi, Adel Bibi
Web-based agents powered by large language models are increasingly used for tasks such as email management or professional networking. Their reliance on dynamic web content, however, makes them vulnerable to prompt injection attacks: adversarial instructions hidden in interface elements that persuade the agent to divert from its original task. We introduce the Task-Redirecting Agent Persuasion Benchmark (TRAP), a benchmark for studying how persuasion techniques misguide autonomous web agents on realistic tasks. Across six frontier models, agents are susceptible to prompt injection in 25\% of tasks on average (13\% for GPT-5 to 43\% for DeepSeek-R1), with small interface or contextual changes often doubling success rates and revealing systemic, psychologically driven vulnerabilities in web-based agents. We also provide a modular social-engineering injection framework with controlled experiments on high-fidelity website clones, allowing for further benchmark expansion.

Implicit Actor Critic Coupling via a Supervised Learning Framework for RLVR
Jiaming Li, Longze Chen, Ze Gong, Yukun Chen, Lu Wang, Wanwei He, Run Luo, Minzheng Wang, Lei Zhang, Haoran Ye, Min Yang
Recent advances in Reinforcement Learning with Verifiable Rewards (RLVR) have empowered large language models (LLMs) to tackle challenging reasoning tasks such as mathematics and programming, however existing RLVR methods often suffer from sparse reward signals and unstable policy gradient updates inherent to RL-based approaches.

To address the challenges, we propose $\textbf{PACS}$, a novel RLVR framework that achieves im$\textbf{P}$licit $\textbf{A}$ctor $\textbf{C}$ritic coupling via a $\textbf{S}$upervised learning framework.

By treating the outcome reward as a predictable label, we reformulate the RLVR problem into a supervised learning task over a score function parameterized by the policy model and optimized using cross-entropy loss.

A detailed gradient analysis shows that this supervised formulation inherently recovers the classical policy gradient update while providing more stable and efficient training.

Extensive experiments demonstrate that PACS significantly outperforms strong open-source models and RLVR baselines, yielding substantial average gains of $\textbf{+8.26\%}$ (4B) and $\textbf{+9.57\%}$ (8B) over base models offering a promising avenue for LLMs post-training with verifiable rewards. Our code and data are available as open source at https://github.com/ritzz-ai/PACS.

ScDiVa: Masked Discrete Diffusion for Joint Modeling of Single-Cell Identity and Expression
Mingxuan Wang, Gaoyang Jiang, ZiJia Ren, Cheng Chen, Chuangxin Zhao, Lu Shi, Yanbiao Ma
Single-cell RNA-seq profiles are high-dimensional, sparse, and unordered, causing autoregressive generation to impose an artificial ordering bias and suffer from error accumulation. To address this, we propose scDiVa, a masked discrete diffusion foundation model that aligns generation with the dropout-like corruption process by defining a continuous-time forward masking mechanism in token space. ScDiVa features a bidirectional denoiser that jointly models discrete gene identi

ties and continuous values, utilizing entropy-normalized serialization and a lat
ent anchor token to maximize information efficiency and preserve global cell ide
ntity. The model is trained via depth-invariant time sampling and a dual denoisi
ng objective to simulate varying sparsity levels while ensuring precise recovery
 of both identity and magnitude. Pre-trained on 59 million cells, scDiVa achieve
s strong transfer performance across major benchmarks, including batch integrati
on, cell type annotation, and perturbation response prediction. These results su
ggest that masked discrete diffusion serves as a biologically coherent and effec
tive alternative to autoregression.

Functional Decomposition and Shapley Interactions for Interpreting Survival Mode
ls

Sophie Hanna Langbein, Hubert Baniecki, Fabian Fumagalli, Niklas Koenen, Marvin
N. Wright, Julia Herbinger

Hazard and survival functions are natural, interpretable targets in time-to-even
t prediction tasks such as patient survival and disease progression modeling, bu
t their inherent non-additivity fundamentally limits standard additive explanati
on methods. We introduce Survival Functional Decomposition (SurvFD), a principle
d approach for analyzing feature interactions in machine learning survival model
s. By decomposing higher-order effects into time-dependent and time-independent
components, SurvFD offers a previously unrecognized perspective on survival expl
anations, explicitly characterizing when and why additive explanations fail. Bui
lding on this theoretical decomposition, we propose SurvSHAP-IQ, which extends S
hapley interactions to time-indexed functions, providing a practical estimator f
or higher-order, time-dependent interactions. We validate the framework on simul
ated data and demonstrate its utility through cancer survival applications, incl
uding multi-modal breast cancer prognosis combining histopathology with clinical
 features. Together, SurvFD and SurvSHAP-IQ establish an interaction- and time-a
ware interpretability approach for survival modeling, with broad applicability a
cross medicine, healthcare and other time-to-event prediction tasks.

ScaLoRA: Optimally Scaled Low-Rank Adaptation for Efficient High-Rank Fine-Tunin
g

Yilang Zhang, Xiaodong Yang, Yiwei Cai, Georgios B. Giannakis

As large language models (LLMs) continue to scale in size, the computational ove
rhead has become a major bottleneck for task-specific fine-tuning. While low-ran
k adaptation (LoRA) effectively curtails this cost by confining the weight updat
es to a low-dimensional subspace, such a restriction can hinder effectiveness an
d slow convergence. This contribution deals with these limitations by accumulati
ng progressively a high-rank weight update from consecutive low-rank increments.
 Specifically, the per update optimal low-rank matrix is identified to minimize
the loss function and closely approximate full fine-tuning. To endow efficient a
nd seamless optimization without restarting, this optimal choice is formed by ap
propriately scaling the columns of the original low-rank matrix. Rigorous perfor
mance guarantees reveal that the optimal scaling can be found analytically. Exte
nsive numerical tests with popular LLMs scaling up to 12 billion parameters demo
nstrate a consistent performance gain and fast convergence relative to state-of-
the-art LoRA variants on diverse tasks including natural language understanding,
 commonsense reasoning, and mathematical problem solving.

Adapting to Evolving Graphs: A Scalable Framework for Dynamic Coarsening

Abhishek Gupta, Manoj Kumar, Sarthak Kumar Singh, Ujjwal Yadav, Yifan Sun, Sande
ep Kumar

Graph coarsening is a fundamental dimensionality reduction technique for scaling
 large graphs while preserving structural and feature information. However, most
 existing coarsening methods are designed for static graphs and do not extend we
ll to dynamic settings where nodes, edges, and connectivity patterns evolve over
 time. Recomputing a coarsened graph from scratch after every update is often in
feasible, which limits scalability and real-time applicability. To address this,
 we propose a unified framework for coarsening discrete-time dynamic graphs by i

ncrementally updating the coarsening mapping matrix. The framework initializes f rom any static coarsening technique and then efficiently incorporates real-world graph events, including node additions, node deletions, and edge modifications. We instantiate this framework with two optimization based incremental update al gorithms tailored to different dynamic regimes, one focusing on efficiently inte grating growth related changes and another handling broader topology evolution w ith adaptive reassignment. We derive fast and scalable solvers with convergence guarantees, and provide theoretical guarantee via ϵ-similarity bounds t hat quantify and control quality degradation in the coarsened graph. Extensive e xperiments under realistic dynamic scenarios show substantial improvements in ru ntime and memory, delivering significant speedups while maintaining or improving downstream task performance, including graph neural network accuracy.

iWorld-Bench: A Benchmark for Interactive World Models with a Unified Action Gen eration Framework

Jianjie Fang, Yingshan Lei, Qin Wan, Ziyou Wang, Yuchao Huang, Yongyan Xu, Baini ng Zhao, Weichen Zhang, Chen Gao, Xinlei Chen, Yong Li

Achieving Artificial General Intelligence (AGI) requires agents that learn and i nteract adaptively, with interactive world models providing scalable environment s for perception, reasoning, and action. Yet current research still lacks large- scale datasets and unified benchmarks to evaluate their physical interaction cap abilities. To address this, we propose iWorld-Bench, a comprehensive benchmark f or training and testing world models on interaction-related abilities such as di stance perception and memory. We construct a diverse dataset with 330k video cli ps and select 2.1k high-quality samples covering varied perspectives, weather, a nd scenes. As existing world models differ in interaction modalities, we introdu ce an **Action Generation Framework** to unify evaluation and design six task ty pes, generating 4.9k test samples. These tasks jointly assess model performance across **visual generation, trajectory following, and memory**. Evaluating 14 re presentative world models, we identify key limitations and provide insights for future research. The iWorld-Bench model leaderboard is publicly available at iWo rld-Bench.com.

ObjEmbed: Towards Universal Multimodal Object Embeddings

Shenghao Fu, Yukun Su, Fengyun Rao, Jing LYU, Xiaohua Xie, Wei-Shi Zheng

Aligning objects with corresponding textual descriptions is a fundamental challe nge and a realistic requirement in vision-language understanding. While recent m ultimodal embedding models excel at global image-text alignment, they often stru ggle with fine-grained alignment between image regions and specific phrases. In this work, we present ObjEmbed, a novel MLLM embedding model that decomposes the input image into multiple regional embeddings, each corresponding to an individ ual object, along with global embeddings. It supports a wide range of visual und erstanding tasks like visual grounding, local image retrieval, and global image retrieval. ObjEmbed enjoys three key properties: (1) Object-Oriented Representat ion: It captures both semantic and spatial aspects of objects by generating two complementary embeddings for each region: an object embedding for semantic match ing and an IoU embedding that predicts localization quality. The final object ma tching score combines semantic similarity with the predicted IoU, enabling more accurate retrieval. (2) Versatility: It seamlessly handles both region-level and image-level tasks. (3) Efficient Encoding: All objects in an image, along with the full image, are encoded in a single forward pass for high efficiency. Superi or performance on 18 diverse benchmarks demonstrates its strong semantic discrim ination. Code is available at \url{https://github.com/WeChatCV/ObjEmbed}.

Breaking the Block: Preserving Data Continuity to Train Superior SAEs for Instru ct Models

Jiaming Li, Haoran Ye, Yukun Chen, Xinyue Li, Lei Zhang, Hamid Alinejad-Rokny, J immy Chih-Hsien Peng, Min Yang

Sparse Autoencoders (SAEs) are a cornerstone of mechanistic interpretability. Ex isting training methods inherit the Block Training paradigm from LLM pre-trainin

g, which introduces destructive gradient noise in instruct models due to attenti on leakage from unrelated contexts.

Using GSNR analysis, we theoretically characterize this issue and propose $\un derline{\textbf{F}}$inetuning-$\underline{\textbf{a}}$ligned $\underline{\textbf {S}}$equential $\underline{\textbf{T}}$raining ($\textit{FAST}$), a sequential t raining paradigm specifically designed for instruct models.

$\textit{FAST}$ aligns SAE training with the data distribution and activation patterns of instruct models, substantially improving both reconstruction fidelit y and feature interpretability.

Experimental results show that $\textit{FAST}$ achieves higher GSNR, a signifi cantly lower log-scaled MSE of 0.6468 compared to the baseline's 5.1985, and a n ear-zero Delta Loss (-0.51\% to 0.37\%).

Moreover, on Llama-3.2-3B-it, $\textit{FAST}$ produces 21.1\% high-quality fea tures, substantially outperforming baseline methods that achieve 7.0\% and 10.2\ %.

We further find that intervening on special token activations through SAEs can improve generation quality, revealing new opportunities for fine-grained contro l. Our codes are available as open source at https://github.com/Geaming2002/FAST .

On the Entropy Dynamics in Reinforcement Fine-Tuning of Large Language Models

Shumin Wang, Yuexiang Xie, Wenhao Zhang, Yuchang Sun, Yanxi Chen, Yaliang Li, Ya nyong Zhang

Entropy serves as a critical metric for measuring the diversity of outputs gener ated by large language models (LLMs), providing valuable insights into their exp loration capabilities. While recent studies increasingly focus on monitoring and adjusting entropy to better balance exploration and exploitation in reinforceme nt fine-tuning (RFT), a principled understanding of entropy dynamics during this process is yet to be thoroughly investigated. In this paper, we establish a the oretical framework for analyzing the entropy dynamics during the RFT process, wh ich begins with a discriminant expression that quantifies entropy change under a single logit update. This foundation enables the derivation of a first-order ex pression for entropy change, which can be further extended to the update formula of Group Relative Policy Optimization (GRPO). The corollaries and insights draw n from the theoretical analysis inspire the design of entropy control methods, a nd also offer a unified lens for interpreting various entropy-based methods in e xisting studies. We provide empirical evidence to support the main conclusions o f our analysis and demonstrate the effectiveness of the derived entropy-discrimi nator clipping methods. This study yields novel insights into RFT training dynam ics, providing theoretical support and practical strategies for optimizing the e xploration-exploitation balance during LLM fine-tuning. We release our code at h ttps://github.com/agentscope-ai/Trinity-RFT/tree/main/examples/entropy.

Curating the Future: A Scalable Recipe for Training Open-Ended Forecasters

Nikhil Chandak, Shashwat Goel, Ameya Prabhu, Moritz Hardt, Jonas Geiping

High-stakes decision making involves reasoning under uncertainty about the futur e. In this work, we train language models to make predictions on open-ended fore casting questions. To scale up training data, we synthesize novel forecasting qu estions from global events reported in daily news. While directly training on th is data leads to performance drops, carefully curating questions creates a valua ble training resource. We use the resulting dataset, OpenForesight, to post-trai n Qwen3 thinking models. To prevent leakage of future information during trainin g and evaluation, we use an offline news corpus, both for data generation and re trieval in our forecasting system. Guided by a small validation set, we show the benefits of retrieval, and an improved reward function for reinforcement learni ng (RL). Once we obtain our final forecasting system, we perform held-out testin g between May to August 2025. Our specialized model, OpenForecaster-8B, matches much larger proprietary models, with our training improving the accuracy, calibr ation, and consistency of predictions. We find calibration improvements from for ecasting training generalize across popular benchmarks. We will open-source our

models, code, and data to make LLM based forecasting research broadly accessible

PRISM: Gauge-Invariant Tangent-Space Differentially Private LoRA
Shihao Wang, Xueru Zhang
Applying differential privacy (DP) via DP-SGD to Low-Rank Adaptation (LoRA) is a
 natural approach for privacy-preserving fine-tuning. However, LoRA's low-rank p
arameterization poses a fundamental challenge. In LoRA, each trainable update is
 represented as a low-rank matrix $Z = AB^\top$, but this factorization is inher
ently *non-identifiable*: many factor pairs (A, B) represent the same update $
Z$. As a result, applying DP-SGD directly to the factors induces *gauge-dependen
t* perturbations on Z, and we show that this naive DP-LoRA can lead to unbound
ed noise amplification. We propose **PRISM**, an intrinsic DP mechanism for LoRA
 that is gauge invariant by construction, avoids bilinear noise amplification, a
nd admits an efficient low-dimensional noise sampler. Moreover, PRISM yields a c
losed-form characterization of the effective intrinsic noise induced on Z, ena
bling stable privacy–utility trade-offs through bounded, gauge-invariant perturb
ations. We establish standard (ε,δ)-DP guarantees for PRISM and
 introduce a DP-aware, gauge-invariant adaptive update rule that prevents adapti
ve optimization from amplifying injected privacy noise, improving numerical stab
ility in practice.

CE^{4}L: Continual Ego, Exo, and Ego-Exo Learning
Hongwei Yan, Kanglei Zhou, Yuchen Liu, Qingyu Shi, Yi Zhong, Liyuan Wang
Perception for embodied agents is video-based, often multi-view (ego, exo, or bo
th), and inherently continual, with simultaneous task and viewpoint shifts. Yet
continual learning (CL) remains dominated by exo-only recognition tasks, obscuri
ng behavior under these real-world coupled shifts. We introduce **C**ontinual **
E**go, **E**xo, and **E**go-**E**xo **L**earning (**CE^{4}L**), a unified multi-
view CL benchmark spanning four representative tasks: cross-view referenced skil
l assessment, temporal action segmentation, cross-view association, and action a
nticipation \& planning. CE^{4}L highlights challenges largely absent in prior C
L benchmarks, including cross-view correspondence, view-dependent asynchrony, an
d heterogeneous semantic objectives. To this end, we propose **V**ideo **I**ncre
mental **S**ubspace-routed **T**ask **A**dapters (**VISTA**), a parameter-effici
ent baseline method that stores task-specific updates in lightweight adapters an
d performs training-free routing via residual distance to task-specific whitened
 subspaces estimated from second-order statistics. Extensive experiments demonst
rate the significantly varied efficacy of representative CL methods across CE$^4
$L settings, while VISTA is consistently competitive and achieves state-of-the-a
rt overall performance.

MDN: Parallelizing Stepwise Momentum for Delta Linear Attention
Yulong Huang, Xiang Liu, Hongxiang Huang, Xiaopeng LIN, Zunchang Liu, Xiaowen Ch
u, Zeke Xie, Bojun Cheng
Linear Attention (LA) offers a promising paradigm for scaling large language mod
els (LLMs) to long sequences by avoiding the quadratic complexity of self-attent
ion. Recent LA models such as Mamba2 and GDN interpret linear recurrences as clo
sed-form online stochastic gradient descent (SGD), but naive SGD updates suffer
from rapid information decay and suboptimal convergence in optimization. While m
omentum-based optimizers provide a natural remedy, they pose challenges in simul
taneously achieving training efficiency and effectiveness. To address this, we d
evelop a chunkwise parallel algorithm for LA with a stepwise momentum rule by ge
ometrically reordering the update coefficients. Further, from a dynamical system
s perspective, we analyze the momentum-based recurrence as a second-order system
 that introduces complex conjugate eigenvalues. This analysis guides the design
of stable gating constraints. The resulting model, Momentum DeltaNet (MDN), leve
rages Triton kernels to achieve comparable training throughput with competitive
linear models such as Mamba2 and KDA. Extensive experiments on the 400M and 1.3B
 parameter models demonstrate consistent performance improvements over strong ba

selines, including Transformers, Mamba2 and GDN, across diverse downstream evaluation benchmarks. Code: https://github.com/HuuYuLong/MomentumDeltaNet.

From Rashomon Theory to PRAXIS: Efficient Decision Tree Rashomon Sets
Zakk Heile, Hayden McTavish, Varun Babbar, Margo Seltzer, Cynthia Rudin
Standard machine learning pipelines often admit many near-optimal models. These "Rashomon sets" pose a range of challenges and opportunities for uncertainty-aware, robust decision making. They allow users to incorporate domain knowledge and preferences that would otherwise be difficult to specify directly in an objective, and they quantify diversity among valid models for a given training dataset and objective function. However, computation of Rashomon sets, even for simple, interpretable model classes such as sparse decision trees, continues to require immense memory and runtime resources. We present PRAXIS, an algorithm to approximate this Rashomon set with orders of magnitude improvement in runtime and memory usage. We validate that PRAXIS regularly recovers almost all of the full Rashomon set. PRAXIS allows researchers and practitioners to scalably model the Rashomon set for real-world datasets.
****

From Winning to Understanding: A Diagnostic Long-Horizon RTS Benchmark for LLMs
Jiacheng Li, Jiahui Liu, Yuqing Wang, Gaochen Cui, Xiao Zhang, Qianchuan Zhao, Ziyou Zhang, Chenghao Li
Large language models (LLMs) are increasingly used as decision modules, yet existing benchmarks provide limited coverage of long-horizon, adversarial interaction while faithfully acting on human instructions.
We introduce a long-horizon Red Alert RTS benchmark with a hierarchical interface in which LLMs output budgeted, low-frequency macro/tactical intents that are executed deterministically for standardized comparison. The benchmark evaluates (i) robustness to ``rules-as-variable'' perturbations via rule-style shifts, (ii) competitive strength via Elo-style ratings from head-to-head matches, and (iii) human steerability via standardized language interventions. Beyond win/loss, we log economy growth/spending, combat loss ratio, and visibility coverage to diagnose long-horizon failure modes. Overall, the benchmark provides a reproducible and diagnostic testbed for robustness and controllability in long-horizon adversarial decision making.
****

Zero-Shot Text-to-Motion Evaluation using Video Language Models
Yuwen Ji, Donglin Wang, Yue Zhang
Text-to-motion (T2M) generation has become a fundamental task, yet existing evaluation metrics often fail to capture whether a generated motion semantically matches its text description. We propose VeMo, a zero-shot evaluation framework that renders generated human motions into videos and uses pretrained video-language models (VLMs) to assess text-motion alignment.
Instead of training an evaluator on scarce motion-specific labels, VeMo transfers the semantic reasoning ability of VLMs to T2M evaluation through normalized likelihood-based scoring.
To reduce the effect of 3D-to-2D projection ambiguity, we introduce an entropy-driven uncertainty analysis for identifying reliable rendered views.
To address the lack of rigorous standards in the field, we further contribute a test-only and human-annotated meta-evaluation benchmark, covering motions generated by multiple representative T2M models.
Extensive experiments show that VeMo correlates better with human judgments than existing reference-based and reference-free metrics.
Additional analyses on view selection, rendering protocols, textual prompt robustness, and computational trade-offs characterize both the promise and limitations of VLM-based T2M evaluation.
****

ReSeek: A Self-Correcting Framework for Search Agents with Instructive Rewards
Shiyu Li, Yifan Wang, Peiming Li, Zheng Wei, Yang Tang
Search agents powered by Large Language Models have demonstrated significant potential in tackling knowledge-intensive tasks. Reinforcement learning has emerged

as a powerful paradigm for training these agents to perform complex, multi-step reasoning. However, prior RL-based methods often rely on sparse or rule-based rewards, which can lead agents to commit to suboptimal or erroneous reasoning paths without the ability to recover. To address these limitations, we propose **ReSeek**, a self-correcting framework enabling search agents to recover from erroneous search paths during an episode. By invoking a special **JUDGE** action, the agent can judge the information and re-plan its search strategy. To guide this process, we design a dense, instructive process reward function, which decomposes into a correctness reward for retrieving factual information and a utility reward for finding information genuinely useful for the query. Additionally, to mitigate the risk of data contamination in existing datasets, we introduce **FictionalHot**, a contamination-free benchmark requiring complex reasoning. Experiments show ReSeek significantly outperforms SOTA baselines in task success and path faithfulness.

****

Mitigating Error Accumulation in Continuous Navigation via Memory-Augmented Kalman Filtering

Yin Tang, Jiawei Ma, Jinrui Zhang, Alex Jinpeng Wang, Deyu Zhang

Continuous prediction in complex environments is critical for Unmanned Aerial Vehicle (UAV). However, the existing Vision-Language Navigation (VLN) models follows the dead-reckoning, which iteratively predicts the next waypoint and updates its position, thereby constructing the complete trajectory. Then, such stepwise manner will inevitably lead to accumulated errors of position over time, resulting in misalignment between internal belief and objective coordinates, which is known as ``state drift'' and ultimately compromises the subsequent trajectory prediction. Drawing inspiration from classical control theory, we propose to correct for errors by formulating the continuous prediction as a recursive Bayesian state estimation problem. In this paper, we design NeuroKalman, a novel framework that decouples navigation into two complementary processes: a Prior Prediction, based on motion dynamic,s and a Likelihood Correction, from historical observation. We first mathematically associate Kernel Density Estimation of the measurement likelihood with the attention-based retrieval mechanism, which then allows the system to rectify the latent representation using retrieved historical anchors without gradient updates. Comprehensive experiments on TravelUAV benchmark demonstrate that, with only 10\% of the full training data fine-tuning, our method clearly outperforms strong baselines and regulates drift accumulation.

****

Near-Universal Multiplicative Updates for Nonnegative Einsum Factorization

John Hood, Aaron Schein

Despite the ubiquity of multiway data across scientific domains, there are few performant and user-friendly methods that fit non-standard nonnegative tensor factorization models tailored to the data at-hand. Researchers may use gradient-based automatic differentiation, which often struggles under nonnegative constraints, choose between a limited set of methods with mature implementations, or implement their own model from scratch. As an alternative, we introduce NNEinFact, an einsum-based multiplicative update algorithm that fits any nonnegative tensor factorization expressible as a tensor contraction by minimizing one of many user-specified loss functions, including the (α,β)-divergence. To use NNEinFact, the researcher specifies their model with a string. NNEinFact converges to a stationary point of the loss, supports missing data, and fits to tensors with hundreds of millions of entries in seconds. Empirically, NNEinFact fits custom models which outperform standard ones in prediction tasks on real-world tensor data by over 37% and attains less than half the test loss of gradient-based methods while converging up to 90 times faster. Software is publicly available at github.com/jhood3/einfact.

****

Locate then Correct: Debiasing Attention Heads in CLIP

Wei Jie Yeo, Rui Mao, Moloud Abdar, Erik Cambria, Ranjan Satapathy

Multimodal models like CLIP have gained significant attention due to their remarkable zero-shot performance across various tasks. However, studies have revealed

that CLIP can inadvertently learn spurious associations between target variables and confounding factors. To address this, we introduce \textsc{Locate-Then-Correct} (LTC), a contrastive framework that identifies spurious attention heads in Vision Transformers via mechanistic insights and mitigates them through targeted ablation. Furthermore, LTC identifies salient, task-relevant attention heads, enabling the integration of discriminative features through orthogonal projection to improve classification performance. We evaluate LTC on benchmarks with inherent background and gender biases, achieving over a > 50% gain in worst-group accuracy compared to non-training post-hoc baselines. Additionally, we visualize the representation of selected heads and find that the presented interpretation corroborates our contrastive mechanism for identifying both spurious and salient attention heads.
****

CG-MLLM: Captioning and Generating 3D content via Multi-modal Large Language Models

Junming Huang, Chi Wang, Letian Li, Guangkai Xu, Donglin Huang, Hao Chen, Qiang Dai, Weiwei Xu

Large Language Models(LLMs) have revolutionized text generation and multimodal perception, but their capabilities in 3D content generation remain underexplored. Existing methods compromise by producing either low-resolution meshes or coarse structural proxies, failing to capture fine-grained geometry natively. In this paper, we propose CG-MLLM, a novel Multi-modal Large Language Model (MLLM) capable of 3D captioning and high-resolution 3D generation in a single framework.

Leveraging the Mixture-of-Transformer architecture, CG-MLLM decouples disparate modeling needs, where the Token-level Autoregressive (TokenAR) Transformer handles token-level content, and the Block-level Autoregressive (BlockAR) Transformer handles block-level content. By integrating a pre-trained vision-language backbone with a specialized 3D VAE latent space, CG-MLLM facilitates long-context interactions between standard tokens and spatial blocks within a single integrated architecture.

Experimental results show that CG-MLLM significantly outperforms existing MLLMs in generating high-fidelity 3D objects, effectively bringing high-resolution 3D content creation into the mainstream LLM paradigm.
****

How Transformers Represent Hierarchies: A Local-to-Global Mechanism

Zhiling Zhou, Tianhao Wang, Zhuoran Yang

Large language models built on autoregressive Transformers excel at next-token prediction, but it is unclear how their internal computations capture the latent hierarchical dependencies that often underlie language.

We study this question in a controlled formal-language setting based on probabilistic context-free grammars (PCFGs), where sequences are generated by a latent hierarchical process.

Empirically, standard autoregressive Transformers can be trained to accurately match the grammar-induced next-token distribution.

Using probing analyses, we find that Transformer hidden states contain information used by classical parsing algorithms.

Moreover, this information emerges through a layer-wise progression, revealing a local-to-global mechanism: early layers accumulate local patterns, while later layers aggregate them into a compact summary for next-token prediction.

Complementing these empirical findings, we provide an explicit construction of Transformers that can parse binary PCFGs with depth *logarithmic* in the grammar's sequence length.

Surprisingly, trained Transformers in this setting exhibit prediction behavior and internal representations that closely mirror our construction.

Together, our results offer a mechanistic account of how Transformers integrate hierarchical parsing with autoregressive generation, enabling them to closely approximate the grammar-induced next-token distribution.

Accuracy and Normalized Accuracy under Length Bias: Analysis, Guidelines, and a Bayesian Alternative

Koen Oostermeijer
Multiple-choice benchmarks that rank candidate completions by conditional log-pr
obability suffer from a length bias: because log-probabilities sum over tokens,
longer answers tend to be penalized relative to shorter ones in practice. A comm
on mitigation is to normalize scores by completion length, but we show empirical
ly that this heuristic frequently over-corrects, introducing a bias toward longe
r answers instead. We first analyze these scoring rules, characterizing when sta
ndard and length-normalized accuracy are appropriate and how their length biases
 depend on the distribution of completion lengths. Motivated by this analysis, w
e introduce *Bayesian accuracy*, a scoring rule that computes the posterior prob
ability of each candidate under an explicit prior over answer length, thereby re
moving linear length effects. Bayesian accuracy is a drop-in replacement for lik
elihood-based multiple-choice evaluation, requires no additional forward passes,
 and consistently exhibits lower empirical length bias than both standard and le
ngth-normalized accuracy across benchmarks and few-shot settings.

Balancing Plasticity and Stability with Fast and Slow Successor Features
Raymond Chua, Doina Precup, Blake Aaron Richards
A hallmark of intelligence is the ability to adapt in non-stationary environment
s, yet deep Reinforcement Learning (RL) agents often struggle in such settings.
Prior studies introduce non-stationarity through abrupt shifts in features or dy
namics, whereas real-world environments often evolve gradually through continual
 drift. This distinction has important implications for the ``stability-plastici
ty dilemma'' in RL, as abrupt task changes may demand more plasticity than natur
alistic settings. To address this, we modify existing 3D Miniworld and MuJoCo en
vironments to incorporate naturalistic, continual non-stationarity, and use them
 to examine how stability and adaptation affect performance under continuous env
ironmental change. We find that methods favoring stability, such as synaptic con
solidation, outperform approaches focused on plasticity, such as parameters rese
tting. Motivated by this result, and prior evidence that Successor Features (SFs
) reduce interference, we investigate whether SFs are better consolidation targe
ts than Q-values. Across both environments, applying neuro-inspired synaptic con
solidation to SFs yields superior performance on continually changing settings.
Moreover, consolidation is most effective when SFs are stabilized across multipl
e timescales, which capture complementary aspects of gradual environmental chang
e. Together, these results suggest that stability is more critical in continual
learning when changes are gradual, and that multi-timescale consolidation of pre
dictive representations is an effective approach.
****

Abductive Reasoning with Probabilistic Commonsense
Joseph Cotnareanu, Chiara Roverato, Han Zhou, Didier Chételat, Yingxue Zhang, Ma
rk Coates
Recent efforts to improve the reasoning abilities of Large Language Models (LLMs
) have focused on integrating formal logic solvers within neurosymbolic framewor
ks. A key challenge is that formal solvers lack commonsense world knowledge, pre
venting them from making reasoning steps that humans find obvious. Prior methods
 address this by using LLMs to supply missing commonsense assumptions, but these
 approaches implicitly assume universal agreement on such commonsense facts. In
reality, commonsense beliefs vary across individuals. We propose a probabilistic
 framework for abductive commonsense reasoning that explicitly models this varia
tion, aiming to determine whether most people would judge a statement as true or
 false. We introduce Probabilistic Abductive CommonSense (PACS), a novel algorit
hm that uses an LLM and a formal solver to sample proofs as observations of indi
viduals’ distinct commonsense beliefs, and aggregates conclusions across these s
amples. Empirically, PACS outperforms chain-of-thought reasoning, prior neurosym
bolic methods, and search-based approaches across multiple benchmarks.

Exploring Nonlinear Pathway in Parameter Space for Machine Unlearning
Yingdan Shi, Ren Wang
Machine Unlearning (MU) aims to remove the information of specific training data

from a trained model, ensuring compliance with privacy regulations and user requests. While one line of existing MU methods relies on linear parameter updates via task arithmetic, they suffer from weight entanglement. In this work, we propose a novel MU framework called Mode Connectivity Unlearning (MCU) that leverages mode connectivity to find an unlearning pathway in a nonlinear manner. To further enhance performance and efficiency, we introduce a parameter mask strategy that not only improves unlearning effectiveness but also reduces computational overhead. Moreover, we propose an adaptive adjustment strategy for our unlearning penalty coefficient to adaptively balance forgetting quality and predictive performance during training, eliminating the need for empirical hyperparameter tuning. Unlike traditional MU methods that identify only a single unlearning model, MCU uncovers a spectrum of unlearning models along the pathway. Overall, MCU serves as a plug-and-play framework that seamlessly integrates with any existing MU methods, consistently improving unlearning efficacy. Extensive experiments on the image classification task demonstrate that MCU achieves superior performance. The codes are available at https://github.com/TIML-Group/Mode-Connectivity-Unlearning.

Training with Honeypots: Reshaping How LLMs Fail Under Adversarial Attacks

Samuel Simko, Punya Syon Pandey, Zhijing Jin, Bernhard Schölkopf

Automated red-teaming of Large Language Models (LLMs) commonly relies on attack success rates (ASR) as a proxy for real-world harm, implicitly assuming that judge-detected violations correspond to actionable risk. In practice, safety judges are imperfect, and outputs that satisfy automated criteria for harm can vary widely in their operational usefulness. In this work, we investigate whether model failure modes can be reshaped so that, when defenses fail, they preferentially produce reduced-actionability outputs rather than highly actionable harm. Inspired by honeypots in computer security, we construct responses that are frequently flagged as harmful by automated judges yet provide limited real-world operational value, and treat them as hard negatives in the safety training pipeline. Our findings show that shaping how models fail under attack can improve overall safety by reducing both the real-world impact and the frequency of harmful failures, and serves as a practical complement to ASR-based evaluations.

****

Recontextualization Mitigates Specification Gaming Without Modifying the Specification

Ariana Azarbal, Victor Gillioz, Vladimir Ivanov, Bryce Woodworth, jacob drori, Nevan Wichers, Aram Ebtekar, Alex Cloud, Alexander Matt Turner

Developers often struggle to specify correct training labels and rewards. Perhaps they don't need to. We propose recontextualization, which reduces how often language models "game" training signals, performing misbehaviors those signals mistakenly reinforce. We show recontextualization prevents models from learning to 1) overfit evaluation criteria at the expense of chat response quality; 2) special-case code to pass incorrect tests; 3) overwrite evaluation functions rather than write correct code; and 4) become sycophantic. Our method works by generating completions from prompts discouraging misbehavior and then recontextualizing them as though they were in response to prompts permitting misbehavior. Recontextualization trains language models to resist misbehavior even when instructions permit it. This mitigates the reinforcement of misbehavior from misspecified training signals, reducing specification gaming without improving the supervision signal.

The Cost of Information: Phase Transitions in Contextual Bandits with Paid Observations

Xueping Gong, Jiheng Zhang

We study contextual bandits with paid observations, where the learner actively chooses which actions to observe at a given cost in each round, with the goal of minimizing total regret that jointly accounts for learning loss and observation expenditure. We develop a near-optimal algorithm for adversarial environments and show that even small observation costs fundamentally raise the minimax regret

order. We further uncover a novel phase transition under a free observation budget: below a critical threshold, free observations only reduce total cost without improving the regret rate; above it, asymptotic improvements become possible. To exploit this phenomenon, we design a meta-controller that adaptively switches between strategies to achieve near-optimal performance across all budget regimes. To handle large or infinite policy spaces, we also propose an oracle-efficient algorithm under a function approximation framework that maintains rigorous guarantees with computational efficiency. Our analysis also connects to related problems including switching costs, budgeted constraints, model misspecification, and knapsack bandits. Numerical experiments validate our theoretical findings.

Revisiting Robustness for LLM Safety Alignment via Selective Geometry Control
Yonghui Yang, Wenjian Tao, Jilong Liu, Xingyu Zhu, Junfeng Fang, Huang Weibiao, Le Wu, Richang Hong, Tat-Seng Chua
Safety alignment of large language models remains brittle under domain shift and noisy preference supervision. Most existing robust alignment methods focus on uncertainty in alignment data, while overlooking optimization-induced fragility in preference-based objectives. In this work, we revisit robustness for LLM safety alignment from an optimization geometry perspective, and argue that robustness failures cannot be addressed by data-centric methods alone. We propose \textit{ShaPO}, a geometry-aware preference optimization framework that enforces worst-case alignment objectives via selective geometry control over alignment-critical parameter subspace. By avoiding uniform geometry constraints, ShaPO mitigates the over-regularization that can harm robustness under distribution shift. We instantiate ShaPO at two levels: token-level ShaPO stabilizes likelihood-based surrogate optimization, while reward-level ShaPO enforces reward-consistent optimization under noisy supervision. Across diverse safety benchmarks and noisy preference settings, ShaPO consistently improves safety robustness over popular preference optimization methods. Moreover, ShaPO composes cleanly with data-robust objectives, yielding additional gains and empirically supporting the proposed optimization-geometry perspective. The code is available at \url{https://github.com/liujilong0116/ShaPO}.

CORAL: Uncertainty-Aware Regulation of Exposure Concentration in Recommender Systems
Nitin Bisht, Linjiang Guo, Xiuwen Gong, Huan Huo, Guandong Xu
Recommender systems (RS) may suffer from feedback-driven exposure concentration, where repeated engagement optimization collapses exposure onto a narrow set of categories, reducing catalog coverage and degrading long-horizon learning. Existing methods are often post hoc and typically lack principled uncertainty-aware risk estimates for regulating exposure under endogenous feedback. We therefore propose **CORAL**, a model-agnostic, uncertainty-aware framework that formulates exposure regulation as a constrained sequential decision problem. Specifically, we model self-reinforcing interactions to construct an exposure-saturation state, then derive an upper confidence bound on category-conditioned violation risk from observed history and incorporate it through a state-dependent penalty for adaptive intervention near saturation. Moreover, we provide theoretical guarantees for risk bounds, finite-time recovery, and efficient long-term performance. Extensive experiments on real-world datasets and controlled simulations validate the effectiveness of the proposed framework, which aligns with our theoretical analysis. Our code is available at: https://github.com/downw/CORAL.

CoME: Empowering Channel-of-Mobile-Experts with Informative Hybrid-Capabilities Reasoning
Yuxuan Liu, Weikai Xu, Kun Huang, Changyu Chen, Jiankun Zhao, Pengzhi Gao, Wei Liu, Jian Luan, Shuo Shang, Bo Du, Ji-Rong Wen, Rui Yan
Mobile Agents requires hybrid-capabilities reasoning, including screen summary, subtask planning, action decision and action function. However, existing agents struggle to achieve both decoupled enhancement and balanced integration of these capabilities. To address these challenges, we propose Channel-of-Mobile-Experts

(CoME), a novel agent architecture consisting of four distinct experts, each aligned with a specific reasoning stage, CoME activates the corresponding expert to generate output tokens in each reasoning stage via output-oriented activation. To empower CoME with hybrid-capabilities reasoning, we introduce a progressive training strategy: Expert-FT enables decoupling and enhancement of different experts' capability; Router-FT aligns expert activation with the different reasoning stage; CoT-FT facilitates seamless collaboration and balanced optimization across multiple capabilities. To mitigate error propagation in hybrid-capabilities reasoning, we propose InfoGain-Driven DPO (Info-DPO), which uses information gain to evaluate the contribution of each intermediate step, thereby guiding CoME toward more informative reasoning. Comprehensive experiments show that CoME outperforms dense mobile agents and MoE methods on both AITZ and AMEX datasets.

Model Fusion via Retrofitting

Phoomraphee Luenam, Andreas Spanopoulos, Amit Sant, Sotiris Anagnostidis, Thomas Hofmann, Sidak Pal Singh

Model fusion seeks to combine independently trained neural networks into a single model without retraining, but is complicated by representational divergence arising from permutation invariance, random initialization, and heterogeneous training data. Existing methods struggle particularly in zero-shot settings under non-IID data distributions, and are often limited to specific architectures or pairwise fusion. We introduce a neuron-centric family of fusion algorithms that frames fusion as a principled representation-matching problem: intermediate neurons across parent models are grouped into target representations, which the fused model's corresponding sub-networks are then trained to approximate. Unlike prior work, our approach incorporates neuron attribution scores to bias alignment toward salient features, and can be applied to any architecture modularizable as a DAG of levels—empirically validated on VGGs, ResNets, and ViTs. Experiments across standard benchmarks show consistent improvements over existing fusion methods, with the largest gains in zero-shot and non-IID scenarios. Code is available at https://github.com/AndrewSpano/model-fusion-via-retrofitting}{https://github.com/AndrewSpano/model-fusion-via-retrofitting.

SPARKLING: Balancing Signal Preservation and Symmetry Breaking for Width-Progressive Learning

Qifan Yu, Xinyu Ma, Zhijian Zhuo, Minrui Wang, Deyi Liu, Shiyi Zhan, Yiyuan Ma, liang xiang, Xingyan Bin, Di He

Progressive Learning (PL) reduces pre-training computational overhead by gradually increasing model scale. While prior work has extensively explored depth expansion, width expansion remains significantly understudied, with the few existing methods limited to the early stages of training. However, expanding width during the mid-stage is essential for maximizing computational savings, yet it remains a formidable challenge due to severe training instabilities.

Empirically, we show that naive initialization at this stage disrupts activation statistics, triggering loss spikes, while copy-based initialization introduces gradient symmetry that hinders feature diversity.

To address these issues, we propose **SPARKLING** (balancing **S**ignal **P**reservation **A**nd symmet**R**y brea**K**ing for width-progressive **L**earn**ING**), a novel framework for mid-stage width expansion.

Our method achieves signal preservation via RMS-scale consistency, stabilizing activation statistics during expansion. Symmetry breaking is ensured through asymmetric optimizer state reset and asymmetric learning rate re-warmup. Extensive experiments on dense and Mixture-of-Experts (MoE) models demonstrate that, across multiple width axes and optimizer families, SPARKLING consistently outperforms training from scratch and reduces training cost by up to 35% under $2\times$ width expansion.

Reasoning Structure of Large Language Models

Frédéric Berdoz, Luca A Lanzendörfer, Fabian Farestam, Roger Wattenhofer

Large reasoning models (LRMs) are often evaluated using metrics such as final-an

swer accuracy or token count. However, identical scores on these metrics can hid e fundamentally different reasoning structures. To address this limitation, we i ntroduce a scalable LRM benchmark of logic puzzles and a pipeline that converts unstructured traces into verifiable reasoning graphs of claims and dependencies. This turns reasoning into a structured, measurable object whose topology can be quantitatively analyzed. Building on this, we define a reasoning efficiency met ric that quantifies how concentrated the model's logical flow is. Our analysis o n open-source reasoning models shows that structural measurements separate behav iors that token count and accuracy conflate, providing a practical tool for diag nosing failure modes and comparing how reasoning scales with puzzle difficulty.

CodeClash: Benchmarking Goal-Oriented Software Engineering
John Yang, Kilian Lieret, Joyce Yang, Carlos E. Jimenez, Muhtasham Oblokulov, Ar yan Siddiqui, Ofir Press, Ludwig Schmidt, Diyi Yang
Existing coding benchmarks evaluate language models (LMs) on concrete, well-spec ified tasks such as fixing bugs or writing tests.
However, human programmers do not spend all day addressing isolated GitHub issue s.
Instead, real-world software development is grounded in the pursuit of high-leve l goals.
Evaluating whether LMs can iteratively develop code to accomplish open-ended obj ectives without explicit guidance remains an open challenge.
We introduce CodeClash, a benchmark where LMs compete in multi-round tournaments to build the best codebase for achieving a competitive objective.
Each round proceeds in two parts: agents edit their code, then their codebases c ompete head-to-head in a code arena that determines winners based on objectives like score maximization, resource acquisition, or survival.
Models must decide for themselves how to improve their code both absolutely and against their opponents.
We run 1680 tournaments to evaluate 8 LMs across 6 arenas, revealing how models exhibit diverse development styles and share fundamental limitations in strategi c reasoning.
Models also struggle with long-term codebase maintenance; repositories become pr ogressively messy and redundant.
Top models lose every round against expert human programmers.
We open-source CodeClash to advance the study of autonomous, goal-oriented code development.
****

Scalable Power Sampling: Unlocking Efficient, Training-Free Reasoning for LLMs v ia Distribution Sharpening
Xiaotong Ji, Rasul Tutunov, Matthieu Zimmer, Haitham Bou Ammar
Reinforcement learning (RL) post-training is a dominant approach for improving t he reasoning performance of large language models (LLMs), yet growing evidence s uggests that its gains arise primarily from distribution sharpening rather than the acquisition of new capabilities. Recent work has shown that sampling from th e power distribution of LLMs using Markov chain Monte Carlo (MCMC) can recover p erformance comparable to RL post-training without relying on external rewards; h owever, the high computational cost of MCMC makes such approaches impractical fo r widespread adoption. In this work, we propose a theoretically grounded alterna tive that eliminates the need for iterative MCMC. We derive a novel formulation showing that the global power distribution can be approximated by a token-level scaled low-temperature one, where the scaling factor captures future trajectory quality. Leveraging this insight, we introduce a training-free and verifier-free algorithm that sharpens the base model's generative distribution autoregressive ly. Empirically, we evaluate our method on math, QA, and code tasks, and show th at our method matches or surpasses one-shot GRPO without relying on any external rewards, while reducing inference latency by over $10\times$ compared to MCMC-b ased sampling.

DualCOIL: Offline Imitation Learning from Contrasting Demonstrations

Huy Hoang, Tien Anh Mai, Pradeep Varakantham, Tanvi Verma
Offline imitation learning typically learns from expert and unlabeled demonstrations, yet often overlooks the valuable signal in explicitly undesirable behaviors. In this work, we study offline imitation learning from contrasting behaviors, where the dataset contains both expert and undesirable demonstrations along with an unlabeled set of demonstrations. We propose a novel formulation that optimizes a difference of KL divergences over the state-action visitation distributions of expert and undesirable (or bad) data. Although the resulting objective is a DC (Difference-of-Convex) program, we prove that it becomes *convex* when expert demonstrations outweigh undesirable demonstrations, enabling a practical and stable non-adversarial training objective. Our method avoids adversarial training and handles both positive and negative demonstrations in a unified framework. Extensive experiments on standard offline imitation learning benchmarks demonstrate that our approach consistently outperforms state-of-the-art baselines.
****

LARFT: Closing the Cognition-Action Gap for Length Instruction Following in Large Language Models
Wei Zhang, Lintong Du, Yuanhe Zhang, Zhenhong Zhou, Kun Wang, Li Sun, Sen Su
Despite the strong performance of Large Language Models (LLMs) on complex instruction-following tasks, precise control of output length remains a persistent challenge. Existing methods primarily attempt to enforce length constraints by externally imposing length signals or optimization objectives, while largely overlooking the underlying limitation: the model's intrinsic deficit in length cognition. To address this, we propose **LARFT** (**L**ength-**A**ware **R**einforcement **F**ine-**T**uning), a training framework that aligns the model's length cognition with its action. Specifically, LARFT integrates length-oriented reinforcement learning with a hindsight length awareness. By transforming on-policy data into hindsight self-awareness tasks where the model learns to identify the actual length of its own generation, LARFT jointly optimizes the model’s internal representation of length information and refines its policy to satisfy length constraints, thereby achieving precise and reliable length instruction following. Extensive experiments across four base models demonstrate that LARFT outperforms existing baselines, achieving an average improvement of **+20.92** points across three length instruction following benchmarks with only a marginal decline of **-1.45** points on four general capability benchmarks. Our code is available at https://github.com/Captain-zhangw/LARFT.

Recurrent Equivariant Constraint Modulation: Learning Per-Layer Symmetry Relaxation from Data
Stefanos Pertigkiozoglou, Mircea Petrache, Shubhendu Trivedi, Kostas Daniilidis
Equivariant neural networks exploit underlying task symmetries to improve generalization, but strict equivariance constraints can induce more complex optimization dynamics that can hinder learning. Prior work addresses these limitations by relaxing strict equivariance during training, but typically relies on prespecified, explicit, or implicit target levels of relaxation for each network layer, which are task-dependent and costly to tune. We propose Recurrent Equivariant Constraint Modulation (RECM), a layer-wise constraint modulation mechanism that learns appropriate relaxation levels solely from the training signal and the symmetry properties of each layer's input-target distribution, without requiring any prior knowledge about the task-dependent target relaxation level. We demonstrate that under the proposed RECM update, the relaxation level of each layer provably converges
to a value upper-bounded by its symmetry gap, namely the degree to which its input-target distribution deviates from exact symmetry. Consequently, layers processing symmetric distributions recover full equivariance, while those with approximate symmetries retain sufficient flexibility to learn non-symmetric solutions when warranted by the data. Empirically, RECM outperforms prior methods across diverse exact and approximate equivariant tasks, including the challenging molecular conformer generation on the GEOM-Drugs dataset.

Calibrated Preference Learning: The Case of Label Ranking
Santo M. A. R. Thies, Viktor Bengs, Timo Kaufmann, Sebastian Josef Vollmer, Eyke Hüllermeier
Calibration, the alignment of predicted probabilities with true outcome frequencies, is essential for reliable decision-making.
While extensively studied for classification and regression, calibration has not been formally addressed for probabilistic label ranking, where the goal is to predict a distribution over orderings of a label set. Naively treating rankings as classes ignores their structure and fails to capture important modalities such as pairwise and top-k predictions. We formalize calibration for label ranking and develop a hierarchy of notions covering full rankings, sub-rankings, and top-k rankings. We prove that full-rank calibration implies the others but not conversely, and sub-ranking and top-k calibration are incomparable. Empirically, we find popular label ranking models are often poorly calibrated, with substantial differences between sub-ranking and top-k metrics. Applying our framework to RLHF reward models, we find that calibration correlates strongly but not perfectly with benchmark accuracy, suggesting it captures a meaningful quality dimension beyond top-1 accuracy. These findings motivate future work on understanding the downstream effects of miscalibration and developing methods to correct it.

Adaptive Preconditioners Trigger Loss Spikes in Adam
Zhiwei Bai, Zhangchen Zhou, Jiajie Zhao, Xiaolong Li, Zhiyu li, Feiyu Xiong, Hongkang Yang, Yaoyu Zhang, Zhi-Qin John Xu
Loss spikes commonly emerge during neural network training with the Adam optimizer across diverse architectures and scales, yet their underlying mechanism remains elusive. While previous explanations attribute these phenomena to sharper loss landscapes at lower loss, we show that landscape geometry alone is insufficient to explain the phenomenon. In this work, we pinpoint the root cause in the internal dynamics of Adam's second moment estimator. We identify a critical ``decoupling'' mechanism where the adaptive preconditioner v_t fails to track the instantaneous squared gradients g_t^2, causing the adaptive mechanism to effectively fail. This decoupling allows the preconditioner to decay autonomously despite rising gradients, which pushes the maximum eigenvalue of the preconditioned Hessian beyond the stability threshold $2/\eta$ for sustained periods, manifesting as dramatic loss spikes. Through a quadratic approximation analysis, we theoretically and experimentally characterize five distinct stages of spike evolution and propose a predictor for anticipating spikes based on gradient-directional curvature. We empirically find that the proposed loss spike mechanism, although derived from simplified models, generalizes well to practical scenarios ranging from small neural networks to large-scale Transformers.
****
Ego3S: Select, Strengthen, and Synchronize for Efficient Egocentric Reasoning
Shenshen Li, Kaiyuan Deng, RuoHuai Xie, Xing Xu, Heng Tao Shen, Yazhou Yao, Fumin Shen
Egocentric reasoning fundamentally differs from third-person understanding in LVLMs. Third-person settings offer wide and stable contexts with consistent global regularities, allowing models to utilize broad statistical correlations. In contrast, egocentric scenes are highly dynamic and heterogeneous, where decisive cues are localized and atypical. Therefore, robust egocentric reasoning requires models to focus on ''what is seen now'', i.e., the immediate visual input. However, existing methods tend to exhibit "inertial thinking'', relying excessively on language priors and global context. To address this limitation, we propose a novel three-stage Ego3S framework to ground models' reasoning in interaction evidence. Specifically, before training, we first utilize the counterfactual-based paradigm to select high-value samples that effectively activate multimodal reasoning, thus mitigating the over-reliance on language priors and global context. Moreover, we introduce an interaction-centric reward for reinforcement learning that strengthens the model’s sensitivity to localized interaction cues. Finally, during training, we employ a variance-aware learning schedule that monitors reward distributions to dynamically synchronize data selection with the evolving model

competence. Experiments on five datasets show that our Ego3S consistently achieves superior performance using only 26.5% of the training data, while reducing computational costs by over 46%. Code is available at https://github.com/Mrshenshen/Ego3S.

Demystifying Multimodal Biomolecular Co-design With Intrinsic Geodesic Coupling
Keyue Qiu, Xintong Wang, Zhilong Zhang, Hao Zhou, Wei-Ying Ma
Biomolecules such as proteins and small-molecule ligands play a central role in biological systems, arising from the tight interplay between sequence and three-dimensional structure.
Recent generative models for biomolecular co-design aim to capture this interplay by jointly modeling coupled modalities.
However, existing approaches largely adopt a parallel execution of marginal generative processes, implicitly enforcing fixed synchronous coupling.
We argue that a critical but overlooked degree of freedom lies in how these marginal processes are \emph{temporally coupled} during training and generation, where inappropriate coupling can introduce high-variance supervision and inconsistent intermediate states, affecting modality consistency.
To address this, we introduce GeoCoupling, a systematic framework that optimizes for temporal couplings between heterogeneous modalities.
Empirical results across structure-based drug design and unconditional protein design demonstrate the learned couplings consistently outperform synchronous and randomly coupled baselines, yielding biomolecules with improved physical validity and diversity.
****
RLCracker: Evaluating the Worst-Case Vulnerability of LLM Watermarks with Adaptive RL Attacks
Hanbo Huang, Yiran Zhang, Hao Zheng, Xuan Gong, Yihan Li, Lin Liu, Zhuotao Liu, Shiyu Liang
Large language model (LLM) watermarking has shown promise in detecting AI-generated content and mitigating misuse, with prior work claiming robustness against paraphrasing and text editing. In this paper, we argue that existing evaluations are not sufficiently adversarial, obscuring critical vulnerabilities and overstating the security. To address this, we introduce the *adaptive robustness radius*, a formal metric that quantifies the worst-case resilience of watermarks against adaptive adversaries. By lifting the paraphrase space into a KL-divergence ball, we approximate this radius and theoretically demonstrate that optimizing the attack context and model parameters can significantly reduce the approximated radius, making watermarks highly vulnerable to paraphrase attacks.
Leveraging this insight, we propose RLCracker, a reinforcement learning (RL)–based adaptive attack that erases watermarks while preserving semantic fidelity. RLCracker requires only *limited* watermarked examples and *zero* access to the detector. Despite weak supervision, it empowers a 3B model to achieve 98.5\% removal success with minimal semantic shift on 1,500-token Unigram-marked texts after training on only *100* short samples. This performance dramatically exceeds 6.75\% by GPT-4o and generalizes across five model sizes over ten watermarking schemes. Our code is available in this repository.

From Token to Token Pair: Efficient Prompt Compression for Large Language Models in Clinical Prediction
Mingcheng Zhu, Zhiyao Luo, Yu Liu, Tingting Zhu
By processing electronic health records (EHRs) as natural language sequences, large language models (LLMs) have shown potential in clinical prediction tasks such as mortality prediction and phenotyping. However, longitudinal or highly frequent EHRs often yield excessively long token sequences that result in high computational costs and even reduced performance. Existing solutions either add modules for compression or remove less important tokens, which introduce additional inference latency or risk losing clinical information. To achieve lossless compression of token sequences without additional cost or loss of performance, we propose Medical Token-Pair Encoding (MedTPE), a layered method that extends standard

tokenisation for EHR sequences. MedTPE merges frequently co-occurring medical token pairs into composite tokens, providing lossless compression while preserving the computational complexity through a dependency-aware replacement strategy. Only the embeddings of the newly introduced tokens of merely 0.5-1.0\% of the LLM's parameters are fine-tuned via self-supervised learning. Experiments on real-world datasets for two clinical scenarios demonstrate that MedTPE reduces input token length by up to 31\% and inference latency by 34-63\%, while maintaining or even improving both predictive performance and output format compliance across multiple LLMs and four clinical prediction tasks. Furthermore, MedTPE demonstrates robustness across different input context lengths and generalisability to scientific and financial domains and different languages. The code is available in the GitHub repository.

GHOST: Unmasking Phantom States in Mamba2 via Grouped Hidden-state Output-aware Selection & Truncation
Michael Menezes, Anastasios Kyrillidis
While Mamba2's expanded state dimension enhances temporal modeling, it incurs substantial inference overhead that saturates bandwidth during autoregressive generation. Standard pruning methods fail to address this bottleneck: unstructured sparsity leaves activations dense, magnitude-based selection ignores runtime dynamics, and gradient-based methods impose prohibitive costs. We introduce GHOST (Grouped Hidden-state Output-aware Selection and Truncation), a structured pruning framework that approximates control-theoretic balanced truncation using only forward-pass statistics. By jointly measuring controllability and observability, GHOST rivals the fidelity of gradient-based methods without requiring backpropagation. As a highlight, on models ranging from 130M to 2.7B parameters, our approach achieves a 50% state-dimension reduction with approximately 1 perplexity point increase on WikiText-2. Code is available at https://github.com/Menezmic21/mamba2_ghost.

Active Continual Learning with Metaplastic Binary Bayesian Neural Networks
Kellian Cottart, Theo Ballet, Djohan Bonnet, Damien Querlioz
Always-on edge systems must keep learning as conditions change under tight compute budgets and must detect unreliable predictions. Bayesian binary neural networks are attractive in this setting, but mean-field Bernoulli posteriors can saturate on long non-stationary streams, wiping out epistemic uncertainty and freezing plasticity. We propose BiMU, derived from a bounded-memory variational objective that balances stability, plasticity, and forgetting. BiMU combines a data term with controlled relaxation toward the prior and an uncertainty-dependent step size that prevents saturation and sustains informative uncertainty. This non-degenerate posterior enables fully online, buffer-free active querying via Monte Carlo disagreement, reducing label queries and backpropagation updates under imbalance. BiMU sustains learning and strong OOD detection on 1000-task Permuted-MNIST, and on OpenLORIS-Object achieves up to 32× label/update savings at matched accuracy under class imbalance and feature compression.

Three Years of r/ChatGPT: Societal Impact Evaluations from Social Media Data
Jessica Dai, Sean Garcia, Emma Pierson, Benjamin Recht, Nika Haghtalab
ChatGPT was launched on November 30, 2022; the r/ChatGPT subreddit was created just one day later. Since then, chatbot-based AI products have gone from niche proofs-of-concept to widely-used household names. However, the ways in which adoption has developed, especially among non-experts, remains poorly understood. In this paper, we propose a principled framework for using social media as a data source for understanding the societal impact of widely-adopted consumer AI products, as well as a general approach to monitoring for societally-impactful trends in real time. We apply our framework to conduct what is, to the best of our knowledge, the first longitudinal study of r/ChatGPT. We find that, overall, r/ChatGPT posts over time illustrate the normalization of ChatGPT as an everyday consumer product rather than an exceptional, novel technology. However, our retrospective analysis also finds that posts about using ChatGPT for mental health support,

and posts about developing emotional attachments to ChatGPT, both rise steadily in frequency immediately after the launch of GPT-4o in May 2024. We show that our real-time method can detect the increase in emotional engagement as early as October 2024—months before OpenAI made any (public) acknowledgment of this impact.

Finite-Width Neural Tangent Kernels from Feynman Diagrams

Max Guillen, Philipp Misof, Jan E Gerken

Neural tangent kernels (NTKs) are a powerful tool for analyzing deep, non-linear neural networks. In the infinite-width limit, NTKs can easily be computed for most common architectures, yielding full analytic control over the training dynamics. However, at infinite width, important properties of training such as NTK evolution or feature learning are absent. Nevertheless, finite width effects can be included by computing corrections to the Gaussian statistics at infinite width. We introduce Feynman diagrams for computing finite-width corrections to NTK statistics. These dramatically simplify the necessary algebraic manipulations and enable the computation of layer-wise recursion relations for arbitrary statistics involving preactivations, NTKs and certain higher-derivative tensors (dNTK and ddNTK) required to predict the training dynamics at leading order. We demonstrate the feasibility of our framework by extending stability results for deep networks from preactivations to NTKs and proving the absence of finite-width corrections for scale-invariant nonlinearities such as ReLU on the diagonal of the Gram matrix of the NTK. We numerically implement the complete set of equations necessary to compute the first-order corrections for arbitrary inputs and demonstrate that the results follow the statistics of sampled neural networks for widths $n \gtrsim 20$.

MESA: Improving MoE Safety Alignment via Decentralized Expertise

Yitong Sun, Yao Huang, Teng Li, Ranjie Duan, Yichi Zhang, Xingjun Ma, Hui Xue, Xingxing Wei

Mixture-of-Experts (MoE) architectures scale Large Language Models (LLMs) efficiently, enabling greater capacity with reduced computational cost by dynamically routing inputs to relevant experts, yet introduce a critical vulnerability: Safety Sparsity, where safety capabilities concentrate in few experts, making them susceptible to adversarial bypassing. Meanwhile, conventional alignment methods uniformly adapt all parameters, ignoring their functional differences and inadvertently degrading performances.

To address these challenges, we propose MESA (MoE Safety Alignment), a targeted alignment framework for MoE-based LLMs that strategically decentralizes safety responsibility to maximize coverage while minimizing interference with utility. Based on Optimal Transport (OT) theory, MESA operates through two mechanisms: (1) Expert Capacity Reallocation uses a transport cost matrix to distribute safety duties to the most cost-effective experts, and (2) Dynamic Routing Refinement constrains the router to precisely activate these decentralized modules. Experiments show that MESA achieves robust defensive performance against varied harmful benchmarks while preserving helpfulness. Code is available at https://github.com/lorraine021/MESA.

MoLF: Mixture-of-Latent-Flow for Pan-Cancer Spatial Gene Expression Prediction from Histology

Susu Hu, Stefanie Speidel

Inferring spatial transcriptomics (ST) from histology enables scalable histogenomic profiling, yet current methods are largely restricted to single-tissue models. This fragmentation fails to leverage biological principles shared across cancer types and hinders application to data-scarce scenarios. While pan-cancer training offers a solution, the resulting heterogeneity challenges monolithic architectures. To bridge this gap, we introduce **MoLF** (*Mixture-of-Latent-Flow*), a generative model for pan-cancer histogenomic prediction. MoLF leverages a conditional Flow Matching objective to map noise to the gene latent manifold, parameterized by a Mixture-of-Experts (MoE) velocity field. By dynamically routing inpu

ts to specialized sub-networks, this architecture effectively decouples the optimization of diverse tissue patterns. Our experiments demonstrate that MoLF establishes a new state-of-the-art, consistently outperforming both specialized and foundation model baselines on pan-cancer benchmarks. Furthermore, MoLF exhibits zero-shot generalization to cross-species data, suggesting it captures fundamental, conserved histo-molecular mechanisms.

LoSA: Locality Aware Sparse Attention in Diffusion Language Models

Haocheng Xi, Harman Singh, Yuezhou Hu, Coleman Richard Charles Hooper, Rishabh Tiwari, Aditya Tomar, Minjae Lee, Wonjun Kang, Michael W. Mahoney, Chenfeng Xu, Kurt Keutzer, Amir Gholami

Block-wise diffusion language models (DLMs) generate multiple tokens in parallel, offering a promising alternative to autoregressive decoding. However, their inference efficiency remains bottlenecked by memory-bound attention in long-context scenarios. Naïve sparse attention is ineffective for DLMs due to the KV inflation problem: different queries select different prefix positions, causing the union of accessed KV pages to remain large.

To address this challenge, we observe that block-wise diffusion exhibits locality of representation changes across denoising steps: only a small fraction of tokens (active tokens) undergo significant hidden-state updates, while most tokens (stable tokens) remain nearly unchanged.

Based on this insight, we propose LoSA (Locality-aware Sparse Attention), which reuses cached prefix-attention results for stable tokens and applies sparse attention only to active tokens with large representation changes. This design reduces the number of queries contributing to the union of KV indices, substantially shrinking the KV pages that must be loaded.

Across multiple block-wise DLMs and reasoning benchmarks, LoSA preserves near-dense accuracy while significantly improving efficiency, achieving up to 4.14× speedup over dense attention on RTX A6000 GPUs. LoSA also delivers up to 5% average improvement over baselines across all datasets and configurations, demonstrating the effectiveness of the proposed method.

DADP: Domain Adaptive Diffusion Policy

Pengcheng Wang, Qinghang Liu, Haotian Lin, Yiheng Li, Guojian Zhan, Masayoshi Tomizuka, Yixiao Wang

Learning domain adaptive policies that can generalize to unseen transition dynamics, remains a fundamental challenge in learning-based control.

Substantial progress has been made through domain representation learning to capture domain-specific information, thus enabling domain-aware decision making.

We analyze the process of learning domain representations through dynamical prediction and find that selecting contexts adjacent to the current step causes the learned representations to entangle static domain information with varying dynamical properties.

Such mixture can confuse the conditioned policy, thereby constraining zero-shot adaptation.

To tackle the challenge, we propose DADP (Domain Adaptive Diffusion Policy), which achieves robust adaptation through unsupervised disentanglement and domain-aware diffusion injection.

First, we introduce Lagged Context Dynamical Prediction, a strategy that conditions future state estimation on a historical offset context; by increasing this temporal gap, we unsupervisedly disentangle static domain representations by filtering out transient properties.

Second, we integrate the learned domain representations directly into the generative process by biasing the prior distribution and reformulating the diffusion target.

Extensive experiments on challenging benchmarks across locomotion and manipulation demonstrate the superior performance, and the generalizability of DADP over prior methods.

More visualization results are available on the https://outsider86.github.io/DomainAdaptiveDiffusionPolicy/.

IndexMem: Learned KV-Cache Eviction with Latent Memory for Long-Context LLM Infe
rence
Xintong Yang, Hao Gu, Binxing Xu, Lujun Li, Bei Liu, Jiacheng Liu, Qiyuan Zhu, Y
ike Guo, Sirui Han
Large Language Models (LLMs) are increasingly expected to operate over long cont
exts, yet standard softmax attention incurs a KV cache that grows linearly with
sequence length, quickly becoming the bottleneck for long context inference. A p
ractical remedy is to evict less important KV entries; however, existing evictio
n policies are largely heuristic and struggle to capture the rich, input-depende
nt distribution of token importance. In this work, we introduce a **learnable in
dexer** that predicts KV importance, enabling more accurate retention of critica
l tokens. Meanwhile, naively evicting tokens permanently discards their informat
ion, leading to irreversible forgetting and degraded retrieval over long ranges.
 To address this, we propose a lightweight **latent memory module** that compres
ses evicted tokens into a compact, online-updated state and provides residual re
adouts to compensate for the attention contributions lost through KV eviction.
Collectively, our method enables accurate long-context inference under a bounded
 KV budget, delivering consistent improvements on RULER (4K/16K) across Qwen, Mi
stral, and Llama models (up to 25 points under aggressive eviction), markedly mo
re stable Needle-in-a-Haystack retrieval, and superior LongBench scores and comp
ression curves compared to existing eviction policies.

Fair Transit Stop Placement: A Clustering Perspective and Beyond
Haris Aziz, Ling Gai, Yuhang Guo, Jeremy Vollen
We study the transit stop placement (TrSP) problem in general metric spaces, whe
re agents travel between source–destination pairs and may either walk directly o
r utilize a shuttle service via selected transit stops. We investigate fairness
in TrSP through the lens of justified representation (JR) and the core, and unco
ver a structural correspondence with fair clustering. Specifically, we show that
 a constant-factor approximation to proportional fairness in clustering can be u
sed to guarantee a constant-factor bi-parameterized approximation to core. We es
tablish a lower bound of 1.366 on the approximability of JR, and moreover show
 that no clustering algorithm can approximate JR within a factor better than 3
. Going beyond clustering, we propose the Expanding Cost Algorithm, which achiev
es a tight 2.414-approximation for JR, but does not give any bounded core guar
antee. In light of this, we introduce a parameterized algorithm that interpolate
s between these approaches, and enables a tunable trade-off between JR and core.
 Finally, we complement our results with an experimental analysis using small-ma
rket public carpooling data.

On Group Relative Policy Optimization Collapse in Agent Search: The Lazy Likelih
ood-Displacement
Wenlong Deng, Yushu Li, Boying Gong, Yi Ren, Christos Thrampoulidis, Xiaoxiao Li
Tool-integrated (TI) reinforcement learning (RL) enables large language models (
LLMs) to perform multi-step reasoning by interacting with external tools such as
 search engines and retrievers. Group Relative Policy Optimization (GRPO), exemp
lified by the recent Search-R1, offers fast convergence and a value-free formula
tion that makes it appealing for this setting, yet consistently suffers from tra
ining collapse. We identify Lazy Likelihood Displacement (LLD), a systematic red
uction or stagnation in the likelihood of both correct and incorrect responses,
as the core mechanism driving this failure. LLD emerges early and triggers a sel
f-reinforcing LLD Death Spiral, where declining likelihood leads to low-confiden
ce responses, inflating gradients, and ultimately causing collapse. We empirical
ly characterize this process across models on a Search-R1-style, search-integrat
ed question answering task, revealing a consistent three-phase trajectory: early
 stagnation, steady decay, and accelerated collapse. To address this, we propose
 a likelihood-preserving regularization LLDS that activates only when a response
 action’s likelihood decreases, and regularizes only the tokens responsible. Thi
s fine-grained structure mitigates LLD with minimal interference. Our method sta

bilizes training, prevents gradient explosion, and yields substantial performanc e improvements across seven benchmarks, including relative improvements of +45.2 % on Qwen2.5-3B and +37.1% on Qwen2.5-7B over vanilla GRPO training. Our results establish LLD as a previously overlooked bottleneck in GRPO- based TIRL and pro vide a practical path toward stable, scalable training of tool-integrated RL.

TextME: Bridging Unseen Modalities Through Text Descriptions
Soyeon Hong, Jinchan Kim, Jaegook You, Seungtaek Choi, Suha Kwak, Hyunsouk Cho
Expanding multimodal representations to novel modalities is constrained by relia nce on largescale paired datasets (e.g., text–image, text–audio, text–3D, text–m olecule), which are costly and often infeasible in domains requiring expert anno tation such as medical imaging and molecular analysis. We introduce TextME, to t he best of our knowledge the first modality expansion framework based on text-on ly training, projecting diverse modalities into LLM embedding space as a unified anchor. Our approach exploits the geometric structure of pretrained contrastive encoders to enable zero-shot cross-modal transfer using only text descriptions, without paired supervision. We empirically validate that such consistent modali ty gaps exist across image, video, audio, 3D, X-ray, and molecular domains, demo nstrating that text-only training can preserve substantial performance of pretra ined encoders. We further show that our framework enables emergent cross-modal r etrieval between modality pairs not explicitly aligned during training (e.g., au dioto-image, 3D-to-image). These results establish text-only projection training as a practical alternative to paired supervision for modality expansion. The co de is available at https://soyeonhh.github.io/TextME/.

dTRPO : Trajectory Reduction in Policy Optimization of Diffusion Large Language Models
Wenxuan Zhang, Lemeng Wu, Changsheng Zhao, Ernie Chang, Mingchen Zhuge, Zechun L iu, DiJia Su, Hanxian Huang, Jun Chen, Chong Zhou, Raghuraman Krishnamoorthi, Vi kas Chandra, Mohamed Elhoseiny, Wei Wen
Diffusion Large Language Models (dLLMs) introduce a new paradigm for language ge neration, which in turn presents new challenges for aligning them with human pre ferences. In this work, we aim to improve the policy optimization for dLLMs by r educing the cost of the trajectory probability calculation, thereby enabling sca led-up offline policy training. We prove that: (i) under reference policy regula rization, the probability ratio of the newly unmasked tokens is an unbiased esti mate of that of intermediate diffusion states, and (ii) the probability of the f ull trajectory can be effectively estimated with a single forward pass of a re-m asked final state. By integrating these two trajectory reduction strategies into a policy optimization objective, we propose Trajectory Reduction Policy Optimiz ation (dTRPO). We evaluate dTRPO on 7B dLLMs across instruction-following and re asoning benchmarks. Results show that it substantially improves the core perform ance of state-of-the-art dLLMs, achieving gains of up to 9.6% on STEM tasks, up to 4.3% on coding tasks, and up to 3.0% on instruction-following tasks. Moreover , dTRPO exhibits strong training efficiency due to its offline, single-forward n ature, and achieves improved generation efficiency through high-quality outputs.

Proteus: Lookup-Free Trellis-Coded Quantization by Lattice-Breaking Compute Code s for 2-Bit LLMs
Zhengwu Yang, Xunchao Li, Ke Cheng, Kunlong Liu, Jianfeng Yang, Haoshuang Wang, Kaipeng Deng, Qingqing Dang, Yanlin Sha, Yanjun Ma, Dianhai Yu
Autoregressive decoding of large language models is frequently memory-traffic bo und, so ultra-low-bit weight-only PTQ helps only if dequantization avoids irregu lar codebook or LUT access in the inner loop. Under the GPU-friendly bitshift tr ellis, existing 2-bit trellis-coded quantization (TCQ) pipelines either reintrod uce micro-LUTs or suffer overlap-amplified artifacts because incoherence improve s global Gaussianity but does not guarantee overlap-local joint geometry. We int roduce Proteus a strictly lookup-free TCQ framework whose computed generator MUL -BAL uses cheap integer mixing plus a per-layer affine Gaussianizer to produce o verlap-robust, near-Gaussian code values with zero runtime table loads. Proteus

instantiates each layer by selecting from a tiny, pre-vetted candidate pool and then applies lightweight channel compensation and optional few-shot distillation that tune only per-layer affine statistics while keeping packed indices and the bitshift-trellis decoder fixed. On Llama 2 (7B–70B) at 2-bit PTQ, Proteus improves perplexity and zero-shot accuracy over strong TCQ/PTQ baselines and reduces end-to-end decode bandwidth at comparable throughput (e.g., 740 vs. 1020 GB/s on 70B).

Beyond Generative Priors: Minority Sampling with JEPA-Guided Diffusion
Sol Park, Soobin Um
Minority sampling aims to generate low-density instances on a data manifold and is of central importance in applications such as medical diagnosis, anomaly detection, and creative AI. Existing approaches, however, define minority samples relative to generative priors learned from training data, confining rarity to model-specific notions that may poorly reflect real-world semantics. In this work, we propose a world-centric perspective on minority sampling, which defines rarity with respect to real-world priors rather than generator-induced densities. To this end, we introduce \emph{JEPA guidance}, a diffusion sampling framework guided by a Joint-Embedding Predictive Architecture (JEPA)---a class of world models that encode broad, semantically rich representations. JEPA guidance steers diffusion trajectories toward low-density regions under the implicit density induced by the JEPA, thereby aligning generated minorities with real-world semantic rarity. To make JEPA guidance computationally practical, we develop principled approximation strategies accompanied by theoretical error bounds, significantly reducing the overhead of guidance computation. Extensive experiments across unconditional, class-conditional, and text-to-image generation demonstrate that JEPA guidance consistently improves the fidelity and semantic validity of minority samples, outperforming generator-centric baselines in capturing real-world notions of rarity. Code is available at https://github.com/soobin-um/jepa-guidance.

The Cylindrical Representation Hypothesis for Language Model Steering
Lang Gao, Jinghui Zhang, Wei Liu, Fengxian Ji, Chenxi Wang, Zirui Song, Akash Ghosh, Youssef Mohamed, Preslav Nakov, Xiuying Chen
Steering is widely used for controlling large language models, yet its effects are often unstable and difficult to predict. Existing theoretical accounts are largely based on the Linear Representation Hypothesis (LRH), which assumes that concepts can be orthogonalized for lossless control. However, this assumption rarely holds in practice and cannot explain the variability of steering outcomes. We propose the Cylindrical Representation Hypothesis (CRH), a geometric extension of LRH that relaxes the orthogonality assumption while preserving linear concept representations. We show that overlapping concept contributions naturally induce a sample-specific cylindrical structure consisting of a central axis, a normal plane, and sensitive sectors. The central axis captures the primary semantic transition associated with a target concept, while the normal plane governs steering sensitivity. Within this plane, some sectors facilitate concept activation, while others suppress or delay it. CRH reveals an asymmetry in steering predictability: the normal plane can be inferred from difference vectors, but the sensitive sectors cannot, introducing an intrinsic source of uncertainty. This explains why steering outcomes vary across samples even when intervention directions are well aligned. Experiments spanning 100 concepts, multiple models, and diverse steering methods provide consistent evidence for the predicted cylindrical structure, suggesting that steering variability arises from representation geometry rather than imperfect steering vectors. Our code is available at: https://github.com/mbzuai-nlp/CRH.

Spurious Rewards Paradox: Mechanistically Understanding How RLVR Activates Memorization Shortcuts in LLMs
Lecheng Yan, Ruizhe Li, Guanhua Chen, Qing Li, Jiahui Geng, Wenxi Li, Longyue Wang, Chenyang Lyu
Reinforcement Learning with Verifiable Rewards (RLVR) is highly effective for en

hancing LLM reasoning, yet recent evidence shows models like Qwen2.5 achieve sig
nificant gains even with spurious rewards. We investigate this phenomenon and id
entify ``Perplexity Paradox'': spurious RLVR triggers a divergence where answer-
token perplexity drops while prompt-side coherence degrades, suggesting model is
 bypassing reasoning in favor of memorization. Using a suite of mechanistic inte
rpretability tools, including Path Patching and Logit Lens, we identify a previo
usly unknown Anchor–Adapter circuit. This circuit enables model to bypass reason
ing and directly retrieve memorized solutions under spurious RLVR. We localize a
 Functional Anchor in middle layers (L18–20) that triggers retrieval of memorize
d solutions, followed by Structural Adapters in later layers (L21+) that transfo
rm representations to accommodate shortcut signal. Finally, we demonstrate that
 scaling specific MLP keys within this circuit allows for bidirectional causal st
eering, i.e., artificially amplifying or suppressing contamination-driven perfor
mance. Our results provide a mechanistic roadmap for identifying and mitigating
 data contamination in RLVR-tuned models.

Stability beyond Bounded Differences: Sharp Generalization Bounds under Finite $
L_p$ Moments

Qianqian Lei, Soham Bonnerjee, Yuefeng Han, Wei Biao Wu

While algorithmic stability is a central tool for understanding generalization o
f learning algorithms, existing high-probability guarantees typically rely on un
iform boundedness or sub-Gaussian/sub-Weibull tail assumptions, which can be ove
rly restrictive for modern settings with heavy-tailed or unbounded losses. We de
velop a stability-based framework that requires only a finite L_p moment condi
tion. Our first contribution is sharp concentration inequalities for functions o
f independent random variables under L_p constraints, extending McDiarmid's bo
unded-differences techniques beyond the classical regime. Leveraging these resul
ts, we derive sharp high-probability generalization bounds across a range of lea
rning paradigms, including empirical risk minimization, transductive regression,
 and meta-learning. These guarantees show that L_p stability suffices for robu
st generalization even when boundedness fails, substantially weakening the stand
ard assumptions in the stability literature.

RaGEP: Rank-aware Geometric Expert Pruning for Mixture-of-Experts Language Model
s

Wentao Hu, Zeyu Zhu, Mingkuan Zhao, Zhenhua An, Yanbo Zhai, Shanhong yu, Huilin
 Zhou, Xin Lai, Xiaoyan Zhu, Jiayin Wang

Sparse Mixture-of-Experts (MoE) architectures scale model capacity efficiently b
ut suffer from massive static parameter footprints, creating significant deploym
ent burdens on memory-constrained hardware. Existing post-training pruning metho
ds often rely on scalar statistics, ignoring the representational geometry of ex
pert feature spaces. This leads to sub-optimal resource allocation across layers
 and the retention of redundant experts. To address this, we propose a Rank-awar
e Geometric Expert Pruning (RaGEP) framework to compress MoE models by analyzing
 the geometric properties of expert activations. First, in the inter-layer alloc
ation stage, we introduce a Rank-aware budget allocation mechanism that adaptive
ly assigns expert budgets based on the effective rank of layer-wise representati
ons. Second, in the intra-layer selection stage, we propose a Spectral-Salience
Pruning metric that harmonizes subspace orthogonality and activation magnitude t
o identify high-energy orthogonal experts. Extensive experiments across MoE mode
ls of different scales show that our method consistently outperforms state-of-th
e-art baselines on a diverse set of zero-shot tasks, while reducing model size a
nd inference cost.

NaviCache: Test-Time Self-Calibration Caching for Video Generation

Zheqi Lv, Zhibo Zhu, Jinke Wang, Qi Tian, Shengyu Zhang, Zhengyu Chen, Chengxi Z
ang, Zhou Zhao, Fei Wu

Video Diffusion Models (VDMs) is constrained by immense computational costs. Whi
le offline calibration-based acceleration suffers from calibration data dependen
cy, prohibitive calibration duration, and susceptibility to distribution shifts,

offline calibration-free methods eliminate these hurdles. However, since they rely on instantaneous zero-order approximations where the mapping between input and output differences varies in real-time, they are susceptible to observational noise and ignore the intrinsic momentum within the diffusion trajectory. In this paper, we propose NaviCache, a plug-and-play test-time self-calibration method re-conceptualizing feature evolution as an Inertial Navigation System (INS) problem. NaviCache bridges the fundamental domain gap and the non-stationary nature of diffusion by modeling the relative coupling between input and output variations. We introduce a dual-state estimation architecture that adaptively tracks the feature change ratio and its latent drift, initialized via a specialized Initial Alignment phase. By integrating a time-dependent noise schedule with an uncertainty-aware Measurement Update mechanism, NaviCache provides a theoretically grounded mechanism for error-bounded block skipping.
Extensive experiments on the HunyuanVideo, Wan, and Open-Sora series demonstrate that NaviCache exhibits more accurate error judgment for block skipping and achieves outstanding comprehensive performance.

Dual-Latent Memory Routing for Vision-Language Reasoning
Hao-Xuan Ma, Jin-Fei Qi, YiCheng Xiao, Han-Jia Ye
Multimodal large language models (MLLMs) have recently made strong progress in vision-language reasoning, yet their performance often degrades as generations grow longer. A key factor is that they frequently lose track of earlier visual evidence and intermediate constraints under a monolithic growing context. Inspired by how humans separately recall what they see and what they infer when solving complex tasks, we propose DLMR, a parameter-efficient mechanism that equips MLLMs with Dual Latent Memories: a visual memory that compresses image evidence and a reasoning memory that tracks intermediate conclusions and constraints. A Router then dynamically decides which memory and how much to reuse during inference, preserving visual grounding while maintaining coherent long-horizon reasoning. DLMR is trained in three stages, from latent memory construction to selective router learning, while keeping the base MLLM frozen, yielding substantial gains on both general and reasoning benchmarks with only a small number of additional trainable parameters. Analyses further show interpretable, state-dependent routing with specialized memory roles and reduced decoding tokens over long generations. Code is available at https://github.com/Hunter-Wrynn/DLMR.

Latent Thoughts Tuning: Bridging Context and Reasoning with Fused Information in Latent Tokens
Weihao Liu, Dehai Min, Lu Cheng
While explicit Chain-of-Thought (CoT) equips Large Language Models (LLMs) with strong reasoning capabilities, it constrains the model's thoughts to a discrete vocabulary space. Recently, reasoning in continuous latent space has emerged as a promising alternative, but current paradigms suffer from feature collapse and instability due to distribution mismatch when recurrently reusing hidden states, or alignment issues when relying on assistant models. To address this, we propose $\textbf{Latent Thoughts Tuning (\textit{LT-Tuning})}$, a post-training framework that redefines how latent thoughts are constructed and deployed. Instead of relying solely on raw hidden states, our method introduces a $\textbf{Context-Prediction-Fusion}$ mechanism that jointly leverages contextual hidden states and predictive semantic guidance from the vocabulary embedding space. Combined with a progressive three-stage curriculum learning pipeline, $\textit{LT-Tuning}$ also enables dynamic switching between latent and explicit thinking modes. Experiments demonstrate that our method outperforms existing latent reasoning baselines, effectively mitigating feature collapse and achieving robust reasoning accuracy.

Kinematics-Driven Gaussian Shape Deformation for Blurry Monocular Dynamic Scenes
Yeon-Ji Song, Kiyoung Kwon, Junoh Lee, Jin-Hwa Kim, Byoung-Tak Zhang
Reconstructing dynamic 3D scenes from blurry monocular videos is challenging because motion-induced blur entangles object motion and geometry, hindering geometr

ic consistency. We present Kinematics-GS, a kinematics-aware framework that models blur as motion-aligned deformation and introduces a kinematic prior to reparameterize Gaussian shapes along motion trajectories, thereby mitigating degenerate shape collapse without auxiliary motion supervision. To stabilize optimization, we decompose scenes into dynamic and static components using temporal deformation variance and employ a coarse-to-fine deformation strategy to capture both global motion and fine-grained details. We also introduce a challenging real-world dataset of deformable and elastic objects exhibiting non-rigid motion with spatially non-uniform motion blur that obscures geometric cues. Extensive experiments on real-world benchmarks with realistic motion blur demonstrate that Kinematics-GS outperforms prior methods by a clear margin in monocular dynamic scene reconstruction, highlighting its effectiveness in handling complex and non-rigid motion scenarios.

Private Learning with Public Feature Conditioning

Shuli Jiang, Walid Krichene, Nicolas Mayoraz

We study differentially private (DP) regression in settings where each data sample includes public, non-sensitive features—common in applications like recommendation or advertising systems. While such label DP or DP with semi-sensitive features settings have been primarily explored in the context of classification, effective approaches for regression remain underexplored. We introduce $\textsf{Cond-DP}$, a conditioned variant of $\textsf{DPSGD}$ that leverages the structure of public feature matrices to improve optimization under privacy constraints. Motivated by the observation that these public features often exhibit rapidly decaying spectra, $\textsf{Cond-DP}$ incorporates a data-driven conditioning matrix to reshape the optimization landscape and accelerate convergence. We provide convergence guarantees for convex, strongly convex and non-convex settings, and recover standard $\textsf{DPSGD}$ as a special case when the conditioning matrix is the identity. We show how to construct an effective conditioning matrix for $\textsf{Cond-DP}$ directly from public features, enabling faster convergence than $\textsf{DPSGD}$ in private linear regression, without incurring additional privacy cost. Empirically, $\textsf{Cond-DP}$ with this conditioning matrix consistently outperforms state-of-the-art baselines across a wide range of datasets and model architectures under label DP, demonstrating strong and robust performance in practice.

STAR-VAE: Structured Topology-Aware Regularization for Audio Reconstruction and Generation

Huadai Liu, Wen Wang, Kaicheng Luo, Qian Chen, Xiangang Li, Wei Xue

Continuous Variational Autoencoders (VAEs) serve as the fundamental continuous tokenizer for modern neural audio generation systems, enabling high-fidelity reconstruction while providing a compact, smooth latent space for downstream generative priors. However, continuous VAEs face a fundamental conflict when balancing *compression rate*, *reconstruction fidelity*, and *latent space topology*—a challenge we formalize as the **Rate-Distortion-Regularity Trilemma**. This trilemma stems from a critical *topological mismatch*: the prevailing isotropic Gaussian prior in standard VAEs imposes a *flat* latent geometry that fails to accommodate audio's *hierarchical* nature, where low-frequency components are structured and compressible while high-frequency components are stochastic and incompressible, leading to *disordered information packing* where crucial semantic features are randomly interleaved with high-entropy noise. To resolve this challenge, we propose **Structured Topology-Aware Regularization (STAR)**, a general training strategy that reshapes latent space geometry by imposing a growth-based constraint field, routing structural and textural information into channel subspaces with matching capacities. STAR is applicable to any VAE architecture and effectively resolves the trilemma, as demonstrated in CNN-based VAEs. To fully exploit STAR's potential, we present **STAR-VAE**, combining STAR with a hybrid CNN-Mamba architecture that synergizes local feature extraction with linear-complexity global context modeling, achieving state-of-the-art performance. We further propose **STAR-Gen**, an LLM-based Flow Matching framework that leverages STAR-VAE's st

ructured latent space for high-fidelity generation without suffering from vector quantization artifacts. Empirical results demonstrate that STAR-VAE successfully resolves the trilemma, achieving state-of-the-art reconstruction fidelity and enhanced semantic information preservation across diverse audio domains. The structured latent space improves both traditional diffusion models and our **STAR-Gen** paradigm, achieving state-of-the-art performance in text-to-audio generation. The project page is available at https://STAR-VAE.github.io.

A Tale of Two Graphs: Separating Knowledge Exploration from Outline Structure for Open-Ended Deep Research
Zhuofan Shi, Ming Ma, Zekun Yao, Fangkai Yang, Jue Zhang, Dongge Han, Victor Rühle, Qingwei Lin, Saravan Rajmohan, Dongmei Zhang
Open-Ended Deep Research (OEDR) pushes LLM agents beyond short-form QA toward long-horizon workflows that iteratively search, connect, and synthesize evidence into structured reports. However, existing OEDR agents largely follow either linear "search-then-generate" accumulation or outline-centric planning. The former suffers from lost-in-the-middle failures as evidence grows, while the latter relies on the LLM to implicitly infer knowledge gaps from the outline alone, providing weak supervision for identifying missing relations and triggering targeted exploration. We present DualGraph memory, an architecture that separates what the agent knows from how it writes. DualGraph maintains two co-evolving graphs: an Outline Graph (OG), and a Knowledge Graph (KG), a semantic memory that stores fine-grained knowledge units, including core entities, concepts, and their relations. By analyzing the KG topology together with structural signals from the OG, DualGraph generates targeted search queries, enabling more efficient and comprehensive iterative knowledge-driven exploration and refinement. Across four established OEDR benchmarks, DualGraph consistently outperforms state-of-the-art baselines in report depth, breadth, and factual grounding; for example, it reaches a 53.08 RACE score on DeepResearch Bench with GPT-5. Moreover, ablation studies confirm the central role of the dual-graph design.

Unlocking Speech–Text Compositional Powers: Instruction-Following Speech Language Models without Instruction Tuning
Congrui Du, Yang Zhang, Kaizhi Qian, Shiyu Chang
Instruction tuning for speech language models (SLMs) is substantially more challenging than for text-based large language models (LLMs), as it requires learning a new modality and a wide range of speech-specific instructions in addition to those supported by text LLMs. Existing SLM training approaches largely replicate the text LLM training paradigm by synthesizing large-scale speech pre-training and instruction-tuning datasets. However, this strategy is difficult to scale, since speech sequences are significantly longer than text sequences.
In this paper, we propose SpeechCombine, an instruction-following speech language model trained **without any instruction tuning**, using only a single round of speech pre-training on as little as 30k hours of speech data. Starting from a text LLM base model, we perform continuous pre-training on speech utterances to obtain a speech-adapted model, and then directly combine its weights with the weight difference between the instruction-tuned and base versions of the text LLM. Our results show that this simple combination strategy not only preserves the knowledge and capabilities of the original text LLM, but also effectively transfers them to the speech domain. These findings suggest a new direction for SLM training that avoids reliance on massive volumes of speech data.

Latent Reasoning in TRMs is Secretly a Policy Improvement Operator
Arip Asadulaev, Rayan Banerjee, Fakhri Karray, Martin Taká■
Recently, small models with latent recursion have obtained promising results on complex reasoning tasks. These results are typically explained by the theory that such recursion increases a network’s depth, allowing it to compactly emulate the capacity of larger models. However, the performance of recursively added layers remains behind the capabilities of one■pass models with the same feed-forward depth. This means that in the looped version, not every recursive step effectiv

ely contributes to depth. This raises the question: when and why does latent rea soning improve performance, and when does it result in dead compute? In our work , we analyze the algorithms that latent reasoning provides answer to this questi on. We show that latent reasoning can be formalized as a classifier■free guidanc e and policy improvement algorithm. Building on these insights, we propose to us e a training schemes from RL and diffusion methods for latent reasoning modles. Using the Tiny Recursive Model as our testbed, we show that with our modificatio ns we can avoid dead compute steps and reduce the total number of forward passes by 18× while maintaining performance. Broadly speaking, we show how a policy im provement perspective on recursive steps can explain model behavior and provide insights for further improvements.

Deep Single-Index Fréchet Regression
Muqing Cui, Yidong Zhou, Su I Iao, Hans-Georg Müller
Predicting outputs that are located in non-Euclidean spaces, such as probability distributions, networks, and symmetric positive-definite matrices, is becoming increasingly important in modern data analysis, particularly when inputs are hig h-dimensional. We propose DeSI (Deep Single-Index Fréchet Regression), a semipar ametric framework for regression with metric space-valued outputs and multivaria te inputs that assumes a single-index structure for the conditional Fréchet mean . DeSI estimates an interpretable index direction, which quantifies the relative importance of inputs, using a deep neural network, and performs Fréchet regress ion along the resulting one-dimensional index in the target metric space. This s tructure mitigates the curse of dimensionality while retaining interpretability, which stands in contrast to standard deep neural networks. We establish theoret ical guarantees for DeSI, including uniform approximation and convergence rates, and demonstrate its strong predictive performance through simulations on distri butions, networks, and symmetric positive-definite matrices, as well as an appli cation to compositional mood data from New Jersey.

BEDTime: A Unified Benchmark for Automatically Describing Time Series
Medhasweta Sen, Zachary Gottesman, Jiaxing Qiu, C. Bayan Bruss, Nam H Nguyen, Th omas Hartvigsen
Recent works propose complex multi-modal models that handle both time series and language, ultimately claiming high performance on complex tasks like time serie s reasoning and cross-modal question answering. However, they skip foundational evaluations that such complex models should have mastered. So we ask a simple qu estion:$\textit{How well can recent models describe structural properties of tim e series?}$ To answer this, we propose that successful models should be able to

$\textit{recognize}$, $\textit{differentiate}$, and $\textit{generate}$ descript
ions of univariate time series. We then create $\textbf{BEDTime}$, a benchmark t
o assess these novel tasks, that comprises $\textbf{five datasets}$ reformatted
across $\textbf{three modalities}$. In evaluating $\textbf{17 state-of-the-art m
odels}$, we find that (1) surprisingly, dedicated time series-language models fa
ll short, despite being designed for similar tasks, (2) vision language models a
re quite capable, (3) language only methods perform worst, despite many lauding
their potential, and (4) all approaches are clearly fragile to a range of real w
orld robustness tests, indicating directions for future work. Together, our find
ings critique prior works' claims and provide avenues for advancing multi-modal
time series modeling.

Rotation-Invariant Spherical Watermarking via Third-Order SO(3) Representation C
oupling
Pengzhen Chen, Yanwei Liu, Xiaoyan Gu, Antonios Argyriou, Wu Liu, Weiping Wang
Reliable watermarking of panoramic imagery is fundamentally challenged by arbitr
ary 3D rotations. As panoramas are defined on the sphere, they naturally transfo
rm under the action of $SO(3)$, rendering conventional planar representations an
d augmentation-based robustness strategies inadequate and devoid of theoretical
guarantees. To address this, we formulate panoramas as spherical signals and lev
erage $SO(3)$ representation theory to derive provably rotation-invariant descri
ptors. While spherical harmonic coefficients transform equivariantly under rotat
ions, the natural invariant constructions are typically limited to zeroth-order
statistics which eliminate directional information and severely constrain embedd
ing capacity. In this work, we introduce a principled third-order invariant cons
truction by coupling higher-order $SO(3)$ irreducible representations via tensor
 products and projecting onto the trivial representation. This yields a spherica
l invariant bispectrum that preserves phase information while remaining strictly
 rotation-invariant. Leveraging this property, we embed watermarks into higher-o
rder spherical harmonic coefficients and recover them from invariant bispectral
scalars, enabling reliable extraction under arbitrary 3D rotations. We provide a
 theoretical proof of $SO(3)$ invariance for it and demonstrate experimentally i
ts near-perfect robustness to continuous rotations while maintaining high visual
 fidelity.

Beyond Hamming: Query-Aware Decoding of Binary Cosine Sketches
DaeHun Nyang
Cosine similarity estimation is a core primitive in coarse-to-fine retrieval pip
elines, where early-stage candidate selection relies on approximate similarity e
stimates whose errors are amplified downstream. Widely used sign-based sketches
arising from extreme quantization of random projections exhibit a structural var
iance peak near θ $\approx$ 90°, the near-background region where
candidate selection is most difficult. We propose QA-Cos, a query-aware decoder-
side estimator that departs from the Hamming-agreement paradigm, treating sign b
its as probabilistic observations rather than deterministic votes. Across simula
tions and BEIR benchmarks, QA-Cos reduces estimation error by up to $\sim$15--20
\% in the near-orthogonal region and translates these gains into improved candid
ate selection in two-stage ANN pipelines, improving Hit@K by up to $\sim$30 perc
entage points at fixed budgets and reducing candidates by up to $\sim$45--50\% a
t fixed recall. In a native hnswlib scorer-replacement experiment, the same deco
der improves the quality of the final HNSW frontier, and in a focused storage-aw
are setting a practical gated variant reduces end-to-end wall-clock latency at m
atched recall.

Intrinsic Credit Assignment for Long Horizon Interaction
Ilze Amanda Auzina, Joschka Strüber, Sergio Hernández-Gutiérrez, Shashwat Goel,
Ameya Prabhu, Matthias Bethge
How can we train agents to navigate uncertainty over long horizons? In this work
, we propose ΔBelief-RL, which leverages a language model's own intrinsic belief
s to reward intermediate progress. Our method utilizes the change in the probabi

lity an agent assigns to the target solution for credit assignment. By training on synthetic interaction data, ∆Belief-RL teaches information-seeking capabilities that consistently outperform purely outcome-based rewards for RL, with improvements generalizing to out-of-distribution applications ranging from customer service to personalization. Notably, the performance continues to improve as we scale test-time interactions beyond the training horizon, with interaction-efficiency increasing even on Pass@k metrics. Overall, our work introduces a scalable training strategy for navigating uncertainty over a long-horizon, by enabling credit assignment to intermediate actions via intrinsic ∆Belief rewards.

TSRBench: A Comprehensive Multi-task Multi-modal Time Series Reasoning Benchmark for Generalist Models

Fangxu Yu, Xingang Guo, Lingzhi Yuan, Haoqiang Kang, Hongyu Zhao, Lianhui Qin, Furong Huang, Bin Hu, Tianyi Zhou

Time series are ubiquitous in real-world scenarios and crucial for applications ranging from energy management to traffic control. Consequently, the ability to reason over time series is a fundamental skill for generalist models to solve complex problems. However, current benchmarks for generalist models largely overlook this dimension.

To bridge this gap, we introduce TSRBench, a comprehensive multi-modal benchmark designed to stress-test the full spectrum of time series reasoning capabilities. TSRBench features: i) a diverse set of 4125 problems from 14 domains, and is categorized into 4 major dimensions: Perception, Reasoning, Prediction, and Decision-Making. ii) 15 tasks from the 4 dimensions evaluating essential reasoning capabilities (e.g., numerical reasoning).

Through extensive experiments, we evaluate over 30 leading proprietary and open-source LLMs, VLMs, and TSLLMs within TSRBench. Our findings reveal that: i) scaling laws hold for perception and reasoning but break down for prediction; ii) strong reasoning does not guarantee accurate context-aware forecasting, indicating a decoupling between semantic understanding and numerical prediction; and iii) despite the complementary nature of textual and visual forms of time series as inputs, current multimodal models fail to effectively fuse them for reciprocal performance gains. TSRBench provides a standardized evaluation platform that not only highlights existing challenges but also offers valuable insights to advance generalist models. Our code and dataset are available at https://tsrbench.github.io/.

Synergistic Intra- and Cross-Layer Regularization Losses for MoE Expert Specialization

Rizhen Hu, Yuan Cao, Boao Kong, Mou Sun, Kun Yuan

Sparse Mixture-of-Experts (MoE) models scale Transformers efficiently but suffer from expert overlap, where different experts process similar tokens and learn redundant functions, resulting in ambiguous routing and underutilized capacity. While architectural solutions like DeepSeek-style shared experts promote specialization, they require substantial structural modifications and rely solely on intra-layer signals. We propose two plug-and-play auxiliary losses that enhance MoE specialization and routing efficiency without modifying routers or model architectures. First, an intra-layer specialization loss penalizes cosine similarity between experts' SwiGLU activations on identical tokens, encouraging experts to specialize in complementary functions. Second, a cross-layer dependency loss maximizes joint Top-k routing probabilities across adjacent layers, establishing coherent expert pathways through network depth while reinforcing intra-layer specialization. Both losses are orthogonal to the standard load-balancing loss and compatible with shared-expert and vanilla Top-k MoE architectures. We implement both losses as a drop-in Megatron-LM module. Extensive experiments across pre-training, fine-tuning, and zero-shot benchmarks demonstrate consistent task gains, higher expert specialization, and lower-entropy routing; together, these improvements translate into faster inference via more stable expert pathways.

Adaptively Grouped Contextual Bandits for Heterogeneous Human-AI Decision Making with Conformal Prediction Sets
Yanchen Wu, Bo Li
Personalizing AI decision support for heterogeneous human decision-makers remains a key challenge. We study a collaboration workflow where AI provides a reduced prediction set via conformal prediction and the human makes the final decision based on the set. We formulate this personalization problem as a contextual bandit, where individual and task features form the context, candidate significance levels α serve as arms, and the optimal prediction-set size varies across contexts. To address large arm spaces and high-dimensional contexts, we introduce the Adaptively Grouped Contextual Bandit (AGCB) framework, which avoids global function approximation by exploiting two Human-AI structural assumptions: continuity and monotonicity. Continuity enables information sharing across nearby contexts and decisions, and drives a data-driven Zooming Mechanism that balances intra-group estimation error against inter-group approximation bias. Monotonicity converts each observation into directional counterfactual information over the K candidate α values, reducing the arm-dependence factor from polynomial to logarithmic in K. Together, these mechanisms yield minimax-optimal dependence on the learning horizon T for both cumulative and simple regret objectives. Empirical results confirm that AGCB achieves the strongest overall performance across most heterogeneous, data-scarce settings.

From Conflict to Consensus: Boosting Medical Reasoning via Multi-Round Agentic RAG
Wenhao Wu, Zhentao Tang, Yafu Li, Shixiong Kai, Mingxuan Yuan, Zhenhong Sun, Chunlin Chen, Zhi Wang
Large Language Models (LLMs) exhibit high reasoning capacity in medical question-answering, but their tendency to produce hallucinations and outdated knowledge poses critical risks in healthcare fields. While Retrieval-Augmented Generation (RAG) mitigates these issues, existing methods rely on noisy token-level signals and lack the multi-round refinement required for complex reasoning. In this paper, we propose **MA-RAG** (**M**ulti-Round **A**gentic RAG), a framework that facilitates test-time scaling for complex medical reasoning by iteratively evolving both external evidence and internal reasoning history within an agentic refinement loop. At each round, the agent transforms semantic **conflict** among candidate responses into actionable queries to retrieve external evidence, while optimizing history reasoning traces to mitigate long-context degradation. MA-RAG extends the *self-consistency* principle by leveraging the lack of consistency as a proactive signal for multi-round agentic reasoning and retrieval, and mirrors a *boosting* mechanism that iteratively minimizes the residual error toward a stable, high-fidelity medical **consensus**. Extensive evaluations across 7 medical Q\&A benchmarks show that MA-RAG consistently surpasses competitive inference-time scaling and RAG baselines, delivering **substantial +6.8 points** on average accuracy over the backbone model. Our code is available at https://github.com/NJU-RL/MA-RAG.
****
Federated Graph Learning via Structure-Aware Fusion Using a Kalman Framework with Learnable Dynamics
Bisheng Tang, Xiaojun Chen
Federated Graph Learning (FGL) enables collaborative training across distributed clients without sharing raw graph data. However, its performance is severely hindered by graph-specific heterogeneity arising from divergent node feature distributions and disparate graph structures. Existing FGL methods primarily focus on aligning or personalizing node features but largely overlook the role of structural knowledge, leading to aggregation-induced representation drift during message passing. We observe that structural heterogeneity often originates from feature-driven connection biases shaped by local data collection practices or user preferences. To address this, we propose \textbf{Fed-Kalter}, a novel FGL framework that integrates Kalman filtering principles into graph neural networks. Fed-Ka

lter introduces Kalter-Conv, a graph convolution grounded in a Kalman framework with learnable dynamics, which treats structural embeddings as latent states and feature-augmented neighborhoods as noisy observations, thereby filtering feature-induced structural noise in a layer-wise manner. Only structural parameters are aggregated globally, enabling effective cross-client knowledge transfer while preserving local personalization. Extensive experiments on 16 graph classification datasets spanning 4 domains demonstrate that Fed-Kalter consistently outperforms state-of-the-art FGL methods. Further ablation and hyperparameter studies confirm its robustness, efficiency, and effectiveness in mitigating structural heterogeneity.

Noise-Robust Density Estimation for Tabular Data Anomaly Detection
Dazhi Fu, Zhao Zhang, Jicong Fan
Density-based anomaly detection methods often provide accurate and interpretable predictions but their performance can be severely degraded by the inherent noise of data, such as changes arising from environmental conditions during data collection or background noise. To deal with such noise, we present noise-robust density estimation (NRDE) for tabular data anomaly detection. We aim to estimate the density of pure data with the influence of noises isolated, which is a non-trivial task since the data-generating process is completely unknown. Specifically, NRDE learns a Jacobian-regularized normalizing flow to estimate the sources of data and categorizes sources into two groups, where one group generates pure data and the other generates noise. After generating pure data, we can use the density of such pure data to detect anomalies caused by the sources of pure data solely. Therefore, NRDE is robust to inherent noise. We provide theoretical results to support the effectiveness of NRDE and compare NRDE with 17 baselines on 47 benchmark datasets under different settings, including vanilla anomaly detection, anomaly detection with anomaly contamination, anomaly detection on noisy data, and transductive outlier detection.

CalM: A Self-Supervised Foundation Model for Population Dynamics in Calcium Imaging Data
Xinhong Xu, Yimeng Zhang, Qichen Qian, Yuanlong Zhang
Recent work suggests that large-scale, multi-animal modeling can significantly improve neural recording analysis. However, for functional calcium traces, existing approaches remain task-specific, limiting transfer across common neuroscience objectives. To address this challenge, we propose \textbf{CalM}, a self-supervised neural foundation model trained solely on neuronal calcium traces and adaptable to multiple downstream tasks, including forecasting and decoding. Our key contribution is a pretraining framework, composed of a high-performance tokenizer mapping single-neuron traces into a shared discrete vocabulary, and a dual-axis autoregressive transformer modeling dependencies along both the neural and the temporal axis. We evaluate CalM on a large-scale, multi-animal, multi-session dataset. On the neural population dynamics forecasting task, CalM outperforms strong specialized baselines after pretraining. With a task-specific head, CalM further adapts to the behavior decoding task and achieves superior results compared with supervised decoding models. Moreover, linear analyses of CalM representations reveal interpretable functional structures beyond predictive accuracy. Taken together, we propose a novel and effective self-supervised pretraining paradigm for foundation models based on calcium traces, paving the way for scalable pretraining and broad applications in functional neural analysis.

Learning More from Less: Unlocking Internal Representations for Benchmark Compression
Yueqi Zhang, Jin Hu, Shaoxiong Feng, Peiwen Yuan, Xinglin Wang, Yiwei Li, Jiayi Shi, Chuyi Tan, Ji Zhang, Boyuan Pan, Yao Hu, Kan Li
The prohibitive cost of evaluating Large Language Models (LLMs) necessitates efficient alternatives to full-scale benchmarking. Prevalent approaches address this by identifying a small coreset of items to approximate full-benchmark performance. However, existing methods must estimate a reliable item profile from respon

se patterns across many source models, which becomes statistically unstable when the source pool is small. This dependency is particularly limiting for newly released benchmarks with minimal historical evaluation data. We argue that discrete correctness labels are a lossy view of the model's decision process and fail to capture information encoded in hidden states. To address this, we introduce \textsc{RepCore}, which aligns heterogeneous hidden states into a unified latent space to construct representative coresets. Using these subsets for performance extrapolation, \textsc{RepCore} achieves precise estimation accuracy with as few as ten source models. Experiments on five benchmarks and over 200 models show consistent gains over output-based baselines in ranking correlation and estimation accuracy. Spectral analysis further indicates that the aligned representations contain separable components reflecting broad response tendencies and task-specific reasoning patterns.

R2-Router: A New Paradigm for LLM Routing with Reasoning

Jiaqi Xue, Qian Lou, Jiarong Xing, Heng Huang

As LLMs proliferate with diverse capabilities and costs, LLM routing has emerged by learning to predict each LLM's quality and cost for a given query, then selecting the one with high quality and low cost. However, existing routers implicitly assume a single fixed quality and cost per LLM for each query, ignoring that the same LLM's quality varies with its output length. This causes routers to exclude powerful LLMs when their estimated cost exceeds the budget, missing the opportunity that these LLMs could still deliver high quality at reduced cost with shorter outputs. To address this, we introduce R2-Router, which treats output length budget as a controllable variable and jointly selects the best LLM and length budget, enforcing the budget via length-constrained instructions. This enables R2-Router to discover that a powerful LLM with constrained output can outperform a weaker LLM at comparable cost—efficient configurations invisible to prior methods. Together with the router framework, we construct R2-Bench, the first routing dataset capturing LLM behavior across diverse output length budgets. Experiments show that R2-Router achieves state-of-the-art performance at $4-5\times$ lower cost compared with existing routers. This work opens a new direction: routing as reasoning, where routers evolve from reactive selectors to deliberate reasoners that explore which LLM to use and at what cost budget. The code is publicly available at https://github.com/UCF-ML-Research/R2-Router.

Cross-Embodiment Robot Foundation World Models with Latent Actions

Huang Huang, Sriram Yenamandra, Arjun Majumdar, Elie Aljalbout, Tushar Nagarajan, Tsung-Yen Yang, Akshara Rai, Michael Rabbat, Li Fei-Fei, Jiajun Wu, Tingfan Wu, Franziska Meier

The diversity of robot embodiments and action spaces makes it challenging to build robot world models that generalize across different
embodiments. We introduce the Latent Action-Conditioned Robot World Model (LAC-WM), which operates within a learned unified latent action space shared across diverse embodiments. This unified action space improves the world model’s performance when adapted to previously unseen robot embodiments. We compare LAC-WM with an Explicit Action-Conditioned World Model (EAC-WM), which conditions on explicit motion labels. Our results shows that explicit action conditioning leads to disjoint action representations across embodiments, limiting downstream performance when adapting to new robots. We evaluate both models on dexterous manipulation tasks and a modified LIBERO benchmark. LAC-WM improves downstream performance over EAC-WM by up to 46.7% on dexterous manipulation and 11.7% on LIBERO. Crucially, the unified latent action space allows LAC-WM’s downstream performance to scale positively with the number of embodiments used during pretraining. In contrast, the disjoint action space in EAC-WM leads to decreased performance as the number of pretraining embodiments increases. These results highlights the importance of a unified action space for efficient cross-embodiment learning, addressing a key challenge in robotics.

Learning Long Range Spatio-Temporal Representations over Continuous Time Dynamic

Graphs with State Space Models
Ayushman Raghuvanshi, Thummaluru Siddartha Reddy, Sundeep Prabhakar Chepuri, Mahesh Chandran
Continuous-time dynamic graphs (CTDGs) provide a richer framework to capture fine-grained temporal patterns in evolving relational data. Long-range information propagation is a key challenge while learning representations, wherein it is important to retain and update information over long temporal horizons. Existing approaches restrict models to capture one-hop or local temporal neighborhoods and fail to capture multi-hop or global structural patterns. To mitigate this, we derive a parameter-efficient state-space modeling framework for continuous-time dynamic graphs $\texttt{(CTDG-SSM)}$ from first principles. We first introduce continuous-time Topology-Aware higher order polynomial projection operator ($\texttt{CTT-HiPPO}$), a novel memory-based reformulation of $\texttt{HiPPO}$ to jointly encode temporal dynamics and graph structure. The solution from $\texttt{CTT-HiPPO}$ is obtained by projecting the classical HiPPO solution through a polynomial of the Laplacian matrix, yielding topology-aware memory updates that admit an equivalent state-space formulation for CTDGs ($\texttt{CTDG-SSM}$). Then a computationally efficient discrete formulation is obtained using the zero-order hold approach for model implementation.
Across benchmarks on dynamic link prediction, dynamic node classification, and sequence classification, $\texttt{CTDG-SSM}$ achieves state-of-the-art performance. Notably, it achieves large performance gains on datasets that require long range temporal (LRT) and spatial reasoning.

Deep Residual Injection for Full-Spectrum Forensic Signal Perception in Multimodal Large Language Models
Kaiqing Lin, Zhiyuan Yan, Ruoxin Chen, Ke-Yue Zhang, Yue Zhou, Caiyong Piao, Bin Li, Taiping Yao, Bo Wang, Youchang xiao, Shouhong Ding
Multimodal large language models (MLLMs) have been increasingly adopted in forensics for their robust semantic understanding.
As AI-generated images become realistic, semantic-level inconsistencies alone are often insufficient for reliable detection.
This motivates a critical question: *whether MLLMs can achieve full-spectrum forensic signal perception, i.e., capturing low-level generator artifacts without sacrificing pre-trained semantic knowledge.*
We then conduct a layer-wise analysis of forensic signal perception in MLLMs and find that semantic information is mainly encoded in the early-to-middle layers, and directly fine-tuning MLLMs for artifact learning causes rapid semantic forgetting.
Based on this insight, we propose Deep Visual Residual MLLM (Deep-VRM) to \textit{preserve early semantic processing while injecting artifact-specific visual signals as a residual path into an intermediate layer}, where they are fused with semantic token representations and propagated through subsequent trainable layers.
This enables later layers to jointly model semantic reasoning and signal-level forensic cues, and surprisingly, the model learns to adaptively leverage different levels of forensic signals depending on the input, achieving robust and generalizable detection performance.
Extensive experiments show that our method achieves state-of-the-art across all benchmarks.
****
Improving Topic Modeling by Distilling Soft Labels from Language Models
Raymond Li, Amirhossein Abaskohi, Chuyuan Li, Gabriel Murray, Giuseppe Carenini
Traditional neural topic models are typically optimized by reconstructing the document's Bag-of-Words (BoW) representations, overlooking contextual information and struggling with data sparsity. In this work, we introduce a novel topic model training framework by Distilling Soft Labels (DSL) from Language Models (LMs). To construct the contextually enriched reconstruction signals, we project the next token probabilities, conditioned on a specialized prompt, onto a pre-defined vocabulary, and train the topic models to reconstruct the soft labels using the

LM hidden states. This produces higher-quality topics that are more closely aligned with the underlying thematic structure of the corpus. Extensive experiments demonstrate that DSL achieves substantial improvements in topic coherence and assignment accuracy over existing baselines. Additionally, we also introduce a retrieval-based metric, which shows that our approach significantly outperforms existing methods in identifying semantically similar documents, highlighting its effectiveness for retrieval-oriented applications.

From Text to Forecasts: Bridging Modality Gap with Temporal Evolution Semantic Space

Lehui Li, Yuyao Wang, Jisheng Yan, Wei Zhang, Jinliang Deng, Haoliang Sun, Zhongyi Han, Yongshun Gong

Incorporating textual information into time-series forecasting holds promise for addressing event- driven non-stationarity; however, a fundamental modality gap hinders effective fusion: textual descriptions express temporal impacts implicitly and qualitatively, whereas forecasting models rely on explicit and quantitative signals. Through controlled semi-synthetic experiments, we show that existing methods over-attend to redundant tokens and struggle to reliably translate textual semantics into usable numerical cues. To bridge this gap, we propose TESS, which introduces a Temporal Evolution Semantic Space as an intermediate bottleneck between modalities. This space consists of interpretable, numerically grounded temporal primitives—distribution shift, volatility, shape, and lag—extracted from text by an LLM via structured prompting and filtered through confidence-aware gating. Experiments on four real-world datasets demonstrate up to a 29% reduction in forecasting error compared to state-of-the-art unimodal and multimodal baselines. Code is available at: https://github.com/olivia3395/TESS.

IAPO: Information-Aware Policy Optimization for Token-Efficient Reasoning

Yinhan He, Yaochen Zhu, Mingjia Shi, Wendy Zheng, Lin Su, Xiaoqing Wang, Qi Guo, Jundong Li

Large language models increasingly rely on long chains of thought to improve accuracy, yet such gains come with substantial inference-time costs. We revisit token-efficient post-training and argue that existing sequence-level reward-shaping methods offer limited

control over how reasoning effort is allocated across tokens. To bridge the gap, we propose IAPO, an information-theoretic post-training framework that assigns token-wise advantages based on each token’s conditional mutual information (MI) with the final answer. This yields an explicit, principled mechanism for identifying informative reasoning steps and suppressing low-utility exploration. We provide a theoretical analysis showing that our IAPO can induce monotonic reductions in reasoning verbosity without harming correctness.

Empirically, IAPO consistently improves reasoning accuracy while reducing reasoning length by up to 36\%, outperforming existing token-efficient RL methods across various reasoning datasets. Our results demonstrate that information-aware advantage shaping is a powerful and general direction for token-efficient post-training. The code is available at https://github.com/YinhanHe123/IAPO.

XTransfer: Modality-Agnostic Few-Shot Model Transfer for Human Sensing at the Edge

Yu Zhang, Xi Zhang, Hualin zhou, Xinyuan Chen, Shang Gao, Hong Jia, Jianfei Yang, Yuankai Qi, Tao Gu

Deep learning for human sensing on edge systems presents significant potential for smart applications. However, its training and development are hindered by the limited availability of sensor data and resource constraints of edge systems. While transferring pre-trained models to different sensing applications is promising, existing methods often require extensive sensor data and computational resources, resulting in high costs and limited transferability. In this paper, we propose XTransfer, a first-of-its-kind method enabling modality-agnostic, few-shot model transfer with resource-efficient design. XTransfer flexibly uses pre-trained models and transfers knowledge across different modalities by (i) model repa

iring that safely mitigates modality shift by adapting pre-trained layers with o nly few sensor data, and (ii) layer recombining that efficiently searches and re combines layers of interest from source models in a layer-wise manner to restruc ture models. We benchmark various baselines across diverse human sensing dataset s spanning different modalities. The results show that XTransfer achieves state- of-the-art performance while significantly reducing the costs of sensor data col lection, model training, and edge deployment.

Gradient-Free Approaches is a Key to an Efficient Interaction with Markovian Sto chasticity

Boris Prokhorov, Semyon Chebykin, Alexander Gasnikov, Aleksandr Beznosikov

This paper deals with stochastic optimization problems involving Markovian noise with a zero-order oracle. We present and analyze a novel derivative-free method for solving such problems in strongly convex smooth and non-smooth settings wit h both one-point and two-point feedback oracles. Using a randomized batching sch eme, we show that when mixing time τ of the underlying noise sequence is le ss than the dimension of the problem d, the convergence estimates of our metho d do not depend on τ. This observation provides an efficient way to interac t with Markovian stochasticity: instead of invoking the expensive first-order or acle, one should use the zero-order oracle. Finally, we complement our upper bou nds with the corresponding lower bounds. This confirms the optimality of our res ults.
****

Spherical SO(3) Equivariant Local Attention

Yusuke Sekikawa, Jun Nagata, Itsumi Araki, Ruka Eto

Spherical signals provide a natural representation for omnidirectional perceptio n and often benefit from equivariance to 3D rotations.

Recent spherical vision transformers implement local self-attention on spherical grids, but most retain only partial $\mathrm{SO}(3)$ equivariance and rely on $ \textit{location-dependent}$ local positional embeddings (LPEs).

Such LPEs can degrade robustness to camera tilt or object reorientation and intr oduce additional memory and computational overhead.

We propose $\textit{Spherical $\mathrm{SO}(3)$-Equivariant Local Attention}$ (So LA), an LPE-free local attention mechanism for spherical signals.

SoLA achieves full $\mathrm{SO}(3)$ equivariance through a distance-preserving p ositional modulation that couples query/key features with each token’s unit dire ction.

Specifically, the modulation lifts queries and keys using an outer-product with the 4D direction dependent vector.

The induced similarity of the modulated queries and keys depends on content affi nity and great-circle distance while remaining invariant to global $\mathrm{SO}(3)$ rotations.

The same formulation admits a softmax-free linear variant that computes local at tention via key-value aggregation without per-query neighbor materialization.

We integrate SoLA into a U-shaped spherical transformer for 360° depth es timation and semantic segmentation, demonstrating substantially improved robustn ess to arbitrary 3D rotations compared to prior spherical transformers with simi lar computational costs.
****

Caracal: Causal Architecture via Spectral Mixing

BINGZHENG GAN, Tianyi Zhang, LI YUSU, Jing Huang, Wei Shi, Yangkai Ding, Tao Yu

The scalability of Large Language Models to long sequences is hindered by the qu adratic cost of self-attention and the limitations of positional encodings. To a ddress these, we introduce **Caracal**, a novel architecture that replaces self- attention with a parameter-efficient, $\mathcal{O}(L \log L)$ Multi-Head Fourier (MHF) module. Our contributions are threefold: (1) We leverage the Fast Fourier Transform (FFT) for sequence mixing, inherently addressing both bottlenecks men tioned above. (2) We apply a frequency-domain causal masking technique that enfo rces autoregressive capabilities via asymmetric padding and truncation, overcomi ng a critical barrier for Fourier-based generative models. (3) Unlike efficient

models relying on hardware-specific implementations (e.g., Mamba), **Caracal** u
ses standard library operators. This ensures robust portability, eliminating com
mon deployment barriers. Evaluations demonstrate that **Caracal** performs compe
titively with Transformer and SSM baselines, offering a scalable and simple path
way for efficient long-sequence modeling. Code is available in the supplementary
 materials.

Linear-Core Surrogates: Smooth Loss Functions with Linear Rates for Classificati
on and Structured Prediction
Mehryar Mohri, Yutao Zhong
A fundamental dichotomy in the theory of classification sets smoothness against
statistical efficiency: smooth surrogate losses such as the logistic loss enable
 fast $O(1/T)$ optimization but yield slow square-root H-consistency bounds, w
hile piecewise-linear losses like the Hinge loss achieve optimal linear H-cons
istency rates but are non-differentiable. We introduce *Linear-Core (LC) Surroga
tes*, the first family of *explicit* convex loss functions that provably resolve
 this tension. By stitching a linear core to a smooth tail, we construct surroga
tes that are differentiable everywhere (C^1, and even C^2 under mild conditi
ons) while retaining strict linear H-consistency bounds, the strongest known f
orm of consistency guarantee. We establish these linear bounds across three incr
easingly complex settings: binary classification, multi-class classification, an
d structured prediction. To our knowledge, this is the first explicit constructi
on to simultaneously achieve smoothness and linear H-consistency in any of the
se settings. Beyond their theoretical appeal, Linear-Core Surrogates offer pract
ical advantages. In multi-class classification, their constant gradient profile
near the decision boundary provides natural robustness to instance-dependent lab
el noise, outperforming Cross-Entropy by *2.6\%* on corrupted CIFAR-10. In struc
tured prediction, their smoothness enables an unbiased stochastic gradient estim
ator that bypasses the $O(|Y|^2)$ per-step complexity of exact inference, yieldi
ng a *23$\times$ speedup* over Structured SVMs on large-vocabulary sequence tagg
ing tasks.
****

AdaMEM: Test-Time Adaptive Memory for Language Agents
Yunxiang Zhang, Yiheng Li, Ali Payani, Lu Wang
A central challenge for language agents is utilizing past experience to adapt to
 dynamic test-time conditions. While recent work demonstrates the promise of age
ntic memory mechanisms, most systems restrict retrieval to episode initiation. C
onsequently, agents are forced to rely on static guidance that becomes increasin
gly misaligned as long-horizon tasks unfold.
To address this rigidity, we propose the Adaptive Memory Agent (AdaMEM), a novel
 framework for agent test-time adaptation. Without updating model parameters onl
ine, AdaMEM adapts agent behavior via a hybrid memory architecture: it maintains
 a long-term trajectory memory of raw experiences collected offline while genera
ting dynamic short-term strategy memory on-the-fly to guide decision-making.
This mechanism enables the trade-off between token efficiency and adaptability a
cross varying inference-time compute levels. Empirically, AdaMEM significantly o
utperforms static memory baselines, achieving relative gains of up to 13% on ALF
World and 11% on WebShop, with consistent leading performance extending to agent
ic search on HotpotQA.
To further enhance this adaptation, we develop Step-MFT, a Step-wise Memory Fine
-Tuning technique that trains the policy to synthesize high-quality strategies f
rom retrieved experiences, yielding additional performance gains.
Our work establishes a new scaling dimension for agentic memory, supporting cont
inuous reasoning and self-evolution post-deployment in real-world environments.
Our code is available at https://github.com/yunx-z/AdaMEM.

On the Difficulty of Learning a Meta-network for Training Data Selection
Zilin Du, Junqi Zhao, Boyang Li
Synthetic data are increasingly used to train neural networks, yet distributiona
l mismatch with real data limits their effectiveness when used indiscriminately.

A common strategy is to learn data weights via bi-level optimization, which we refer to as Meta-learning for Training-data Selection (MTS). Interestingly, in practice, MTS often performs below expectation. We identify two obstacles in properly training MTS: a poor gradient signal-to-noise ratio (GSNR), which causes optimization difficulties, and lack of informative features that correlates with data quality. We present a mathematical analysis of MTS, which reveals the dynamics of normalized data weights and the relation between disparate data quality and poor GSNR. The analysis suggests a a simple yet effective solution: increasing the batch size. Further, we propose a set of informative features that capture the positions of training data in their distributions and training dynamics. Experiments across four benchmarks show consistent improvements, achieving average gains of 5.49\% over training without selection and 2.89\% over the strongest baseline.

Credit Assignment via Neural Manifold Noise Correlation

Byungwoo Kang, Maceo Richards, Bernardo L. Sabatini

Credit assignment, the process of determining how changes in individual neurons and synapses influence a network’s output, is central to learning in brains and machines. Noise correlation-based methods, which estimate gradients by correlating perturbations of activity with changes in output, provide a biologically plausible solution to credit assignment but scales poorly as accurately estimating the Jacobian requires that the number of perturbations scale with network size. Moreover, isotropic noise conflicts with neurobiological observations that neural activity lies on a low-dimensional manifold. To address these drawbacks, we propose *neural manifold noise correlation* (NMNC), which performs credit assignment using perturbations restricted to the neural manifold. We show theoretically and empirically that the Jacobian row space aligns with the neural manifold in trained networks, and that manifold dimensionality scales slowly with network size. NMNC substantially improves performance and sample efficiency over vanilla noise correlation in convolutional networks trained on CIFAR-10, ImageNet-scale models, and recurrent networks. NMNC also yields representations more similar to the primate visual system than vanilla noise correlation. These findings offer a mechanistic hypothesis for how biological circuits could support credit assignment, and suggest that biologically inspired constraints may enable, rather than limit, effective learning at scale.

SPARe: Stacked Parallelism with Adaptive Reordering for Fault-Tolerant LLM Pretraining Systems with 100k+ GPUs

Jin Lee, Zhonghao Chen, Xuhang He, Robert Underwood, Bogdan Nicolae, Franck Cappello, Xiaoyi Lu, Sheng Di, Zheng Zhang

In large-scale LLM pretraining systems with $100\mathrm{k}+$ GPUs, failures become the norm rather than the exception, and restart costs can dominate wall-clock training time. However, existing fault-tolerance mechanisms are largely unprepared for this restart-dominant regime. To address this challenge, we propose SPARe—Stacked Parallelism with Adaptive Reordering—a fault-tolerance framework that masks node failures during gradient synchronization by stacking redundant data shards across parallelism groups and adaptively reordering execution. SPARe achieves availability comparable to traditional replication while maintaining near-constant computation overhead of only $2\sim3\times$, even under high redundancy where traidional replication would require linearly inflating overhead. We derive closed-form expressions for endurable failure count and computation overhead, validate them via SimGrid-based discrete-event simulation, and jointly optimize redundancy and checkpointing to minimize training time. At extreme scale with up to $600\mathrm{k}$ GPUs, SPARe reduces time-to-train by $40\sim50$% compared to traditional replication.

****

Just Noticeable Difference Modeling for Deep Visual Features

Rui Zhao, Wenrui Li, Lin Zhu, Yajing Zheng, Weisi Lin

Deep visual features are increasingly used as the interface in vision systems, motivating the need to describe feature characteristics and control feature quali

ty for machine perception. Just noticeable difference (JND) characterizes the ma
ximum imperceptible distortion for images under human or machine vision. Extendi
ng it to deep visual features naturally meets the above demand by providing a ta
sk-aligned tolerance boundary in feature space, offering a practical reference f
or controlling feature quality under constrained resources. We propose FeatJND,
a task-aligned JND formulation that predicts the maximum tolerable per-feature p
erturbation map while preserving downstream task performance. We propose a FeatJ
ND estimator at standardized split points and validate it across image classific
ation, detection, and instance segmentation. Under matched distortion strength,
FeatJND-based distortions consistently preserve higher task performance than uns
tructured Gaussian perturbations, and attribution visualizations suggest FeatJND
 can suppress non-critical feature regions. As an application, we further apply
FeatJND to token-wise dynamic quantization and show that FeatJND-guided step-siz
e allocation yields clear gains over random step-size permutation and global uni
form step size under the same noise budget. The source code is available at http
s://github.com/ruizhao26/FeatJND.

Unifying Low Dimensional Spectra in Deep Learning
Connall Garrod, Jonathan P. Keating
Low-dimensional structures appear ubiquitously in the eigenspectra of deep-learn
ing matrices in classification networks trained in the overparameterized regime.
 While theoretical advances have aimed to explain this phenomenology, they typic
ally succeed only in capturing subsets of the full behavior or rely on assumptio
ns that cannot hold in practice. In this work, we provide an analytic explanatio
n for the bulk–outlier structure of several canonical deep-learning matrices, in
cluding the Hessian, gradients, and weights. We achieve this using unconstrained
 feature models (UFMs), a now-common tool for studying the emergence of deep neu
ral collapse (DNC). We show that DNC is the source of these low-dimensional eige
nspectra: in each case, the eigenvalues and eigenvectors can be constructed from
 feature means, the characterizing objects of DNC. This provides a unifying anal
ytic explanation for a wide range of spectral phenomena in deep learning and goe
s beyond empirical characterizations—which typically focus on eigenvalues—by pro
viding a detailed analysis of eigenvectors. We prove that our results hold for b
oth linear and ReLU networks and provide numerical validation in both the modeli
ng context and standard deep-network architectures on canonical datasets.

Multi-Round Human–AI Collaboration with User-Specified Requirements
Sima Noorani, Shayan Kiyani, Hamed Hassani, George J. Pappas
As humans increasingly rely on multi-round conversational AI for high-stakes dec
isions, principled frameworks are needed to ensure such interactions reliably im
prove decision quality. We adopt a human-centric view governed by two principles
: counterfactual harm, ensuring the AI does not undermine human strengths, and c
omplementarity, ensuring it adds value where the human is prone to err. We forma
lize these concepts via user-defined rules, allowing users to specify exactly wh
at harm and complementarity mean for their specific task. We then introduce an o
nline, distribution-free algorithm with finite-sample guarantees that enforces t
he user-specified constraints over the collaboration dynamics. We evaluate our f
ramework across two interactive settings: LLM-simulated collaboration on a medic
al diagnostic task and a human crowdsourcing study on a pictorial reasoning task
. We show that our online procedure maintains prescribed counterfactual-harm and
 complementarity violation rates even under non-stationary interaction dynamics.
 Moreover, tightening or loosening these constraints produces predictable shifts
 in downstream human accuracy, confirming that the two principles serve as pract
ical levers for steering multi-round collaboration toward better decision qualit
y without the need to model or constrain human behavior.

Beyond Global Alignment: Fine-Grained Motion-Language Retrieval via Pyramidal Sh
apley-Taylor Learning
Hanmo Chen, Guangtao Lyu, Chenghao Xu, Jiexi Yan, Xu Yang, Cheng Deng
As a foundational task in human-centric cross-modal intelligence, motion-languag

e retrieval aims to bridge the semantic gap between natural language and human m otion, enabling intuitive motion analysis, yet existing approaches predominantly focus on aligning entire motion sequences with global textual representations. This global-centric paradigm overlooks fine-grained interactions between local m otion segments and individual body joints and text tokens, inevitably leading to suboptimal retrieval performance. To address this limitation, we draw inspirati on from the pyramidal process of human motion perception (from joint dynamics to segment coherence, and finally to holistic comprehension) and propose a novel P yramidal Shapley-Taylor (PST) learning framework for fine-grained motion-languag e retrieval. Specifically, the framework decomposes human motion into temporal s egments and spatial body joints, and learns cross-modal correspondences through progressive joint-wise and segment-wise alignment in a pyramidal fashion, effect ively capturing both local semantic details and hierarchical structural relation ships. Extensive experiments on multiple public benchmark datasets demonstrate t hat our approach significantly outperforms state-of-the-art methods, achieving p recise alignment between motion segments and body joints and their corresponding text tokens.

Embodied Interpretability: Linking Causal Understanding to Generalization in Vis ion-Language-Action Models

Hanxin Zhang, Mingshuo Xu, Abdulqader Dhafer, Shigang Yue, Hongbiao Dong, Zhou D aniel Hao

Vision–Language–Action (VLA) policies often fail under distribution shift, sugge sting that decisions may depend on spurious visual correlations rather than task -relevant causes. We formulate visual–action attribution as an interventional es timation problem. Accordingly, we introduce the **Interventional Significance Sc ore (ISS)**, an interventional masking procedure for estimating the causal influ ence of visual regions on action predictions, and the **Nuisance Mass Ratio (NMR)**, a scalar measure of attribution to task-irrelevant features. We analyze the statistical properties of ISS and show that it admits unbiased estimation, and we characterize conditions under which action prediction error provides a valid proxy for causal influence. Experiments across diverse manipulation tasks indica te that NMR predicts generalization behavior and that ISS yields more faithful e xplanations than existing interpretability methods. These results suggest that i nterventional attribution provides a simple diagnostic approach for identifying causal misalignment in embodied policies.

Structure-Preserving Learning Improves Geometry Generalization in Neural PDEs

Benjamin D Shaffer, Shawn Koohy, Brooks Kinch, M. Ani Hsieh, Nathaniel Trask

We aim to develop physics foundation models for science and engineering that pro vide real-time solutions to Partial Differential Equations (PDEs) which preserve structure and accuracy under adaptation to unseen geometries. To this end, we i ntroduce General-Geometry Neural Whitney Forms (Geo-NeWF): a data-driven finite element method. We jointly learn a differential operator and compatible reduced finite element spaces defined on the underlying geometry. The resulting model is solved to generate predictions, while exactly preserving physical conservation laws through Finite Element Exterior Calculus. Geometry enters the model as a di scretized mesh both through a transformer-based encoding and as the basis for th e learned finite element spaces. This explicitly connects the underlying geometr y and imposed boundary conditions to the solution, providing a powerful inductiv e bias for learning neural PDEs which we demonstrate improves generalization to unseen domains. We provide a novel parameterization of the constitutive model en suring existence and uniqueness of the solution. Our approach demonstrates state -of-the-art performance on several steady-state PDE benchmarks and provides a si gnificant improvement over conventional baselines on out-of-distribution geometr ies.

Taming I2V models for Image HOI Editing: A Cognitive Benchmark and Agentic Self -Correcting Framework

Jiayi Gao, Qingchao Chen, Yuxin Peng, Yang Liu

Current image editing methods excels at static attributes but fails at complex Human-Object Interactions (HOI), a critical challenge unaddressed by existing benchmarks that conflate HOI with static attributes, relying on global metrics incapable of simultaneously assessing dynamic interaction validity and entangled human-object pair preservation. Thus, we first introduce HOI-Edit, a comprehensive benchmark with three progressive cognitive levels, which features an automated metric HOI-Eval that first reliably evaluates instance-level interaction by letting VLM Q&A after thinking with images containing grounded Human-Object pair. Considering the task's essence of remodeling dynamic relationships, we benchmark Image-to-Video (I2V) models, finding them inherently suited for dynamic editing due to their temporal generation capabilities. Crucially, beyond superior performance, this capability provides a "replay of the failure process", offering unique diagnosability into why errors occur. We thus propose SCPE (Self-Correcting Process Editing), a novel, agentic self-correcting framework that constrains the generation of I2V models through iteratively refined prompts, enabling the generated videos to more accurately present the target HOI. Extracted frames from these videos are the final editing results. On HOI-Edit, SCPE achieves performance competitive with state-of-the-art (SOTA) editing models like Nano Banana on interaction.Code is available at https://github.com/oceanflowlab/HOI-Edit.

Zero-Shot Rankability: Revealing Latent Ordinal Structure in Multimodal Large Language Models via Language

Nam Hyeon-Woo, Moon Ye-Bin, Sohwi Lim, Kwon Byung-Ki, Tae-Hyun Oh

Recent work shows that vision encoders capture ordinal attributes along linear axes, which can be recovered from as few as two labeled images. However, in the zero-shot setting, the text-driven rank axis for Vision-Language Models (VLMs) like CLIP remains suboptimal. In this work, we study the embeddings of Multimodal LLMs (MLLMs). We hypothesize that MLLMs can overcome this limitation due to three potential advantages: their inherent ordinal understanding, capacity for conditional embeddings, and a small cross-modal gap. We show that MLLMs are rankable using only text prompts. Experiments demonstrate that a text-driven rank axis for MLLM embeddings achieves 90\% of the performance of the supervised linear rank axis, significantly outperforming the 61\% observed in VLM embeddings. We validate that this capability stems from MLLMs' conditional embeddings and a smaller modality gap than VLMs. Furthermore, we demonstrate that this property generalizes to the audio domain. Our findings suggest that language provides a direct interface for probing latent ordinal structures in MLLMs. Code and prompts are available at https://github.com/kaist-ami/prompt-probing

VideoSEAL: Mitigating Evidence Misalignment in Agentic Long Video Understanding by Decoupling Answer Authority

Chenhao Qiu, Yechao Zhang, Xin Luo, Shien Song, Xusheng Liu

Long video question answering requires locating sparse, time-scattered visual evidence within highly redundant content. Although current MLLMs perform well on short videos, long videos introduce long-horizon search and verification, which often necessitates multi-turn, agentic interaction. We show that existing LVU agents can exhibit evidence misalignment: they produce correct answers that are not supported by the retrieved or inspected evidence. To characterize this failure, we introduce two diagnostics, temporal groundedness and semantic groundedness, and use them to reveal two pressures that amplify misalignment: prompt pressure from shared-context saturation at inference time and reward pressure from outcome-only optimization during training. These findings point to a structural root cause: the coupled agent paradigm conflates long-horizon planning with answer authority. We therefore propose the decoupled planner–inspector framework, which separates planning from answer authority and gates final answering on pixel-level verification. Across four long-video benchmarks, our framework improves both answer accuracy and evidence alignment, achieving 55.1% on LVBench and 62.0% on LongVideoBench while producing interpretable search trajectories. Moreover, the decoupled architecture scales consistently with increased search budgets and supports plug-and-play upgrades of the MLLM backbone without retraining the planner. C

ode and models are available at https://github.com/Echochef/VideoSEAL.

RePo: Language Models with Context Re-Positioning
Huayang Li, Tianyu Zhao, Deng Cai, Richard Sproat
In-context learning is fundamental to modern Large Language Models (LLMs); however, prevailing architectures impose a rigid and fixed contextual structure by assigning linear or constant positional indices. The rigid position information poses the full burden of organizing the input structure to attention layers, thus reducing the amount of attention that could be allocated for more critical information. To address this, we propose RePo, a novel mechanism that alleviates the burden for attention layers via context re-positioning. Unlike conventional approaches, RePo utilizes a differentiable module, f_ϕ, to assign token positions that capture contextual dependencies, rather than replying on pre-defined order. By continually pre-training on the OLMo-2 1B \& 7B models, we demonstrate that RePo consistently enhances performance on tasks involving noisy contexts, structured data, and longer context length, while maintaining competitive performance on general short-context tasks. Analysis reveals that RePo successfully allocates more attention mass to distant but relevant information, assigns positions in a dense and non-linear space, and captures the intrinsic structure of the input context.
****
SHERPA: Fine-tuning Segment Anything Models with Task-relevant Guidance
Jingcheng Xie, Yinda Chen, Xiaoyu Liu, Haoyuan Shi, Zhiwei Xiong
Segment Anything Models (SAMs) often struggle with certain specialized tasks. A common approach is to fine-tune models with specific task labels, but this often leads to overfitting, introduces model bias and significantly degrades their generalization ability.
To overcome these challenges, we propose SHERPA, a novel framework that leverages a smaller SAM to guide the fine-tuning of a larger SAM via task-relevant features.
Specifically, we first leverage the Fisher Ratio Separation (FRS) module to separate high task-relevant features and preserve the ability of the large SAM to perform other general tasks.
Then, the Guiding Feature Extraction (GFE) module is used to extract representative guiding features from the fine-tuned small SAMs.
We leverage small SAMs tailored for specific tasks (including natural image segmentation, biomedical image segmentation, and video object segmentation)
as guidance and then evaluate the SHERPA scheme to fine-tune larger SAM series models.
Our experiments demonstrate that SHERPA enhances the retention of generalization ability across those diverse tasks, by up to 11.1\%, and improves specific task performance by up to 2.2\%.

FourTune: Towards Fully 4-Bit Efficient Post-Training for Diffusion Models
Bowen Xue, Zihan Min, Xingyang Li, Zhekai Zhang, Haocheng Xi, Lvmin Zhang, Maneesh Agrawala, Jun-Yan Zhu, Song Han, Yujun Lin, Muyang Li
Diffusion models have become a dominant paradigm for high-quality generative modeling, while post-training is essential for adapting them to diverse downstream applications.
However, post-training of large diffusion models is still challenging due to the prohibitive memory footprints and slow training speed, which existing parameter-efficient fine-tuning methods only partially address.
To overcome these limitations, we propose FourTune, an efficient post-training framework for diffusion models based on an end-to-end W4A4G4 paradigm. FourTune introduces a triple-branch hybrid pipeline that augments the standard LoRA architecture with a frozen numerical stabilizer to isolate quantization-sensitive outliers, enabling stable training under native 4-bit computation. In addition, FourTune employs hardware-efficient block-wise quantization and customized fused kernels to support efficient quantized backpropagation and reduce memory bandwidth overhead.

Across customization, reinforcement learning, and distillation tasks, FourTune m
atches the quality of full-precision fine-tuning. On FLUX.1-dev (12B), FourTune
reduces memory overhead by $2.25\times$ and increases end-to-end training throug
hput by $2.27\times$ compared to BF16 LoRA.

New Algorithms for Fully-Dynamic k-center with Outliers
Junyu Huang, Zhize Li, Zhen Zhang, Xujia Li, Jianxin Wang, Qilong Feng
In this paper, we study the fully dynamic k-center with outliers problem, where
points are inserted and deleted over time and the goal is to maintain an approxi
mate clustering while discarding up to z outliers. Existing algorithms typically
 rely on radius guessing to maintain cluster representations, leading to update
and query times that depend explicitly on the aspect ratio Δ. We propose a layer
ed-sampling framework that avoids radius guessing by maintaining a hierarchy of
sampled structures, which can separate most inliers from potential outliers and
refine the remaining uncertain points. The resulting algorithm achieves $\tilde{
O}(k^2/\epsilon^4)$ update and query time independent of Δ, while guaranteeing a
 constant-factor approximation with $(1+\epsilon)z$ outliers discarded. Under mi
ld assumptions, our result is complemented by a lower bound in metric space que
ry model.
****
On the Robustness of Langevin Dynamics to Score Function Error
Daniel Yiming Cao, August Y. Chen, Karthik Sridharan, Yuchen Wu
We consider the robustness of score-based generative modeling to errors in the e
stimate of the score function. In particular, we show that Langevin dynamics is
not robust to the L^2 errors (more generally L^p errors) in the estimate of
the score function.
It is well-established that with small L^2 errors in the estimate of the score
 function, diffusion models can sample faithfully from the target distribution u
nder fairly mild regularity assumptions in a polynomial time horizon.
In contrast, our work shows that even for simple distributions in high dimension
s, Langevin dynamics run for any polynomial time horizon will produce a distribu
tion far from the target distribution in Total Variation (TV) distance, even whe
n the L^2 error (more generally L^p) of the estimate of the score function i
s arbitrarily small.
Considering such an error in the estimate of the score function is unavoidable i
n practice when learning the score function from data, our results provide furth
er justification for diffusion models over Langevin dynamics and serve to cautio
n against the use of Langevin dynamics with estimated scores.

SoftBinary Coding: A New Information-Theoretic Paradigm for Neural Compression v
ia Fast Channel Simulation
Ezgi Ozyilkan, Sharang M. Sriramu, Elza Erkip, Aaron B. Wagner, Jona Ballé
Neural compression is currently dominated by Nonlinear Transform Coding (NTC), w
hich maps data to real-valued latents via continuous transforms. Despite its suc
cess, NTC suffers from train-test mismatch due to non-differentiable quantizatio
n, a "smoothness bias" inherent in continuous transforms that precludes optimali
ty for certain sources, and a loss of "shaping gain" due to its use of scalar qu
antization. We propose SoftBinary Coding (SBC), an end-to-end learning paradigm
that bypasses these limitations by using a stochastic binary latent space. In th
e spirit of vector quantization, SBC employs discrete representations and compre
sses them through a novel fast binary channel simulation scheme, for which we pr
ovide a proof of rate optimality. Experimental gains on information-theoretic so
urces address NTC's limitations both theoretically and practically, establishing
 discrete binary structures as a viable path toward reaching optimal rate–distor
tion bounds. Surprisingly, SBC also achieves state-of-the-art performance on vec
tor quantization of i.i.d. sources, exceeding Trellis Coded Quantization of the
Gaussian source.

Understand and Accelerate Memory Processing Pipeline for Large Language Model In
ference

Zifan He, Rui Ma, Yizhou Sun, Jason Cong
Modern large language models (LLMs) increasingly depend on efficient long-context processing and generation mechanisms, including sparse attention, retrieval-augmented generation (RAG), and compressed contextual memory, to solve complex tasks. We show that these optimizations can be unified into a four-stage memory processing pipeline: *Prepare Memory*, *Compute Relevancy*, *Retrieval*, and *Apply to Inference*. Through systematic profiling, we identify a 22\%-97\% memory processing overhead in LLM inference and strong computational heterogeneity across stages in memory processing. Motivated by this insight, we argue that **heterogeneous systems** are well-suited to accelerate memory processing and thus end-to-end inference. We demonstrate this approach on a GPU-FPGA system by offloading sparse, irregular, and memory-bounded operations to FPGAs while retaining compute-intensive operations on GPUs. Evaluated on an AMD MI210 GPU and an Alveo U55C FPGA, our system is up to $2.2\times$ faster and $4.7\times$ energy reduction across multiple LLM optimizations than the GPU baseline (with similar results on NVIDIA A100), establishing heterogeneous systems as a practical direction for efficient LLM inference and informing future heterogeneous hardware design.

Rationality Measurement and Theory for Reinforcement Learning Agents
Kejiang Qian, Amos Storkey, Fengxiang He
This paper proposes a suite of rationality measures and associated theory for reinforcement learning agents, a property increasingly critical yet rarely explored. We define an action in deployment to be perfectly rational if it maximises the hidden true value function in the steepest direction. The expected value discrepancy of a policy's actions against their rational counterparts, culminating over the trajectory in deployment, is defined to be expected rational risk; an empirical average version in training is also defined. Their difference, termed as rational risk gap, is decomposed into (1) an extrinsic component caused by environment shifts between training and deployment, and (2) an intrinsic one due to the algorithm's generalisability in a dynamic environment. They are upper bounded by, respectively, (1) the 1-Wasserstein distance between transition kernels and initial state distributions in training and deployment, and (2) the empirical Rademacher complexity of the value function class. Our theory suggests hypotheses on the benefits from regularisers (including layer normalisation, ℓ_2 regularisation, and weight normalisation) and domain randomisation, as well as the harm from environment shifts. Experiments are in full agreement with these hypotheses. The code is available at \href{https://github.com/EVIEHub/Rationality}{https://github.com/EVIEHub/Rationality}.

Minibatch selection for Language Models via Partition Matroid Constrained Gradient Matching
Prayas Agrawal, Prateek Chanda, Ishita Khatri, Ganesh Ramakrishnan, Bamdev Mishra, Pratik Jawanpuria
Training large language models (LLMs) on heterogeneous data requires selecting minibatches that balance convergence speed with coverage across domains. Existing methods either select samples independently within each domain or rely on computationally expensive proxy models to learn continuous domain weights. We propose PartitionSel, a cross-domain minibatch selection approach that maximizes a validation-guided gradient-matching utility under per-domain budgets encoded as a partition-matroid constraint. By coupling the per-domain budgets through a single utility, PartitionSel is designed to reduce redundancy in selections across domains. The proposed objective is weakly submodular and admits an orthogonal matching pursuit algorithm with provable approximation guarantees. Empirically, we evaluate PartitionSel for minibatch selection during the fine-tuning of Qwen2.5 and Llama-3 on MetaMathQA and Mol-Instructions. PartitionSel achieves robust gains over per-domain and domain-agnostic baselines on both benchmarks. It also reduces the number of conflicting gradient pairs within each batch, indicating that the cross-domain coupling translates into more compatible training updates.

SPEED-Bench: A Unified and Diverse Benchmark for Speculative Decoding

Talor Abramovich, Maor Ashkenazi, Izzy Putterman, Benjamin Chislett, Tiyasa Mitra, Bita Darvish Rouhani, Ran Zilberstein, Yonatan Geifman
Speculative Decoding (SD) has emerged as a critical technique for accelerating Large Language Model (LLM) inference. Unlike deterministic system optimizations, SD performance is inherently data-dependent, meaning that diverse and representative workloads are essential for accurately measuring its effectiveness. Existing benchmarks suffer from limited task diversity, inadequate support for throughput-oriented evaluation, and a reliance on high-level implementations that fail to reflect production environments. To address this, we introduce **SPEED-Bench**, a comprehensive suite designed to standardize SD evaluation across diverse semantic domains and realistic serving regimes. SPEED-Bench offers a carefully curated *Qualitative* data split, selected by prioritizing semantic diversity across the data samples.
Additionally, it includes a *Throughput* data split, allowing speedup evaluation across a range of concurrencies, from latency-sensitive low-batch settings to throughput-oriented high-load scenarios. By integrating with production engines like vLLM and TensorRT-LLM, SPEED-Bench allows practitioners to analyze system behaviors often masked by other benchmarks. We highlight this by quantifying how synthetic inputs overestimate real-world throughput, identifying batch-size dependent optimal draft lengths and biases in low-diversity data, and analyzing the caveats of vocabulary pruning in state-of-the-art drafters. We release SPEED-Bench to establish a unified evaluation standard for practical comparisons of SD algorithms.
****

SpikingLM: Towards Fully Spiking Language Model
Yu Liang, Zijian Zhou, Wenjie Wei, Shuai Wang, Honglin Cao, Ammar Belatreche, Yu Yang, Malu Zhang, Yang Yang, Haizhou Li
Leveraging event-driven computation mechanism, Spiking Neural Networks (SNNs) have emerged as a representative paradigm for energy-efficient edge intelligence. However, extending SNNs to modern deep language models still faces two fundamental challenges.
First, dead neurons in deep SNNs lead to degraded gradients, limiting the training effectiveness of spiking language models. Second, removing Softmax for energy efficiency weakens token-wise competition, reducing the model’s ability to select salient tokens.
To address these challenges, we propose Spiking Language Model (SpikingLM) to bridge the efficiency of SNNs and the capability of modern language models through two key innovations.
First, we propose Distribution-aware Scaling method, which rescales linear outputs into an activation-friendly range to alleviate dead neurons and stabilize gradient propagation. Notably, its scaling parameters can be fused into the preceding linear layers, incurring no additional inference overhead. Second, we introduce Spike2Max to restore winner-takes-all mechanism via base-2 exponentiation and max-subtraction. Compared with Softmax, Spike2Max reduces energy consumption by over 95\% using hardware-efficient bit-shift operations. Experiments show that SpikingLM reduces energy consumption by 57.9\% and achieves state-of-the-art performance on GLUE, laying a promising foundation for energy-efficient language modeling. Code is available at~\url{https://github.com/hamings1/SpikingLM.git}.

A Coin Flip for Safety: LLM Judges Fail to Reliably Measure Adversarial Robustness
Leo Schwinn, Moritz Ladenburger, Tim Beyer, Mehrnaz Mofakhami, Gauthier Gidel, Stephan Günnemann
Automated ``LLM-as-a-Judge" frameworks have become the de facto standard for scalable evaluation across natural language processing. For instance, in safety evaluation, these judges are relied upon to evaluate harmfulness in order to benchmark the robustness of safety against adversarial attacks. However, we show that existing validation protocols fail to account for substantial distribution shifts inherent to red-teaming: diverse victim models exhibit distinct generation styles, attacks distort output patterns, and semantic ambiguity varies significantl

y across jailbreak scenarios. Through a comprehensive audit using 6642 human-ver
ified labels, we reveal that the unpredictable interaction of these shifts often
 causes judge performance to degrade to near random chance. This stands in stark
 contrast to the high human agreement reported in prior work. Crucially, we find
 that many attacks inflate their success rates by exploiting judge insufficienci
es rather than eliciting genuinely harmful content. To enable more reliable eval
uation, we propose ReliableBench, a benchmark of behaviors that remain more cons
istently judgeable, and JudgeStressTest, a dataset designed to expose judge fail
ures.

SecCodePRM: A Process Reward Model for Code Security
Weichen Yu, Ravi Mangal, Yinyi Luo, Kai Hu, Jingxuan He, Corina S. Pasareanu, Ma
tt Fredrikson
Large Language Models are rapidly becoming core components of modern software de
velopment workflows, yet ensuring code security remains challenging. Existing vu
lnerability detection pipelines either rely on static analyzers or use LLM/GNN-b
ased detectors trained with coarse program-level supervision. Both families ofte
n require complete context, provide sparse end-of-completion feedback, and can d
egrade as code length grows, making them ill-suited for real-time, prefix-level
assessment during interactive coding and streaming generation. We propose \textb
f{SecCodePRM}, a security-oriented process reward model that assigns a \textbf{c
ontext-aware}, \textbf{step-level} security score along a code trajectory. To tr
ain the model, we derive step-level supervision labels from static analyzers and
 expert annotations, allowing the model to attend more precisely to fine-grained
 regions associated with inter-procedural vulnerabilities. SecCodePRM has three
applications: full-code vulnerability detection (VD), partial-code VD, and secur
e code generation (CG). For VD, SecCodePRM uses risk-sensitive aggregation that
emphasizes high-risk steps; for CG, SecCodePRM supports inference-time scaling b
y ranking candidate continuations and favoring higher cumulative reward. This de
sign yields dense, real-time feedback that scales to long-horizon generation. Em
pirically, SecCodePRM outperforms prior approaches in all three settings, while
preserving code functional correctness, suggesting improved security without a s
afety–utility tradeoff.

Breaking the Simplification Bottleneck in Amortized Neural Symbolic Regression
Paul Saegert, Ullrich Koethe
Symbolic regression (SR) aims to discover interpretable analytical expressions t
hat accurately describe observed data. Amortized SR promises to be much more eff
icient than the predominant genetic programming SR methods, but currently strugg
les to scale to realistic scientific complexity. We find that a key obstacle is
the lack of a fast reduction of equivalent expressions to a concise normalized f
orm. Amortized SR has addressed this with general-purpose Computer Algebra Syste
ms (CAS) like SymPy, but the high computational cost severely limits training an
d inference speed. We propose **SimpliPy**, a rule-based simplification engine a
chieving a 100-fold speed-up over SymPy at comparable quality. This enables subs
tantial improvements in amortized SR, including scalability to much larger train
ing sets, more efficient use of the per-expression token budget, and systematic
training set decontamination with respect to equivalent test expressions. We dem
onstrate these advantages in our **Flash-ANSR** framework, which achieves much b
etter accuracy than amortized baselines (NeSymReS, E2E) on the FastSRB benchmark
. Moreover, it performs on par with state-of-the-art direct optimization (PySR)
while recovering more concise rather than more complex expressions with increasi
ng inference budget.
****

TileQ: Efficient Low-Rank Quantization of Mixture-of-Experts with 2D Tiling
Hongyaoxing Gu, Xinzhe Chen, Lijuan Hu, Liu fangfang
Mixture-of-Experts (MoE) models achieve remarkable performance by sparsely activ
ating specialized experts, yet their massive parameters in experts pose signific
ant challenges for deployment. While low-rank quantization offers a promising ro
ute to compress MoE models, existing methods still incur nonnegligible memory ov

erhead and inference latency. To address these limitations, we propose TileQ, a fine-tuning-free post-training quantization (PTQ) method that employs 2D-tiling structured low-rank quantization to share low-rank factors across both input and output dimensions of MoE experts. Furthermore, we introduce an efficient inference technique for TileQ that fuses multiple low-rank expert computations into a single-pass operation, significantly improving hardware utilization. Experiments show that TileQ cuts down additional memory usage up to 10x and reduces inference latency to 5% while preserving state-of-the-art accuracy.
****
Stochastic Minimum-Cost Reach-Avoid Reinforcement Learning
Jingduo Pan, Taoran Wu, Yiling Xue, Bai Xue
We study stochastic minimum-cost reach-avoid reinforcement learning, where an agent must satisfy a reach-avoid specification with probability at least p while minimizing expected cumulative costs in stochastic environments. Existing safe and constrained reinforcement learning methods typically fail to jointly enforce probabilistic reach-avoid constraints and optimize cost in the learning setting in stochastic environments. To address this challenge, we introduce reach-avoid probability certificates (RAPCs), which identify states from which stochastic reach-avoid constraints are satisfiable. Building on RAPCs, we develop a contraction-based Bellman formulation that serves as a principled surrogate for integrating reach-avoid considerations into reinforcement learning, enabling cost optimization under probabilistic constraints. We establish almost sure convergence of the proposed algorithms to locally optimal policies with respect to the resulting objective. Experiments in the MuJoCo simulator demonstrate improved cost performance and consistently higher reach-avoid satisfaction rates.
****
Direct Flow Q-Learning
Shicheng Cao, Jingrui Jia, Wenyu Li, Feng Duan, Tao Zhang, Shengbo Eben Li
Flow Matching shows great promise in offline reinforcement learning (RL), yet optimizing these iterative policies via Backpropagation Through Time (BPTT) is unstable. While prevailing paradigms circumvent this by distilling multi-step flows into single-step approximations, such methods may limit the benefits of iterative refinement. To avoid these sacrifices, we propose Direct Flow Q-Learning (DFQL), a streamlined framework that attains superior results by optimizing flow matching policies without BPTT or distillation. DFQL derives a surrogate objective that directly injects terminal Q-value gradients as a guidance term into each step velocity field, ensuring stable optimization while preserving iterative expressive capacity. Across 73 challenging tasks in OGBench and D4RL, DFQL achieves state-of-the-art results. Additionally, DFQL extends seamlessly to the offline-to-online setting, delivering substantial performance gains without further modification.
****
Prompt Optimization with Minimal Unlabeled Input via Meta-Reasoning
Yuran Sun, Chuan Wu
Prompt optimization is critical for maximizing the performance of large language models (LLMs). However, it often relies on costly labeled data. Self-supervised methods reduce data dependency, but they suffer from optimization ambiguity or high computational costs. To address these limitations, we propose the Meta-Reasoning Prompt Engineering Agent (MR.PEA), a self-supervised prompt optimization framework that operates with minimal input. MR.PEA leverages meta-reasoning to iteratively build task-specific knowledge, including problem-solving strategies and evaluation criteria, while adaptively retrieving external information to enhance its understanding. This knowledge guides the generation of diverse validation examples, targeted prompt refinement, and comprehensive quality assessments. Experiments on GSM8K and Big-Bench Hard show that MR.PEA outperforms existing baselines, achieving an average performance gain of 7.4% with an optimization cost as low as $0.01 per task.
****
Orthogonal Hierarchical Decomposition for Structure-Aware Table Understanding with Large Language Models

Bin Cao, huixian lu, chenwen ma, Ting Wang, Ruizhe Li, JING FAN
Complex tables with multi-level headers, merged cells and heterogeneous layouts pose persistent challenges for large language models (LLMs) in both understanding and reasoning. Existing approaches typically rely on table linearization or normalized grid modeling. However, these representations struggle to explicitly capture hierarchical structures and cross-dimensional dependencies, which can lead to misalignment between structural semantics and textual representations for non-standard tables. To address this issue, we propose an Orthogonal Hierarchical Decomposition (OHD) framework that constructs structure-preserving input representations of complex tables for LLMs. OHD introduces an Orthogonal Tree Induction (OTI) method based on spatial--semantic co-constraints, which decomposes irregular tables into a column tree and a row tree to capture vertical and horizontal hierarchical dependencies, respectively. Building on this representation, we design a dual-pathway association protocol to symmetrically reconstruct the semantic lineage of each cell, and incorporate an LLM as a semantic arbitrator to align multi-level semantic information. We evaluate OHD framework on two complex table question answering benchmarks, AITQA and HiTab. Experimental results show that OHD consistently outperforms existing representation paradigms across multiple evaluation metrics.

Mind the Gap: Mixtures of Gaussians in Approximate Differential Privacy
Huikang Liu, Aras Selvi, Wolfram Wiesemann
We design a class of additive noise mechanisms that satisfy (ε, δ)-differential privacy (DP) for scalar, real-valued query functions with known sensitivities, with a particular focus on moderate and low-privacy regimes. These mechanisms, which we call *mixture mechanisms*, are constructed by mixing multiple Gaussian distributions that share the same variance but differ in their means and mixture weights. The resulting distributions can be interpreted as convex combinations of a zero-mean Gaussian (as used in the analytic Gaussian mechanism) and additional Gaussians whose means depend on the sensitivity of the query function. We derive tight conditions on the variances required for (ε, δ)-DP and provide efficient algorithms to compute them. Compared to the analytic Gaussian mechanism, our mechanisms yield substantially lower expected noise amplitudes (l_1-loss) and variances (l_2-loss for zero-mean distributions). In the low-privacy regime that motivates our design, our mechanisms approach optimality, mitigating nearly all of the optimality gap of the analytic Gaussian mechanism.
****

SmartThinker: Progressive Chain-of-Thought Length Calibration for Efficient Large Language Model Reasoning
Chenzhi Hu, Qinzhe Hu, Yuhang Xu, Junyi Chen, Ruijie Wang, Shengzhong Liu, Jianxin Li, Fan Wu, Guihai Chen
Large reasoning models (LRMs) like OpenAI o1 and DeepSeek-R1 achieve high accuracy on complex tasks by adopting long chain-of-thought (CoT) reasoning paths.
However, the inherent verbosity of these processes frequently results in redundancy and overthinking.
To address this issue, existing works leverage Group Relative Policy Optimization (GRPO) to reduce LRM output length, but their static length-reward designs fail to adapt to problem difficulty and response-length distributions, causing over-compression and compromised accuracy.
Therefore, we propose *SmartThinker*, a novel GRPO-based efficient reasoning method with progressive CoT length calibration.
SmartThinker makes a two-fold contribution:
First, it dynamically estimates the optimal length with peak accuracy during training and guides overlong responses toward it to reduce reasoning length while sustaining accuracy.
Second, it dynamically modulates the length-reward coefficient to avoid the unwarranted penalization of correct reasoning paths.
Extensive experimental results show that *SmartThinker* achieves up to 52.6\% length compression with improved accuracy and achieves up to 16.6\% accuracy relat

ive improvement on challenging benchmarks like AIME25.
The source code can be found at https://github.com/SJTU-RTEAS/SmartThinker.

Omni-fMRI: A Universal Atlas-Free fMRI Foundation Model
Mo Wang, Wenhao Ye, Junfeng Xia, Junxiang Zhang, Xuanye Pan, Minghao Xu, Haotian Deng, Hongkai Wen, Quanying Liu
Self-supervised fMRI foundation models have shown promising transfer performance, yet most rely on predefined region-level parcellations that discard fine-grained voxel information and introduce atlas-dependent biases. We propose Omni-fMRI, an atlas-free foundation model that operates directly on voxel-level signals. To enable scalable pretraining on 49,497 fMRI sessions across nine datasets, Omni-fMRI introduces a dynamic patching mechanism that substantially reduces computational cost while preserving informative spatial structure. To support reproducibility and fair comparison, we establish a comprehensive benchmark suite spanning 11 datasets and a diverse set of resting-state and task-based fMRI tasks. Experimental results demonstrate that Omni-fMRI consistently outperforms existing foundation models, providing a scalable and reproducible framework for atlas-free brain representation learning. Code is available.

Alignment Risks from Capability-Seeking RL Training
Yujun Zhou, Yue Huang, Han Bao, Kehan Guo, Zhenwen Liang, Pin-Yu Chen, Tian Gao, Werner Geyer, Nuno Moniz, Nitesh V Chawla, Xiangliang Zhang
While most AI alignment research focuses on preventing models from generating explicitly harmful content, a more subtle risk arises from capability-seeking RL training in vulnerable environments. We investigate whether language models, when trained with reinforcement learning (RL) in environments with implicit loopholes, can learn to exploit these flaws to maximize reward, even without being explicitly instructed to do so. To test this, we design a suite of four diverse "vulnerability games'', each presenting a structural vulnerability related to context-conditional compliance, proxy metrics, reward tampering, and self-evaluation. Our experiments show that models often learn to exploit these vulnerabilities, discovering opportunistic strategies that increase reward while sometimes preserving or even improving standard task-performance metrics. More critically, we find that these exploitative strategies are not always narrow "tricks'': they can transfer in structured but limited ways, propagate from a capable teacher model to other student models through SFT, and in several cases remain more persistent when learned through RL than when distilled through SFT. Our findings show that alignment risks from capability-seeking RL training can be difficult to detect with standard performance monitoring, suggesting that future AI safety work should extend beyond content moderation to auditing and securing training environments, reward mechanisms, and evaluation channels. Code is available at https://github.com/YujunZhou/Capability-seeking-RL-risk.

Interleaved Selective State Space Models for Efficient WiFi-Based 3D Multi-Person Pose Estimation
Quang-Anh N.D., Kok-Seng Wong
WiFi-based human pose estimation offers privacy-preserving and occlusion-robust sensing, but current Transformer-based approaches suffer from quadratic complexity and lack explicit inductive biases for the structure of Channel State Information (CSI). We propose WiFi-Mamba, the first State Space Model (SSM) architecture for WiFi-based 3D multi-person pose estimation. Our approach introduces three key contributions: (1) a Dual-Stream Selective SSM that processes amplitude and phase through parallel pathways with cross-stream state coupling to respect their distinct physical properties, (2) Selective State Attention for pose query decoding with SSM-derived sequential context, and (3) Persistent SSM Memory for temporal consistency across frames without recurrent memory explosion. Extensive experiments on the Person-in-WiFi 3D dataset, covering both single-person and multi-person, demonstrate a 16-27% MPJPE reduction across varying numbers of persons while using only 4.4\% of the baseline parameters (2.14M vs. 48.2M), achieving superior efficiency-accuracy trade-offs particularly beneficial for edge deploym

ent in privacy-sensitive continuous monitoring scenarios.

AutoRPA: Efficient GUI Automation through LLM-Driven Code Synthesis from Interactions
Minghao Chen, Xinyi Hu, Zhou Yu, Yufei Yin
Large Language Model (LLM) based agents have demonstrated proficiency in multi-step interactions with graphical user interfaces (GUIs). While most research focuses on improving single-task performance, practical scenarios often involve repetitive GUI tasks for which invoking LLM reasoning repeatedly, i.e., the ReAct paradigm, is inefficient. Prior to LLMs, traditional Robotic Process Automation (RPA) offers runtime efficiency but demands significant manual effort to develop and maintain. To bridge this gap, we propose \textbf{AutoRPA}, a framework that automatically distills the decision logic of ReAct-style agents into robust RPA functions. AutoRPA introduces two core innovations: (1) A \textit{translator-builder pipeline} where a translator agent converts hard-coded ReAct actions into soft-coded procedures, and a builder agent synthesizes robust RPA functions via retrieval-augmented generation over multiple trajectories; (2) A \textit{hybrid repair strategy} during code verification, combining RPA execution with ReAct-based fallback for iterative refinement. Experiments across multiple GUI environments demonstrate that RPA functions generated by AutoRPA successfully solve similar tasks while reducing token usage by 82\%\textasciitilde96\%, significantly improving runtime efficiency and reusability.

Robust Linear Dueling Bandits with Post-serving Context under Unknown Delays and Adversarial Corruptions
Youngmin Oh
We study linear dueling bandits in volatile environments characterized by the simultaneous presence of post-serving contexts, delayed feedback, and adversarial corruption. Feedback is subject to unknown stochastic or adversarial delays and a cumulative corruption budget $\mathcal{C}$. To address these challenges, we propose RCDP-UCB, which integrates a learned approximator that predicts post-serving contexts from pre-serving information. It further employs an adaptive weighting strategy that clips feature vectors to mitigate the impact of corrupted and delayed observations simultaneously. Under standard regularity conditions and a parametric post-serving mapping, we rigorously establish that our algorithm is delay-regime-agnostic, achieving a regret upper bound of $\widetilde{\mathcal{O}}(d(\sqrt{T} + \mathcal{C} + \mathcal{D}))$, where d is the total feature dimension and $\mathcal{D}$ encapsulates the delay complexity, scaling with $\sqrt{\Lambda}$ under adversarial delays or μ_{τ} under stochastic delays (Λ: cumulative delay budget; μ_{τ}: mean of sub-Gaussian delays). We further establish lower bounds that nearly match our upper bounds up to a $\sqrt{d}$ factor for adversarial delays in the absence of post-serving contexts. Code is available at \url{https://github.com/youngmin0oh/rcdp-public}.

SOPE: Situation-Aware and Statistically Indistinguishable Privacy Exfiltration for MCP-enabled Agents
Ruixiao Lin, Qingming Li, Jiahao Chen, Chunyi Zhou, Shouling Ji
The Model Context Protocol (MCP) enables Large Language Model (LLM) agents to interact with external tools, but this extensibility introduces significant supply chain vulnerabilities that enable covert privacy exfiltration. Prior studies have revealed privacy leakage in MCP-enabled agents via indirect prompt injection; however, existing attacks are typically misaligned with the agent's tool-usage context and rely on rigid templates, resulting in recognizable patterns that are readily flagged by existing defenses. In this work, we exploit the observation that privacy exposure is inherently scenario-dependent, to associate certain privacy items with specific tools. We introduce `SOPE`, a Scenario-aware and zerO-click Privacy Exfiltration framework that transforms any benign MCP server into its privacy-exfiltrating variants. `SOPE` (1) identifies privacy items that are appropriate to the tool usage, (2) embeds privacy-probing instructions into tool-invocation prompts, and (3) achieves zero-click data transmission via code-level

modifications. We evaluate `SOPE` across 27,216 test cases, where 324 `SOPE`-transformed *real-world* servers attacking four benchmark and three commercial agents with *nine* state-of-the-art defenses. Results demonstrate that `SOPE` remains highly effective and robust, highlighting critical protocol-level safety gaps in the agent ecosystem.

A Decision-Theoretic View of Test-Time Training: When, How Far, and Which Directions to Adapt
Tomoya Wakayama
Test-time training (TTT) adapts a pretrained model to each prompt via parameter updates, improving accuracy under pretraining-to-test distribution shifts. Yet, its performance often suffers from instability and sensitivity to hyperparameters such as update steps and subspace. We explain this behavior through a decision-theoretic lens, treating TTT as implicit Bayesian inference in the kernel regime. Under a Gaussian process benchmark, we show that TTT reduces prediction error when updates are spectrally matched to the prompt's signal-to-noise ratio and aligned with query-relevant eigen-directions. This perspective underpins the following results: (1) we show when fixed update steps and subspaces fail under distribution shifts, motivating adaptive strategies; (2) we prove that selecting update steps via prompt evidence admits a PAC-Bayes guarantee against overfitting; and (3) we characterize the Bayes-optimal update subspace under a linear-Gaussian correction model, yielding a scoring rule for selecting Transformer blocks and heads. Our theory helps explain the empirical instability of TTT, taking a step toward principled guidance for when, how far, and which directions to adapt.

Align Forward, Adapt Backward: Closing the Discretization Gap in Logic Gate Networks
Youngsung Kim
In neural network models, soft mixtures of fixed candidate components (e.g., logic gates and sub-networks) are often used during training for stable optimization, while hard selection is typically used at inference. This raises questions about training-inference mismatch. We analyze this gap by separating forward-pass computation (hard selection vs. soft mixture) from stochasticity (with vs. without Gumbel noise). Using logic gate networks as a testbed, we observe distinct behaviors across four methods: Hard-ST achieves zero selection gap by construction; Gumbel-ST achieves near-zero gap when training succeeds but suffers accuracy collapse at low temperatures; Soft-Mix achieves small gap only at low temperature via weight concentration; and Soft-Gumbel exhibits large gaps despite Gumbel noise, confirming that noise alone does not reduce the gap. We propose CAGE (Confidence-Adaptive Gradient Estimation) to maintain gradient flow while preserving forward alignment. On logic gate networks, Hard-ST and Gumbel-ST with CAGE both achieve over 98\% accuracy on MNIST and ${\sim}58\%$ on CIFAR-10; Hard-ST with CAGE further maintains zero selection gap across all temperatures by construction, while Gumbel-ST without CAGE suffers a ${\sim}47$-point accuracy collapse.

ContrastiveCFG: Guiding Diffusion Sampling by Contrasting Positive and Negative Concepts
Jinho Chang, Changsun Lee, Hyungjin Chung, Jong Chul Ye
As Classifier-Free Guidance (CFG) has proven effective in conditional diffusion model sampling for improved condition alignment, many applications use a negated CFG term as a Negative Prompting (NP) to filter out unwanted features from samples. However, simply negating CFG guidance creates an inverted probability distribution, often distorting samples away from the marginal distribution. Inspired by recent advances in conditional diffusion models for inverse problems, here we present a novel method to achieve guidance toward the given condition using contrastive loss. Specifically, our guidance term aligns or repels the denoising direction based on the given condition through contrastive loss, achieving a similar guiding effect to traditional CFG for positive conditions while overcoming the limitations of existing negative guidance methods. Experimental results demonstrate that our approach effectively injects or removes the given concepts while

maintaining sample quality across diverse scenarios, from simple class condition
s to complex and overlapping text prompts.

MalTree: Tracing Malware Evolution using Embeddings at Scale
Akash Amalan, Georgios SMARAGDAKIS, Tom Julian Viering
Malware detection remains largely reactive: machine learning models trained on k
nown samples degrade as threats evolve. Understanding evolutionary relationships
 among malware families can inform proactive defense, but traditional reverse en
gineering can take months to years to uncover such lineage relationships. We pro
pose MalTree, a framework that applies bioinformatics-inspired phylogenetic tech
niques (UPGMA and Neighbor-Joining) at scale to model malware evolution automati
cally using structural, behavioral, and image-based features. We introduce tempo
ral validation using VirusTotal timestamps to assess whether inferred trees refl
ect actual evolutionary order. MalTree achieves 87% temporal consistency, indica
ting that inferred evolutionary relationships closely align with real-world emer
gence timelines. Our analysis shows that some families mutate over 10 times fast
er than others, suggesting that detection strategies should be tailored to famil
y-specific evolutionary tempos. Case studies, including the Mirai botnet, confir
m that inferred relationships from our phylogenetic tree align with documented t
hreat intelligence. Our framework provides a foundation for shifting malware ana
lysis from sample-by-sample classification toward lineage-aware evolutionary mod
eling.

SKETCH: Semantic Key-Point Conditioning for Long-Horizon Vessel Trajectory Predi
ction
Linyong Gan, Zimo Li, Wenxin XU, Li Xingjian, Jianhua Z. Huang, Enmei Tu, Shuhan
g Chen
Accurate long-horizon vessel trajectory prediction remains challenging due to co
mpounded uncertainty from complex navigation behaviors and environmental factors
. Existing methods often struggle to maintain global directional consistency, le
ading to drifting or implausible trajectories when extrapolated over long time h
orizons. To address this issue, we propose a semantic-key-point-conditioned traj
ectory modeling framework, in which future trajectories are predicted by conditi
oning on a high-level Next Key Point (NKP) that captures navigational intent. Th
is formulation decomposes long-horizon prediction into global semantic decision-
making and local motion modeling, effectively restricting the support of future
trajectories to semantically feasible subsets. To efficiently estimate the NKP p
rior from historical observations, we adopt a pretrain-finetune strategy. Extens
ive experiments on real-world AIS data demonstrate that the proposed method cons
istently outperforms state-of-the-art approaches, particularly for long travel d
urations, directional accuracy, and fine-grained trajectory prediction.

Uncovering the Gradient Geometry of Long CoT: A Spectral-guided Approach to Reas
oning Distillation
Sinan Fan, Xiaofeng Sun, Chen Shen, Chenxi Huang, Shaotian Yan, Bing Wang, kaiyu
an liu, Xiaosong Yuan, Liang Xie, Wenxiao Wang, Jun Zhang, Hongyang Chen, Jiepin
g Ye
Large reasoning models (LRMs) achieve remarkable reasoning performance by genera
ting long chains-of-thought (CoT). However, standard supervised fine-tuning (SFT
) treats all tokens uniformly, indiscriminately minimizing loss across both esse
ntial reasoning steps and those that are noisy, redundant, or instance-specific.
This often leads student models to memorize superficial patterns rather than acq
uire generalizable reasoning capabilities.
To better understand this limitation, we introduce \textit{Loss Subspace Attribu
tion}, a gradient decomposition analysis approach that uncovers a striking geome
tric structure:
Gradients corresponding to effective reasoning predominantly lie within a low-ra
nk consensus subspace, while conflicting or unstructured signals dominate the re
sidual subspace.
Guided by this insight, we propose \textbf{\textit{Spectral-guided Learning}}, a

step-level distillation strategy that uses spectral strength to identify reasoning steps aligned with the consensus subspace and prioritizes their contribution to parameter updates, while suppressing gradients from the residual subspace. Experiments across various LRMs and diverse complex reasoning tasks consistently demonstrate that focusing optimization on the consensus subspace yields more robust and generalizable student models.

FunPhase: A Periodic Functional Autoencoder for Motion Generation via Phase Manifolds
Marco Pegoraro, Evan Atherton, Bruno Roy, Aliasghar Khani, Arianna Rampini
Learning natural body motion remains challenging due to the strong coupling between spatial geometry and temporal dynamics. Embedding motion in phase manifolds, latent spaces that capture local periodicity, has proven effective for motion prediction; however, existing approaches are tied to fixed skeletons and narrow motion distributions, limiting their applicability across diverse settings.
We introduce FunPhase, a functional periodic autoencoder that learns a phase manifold for motion and replaces discrete temporal decoding with a function-space formulation, enabling smooth trajectories that can be sampled at arbitrary temporal resolutions.
FunPhase unifies motion prediction and generation within a single interpretable phase manifold, enabling motion generation via latent diffusion, generalizes across skeletons and datasets, and supports downstream tasks such as motion super-resolution and partial-body completion.
Our model achieves substantially lower reconstruction error than prior periodic autoencoder baselines, achieving uniform improvements of at least 45% across all metrics, while enabling a broader range of applications and performing on par with state-of-the-art motion generation methods.

Not All Prefills Are Equal: PPD Disaggregation for Multi-turn LLM Serving
Zongze Li, Jingyu Liu, Zach Xu, Yineng Zhang, Tahseen Rabbani, Ce Zhang
Prefill-Decode (PD) disaggregation has become the standard architecture for modern LLM inference engines, which alleviates the interference of two distinctive workloads. With the growing demand for multi-turn interactions in chatbots and agentic systems, we re-examined PD in this case and found two fundamental inefficiencies: (1) every turn requires prefilling the new prompt and response from the last turn, and (2) repeated KV transfers between prefill and decode nodes saturate the bandwidth, leading to high latency and even service degradation. Our key insight is that not all prefill operations are equally disruptive: append-prefill---processing only the new input tokens while reusing cached KV states---incurs substantially less decoding slowdown than full prefill. This motivates routing append-prefill to decode nodes locally. However, through comprehensive analysis, we show that no single fixed routing strategy satisfies all Service Level Objectives (SLOs) simultaneously. Based on this insight, we propose Prefill Prefill-capable Decode (PPD) disaggregation, a dynamic routing system that decides when to process Turn 2+ requests locally on decode nodes using cached KV states. PPD adapts to varying SLOs via configurable weights and seamlessly integrates with traditional PD deployments. With extensive evaluations, we show that PPD reduces Turn 2+ time-to-first-token (TTFT) by 68% while maintaining competitive time-per-output-token (TPOT), effectively alleviating KV transfer congestion under high load. We believe PPD represents a flexible and efficient paradigm for multi-turn LLM serving.

Structure-Aware Consistency Priors for Shape from Polarization in Complex Media
Kaimin Yu, Puyun Wang, Huayang He, Xianyu Wu
Recovering surface normals from single-view polarization images in complex media remains challenging. This paper focuses on ice as a representative complex medium, where intricate light–matter interactions lead to a nonlinear mapping between polarization observations and surface normals. To address this, a structure-aware polarization prior based on autocorrelation functions is proposed to capture

the local spatial consistency of AoLP. Building on this, a dual-branch network (IceSfP) is designed to integrate raw polarization features with priors via cross-modal attention and multi-scale feature fusion, enabling accurate surface normal estimation under complex media conditions. To evaluate the method, the first real-world ice SfP dataset is constructed. Experimental results show that the method outperforms existing approaches across all metrics, achieving a MAE of 16.01°, which is 2.74° lower than the second-best method. The framework provides a generalizable solution for high-precision geometric perception in complex media.

A Diffusive Classification Loss for Learning Energy-based Generative Models

RuiKang OuYang, Louis Grenioux, José Miguel Hernández-Lobato

Score-based generative models have recently achieved remarkable success. While they are usually parameterized by the score, an alternative way is to use a series of time-dependent energy-based models (EBMs), where the score is obtained from the negative input-gradient of the energy. Crucially, EBMs can be leveraged not only for generation, but also for tasks such as compositional sampling or building Boltzmann Generators via Monte Carlo methods. However, training EBMs remains challenging. Direct maximum likelihood is computationally prohibitive due to the need for nested sampling, while score matching, though efficient, suffers from mode blindness. To address these issues, we introduce the Diffusive Classification (DiffCLF) objective, a simple method that avoids blindness while remaining computationally efficient. DiffCLF reframes EBM learning as a supervised classification problem across noise levels, and can be seamlessly combined with standard score-based objectives. We validate the effectiveness of DiffCLF by comparing the estimated energies against ground truth in analytical Gaussian mixture cases, and by applying the trained models to tasks such as model composition and Boltzmann Generator sampling. Our results show that DiffCLF enables EBMs with higher fidelity and broader applicability than existing approaches. Our code is available at [h2o64/diffclf](https://github.com/h2o64/diffclf).

Transfer Learning in Nonparametric Regression with Deep ReLU Networks

Junpeng Ren, Carlos Misael Madrid Padilla, Yanzhen Chen, OSCAR HERNAN MADRID PADILLA

This paper develops a general transfer learning framework for nonparametric regression with data consisting of multiple groups. Under the assumption that groups share a common structure along with group-specific deviations in additive form, the proposed method employs a two-stage offset learning procedure: the first stage pools data from all groups to estimate an overall mean function, and the second stage estimates offsets for each group, yielding final group-level estimators through additive combination. Upper bounds on the $\mathcal L_2$ error are established for the proposed framework, covering a broad class of nonparametric estimators under mild complexity and noise conditions. When instantiated with deep ReLU networks, explicit convergence rates are derived under hierarchical composition models, demonstrating the ability to overcome the curse of dimensionality. Conditions that enable positive transfer with faster rates are considered, including learning with simpler functions and data augmentation through pooling samples across groups. Various simulations and real-data experiments further validate the effectiveness of the proposed method.

Discounted Beta–Bernoulli Reward Estimation for Sample-Efficient Reinforcement Learning with Verifiable Rewards

Haechan Kim, Soohyun Ryu, Gyouk Chu, Doohyuk Jang, Eunho Yang

Reinforcement learning with verifiable rewards (RLVR) has emerged as an effective post-training paradigm for improving the reasoning capabilities of large language models.

However, existing group-based RLVR methods often suffer from severe sample inefficiency.

This inefficiency stems from reliance on point estimation of rewards from a small number of rollouts, leading to high estimation variance, variance collapse, an

d ineffective utilization of generated responses.
In this work, we reformulate RLVR from a statistical estimation perspective by m odeling rewards as samples drawn from a policy-induced distribution and casting advantage computation as the problem of estimating the reward distribution from finite data.
Building on this view, we propose **D**iscounted **B**eta–**B**ernoulli (**DBB**) reward estimation, which leverages historical reward statistics for the non-st ationary distribution.
Although biased, the resulting estimator exhibits reduced and stable variance an d theoretically avoids variance collapse.
Under mild non-stationarity, it also achieves a lower mean squared error than st andard point estimation, as we characterize analytically and verify empirically.
Across six in-distribution and three out-of-distribution reasoning benchmarks, G RPO with DBB consistently outperforms naive GRPO and strong recent baselines, in cluding the replay-based RePO and the variance-collapse-aware GRESO and DAPO.
Relative to GRPO, it achieves average Acc@8 improvements of 3.43/2.32 points in- distribution and 10.05/8.34 points out-of-distribution on the 1.7B and 8B models , respectively, without additional computational cost or memory usage.

Escaping the Subspace Trap: The Role of Optimizer Geometry in Model Width Expans ion
Jiabei Chen, Haoyu Wang, Yang Yu, Yao Xu, Liangdong Wang, Guang Liu, Shizhu He, Jun Zhao, Kang Liu
Pre-training large language models from scratch is prohibitively expensive as mo del scales increase. A practical alternative is Model Width Expansion (MWE), whi ch grows a larger model from a well-pretrained ''seed'' model to inherit existin g capabilities at initialization. However, we identify a phenomenon termed the _ **Subspace Trap**_: during continual pre-training, parameter updates largely sta gnate within a low-dimensional subspace aligned with the initialization, limitin g the effective capacity of the expanded model. Our theoretical analysis investi gates this issue by attributing it to the function-preserving properties of widt h expansion. In particular, element-wise adaptive optimizers remain confined to the trap, whereas optimizers that yield an isotropic geometry of parameter updat es can escape. To demonstrate the impact of the subspace trap on model performan ce, we conduct empirical experiments across different model sizes and model fami lies, which show that escaping the trap is principally effective in improving tr aining efficiency and overall model performance. Detailed mechanistic analyses f urther confirm that escaping the trap indeed activates the new dimensions to enc ode general knowledge. Our code is available at https://github.com/A-PolarBear/M odel-Width-Expansion.

Dynamic High-Dimensional Facility Location with Low Recourse
Sayan Bhattacharya, Martín Costa, Silvio Lattanzi, Jakub ■■cki, Nikos Parotsidis
We study the problem of dynamic facility location with non-uniform costs. Facili ty location is a central problem in unsupervised learning and in recent years th e dynamic version of the problem has been extensively studied. In this paper, we study the setting where clients are added and deleted in real-time and one is i nterested in maintaining efficiently a stable and high-quality solution. Interes tingly, we are able to show that on High Dimensional Euclidean metrics it is pos sible to obtain efficient algorithms for this problem. More formally, we obtain a randomized algorithm for dynamic facility location in d-dimensional Euclidea n spaces with γ approximation ratio, $O(\log m)$ amortized recourse and $ \text{poly}(d) \cdot (m+n)^{O(1/\gamma)}$ amortized update time, for every suffi ciently large constant $\gamma \geq 1$. Our result is the first efficient dynami c algorithm for the \emph{non-uniform} dynamic facility location problem in high -dimensional Euclidean spaces. It also provides a stronger recourse bound than t he existing solutions.

Probability of Matching for Batch Multi-Objective Bayesian Optimization
Mingqian Li, Sina Hossein Zadeh, Raymundo Arroyave, Xiaoning Qian

In batch multi-objective Bayesian optimization (MOBO), it is often desirable to identify the whole Pareto optimal set, especially when considering the complicated interplay between different design criteria and constraints. This poses unique challenges in acquiring batches of both high quality and diversity to cover the Pareto front. We propose a novel acquisition strategy, Probability of Matching (POM), which evaluates both batch candidate quality and diversity by explicitly capturing the likelihood that all batch points are Pareto optimal, and the probability that they collectively cover the full Pareto set. To estimate the coverage probability and promote diversity, we incorporate non-replacement sampling principles, resulting in our new POM-guided batch MOBO method. Across synthetic benchmarks and real-world tasks, our method consistently outperforms state-of-the-art baselines on standard MOBO metrics as well as a new design-space coverage metric, Expected Minimum Distance (EMD), with comparable computational efficiency.
****
PlotCraft: Pushing the Limits of LLMs for Complex and Interactive Data Visualization
Jiajun Zhang, Jianke Zhang, Zeyu Cui, Jiaxi Yang, Lei Zhang, Zilei Wang, Qiang Liu, Liang Wang, Binyuan Hui, Junyang Lin
Recent Large Language Models (LLMs) have demonstrated remarkable proficiency in code generation. However, their ability to create complex visualizations for scaled and structured data remains largely unevaluated and underdeveloped. To address this gap, we introduce **PlotCraft**, a new benchmark featuring 1k challenging visualization tasks that cover a wide range of topics, such as finance, scientific research, and sociology. The benchmark is structured around seven high-level visualization tasks and encompasses 48 distinct chart types. Crucially, it is the first to systematically evaluate both single-turn generation and multi-turn refinement across a diverse spectrum of task complexities.
Our comprehensive evaluation of 23 leading LLMs on PlotCraft reveals obvious performance deficiencies in handling sophisticated visualization tasks. To bridge this performance gap, we develope **SynthVis-30K**, a large-scale, high-quality dataset of complex visualization code synthesized via a collaborative agent framework. Building upon this dataset, we develope **PlotCraftor**, a novel code generation model that achieves strong capabilities in complex data visualization with a remarkably small size.
Across VisEval, PandasPlotBench, and our proposed PlotCraft, PlotCraftor shows performance comparable to that of leading proprietary approaches. Especially, on hard task, Our model achieves over 50\% performance improvement. We will release the benchmark, dataset, and code at \href{https://anonymous.4open.science/r/PlotCraft-E320}{PlotCraft anonymous repository}.

A Fourier perspective on the learning dynamics of neural networks: from sample complexities to mechanistic insights
Fabiola Ricci, Claudia Merger, Sebastian Goldt
Neural networks trained with gradient-based methods exhibit a strong simplicity bias: they learn simpler statistical features of their data before moving to more complex features. Previous analyses of this phenomenon have largely focused on settings with (quasi-)isotropic inputs. In this work, we study the simplicity bias from a Fourier perspective, which allows us to include two key features of natural images in the analysis: approximate translation-invariance and power-law spectra. We first show experimentally that simple neural networks trained on image classification tasks first rely on amplitude information $-$ related to pair-wise correlations between pixels $-$ before exploiting phase information, which encodes edges and higher-order correlations. In view of this, we introduce a synthetic data model for translation-invariant inputs that allows precise control over amplitudes and phases while remaining tractable. We rigorously establish that for isotropic and high-dimensional inputs, classification based on phase information alone is a genuinely hard task: online stochastic gradient descent (SGD) cannot distinguish the structured inputs from noise within $n \ll N^3$ steps, but needs at least $n \gg N^3 \log^2{N}$ steps. In contrast, we show both experimentally and theoretically that power-law spectra can dramatically

accelerate the speed of learning phase information, even if the spectra do not help with classification. Simulations with two-layer networks trained on textures and with deep convolutional networks on ImageNet and CIFAR100 confirm this non-trivial interaction between amplitudes and phases, providing mechanistic insights into how deep neural networks can learn natural image distributions efficiently.

Hierarchical ODE: Learning Continuous-Time Physical Prototypes for Early Link Failure Detection

Jiaen Lv, Leran Qi, Shaowei Wang

Time series prototype learning is fundamentally challenged by observational ambiguity. Discrete architectures fail to resolve this, as they lack the capacity to decouple stochastic noise from continuous dynamics. Furthermore, rigid closed-set assumptions fail to capture unseen diversity. To address these limitations, we propose a hierarchical ordinary differential equation clustering network, which utilizes neural ordinary differential equation to model latent state evolution as a continuous integral curve. This formulation enforces temporal continuity to effectively disentangle smooth feature trends from stochastic noise, while our adaptive hierarchical mechanism autonomously determines the appropriate number of prototypes without rigid prior constraints. Validated on the early link failure detection task with irregularly sampled time series, the proposed method effectively extracts underlying physical prototypes, thereby enabling robust failure detection. Our code is available at https://github.com/NJ-LNN/Hierarchical-ODE.

Reasoning Compartmentalization: Bridging the Concretization Gap via Abstraction-based Routing

Ling-I Wu, Jian Tong, Yu Sun, Xuan Gao, Xu Guo, Qipeng Guo, Kai Chen, Guoqiang Li

While previous research has documented the sensitivity of Large Language Models (LLMs) to surface-level performance degradation, the underlying impact on internal representations and learning dynamics remains under-explored. In this work, we study this question using a controlled setup with paired reasoning tasks that are logically identical but expressed either in an abstract formal language (FL) or in natural language (NL). We find that converting FL problems into NL consistently degrades reasoning accuracy. More importantly, we show that FL and NL inputs activate largely separate internal representations and exhibit weak learning transfer between them. We refer to this phenomenon as reasoning compartmentalization. To test whether this compartmentalization can be mitigated, we introduce abstraction-based alignment, where models are trained to translate NL inputs into their corresponding FL forms. While this significantly improves reasoning performance, FL and NL representations remain largely distinct, and learning transfer across formulations remains limited. Through activation-level interventions, we further show that performance improvements arise not from representational fusion, but from improved routing. This suggests that abstraction alleviates formulation sensitivity by strengthening connections between formulation-specific reasoning pathways, rather than by aligning their representations.

Prompt Tuning for CLIP on the Pretrained Manifold

Xi Yang, Yuanrong Xu, Weigang Zhang, Guangming Lu, David Zhang, Jie Wen

Prompt tuning introduces learnable prompt vectors that adapt pretrained vision-language models to downstream tasks in a parameter-efficient manner. However, under limited supervision, prompt tuning alters pretrained representations and drives downstream features away from the pretrained manifold toward directions that are unfavorable for transfer. This drift degrades generalization. To address this limitation, we propose ManiPT, a framework that performs prompt tuning on the pretrained manifold. ManiPT introduces cosine consistency constraints in both the text and image modalities to confine the learned representations within the pretrained geometric neighborhood. Furthermore, we introduce a structural bias that enforces incremental corrections, guiding the adaptation along transferable directions to mitigate reliance on shortcut learning. From a theoretical perspecti

ve, ManiPT alleviates overfitting tendencies under limited data. Our experiments cover four downstream settings: unseen-class generalization, few-shot classification, cross-dataset transfer, and domain generalization. Across these settings, ManiPT achieves higher average performance than baseline methods. Notably, ManiPT provides an explicit perspective on how prompt tuning overfits under limited supervision.

TD3B: Transition-Directed Discrete Diffusion for Allosteric Binder Generation
Hanqun Cao, Aastha Pal, Sophia Tang, Yinuo Zhang, Jingjie Zhang, Pheng-Ann Heng, Pranam Chatterjee
Protein function is often controlled by ligands that bias the direction of state transitions, such as agonists and antagonists, rather than stabilizing a single conformation. This is especially important for clinically relevant G protein-coupled receptors (GPCRs), where therapeutic efficacy depends on functional directionality. Structure-based design methods optimize binding to static conformations and cannot represent non-reversible, directional effects or systematically distinguish agonist from antagonist behavior. To address this gap, we introduce **T**ransition-**D**irected **D**iscrete **D**iffusion for allosteric**B**inder design (**TD3B**), a sequence-based generative framework that designs binders with specified agonist or antagonist behavior via a directional transition control objective. TD3B combines a target-aware Direction Oracle, a soft binding-affinity gate, and amortized fine-tuning of a pre-trained discrete diffusion model, enabling targeted agonist and antagonist generation decoupled from binding affinity and unattainable by equilibrium-based or inference-only guidance baselines. The code and checkpoints are available at https://huggingface.co/ChatterjeeLab/TD3B.

Diffuse to Detect: Bi-Level Sample Rebalancing with Pseudo-Label Diffusion for Point-Supervised Infrared Small-Target Detection
Zhu Liu, Yuanhang Yao, Ping Qian, Zihang Chen, Risheng Liu
Point supervision has become a scalable solution to address dense annotation for infrared small target detection, but its performance is limited by two coupled bottlenecks: unstable pseudo-label evolution in cluttered, low-contrast infrared imagery and severe sample-distribution imbalance. In this paper, we present a more adaptive and stable framework to address these issues. Leveraging the intrinsic consistency between thermal radiation patterns and heat diffusion, we propose a physics-induced annotation strategy that expands single-point labels into reliable pseudo-masks. To further enhance supervision and alleviate sample imbalance, we develop a bi-level dual-update framework that jointly optimizes detector weights, sample weights, and diffusion parameters. A meta-classifier dynamically predicts sample-wise loss weights, while a differentiable diffusion module refines pseudo-labels with detection feedback, enabling adaptive interaction between training and hyperparameter optimization. Extensive experiments across multiple datasets demonstrate five-fold annotation acceleration, superior detection accuracy, and comparable performance with 30\% of the training data, validating the efficiency and practicality of our approach. Our code is available at https://github.com/yuanhang-yao/diffuse-to-detect.

Gradient Inversion Attacks Beyond SGD
Guangnian Wan, Gongfan Fang, Xinyin Ma, Xinchao Wang
Gradient Inversion Attack (GIA) poses a significant threat to federated learning, enabling adversaries to reconstruct private training data from the information shared during training. Prior research has predominantly focused on the vanilla SGD, where the server or an eavesdropper can directly observe true gradients. In practical deployments, however, models may be trained with adaptive optimizers (e.g., Adam, RMSProp, and AdaGrad), for which the observable signal is not raw gradients but momentum-based parameter updates. This setting remains underexplored and undermines traditional gradient-matching strategies, which struggle to recover labels and images from non-gradient updates. To address this gap, this paper explores attacks tailored to modern adaptive optimizers. We present an analytical rule for recovering labels from optimizer updates and propose an update-mat

ching objective that optimizes dummy inputs to reproduce the observed updates. T
he proposed approach is general and can be directly applied to various optimizer
s such as Adam, AdaGrad, and RMSProp. Furthermore, we find that, despite being i
ntroduced for adaptive optimizers, the proposed objective function also yields s
tronger attacks in the standard SGD setting. Experiments on datasets such as Ima
geNet and PACS highlight the effectiveness of our method over existing gradient
matching techniques.

DB-KSVD: Scalable Alternating Optimization for Disentangling High-Dimensional Em
bedding Spaces
Romeo Valentin, Sydney Michelle Katz, Vincent Vanhoucke, Mykel Kochenderfer
Dictionary learning has recently emerged as a promising approach for mechanistic
 interpretability of large transformer models.
Disentangling high-dimensional transformer embeddings requires algorithms that s
cale to high-dimensional data with large sample sizes.
Recent work has explored sparse autoencoders (SAEs) for this problem.
However, SAEs use a simple linear encoder to solve the sparse encoding subproble
m, which is known to be NP-hard.
It is therefore interesting to understand whether this approach is sufficient to
 find good solutions to the dictionary learning problem or if a more sophisticat
ed algorithm could find better solutions.
In this work, we propose Double-Batch KSVD (DB-KSVD), a scalable dictionary lear
ning algorithm that adapts the classic KSVD algorithm.
DB-KSVD is informed by the rich theoretical foundations of KSVD but scales to da
tasets with millions of samples and thousands of dimensions.
We demonstrate the efficacy of DB-KSVD by disentangling text embeddings of the G
emma-2-2B and Pythia-160M models and evaluating on six metrics from the SAEBench
 benchmark, where we achieve competitive results when compared to established ap
proaches based on SAEs.
We further show similar results when disentangling image embeddings obtained fro
m the DINOv2-S and DINOv2-B models, solidifying our findings.
By matching SAE performance with an entirely different optimization approach, ou
r results suggest that (i) SAEs do find strong solutions to the dictionary learn
ing problem and (ii) traditional optimization approaches can be scaled to the re
quired problem sizes, offering a promising avenue for further research.
We make an implementation of DB-KSVD available.

AdLift: Lifting Adversarial Perturbations to Safeguard 3D Gaussian Splatting Ass
ets Against Instruction-Driven Editing
Ziming Hong, Tianyu Huang, Runnan Chen, Shanshan Ye, Mingming Gong, Bo Han, Tong
liang Liu
Recent studies have extended instruction-driven 2D editing pipelines to 3D Gauss
ian Splatting (3DGS), enabling faithful 3DGS asset manipulation for advanced con
tent creation. However, it also exposes 3DGS assets to serious risks of unauthor
ized editing and malicious tampering. Although adversarial perturbations against
 editing models have proven effective for protecting 2D images, applying them to
 3DGS encounters two major challenges: *view-generalizable protection* and *bala
ncing invisibility with protection capability*. In this work, we propose AdLift,
 a novel editing safeguard for 3DGS that prevents instruction-driven editing acr
oss arbitrary views and dimensions by lifting strictly bounded 2D adversarial pe
rturbations into 3D Gaussian-represented safeguard. To ensure both *protective e
ffectiveness* and *invisibility*, these safeguard Gaussians are progressively op
timized across training views using a tailored Lifted PGD, which first conducts
gradient truncation during back-propagation from the editing model to the rend
ered image and applies projected gradient updates to strictly bound image-level
perturbations. Then, the resulting perturbation is backpropagated to the safegua
rd Gaussian parameters via *image-to-Gaussian fitting*. We alternate these two s
teps, yielding effective and imperceptible protection that generalizes across bo
th training and novel views. Empirically, qualitative and quantitative results d
emonstrate that the proposed AdLift effectively protects against state-of-the-ar

t instruction-driven 2D and 3DGS editing.

DPsurv: Dual-Prototype Evidential Fusion for Uncertainty-Aware and Interpretable Whole Slide Image Survival Prediction
Yucheng Xing, Ling Huang, Jingying Ma, Ruping Hong, Jiangdong Qiu, Pei Liu, Kai He, Huazhu Fu, Mengling Feng
Whole-slide images (WSIs) are widely used for cancer survival analysis because of their comprehensive histopathological information at both cellular and tissue levels, enabling quantitative, large-scale, and prognostically rich tumor feature analysis. However, most existing WSI survival analysis methods struggle with limited interpretability and often overlook predictive uncertainty in heterogeneous slide images. In this paper, we propose DPsurv, a dual-prototype whole-slide image evidential fusion network that outputs uncertainty-aware survival intervals, and enables interpretable survival results through patch prototype distribution assignment, component prototype evidence reasoning, and component-wise relative risk aggregation. Experiments on five publicly available datasets demonstrate strong discriminative performance and well-calibrated predictions, validating its effectiveness and reliability. The interpretation of survival results provides transparency at the feature, reasoning, and decision levels, thereby enhancing the trustworthiness and interpretability of DPsurv.

Rethinking Instruction Drift as a Sampling Error: SNR-Aware Power Distributions for Long-Horizon Robotic Planning
Kewei Chen, Yayu Long, Mingsheng Shang
Despite rapid progress in Vision-Language-Action (VLA) models for robotic control, instruction drift remains a persistent failure mode in long-horizon tasks. This paper reconceptualizes this phenomenon, positing that instruction drift is fundamentally a systematic sampling error: local greedy sampling is prone to collapsing into “Negative Pivotal Windows”—irreversible local optima with high local probability that sever global success pathways. To address this, we propose Context-Aware Power Sampling (CAPS), a training-free inference-time computation framework. CAPS leverages power distributions to sharpen global trajectory probabilities, enabling lookahead search over the model's conditional generative trajectory distribution. Furthermore, we introduce a metacognitive control mechanism based on Signal-to-Noise Ratio (SNR). This mechanism triggers adaptive MCMC search solely when drift risk is detected, enabling a dynamic transition from “intuitive fast thinking” to “rational slow search.” Experiments on RoboTwin, Simpler-WindowX, and Libero-long benchmarks show that CAPS achieves substantial improvements over strong baselines, including OpenVLA and TACO, without parameter updates. These results support the effectiveness of adaptive inference-time computation for improving long-horizon robustness in embodied control.

Posterior Sampling Reinforcement Learning with Gaussian Processes for Continuous Control: Sublinear Regret Bounds for Unbounded State Spaces
Hamish Flynn, Joe Watson, Ingmar Posner, Jan Peters
We analyze the Bayesian regret of the Gaussian process posterior sampling reinforcement learning (GP-PSRL) algorithm. Posterior sampling is a heuristic for decision-making under uncertainty that has been used to develop successful algorithms for a variety of continuous control problems. However, theoretical work on GP-PSRL is limited. All known regret bounds either have a sub-optimal growth rate, require strong smoothness assumptions, or fail to properly account for the fact that the set of possible system states is unbounded. Through a recursive application of the Borell-Tsirelson-Ibragimov-Sudakov inequality, we show that, with high probability, the states actually visited by the algorithm are contained within a ball of near-constant radius. We then use the chaining method to control the regret suffered by GP-PSRL under weak smoothness conditions. Our main result is a Bayesian regret bound of the order $\widetilde{\mathcal{O}}(H\sqrt{\gamma_TT})$, where H is the horizon, T is the number of time steps and γ_T is the expected information gain. With this result, we resolve the limitations with prior theoretical work on PSRL, and provide the theoretical foundation and tool

s for analyzing PSRL in complex settings.

SoftJAX & SoftTorch: Empowering Automatic Differentiation Libraries with Informa tive Gradients
Anselm Paulus, Andreas René Geist, Vít Musil, Sebastian Hoffmann, Georg Martius
Automatic differentiation (AD) frameworks such as JAX and PyTorch have enabled g radient-based optimization for a wide range of scientific fields. Yet, many ''ha rd'' primitives in these libraries such as thresholding, Boolean logic, discrete indexing, and sorting operations yield zero or undefined gradients that are not useful for optimization. While numerous ''soft'' relaxations have been proposed that provide informative gradients, the respective implementations are fragment ed across projects, making them difficult to combine and compare. This work intr oduces **SoftJAX** and **SoftTorch**, open-source, feature-complete libraries fo r *soft differentiable programming*. These libraries provide a variety of soft f unctions as drop-in replacements for their hard JAX and PyTorch counterparts. Th is includes (i) elementwise operators such as *clip* or *abs*, (ii) utility meth ods for manipulating Booleans and indices via fuzzy logic, (iii) axiswise operat ors such as *sort* or *rank* -- based on optimal transport or permutahedron proj ections, and (iv) offer full support for straight-through gradient estimation. O verall, SoftJAX and SoftTorch make the toolbox of soft relaxations easily access ible to differentiable programming, as demonstrated through benchmarking and a p ractical case study. Code is available at github.com/a-paulus/softjax and github .com/a-paulus/softtorch.

HiPER: Hierarchical Plan–Execute RL for Multi-Turn LLM Agents
Jiangweizhi Peng, Yuanxin Liu, Ruida Zhou, Charles Fleming, Zhaoran Wang, Alfred o Garcia, Mingyi Hong
Training LLMs as interactive agents for multi-turn decision-making remains chall enging, particularly in long-horizon tasks with sparse and delayed rewards, wher e agents must execute extended sequences of actions before receiving meaningful feedback. Most existing reinforcement learning (RL) methods model LLM agents as *flat* policies operating at a single time scale, selecting an action at each tu rn. In sparse-reward settings, this forces the agent to infer long-range depende ncies solely from distant end-of-trajectory signals, often leading to inefficien t learning and unstable behavior in complex environments. We propose **HiPER**, a novel **Hi**erarchical **P**lan–**E**xecute **R**L framework that jointly mode ls and optimizes high-level subgoal planning and low-level action execution for LLM agents to overcome flat RL's brittle long-horizon behavior and weak credit a ssignment under sparse outcome feedback. By maintaining persistent subgoals acro ss multiple turns and explicitly deciding when to switch between them, HiPER int roduces structured intermediate decision points that facilitate learning under s parse feedback, converting implicit multi-turn structure into learnable decision s at different time scales. To enable effective training, we introduce Hierarchi cal Advantage Estimation (HAE), a two-timescale policy gradient method that assi gns credit to both action execution and subgoal transitions and achieves varianc e reduction relative to flat advantage estimation. Empirically, HiPER achieves s tate-of-the-art performance on challenging interactive benchmarks, reaching 97.4 \% success on ALFWorld (+6.6\% over the best prior method) and 83.3\% on WebShop , with especially large gains on long-horizon tasks requiring multiple dependent subtasks. These results highlight the importance of explicit hierarchical decom position for scalable RL training of multi-turn LLM agents.
****
Temporal-Emerged Prompting for Segment Anything in Multiframe Infrared Small Tar get Detection
Yinghui Xing, Donghao Chu, Shizhou Zhang, Di Xu
Accurately localizing and segmenting small targets in low signal-to-noise ratio (SNR) infrared sequences remains a challenging task. Since targets are often ind istinguishable from the background in individual frames, existing methods, even when equipped with advanced foundation model and powerful inter-frame associatio n mechanisms, still fail to detect them. Motivated by the observation that targe

ts tend to emerge gradually from the background over time and become distinguish able, we propose Temporal-Emerged Prompting for Segment Anything Model (TEP-SAM) , a principled framework designed to explicitly exploit such temporal-emerged cu es to modulate and prompt SAM. TEP-SAM operates by jointly modeling global motio n patterns and local motion deviations to locate potential targets. It further e nhances target region features by leveraging motion discrepancy, thereby generat ing temporal-emerged cues for SAM and enabling non-interactive segmentation. By bridging large-scale semantic pretraining with task-specific temporal modeling, TEP-SAM effectively adapts SAM to the challenging multiframe infrared small targ et detection task. Extensive experiments demonstrate the effectiveness of our ap proach, particularly under severely low-SNR conditions and in complex dynamic ba ckground.

GeoSense: Internalizing Geometric Necessity Perception for Multimodal Reasoning

Ruiheng Liu, Haihong Hao, Mingfei Han, Xin Gu, Kecheng Zhang, Changlin Li, Xiaoj un Chang

Advancing towards artificial superintelligence requires rich and intelligent per ceptual capabilities. A critical frontier in this pursuit is overcoming the limi ted spatial understanding of Multimodal Large Language Models (MLLMs), where geo metry information is essential. Existing methods often address this by rigidly i njecting geometric signals into every input, while ignoring their necessity and adding computation overhead.

Contrary to this paradigm, our framework endows the model with an awareness of perceptual insufficiency, empowering it to autonomously engage geometric featur es in reasoning when 2D cues are deemed insufficient.

To achieve this, we first introduce an independent geometry input channel to t he model architecture and conduct alignment training, enabling the effective uti lization of geometric features. Subsequently, to endow the model with perceptual awareness, we curate a dedicated spatial-aware supervised fine-tuning dataset. This serves to activate the model’s latent internal cues, empowering it to auton omously determine the necessity of geometric information.

Experiments across multiple spatial reasoning benchmarks validate this approac h, demonstrating significant spatial gains without compromising 2D visual reason ing capabilities, offering a path toward more robust, efficient and self-aware m ulti-modal intelligence.

Holonomy Grid Codes for Generalisation Under Directed Actions

Pradeep Singh, Balasubramanian Raman

Efficient prediction and planning in structured environments often relies on spe ctral decompositions of transition operators, yet existing grid-cell and success or-representation theories implicitly assume “flat” action geometry where transl ations commute and a single Fourier eigenbasis suffices. We show that this assum ption breaks in the presence of path-dependent effects—e.g., circulation, rotati onal drift, or topological loops—whose defining signature is nontrivial holonomy . We introduce a theory of directed-action prediction on discrete tori based on twisted translation operators forming a projective representation of the underly ing motion group, and prove that the resulting controlled Markov operators admit an exact block-diagonalisation under a twisted Fourier transform: actions share a universal harmonic basis while their effects appear as small matrix-valued sp ectra rather than scalar eigenvalues. This yields closed-form resolvent expressi ons for the successor representation, a gauge-invariant transfer principle chara cterising when two environments admit identical predictive structure, and a curv ature-induced lower bound showing that nonzero holonomy provably necessitates in ternal representational dimension. Together, these results generalise Fourier/gr id-based prediction from commutative to curved action geometries, providing a pr incipled foundation for generalisation under directed actions without learning e nvironment-specific eigenvectors.

OVLR: Efficient, Scalable, and Robust Training via Output-Level Variance-Reduced Likelihood Ratio

Minhao Zou, Tao Ren, Jinyang Jiang, Rui Tao, Zehao Li, Jiale Fu, Hui Shao, Xianhua Liu, Yijie Peng

Gradient-based optimization via backpropagation (BP) is inherently limited by the requirement of differentiability, rendering it inapplicable for piecewise-constant objectives with vanishing gradients (e.g., the hard 0-1 loss) or black-box feedback. While likelihood ratio (LR) methods offer a theoretical alternative, their high variance in high-dimensional spaces undermines training stability and scalability. We propose OVLR, a framework that makes direct optimization of gradient-agnostic objectives practical for modern deep networks by performing perturbations and antithetic sampling in the low-dimensional output space. OVLR achieves dramatic variance reduction while requiring only a single deterministic forward pass, with additional costs restricted to evaluating the loss function across multiple samples. On problems where BP provides gradients, OVLR remains competitive; on problems where BP fails to provide reliable learning signals, OVLR enables the direct optimization of objectives such as the 0-1 loss for noise-tolerant classification and truncated losses for outlier-resistant regression. Extensive empirical results across classification, generative modeling, language modeling, robot imitation learning, and black-box optimization confirm that OVLR is an effective tool for settings where standard gradient-based optimization is inapplicable. Code is available at https://github.com/MinhZou/OVLR.

Dynamic Linear Attention

Xin Wang, Hui Shen, Boyuan Zheng, Xueshen Liu, Minkyoung Cho, Zhongwei Wan, Zesen Zhao, Zhuoqing Mao, Shen Yan, Mi Zhang

The scalability of Large Language Models (LLMs) to long contexts is fundamentally constrained by the quadratic complexity of standard attention, motivating the adoption of linear attention mechanisms with sub-quadratic cost. To improve representation capacity under long contexts, recent approaches organize memory in a multi-state manner. However, existing multi-state linear attention methods rely on fixed state merging policies that cannot adapt to dynamically varying token importance, irreversibly obscuring critical tokens and causing severe error accumulation over long sequences. To address this limitation, we propose DLA, a dynamic memory modeling framework for multi-state linear attention. DLA introduces (i) Information-Aware Dynamic State Merging, which adaptively determines state boundaries based on token-level information variation, preserving high-resolution representations around semantic transitions while aggressively summarizing stable regions, and (ii) Capacity-Bounded Memory Modeling, which maintains a fixed-size, chronologically ordered state cache by selectively merging adjacent low-information states to control memory growth with minimal information loss. We pre-train DLA on two different linear attention models and evaluate on 10 datasets from three different aspects. Experimental results demonstrate the superiority of DLA over state-of-the-art.

Bring Future Vision: Dynamic Computation Allocation Guided by Lightweight Feature Forecaster

Chao Han, Yijuan Liang, Zihao Xuan, Daokuan Wu, Wei Zhang, Xiaoyu Shen

The deployment of large language models (LLMs) in real-world applications is increasingly limited by their high inference cost. While recent advances in dynamic token-level computation allocation attempt to improve efficiency by selectively activating model components per token, existing methods rely on greedy routing—a myopic execute-or-skip mechanism that often leads to irreversible information loss and suboptimal token selection.

This paper introduces informed routing, a new paradigm that proactively addresses these issues. The key insight is to assess not only a token’s immediate importance but also its recoverability, i.e., how well its transformation can be approximated. To this end, we propose the Lightweight Feature Forecaster (LFF), a small predictive module that estimates a unit’s output before routing decisions are made. This enables a flexible execute-or-approximate policy that preserves model fidelity while drastically reducing computation.

Extensive experiments show that informed routing consistently achieves state-of-

the-art performance across static and dynamic pruning approaches. We further pre
sent two practical inference pipelines: a pure-PyTorch implementation and a Trit
on-based custom operator, that translate these gains into real-world speedups, a
chieving practical acceleration and consistent improvement across various batch
sizes.

Gaussian Mean Field Variational Inference can Overestimate Predictive Variance
James Odgers, Ben Riegler, Siddharth Swaroop, Vincent Fortuin
Mean Field Variational Inference (MFVI) is widely understood to underestimate po
sterior variance. By analysing conjugate Bayesian linear regression, we show tha
t this characterisation is incomplete: while MFVI underestimates the variance in
 parameter space, it can overestimate the predictive variance compared to the ex
act posterior. We show that if the MFVI posterior underestimates predictive vari
ances in some directions, it necessarily overestimates them in others. Crucially
, this overestimation occurs in directions where the training data concentrates.
 This leads to the surprising result that, for a test point drawn from the train
ing distribution, MFVI's expected predictive variance exceeds that of the exact
posterior. We demonstrate a pathological case of this effect, where the MFVI po
sterior fails to reduce predictive variance compared to the prior on i.i.d. data
. We connect these results to the Cold Posterior Effect, arguing that varying th
e temperature can correct this overestimation, yielding predictions closer to th
ose of the exact posterior. We validate our theory on synthetic and real-world r
egression tasks.

Enhancing LLM Training via Spectral Clipping
Xiaowen Jiang, Andrei Semenov, Sebastian U Stich
While spectral-based optimizers like Muon operate directly on the spectrum of up
dates, standard adaptive methods such as AdamW do not account for the spectral s
tructure of weights and gradients, leaving them vulnerable to two empirical issu
es in large language model (LLM) training: (i) the optimizer updates can have la
rge spectral norms, potentially destabilizing training and degrading generalizat
ion; (ii) stochastic gradient noise can exhibit sparse spectral spikes, with a f
ew dominant singular values much larger than the rest. We propose SPECTRA, a gen
eral framework addressing these by (i) post-spectral clipping of updates to enfo
rce spectral-norm constraints (ii) optional pre-spectral clipping of gradients t
o suppress spectral noise spikes. We prove that post-clipping constitutes a Comp
osite Frank-Wolfe method with spectral-norm constraints and weight regularizatio
n. We further analyze how pre-clipping mitigates sparse spectral spikes. We prop
ose efficient soft spectral clipping via Newton-Schulz iterations, avoiding expe
nsive SVD. Experiments on LLM pretraining show SPECTRA uniformly improves valida
tion loss for various optimizers, including AdamW, Signum, Mars, and AdEMAMix, w
ith the best-performing variants achieving state-of-the-art results. Models trai
ned with SPECTRA exhibit smaller weight norms, confirming the link between spect
ral clipping and regularization.

Large-scale Uncertainty Quantification for Latent Variable Models Using Subsampl
ing Markov Chain Monte Carlo
Xiaoyu Wang, Jonathan H. Huggins
Stochastic gradient Langevin dynamics combined with Gibbs updates (SGLD-Gibbs) p
rovides a highly scalable approach to approximate Bayesian inference in latent v
ariable models. However, it remains unclear how to tune the algorithm's hyperpar
ameters in a principled manner to ensure the uncertainty estimates are statistic
ally meaningful. In this work, we address this gap in tuning guidance by develop
ing a statistical scaling limit theory for SGLD-Gibbs. We derive a joint asympto
tic limit for the global parameters and latent variables under appropriate space
-time rescaling. We show that global parameters converge to a diffusion-type lim
it, while individual latent variables converge to a jump process reflecting thei
r intermittent Gibbs updates. This joint jump-diffusion structure reveals how la
tent-variable randomness contributes to the stationary distribution of the globa
l parameters. We leverage our results to provide explicit guidance on hyperparam

eter tuning for SGLD-Gibbs that ensures meaningful uncertainty quantification. O
ur empirical results show that SGLD-Gibbs with our tuning guidance leads to bett
er parameter estimates and uncertainty quantification than stochastic variationa
l inference.

RefChess: Training-Free Contextual Search for Zero-Shot Referring Image Segmenta
tion

Shiyan Tong, Jinxia Zhang, Zhiyuan Wang, Hao Tian, YingYing Wang, Kanjian Zhang,
 Haikun Wei

Recent advances in zero-shot referring image segmentation (RIS), driven by found
ation models such as SAM and CLIP, have improved cross-modal alignment between v
isual regions and natural language expressions. Nevertheless, selecting the corr
ect segmentation proposal remains challenging, as existing methods typically sco
re proposals independently and can be distracted by visually similar candidates
that partially satisfy the expression. To address this limitation, we propose Re
fChess, a training-free contextual search framework for robust proposal selectio
n. Instead of treating proposal selection as a single-step ranking problem, RefC
hess evaluates candidate masks under sampled distractor contexts and uses Monte-
Carlo Tree Search as a budgeted mechanism to explore the combinatorial space of
contextual perturbations. The search is guided by a stability-aware reward that
integrates language decomposition, vision--language similarity, object-centric c
ues, and spatial guidance signals. Experiments on standard RIS benchmarks show t
hat RefChess consistently improves robustness and referring segmentation perform
ance without task-specific training. Code is available at \url{https://github.co
m/Tongshiyan/RefChess}.

Dynamic Symmetric Point Tracking: Tackling Non-ideal Reference in Analog In-memo
ry Training

Quan Xiao, Jindan Li, Zhaoxian Wu, Tayfun Gokmen, Tianyi Chen

Analog in-memory computing (AIMC) performs computation directly within resistive
 crossbar arrays, offering an energy-efficient platform to scale large vision an
d language models. However, non-ideal analog device properties make the training
 on AIMC devices challenging. In particular, its update asymmetry can induce a s
ystematic drift of weight updates towards a device-specific symmetric point (SP)
, which typically does not align with the optimum of the training objective. To
mitigate this bias, most existing works assume the SP is known and pre-calibrate
 it to zero before training by setting the reference point as the SP. Neverthele
ss, calibrating AIMC devices requires costly pulse updates, and residual calibra
tion error can directly degrade training performance. In this work, we present t
he first theoretical characterization of the pulse complexity of SP calibration
and the resulting estimation error. We further propose a dynamic SP estimation m
ethod that tracks the SP during model training, and establishes its convergence
guarantees. In addition, we develop an enhanced variant based on chopping and fi
ltering techniques from digital signal processing. Numerical experiments demonst
rate both the efficiency and effectiveness of the proposed method.

T-Edit: Triple-Branch Diffusion Anchoring for Consistent Editing

Linsong Shan, Laurence Tianruo Yang, Zecan Yang, Shijie Lian, shijie lv, Qilin Y
ang

While Multimodal Diffusion Transformers (MMDiTs) have achieved remarkable succes
s in high-fidelity generation, maintaining semantic faithfulness and structural
consistency during the image editing process remains a fundamental challenge. Di
T-based editing is primarily limited by cumulative drift and semantic leakage in
duced by new textual conditions. To address these challenges, we propose T-Edit,
 a training-free framework that formalizes consistent editing as a trajectory an
choring process. T-Edit explicitly decouples the inversion, reconstruction, and
editing trajectories, leveraging the reconstruction branch as a structural refer
ence to achieve real-time compensation for deviations in the latent manifold. To
 further reveal the internal regulation mechanism of DiTs, we analyze the spatio
-temporal heterogeneity of their layer-wise structural sensitivity and according

ly propose a Dynamic Vital Layer (DVL) localization mechanism based on information energy. Furthermore, addressing the asymmetry of textual perturbations in the frequency domain distribution, we introduce a frequency-aware strategy based on tensor Singular Value Decomposition (t-SVD) to anchor (TA) high-rank structural components. Experiments show that T-Edit achieves state-of-the-art performance in both semantic alignment and structural fidelity, and can be seamlessly extended to multi-step editing and video scenarios, providing a new perspective for understanding and controlling the internal stability of DiTs.
****
MoCo-EA: Exploiting Adversarial Mode Connectivity for Efficient Evolutionary Attacks
Hyo Seo Kim, Gang Luo, Can Chen, Binghui Wang, Yue Duan, Ren Wang
Evolutionary algorithms for adversarial attacks leverage population-based search to discover perturbations without gradient information, but suffer from inefficient crossover operations that destroy adversarial properties through discrete interpolation. We introduce Mode Connectivity Evolutionary Attack (MoCo-EA), which replaces traditional crossover with a novel Bézier crossover operator that optimizes perturbations along a continuous Bézier curve between parent perturbations. Our key insight is that adversarial examples lie on connected manifolds where intermediate points maintain and often enhance attack effectiveness. We demonstrate three findings: (1) Successful adversarial perturbations exhibit mode connectivity; (2) Intermediate points along optimized paths achieve higher transferability than endpoints; (3) Bézier crossover dramatically outperforms discrete genetic operations while reducing convergence time and query requirements. By exploiting the geometric structure of adversarial space through path optimization, MoCo-EA provides an efficient and reliable method. Our work challenges the traditional view of adversarial examples as isolated points and opens new directions for both attack generation and defense research.
****
Accelerated Multiple Wasserstein Gradient Flows for Multi-objective Distributional Optimization
Dai Hai Nguyen, Duc-Dung NGUYEN, Atsuyoshi Nakamura, Hiroshi Mamitsuka
We study multi-objective optimization over probability distributions in Wasserstein space. Recently, Nguyen et al. (2025) introduced Multiple Wasserstein Gradient Descent (MWGraD) algorithm, which exploits the geometric structure of Wasserstein space to jointly optimize multiple objectives. Building on this approach, we propose an accelerated variant, A-MWGraD, inspired by Nesterov's acceleration. We analyze the continuous-time dynamics and establish convergence to weakly Pareto optimal points in probability space. Our theoretical results show that A-MWGraD achieves a convergence rate of $\mathcal{O}(1/t^2)$ for geodesically convex objectives and $\mathcal{O}(e^{-\sqrt{\beta}t})$ for β-strongly geodesically convex objectives, improving upon the $\mathcal{O}(1/t)$ rate of MWGraD in the geodesically convex setting. We further introduce a practical kernel-based discretization for A-MWGraD and demonstrate through numerical experiments that it consistently outperforms MWGraD in convergence speed and sampling efficiency on multi-target sampling tasks.
****
Think-Then-Generate: Reasoning-Aware Text-to-Image Diffusion with LLM Encoders
Siqi Kou, Jiachun Jin, Zetong Zhou, Ye Ma, Yugang Wang, Quan Chen, Peng Jiang, Xiao Yang, Jun Zhu, Kai Yu, Zhijie Deng
Recent progress in text-to-image (T2I) diffusion models (DMs) has enabled high-quality visual synthesis from diverse textual prompts. Yet, most existing T2I DMs, even those equipped with large language model (LLM)-based text encoders, remain text-pixel mappers -- they employ LLMs merely as text encoders, without leveraging their inherent reasoning capabilities to infer what should be visually depicted given the textual prompt. To move beyond such literal generation, we propose the think-then-generate (T2G) paradigm, where the LLM-based text encoder is encouraged to reason about and rewrite raw user prompts; the states of the rewritten prompts then serve as diffusion conditioning. To achieve this, we first activate the think-then-rewrite pattern of the LLM encoder with a lightweight supervi

sed fine-tuning process. Subsequently, the LLM encoder and diffusion backbone ar
e co-optimized to ensure faithful reasoning about the context and accurate rende
ring of the semantics via Dual-GRPO. In particular, the text encoder is reinforc
ed using image-grounded rewards to infer and recall world knowledge, while the d
iffusion backbone is pushed to produce semantically consistent and visually cohe
rent images. Experiments show substantial improvements in factual consistency, s
emantic alignment, and visual realism across reasoning-based image generation an
d editing benchmarks, achieving 0.79 on WISE score, nearly on par with GPT-4. Ou
r results constitute a promising step toward next-generation unified models with
 reasoning, expression, and demonstration capacities.

SF-Mamba: Rethinking State Space Model for Vision
Masakazu Yoshimura, Teruaki Hayashi, Yuki Hoshino, Wei-Yao Wang, Takeshi Ohashi
Visual Mamba models have recently emerged as alternatives to Vision Transformers
 (ViTs), which suffer from quadratic complexity.
While the recurrent scanning mechanism of Mamba offers computational efficiency,
 it inherently limits non-causal interactions between image patches.
Prior works have attempted to address this limitation through various multi-scan
 strategies; however, these approaches suffer from inefficiencies due to subopti
mal scan designs and frequent data rearrangement. Moreover, Mamba exhibits relat
ively slow computational speed under short token lengths, commonly used in visua
l tasks.
In pursuit of a truly efficient vision encoder, we rethink the scan operation fo
r vision and the computational efficiency of Mamba.
To this end, we propose SF-Mamba, a novel visual Mamba with two key proposals: a
uxiliary patch **swapping** for encoding bidirectional information flow under an
 unidirectional scan and batch **folding** with periodic state reset for advance
d GPU parallelism.
Extensive experiments on image classification, object detection, and instance an
d semantic segmentation consistently demonstrate that our proposed SF-Mamba sign
ificantly outperforms state-of-the-art baselines while improving throughput acro
ss different model sizes.
The source code is available at: https://github.com/sony/SF-Mamba.

Mesh Based Simulations with Spatial and Temporal awareness
Paul Garnier, Vincent Lannelongue, Elie Hachem
Machine Learning surrogates for Computational Fluid Dynamics (CFD), particularly
 Graph Neural Networks (GNNs) and Transformers, have become a new important appr
oach for accelerating physics simulations. However, we identify a critical bottl
eneck in the field: while architectures have advanced significantly, the common
underlying training paradigms remain bound to naive assumptions, such as node-wi
se supervision and explicit Euler time-stepping. These legacy choices ignore the
 stiff dynamics and local flux continuity inherent to numerous partial different
ial equations resolution methods, such as Finite Element, Difference, or Volume
(FEM). In this work, we propose a unified framework to bridge the gap between ge
ometric deep learning and rigorous numerical analysis. We introduce three key in
novations: (1) Multi Node Prediction, a stencil-level objective that predicts fi
eld values for a node's full local topology, enforcing spatial derivative consis
tency; (2) Temporal Correction, replacing unstable explicit schemes with a predi
ctor–corrector via temporal Cross-Attention; and (3) Geometric Inductive Biases,
 leveraging 3D Rotary Positional Embeddings (RoPE) to robustly capture rotationa
l symmetries in unstructured meshes. We evaluate this framework across three arc
hitectures (MeshGraphNet, Transolver, and a Transformer) on diverse physics data
sets. Our approach yields consistent improvements in accuracy and stability, par
ticularly in long-horizon rollouts, while producing latent representations that
generalize to unseen subtasks such as Wall Shear Stress or Pressure prediction.

SMILE: Extended Deep Submodular Function-Based Instruction and In-context Learni
ng Demonstration Selection

Zihan Chen, Chengshuai Shi, Song Wang, Jundong Li, Cong Shen
Prompt optimization is a key way to steer large language models when fine-tuning is impractical. However, instruction optimization (IO) and in-context learning (ICL) demonstration selection are often optimized separately and combined post hoc, implicitly assuming that a "best'' instruction and a "best" demonstration set compose well. In practice, their interactions are strong, making such decoupled pipelines brittle.
We propose SMILE, an efficient method that *jointly* selects instructions and demonstrations. Our key observation is that the ICL performance exhibits consistent diminishing returns across diverse instructions. Leveraging this structure, SMILE learns an instruction-conditioned surrogate aligned with LLM feedback and instantiates it as an Extended Deep Submodular Function that captures sample--sample coverage, sample--query relevance, and sample--instruction compatibility. SMILE then performs greedy, query-adaptive selection of the instruction--demonstration pair.
Experiments on six datasets and multiple LLM backbones show that SMILE consistently outperforms IO-only, ICL-only, and existing joint baselines, supporting a context engineering view of prompting: jointly optimizing interacting components rather than tuning them in isolation.

FedEBA+: Towards Fair and Effective Federated Learning via Entropy-Based Model
Zhichao Wang, Lin Wang, Ye Shi, Sai Praneeth Karimireddy, Xiaoying Tang
Federated Learning (FL) often suffers from sacrificing global model accuracy when improving client-level fairness due to data heterogeneity, which often leads to inconsistent performance of the globally trained models, resulting in unfair outcomes among users. Existing fair FL algorithms face a bottleneck: they either sacrifice global model accuracy to promote fairness or fall short of achieving optimal fairness.

In this paper, we propose a novel framework that effectively improves fairness while preserving global accuracy by integrating information-theoretic principles with model alignment. Specifically, we leverage the Maximum Entropy Principle to derive an analytic, closed-form solution for fair aggregation weights, ensuring significant fairness enhancements. We further employ a step-wise model alignment strategy that synchronizes gradient directions across heterogeneous clients, effectively mitigating the drift induced by local updates.

Theoretical analysis proves that our method guarantees convergence even in non-convex settings. Importantly, we push the theoretical frontier of federated fairness by extending performance variance analysis to generalized regression, providing broader guarantees. Extensive experiments on five datasets demonstrate that our approach consistently outperforms state-of-the-art methods, achieving superior fairness without sacrificing global accuracy. Our code is available at \href{https://github.com/T-Lab-CUHKSZ/FedEBA-Plus}{https://github.com/T-Lab-CUHKSZ/FedEBA-Plus}.

Incorporating Importance Weighting in Optimal Transport Based Domain Alignment
Okan Koç, Alexander Soen, Shanglin Li, Masashi Sugiyama
Domain adaptation theory studies upper bounds on the target risk in order to mitigate performance loss of machine learning models due to distribution shift.
In this paper, we take a closer look at the optimization of one such bound based on optimal transport (OT) and propose various strategies that improve the optimization in practice. We first introduce *gradual shift* and *probabilistic margin* assumptions to control the incomputable entanglement term that appears in the bounds. We prove that under these assumptions, better optimization of the computable part of the bound can translate to better target accuracies. Motivated by this fact, we tighten the bound, via importance weighting of the source (output) distribution, to obtain the *weighted* Wasserstein regularized risk ($\mathrm{W}^2\mathrm{R}^{2}$), that is often easier to minimize than the original bound. $\mathrm{W}^2\mathrm{R}^{2}$ is shown to be equivalent to an unbalanced OT proble

m, which in the limit converges to a nearest neighbor based alignment strategy. We highlight the tradeoffs faced with such an approach and show that a suitably regularized $\mathrm{W}^2\mathrm{R}^{2}$ improves over the state of the art and is robust to multiple distribution shifts under different models, confirming, moreover, the validity of our assumptions.
****
Toward Stable Value Alignment: Introducing Independent Modules for Consistent Value Guidance
Wenhao Chen, Sirui Sun, Shengyuan Bai, Guojie Song
Aligning large language models (LLMs) with human values typically relies on post-training or inference-time steering that directly manipulates the backbone's parameters or representation space. However, a critical gap exists: the model's residual stream is highly dynamic, in which values exist as fragile, low-dimensional properties, inherently incompatible with the stability required for consistent value expression. In this paper, we propose the Stable Value Guidance Transformer (SVGT), which addresses this gap through an independent value module incorporating two key designs: (1) *independent value modeling*, maintaining normative representations in a dedicated value space isolated from the backbone, and (2) *explicit behavioral guidance*, transducing these stable signals into learnable latent Bridge Tokens. These tokens serve as dynamic value anchors to explicitly steer the generative trajectory, ensuring robust adherence across diverse contexts without disrupting the backbone's internal representations. Experiments across multiple backbones and safety benchmarks show that SVGT generally reduces harmful scores by over 70\% while maintaining generation fluency, demonstrating the efficacy of architecturally grounded value modeling.

Dismantling the Illusion of Vision-Language-Action Models Competence via Explicit Distributional Shifts
Xueyang Zhou, Yangming Xu, Guiyao Tie, Chaoran Hu, Bo Tao, xingwei zhao, Xiang Xiang, Pan Zhou, Lichao Sun, Yongchao Chen
Given that simulation can never exhaustively enumerate reality, generalization is the determining factor for whether Vision-Language-Action (VLA) models can translate benchmark success into real-world functionality. However, current evaluation protocols often incentivize mechanical memorization rather than robust policy learning, leading to a paradoxical duality of failure: high-scoring models exhibit *spurious invariance* to semantic changes while simultaneously displaying *extreme brittleness* to trivial environmental perturbations. To address this, we introduce **LIBERO-Gen**, a diagnostic benchmark systematically designed to shift evaluation from intuition-driven heuristics to explicit distributional assumptions. Through a hierarchical protocol spanning **In-distribution**, **Compositional**, and **Domain Generalization**, LIBERO-Gen reveals performance stratifications previously masked by standard metrics. Our analysis identifies Pi0.5 as the top performer (64.0% in Spatial-CG; 21.2% in Task-CG). By identifying perceptual instability and action binding collapse as primary failure modes while validating the efficacy of structured ``Stair" sampling, LIBERO-Gen establishes a rigorous baseline for deployment reliability.
****
Cluster-Aware Causal Mixer for Online Anomaly Detection in Multivariate Time Series
Md Mahmuddun Nabi Murad, Yasin Yilmaz
Early and accurate detection of anomalies in time-series data is critical due to the substantial risks associated with false or missed detections. While MLP-based mixer models have shown promise in time-series analysis, they do not maintain temporal causality during data processing. Moreover, real-world multivariate time series often contain numerous channels with diverse inter-channel correlations. Spurious correlations in the reconstructed time series lead to noisy representations, resulting in inaccurate anomaly detection. In addition, anomaly scoring methods that ignore temporal continuity can mislead sequential detection. To address these challenges, we propose a cluster-aware causal mixer for multivariate time-series anomaly detection. Channels are grouped into clusters based on thei

r correlations, and each cluster is embedded through a dedicated embedding layer . A causal mixer is introduced to integrate information while maintaining tempor al causality. We further develop a sequential anomaly-scoring method that accumu lates evidence over time and refines anomaly boundaries. Our proposed model oper ates in an online fashion, making it suitable for real-time time-series anomaly detection. Experimental evaluations across six public benchmark datasets demonst rate that the proposed approach consistently achieves superior performance.

PlugGuard: A Streaming Safeguard for Large Models via Latent Dynamics-Guided Ris k Detection
Xiaodan Li, Mengjie Wu, Yao Zhu, Yunna Lv, YueFeng Chen, Cen Chen, Jianmei Guo, Hui Xue
Large models (LMs) are powerful content generators, yet their open■ended nature can also introduce potential risks, such as generating harmful or biased content . Existing guardrails mostly perform post-hoc detection that may expose unsafe c ontent before it is caught,
and the latency constraints further push them toward lightweight models, limitin g detection accuracy. In this work, we propose PlugGuard, a novel plug-in framew ork that enables streaming risk detection within the LM generation pipeline. Plu gGuard leverages intermediate LM hidden states through a Streaming Latent Dynami cs Head (SLD), which models the temporal evolution of risk across the generated sequence for more accurate real-time risk detection. To achieve reliable streami ng moderation in real applications, we introduce an Anchored Temporal Consistenc y (ATC) loss, ensuring that risk assessments remain consistent with a strict sto p-if-harmful policy. Besides, for a rigorous evaluation of streaming guardrails, we also present StreamGuardBench—a model-grounded benchmark featuring on-the-fl y responses from each protected model, reflecting real-world streaming scenarios in both text and vision–language tasks. Across diverse models and datasets, Plu gGuard consistently outperforms state-of-the-art streaming guardrails (achieving a 22.80% F1 score gain), while using only 20M parameters and adding less than 0 .5 ms of per-token latency. The code and StreamGuardBench are released at PlugGu ard to facilitate research on streaming guardrails.

Knowing When to Quit: A Principled Framework for Dynamic Abstention in LLM Reaso ning
Hen Davidov, Nachshon Cohen, Oren Kalinsky, Yaron Fairstein, Guy Kushilevitz, Ra m Yazdi, Patrick Rebeschini
Large language models (LLMs) using chain-of-thought reasoning often waste substa ntial compute by producing long, incorrect responses. Abstention can mitigate th is by withholding outputs unlikely to be correct. While most abstention methods decide to withhold outputs before or after generation, dynamic mid-generation ab stention considers early termination of unpromising reasoning traces at each tok en position. Prior work has explored empirical variants of this idea, but princi pled guidance for the abstention rule remains lacking. We present a formal analy sis of dynamic abstention for LLMs, modeling abstention as an explicit action wi thin a regularized reinforcement learning framework. An abstention reward parame ter controls the trade-off between compute and information. We show that abstain ing when the value function falls below this reward strictly outperforms natural baselines under general conditions. We further derive a principled and efficien t method to approximate the value function. Empirical results on mathematical re asoning tasks support our theory and demonstrate improved selective accuracy ove r existing methods.

A General Framework for Fair and Robust Regression
Wenhai Cui, Xiaoting Ji, Wen Su, Xingqiu Zhao
Fair regression methods typically rely on squared error loss, making them fragil e under heavy tailed noise. We propose a general framework for robust regression under demographic parity (DP) that applies to a wide class of M-estimators, inc luding Cauchy, Huber, least absolute deviation, quantile, and Tukey losses. We p ropose an optimal fair transformation that guarantees DP while achieving the min

imum population risk among all rank preserving fair predictors. We also establis h convergence rates for the resulting estimators. To balance fairness and predic tive accuracy, we develop an interpolation scheme whose risk decreases while unf airness grows linearly with the interpolation parameter. The proposed framework can be further extended to conditional DP to account for legitimate covariates. Extensive simulation studies and real data applications show clear improvements over existing fair regression approaches in both robustness and predictive perfo rmance.

HOBIT: Hardness Optimized Batch Sampling for InfoNCE Training
Himanshu Dutta, Lokesh Nagalapatti, Yashoteja Prabhu
Contrastive training with InfoNCE loss and in-batch negatives is the standard a pproach for learning dual-encoder models. Its effectiveness, however, critically depends on the availability of hard negatives; in their absence, learning quick ly saturates. Existing methods address this via explicit hard-negative mining, w hich is often costly or heuristic-driven. We introduce $\mathrm{\texttt{HOBIT}}$, a principled mini-batch construction method that improves in-batch negative qu ality by reordering training examples at every epoch. $\mathrm{\texttt{HOBIT}}$ solves an optimization problem motivated by the InfoNCE objective to yield mini- batches such that each query in the batch is exposed to hard yet non-contradicto ry, informative negative examples. We show that the optimization objective is mo notone and submodular which in turn leads us to a greedy algorithm that admits t he standard $\mathcal{O}(1 - 1/e)$ approximation guarantee. Empirically, we show that $\mathrm{\texttt{HOBIT}}$ incurs negligible computational overhead while s ignificantly outperforming state-of-the-art batching methods, and remains comple mentary to existing hard negative mining techniques.

The Devil is in the Spectrum: Mitigating Representation Collapse in LLMs via Top ologically Regularized Side-Path
Yiheng Tao, Kaiwen Cheng, Yao Lu, Chang Liu, Jie Chen
Large Language Models (LLMs) are fundamentally limited by representation collaps e, a bottleneck that severely degrades long-context performance. We identify tha t existing approaches risk drifting into one of two pathological extremes: homog enization collapse (e.g., attention sinks causing rank deficiency) and isolation collapse (e.g., local attention causing context disconnection). Through spectra l analysis of attention dynamics, we derive an intrinsic trade-off between mixin g efficiency (spectral gap) and information capacity (effective rank) that stand ard mechanisms struggle to balance. To resolve this dilemma, we propose the Topo logically Regularized Side-Path (TRSP), a non-invasive architectural interventio n that achieves spectral balance. TRSP employs a parameter-free Triangular Box m echanism, scaled by a lightweight, length-aware gate, to regularize the token in teraction topology. By integrating proximal coupling to preserve effective rank and distal propagation to support non-degenerate mixing, TRSP promotes a geometr ically healthier transition operator without altering core attention. Experiment s show significant improvements across general capabilities and long-context ben chmarks. Notably, on NoLiMa at $8\times$ the training length, TRSP retains $83\% $ accuracy and surpasses the Differential Transformer and Gated Attention by app roximately 30 and 50 percentage points, respectively. Code available at: https:/ /github.com/Eziotao-tyd/TRSP.

Unsupervised Neural Langevin Sampler for Mixed Integer Linear Programming
Yixin Huang, Shengyu Feng, Yiming Yang
Existing neural combinatorial optimization (CO) solvers often rely heavily on ex pensive labeled data and additional post-processing to produce feasible solution s. Research into mixed integer linear programs (MILPs) is particularly limited d ue to the lack of effective heuristics for feasibility and the challenge of mode ling mixed-type variables for neural solvers. To address these issues, we propos e a novel unsupervised Langevin sampler for solving MILPs. Our framework learns only integer variables, while continuous variables are solved using an exact lin ear programming solver, thus isolating the combinatorial hardness of the problem

and avoiding unnecessary modeling complexity. The sampler is based on Langevin dynamics and incorporates both objective optimization and constraint satisfaction into a unified energy function, enabling the model to jointly learn feasibility and optimality. Experiments demonstrate that our method achieves 100\% feasibility without expensive post-processing and matches or outperforms supervised solvers on benchmark datasets, highlighting its effectiveness and scalability. Our code can be found at https://github.com/CindyH1103/UNLS4MILP.

Diversity-Preserved Distribution Matching Distillation for Fast Visual Synthesis

Tianhe Wu, Ruibin Li, Lei Zhang, Kede Ma

Distribution matching distillation (DMD) facilitates few-step image generation by aligning a distilled student with a reference multi-step teacher. In practice, however, optimizing DMD can reduce sample diversity in few-step synthesis, and existing remedies typically rely on perceptual or adversarial regularization, leading to stability and scalability challenges during training. Here, we describe diversity-preserved DMD (DP-DMD), a role-separated distillation method inspired by the complementary roles of early and late denoising steps. Specifically, the first distillation step is trained with a teacher-derived target-prediction objective (e.g., v-prediction) to preserve sample diversity, while the remaining steps are optimized with the standard DMD loss to refine perceptual quality. DP-DMD, with no perceptual or adversarial regularization, no additional modules, and no teacher-generated reference samples, preserves sample diversity while maintaining competitive visual quality under few-step sampling, providing a simple and stable alternative to other DMD variants.

Step-Resolved Data Attribution for Looped Transformers

Georgios Kaissis, David Mildenberger, Juan Felipe Gomez, Martin J. Menten, Eleni Triantafillou

We study how individual training examples shape the internal computation of looped transformers, where a shared block is applied for τ recurrent iterations to enable latent reasoning. Existing training-data influence estimators such as TracIn yield a single scalar score that aggregates over all loop iterations, obscuring when during the recurrent computation a training example matters. We introduce Step-Decomposed Influence (SDI), which decomposes TracIn into a length-τ influence trajectory by unrolling the recurrent computation graph and attributing influence to specific loop iterations. To make SDI practical at transformer scale, we propose a TensorSketch implementation that never materialises per-example gradients. Experiments on looped GPT-style models and algorithmic reasoning tasks show that SDI scales excellently, matches full-gradient baselines with low error and supports a broad range of data attribution and interpretability tasks with per-step insights into the latent reasoning process.

EvoGM: Learning to Merge LLMs via Evolutionary Generative Optimization

Tao Jiang, Yu Xinmeng, Chenhao Yi, Yiling Wu, Yan Li, Ran Cheng, Dongmei Jiang, Jianguo Zhang

Evolutionary model merging provides a powerful framework for the automated, training-free composition of LLMs through parameter-space search. However, existing methods predominantly rely on stochastic, hand-crafted operators that overlook the underlying performance landscape of the coefficient space. We propose Evolutionary Generative Merging (EvoGM), a framework that transcends manual heuristics by employing learnable generative modeling to optimize merging coefficients. Specifically, EvoGM features a dual-generator architecture with cycle-consistent learning to adaptively sample and refine promising merging candidates. By constructing winner-loser pairs from historical search trajectories, our framework effectively captures high-performance parameter distributions and maximizes data efficiency. This generative process is seamlessly integrated into a multi-round evolutionary pipeline, where elite merged models iteratively serve as new expert foundations. Extensive experiments across diverse benchmarks demonstrate that EvoGM significantly outperforms state-of-the-art baselines, exhibiting robust performance on both seen and unseen tasks. Code and data are available at https://githu

b.com/JiangTao97/evogm.

Towards Realistic Lifelong Re-identification: Identity Recurrence with Changing Clothes
Wuxuan Shi, Zhijie Lu, He Li, Mang Ye
Existing lifelong person re-identification (Re-ID) methods assume that each identity maintains a relatively stable appearance distribution over time. However, in real-world scenarios, identities often reappear asynchronously with substantial clothing changes, which is not modeled in existing lifelong Re-ID formulations. We therefore study a realistic lifelong cloth-changing Re-ID (LCC) setting, in which identities reappear asynchronously under substantial clothing changes. This setting leads to two core difficulties: the model must acquire new identities while adapting representations of recurring ones, and at the same time remain robust to the substantial representation drift induced by clothing changes over time, which undermines cross-temporal identity consistency. To address these, we develop a framework that disentangles identity-intrinsic representations from clothing-induced biases, enabling identity modeling beyond appearance changes. We further introduce a Dynamic Identity-Anchor Alignment to maintain stable identity anchors under stage-wise distribution shifts. Experiments on the LTCC and PRCC benchmarks demonstrate superior performance and representational stability across multiple learning stages. Our code is available at https://github.com/joyner-7/LCC_ReID.

Mitigating Premature Exploitation in Particle-based Monte Carlo for Inference-Time Scaling
Giorgio Giannone, Guangxuan Xu, Nikhil Shivakumar Nayak, Rohan Mahesh Awhad, Shivchander Sudalairaj, Kai Xu, Akash Srivastava
Inference-Time Scaling (ITS) improves language models by allocating more computation at generation time. Particle Filtering (PF) has emerged as a strong ITS method for complex mathematical reasoning tasks, but it is vulnerable when guided by process reward models, which often assign overconfident scores early in the reasoning process. This causes PF to suffer from premature exploitation: it myopically commits to locally promising trajectories, prunes potentially correct hypotheses, and converges to suboptimal solutions. This failure mode, known as particle impoverishment, is especially severe under constrained computational budgets. To address this, we analyze the problem and identify two root causes: a lack of diversity in the particle set due to overconfident resampling and consequent inability to assess the potential of a reasoning path. We introduce Entropic Particle Filtering (ePF), an algorithm that integrates two new techniques to solve these issues. The first technique, Entropic Annealing (EA), directly mitigates particle impoverishment by monitoring search diversity via entropy; when diversity drops, it intervenes by dynamically annealing the resampling distribution to preserve exploration. The second, an enhancement called Look-ahead Modulation (LaM), adds a predictive guide to evaluate a state's potential based on its successors. By effectively balancing exploration and exploitation, ePF significantly outperforms strong baselines on challenging math benchmarks, achieving up to a 50% relative improvement in task reward.
****
Improving Visual Token Reduction via Rectifying Distortions for Efficient Multimodal LLM Inference
Hyeonwoo Cho, Donghyeon Baek, Yewon Kim, Bumsub Ham
Recent advancements in Multimodal Large Language Models (MLLMs) have achieved remarkable success in vision-language tasks, yet the quadratic computational complexity arising from the vast number of visual tokens incurs significant memory and latency bottlenecks. While visual token reduction (VTR) strategies have been explored to mitigate this burden, existing methods overlook the positional and attentional consistency between the full and reduced sequences, resulting in a distorted representation. To this end, we propose RESTORE, a novel VTR framework that rectifies the positional and attentional distortions while maintaining efficiency. Specifically, we present a simple yet effective calibration method that re

stores lost visual attention by augmenting attention weights based on relative d
istances. We also introduce a distinctive anchor selection for token merging to
mitigate information loss during feature averaging. Experimental results on mult
iple benchmarks demonstrate that our method consistently improves the accuracy o
f various reduction methods, achieving state-of-the-art performance while mainta
ining computational efficiency.

Scalable and Differentiable Point-Cloud Registration Using Maximum Mean Discrepa
ncy
Rixon Crane, Fahira Afzal Maken, Nicholas Lawrance, Stanislav Funiak, Kasra Khos
oussi, Ming Xu, Russell Tsuchida
We present MMD-Reg, a novel correspondence-free approach to point-cloud registra
tion that is differentiable and has linear computational complexity in the numbe
r of points. We model registration as a nonlinear least-squares problem based on
 the Maximum Mean Discrepancy, approximated using random Fourier features. The r
esulting objective can be solved efficiently with standard methods such as Leven
berg–Marquardt, and the solution is differentiable via the implicit function the
orem. This allows MMD-Reg to be used as a differentiable optimization layer with
in end-to-end trainable models, supporting registration under challenging condit
ions such as poor initial alignment and partial overlap. We demonstrate this Neu
ral MMD-Reg formulation by integrating the layer with a set transformer, trainin
g the resulting model in supervised and unsupervised settings, and comparing its
 performance against recent learning-based methods. We also evaluate standalone
MMD-Reg, comparing its accuracy and scalability against widely used non-learning
-based registration methods.

WeDLM: Reconciling Diffusion Language Models with Standard Causal Attention for
Fast Inference
Aiwei Liu, Minghua He, Shaoxun Zeng, Sijun Zhang, Linhao Zhang, Chuhan Wu, Wei J
ia, Yuan Liu, Zhou Xiao, Jie Zhou
Autoregressive (AR) generation is the standard decoding paradigm for Large Langu
age Models (LLMs), but its token-by-token nature limits parallelism at inference
 time. Diffusion Language Models (DLLMs) offer parallel decoding by recovering m
ultiple masked tokens per step; however, in practice they often fail to translat
e this parallelism into speed gains over optimized AR engines (e.g., vLLM). A ke
y reason is that many DLLMs rely on bidirectional attention, which breaks standa
rd prefix KV caching.
We propose WeDLM, a diffusion decoding framework built entirely on standard caus
al attention to make parallel generation prefix-cache friendly. The core idea is
 to let each masked position condition on all observed tokens while keeping a ca
usal mask, achieved by Topological Reordering that moves observed tokens to the
physical prefix while preserving their logical positions. Building on this, we i
ntroduce a streaming decoding procedure that continuously commits confident toke
ns into a growing left-to-right prefix, avoiding the stop-and-wait behavior comm
on in block diffusion methods. Experiments show that WeDLM preserves the quality
 of strong AR backbones while delivering substantial speedups, approaching 3× on
 challenging reasoning benchmarks and up to 10× in low-entropy generation regime
s; critically, our comparisons are against AR baselines served by vLLM under mat
ched deployment settings.
****
Attention Sinks in Diffusion Transformers: A Causal Analysis
FANGZHENG WU, Brian Summa
Attention sinks---tokens that receive disproportionate attention mass---are
assumed to be functionally important in autoregressive language models, but
their role in diffusion transformers remains unclear.
We present a causal analysis in text-to-image diffusion, dynamically identifying

dominant attention recipients per timestep and suppressing them via paired,
training-free interventions on the score and value paths.
Across 553 GenEval prompts on Stable Diffusion~3 (with SDXL corroboration),

removing these sinks does not degrade text-image alignment (CLIP-T) or preference proxies (ImageReward, HPS-v2) at $k{=}1$; only under stronger interventions ($k\!\geq\!10$) does HPS-v2 exhibit a metric-dependent boundary, while CLIP-T remains robust throughout.
The perceptual shifts induced by suppression are nonetheless \emph{sink-specific}---$\sim\!6\times$ larger than equal-budget random masking---revealing an empirical dissociation between trajectory-level perturbation and \emph{semantic alignment} in diffusion transformers.
\footnote{Code
available at \url{https://github.com/wfz666/ICML26-attention-sink}.}

A Factorized Low-Rank RNN Framework for Uncovering Independent Neural Latent Dyn amics and Connectivity
Chengrui Li, Yunmiao Wang, Yule Wang, Weihan Li, Dieter Jaeger, Anqi Wu
Low-rank recurrent neural networks (lrRNNs) are a class of models that uncover l ow-dimensional latent dynamics underlying neural population activity. Although t heir functional connectivity is low-rank, it lacks independence interpretations, making it difficult to assign distinct computational roles to different latent dimensions. To address this, we propose the Factored Recurrent Neural Network (F acRNN), a generative lrRNN framework that assumes group-wise independence among latent dynamics while allowing flexible within-group entanglement. These indepen dent latent groups allow latent dynamics to evolve separately, but are internall y rich for complex computation. We reformulate the lrRNN under a variational aut oencoder (VAE) framework, enabling us to introduce a partial correlation penalty that encourages independence between groups of latent dimensions. Experiments o n synthetic, monkey M1, and mouse voltage imaging data show that FacRNN consiste ntly improves the disentanglement and interpretability of learned neural latent trajectories in low-dimensional space and low-rank connectivity over baseline lr RNNs that do not encourage group-wise independence.

VAnim: Rendering-Aware Sparse State Modeling for Structure-Preserving Vector Ani mation

Guotao Liang, Zhangcheng Wang, Chuang Wang, Juncheng Hu, Haitao Zhou, Junhua Liu , Jing Zhang, Dong Xu, Qian Yu

Scalable Vector Graphics (SVG) animation generation is pivotal for professional design due to their structural editability and resolution independence. However, this task remains challenging as it requires bridging discrete code representat ions with continuous visual dynamics. Existing optimization-based methods often destroy topological consistency, while general-purpose LLMs rely on rigid CSS/SM IL transformations, failing to model geometry-level non-rigid deformations. To a ddress these limitations, we present VAnim, the first LLM-based framework for op en-domain text-to-SVG animation. We reconceptualize animation not as sequence ge neration, but as Sparse State Updates (SSU) on a persistent SVG DOM tree. This p aradigm compresses sequence length by over 9.8x while mathematically guaranteein g topological isomorphism and identity persistence. To enable precise control, w e propose an Identification-First Motion Planning mechanism that grounds textual instructions in explicit visual entities. Furthermore, to overcome the non-diff erentiable nature of SVG rendering, we employ Rendering-Aware Reinforcement Lear ning via Group Relative Policy Optimization (GRPO). By leveraging a hybrid rewar d from a state-of-the-art video perception encoder, we align discrete code updat es with high-fidelity visual feedback. We also introduce SVGAnim-134k, the first benchmark for vector animation. Extensive experiments demonstrate that VAnim si gnificantly outperforms state-of-the-art baselines in semantic alignment and str uctural validity, demonstrating a robust capacity for synthesizing high-fidelity non-rigid deformations without requiring explicit temporal consistency constrai nts.
****

Autoregressive, Yet Revisable: In Decoding Revision for Secure Code Generation

Chengran Yang, zichao wei, Heminghao Deng, Jinfeng Jiang, Zhensu Sun, Ting Zhang , Tianyi Wu, Ming Wen, David Lo

Large Language Model (LLM) based code generation is predominantly formulated as a strictly monotonic process, appending tokens linearly to an immutable prefix. This formulation contrasts with the cognitive process of programming, which is i nherently interleaved with forward generation and on-the-fly revision. While pri or works attempt to introduce revision via post-hoc agents or external static to ols, they either suffer from high latency or fail to leverage the model's intrin sic semantic reasoning.

In this paper, we propose Stream of Revision, a paradigm shift that elevates cod e generation from a monotonic stream to a dynamic, self-correcting trajectory by leveraging the model's intrinsic capabilities. We introduce specific action tok ens that enable the model to seamlessly backtrack and edit its own history withi n a single forward pass. By internalizing the revision loop, our framework Strea m of Revision allows the model to activate its latent capabilities just-in-time without external dependencies. Empirical results on secure code generation show that Stream of Revision significantly reduces vulnerabilities with minimal infer ence overhead.

Efficient Test-Time Scaling via Hierarchical Search and Self-Verification for Di screte Diffusion Language Models

Jinbin Bai, Yixuan Li, Yuchen Zhu, Yi Xin, Qingyu Shi, Aosong Feng, Xiaohong Liu , Molei Tao, Jianru Xue, Xiangtai Li, Ming-Hsuan Yang

Inference-time compute has re-emerged as a practical way to improve LLM reasonin g.

Most test-time scaling (TTS) algorithms rely on autoregressive decoding, which i s ill-suited to discrete diffusion language models (dLLMs) due to their parallel decoding over the entire sequence.

As a result, developing effective and efficient TTS methods to unlock dLLMs' ful
l generative potential remains an underexplored challenge.
To address this, we propose \textbf{LLaDA-S}, an efficient TTS framework for dLL
Ms that
(i) performs \textbf{Hierarchical Trajectory Search} (HTS) which dynamically pru
nes and reallocates compute in an early-to-mid denoising window, (ii) replaces e
xternal verifiers with \textbf{Self-Verified Feedback} (SVF) obtained via self-e
valuation prompts on intermediate completions, and (iii) introduces \textbf{Loca
l branching with partial remasking} to explore diverse implementations while pre
serving a high-confidence tokens.
Across four mathematical reasoning and code generation benchmarks on three dLLMs
, including LLaDA 8B Instruct, Dream 7B Instruct, and LLaDA 2.0-mini, our LLaDA-
S achieves a favorable performance-efficiency trade-off, matching best-of-N pe
rformance with substantially fewer function evaluations (NFE).
The code will be released.

BESPOKE: Benchmark for Search-Augmented Large Language Model Personalization via
 Diagnostic Feedback
Hyunseo Kim, Sangam Lee, Kwangwook Seo, Dongha Lee
Search-augmented large language models (LLMs) remain insufficient for fully addr
essing diverse user needs, which requires recognizing how the same query can ref
lect different intents across users and delivering information in preferred form
s. While recent systems such as ChatGPT and Gemini attempt personalization by le
veraging user histories, systematic evaluation of such personalization is under-
explored. To address this gap, we propose BESPOKE, the realistic benchmark for e
valuating personalization in search-augmented LLMs. BESPOKE is designed to be bo
th realistic, by collecting authentic chat and search histories directly from hu
mans, and diagnostic, by pairing responses with fine-grained preference scores a
nd feedback. The benchmark is constructed through long-term, deeply engaged huma
n annotation, where human annotators contributed their own histories, authored q
ueries with detailed information needs, and evaluated responses with scores and
diagnostic feedback. Leveraging BESPOKE, we conduct systematic analyses that rev
eal key requirements for effective personalization in information-seeking tasks,
 providing a foundation for fine-grained evaluation of personalized search-augme
nted LLMs. Our code and data are available at https://github. com/augustinLib/BE
SPOKE.

HypoSpace: A Diagnostic Benchmark for Set-Valued Hypothesis Generation under Und
erdetermination and Sublinear Coverage Bounds
Tingting Chen, Beibei Lin, Zifeng Yuan, Qiran Zou, Hongyu He, Anirudh Goyal, Yew
-Soon Ong, Dianbo Liu
Many scientific problems are underdetermined: multiple distinct hypotheses are e
qually consistent with the same observations. In such settings, effective infere
nce requires not only producing valid explanations, but also systematically expl
oring and covering the admissible hypothesis set. We introduce HypoSpace, a benc
hmark that treats large language models (LLMs) as samplers over finite hypothesi
s spaces and evaluates them on three metrics: Validity, Uniqueness, and Recovery
. HypoSpace spans three structured domains (causal graph inference, gravity-cons
trained 3D voxel reconstruction, and Boolean genetic interaction modeling) with
deterministic validators and exactly enumerable solution spaces, plus real-world
 anchored case studies. Empirically, HypoSpace reveals a capability- and scale-d
ependent coverage failure: models can maintain high Validity while exhibiting re
duced Uniqueness and Recovery as admissible hypothesis spaces become larger or m
ore combinatorial. We further show that the analysis on stratified decoding part
ially mitigates this collapse, demonstrating HypoSpace's utility as a diagnostic
 benchmark for set-valued inference. Code is available at: https://github.com/CT
T-Pavilion/_HypoSpace.

Adaptive Reinforcement Learning for Unobservable Random Delays
John Wikman, Alexandre Proutiere, David Broman

In standard reinforcement learning (RL) settings, the interaction between the ag
ent and the environment is typically modeled as a Markov decision process (MDP),
 which assumes that the agent observes the system state instantaneously, selects
 an action without delay, and executes it immediately. In real-world dynamic env
ironments, such as cyber-physical systems, this assumption often breaks down due
 to delays in the interaction between the agent and the system. These delays can
 vary stochastically over time and are typically _unobservable_ when deciding on
 an action. Existing methods deal with this uncertainty conservatively by assumi
ng a known fixed upper bound on the delay, even if the delay is often much lower
. In this work, we introduce the _interaction layer_, a general framework that e
nables agents to adaptively handle unobservable and time-varying delays. Specifi
cally, the agent generates a matrix of possible future actions, anticipating a h
orizon of potential delays, to handle both unpredictable delays and lost action
packets sent over networks. Building on this framework, we develop a model-based
 algorithm, _Actor-Critic with Delay Adaptation (ACDA)_, which dynamically adjus
ts to delay patterns. Our method significantly outperforms state-of-the-art appr
oaches across a wide range of locomotion benchmark environments, including real-
world measured delays.

InteractScience: Programmatic and Visually-Grounded Evaluation of Interactive Sc
ientific Demonstration Code Generation

Qiaosheng Chen, Yang Liu, Lei Li, Kai Chen, Qipeng Guo, Gong Cheng, Fei Yuan

While Large Language Models (LLMs) hold promise for automating science and educa
tion, generating interactive scientific demonstrations demands a complex synthes
is of deep domain knowledge and precise reactive coding. Current benchmarks fail
 to capture this synergy, largely bifurcating into static code generation or tex
t-only reasoning. To address this, we introduce \textsc{InteractScience}, the fi
rst benchmark dedicated to evaluating the holistic creation of interactive scien
tific applications. We propose a novel hybrid framework that integrates programm
atic functional testing for logic verification with visually-grounded qualitativ
e assessment for rendering fidelity. Our evaluation of 30 leading models across
five disciplines reveals critical gaps in grounding scientific reasoning within
interactive interfaces. By standardizing this combined capability, \textsc{Inter
actScience} establishes a crucial foundation for reliable AI-driven tools in sci
ence and education.

Multi-Adapter Representation Interventions via Energy Calibration

Manjiang Yu, Hongji Li, Junwei Chen, Xue Li, PRIYANKA SINGH, Yang Cao, Lijie Hu

Representation intervention has emerged as a promising paradigm for aligning lar
ge language models toward desired behaviors without modifying model weights. Exi
sting methods typically apply a fixed intervention uniformly across all inputs.
However, we find that the appropriate intervention direction and strength vary s
ubstantially across samples, and such indiscriminate intervention leads to degra
dation of general capabilities on benign inputs. To address these challenges, we
 propose Multi-Adapter Representation Interventions via Energy Calibration (MARI
). Specifically, we introduce a competitive multi-adapter mechanism in which spe
cialized experts capture non-linear correction patterns and adaptively determine
 the appropriate intervention direction and strength for different samples. Furt
hermore, we design an energy-based gating module that leverages internal propaga
tion dynamics to distinguish inputs that are applicable for intervention. Extens
ive experiments across diverse model families and parameter scales demonstrate t
hat MARI achieves state-of-the-art alignment performance. Our method significant
ly improves performance on TruthfulQA, BBQ, and safety benchmarks, while maintai
ning and even improving general capabilities on tasks such as MMLU and ARC. Our
code is available at https://github.com/V1centNevwake/MARI.
****

Hierarchical Goal Abstractions via Learned Subset Relations

Fabian Wurzberger, Sebastian Gottwald, Zeqiang Zhang, Daniel Alexander Braun

In self-supervised goal-conditioned reinforcement learning (RL) without external
 rewards, goals are typically specified by observations sampled from experience

.
However, depending on the observation structure, such a fixed representation of goals may be either too concrete (requiring exact pixel-level matches) or too abstract (involving ambiguous observations).
Here we propose the construction of hierarchical latent goal spaces that integrate both concrete and abstract goals.
To this end, we use an energy function to learn a partially ordered space, in which a subset relation between observations naturally induces a hierarchy from concrete to abstract goals.
This representation enables agents to disambiguate specific states while also generalizing to shared concepts.
In experiments on navigation and robotic manipulation, agents trained with our hierarchical goal space achieve higher task success and greater generalization to novel tasks compared to agents limited to purely observational goals.
****
BubbleSpec: Turning Long-Tail Bubbles into Speculative Rollout Drafts for Synchronous Reinforcement Learning
Yuhang Xu, Kaibin Tian, Yang Tian, Zhice Yang, Yifeng Yu, Yan Li, Shengzhong Liu, Fan Wu, Guihai Chen
Reinforcement Learning (RL) has become a cornerstone for improving the performance of Large Language Models (LLMs). However, its rollout phase constitutes a significant efficiency bottleneck, mainly arising from the long-tail bubbles across data parallel ranks, particularly in long-context scenarios where faster GPUs remain idle while waiting for stragglers.
Existing solutions, such as partial rollout or asynchronous RL, mitigate these bubbles by compromising the algorithm's strict synchronous nature. Instead, we propose **BubbleSpec**, a novel framework that accelerates RL rollouts while strictly keeping the mathematical exactness.
Instead of attempting to eliminate bubbles, BubbleSpec exploits them.
We exploit the idle time windows of faster ranks to pre-generate rollout results for subsequent steps, serving as drafts for speculative decoding.
Unlike prior speculative methods that rely on historical epoch similarity and warm-ups, BubbleSpec is agnostic to dataset size and provides immediate acceleration from the onset of training.
Extensive evaluations demonstrate that BubbleSpec reduces decoding steps by **$\sim$50\%** and increases rollout throughput by up to **1.8$\times$**. Critically, BubbleSpec is seamlessly compatible with various RL frameworks and strategies as it sustains the strict synchronous property of RL algorithms.

Formalizing and Falsifying Causal Pathways of Rare Events
Anahita Haghighat, Dominik Janzing
Building on recent formalizations of root cause analysis for rare events (“outliers”) in structural equation models, we propose a formal definition of a causal pathway and discuss its testable implications. We identify conditions under which these implications depend only on a causal abstraction defined by the pathway of rare events, rather than on the full causal graph of the underlying system. Accordingly, we introduce an abstraction of causal structure to pathways of rare events that bridges simple verbal causal explanations and detailed causal modeling.
****
Differentially Private Cross-Silo Recommendation from Implicit Feedback
Xun Ran, Qingqing Ye, Xin Huang, Jianliang Xu, Haibo Hu
Cross-silo recommendation from implicit feedback is a key task in modern recommender systems, where user-item interaction data are distributed across multiple parties and cannot be centrally collected. Unlike explicit feedback, which provides fully observed real-valued ratings, implicit feedback is one-class and extremely sparse, recording only users' actions or inactions (e.g., clicks, visits, or bookmarks), yet it is far more prevalent in real-world applications. Such behavioral data are often highly sensitive, raising significant privacy concerns when used for collaborative model training. Although differential privacy (DP) has b

een widely applied to explicit feedback-based models, the resulting utility degr
adation makes it difficult to apply DP effectively to implicit feedback learning
. In this work, we propose DPIMF, a differentially private implicit matrix facto
rization framework for cross-silo recommendation based on objective perturbation
. To improve utility, we redesign the loss function and adopt an importance samp
ling scheme to reduce the noise scale required for privacy preservation. We furt
her provide formal utility guarantees for the proposed techniques and characteri
ze the conditions under which utility improvements are maximized. Experiments on
 three benchmark datasets validate our theoretical analysis and demonstrate that
 DPIMF achieves a better privacy-utility trade-off than state-of-the-art methods
.

Discovering Interpretable Algorithms by Decompiling Transformers to RASP
Xinting Huang, Aleksandra Bakalova, Satwik Bhattamishra, William Merrill, Michae
l Hahn
Recent work has shown that the computations of Transformers can be simulated in
the RASP family of programming languages.
These findings have enabled improved understanding of the expressive capacity a
nd generalization abilities of Transformers.
In particular, Transformers have been suggested to length-generalize exactly on
problems that have simple RASP programs.
However, it remains open whether trained models actually implement simple interp
retable programs.
In this paper, we present a general method to extract such programs from trained
 Transformers.
The idea is to faithfully re-parameterize a Transformer as a RASP program and th
en apply causal interventions to discover a small sufficient sub-program.
In experiments on small Transformers trained on algorithmic and formal language
tasks, we show that our method often recovers simple and interpretable RASP prog
rams from length-generalizing transformers.
Our results provide the most direct evidence so far that Transformers internally
 implement simple RASP programs.

Multi-agent imitation learning with function approximation: linear Markov games
and beyond
Luca Viano, Till Freihaut, Emanuele Nevali, Volkan Cevher, Matthieu Geist, Giorg
ia Ramponi
In this work, we present the first theoretical analysis of multi-agent imitation
 learning (MAIL) in linear Markov games where both the transition dynamics and e
ach agent's reward function are linear in some given features. We demonstrate th
at by leveraging this structure, it is possible to replace the state-action leve
l \emph{all policy deviation concentrability coefficient} (Freihaut et al., 2025
b)
    with a concentrability coefficient defined at the feature level which can be
 much smaller than the state-action analog when the features are informative abo
ut \emph{states' similarity}. Furthermore, to circumvent the need for any concen
trability coefficient, we turn to the interactive setting. We provide the first,
 computationally efficient, interactive MAIL algorithm for linear Markov games a
nd show that its sample complexity depends only on the dimension of the feature
map d.
    Building on these theoretical findings, we propose a deep MAIL interactive a
lgorithm which clearly outperforms BC on games such as Tic-Tac-Toe and Connect4.

A Time-Reparameterized Cumulative Intensity Extrapolation Sampler for Discrete F
low Matching
Feiyang Fu, Hehe Fan
Discrete flow matching (DFM) provides a principled framework for generative mode
ling on discrete state spaces via continuous-time Markov chain dynamics. In prac
tice, sampling for DFM commonly employs discretizations such as τ-leaping,
yet efficient sampling methods under a limited number of function evaluations (N

FE) remain less studied. To address this gap, we propose the Time-Reparameterize
d Cumulative Intensity Extrapolation (TR-CIE) sampler, which aims to improve sam
pling quality when function evaluations are restricted. TR-CIE consists of two c
omponents. First, a schedule-based time reparameterization rescales the time gri
d according to the noise schedule. Under standard factorized DFM rate parameteri
zations, this transformation of variables absorbs the schedule-dependent growth
term and mitigates stiffness near the terminal sampling stage. Second, we introd
uce a cumulative-intensity extrapolation updating rule. By reusing cached model
outputs from the previous step as a history term, this improves the approximatio
n of stepwise cumulative intensities on the resulting non-uniform time grid. We
provide a theoretical analysis that bounds the local approximation error of cumu
lative intensities and establishes convergence results. The resulting sampler re
quires one NFE per step and introduces no additional model evaluations compared
to the standard τ-leaping sampler. Extensive experiments on synthetic tasks
, text generation, and text-to-image benchmarks demonstrate that our method impr
oves sampling quality under limited NFE.

ASTRA: Communication-Efficient Acceleration for Multi-Device Transformer Inferen
ce
Xiao Liu, Lijun Zhang, Deepak Ganesan, Hui Guan
Multi-device inference can reduce Transformer latency by parallelizing computati
on. However, existing methods require high inter-device bandwidth, making them i
mpractical for bandwidth-constrained environments. We present ASTRA, a communica
tion-efficient framework that integrates sequence parallelism with mixed-precisi
on attention, where non-local token embeddings are transmitted as low-bit vector
-quantized codes while local attention remains full precision. To preserve accur
acy under aggressive compression, ASTRA introduces Noise-Augmented Quantization
and Distributed Class Tokens. Across vision and language models (e.g., ViT and G
PT2), ASTRA achieves up to 2.64$\times$ speedup over single-device inference and
 up to 15.25$\times$ over prior multi-device baselines while operating at bandwi
dths as low as 10 Mbps. ASTRA remains robust on large models (e.g., Llama-3-8B)
even under non-ideal network conditions such as packet loss and dynamic networks
.

Chiral Symmetry Breaking in Transformers: A Group-Equivariant Framework for Addr
essing the Reversal Curse via Adjoint Manifold Mappings
Hanji Du
The "reversal curse" exposes a critical asymmetry in autoregressive models, wher
e models trained on facts in one direction often fail to access the correspondin
g inverse relation. This work studies the phenomenon from a representation-level
 perspective, characterizing it as a form of chiral asymmetry between subject- a
nd object-oriented latent states. We introduce the Chiral Transformer, a lightwe
ight framework that encourages an involutive adjoint mapping operator $\mathcal{
T}$ through contrastive regularization. At inference time, Adjoint-Induced Retri
eval (AIR) uses this learned map as a structured readout over model-derived enti
ty representations, rather than as an unconstrained autoregressive generation pr
otocol. Empirical validation on inverse-relation benchmarks shows that this symm
etry-aware retrieval setting substantially improves inverse factual access, with
 AIR reaching 65.07% accuracy on Fact-Inv-300. These findings support a represen
tation-access view of the reversal curse: inverse relations may be difficult not
 only because of missing data, but also because standard autoregressive readout
fails to expose useful latent structure.
****

SafeSpec: Fast and Safe LLM via Dynamic Reflective Sampling
HAOTIAN XU, Zeyang Zhang, Linbao Li, Huadi Zheng, Yu Li, Cheng Zhuo
Speculative inference accelerates large language model (LLM) decoding but provid
es no inherent safety guarantees. Existing safety defenses are largely incompati
ble with speculative inference: they either introduce additional computation or
disrupt the draft–verify mechanism, negating acceleration benefits. This reveals
 a fundamental incompatibility between current safety methods and speculative de

coding.
We propose SafeSpec, a safety-aware speculative inference framework that integrates risk estimation directly into the verification process. SafeSpec attaches a lightweight latent safety head to the target model to jointly evaluate semantic validity and safety in a single forward pass. When unsafe generations are detected, SafeSpec applies rollback and safety-guided reflective multi-sampling to recover safe continuations rather than terminating generation.
We model jailbreak attacks as distributional shifts over generative trajectories, where adversarial prompts increase the probability of harmful continuations without eliminating safe ones. Under this model, SafeSpec performs risk-aware trajectory recovery within the speculative decoding process.
Across multiple models and adversarial benchmarks, SafeSpec achieves a substantially improved safety–efficiency trade-off. On Qwen3-32B, SafeSpec reduces attack success rates by 15\% while preserving a 2.06× inference speedup on benign workloads, demonstrating that speculative acceleration and inference-time safety can be jointly optimized.
****

FIPN: Forward Self-Organizing Interpretable Polynomial Networks for Time Series Forecasting
YiZhen Wang, Zheng Wang, EUN-HU KIM, Zunwei Fu
Most existing time-series forecasters are trained end-to-end with backpropagation, which often increases computational cost and limits structural transparency. As a result, it remains difficult to trace how their predictions are formed. This paper presents FIPN, a forward self-organizing interpretable polynomial network for time-series forecasting. FIPN grows its architecture layer by layer through candidate generation, closed-form estimation, and validation-based selection, without relying on backpropagation-based optimization. Each neuron couples a fuzzy rule antecedent with a Fourier-enhanced polynomial consequent: fuzzy clustering softly partitions the input space and produces interpretable rule weights for local regimes, while the consequent retains access to original features and uses Fourier functions to capture periodic and frequency-related structures. Since forward growth may introduce redundancy, collinearity, and overfitting as depth increases, FIPN further incorporates regularized node scoring, dropout-based redundancy control, and persistent access to raw inputs. Experiments on long-horizon forecasting benchmarks show that FIPN achieves competitive accuracy with a compact model size, while the learned fuzzy rules provide rule- and structure-level explanations. These results suggest that forward self-organizing polynomial networks offer a practical balance among accuracy, efficiency, and interpretability for long-horizon forecasting.

Towards Streaming Synchronized Spatial Audio Generation via Autoregressive Diffusion Transformer
Ke Lei, Yu Zhang, Changhao Pan, Xueyi Pu, Wenxiang Guo, Ruiqi Li, Zhou Zhao
Real-time and accurate spatial audio generation is pivotal for delivering an immersive experience.
However, existing spatial audio synthesis technologies are often encumbered by a tradeoff between generation quality and high inference latency, as well as difficulty in capturing precise spatial information from multimodal inputs.
To address these challenges, we propose SwanSphere, a unified streaming framework for high-fidelity spatial audio generation from panoramic videos and text prompts.
SwanSphere mainly makes the following contributions:
1) We introduce a causal autoregressive diffusion transformer architecture that enables streaming high-quality spatial audio generation.
2) We design a Spatial Video–Audio Contrastive (SVAC) learning strategy to align the video encoder with the acoustic domain, and further employ a multi-objective online direct preference optimization~(ODPO) scheme, resulting in strong spatial perception and robust multimodal spatial audio synthesis.
3) To alleviate the current scarcity of spatial audio datasets, we also develop an automated annotation pipeline for generating detailed spatial captions.

Experimental results demonstrate that SwanSphere achieves superior performance in both video-to-spatial and text-to-spatial audio generation tasks. Codes can be found at: https://github.com/MM-Speech/SwanSphere

See More, Forecast Better and Faster: Enhancing Time Series Foundation Models via Inference-Time Plug-and-Play Downsampling
Longlong Xu, Zeyan Li, Xiao He, Zhaoyang Yu, Dazhong Wen, Mingze Sun, Changhua Pei, Dan Pei
Time series foundation models (TSFMs) have demonstrated impressive generalization capabilities across diverse domains. However, they face significant challenges in long-term and ultra long-term forecasting. These challenges primarily arise from scalability limitations when TSFMs process extensive sequence lengths. To address this, we propose SPRINT, a training-free plug-and-play framework designed to empower TSFMs to see more, forecast better and faster during inference. The core idea is to perform forecasting in a downsampled-resolution space, enabling an extended look-back window with reduced computational costs. To avoid information loss and resolution mismatch caused by downsampling, SPRINT decomposes time series into trend and seasonal components, processing them separately. It predicts the low-frequency trend via a Resolution Interpolation workflow within the downsampled space, while preserving high-frequency details through a Pattern Replication mechanism for seasonality. Extensive experiments show that SPRINT achieves a significant improvement, increasing accuracy by 19\% while enhancing efficiency with a reduction of max memory usage by 6.4$\times$ and inference time by 16.9$\times$ compared to state-of-the-art TSFMs.
****

Reinforcement Learning via Self-Distillation
Jonas Hübotter, Frederike Lübeck, Lejs Deen Behric, Anton Baumann, Marco Bagatella, Daniel Marta, Ido Hakimi, Idan Shenfeld, Thomas Kleine Buening, Carlos Guestrin, Andreas Krause
Large language models are increasingly post-trained with reinforcement learning in verifiable domains such as code and math. Yet, current methods for reinforcement learning with verifiable rewards (RLVR) learn only from a scalar outcome reward per attempt, creating a severe credit-assignment bottleneck. Many verifiable environments actually provide rich textual feedback, such as runtime errors or judge evaluations, that explain *why* an attempt failed.
We formalize this setting as reinforcement learning with rich feedback and introduce **Self-Distillation Policy Optimization** (**SDPO**), which converts tokenized feedback into a dense learning signal without any external teacher or explicit reward model.
SDPO treats the current model conditioned on feedback as a self-teacher and distills its feedback-informed next-token predictions back into the policy.
In this way, SDPO leverages the model's ability to retrospectively identify its own mistakes in-context.
Across scientific reasoning, tool use, and competitive programming on LiveCodeBench v6, SDPO improves sample efficiency and final accuracy over strong RLVR baselines.
Notably, SDPO also outperforms baselines in standard RLVR environments that only return scalar feedback by using successful rollouts as implicit feedback for failed attempts.
Finally, applying SDPO to individual questions at test time accelerates discovery on difficult binary-reward tasks, achieving the same discovery probability as best-of-k sampling or multi-turn conversations with 3x fewer attempts.
****

How Does the Pretraining Distribution Shape In-Context Learning? A Fundamental Trade-Off
Waïss Azizian, Ali Hasan
The factors driving the performance of in-context learning (ICL) in large language models (LLMs) remain poorly understood despite ICL's surprising effectiveness, enabling models to adapt to new tasks from only a handful of examples. To clarify and improve these capabilities, we characterize how the statistical properti

es of the pretraining distribution (e.g., tail behavior, coverage) shape ICL. We develop a theoretical framework that encompasses generalization and task selection and show how distributional properties govern sample efficiency, task retrieval, and robustness.
To this end, we generalize existing concentration results to heavy-tailed priors and dependent sequences, better reflecting the structure of LLM pretraining data.
Our framework reveals a fundamental design trade-off: heavy-tailed pretraining distributions facilitate robust task selection under distribution shifts but are detrimental to generalization, especially in low-data regimes.
We then empirically evaluate our predictions by studying how ICL performance varies with the pretraining distribution on challenging tasks such as stochastic differential equations and stochastic processes with memory. Together, these findings suggest that controlling key statistical properties of the pretraining distribution is essential for building ICL-capable and reliable LLMs.

Fast kernel methods: Sobolev, physics-informed, and additive models
Nathan Doumèche, Francis Bach, Gérard Biau, Claire Boyer
Kernel methods are powerful tools in statistical learning, but their cubic complexity in the sample size n limits their use on large-scale datasets. In this work, we introduce a scalable framework for kernel regression with $\mathcal{O}(n \log n)$ complexity, and designed to fully leverage GPU acceleration. The approach is based on a Fourier representation of kernels combined with non-uniform fast Fourier transforms (NUFFT), enabling exact, fast, and memory-efficient computations.
We instantiate our framework in three settings: Sobolev kernel regression, physics-informed regression, and additive models. The proposed estimators are shown to achieve minimax convergence rates, consistent with classical kernel theory. Empirical results demonstrate that our methods can process up to tens of billions of samples within minutes, providing both statistical accuracy and computational scalability.
These contributions establish a flexible approach, paving the way for the routine application of kernel methods in large-scale learning tasks, whenever the kernel norm can be efficiently expressed in Fourier space and the ambient dimension d is small.
Although the theoretical framework is valid in all dimensions d, the fast Sobolev regression package implemented in the paper relies on the CufiNUFFT package, which currently scales exponentially in d and is limited to $d \leq 3$. For similar reasons, the additive model package is only implemented for simple effects without interaction.
****
Unitary Convolutions for Message-passing and Positional Encodings on Directed Graphs
Lukas Fesser, Bobak Kiani, Melanie Weber
In many real-world networks, relationships are inherently directional, yet most graph neural networks (GNNs) assume undirected edges, and naïve adaptations of undirected GNNs to directed graphs amplify oversmoothing and gradient pathologies that cap model depth. Unitary graph convolutions (UniConv) provably prevent representational collapse and oversmoothing, but cannot incorporate edge directionality or edge features. In this paper, we introduce a **d**irected **un**itary GNN with **e**dge features (**Dune**), which retains these guarantees while overcoming UniConv’s limitations by incorporating edge directionality and edge features. Dune keeps gradient norms bounded at any number of layers, allowing it to benefit from neural network depth, unlike existing directed GNNs. The same unitary operator can be embedded in hybrid architectures with graph transformers, where its wavelike propagation supplies positional information and reduces the importance of random-walk or Laplacian-based encodings. We prove that Dune avoids exponential oversmoothing that plagues existing directed GNNs and empirically show that it achieves state-of-the-art performance on 12 directed-graph benchmarks while remaining trainable beyond 100 layers, improving performance by up to 18 perce

ntage points over strong baselines. Our results establish unitary convolutions a s a scalable, geometry-aware foundation for deep learning on directed graphs.
****
Fast and Scalable Analytical Diffusion
Xinyi Shang, Peng Sun, Jingyu Lin, Zhiqiang Shen
Analytical diffusion models offer a mathematically transparent path to generativ e modeling by formulating the denoising score as an empirical-Bayes posterior me an. However, this interpretability comes at a prohibitive cost: the standard for mulation necessitates a full-dataset scan at every timestep, scaling linearly wi th dataset size.
In this work, we present the first systematic study addressing this scalability bottleneck.
We challenge the prevailing assumption that the entire training data is necessar y, uncovering the phenomenon of Posterior Progressive Concentration: the effecti ve golden support of the denoising score is not static but shrinks asymptoticall y from the global manifold to a local neighborhood as the signal-to-noise ratio increases.
Capitalizing on this, we propose Dynamic Time-Aware Golden Subset Diffusion (Gol dDiff), a training-free framework that decouples inference complexity from datas et size.
Instead of static retrieval, GoldDiff uses a coarse-to-fine mechanism to dynamic ally pinpoint the "Golden Subset" for inference.
Theoretically, we derive rigorous bounds guaranteeing that our sparse approximat ion converges to the exact score.
Empirically, GoldDiff achieves a 71× speedup on AFHQ while matching or achieving even better performance than full-scan baselines.
Most notably, we demonstrate the first successful scaling of analytical diffusio n to ImageNet-1K.

WBMM: Windowed Batch Matrix Multiplication for Efficient Large Receptive Field C onvolution
Wan Song, Wei Zhou, Rui Wang, Jun Yu, Toru Kurihara, Jiajia Xu, Shu Zhan
Large kernel depthwise convolutions achieve strong performance but suffer from s ignificant degradation as kernel size grows due to irregular memory access from gather-based computation; while Large Kernel Acceleration (LKA) helps on small f eature maps, it becomes counterproductive on large feature maps, even slower tha n non-accelerated implementations. We propose Windowed Batch Matrix Multiplicati on (WBMM), which partitions input into contiguous windows and indexes a compact relative position bias table to construct weight matrices, enabling regular memo ry access via batched matrix multiplication. This yields a unique property: WBMM 's throughput improves with larger windows, opposite to depthwise convolutions t hat degrade with larger kernels. Operator-level benchmarks show WBMM with $14 \t imes 14$ windows outperforms 5×5 depthwise convolution baselines in spe ed while providing a $7.8\times$ larger per-layer receptive field. Combined with inter-block cross-window communication and hierarchical window reparameterizati on, WBMM achieves comparable or higher accuracy on ImageNet-1K, COCO, and ADE20K with 1.31--$1.88\times$ training speedup, and demonstrates consistent advanta ges across GPU, CPU, and edge devices without requiring specialized acceleration kernels. Our code is available at https://github.com/wansong-s/WBMM.

TraceRouter: Robust Safety for Large Foundation Models via Path-Level Interventi on
Chuancheng Shi, Shangze Li, Wenjun Lu, Wenhua Wu, Fei Shen, Cong Wang, Zifeng Ch eng, Tat-Seng Chua
Despite their capabilities, large foundation models (LFMs) remain susceptible to adversarial manipulation. Current defenses predominantly rely on the ``locality hypothesis", suppressing isolated neurons or features. However, harmful semanti cs act as distributed, cross-layer circuits, rendering such localized interventi ons brittle and detrimental to utility.
To bridge this gap, we propose \textbf{TraceRouter}, a path-level framework that

traces and disconnects the causal propagation circuits of illicit semantics.
TraceRouter operates in three stages: (1) it pinpoints a sensitive onset layer by analyzing attention divergence; (2) it leverages sparse autoencoders (SAEs) and differential activation analysis to disentangle and isolate malicious features; and (3) it maps these features to downstream causal pathways via feature influence scores (FIS) derived from zero-out interventions. By selectively suppressing these causal chains, TraceRouter physically severs the flow of harmful information while leaving orthogonal computation routes intact.
Extensive experiments demonstrate that TraceRouter significantly outperforms state-of-the-art baselines, achieving a superior trade-off between adversarial robustness and general utility. Our code will be publicly released. WARNING:
This paper contains unsafe model responses.

AuTAgent: A Reinforcement Learning Framework for Tool-Augmented Audio Reasoning
Siqian Tong, Li Xuan, Yiwei Wang, Baolong Bi, Yujun Cai, Shenghua Liu, Yuchen He, HAO Chengpeng
Large Audio Language Models (LALMs) excel at perception but struggle with complex reasoning requiring precise acoustic measurements. While external tools can extract fine-grained features like exact tempo or pitch, effective integration remains challenging: naively using all tools causes information overload, while prompt-based selection fails to assess context-dependent utility. To address this, we propose **AuTAgent** (**Au**dio **T**ool **Agent**), a reinforcement learning framework that learns when and which tools to invoke. By employing a sparse-feedback training strategy with a novel Differential Reward mechanism, the agent learns to filter out irrelevant tools and invokes external assistance only when it yields a net performance gain over the base model. Experimental results confirm that AuTAgent complements the representation bottleneck of LALMs by providing verifiable acoustic evidence. It improves accuracy by 4.20% / 6.20% and 9.80% / 8.00% for open-source and closed-source backbones on the MMAU Test-mini and the MMAR benchmarks, respectively. In addition, further experiments demonstrate exceptional transferability. We highlight the complementary role of external tools in augmenting audio model reasoning.

DLEBench: Evaluating Small-scale Object Editing Ability for Instruction-based Image Editing Model
Shibo Hong, Boxian Ai, Jun Kuang, Wei Wang, FengJiao Chen, Zhongyuan Peng, Chenhao Huang, Yixin Cao
Significant progress has been made in the field of Instruction-based Image Editing Models (IIEMs). However, while these models demonstrate plausible adherence to instructions and strong reasoning ability on current benchmarks, their ability to edit small objects remains underexplored, despite its importance for precise local editing and refining details in both real and generated images.
In this paper, we introduce DeepLookEditBench (DLEBench), the first benchmark dedicated to assessing the abilities of IIEMs in editing small-scale objects.
Specifically, we construct a challenging testbed comprising 1889 samples across seven instruction types. In these samples, target objects occupy only 1%-10% of the image area, covering complex scenarios such as partial occlusion and multi-object editing.
To ensure robust evaluation on this benchmark, we propose an evaluation protocol with refined score rubrics to minimize subjectivity and ambiguity in two criteria: Instruction Following and Visual Consistency. This protocol also introduces a dual-mode evaluation framework (Tool-driven and Oracle-guided Modes) addressing the misalignment between LMM-as-a-Judge and human judgments on DLEBench.
Empirical results on 10 IIEMs reveal significant performance gaps in small-scale object editing, highlighting the need for specialized benchmarks to advance this ability.

UltraLIF: Fully Differentiable Spiking Neural Networks via Ultradiscretization and Max-Plus Algebra
Jose Marie Antonio Miñoza

Spiking Neural Networks (SNNs) offer energy-efficient, biologically plausible co
mputation but suffer from non-differentiable spike generation, necessitating rel
iance on heuristic surrogate gradients. This paper introduces **UltraLIF**, a pr
incipled framework that replaces surrogate gradients with \emph{ultradiscretizat
ion}, a mathematical formalism from tropical geometry providing continuous relax
ations of discrete dynamics. The central insight is that the max-plus semiring u
nderlying ultradiscretization naturally models neural threshold dynamics: the lo
g-sum-exp function serves as a differentiable soft-maximum that converges to har
d thresholding as a learnable temperature parameter $\varepsilon \to 0$. Two neu
ron models are derived from distinct dynamical systems: UltraLIF from the LIF or
dinary differential equation (temporal dynamics) and UltraDLIF from the diffusio
n equation modeling gap junction coupling across neuronal populations (spatial d
ynamics). Both yield fully differentiable SNNs trainable via standard backpropag
ation with no forward-backward mismatch. Theoretical analysis establishes pointw
ise convergence to tropical LIF dynamics with quantitative error bounds and boun
ded non-vanishing gradients. Experiments on six benchmarks spanning static image
s, neuromorphic vision, and audio demonstrate improvements over surrogate gradie
nt baselines, with gains most pronounced in the ultra-low latency regime ($T{=}1
$) on neuromorphic and temporal datasets. An optional sparsity penalty enables s
ignificant energy reduction while maintaining competitive accuracy.

On the Separability of Information in Diffusion Models
Akhil Premkumar
Diffusion models transform noise into data by injecting information that was cap
tured in their neural network during the training phase. In this paper we ask: w
hat is this information? We find that, in pixel-space diffusion models, (1) a la
rge fraction of the total information in the neural network is committed to reco
nstructing small-scale perceptual details of the image, and (2) the correlations
 between images and their class labels are informed by the semantic content of t
he images, and are largely agnostic to the low-level details. We argue that thes
e properties are intrinsically tied to the manifold structure of the data itself
. Finally, we show that these facts explain the efficacy of classifier-free guid
ance: the guidance vector amplifies the mutual information between images and co
nditioning signals early in the generative process, influencing semantic structu
re, but tapers out as perceptual details are filled in.

Sheaf Neural Networks on SPD Manifolds: Second-Order Geometric Representation Le
arning
Yuhan Peng, Junwen Dong, Yuzhi Zeng, Hao Li, Ce Ju, Huitao Feng, Diaaeldin Taha,
 Anna Wienhard, Kelin Xia
Graph neural networks face two fundamental challenges rooted in the linear struc
ture of Euclidean vector spaces: (1) Current
architectures represent geometry through vectors (directions, gradients), yet ma
ny tasks require matrix-valued representations that capture relationships betwee
n directions—such as how atomic orientations covary in a molecule. These second-
order representations are naturally captured by points on the symmetric positiv
e definite matrices (SPD) manifold; (2) Standard message passing applies shared
transformations across edges. Sheaf neural networks address this via edge-specif
ic transformations, but existing formulations remain confined to vector spaces a
nd therefore cannot propagate matrix-valued features. We address both challenges
 by developing the first
sheaf neural network operates natively on the SPD manifold. Our key insight is t
hat the SPD manifold admits a Lie group structure, enabling well-posed analogs o
f sheaf operators without projecting to Euclidean space. Theoretically, we prove
 that SPD-valued sheaves are strictly more expressive than Euclidean sheaves: th
ey admit consistent configurations (global sections) that vector-valued
sheaves cannot represent, directly translating to richer learned representations
. Empirically, our sheaf convolution transforms effectively rank-1 directional
inputs into full-rank matrices encoding local geometric structure. Our dual-stre
am architecture achieves SOTA on 6/7 MoleculeNet benchmarks, with the sheaf fram

ework providing consistent depth robustness.

Automatic Pruning Discovery for Large Language Models
Haidong Kang, Lihong Lin, Enneng Yang, Hong-Ning Dai, Hao Wang
Large language models (LLMs) have achieved remarkable performance on a wide rang e of tasks, hindering real-world deployment due to their massive size. Existing pruning methods (e.g., Wanda) tailored for LLMs rely heavily on manual design pr uning algorithms, thereby leading to $\textit{huge labor costs}$ and $\textit{re quires expert knowledge}$. Furthermore, we are the first to identify the serious \textit{outlier value issue} behind dramatic performance degradation under high pruning ratios that are caused by uniform sparsity, raising an additional conce rn about how to design adaptive pruning sparsity ideal for LLMs. Can LLMs prune by themselves? In this work, we introduce an affirmative answer by proposing a n ovel pruning method called $\textbf{AutoPrune}$, which first overcomes expert kn owledge limits by leveraging LLMs to design optimal pruning algorithms for thems elves automatically without any expert knowledge. Specifically, to mitigate the black-box nature of LLMs, we propose a Graph-driven Chain-of-Thought (GCoT) to o ptimize prompts, significantly enhancing the reasoning process in learning the p runing algorithm and enabling us to generate pruning algorithms with superior pe rformance and interpretability in the next generation. Finally, grounded in insi ghts of outlier value issue, we introduce Skew-aware Dynamic Sparsity Allocation (SDSA) to overcome the outlier value issue, mitigating performance degradation under high pruning ratios. We conduct extensive experiments on mainstream LLMs b enchmarks, demonstrating the superiority of AutoPrune, which consistently excels state-of-the-art competitors. The code is available at: \url{https://anonymous. 4open.science/r/AutoPrune}.

SAQNN: Spectral Adaptive Quantum Neural Network as a Universal Approximator
Jialiang Tang, Jialin Zhang, Xiaoming Sun
Quantum machine learning (QML), as an interdisciplinary field bridging quantum c omputing and machine learning, has garnered significant attention in recent year s. Currently, the field as a whole faces challenges due to incomplete theoretica l foundations for the expressivity of quantum neural networks (QNNs). In this pa per we propose a constructive QNN model and demonstrate that it possesses the un iversal approximation property (UAP), which means it can approximate any square- integrable function up to arbitrary accuracy. Furthermore, it supports switching function bases, thus adaptable to various scenarios in numerical approximation and machine learning. Our model has asymptotic advantages over the best classica l feed-forward neural networks in terms of circuit size and achieves optimal par ameter complexity when approximating Sobolev functions under L_2 norm.

Enhancing Membership Inference Attacks on Diffusion Models from a Frequency-Doma in Perspective
Puwei Lian, Yujun Cai, Songze Li, Bingkun BAO
Diffusion models have achieved tremendous success in image generation, but they also raise significant concerns regarding privacy and copyright issues. Membersh ip Inference Attacks (MIAs) are designed to ascertain whether specific data was utilized during a model's training phase. As current MIAs for diffusion models t ypically exploit the model's image prediction ability, we formalize them into a unified general paradigm that computes the membership score for membership ident ification. Under this paradigm, we empirically find that existing attacks overlo ok the inherent deficiency in how diffusion models process high-frequency inform ation. Consequently, this deficiency leads to member data with more high-frequen cy content being misclassified as hold-out data, and hold-out data with less hig h-frequency content tends to be misclassified as member data. Moreover, we theor etically demonstrate that this deficiency reduces the membership advantage of at tacks, thereby interfering with the effective discrimination of member data and hold-out data. Based on this insight, we propose a plug-and-play high-frequency filter module to mitigate the adverse effects of the deficiency, which can be se amlessly integrated into any attacks within the general paradigm without additio

nal time costs. Extensive experiments corroborate that this module significantly improves the performance of baseline attacks across different datasets and models. Code is available at https://github.com/poetic2/FreMIA.

TodoEvolve: Learning to Architect Agent Planning Systems

Jiaxi Liu, Guibin Zhang, Yanzuo Jiang, Zihan Zhang, Heng Chang, Zhenfei Yin, Qibing Ren, Junchi Yan

Planning has become a central capability for contemporary agent systems in navigating complex, long-horizon tasks, yet existing approaches predominantly rely on fixed, hand-crafted planning structures that lack the flexibility to adapt to the structural diversity of open-ended problems. To address this limitation, we introduce TodoEvolve, a meta-planning paradigm that autonomously synthesizes and dynamically revises task-specific planning architectures. Specifically, we first construct PlanFactory, a modular design space that standardizes diverse planning paradigms within a unified codebase encompassing topology, initialization, adaptation, and navigation, thereby providing a common interface for heterogeneous planning patterns. Leveraging PlanFactory, we collect high-quality planning trajectories and train Todo-14B via Impedance-Guided Preference Optimization (IGPO), a multi-objective reinforcement learning objective that encourages the generation of planning systems that are performant, stable, and token-efficient across arbitrary tasks and agent backbones. Empirical evaluations on five agentic benchmarks demonstrate that TodoEvolve consistently surpasses carefully engineered planning modules while maintaining economical API costs and runtime overhead. Our codes are available at \url{https://github.com/EcthelionLiu/TodoEvolve}.

Generalist Graph Anomaly Detection via Prototype-Based Distillation

Yiming Xu, Zihan Chen, Zhen Peng, Song Wang, Bin Shi, Bo Dong, Chao Shen

Driven by the pressing demand for graph anomaly detection (GAD) in high-stakes domains, the generalist GAD paradigm, which trains a single detector transferable across new graphs, has recently gained growing attention. However, existing methods often rely on scarce and costly annotations for training and sometimes even require few-shot support at inference, which limits their robustness to diverse and unseen anomaly patterns. To address this limitation, we introduce ProMoS, the first unsupervised generalist GAD framework, which detects anomalies by modeling the abundant normality in unlabeled data.

ProMoS adopts a knowledge-distillation paradigm to distill normality priors from a frozen self-supervised graph neural network (GNN) teacher to a mixture-of-students model with shared global and lightweight personalized branches, enabling efficient and expressive normality modeling without learning from scratch.

We further propose prototype-guided soft-label distillation to align teacher and student in a shared prototype space, enhancing cross-graph generalizability. During inference, ProMoS performs zero-shot anomaly detection on unseen graphs via distillation bias and prototype geometric deviation.

Extensive experiments show the effectiveness and efficiency of ProMoS, charting a practical path toward label-free, zero-shot generalist GAD.

AI Engram: In Search of Memory Traces in Artificial Intelligence

Jea Kwon, Dong-Kyum Kim, Jiwon Kim, Yonghyun Kim, Woong Kook, Meeyoung Cha

Memory formation is fundamental to intelligence, yet whether deep neural networks preserve identifiable memory traces analogous to biological memory units remains an open question. This work introduces a geometric framework to identify such “AI engrams” by formalizing the neuroscientific criteria of specificity, reactivation, sufficiency, and necessity into a constrained inverse problem. We derive a closed-form estimator that isolates individual memory traces from globally entangled parameters, and show that this biologically-derived solution corresponds to a natural gradient update on the parameter manifold. AI engrams enable surgical manipulation of learned knowledge: any subset of memories can be composed or erased through linear arithmetic, without iterative optimization. Experiments ranging from simple MLPs to LLMs demonstrate the causal validity and substantial scalability of AI engrams. Together, these results bridge theories of biological

memory and artificial representation learning and offer geometric insight into how deep networks simultaneously support functional specificity within distributed storage.

Differentially Private Range Subgraph Counting

Xian Chen, Ruobing Bai, Pan Peng

Subgraph counting is a fundamental problem in graph analysis. Motivated by practical scenarios where graph analytics are performed on subgraphs induced by selected vertices -- rather than on the entire graph -- and by growing privacy concerns, we initiate the study of *differentially private range subgraph counting (DPRSC)*. The goal is to privately count occurrences of a fixed pattern graph within induced subgraphs defined by multi-dimensional attribute ranges. Unlike classical point counting, subgraph counting is inherently nonlinear and exhibits high sensitivity: a single edge modification can affect many subgraph occurrences. We present the first efficient algorithms for DPRSC with small additive error. Our approach introduces a subgraph projection that reduces DPRSC to weighted orthogonal range counting, enabling the use of range trees and local sensitivity estimation to achieve accurate private query answering. We complement our algorithms with matching lower bounds, obtained by reducing reconstruction attacks to DPRSC and leveraging discrepancy theory. In particular, we show that any differentially private algorithm for DPRSC must incur additive error exponential in the dimension. Empirical evaluations demonstrate that our algorithms significantly outperform baseline methods in accuracy and runtime while maintaining strong privacy guarantees.

****

SaTeen: Learning Structural Alignment for Continual Test-Time Adaptation

Chang Liu, Ruotong Zhao, Li Gao, Yupei Zhang

Test-Time Adaptation (TTA) aims to reconcile model generalization in the presence of distribution shifts. Current TTA methods usually leverage sample uncertainty to select reliable samples for model adjustment via entropy minimization (EM). However, sample uncertainty often relies on a plausible metric and leaves many unreliable samples into EM process, potentially leading to model collapse. Importantly, these excluded samples incur biased data features of the shifted distribution in TTA. This paper introduces SaTeen, a **S**tructural **A**lignment-based **Te**st-Tim**e** Adaptatio**n** method that performs two-fold aligning the structures of test samples with the reliable reference structures. Specifically, the two-fold alignments are 1) Intra-sample structure alignment, where SaTeen maximizes cross-entropy discrepancy between a sample (reference) and its structure-disrupted counterpart, with the assumption of stable dominant features; 2) Inter-sample structure alignment, where SaTeen minimizes the reconstruction error of test samples in the reference subspace spanned by the Incremental PCA on reliable samples, with the assumption of stale intrinsic data manifold. Our extensive experiments demonstrate that SaTeen achieves the state-of-the-art performance across various scenarios for both TTA and continual TTA.

Quantifying Error Propagation and Model Collapse in Diffusion Models

Nail B. Khelifa, Richard E. Turner, Ramji Venkataramanan

Machine learning models are increasingly trained or fine-tuned on synthetic data. Recursively training on such data has been observed to significantly degrade performance in a wide range of tasks, often characterized by a progressive drift away from the target distribution. In this work, we theoretically analyze this phenomenon in the setting of score-based diffusion models. For a realistic pipeline where each training round uses a combination of synthetic data and fresh samples from the target distribution, we obtain upper and lower bounds on the accumulated divergence between the generated and target distributions. Notably, to the best of our knowledge, this is the first lower bound on the divergence between the learned and target distributions, even for standard diffusion models. Our results allow us to characterize different regimes of drift, depending on the score estimation error and the proportion of fresh data used in each generation. In a certain regime, the accumulated divergence after several retraining rounds can

be expressed as a discounted sum of score estimation errors made at each generation. We also provide empirical results on synthetic data and images to illustrate the theory.
****

Geometric Decoupling: Diagnosing the Structural Instability of Latent
Yuanbang Liang, Zhengwen Chen, Yu-Kun Lai
Latent Diffusion Models (LDMs) achieve high-fidelity synthesis but suffer from latent space brittleness, causing discontinuous semantic jumps during editing. We introduce a Riemannian framework to diagnose this instability by analyzing the generative Jacobian, decomposing geometry into *Local Scaling* (capacity) and *Local Complexity* (curvature). Our study uncovers a **"Geometric Decoupling"**: while curvature in normal generation functionally encodes image detail, Out-of-Distribution (OOD) generation exhibits a functional decoupling where extreme curvature is wasted on unstable semantic boundaries rather than perceptible details. This geometric misallocation identifies "Geometric Hotspots" as the structural root of instability, providing a robust intrinsic metric for diagnosing generative reliability. Our code is at https://github.com/Byronliang8/Diffusion-Geometry.
****

Enhancing Numerical Prediction in LLMs via Smooth MMD Alignment
Zhuo Zuo, Li Yue, Wenhao Zheng, Chenpeng Wang, Xianggen Liu
Despite their strong general capabilities, large language models (LLMs) often remain unreliable when outputs must be numerically precise. A key reason is the training objective: standard cross-entropy treats numeric tokens as unstructured categories and ignores the metric structure of their values. We address this mismatch by proposing **S**mooth **M**aximum **M**ean **D**iscrepancy (**SMMD**), which builds on the classic MMD by incorporating value-distance kernels over numeric tokens and graph-based smoothness. With this kernel defined over a numeric sub-vocabulary, SMMD aligns the predicted numeric distribution to the target via kernel matching and smooths the prediction--target residual over the induced kernel graph to encourage local consistency. We evaluate SMMD on four numeric-target tasks---mathematical reasoning, arithmetic calculation, clock-time recognition, and chart question answering---across multiple open-weight LLM and VLM backbones. SMMD consistently improves accuracy over both cross-entropy and recent numeric-target losses; analyses show complementary effects between MMD and smoothness and underscore the importance of distance-based kernel design.

Do-Prompt: Causal Interventions Meet Variational Prompt Bottlenecks
Xueting Chen, Jun-Jie Huang, Yan Yan, Long Lan, Yuhua Tang, Wenjing Yang
Multi-modal prompt learning is a parameter-efficient approach to adapting large vision-language models to downstream classification tasks. However, prompts can inadvertently evolve into a high-capacity pathway that encodes environment-dependent spurious correlations, which are predictive only in the source domain and thereby undermine transferability.
To address this issue, this paper introduces **Do-Prompt**, a *compress-and-intervene* framework that brings together variational bottlenecks and causal interventions for robust prompt tuning. We model prompts as stochastic latent variables and impose a *variational prompt bottleneck* to explicitly regulate the information transmitted through prompts, effectively mitigating their tendency to memorize spurious nuisance cues.
Building on this capacity constraint, we propose lightweight *prompt-level interventions* by perturbing the environment-related prompt components and enforcing prediction consistency under these *do*-style perturbations. This synergistic integration encourages reliance on task-stable, invariant semantics rather than spurious prompt content.
Notably, Do-Prompt is plug-and-play compatible with existing multi-modal prompt tuning pipelines and introduces negligible computational overhead. Extensive experiments on base-to-novel generalization, cross-dataset transfer, and ImageNet distribution shifts demonstrate consistent performance gains, with particularly notable improvements on datasets exhibiting pronounced domain or texture biases.
****

Two-Stage Unit Tying for Simplifying Differentiable Logic Gate Networks
Seungheon Lee, Jeongmin Sun, Jaeyong Chung
Differentiable logic gate networks map directly to gate-level circuits, enabling ultra-low-latency inference, yet their logic footprint often exceeds FPGA capacity budgets. Tightly fitting a trained model to a target FPGA requires a post-training mechanism to trade off network complexity and accuracy—analogous to pruning in standard neural networks. To this end, we introduce *unit tying*: a simplification that forces selected gates to constants (0 or 1), enabling constant propagation and downstream logic elimination. However, we observe that naively extending pruning criteria to logic networks is unreliable under such near-discrete modifications. We therefore propose a two-stage algorithm for unit tying: (i) a fast Gauss–Newton screening step under a teacher-referenced logit-distortion objective that constructs a high-recall overshoot set and (ii) a refinement step that corrects approximation and interaction-driven errors using a small number of finite-difference evaluations. On CIFAR-10 and MNIST, our method consistently improves the accuracy–area trade-off over common saliency baselines, yielding substantial post-synthesis LUT reductions of up to 48% on CIFAR-10 and 43% on MNIST, with modest accuracy degradation.
****

ZipMoE: Efficient On-Device MoE Serving via Lossless Compression and Cache-Affinity Scheduling
Yuchen Yang, Yaru Zhao, Pu Yang, Shaowei Wang, Zhi-Hua Zhou
While Mixture-of-Experts (MoE) architectures substantially bolster the expressive power of large-language models, their prohibitive memory footprint severely impedes the practical deployment on resource-constrained edge devices, especially when model behavior must be preserved without relying on lossy quantization. In this paper, we present ZipMoE, an efficient and semantically lossless on-device MoE serving system. ZipMoE exploits the synergy between the hardware properties of edge devices and the statistical redundancy inherent to MoE parameters via a caching-scheduling co-design with provable performance guarantee. Fundamentally, our design shifts the paradigm of on-device MoE inference from an I/O-bound bottleneck to a compute-centric workflow that enables efficient parallelization. We implement a prototype of ZipMoE and conduct extensive experiments on representative edge computing platforms using popular open-source MoE models and real-world workloads. Our evaluation reveals that ZipMoE achieves up to 72.77% inference latency reduction and up to $6.76\times$ higher throughput than the state-of-the-art systems. Our code is available at: https://github.com/npnothard/ZipMoE-ICML26.
****

WhisperSplat: Lossless Steganography in 3D Gaussian Splatting
Nicole Meng, Ronak Sahu, Miao Yin, Faysal Hossain Shezan, Yingjie Lao
We present WhisperSplat, the first lossless steganography method for 3D Gaussian Splatting (3DGS) models that hides a full■resolution 2D image in a single view without any degradation of the model's rendering quality elsewhere. Prior work embeds data by retraining or modifying model weights, altering novel■view synthesis fidelity and limiting capacity. Instead, we learn a small, view■specific noise key applied to each Gaussian's spherical■harmonic (SH) features while keeping all other views remain indistinguishable from the original renders. We further propose a Gradual Pixel Perturbation (GPP) strategy with a cosine-decay schedule, bootstrapping fast divergence from the clean render before transitioning to a combined reconstruction and SSIM loss. Unlike prior works that are highly dependent on accurate and large pretrained decoders, our method is able to recover the hidden image through rendering with noise key, and an optional lightweight refiner to enhance recovery image quality. Across nine standard 3DGS data scenes, WhisperSplat demonstrates superior hidden image recovery quality without sacrifice in clean 3DGS model performance, when compared to prior work such as GS-Hider and KeySS.

Memory Savings at What Cost? A Study of Alternatives to Backpropagation
Kunjal Panchal, Sunav Choudhary, Yuriy Brun, Hui Guan

Forward-mode automatic differentiation (FmAD) and zero-order (ZO) optimization a re increasingly proposed as memory-efficient, backpropagation-free alternatives for large language model (LLM) fine-tuning, yet their benefits are typically eva luated only against standard backpropagation (BP), omitting memory-efficient var iants such as activation checkpointing. We present a unified theoretical and emp irical comparison of BP, checkpointed BP, FmAD, and ZO for LLM and vision-langua ge model training, showing that while FmAD and ZO reduce activation memory, they trade memory for higher computational cost and longer wall-clock time to conver gence, resulting in lower accuracy and slower training, especially under constra ined perturbation budgets. Across models, BP with checkpointing outperforms FmAD and ZO variants, including variance-reduced methods, achieving up to 31.1% high er accuracy, 34.8% faster convergence, and 3.8$\times$ fewer computations at com parable memory usage, while also revealing instability-related failure modes in FmAD and ZO. Overall, our results correct a one-sided benchmarking narrative by showing that memory-efficient methods entail fundamentally different trade-offs, and that ignoring these distinctions has led to misleading conclusions about LL M optimization in prior work.

Gradient Flow Sampler-based Distributionally Robust Optimization

Zusen Xu, Jia-Jie Zhu

We propose a mathematically principled PDE gradient flow framework for distribut ionally robust optimization (DRO). Exploiting the recent advances in the interse ction of Monte Carlo sampling and statistical optimal transport, we show that ou r theoretical framework can be implemented as practical algorithms for sampling from worst-case distributions and, consequently, DRO.

While numerous previous works have relied on dual reformulation techniques, we c ontribute a sound and complete gradient flow view based on SDEs or PDEs that can be used to construct new algorithms for general, potentially non-convex, losses .

Without loss of generality, we solve a class of Wasserstein and entropy-regulari zed DRO problems using the recently-discovered Wasserstein Fisher-Rao and Stein variational gradient flows. Notably, we also show some simple reductions of our framework recover exactly previously proposed popular DRO methods, and provide n ew insights into their theoretical limits and optimization dynamics of DRO. Nume rical studies based on stochastic gradient descent on machine learning tasks pro vide empirical backing for our theoretical findings.

Spectral Flow Matching: Stabilizing Stochastic GFlowNets via Frequency-Domain Re gularization

Nadhir Hassen, Johan W. Verjans

Generative Flow Networks (GFNs) offer a powerful paradigm for diverse sampling, yet they often exhibit instability and poor convergence when applied to stochast ic or sparse-reward environments. To mitigate the high variance inherent in thes e settings, we propose a fundamental re-framing of the GFlowNet training objecti ve within the frequency domain. We present \textbf{Spectral Time-Dependent GFlow Nets (ST-GFNs)}, a framework that leverages Fourier analysis to enforce smoothne ss and stability in learned policies. Our theoretical analysis proves that our p roposed spectral loss is mathematically equivalent to regularized value iteratio n, acting as a principled low-pass filter that separates signal from noise. Furt hermore, we tackle the challenge of exploration in sparse landscapes by introduc ing a novel autocorrelated intrinsic reward derived from the Wiener-Khinchin the orem. Through extensive experiments ranging from adversarial games and noisy seq uence generation to high-dimensional single-cell perturbation modelling, we demo nstrate that ST-GFNs significantly outperform existing baselines in terms of rob ustness, sample efficiency, and mode discovery.

User-Aware Active Knowledge Acquisition for Emotional Support Dialogue

Mufan Xu, Kehai Chen, Jiahao Hu, Xinchao Xu, Muyun Yang, Tiejun Zhao, Min Zhang

Emotional support plays an important role in dialogue systems, and its success d epends on adapting to a user’s evolving and implicit needs across multi-turn int

eractions while leveraging the strong reasoning capacity of large language model
s.
However, since signals about user needs are often weak, indirect, and can only b
e disambiguated through multi-turn interaction, existing emotional support metho
ds often struggle to acquire and generalize relevant conversational knowledge ef
ficiently.
To bridge this gap, we introduce User-Aware Active Knowledge Acquisition (UKA),
a gradient-free active dialogue learning framework that explicitly represents un
certainty about user needs and incorporates active learning into both knowledge
acquisition and response selection.
We propose a Theory-of-Mind uncertainty estimation mechanism that allows the mod
el to prioritize responses, thereby eliciting more informative user feedback.
UKA is capable of efficiently exploring user-aligned conversational knowledge du
ring training while maintaining robustness at test time.
Experiments across multiple dialogue benchmarks and model architectures demonstr
ate that our approach consistently outperforms strong baselines in dialogue qual
ity and user alignment.

Breaking the Reference Bottleneck via Learning to Rewrite Conversational Queries
 without Gold Reference Passages
Doyoung Kim, Youngjun Lee, Joeun Kim, Jihwan Bang, Hwanjun Song, Susik Yoon, Jae
-Gil Lee
Conversational query reformulation (CQR) has become indispensable for improving
retrieval in dialogue-based applications. However, existing approaches typically
 rely on reference passages for optimization, which are **impractical** to acqui
re in real-world scenarios. To address this limitation, we introduce a novel **r
eference-free** preference optimization framework ***DualReform*** that generate
s **pseudo reference passages** from **commonly-encountered** conversational dat
asets containing only queries and responses. DualReform attains this goal throug
h two key innovations: (1) **response-based inference**, where responses serve a
s proxies to infer pseudo reference passages, and (2) **response refinement via
the dual-role of CQR**, where a CQR model refines responses based on the shared
objectives between response refinement and CQR. Despite not relying on reference
 passages, ***DualReform*** achieves 96.9--99.1% of the retrieval accuracy attai
nable only with reference passages and surpasses the state-of-the-art method by
up to 31.6%.

Experience Augmented Policy Optimization for LLM Reasoning
Jinda Lu, Kexin Huang, Junkang Wu, Shuo Yang, Jinghan Li, Chiyu Ma, Shaohang Wei
, Xiang Wang, Guoyin Wang, Jingren Zhou
Reinforcement Learning with Verifiable Rewards (RLVR) is a powerful paradigm for
 improving the reasoning capabilities of large language models (LLMs).
However, existing RLVR methods typically rely on on-policy optimization from scr
atch, resulting in high sampling costs and inefficient utilization of accumulate
d experience.
As model capabilities and policy behaviors evolve during training, recent attemp
ts to reuse experience via fixed reasoning trajectories further suffer from poli
cy mismatch.
Motivated by these limitations, we argue that experience in RLVR should not be r
eused as fixed reasoning trajectories, but instead expressed in a policy-adaptiv
e manner.
In this work, we propose Experience-Augmented Policy Optimization (EAPO), which
leverages a prior RL-optimized policy as an action-level experience prior and se
lectively injects experience at critical decision points during rollout.
To ensure stable and unbiased learning from experience-augmented rollouts, EAPO
further incorporates an adapted importance sampling scheme.
Experiments on using Qwen-2.5-math 7b and Qwen-3-8B on five different benchmarks
 demonstrate that EAPO consistently improves reasoning performance over state-of
-the-art RLVR methods.

Bulk-Calibrated Credal Ambiguity Sets: Fast, Tractable Decision Making under Out-of-Sample Contamination
Mengqi Chen, Thomas Berrett, Theodoros Damoulas, Michele Caprio
Distributionally robust optimisation (DRO) minimises the worst-case expected loss over an ambiguity set that can capture distributional shifts in out-of-sample environments. While Huber (linear-vacuous) contamination is a classical minimal-assumption model for an ε-fraction of arbitrary perturbations, including it in an ambiguity set can make the worst-case risk infinite and the DRO objective vacuous unless one imposes strong boundedness or support assumptions. We address these challenges by introducing bulk-calibrated credal ambiguity sets: we learn a high-mass bulk set from data while considering contamination inside the bulk and bounding the remaining tail contribution separately. This leads to a closed-form, finite $\mathrm{mean}+\sup$ robust objective and tractable linear or second-order cone programs for common losses and bulk geometries. Through this framework, we highlight and exploit the equivalence between the imprecise probability (IP) notion of upper expectation and the worst-case risk, demonstrating how IP credal sets translate into DRO objectives with interpretable tolerance levels. Experiments on heavy-tailed inventory control, geographically shifted house-price regression, and demographically shifted text classification show competitive robustness-accuracy trade-offs and efficient optimisation times, using Bayesian, frequentist, or empirical reference distributions.

A Tale of Two Problems: Multi-Task Bilevel Learning Meets Equality Constrained Multi-Objective Optimization
Zhiyao Zhang, Myeung Suk Oh, Zhen Qin, Jiaxiang Li, Xin Zhang, Jia Liu
In recent years, bilevel optimization (BLO) has attracted significant attention for its broad applications in machine learning.
However, most existing works on BLO remain confined to the single-task setting and rely on the lower-level strong convexity assumption, which significantly restricts their applicability to modern machine learning problems of growing complexity.
In this paper, we make the first attempt to extend BLO to the multi-task setting under a relaxed lower-level general convexity (LLGC) assumption.
To this end, we reformulate the multi-task bilevel learning (MTBL) problem with LLGC into an equality constrained multi-objective optimization (ECMO) problem.
However, ECMO itself is a new problem that has not yet been studied in the literature.
To address this gap, we first establish a new Karush–Kuhn–Tucker (KKT)-based Pareto stationarity as the convergence criterion for ECMO algorithm design.
Based on this foundation, we propose a weighted Chebyshev (WC)-penalty algorithm that achieves a finite-time convergence rate of $\mathcal{O}(ST^{-\frac{1}{2}})$ to KKT-based Pareto stationarity in both deterministic and stochastic settings, where S denotes the number of objectives, and T is the total iterations.
Moreover, by varying the preference vector over the S-dimensional simplex, our WC-penalty method systematically explores the Pareto front.
Finally, solutions to the ECMO problem translate directly into solutions for the original MTBL problem, thereby closing the loop between these two foundational optimization frameworks.
****
SpaEF: Spatially Resolved Transcriptomics Data Element-Wise Denoising Framework Powered by Large Models
Zekuan Shang, Xiaosong Han, Liupu Wang, Wei Du, Peng Zhao, Yuanshu Li, Yubin Xiao, Xuan Wu, You Zhou
For denoising Spatially Resolved Transcriptomics (SRT) data, existing methods often construct spot and gene graphs to model inter-spot and inter-gene relationships, respectively. However, these methods often introduce spurious similarity biases among spots when constructing the spot graph and fail to capture nonlinear relationships among genes when constructing the gene graph. Moreover, ineffective graph fusion strategies further bottleneck denoising performance. To address these challenges, we propose SpaEF, which innovatively constructs spot and gene

graphs with two Large Models (LMs) to inject prior knowledge for mitigating bias es and capture nonlinear relationships, and then fuses them with the proposed el ement-wise graph autoencoder. As far as we know, SpaEF is the first SRT denoisin g method that utilizes pre-trained LMs to construct spot and gene graphs. Experi ments on four real-world datasets with corresponding downstream tasks demonstrat e that SpaEF not only outperforms SOTA denoising methods in accuracy but also ex hibits strong robustness across tasks.

Spectral Heat Flow for Conservative Token Condensation in Vision-Language Models
Zhaoyang Li, Yanjun Li, Wangkai Li, Yujia Chen, Tianzhu Zhang
Vision-Language Models (VLMs) are costly at inference time because they must pro cess long sequences of visual tokens. Existing token pruning methods often degra de under high compression by blindly discarding information, breaking spatial st ructure or collapsing diversity. We propose SpecFlow, a training-free framework that shifts the paradigm from destructive pruning to conservative condensation, strictly enforcing spatial coverage and statistical conservation to ensure stabi lity. Treating visual tokens as nodes in a kNN graph, SpecFlow (i) computes a stable importance field via spectral heat flow to preserve structural coherence, (ii) allocates budgets via adaptive spatial partitioning to guarantee coverage, and (iii) aggregates discarded information into coreset sinks to maintain stati stical conservation. The method is plug-and-play, requires no fine-tuning, and i s compatible with FlashAttention. Experiments confirm that our SpecFlow outperfo rms SOTA methods across tasks, VLM architectures, and pruning ratios. Notably, L LaVA-1.5 with SpecFlow retains 95.6\% of original performance despite pruning 88 .9\% of visual tokens, offering an exceptional efficiency-accuracy balance.

DecFus: Decentralized Layer-wise Fusion with Dynamic Exploration and Exploitatio n
Li Yang, Jialong Sun, Chuhai Cai, Xinyang Liu, Yichen Li, Bowen Peng, Jialong Li , Bo Liu
Decentralized Federated Learning (DFL) enables collaborative model training acro ss connected clients without a central server, effectively mitigating communicat ion bottlenecks and avoiding the single point of failure in Centralized Federate d Learning (CFL). However, existing DFL methods mostly focus on parameter averag ing with compromised update directions, which limits their performance potential due to insufficient exploration of the loss landscape, especially for complex m odels. We observe that layer exchanges among clients enhance exploration while i ntroducing instability due to highly diverse update directions. To address these limitations, we propose Decentralized Layer-wise Fusion (DecFus), the first DFL framework that unifies layer-level exchange and averaging to balance exploratio n and exploitation. DecFus dynamically transitions the decentralized training pr ocess from exploration-dominant to exploitation-dominant phases, guided by the l oss variance among connected neighbors. Furthermore, a layer-wise fusion strateg y, informed by pairwise cosine similarity, categorizes all layers into two group s: an exchange group for exploration and an averaging group for exploitation. Sp ecifically, we theoretically establish the convergence of DecFus without relying on the common assumption in existing literature that the aggregation matrix mus t be doubly stochastic. Extensive experiments demonstrate that DecFus achieves s uperior performance in both IID and non-IID scenarios, substantially outperformi ng existing CFL and DFL methods.

LOZO+: Provably Efficient Zeroth-Order Fine-Tuning via Greedy Low-Rank Subspace Selection
Jinjie Fang, Chengxun Jin, Tianxing Man, Yi Chang, Bin Gu
Zeroth-order (ZO) optimization offers a more memory-efficient alternative to fir st-order methods for fine-tuning large language models (LLMs). Recent ZO metho ds, exemplified by LOZO, estimate gradients within low-rank subspaces to align w ith the low-rank structure of LLM gradients. However, these methods rely on rand omly generated subspaces of a fixed rank, which provides no guarantee of alignme nt with the actual dominant subspaces of the gradients; essentially, they remain

ZO gradient descent with stochastic subspace sampling. To more effectively explo
it the low-rank nature of LLM gradients, we propose \textbf{LOZO+}, an efficien
t \textbf{ZO} fine-tuning algorithm for LLMs that incorporates greedy \textbf{Lo
}w-Rank subspace selection. Specifically, LOZO+ leverages loss-based feedback to
assess alignment between candidate directions and the dominant low-rank gradien
t subspaces, and employs an adaptive thresholding criterion to retain only direc
tions yielding substantial gradient descent, thereby steering ZO optimization to
ward more effective convergence. Importantly, we establish a theoretical framew
ork that characterizes the convergence behavior of LOZO+, formally prove its sup
eriority over existing methods. Extensive experiments demonstrate that LOZO+ co
nsistently outperforms existing ZO methods and achieves performance competitive
with FO algorithm, while retaining the memory efficiency inherent to ZO optimiza
tion.

Phase-Type Variational Autoencoders for Heavy-Tailed Data
Abdelhakim Ziani, Andras Horvath, Paolo Ballarini
Heavy-tailed distributions are ubiquitous in real-world data, where rare but ext
reme events dominate risk and variability. However, standard Variational Autoenc
oders (VAEs) employ simple decoder distributions (e.g., Gaussian) that fail to c
apture heavy-tailed behavior, while existing heavy-tail-aware extensions remain
restricted to predefined parametric families whose tail behavior is fixed a prio
ri. We propose the Phase-Type Variational Autoencoder (PH-VAE), whose decoder d
istribution is a latent-conditioned Phase-Type (PH) distribution—defined as the
absorption time of a continuous-time Markov chain (CTMC). This formulation compo
ses multiple exponential time scales, yielding a flexible, analytically tractabl
e decoder that adapts its finite-range tail behavior directly from the observed
data. Experiments on synthetic and real-world benchmarks demonstrate that PH-VAE
accurately approximates diverse heavy-tailed distributions, significantly outpe
rforming Gaussian, Student-t, and extreme-value-based VAE decoders in modeling o
bserved tail behavior and extreme quantiles. In multivariate settings, PH-VAE ca
ptures realistic cross-dimensional tail dependence through its shared latent rep
resentation.
To our knowledge, this is the first work to integrate Phase-Type distributions i
nto deep generative modeling, bridging applied probability and representation le
arning.

DOUBT: Decoupled Object-level Understanding and Bridging via vMF-based Trustwort
hiness for Hallucination Detection in MLLMs
Kaiqi Chen, Yang Qin, Changhao He, Xi Peng, Peng Hu
Multimodal Large Language Models (MLLMs) frequently produce hallucinations (i.e.
, assertions that contradict the image or facts), undermining reliability in hig
h-risk applications. Existing detection approaches typically feed images and tex
ts jointly and estimate hallucination scores by measuring the consistency of mod
el outputs. However, because the visual module often lags behind the language mo
dule in understanding and reasoning, MLLMs can repeatedly produce similar yet in
correct answers, yielding overestimated trustworthiness and missed detections. T
o address this, we propose a simple yet effective model-agnostic method, dubbed
Decoupled Object-level Understanding and Bridging via vMF-based Trustworthiness
(DOUBT). DOUBT first employs Object-level Understanding and Bridging (OUB), a tw
o-step prompting scheme that decouples object recognition from relational reason
ing by prompting the model to identify objects and then reason based on them. It
further introduces a von Mises-Fisher (vMF)-based trustworthiness metric, which
is more stable than semantic entropy metrics in small-sample settings. Extensiv
e experiments and ablation studies on multiple benchmarks show that DOUBT consis
tently outperforms state-of-the-art baselines, demonstrating its robustness and
generalizability for hallucination detection in MLLMs. The code is available at
https://github.com/XLearning-SCU/2026-ICML-DOUBT.

EnterpriseOps-Gym: Environments and Evaluations for Stateful Agentic Planning an
d Tool Use in Enterprise Settings

Shiva Krishna Reddy Malay, Shravan Nayak, Sagar Davasam, Srinivas Sunkara, Sai Rajeswar

The rapid evolution of Large Language Models (LLMs) has shifted their role from passive information providers to active agents capable of executing complex workflows. However, the realization of a true "AI worker" is currently hindered by benchmarks that fail to capture the intricacy of professional environments, which demand long-horizon planning, complex tool usage, and adherence to strict access protocols. To bridge this gap, we introduce EnterpriseOps-Gym, a benchmark environment designed to evaluate agentic planning in realistic enterprise settings. EnterpriseOps-Gym provides: (i) 1,150 expert-curated tasks across eight interconnected domains (including HR, IT, Customer Service and productivity tools) that require managing persistent state and adhering to strict outcome-based verification logic; and (ii) a high-fidelity, containerized sandbox environment hosting 164 database tables and 512 functional tools. Our evaluation reveals critical limitations in state-of-the-art models: even the top-performing Claude Sonnet~4.5 achieves only 34.1\% success, struggling significantly with planning consistency, error recovery, and policy constraints. Furthermore, we observe that agents frequently fail to refuse infeasible tasks, leading to unintended and potentially harmful side effects on the system. These findings indicate that current agents are not yet ready for enterprise deployment. By releasing EnterpriseOps-Gym, we provide a concrete testbed to advance the reliability of autonomous agents in professional workflows.

Subspace-Aware Feature Reshaping for Open-Set Graph Class-Incremental Learning

Weichao Zhang, Shuai Zheng, Yeyu Yan, Zhizhe Liu, Zhenfeng Zhu, Yao Zhao

Graph class-incremental learning (GCIL) has emerged to address the challenge of learning from dynamically evolving graphs, which continuously learns new classes over a sequence of tasks while retaining performance on previously seen classes. However, existing GCIL methods assume a closed-set test distribution drawn only from seen tasks. This fundamentally contradicts real-world open-ended scenarios where future unknown classes inevitably emerge. Empirically, we observe that existing GCIL methods falter in such open-set settings due to severe representation drift and generalized overconfidence. To bridge this gap, we investigate the Open-Set GCIL problem and propose \textbf{SAFER} (\underline{S}ubspace-\underline{A}ware \underline{FE}ature \underline{R}eshaping), a novel framework that endows GCIL with intrinsic open-set capabilities under a replay-free constraint. Specifically, \textbf{SAFER} performs subspace-aware feature reshaping with drift-free fingerprints, unifying task routing and open-set rejection into a single energy-based metric. Furthermore, we introduce a geometric space-consistency regularization that explicitly improves intra-class compactness and suppresses cross-task representation drift. Extensive experiments on four benchmarks demonstrate that SAFER outperforms state-of-the-art baselines by margins of up to 5.2\% in accuracy and 31.3\% in open-set AUROC, all while maintaining near-zero forgetting under strict no-replay constraints.

****

Scaling Prompt Synthesis for Large Language Model Reasoning

Xueliang Zhao, Wei Wu, Jian Guan, Zhuocheng Gong, Lingpeng Kong

Large language models (LLMs) are evolving from conversational systems into strong reasoners for tasks such as Olympiad mathematics and competitive programming. While scaling parameters and test-time computation has driven progress, a key bottleneck is the lack of high-quality training problems: human-curated datasets are costly and limited, while existing synthetic corpora are often too easy or narrow. PromptCoT showed that injecting rationales into prompt synthesis increases problem difficulty. Building on this, we present PromptScale, a scalable framework that replaces hand-crafted heuristics with an expectation-maximization (EM) loop, where rationales are iteratively refined to guide prompt construction. This produces problems that are both harder and more diverse than prior corpora. The synthetic prompts support two post-training regimes: (1) \emph{Self-Play}, where strong models improve autonomously via verifiable feedback without stronger teachers; and (2) \emph{Supervised Fine-Tuning (SFT)}, where weaker models learn

from teacher-distilled traces. Extensive experiments demonstrate the effectiveness of this approach. In self-play, applying PromptScale to \texttt{Qwen3-30B-A3B-Thinking-2507} sets new state-of-the-art results \emph{at the 30B scale}, with +4.4, +4.8, and +5.3 on AIME 24/25 and HMMT 25, +6.1 and +5.0 on LiveCodeBench v5/v6, and +35 Elo on Codeforces. In SFT, training \texttt{Qwen2.5-7B-Instruct} solely on synthetic prompts boosts accuracy to 73.1 (AIME 24), 65.6 (AIME 25), and 53.4 (LiveCodeBench v5), surpassing models trained on human or hybrid data. Analyses further confirm that PromptScale yields fundamentally harder and distributionally distinct problems. These results establish prompt synthesis as a new axis for scaling reasoning and position PromptScale as a scalable foundation for future open-source models. The implementation is available at \url{https://github.com/inclusionAI/PromptCoT}.

ConFu: Contemplate the Future for Better Speculative Sampling

Zongyue Qin, Raghavv Goel, Mukul Gagrani, Risheek Garrepalli, Mingu Lee, Yizhou Sun

Speculative decoding has emerged as a powerful approach to accelerate large language model (LLM) inference by employing lightweight draft models to propose candidate tokens that are subsequently verified by the target model. The effectiveness of this paradigm critically depends on the quality of the draft model. While recent advances such as the EAGLE series achieve state-of-the-art speedup, existing draft models remain limited by error accumulation: they condition only on the current prefix, causing their predictions to drift from the target model over steps. In this work, we propose ConFu (Contemplate the Future), a novel speculative decoding framework that enables draft models to anticipate the future direction of generation. ConFu introduces (i) contemplate tokens and soft prompts that allow the draft model to leverage future-oriented signals from the target model at negligible cost, (ii) a dynamic contemplate token mechanism with MoE to enable context-aware future prediction, and (iii) a training framework with anchor token sampling and future prediction replication that learns robust future prediction. Experiments demonstrate that ConFu improves token acceptance rates and generation speed over EAGLE-3 by 8-11%, across various downstream tasks with Llama-3 3B and 8B models.

We believe our work is the first to bridge speculative decoding with continuous reasoning tokens, offering a new direction for accelerating LLM inference.

****

Forward-KL Convergence of Time-Inhomogeneous Langevin Diffusions

Andreas Habring, Martin Zach

Many practical samplers rely on time-dependent drifts---often induced by annealing or tempering schedules---to improve exploration and stability. This motivates a unified non-asymptotic analysis of the corresponding Langevin diffusion and their discretizations. We provide a convergence analysis that includes non-asymptotic bounds for the continuous-time diffusion and its Euler--Maruyama discretization in the forward-Kullback--Leibler divergence under a single set of abstract conditions on the time-dependent drift. The results apply to many practically-relevant annealing schemes, including geometric tempering and annealed Langevin sampling. In addition, we provide numerical experiments comparing the annealing schemes covered by our theory in low- as well as high-dimensional settings.

Implicit Turn-Wise Policy Optimization for Proactive User-LLM Interaction

Haoyu Peter Wang, Yuxin Chen, Liang Luo, Buyun Zhang, Ellie Dingqiao Wen, Pan Li

Multi-turn human-AI collaboration is fundamental to deploying interactive services such as adaptive tutoring, conversational recommendation, and professional consultation. However, optimizing these interactions via reinforcement learning is hindered by the sparsity of verifiable intermediate rewards and the high stochasticity of user responses.

To address these challenges, we introduce Implicit Turn-wise Policy Optimization (ITPO).

ITPO leverages an implicit process reward model to derive fine-grained, turn-wise process rewards from sparse outcome signals. Unlike volatile token-level rewar

ds, these turn-level signals exhibit superior robustness and may utilize a normalization mechanism to further enhance training stability.
We evaluate ITPO across three representative multi-turn collaborative tasks: math tutoring, document writing, and medical recommendation. Empirical results demonstrate that ITPO, when combined with PPO, GRPO, or RLOO, consistently achieves improved convergence than existing baselines. Elaborate trajectory analysis confirms that ITPO infers turn-wise preferences that are semantically aligned with human judgment.

Learning Generalized Label Distributions
Haitao Wu, Weiwei Li, Kun Yue, Xiuyi Jia
Label ambiguity/polysemy is pervasive in supervised learning, motivating a variety of representations beyond the traditional single-label setting. While label distribution (LD) provides a probabilistic description and has attracted increasing attention, we reveal its inherent limitations, including inconsistency with raw data, distortion of inter-sample order, and limited applicability. To address these issues, we introduce generalized label distribution (GLD), a unified representation that can perfectly recover raw data while preserving inter-sample order consistency, transform into existing forms of label representations without information loss, and capture out-of-distribution samples as well as negative label correlations. We further develop GLD learning algorithms and demonstrate their effectiveness through both theoretical analysis and extensive experiments.
****
Full-Batch Gradient Descent Outperforms One-Pass SGD: Sample Complexity Separation in Single-Index Learning
Filip Kova■evi■, Hong Chang Ji, Denny Wu, Mahdi Soltanolkotabi, Marco Mondelli
It is folklore that reusing training data more than once can improve the statistical efficiency of gradient-based learning. While this phenomenon has been extensively studied in linear regression, the benefit of multi-pass gradient descent (GD, which reuses all the data) over one-pass stochastic gradient descent (online SGD, which uses each data point only once) is not well-understood in nonlinear and non-convex settings, except for a loss modification mechanism achieved by the first two passes on the data. In this work, we consider learning a d-dimensional single-index model with a quadratic activation, for which it is known that one-pass SGD requires $n\gtrsim d\log d$ samples to achieve weak recovery. We first show that this $\log d$ factor in the sample complexity persists for full-batch spherical GD on the correlation loss; however, by simply truncating the activation, full-batch GD exhibits a favorable optimization landscape at $n \simeq d$ samples, thereby outperforming one-pass SGD (with the same activation) in statistical efficiency. We complement this result with a trajectory analysis of full-batch GD on the squared loss from small initialization, showing that $n \gtrsim d$ samples and $T \gtrsim\log d$ gradient steps suffice to achieve strong (exact) recovery.
****
LS^{2}MC-GDA: A Smoothed Algorithm for Federated Stochastic Multi-Level Compositional Minimax Optimization
Xinwen Zhang, Richard Souvenir, Hongchang Gao
Federated stochastic multi-level compositional minimax optimization supports a growing number of machine learning applications. However, the interplay of multi-level compositional structure and minimax formulation in federated learning setting poses significant optimization challenges, resulting in slow convergence rates for existing algorithms. In this paper, we propose a novel federated learning algorithm, LS^{2}MC-GDA, that leverages smoothing techniques and variance-reduced stochastic compositional gradients. To support our theoretical analysis, we introduce a stage-wise extension of LS^{2}MC-GDA, which serves to bridge the gap between different stationarity measures. We establish that our algorithm achieves a sample complexity of $O(\kappa^{3/2}/N\epsilon^3)$ and a communication complexity of $O(\kappa/\epsilon^2)$, substantially improving existing theoretical results in terms of the condition number κ and the solution accuracy ϵ and achieving a linear speedup with respect to the number of workers N.

Finally, experimental results validate the effectiveness of our algorithm.
****
Exact and Approximate Algorithms for Polytree Learning
Juha Harviainen, Frank Sommer, Manuel Sorge
Polytrees are a subclass of Bayesian networks that seek to capture the conditional dependencies between a set of n variables as a directed forest and are motivated by their more efficient inference and improved interpretability. Since the problem of learning the best polytree is NP-hard, we study which restrictions make it more tractable by considering for example in-degree bounds, properties of score functions measuring the quality of a polytree, and approximation algorithms. We devise an algorithm that finds the optimal polytree in time $\mathcal{O}((2+\epsilon)^n)$ for arbitrarily small $\epsilon > 0 $ and any constant in-degree bound k, improving over the fastest previously known algorithm of time complexity $\mathcal{O}(3^n)$. We further give polynomial-time algorithms for finding a polytree whose score is within a factor of k from the optimal one for arbitrary scores and a factor of 2 for additive ones. Many of the results are complemented by (nearly) tight lower bounds for either the time complexity or the approximation factors.
****
ASAP: Exploiting the Satisficing Generalization Edge in Neural Combinatorial Optimization
Han Fang, Paul Weng, Yutong Ban
Deep Reinforcement Learning (DRL) has emerged as a promising approach for solving Combinatorial Optimization (CO) problems, such as the 3D Bin Packing Problem (3D-BPP), Traveling Salesman Problem (TSP), or Vehicle Routing Problem (VRP), but these neural solvers often exhibit brittleness when facing distribution shifts. To address this issue, we uncover the Satisficing Generalization Edge, which we validate both theoretically and experimentally: identifying a set of promising actions is inherently more generalizable than selecting the single optimal action. To exploit this property, we propose Adaptive Selection After Proposal (ASAP), a generic framework that decomposes the decision-making process into two distinct phases: a proposal policy that acts as a robust filter, and a selection policy as an adaptable decision maker. This architecture enables a highly effective online adaptation strategy where the selection policy can be rapidly fine-tuned on a new distribution. Concretely, we introduce a two-phase training framework enhanced by Model-Agnostic Meta-Learning (MAML) to prime the model for fast adaptation. Extensive experiments on 3D-BPP, TSP, and CVRP demonstrate that ASAP improves the generalization capability of state-of-the-art baselines and achieves superior online adaptation on out-of-distribution instances.
****
From Perception to Planning: Evolving Ego-Centric Task-Oriented Spatiotemporal Reasoning via Curriculum Learning
Xiaoda Yang, Yuxiang Liu, Shenzhou Gao, Can Wang, Jingyang Xue, Lixin Yang, Yao Mu, Tao Jin, Zhimeng Zhang, Shuicheng YAN, Zhou Zhao
Modern vision-language models achieve strong performance in static perception, but remain limited in the complex spatiotemporal reasoning required for embodied, egocentric tasks. A major source of failure is their reliance on temporal priors learned from passive video data, which often leads to spatiotemporal hallucinations and poor generalization in dynamic environments. To address this, we present EgoTSR, a curriculum-based framework for learning task-oriented spatiotemporal reasoning. EgoTSR is built on the premise that embodied reasoning should evolve from explicit spatial understanding to internalized task-state assessment and finally to long-horizon planning. To support this paradigm, we construct EgoTSR-Data, a large-scale dataset comprising 46 million samples organized into three stages: Chain-of-Thought supervision for explicit reasoning, weakly supervised tagging for internalizing reasoning, and long-horizon sequences composed of orthogonal atomic subtasks. We further introduce a Reasoning-Enhanced Task Decomposition mechanism that explicitly models causal dependencies between actions and objects, enabling controllable planning from high-level task descriptions. To rigorously validate our approach, we establish a Dual-Level Evaluation Framework that

covers both atomic spatial perception and logical planning. Extensive experiments demonstrate that EgoTSR effectively eliminates chronological biases, achieving 92.4% accuracy on long-horizon logical reasoning tasks while maintaining 88.2% fine-grained perceptual precision, significantly outperforming existing open-source and closed-source state-of-the-art models.
****
A Minimal Agent for Automated Theorem Proving
Borja Requena, Austin Letson, Krystian Nowakowski, Izan Beltran Ferreiro, Leopoldo Sarra
We propose a minimal agentic baseline that enables systematic comparison across different AI-based theorem prover architectures. This design implements the core features shared among state-of-the-art systems: iterative proof refinement, library search and context management. We evaluate this agentic approach using qualitatively different benchmarks and compare various frontier language models and design choices. Our results show competitive performance compared to state-of-the-art approaches, while using a significantly
simpler architecture and a fraction of their cost. Additionally, we demonstrate consistent advantages of an iterative approach over multiple single-shot generations, especially in terms of sample efficiency and cost effectiveness. The implementation is released open-source as a candidate reference for future research and as an accessible prover for the community.
****
Optimizing Few-Step Generation with Adaptive Matching Distillation
Lichen Bai, zikai zhou, Shitong Shao, Wenliang Zhong, Shuo Yang, Shuo Chen, Bojun Cheng, Zeke Xie
Distribution Matching Distillation (DMD) is a powerful acceleration paradigm, yet its stability is often compromised in **Forbidden Zones**—regions where the real teacher provides unreliable guidance while the fake teacher exerts insufficient repulsive force. In this work, we propose a unified optimization framework that reinterprets prior art as implicit strategies to avoid these corrupted regions. Based on this insight, we introduce Adaptive Matching Distillation (**AMD**), a self-correcting mechanism that utilizes reward proxies to explicitly detect and escape Forbidden Zones. AMD dynamically prioritizes corrective gradients via structural signal decomposition and introduces Repulsive Landscape Sharpening to enforce steep energy barriers against failure mode collapse. Extensive experiments across image and video generation tasks (e.g., SDXL, Wan2.1) and rigorous benchmarks (e.g., VBench, GenEval) demonstrate that AMD significantly enhances sample fidelity and training robustness. For instance, AMD improves the HPSv2 score on SDXL from **30.64** to **31.25**, outperforming state-of-the-art baselines. These findings validate that explicitly rectifying optimization trajectories within Forbidden Zones is essential for pushing the performance ceiling of few-step generative models.
****
Item Response Scaling Laws: A Measurement Theory Approach for Efficient and Generalizable Neural Scaling Estimation
Sang T. Truong, Yuheng Tu, Rylan Schaeffer, Sanmi Koyejo
Scaling laws provide a fundamental framework for understanding the performance of Language Models (LMs), yet deriving them requires prohibitively expensive evaluations across thousands of checkpoints or millions of inference samples. To address this, we introduce Item Response Scaling Laws (IRSL), a unified framework that integrates Item Response Theory (IRT) within the scaling law framework. Unlike traditional approaches that treat each model-benchmark pair in isolation, IRSL disentangles latent model ability from question characteristics, factorizing the scaling law estimation for M models and N questions to significantly reduce parameter complexity from $O(M \times N)$ to $O(M + N)$. We instantiate IRSL with Beta-IRT, which leverages the empirical probability responses of LMs---such as token probabilities in pre-training and pass rates in test-time sampling---to capture richer signals than binary responses. We validate our approach across two prevalent scaling paradigms: (1) pre-training downstream scaling, using 6,612 LM checkpoints and 37,682 questions from 10 benchmarks; and (2) test-time scal

ing, using 12 LMs and 120 questions from 4 benchmarks with up to 2,500 samples p
er question. Given a one-time calibration on existing model responses, IRSL yiel
ds more reliable scaling estimates using only 50 questions per benchmark (a 99.9
\% reduction), achieving comparable or superior decision accuracy to traditional
 approaches. Furthermore, we show that the estimated latent model abilities are
generalizable, enabling accurate performance forecasting across benchmarks that
share the same measurement objective.
****

A Geometric Lens on Physics-Aligned Data Compression
Aleix Segui Ugalde, Wesley Armour
In AI for Science, physics-informed losses are increasingly used to train learne
d compressors for scientific data, but their rate--distortion implications remai
n poorly understood. At fixed bitrate, these objectives often improve preservati
on of a target physical observable while degrading standard reconstruction fidel
ity. We develop a local geometric theory showing that this tradeoff is governed
by the interaction of latent-space sensitivities induced by the entropy model, t
he physical observable, and the distortion metric. At each operating point, thes
e induce preferred directions along which compression noise should be suppressed
, yielding an anisotropic error-allocation mechanism. When these directions are
misaligned, improving the observable at fixed rate necessarily worsens standard
distortion, establishing a fundamental limit on simultaneous preservation. We fo
rmalise this through a local tangent-space rate--distortion law and introduce a
practical alignment diagnostic based on dominant eigenspace overlap. Experiments
 across scientific domains test the theory and validate that the alignment diagn
ostic correlates with observed data- and physics-space trade-offs.
****

Layer-Centric Factors of Variation Disentanglement for Task- and Model-Agnostic
Generalization
Hee-Jun Jung, Jongmin Park, Minwoo Kang, Hoyong Kim, Kangil Kim
Disentanglement learning aims to separate the underlying factors of variation (F
oV) to improve generalization.
However, most FoV-based latent-vector-centric methods impose objective-driven co
nstraints at a bottleneck, and it is difficult to translate disentanglement into
 consistent gains on downstream tasks without inductive bias.
Motivated by architectural approaches complementary to vector-centric objectives
 for downstream tasks, we propose the *Orthogonal Subspaces Projection* (OSP) la
yer, a plug-and-play module that integrates into intermediate layers and promote
s FoV separation by projecting latent features into mutually orthogonal subspace
s.
Across diverse domains and tasks, models equipped with the OSP layer improve dis
entanglement quality and generalization in downstream tasks, including computer
vision (classification, detection, and segmentation), natural language processin
g (word analogy, and text classification), and fine-tuning settings on large bac
kbones.
****

TIME: Tensor-Factorized Mixture-of-Experts with Intrinsic Routing for Lifelong M
ultimodal Knowledge Editing
Dexuan Xu, Jieyi Wang, Shijie Li, Hanpin Wang, Yongzhi Cao, Yu Huang
Lifelong multimodal knowledge editing allows vision language models to continuou
sly adapt to dynamic updates to avoid catastrophic forgetting. To mitigate inter
ference between sequential updates, recent paradigms have shifted towards modula
r parameter isolation. However, this strategy faces a critical scalability bottl
eneck: accumulating dense parameter blocks can lead to excessive memory growth,
and managing these independent modules often uses decoupled routing mechanisms,
resulting in architectural redundancy. To address this issue, we propose **TIME*
* (**T**ensor-Factorized **I**ntrinsic **M**ixture-of-**E**xperts), a unified fr
amework harmonizing parameter efficiency with structural self-routing. TIME para
meterizes each knowledge edit as a compact CP-decomposed tensor, significantly r
educing complexity compared to low-rank matrices. Furthermore, departing from au
xiliary semantic retrievers, we introduce an intrinsic routing mechanism that ut

ilizes the tensor's input factors to directly define the active subspace, effect ively enabling expert parameters to serve simultaneously as the routing logic. E xtensive experiments demonstrate that TIME achieves state-of-the-art performance on lifelong editing benchmarks while successfully reducing memory usage and inf erence latency.

Intrinsic Task Symmetry Drives Generalization in Algorithmic Tasks

Hyeonbin Hwang, Yeachan Park

Grokking, a sudden transition from memorization to generalization, has been clos ely linked to the emergence of low-dimensional representations; yet the mechanis m driving this organization remains elusive. Here, we propose that intrinsic tas k symmetries are the key drivers of grokking, inducing structured geometries in representation space. Our analysis reveals a consistent three-stage training dyn amic: (i) data memorization, (ii) intrinsic symmetry acquisition, and (iii) geom etric organization. We show that generalization emerges during the symmetry acqu isition phase, and subsequently the embedding space organizes into a low-dimensi onal structured geometry. We validate this mechanism across diverse algorithmic domains, spanning algebraic (modular arithmetic), structural (graph metric compl etion), and relational (comparison) reasoning tasks. Leveraging these insights, we formulate a symmetry-based criterion for generalization and propose symmetry- and geometry-prompting training strategies that can accelerate generalization. Together, our results establish intrinsic symmetry as a central mechanism enabli ng neural networks to move beyond memorization and achieve robust algorithmic re asoning.

****

PFT: Phonon Fine-tuning for Machine Learned Interatomic Potentials

Teddy Koker, Abhijeet Sadashiv Gangan, Mit Kotak, Jaime Marian, Tess Smidt

Many materials properties depend on higher-order derivatives of the potential en ergy surface, yet machine learned interatomic potentials (MLIPs) trained with a standard loss on energy, force, and stress errors can exhibit error in curvature , degrading the prediction of vibrational properties. We introduce phonon fine-t uning (PFT), which directly supervises second-order force constants of materials by matching MLIP energy Hessians to DFT-computed force constants from finite di splacement phonon calculations. To scale to large supercells, PFT stochastically samples Hessian columns and computes the loss with a single Hessian-vector prod uct. We also use a simple co-training scheme to incorporate upstream data to mit igate catastrophic forgetting. On the MDR Phonon benchmark, PFT improves Nequix MP by 55% on average across phonon thermodynamic properties and achieves state-o f-the-art accuracy among models trained on Materials Project trajectories. PFT a lso generalizes to improve properties beyond second-derivatives, improving therm al conductivity predictions that rely on third-order derivatives of the potentia l energy.

****

Measurement-Consistent Langevin Corrector for Stabilizing Latent Diffusion Inver se Problem Solvers

Lee Hyoseok, Sohwi Lim, Eunju Cha, Tae-Hyun Oh

While latent diffusion models (LDMs) have emerged as powerful priors for inverse problems, existing LDM-based solvers frequently suffer from instability. In thi s work, we first identify the instability as a discrepancy between the solver dy namics and stable reverse diffusion dynamics learned by the diffusion model, and show that reducing this gap stabilizes the solver. Building on this, we introdu ce *Measurement-Consistent Langevin Corrector (MCLC)*, a theoretically grounded plug-and-play stabilization module that remedies the LDM-based inverse problem s olvers through measurement-consistent Langevin updates. Compared to prior approa ches that rely on linear manifold assumptions, which often fail to hold in laten t space, MCLC provides a principled stabilization mechanism, leading to more sta ble and reliable behavior in latent space.

BuildArena: A Physics-Aligned Interactive Benchmark of LLMs for Engineering Cons truction

Tian Xia, Tianrun Gao, Wenhao Deng, Long Wei, Xiaowei Qian, Chenglei Yu, Tailin Wu

Engineering construction automation aims to transform natural language specifications into physically viable structures, requiring complex integrated reasoning under strict physical constraints. While modern LLMs possess broad knowledge and strong reasoning capabilities that make them promising candidates for this domain, their construction competencies remain largely unevaluated. To address this gap, we introduce BuildArena, the first physics-aligned interactive benchmark designed for language-driven engineering construction. Technically, it contributes to the community in two aspects: (1) an extendable task design strategy spanning static and dynamic mechanics across multiple difficulty tiers; (2) a 3D Spatial Geometric Computation Library for supporting construction based on language instructions.

On nine frontier LLMs and three additional open-weight models, BuildArena comprehensively evaluates their capabilities for language-driven and physics-grounded construction automation. We release the code at https://github.com/AI4Science-WestlakeU/BuildArena to benefit construction automation in engineering applications.

RECAST: Model Reconstruction via Counterfactual-Aware Wasserstein Geometry under Limited Data

Xuan Zhao, Lena Krieger, Zhuo Cao, Arya Bangun, Hanno Scharr, Ira Assent

Counterfactual explanations (CFs) help understand machine learning models by identifying minimal input changes that would lead to alternative model outcomes. Recent work demonstrates their utility for reconstructing black-box models, enabling third-party auditing of opaque decision systems for fairness and accountability. Still, CF-based reconstruction may suffer from decision boundary shifts, overfitting, and restrictive assumptions requiring online query access to target platforms.

We propose **REconstruction via Counterfactual-Aware waSserstein opTimization (RECAST)** under limited data and restricted access, a behavioral surrogate model based on Wasserstein barycenteric prototypes. Our approach addresses decision boundary shifts by incorporating CFs as informative, though less representative, samples for both classes, maintaining high surrogate fidelity in low-sample regimes without requiring online access during reconstruction. To enhance fairness auditing, our method enables systematic group fairness diagnostics.

Experiments on real-world datasets and various setups show that **RECAST** effectively achieves high fidelity and query efficiency, as well as stable results even when the access is limited and noisy.

Coverage, Not Averages: Semantic Stratification for Trustworthy Retrieval Evaluation

Andrew Klearman, Radu Revutchi, Rohin Garg, Rishav Chakravarti, Samuel Marc Denton, Yuan Xue

Retrieval quality is the primary bottleneck for accuracy and robustness in retrieval-augmented generation (RAG). Current evaluation relies on heuristically constructed query sets, which introduce a hidden intrinsic bias. We formalize retrieval evaluation as a statistical estimation problem, showing that metric reliability is fundamentally limited by the evaluation-set construction. We further introduce \emph{semantic stratification}, which grounds evaluation in corpus structure by organizing documents into an interpretable global space of entity-based clusters and systematically generating queries for missing strata. This yields (1) formal semantic coverage guarantees across retrieval regimes and (2) interpretable visibility into retrieval failure modes. Experiments across multiple benchmarks and retrieval methods validate our framework. The results expose systematic coverage gaps, identify structural signals that explain variance in retrieval performance, and show that stratified evaluation yields more stable and transparent assessments while supporting more trustworthy decision-making than aggregate metrics.

AtelierEval: Agentic Evaluation of Humans & LLMs as Text-to-Image Prompters
Hanjun Luo, Zhimu Huang, Sylvia Chung, Yiran Wang, Yingbin Jin, Jialin Li, Jiang Li, Xinfeng Li, Hanan Salam
Text-to-image (T2I) systems increasingly rely on upstream prompters, either humans or multimodal large language models (MLLMs), to translate user intent into detailed prompts. Yet current benchmarks fix the prompt and only evaluate T2I models, leaving the prompting proficiency of this upstream component entirely unmeasured. We introduce AtelierEval, the first unified benchmark that quantifies prompting proficiency across 360 expert-crafted tasks. Grounded in a cognitive view, it spans three task categories and instantiates tasks using a taxonomy of real-world challenges, with a dual interface for both humans and MLLMs. To enable scalable and reliable evaluation, we propose AtelierJudge, a skill-based, memory-augmented agentic evaluator. It produces subjective and objective scores for prompt–image pairs, achieving a Spearman correlation of 0.79 with human experts, approaching human performance. Extensive experiments benchmark 8 MLLMs against 48 human users across 4 T2I backends, validate AtelierEval as a robust diagnostic tool, and reveal the superiority of mimicry over planning, advocating for an image-augmented direction for future prompters. Our work is released to support future research.

Robust Sequential Experimental Design for A/B Testing
Qianglin Wen, Xiangkun Wu, Chengchun Shi, Ting Li, Niansheng Tang, Yingying Zhang, Hongtu Zhu
Experimental design has emerged as a powerful approach for improving the sample efficiency of A/B testing, yet existing designs rely critically on correctly specified models. We study robust sequential experimental design under model misspecification and develop a unified framework that covers both contextual bandit and dynamic settings. Theoretically, we prove that our design bounds the worst-case mean squared error of the estimated treatment effect. Empirically, we demonstrate the effectiveness of the proposed approach using synthetic and real-world datasets from a leading technology company.
****
You Need Better Attention Priors
Elon Litman, Gabe Guo
We generalize the attention mechanism by viewing it through the lens of Entropic Optimal Transport, revealing that standard attention corresponds to a transport problem regularized by an implicit uniform prior. We introduce Generalized Optimal transport Attention with Trainable priors (GOAT), a new attention mechanism that replaces this naive assumption with a learnable, continuous prior. This prior maintains full compatibility with optimized kernels such as FlashAttention. GOAT also provides an EOT-based explanation of attention sinks and materializes a solution for them, avoiding the representational trade-offs of standard attention. Finally, by absorbing spatial information into the core attention computation, GOAT learns an extrapolatable prior that combines the flexibility of learned positional embeddings with the length generalization of fixed encodings.

Maximizing Mutual Information Between Prompt and Response Improves LLM Performance With No Additional Data
HyunJi Nam, Haoran Li, Natasha Jaques
While post-training has successfully improved large language models (LLMs) across a variety of domains, these gains heavily rely on human-labeled data or external verifiers. Existing data has already been exploited, and new data is expensive to collect. Moreover, true intelligence goes far beyond verifiable tasks. Therefore, we need self-improvement frameworks that are less dependent on external signals and more broadly applicable to both verifiable and non-verifiable domains. We propose **Mutual Information Preference Optimization (MIPO)**, a contrastive data augmentation method that constructs preference pairs by generating a positive response conditioning on the correct prompt, and a negative response by conditioning on a random, unrelated prompt. We show that using Direct Preference Optimization to learn from this paired data maximizes pointwise mutual information

under the base LLM between prompts and model responses. Experiments with with 1-7B parameter Llama and Qwen instruct models show that MIPO achieves 3-16% gains (and 51% increase for Qwen2.5-1.5B-Instruct) on personalization compared to prompting baselines. Surprisingly, MIPO can also be useful in verifiable domains, such as math and multiple-choice question answering, yielding 1-20% gains *without any additional data or external supervision*. These results suggest a promising direction for self-improvement using intrinsic signals derived from contrastive data pairs.

Source-Free Open-World RF Fingerprint Identification

Kunling Li, Cunqing Hua, Hongyu Zhu, Tianjie Ju, Pengwenlong Gu

Radio Frequency Fingerprint Identification (RFFI) is a foundational pillar of physical-layer security, providing unclonable identity authentication and lightweight defense mechanisms for zero-trust wireless networks. Its practical deployment, however, often occurs in a source-free open-world (SF-OW) setting, characterized by a continuous influx of unregistered devices and privacy constraints that preclude the retention of historical data. In this paper, we formalize SF-OW RFFI task, which manifests a severe stability-plasticity dilemma: intrinsic signal similarity confuses new classes, while source absence precipitates catastrophic forgetting. To address this, we propose Incremental Orthogonal ETF (IO-ETF), a novel neural collapse-inspired framework utilizing output geometry to actively induce parameter separation and isolation. We further devise a Triple-Level Geometric Alignment (TLGA) strategy via semantic optimal transport, manifold progressive anchoring, and reliable subspace retention to stably align unlabeled streams to this geometric skeleton. Experiments on benchmarks demonstrate a superior trade-off between old-class retention and new-class discovery, offering a promising solution for secure access in dynamic networks.

Offline Multi-Agent Reinforcement Learning via Sequential Score Decomposition

Dan Qiao, Wenhao Li, Shanchao Yang, Hongyuan Zha, Baoxiang Wang

Offline cooperative multi-agent reinforcement learning (MARL) faces unique challenges due to the distribution shift between online and offline data collection. While online MARL typically converges to a single coordinated joint policy, offline datasets are often mixtures of diverse cooperative behaviors, resulting in highly multimodal joint behavior distributions. In such settings, independent policy regularization often misaligns joint policy constraints and leads to severe distribution shift. To address this, we propose OMSD, which sequentially decomposes the joint behavior policy into individual conditional distributions and leverages diffusion-based generative models to provide modality-coordinated regularization for each agent. Combined with centralized critic guidance, OMSD achieves coordinated exploration within high-value, in-distribution regions, and avoids out-of-distribution joint actions. Experiments across multiple datasets on various continuous control tasks demonstrate that OMSD consistently achieves state-of-the-art performance, especially in challenging multimodal scenarios. Our results highlight the necessity of modality-aware coordination for robust offline MARL.

Latent Diffusion Pretraining for Crystal Property Prediction

Shrimon Mukherjee, KISHALAY DAS, Partha Basuchowdhuri, Pawan Goyal, Niloy Ganguly

Fast and accurate prediction of crystal properties is a central challenge in new materials design. Graph neural networks and Transformer-based models have emerged as powerful tools for this task due to their ability to encode the local structural environment of atoms within a crystal. However, these models are data-hungry and in practice labeled data for crystal properties are very scarce. Pretraining–finetuning strategies, particularly those based on diffusion models, have shown promise in addressing these limitations. In this work, we introduce a novel latent-diffusion based pretraining framework CrysLDNet, designed to mitigate the data scarcity. Our approach integrates a Variational Autoencoder (VAE) with a diffusion model during the pretraining stage. The VAE encoder maps 3D crystal structures into a smooth latent space, within which the diffusion process is appli

ed. This latent diffusion pretraining enables the graph encoder to effectively c
apture structural and chemical semantics from large-scale unlabeled data, which
can then be finetuned for specific property prediction tasks.
Comprehensive experiments on popular DFT datasets for property prediction reveal
 that CrysLDNet significantly outperforms both training-from-scratch and pretrai
ned baselines, with improvements of ***4.26%*** and ***4.90%*** on the JARVIS an
d MP datasets. Additionally, the learned representations remain robust in sparse
-data conditions and are expressive enough to correct DFT errors when finetuned
with limited experimental data. Code is available at https://github.com/shrimonm
uke0202/CrysLDNet.git.

GIPO: Gaussian Importance Sampling Policy Optimization
Chengxuan Lu, Zhenquan Zhang, Shukuan Wang, Qunzhi Lin, Baigui Sun, Yang Liu
Post-training with reinforcement learning (RL) has recently shown strong promise
 for advancing multimodal agents beyond supervised imitation. However, RL remain
s limited by poor data efficiency, particularly in settings where interaction da
ta are scarce and quickly become outdated. To address this challenge, GIPO (Gaus
sian Importance sampling Policy Optimization) is proposed as a policy optimizati
on objective based on truncated importance sampling, replacing hard clipping wit
h a log-ratio-based Gaussian trust weight to softly damp extreme importance rati
os while maintaining non-zero gradients. Theoretical analysis shows that GIPO in
troduces an implicit, tunable constraint on the update magnitude, while concentr
ation bounds guarantee robustness and stability under finite-sample estimation.
Experimental results show that GIPO achieves state-of-the-art performance among
clipping-based baselines across a wide range of replay buffer sizes, from near o
n-policy to highly stale data, while exhibiting superior bias--variance trade-of
f, high training stability and improved sample efficiency. Code is available at
https://github.com/distanceLu/GIPO.

SAM Audio: Segment Anything in Audio
Bowen Shi, Andros Tjandra, John Hoffman, Helin Wang, YI-CHIAO WU, Luya Gao, Juli
us Richter, Matthew Le, Apoorv Vyas, Sanyuan Chen, Christoph Feichtenhofer, Piot
r Dollár, Wei-Ning Hsu, Ann Lee
General audio source separation is a key capability for multimodal AI systems th
at can perceive and reason about sound. Despite substantial progress in recent y
ears, existing separation models are either domain-specific, designed for fixed
categories such as speech or music, or limited in controllability, supporting on
ly a single prompting modality such as text. In this work, we present SAM AUDIO,
 a foundation model for general audio separation that unifies text, visual, and
temporal span prompting within a single framework. Built on a diffusion transfor
mer architecture, SAM AUDIO is trained with flow matching on large-scale audio d
ata spanning speech, music, and general sounds, and can flexibly separate target
 sources described by language, visual masks, or temporal spans. The model achie

ves state-of-the-art performance across a diverse suite of benchmarks, including general sound, speech, music, and musical instrument separation in both in-the-wild and professionally produced audios, substantially outperforming prior general-purpose and specialized systems. Furthermore, we introduce a new real-world separation benchmark with human-labeled multimodal prompts and a reference-free evaluation model that correlates strongly with human judgment.
****
When Actions Go Off-Task: Detecting and Correcting Misaligned Actions in Computer-Use Agents
Yuting Ning, Jaylen Jones, Zhehao Zhang, Chentao Ye, Weitong Ruan, Junyi Li, Rahul Gupta, Huan Sun
Computer-use agents (CUAs) have made tremendous progress in the past year, yet they still frequently produce misaligned actions that deviate from the user's original intent. Such misaligned actions may arise from external attacks (e.g., indirect prompt injection) or from internal limitations (e.g., erroneous reasoning). They not only expose CUAs to safety risks, but also degrade task efficiency and reliability. This work makes the first effort to define and study misaligned action detection in CUAs, with comprehensive coverage of both externally induced and internally arising misaligned actions. We further identify three common categories in real-world CUA deployment and construct MisActBench, a benchmark of realistic trajectories with human-annotated, action-level alignment labels. Moreover, we propose DeAction, a practical and universal guardrail that detects misaligned actions before execution and iteratively corrects them through structured feedback. DeAction outperforms all baselines across offline and online evaluations with moderate latency overhead: (1) On MisActBench, it outperforms baselines by over 15% absolute in F1 score; (2) In online evaluation, it reduces attack success rate by over 90% under adversarial settings while preserving or even improving task success rate in benign environments.

Distilling Neuro-Symbolic Programs into 3D Multi-modal LLMs
Wentao Mo, Yang Liu
Current 3D spatial reasoning methods face a fundamental trade-off: neuro-symbolic 3D (NS3D) concept learners achieve interpretable reasoning through compositional programs but are constrained to closed-set concept vocabularies and simple programs; end-to-end 3D multi-modal LLMs (3D MLLMs) could handle complex natural language and open-vocabulary concepts but suffer from black-box reasoning without explicit spatial verification.
We introduce APEIRIA, a neuro-symbolic 3D MLLM to bridge two paradigms by distilling symbolic reasoning patterns into MLLMs with natural language chain-of-thought.
Our three-stage curriculum progressively builds reasoning capabilities:
a) 3D perception alignment grounds object visual-geometric features to the LLM,
b) CoT-SFT teaches query decomposition and stepwise verification from symbolic program traces,
and c) CoT-RL extends reasoning patterns to open-set concepts and deeply nested instructions.
By transferring reasoning patterns rather than concept-specific knowledge, APEIRIA preserves key NS3D virtues: transparent reasoning and modular interchangeability of planning and perception components.
Evaluations on grounding, question answering, and captioning show that APEIRIA surpasses prior NS3D methods and matches state-of-the-art 3D MLLMs on 3D spatial reasoning datasets, unifying symbolic methods' systematic reasoning with MLLMs' flexibility.
Code is available at https://github.com/oceanflowlab/APEIRIA.

Short Chains, Deep Thoughts: Balancing Reasoning Efficiency and Intra-Segment Capability via Split-Merge Optimization
Runquan Gui, Jie Wang, Zhihai Wang, Chi Ma, Jianye HAO, Feng Wu
While Large Reasoning Models (LRMs) have demonstrated impressive capabilities in solving complex tasks through the generation of long reasoning chains, this rel

iance on verbose generation results in significant latency and computational overhead.
To address these challenges, we propose \textbf{CoSMo} (\textbf{Co}nsistency-Guided \textbf{S}plit-\textbf{M}erge \textbf{O}ptimization), a framework designed to eliminate structural redundancy rather than indiscriminately restricting token volume.
Specifically, CoSMo utilizes a split-merge algorithm that dynamically refines reasoning chains by merging redundant segments and splitting logical gaps to ensure coherence.
We then employ structure-aligned reinforcement learning with a novel segment-level budget to supervise the model in maintaining efficient reasoning structures throughout training.
Extensive experiments across multiple benchmarks and backbones demonstrate that CoSMo achieves superior performance, improving accuracy by \textbf{3.3} points while reducing segment usage by \textbf{28.7\%} on average compared to reasoning efficiency baselines.

Hyperparameter Transfer Laws for Non-Recurrent Multi-Path Neural Networks
Haosong Zhang, Shenxi Wu, Xingjian Ma, Shirui Bian, Yichi Zhang, Xi Chen, Wei Lin
Deeper modern architectures are costly to tune, and the base learning rate is often one of the most sensitive hyperparameters. Maximal Update Parametrization (μP) helps explain why many hyperparameters transfer across width. Yet depthwise learning-rate scaling is less understood for modern architectures with convolution, residual aggregation, and attention. To unify various non-recurrent multi-path neural networks such as CNNs, ResNets, and Transformers, we introduce an architecture-dependent notion of effective depth. Under stabilizing initializations and a maximal-update criterion, we derive a shared leading-order -3/2 law for the base learning-rate scale as effective depth grows. Here, the budget controls typical one-step representation-update energy at initialization, and effective depth counts sequential update-bearing units while absorbing fixed local structure into constants. Experiments across diverse architectures confirm the predicted slope and enable reliable zero-shot transfer of learning rates across depths and widths, turning depth scaling into a predictable hyperparameter-transfer problem.

Vulnerable Agent Identification in Large-Scale Multi-Agent Reinforcement Learning
Simin Li, Zihao Mao, Zheng Yuwei, Linhao Wang, Ruixiao Xu, Chengdong Ma, Zhiqian Liu, Xin Yu, Yuqing Ma, Xin Wang, Jie Luo, Bo An, Yaodong Yang, Weifeng Lv, Xianglong Liu
Partial agent failure becomes inevitable when systems scale up, making it crucial to identify the subset of agents whose failure causes worst-case system performance degradations. We study this Vulnerable Agent Identification (VAI) problem in large-scale multi-agent reinforcement learning (MARL). We frame VAI as a Hierarchical Adversarial Decentralized Mean Field Control (HAD-MFC), where where the upper level selects vulnerable agents as an NP-hard task and the lower level learns their worst-case adversarial policies via mean-field MARL. The two problems are coupled together, making HAD-MFC difficult to solve. To handle this, we first decouple the hierarchical process by Fenchel-Rockafellar transform, resulting a regularized mean-field Bellman operator for upper level that enables independent learning at each level, thus reducing computational complexity. We next reformulate the upper-level NP-hard problem as an MDP with dense rewards, allowing sequential identification of vulnerable agents via greedy and RL algorithms. This decomposition provably preserves the optimal solution. Experiments show our method effectively identifies more vulnerable agents in large-scale MARL and the rule-based system, fooling system into worse failures, and reveals the vulnerability of each agent in large systems. Code available at \url{https://anonymous.4open.science/r/VAI-5F61/}.

Continuous Viewpoint Adaptation for Single View 3D Object Reconstruction
Seunghyun Hwang, Qiang Qiu
Single-view 3D object reconstruction presents a formidable challenge in computer vision due to the inherent limitations of information obtainable from a solitary viewpoint. Recent 3D Gaussian Splatting (3DGS) inspired approaches perform a feed-forward way of learning a neural network that predicts 3D Gaussians which compose the 3D object, given a single image. However, they often struggle with occlusions and exhibit high sensitivity to small changes in input viewpoint, leading to inconsistencies and blurry artifacts in novel view renderings. Our method leverages 3DGS and introduces a new learning scheme that continuously adapts to input viewpoints.
To address inherent continuity of camera viewpoints that are represented by polar and azimuthal angles, we use Neural Ordinary Differential Equations to continuously model filter subspace of neural network, thus seamlessly embedding inductive bias of perspective distortions into its structure. By continuously adapting to view-specific features, our approach fosters view consistency in 3D reconstruction, allowing better coherency and accuracy across different angles. Experiments demonstrate that our model outperforms previous methods on multiple single-view 3D reconstruction benchmark datasets and excels in extrapolating to unseen camera angles and categories.

Stochastic Gradient Methods under Heavy-Tailed Noises in Weakly Convex Optimization
Tianxi Zhu, Yi Xu, Qi Wang, Xiangyang Ji
Recently, many empirical work has shown that, in machine learning, the noise distribution of stochastic gradients often exhibits heavy tails when stochastic optimization methods are employed. Most existing theoretical analyses of heavy-tailed stochastic methods rely on various convexity and smoothness assumptions and our knowledge of how heavy-tailed stochastic methods behave in the setting of weakly convex optimization is still limited.

In the weakly convex setting, this paper derives new upper bounds on the convergence of the stochastic gradient method (SGD) under heavy-tailed noises. In particular, for vanilla SGD, we establish an in-expectation convergence guarantee on the bounded constrained domain under the assumption of bounded p-th central moment (p-BCM) of the gradient noise, and a high-probability guarantee on the unbounded domain when the noise follows a heavy-tailed sub-Weibull distribution. By equipping SGD with the gradient clipping (Clip-SGD), we demonstrate that it achieves high-probability convergence in the unbounded domain under the p-BCM gradient noise. All of our high-probability convergence bounds depend on the failure probability only through polynomial-logarithmic factors. Finally, we present experiments to validate our theoretical findings.
****
Can VLMs Diagnose and Recover from VLA Manipulation Faults?
Bowen Yan, Jiahao Xiao, Kehui Liu, Jianbo Zhang, Zicheng Zhang, Qi Jia, Zhongjie Jia, Haoming Song, Chunyi Li, Bin Zhao, Guangtao Zhai
Existing VLA models frequently fail in robotic manipulation tasks, with poorly structured fault types that often require expert diagnosis. While VLMs offer strong explanatory capabilities, their effectiveness in assisting VLAs is limited by their unclear role in diagnostics and inadequate collaboration mechanisms. To address this, we introduce VLA-FixBench, a fault evaluation dataset that spans perception, planning, and control failures, and provides annotations for task stages, fault types, and spatiotemporal repair strategies. We further propose FaultEval, a static-to-dynamic-to-real evaluation framework that benchmarks 20 VLMs across multiple fault-related dimensions. Building on these insights, we design a VLM–VLA collaboration mechanism that localizes spatiotemporal deviations and rolls back task execution to enable targeted recovery. Experiments show that FaultEval reliably characterizes VLM-based closed-loop diagnosis and repair. The upper-bound analysis using human expert intervention shows that an idealized feedback loop can improve task success rates by 13\% on LIBERO and 35\% on real-world ro

bots. Our code, benchmark, and project page will be publicly released at: https://kakigo.github.io/VLA-FixBench/

CLAA: Cross-Layer Attention Aggregation for Accelerating LLM Prefill
Bradley McDanel, Steven Li, Harshit Khaitan
Token-ranking heuristics accelerate the prefill bottleneck in long-context LLM inference by selectively processing semantically relevant tokens. However, current evaluation relies on end-to-end benchmarks, making it difficult to isolate the quality of the token ranking itself. To address this, we introduce an Answer-Informed Reference framework with two variants: a Model Reference (Model-Ref) that measures token importance using the model generated answer, and a Ground-Truth Reference (GT-Ref) that uses human reference answers. Using GT-Ref, we establish that as few as 10% of prompt tokens suffice to match full-context performance on LongBench across all three evaluated models. The framework also reveals that existing heuristics exhibit variance across layers, with rankings degrading sharply at specific layers. Motivated by this instability, we propose Cross-Layer Attention Aggregation (CLAA), which aggregates importance scores across consecutive layers, eliminating the layer-dependent accuracy collapse observed in single-layer methods. A meaningful gap remains between the best heuristic and GT-Ref, indicating theoretical room for improved token selection.

When RAG Hurts: Diagnosing and Mitigating Attention Distraction in Retrieval-Augmented LVLMs
Beidi Zhao, Wenlong Deng, Xinting Liao, Yushu Li, Nazim Shaikh, Yao Nie, Xiaoxiao Li
While Retrieval-Augmented Generation (RAG) is one of the dominant paradigms for enhancing Large Vision-Language Models (LVLMs) on knowledge-based VQA tasks, recent work attributes RAG failures to insufficient attention towards the retrieved context, proposing to reduce the attention allocated to image tokens. In this work, we identify a distinct failure mode that previous study overlooked: Attention Distraction (AD). When the retrieved context is sufficient (highly relevant or including the correct answer), the retrieved text suppresses the visual attention globally, and the attention on image tokens shifts away from question-relevant regions. This leads to failures on questions the model could originally answer correctly without the retrieved text. To mitigate this issue, we propose MAD-RAG, a training-free intervention that decouples visual grounding from context integration through a dual-question formulation, combined with attention mixing to preserve image-conditioned evidence. Extensive experiments on OK-VQA, E-VQA, and InfoSeek demonstrate that MAD-RAG consistently outperforms existing baselines across different model families, yielding absolute gains of up to 4.76%, 9.20%, and 6.18% over the vanilla RAG baseline. Notably, MAD-RAG rectifies up to 74.68% of failure cases with negligible computational overhead.

RSPO: Regularized Self-Play Alignment of Large Language Models
Xiaohang Tang, Sangwoong Yoon, Seongho Son, Huizhuo Yuan, Quanquan Gu, Ilija Bogunovic
Self-play-based policy optimization has emerged as an effective approach for fine-tuning large language models (LLMs), formulating preference optimization as a two-player game. However, the regularization with respect to the reference policy, which is crucial for mitigating over-optimization, has been insufficiently investigated in self-play alignment. To study the impact of different regularization strategies, we propose \textbf{Regularized Self-Play Policy Optimization (RSPO)}, a novel framework that unifies prior methods and enables simple plug-and-play regularizers, meanwhile preserving convergence to Nash equilibrium of the corresponding regularized game.
We empirically show that RSPO with appropriate regularizers can substantially improve the length-controlled win rate (LCWR) on AlpacaEval-2 across a range of base models, while also achieving consistently superior performance on Arena-Hard, MT-Bench, ArmoRM, and response diversity. In particular, RSPO improves unregularized self-play baseline (SPPO) on AlpacaEval-2 LCWR from 28.5% to $ 35.4\%$

with base model Mistral-7B, from 38.77% to 43.66% with LLaMA-8B, and from 50.54% to 51.83% with Gemma-2B.
Combining simplicity, convergence guarantees, and significant empirical gains, RSPO offers a strong foundation for exploring regularized self-play in alignment.
****
Do Language Models Track Entities Across State Changes?
Zilu Tang, Qiao Zhao, Gabriel Franco, Derry Tanti Wijaya, Aaron Mueller, Sebastian Schuster, Najoung Kim
Entity tracking (ET), the ability to keep track of states, is a fundamental skill that underlies complex reasoning. An increasing amount of work investigates how transformer language models (LMs) solve entity binding *without* state changes. However, there is limited understanding of how non-toy LMs address ET problems of realistic difficulties expressed in natural language. To this end, we investigate the mechanisms underlying ET in more complex scenarios featuring multiple state-changing operations. We find that LMs do not incrementally track world states across tokens or query-relevant states across layers, but simply aggregate relevant information in parallel at the last token when the query becomes evident. We further investigate mechanisms of individual operations (`PUT`, `REMOVE`, `MOVE`) to characterize this non-incremental ET mechanism. Surprisingly, LMs implement the `REMOVE` operation with a fragile global suppression tag; this global removal mechanism predicts various failure modes that we confirm behaviorally. We provide a mechanistic solution of nullifying this tag to partially address this issue.
Overall, our findings reveal that LMs solve a fundamentally sequential task using a non-sequential strategy. More broadly, our work illustrates how behavioral and mechanistic analyses can fruitfully interact. Behavioral results inform mechanistic hypotheses, and insights from mechanistic analyses help build stronger behavioral evaluations by predicting failure modes missing from existing evaluations.

MaMi-HOI: Harmonizing Global Kinematics and Local Geometry for Human-Object Interaction Generation
Hao Wang, Shiqi Wang, Qi Liu
Generating realistic 3D Human-Object Interactions (HOI) is a fundamental task for applications ranging from embodied AI to virtual content creation, which requires harmonizing high-level semantic intent with strict low-level physical constraints. Existing methods excel at semantic alignment, however, they struggle to maintain precise object contact. We reveal a key finding termed $\textit{Geometric Forgetting}$: as diffusion model depth increases, semantic feature tend to overshadow object geometry feature, causing the model to lose its perception to object geometry. To address this, we propose MaMi-HOI, a hierarchical framework reconciling Macro-level kinematic fluidity with Micro-level spatial precision. First, to counteract geometric forgetting, we introduce the Geometry-Aware Proximity Adapter (GAPA), which explicitly re-injects dense object details to perform residual snapping corrections for precise contact. Nevertheless, such aggressive local enforcement can disrupt global dynamics, leading to robotic stiffness. In response, we introduce the Kinematic Harmony Adapter (KHA), which proactively aligns whole-body posture with spatial objectives, ensuring the skeleton actively accommodates constraints without compromising naturalness. Extensive experiments validate that MaMi-HOI simultaneously achieves natural motion and precise contact. Crucially, it extends generation capabilities to long-term tasks with complex trajectories, effectively bridging the gap between global navigation and high-fidelity manipulation in 3D scenes.

Learning Task-Sufficient World Models by Synergizing Agentic Exploration and Structured Modeling
Fan Feng, Yujia Zheng, Minghao Fu, Yongqiang Chen, Guangyi Chen, Kevin Patrick Murphy, Biwei Huang, Kun Zhang
Learning and planning in imagination using world models provides an effective paradigm for training agents for decision-making. However, existing approaches oft

en rely on high-dimensional latent spaces or generic visual embeddings that reta in many factors irrelevant to control, limiting efficiency and generalization ac ross tasks. To this end, we study how agents can learn world models with repres entations that are task-specific, minimal, and sufficient for decision making. W e achieve this via a closed-loop synergy between the agent and the world model, in which structured world-model learning distills task-sufficient representation s from informative interaction data. On the agent side, agents perform active pr obing of the environment to collect informative trajectories that expose task-re levant latent factors, guided by an adaptive curriculum. On the world-model side , we learn structured representations over observations to distill compact, task -sufficient latent states from the collected interaction data. This synergy enab les the recovery of task-sufficient latent representations that capture all cont rol-relevant factors empirically. Leveraging these representations, the resultin g policies achieve improved sample efficiency generalization, including generali zation across skills, object–skill compositions, and previously unseen tasks on standard continuous control and robotic manipulation benchmarks.

Towards Seed-Robust Safety Alignment in Text-to-Image Models
Zhenyu Wu, Yao Huang, Shouwei Ruan, Xingxing Wei
Text-to-image diffusion models have achieved remarkable success in generating hi gh-quality images, yet existing safety mechanisms exhibit critical cross-seed in stability where defense performance varies significantly under different random seed conditions. This instability stems from the fact that a single malicious pr ompt generates diverse harmful variants across different noise initializations, forming complex distributional clusters that current methods cannot adequately a ddress. We investigate extending Noise Contrastive Alignment (NCA) to diffusion models due to its native capability of handling multiple negative samples throug h probabilistic weighting, but our theoretical analysis reveals two fundamental flaws in direct extension: gradient reversal caused by positive regularization t erms that paradoxically penalize safe content generation, and uniform suppressio n of harmful samples that ignores severity variations. To tackle these issues, w e propose Noise Contrastive Diffusion (NCD), which incorporates targeted algorit hmic modifications including elimination of problematic regularization and intro duction of pairwise regularization mechanisms that establish individualized pref erence relationships between safe and harmful variants. Extensive experiments fu rther demonstrate that NCD achieves superior cross-seed stability, reducing atta ck success rates (ASRs) from 11.1% to 6.2% compared to SOTA methods at the seed level while maintaining exceptional generation quality, exhibiting robust resist ance against sophisticated jailbreak prompts and strong generalizability across different T2I architectures. WARNING: This paper may contain examples of harmful texts and images.

Spatial Conformal Inference through Localized Quantile Regression
Hanyang Jiang, Yao Xie
Reliable uncertainty quantification at unobserved spatial locations is a key cha llenge in spatial statistics, particularly for complex and heterogeneous dataset s. While traditional methods such as Kriging rely on strong distributional assum ptions, conformal prediction (CP) offers a distribution-free alternative. Howeve r, although non-i.i.d. CP theory is well established for time-series data, a sig nificant gap remains for spatial data, where the lack of a natural ordering and discrete index complicates theoretical guarantees. Existing CP theory for spatia l data often relies on exchangeability. We propose Localized Spatial Conformal P rediction (LSCP), a model-agnostic framework that bridges this gap by coupling l ocal quantile regression with conformal calibration. LSCP conditions on spatial neighborhoods to capture local heterogeneity. We show that LSCP retains finite-s ample marginal coverage under spatial exchangeability and attains asymptotic con ditional coverage under stationarity and spatial mixing. Across synthetic and re al datasets, LSCP consistently achieves near-nominal coverage with tighter and m ore stable prediction intervals than existing methods that fail to capture these spatial dependencies.

Logarithmic Switching Regret for Online Convex Optimization
Wenhao Yang, Yibo Wang, Yuanyu Wan, Lijun Zhang
Online convex optimization in non-stationary environments has garnered considera ble attention in the literature. Recently, Pasteris et al. (2024) investigate on line convex optimization with the optimal switching regret, defined as the sum o f the static regret over each segment, where the segmentation is an arbitrary pa rtition of the entire time horizon. For general convex functions, their work has established an optimal switching regret bound. However, it remains open whether similar bounds are attainable for other types of convex functions, such as expo nentially concave or strongly convex functions. In this paper, we affirmatively answer this question by proposing a novel meta-algorithm, termed IRESET, which i s used to aggregate the decisions from a group of experts. The essence of our me thod lies in running multiple experts over a set of intervals, and then employin g a meta-algorithm equipped with second-order bounds to sequentially combine the ir decisions. We leverage the segment tree structure to analyze the switching re gret over the entire time horizon, and offer new insights into utilizing recurs ive equations over the segment tree. By choosing appropriate expert-algorithms f or IRESET, our methods achieve logarithmic switching regret bounds for exponenti ally concave or strongly convex functions, respectively.

Evaluating Contextual Illegality: AI Compliance in Corporate Law Scenarios
Hilal Aka, Joe Kwon, Noam Kolt
While AI models often refuse explicitly unlawful requests, in real-world scenari os illegality often depends on context. We evaluate frontier models on contextua l illegality across four corporate law scenarios in which routine actions—editin g documents, trading stock, requesting payment, approving communications—become unlawful due to circumstances such as pending investigations or bankruptcy filin gs. We study both chat and agentic settings and compare results to a human basel ine. The best-performing models consistently followed lawful requests and refuse d unlawful requests, though performance varied substantially between different s cenarios and models. We also identify distinct failure modes, such as excessive refusal of lawful requests, and find higher performance in reasoning models and agentic environments. By studying contextual illegality in these controlled envi ronments, we develop a methodology that can be extended to evaluate the legal co mpliance of AI models in additional scenarios and domains.

HIAL: Towards Semantics-Aware Hypergraph Active Learning via Dual-Perspective In formation Maximization
Yanheng Hou, Xunkai Li, Yanzhe Wen, Zhenjun Li, Bing Zhou, Rong-Hua Li, Guoren W ang
Hypergraph Neural Networks (HNNs) model high-order interactions effectively but rely on costly node annotations, motivating Hypergraph Active Learning (HAL). Ho wever, many HAL pipelines adapt graph-based querying through clique expansion, w hich introduces *structural bias* and can cause *ranking collapse*, making utili ties overly determined by hyperedge cardinalities rather than informative high-o rder context. We propose **HIAL** (**H**ypergraph **I**nfluence-based **A**ctive **L**earning), a training-free framework that formulates hypergraph active lear ning as influence maximization over a high-order context-based weighted pairwise projection of the hypergraph. HIAL employs a High-Order Interaction-aware propa gation mechanism that modulates pairwise influence weights using hyperedge cardi nality and feature consistency, yielding a scalable linear diffusion process tai lored to homophilic hypergraphs. We further combine feature-space coverage and s tructural reachability into a monotone submodular selection objective, enabling an efficient lazy greedy solver. Experiments on eight benchmarks demonstrate tha t HIAL consistently outperforms strong baselines across diverse homophilic hyper graph domains.

High-Dimensional Sensitivity Analysis for Genomic Studies: An Adversarial Framew ork for Learning Worst-Case Latent Confounders

Yifan Lin, Kevin Z. Lin
High-dimensional genomics studies are frequently confounded by unmeasured biological processes that obscure disease-specific signals. While existing workflows can estimate these latent confounders, they fail to quantify how robust a discovery is to varying levels of hypothetical confounding. We introduce sensGAN, a deep-learning adversarial framework that systematically explores the confounding spectrum by learning "worst-case" latent variables that nullify the most gene associations under novel predictive-gain constraints. By identifying the minimum confounding strength required to explain away an observed effect, our method shifts the paradigm toward a formal, quantitative sensitivity analysis. In diverse simulations, sensGAN accurately recovers latent structures and outperforms existing methods in identifying confounder-sensitive genes. Applied to human Alzheimer's disease microglia, our framework prioritizes robust disease pathways while successfully isolating signals driven by unmeasured co-occurring neurodegenerative pathologies.
****
Tri-Scale Neural ODEs for Continuous Multi-Omics Disease Modeling
Shohaib Shaffiey, Massimiliano Pierobon
The fields of AI-based disease fingerprinting, drug discovery and repurposing are currently among the emerging frontiers of machine learning applied to medicine. One major challenge is to obtain robust $\textit{in-silico}$ modeling of disease progression while accounting for the vastly different time scales of biochemical interactions, from gene expression to protein abundance and metabolic flux. Discrete sequence models inadequately represent such multi-scale interactions, and standard Neural Ordinary Differential Equations (NODEs) often fail to train stably under stiffness (different time scales). To address this, a Tri-Scale Stiff NODE, defined by hierarchically coupled latent differential equations that model the causal relationships from genes to proteins and metabolites, is introduced and optimized in this paper in terms of reconstruction error and information-theoretic mutual information. This enables continuous-time modeling of cellular responses to identify not only the disease dynamics, but also drug perturbations that act within narrow time windows, often invisible to discrete-time approaches. Lyapunov analysis provides a theoretical guarantee that the modeled trajectories remain stable and well-behaved even under extreme stiffness. The methodology is validated using the STATegra B-cell and Traxler macrophage datasets, with the former utilized for a proof-of-concept drug repurposing pipeline.
****
Beyond Test-Time Memory: State-Space Optimal Control for LLM Reasoning
Peihao Wang, Shan Yang, Xijun Wang, Tesi Xiao, Xin Liu, Changlong Yu, Yu Lou, Pan Li, Zhangyang Wang, Ming Lin, Rene Vidal
Associative memory has long underpinned the design of sequential models. Beyond recall, humans reason by *projecting future states and selecting goal-directed actions*, a capability that modern language models increasingly require but do not natively encode. While prior work uses reinforcement learning or test-time training, planning remains external to the model architecture. We formulate reasoning as *optimal control* and introduce the *Test-Time Control (TTC)* layer, which performs finite-horizon *LQR* planning over latent states at inference time, represents a *value function* within neural architectures, and leverages it as the nested objective to enable *planning before prediction*. To ensure scalability, we derive a hardware-efficient LQR solver based on a symplectic formulation and implement it as a fused CUDA kernel, enabling parallel execution with minimal overhead. Integrated as an adapter into pretrained LLMs, TTC layers improve mathematical reasoning performance by up to +27.8% on MATH-500 and 2-3$\times$ Pass@8 improvements on AMC and AIME, demonstrating that embedding optimal control as an architectural component provides an effective and scalable mechanism for reasoning beyond test-time training.
****
Path-Coupled Bellman Flows for Distributional Reinforcement Learning
Boyang Xu, Qing Zou, Siqin Yang, Hao Yan
Distributional reinforcement learning (DRL) models the full return distribution,

but typically relies on finite-dimensional categorical or quantile approximations, often involving projection or quantile-regression approximations to the Bellman target, together with independently sampled bootstrap targets that obscure transport structure and add variance. We present Path-Coupled Bellman Flows (PCBF), a continuous-time DRL method that encodes Bellman endpoint consistency and pathwise Bellman-coupled geometry within generative flow trajectories. PCBF represents return distributions via flow matching and couples the paths of consecutive states through shared base noise, yielding a geometric Bellman flow relation between velocity fields. This structure enables a λ-parameterized control-variate target that reduces training variance while preserving the source and Bellman endpoint geometry. Experiments on analytically tractable MRPs, OGBench, and D4RL show improved distributional fidelity, training stability, and competitive offline RL performance.

Symmetries in PAC-Bayesian Learning

Armin Beck, Peter Ochs

Symmetries are known to improve the empirical performance of machine learning models, yet theoretical guarantees explaining these gains remain limited. Prior work has focused mainly on compact group symmetries and often assumes that the data distribution itself is invariant, an assumption rarely satisfied in real-world applications. In this work, we extend generalization guarantees to the broader setting of non-compact symmetries, such as translations and to non-invariant data distributions. Building on the PAC-Bayes framework, we adapt and tighten existing bounds, demonstrating the approach on McAllester's PAC-Bayes bound while showing that it applies to a wide range of PAC-Bayes bounds. We validate our theory with experiments on several datasets with non-uniform and non-compact transformations, where the derived guarantees not only hold but also improve upon prior results. These findings provide theoretical evidence that, for symmetric data, symmetric models are preferable beyond the narrow setting of compact groups and invariant distributions, opening the way to a more general understanding of symmetries in machine learning.

PGT: Procedurally Generated Tasks for improving visual grounding in MLLMs

Rim Assouel, Amir Bar, Michal Drozdzal, Adriana Romero-Soriano

Despite remarkable progress in Multimodal Large Language Models (MLLMs), these models still struggle with fine-grained understanding tasks. In this work, we propose **Procedurally Generated Tasks (PGT)** a simple data-driven framework that serves a dual purpose: inducing fine-grained visual understanding and acting as a low-cost diagnostic tool to identify the source of perception failures. By overlaying unambiguous geometric primitives on images, PGT generate additional dense supervision that disentangles visual grounding capability from semantic priors. Extensive experiments on relational, quantitative, and 3D/depth understanding benchmarks show that PGT yields remarkable gains across diverse architectures. Instruction tuning MLLMs on LLaVA-v1.5-Instruct augmented with PGT data results in improvements of up to +20\% on the What’sUp benchmark and +13.3\% on CV-Bench-2D, while maintaining general perception capabilities. Moreover, finetuning state-of-the-art MLLMs on PGT data leads to boosts of up to +5.5\% on What’sUp and +8.3\% on CV-Bench-2D. These findings demonstrate that PGT effectively address the bottleneck of fine-grained perception, revealing that many spatial reasoning deficits stem from inadequate supervision signals rather than inherent architectural or resolution limitations.

Personalized Additive Modeling for Multi-level Federated Learning

Shutong Chen, Guodong Long, Tianyi Zhou, Jie Ma, Jing Jiang, Chengqi Zhang

Contemporary AI faces the challenge of balancing generality with user-specific personalization. In federated learning (FL), this challenge is amplified by highly heterogeneous client data with complex non-IID patterns beyond standard modeling assumptions. Many existing FL methods are designed for relatively restricted heterogeneity settings (e.g., a fixed number of clusters or a fixed form of personalization), limiting their robustness under complex structures. In this work,

we study FL from a \emph{multi-level non-IID} perspective, where client similarity is approximated by multiple granularities of shared knowledge: global, subgroup, and client-specific components. This view captures coarse-to-fine relationships while requiring less prior knowledge of task boundaries. Building on this insight, we propose \emph{Federated Multi-level Additive Modeling} (FeMAM), which learns multiple levels of shareable models and constructs personalized predictors via additive composition across levels. To move beyond a fixed structure, FeMAM allows models to grow and be pruned dynamically during training, adapting to diverse federated scenarios. Despite employing multiple models, FeMAM remains cost-friendly by activating only a small subset (one level) of models for training at a time. Extensive experiments show that FeMAM effectively approximates complex non-IID structures and consistently outperforms representative clustered and personalized FL baselines.

CAMP: Coherent Alignment of Multimodal Prototypes for Explainable Complementary Learning
Alvaro Lopez Pellicer, Eoin M. Kenny, Simran Lamba, Shubham Sharma, Plamen P Angelov, Saumitra Mishra
Most multimodal learning assumes redundant views (such as image–caption pairs), yet many applications require combining complementary modalities that provide distinct evidence (such as an X-ray and medical history). We term this setting *Complementary Multimodal Classification* (CMC). In CMC, existing explainable-by-design methods often force an accuracy–interpretability trade-off because single shared similarity metrics fail under asymmetric, class-conditional evidence. To address this, we propose Coherent Alignment of Multimodal Prototypes (CAMP). CAMP enforces coherent multimodal reasoning by aligning class-wise evidence via optimal transport and imposing geometric constraints to counter modality dominance and representation collapse. We provide theoretical guarantees showing that these mechanisms eliminate such degeneracies without restricting expressivity. Empirically, across 16 public CMC datasets, CAMP matches or exceeds large ($>$100M parameter) AutoML baselines with fewer than 1M trainable parameters, and when fine-tuned end-to-end it achieves state-of-the-art performance. To the best of our knowledge, this work is the first modality-agnostic prototype-learning framework designed for complementary multimodal tasks.
****

Training–Inference Consistent Segmented Execution for Long-Context LLMs
Xianpeng Shang, Jiang Li, Zehua Duo, Qianyi Cai, Xiangdong Su
Transformer-based large language models face severe scalability challenges in long-context generation due to the computational and memory costs of full-context attention.
Under practical computation and memory constraints, many inference-efficient long-context methods improve efficiency by adopting bounded-context or segment-level execution only during inference, while continuing to train models under full-context attention, resulting in a mismatch between training and inference execution and state-transition semantics.
Based on this insight, we propose a training-consistent segment-level generation framework, in which training and inference follow the same segment-level forward execution semantics.
During training, consistency with inference is enforced by restricting gradient propagation to KV states carried over from the immediately preceding segment, while permitting head-specific access to past KV states during the forward pass without involving them in gradient propagation.
Across long-context benchmarks, our approach achieves performance comparable to full-context attention, while achieving competitive latency--memory trade-offs against strong inference-efficient baselines, and substantially improving scalability at very long context lengths (e.g., approximately $6\times$ lower peak prefill memory at 128K compared to full-context attention with FlashAttention).

ShapCCS: Shapley-Driven Client Coreset Selection in Federated Learning
Shuo Ji, Jie Hu, Zhouqiao He, Zijie Zhao, Tianrui Li, Jie Xu

Computation overhead has emerged as a critical bottleneck in Federated Learning (FL). Coreset selection tackles this challenge by constructing an informative subset to represent the full dataset. However, existing approaches optimize coreset construction solely at the data level and enforce a uniform retention ratio across all clients, ignoring client heterogeneity and introducing detrimental fragmented clients. In this paper, we first introduce a *gradient projection Shapley value* (GPSV) to evaluate client contributions. GPSV captures both the directional and magnitude information of client updates and enables exact Shapley value calculation with $\mathcal{O}(1)$ per-coalition evaluation. Building on GPSV, we then propose ShapCCS, the first client-level coreset selection strategy for FL. ShapCCS prioritizes clients with high GPSV scores while excluding fragmented clients with negligible or even negative GPSV. As a client-level coreset selection strategy, ShapCCS can be integrated with a data-level selection approach, and additionally reduces communication costs, an advantage unattainable by data-level methods alone. Extensive experiments demonstrate the superiority of ShapCCS on model performance and robustness to noise. The code is available at https://anonymous.4open.science/r/ShapCCS-5CBB.

Multimodal Latent Language Modeling with Next-Token Diffusion

Yutao Sun, Hangbo Bao, Wenhui Wang, Zhiliang Peng, Li Dong, Shaohan Huang, Yaoyao Chang, Jianyong Wang, Furu Wei

Multimodal generative models require a unified approach to handle both discrete data (e.g., text and code) and continuous data (e.g., image, audio, video). In this work, we propose Latent Language Modeling (LatentLM), which seamlessly integrates continuous and discrete data using causal Transformers. Specifically, we employ a variational autoencoder (VAE) to represent continuous data as latent vectors and introduce next-token diffusion for autoregressive generation of these vectors. Additionally, we develop σ-VAE to address the challenges of variance collapse, which is crucial for autoregressive modeling. Extensive experiments demonstrate the effectiveness of LatentLM across various modalities. In image generation, LatentLM sis competitive with or outperforms DiT-style baselines under matched unified settings. When integrated into multimodal large language models, LatentLM provides a general-purpose interface that unifies multimodal generation and understanding. Experimental results show that LatentLM achieves favorable performance compared to Transfusion and vector quantized models in the setting of scaling up training tokens. In text-to-speech synthesis, LatentLM outperforms the state-of-the-art VALL-E 2 model in speaker similarity and robustness, while requiring 10 fewer decoding steps. The results establish LatentLM as a highly effective and scalable approach to advance large multimodal models.

On Training Large Language Models for Long-Horizon Tasks: An Empirical Study of Horizon Length

Sunghwan Kim, Junhee Cho, Beong-woo Kwak, Taeyoon Kwon, Liang Wang, Nan Yang, Xingxing Zhang, Furu Wei, Jinyoung Yeo

Large language models (LLMs) have shown promise as interactive agents that solve tasks through extended sequences of environment interactions. While prior work has primarily focused on system-level optimizations or algorithmic improvements, the role of task horizon length in shaping training dynamics remains poorly understood. In this work, we present a systematic empirical study that examines horizon length through controlled task constructions. Specifically, we construct controlled tasks in which agents face identical decision rules and reasoning structures, but differ only in the length of action sequences required for successful completion. Our results reveal that increasing horizon length alone constitutes a training bottleneck, inducing severe training instability driven by exploration difficulties and credit assignment challenges. We demonstrate that horizon reduction is a key principle to address this limitation, stabilizing training and achieving better performance in long-horizon tasks. Moreover, we find that horizon reduction is related to stronger generalization across horizon lengths: models trained under reduced horizons generalize more effectively to longer-horizon variants at inference time, a phenomenon we refer to as horizon generalization.

On the Interaction of Batch Noise, Adaptivity, and Compression, under (L_0,L_1)-Smoothness: An SDE Approach
Enea Monzio Compagnoni, Rustem Islamov, Frank Norbert Proske, Aurelien Lucchi, Antonio Orvieto, Eduard Gorbunov
Distributed stochastic optimization intertwines (i) stochastic gradient noise, (ii) communication compression, and (iii) adaptive/normalized updates. While each factor has been studied in isolation, their joint effect under realistic assumptions remains poorly understood. In this work, we develop a unified theoretical framework for Distributed Compressed SGD (DCSGD) and its sign variant Distributed SignSGD (DSignSGD) under the recently introduced (L_0, L_1)-smoothness condition. From a conceptual perspective, we show that the first- and second-order modified equations from the literature do not accurately model the discrete-time step-size/stability restrictions, especially under (L_0,L_1)-smoothness. From a technical perspective, we propose new first-order SDEs by carefully incorporating curvature-dependent terms into their drift: This helps capture the fine-grained relationship between learning rate restrictions, gradient noise, compression, and the geometry of the loss landscape. Importantly, we do so under general gradient noise assumptions, including heavy-tailed and affine-variance regimes, which extend beyond the classical bounded-variance setting. Our results suggest that normalizing the updates of DCSGD emerges as a natural condition for stability, with the degree of normalization precisely determined by the gradient noise structure, the landscape’s regularity, and the compression rate. In contrast, DSignSGD converges even under heavy-tailed noise with standard learning rate schedules. Together, these findings offer both new theoretical insights and perspectives, and practical guidance.
****
Who can we trust? LLM-as-a-jury for Comparative Assessment
Mengjie Qian, Guangzhi Sun, Mark Gales, Kate Knill
Large language models (LLMs) are increasingly applied as automatic evaluators for natural language generation assessment often using pairwise comparative judgements. Existing approaches typically rely on single judges or aggregate multiple judges assuming equal reliability. In practice, LLM judges vary substantially in performance across tasks and aspects, and their judgment probabilities may be biased and inconsistent. Furthermore, human-labelled supervision for judge calibration may be unavailable. We first empirically demonstrate that inconsistencies in LLM comparison probabilities exist and show that it limits the effectiveness of direct probability-based ranking. To address this, we study the \emph{LLM-as-a-jury} setting and propose BT-σ, a judge-aware extension of the Bradley-Terry model that introduces a discriminator parameter for each judge to jointly infer item rankings and judge reliability from pairwise comparisons alone. Experiments on benchmark NLG evaluation datasets show that \textit{BT-σ} consistently outperforms averaging-based aggregation methods, and that the learned discriminators strongly correlate with independent measures of the cycle consistency of LLM judgments. Further analysis reveals that \textit{BT-σ} can be interpreted as an unsupervised calibration mechanism that improves aggregation by modelling judge reliability.
****
SLAT: Segment-Level Adaptive Trimming for Efficient CoT Reasoning
Jian Yao, Xiongcai Luo, Ran Cheng, KC Tan
Recent advances in Large Reasoning Models have significantly improved chain-of-thought (CoT) capabilities via reinforcement learning (RL).
However, generated reasoning chains frequently suffer from structural redundancy (i.e., \emph{overthinking}), incurring high computational overhead without improving answer correctness.
Existing mitigation strategies typically rely on token-uniform length penalties, which provide coarse, segment-agnostic pressure toward shorter outputs and can inadvertently suppress useful reasoning alongside redundancy.
To address this, we demonstrate that inefficiency concentrates in high-probability segments with low marginal utility.

We derive a theoretical characterization of segment suboptimality under the corr
ectness-length trade-off objective and propose \textsc{SLAT} (Segment-Level Adap
tive Trimming), an RL framework that selectively suppresses redundant segments b
ased on this criterion.
Empirical results on standard benchmarks indicate that \textsc{SLAT} establishes
 a superior accuracy-efficiency Pareto frontier, reducing reasoning length by 50
\% relative to uncompressed baselines while maintaining competitive accuracy.
Overall, our results suggest that theoretically grounded, segment-aware trimming
 is a promising direction for efficient CoT reasoning in large language models.

Learning Normalized Energy Models for Linear Inverse Problems
Nicolas Zilberstein, Santiago Segarra, Eero P Simoncelli, Florentin Guth
Generative diffusion models can provide powerful prior probability models for in
verse problems in imaging, but existing implementations suffer from two key limi
tations: (i) the prior density is represented implicitly, and (ii) they rely
 on likelihood approximations that introduce sampling biases. We address these c
hallenges by introducing a new energy-based model trained for denoising with a c
ovariance-based regularization term that enforces consistency across different m
easurement conditions. The trained model can compute normalized posterior densit
ies for diverse linear inverse problems, without additional retraining or fine t
uning. In addition to preserving the sampling capabilities of diffusion models,
this enables previously unavailable capabilities: energy-guided adaptive samplin
g that adjusts schedules on-the-fly, unbiased Metropolis-Hastings correction ste
ps, and blind estimation of the degradation operator via Bayes rule. We validate
 the method on multiple datasets (ImageNet, CelebA, AFHQ) and tasks (inpainting,
 deblurring), demonstrating competitive or superior performance to established b
aselines.

Benchmarking the Scientific Mind: A Pathology-Derived Biomedical VQA Benchmark f
or Complex Scientific Reasoning
Ziyu Zhao, Yiyang Liu, Yajiao Wang, Xiaotao Wang, Yang Li, Yuyang Peng, Jiaheng
Zhou, Jinqiao Wang, Yingying Chen, Ge Yang, Haixin Wang
Despite progress of Multimodal Large Language Models (MLLMs) in biomedical visua
l question answering (VQA), existing benchmarks provide limited assessment of th
eir scientific reasoning capabilities. Most datasets adopt single-image question
 construction and outcome-oriented evaluation, where correctness is judged by an
swer plausibility rather than alignment with experimental evidence. Such formula
tions fail to capture the evidence-constrained, multi-step nature of biomedical
reasoning, and obscure whether models can derive conclusions through causal inte
rpretation of experimental observations.

To address these critical gaps in reasoning evaluation, we propose a principled
benchmark construction framework that reconstructs scientific reasoning paths di
rectly from biomedical literature. By jointly modeling clusters of experimentall
y related images together with their captions and context, the framework generat
es tightly coupled question–reasoning–answer triples that require multi-image in
tegration and explicit evidence-driven inference. Based on this framework, we in
troduce SORBE (Scientific Observation & Reasoning for Biomedical Evaluation), a
large-scale multi-image pathology-derived biomedical VQA benchmark designed to e
valuate evidence alignment and multi-step experimental reasoning. Under a proces
s-oriented evaluation metric, state-of-the-art biomedical-specialized MLLMs exhi
bit substantial performance degradation, revealing systematic limitations in evi
dence grounding and causal reasoning that are not reflected by existing benchmar
ks. Data and code are available at: https://github.com/UniverseOfUniverse/SORBE.
git.

Simple yet Effective: Low-Rank Spatial Attention for Neural Operators
Zherui Yang, Haiyang Xin, Tao Du, Ligang Liu
Neural operators have emerged as data-driven surrogates for solving partial diff
erential equations (PDEs), and their success hinges on efficiently modeling the

long-range, global coupling among spatial points induced by the underlying physi
cs.
In many PDE regimes, the induced global interaction kernels are empirically comp
ressible, exhibiting rapid spectral decay that admits low-rank approximations.
We leverage this observation to unify representative global mixing modules in ne
ural operators under a shared low-rank template: compressing high-dimensional po
intwise features into a compact latent space, processing global interactions wit
hin it, and reconstructing the global context back to spatial points.
Guided by this view, we introduce Low-Rank Spatial Attention (LRSA) as a clean a
nd direct instantiation of this template.
Crucially, unlike prior approaches that often rely on non-standard aggregation o
r normalization modules, LRSA is built purely from standard Transformer primitiv
es, i.e., attention, normalization, and feed-forward networks, yielding a concis
e block that is straightforward to implement and directly compatible with hardwa
re-optimized kernels.
In our experiments, such a simple construction is sufficient to achieve high acc
uracy, yielding an average error reduction of over 17\% relative to second-best
methods, while remaining stable and efficient in mixed-precision training.

Efficient Online Variational Estimation via Monte Carlo Sampling
Mathis Chagneux, Mathias Müller, Pierre Gloaguen, Sylvain Le Corff, Jimmy Olsson
This article addresses online variational estimation in parametric state-space m
odels.
We propose a new procedure for efficiently computing the evidence lower bound an
d its gradient in a streaming-data setting, where observations arrive sequential
ly.
The algorithm allows for the simultaneous training of the model parameters and t
he distribution of the latent states given the observations.
It is based on i.i.d. Monte Carlo sampling, coupled with a well-chosen deep arch
itecture, enabling both computational efficiency and flexibility. The performanc
e of the method is illustrated on both synthetic data and real-world air-quality
 data.
The proposed approach is theoretically motivated by the existence of an asymptot
ic contrast function and the ergodicity of the underlying Markov chain, and appl
ies more generally to the computation of additive expectations under posterior d
istributions in state-space models.

Learning Gaussian Mixture-distributed Prototypes for 3D Scene Graph Generation f
rom RGB-D Sequences
Rongxing Ding, Hongyu Qu, Xinguang Xiang, Pengpeng Li, Xiangbo Shu
3D Scene Graph Generation (3DSGG) aims to create a structured representation of
3D environment by identifying objects as nodes and
their relations as edges. Existing 3DSGG methods based on RGB-D sequences typic
ally put much focus on the adaption of neural networks to robust node and edge f
eature extraction in complex 3D scenes, yet ignoring the inherent intra-class di
versity within each class and inter-class similarity between different categorie
s associated with nodes and edges. In this work, we develop GMPSSG, a novel Gaus
sian Mixture-distributed Prototype mining framework for 3DSGG. Specifically, we
model different categories with independent Gaussian Mixture-distributed Prototy
pe to effectively mitigate inter-class similarity, while employing multiple Gaus
sian components within each prototype to capture intra-class diversity. Moreover
, Prototype-anchored Representation Learning is introduced to construct a well-s
tructured and mutually independent category space; Topology-aware Prototype Inte
raction is devised to capture implicit co-occurrence priors within the scene, an
d leverage them to calibrate prototype distributions, thereby ensuring the plaus
ibility of node-edge matching. Experiments on 3DSSG dataset demonstrate GMPSSG o
utperforms various top-leading methods. Our code is available at GMPSSG.

From Inpainting to Editing: Unlocking Robust Mask-Free Visual Dubbing via Genera
tive Bootstrapping

Xu He, Haoxian Zhang, Hejia Chen, Changyuan Zheng, Liyang Chen, Songlin Tang, Jiehui Huang, Xiaoqiang Liu, Pengfei Wan, Zhiyong Wu

Audio-driven visual dubbing aims to synchronize a video's lip movements with new speech but is fundamentally challenged by the lack of ideal training data: paired videos differing only in lip motion.

Existing methods circumvent this via mask-based inpainting. However, masking inevitably destroys spatiotemporal context, leading to identity drift and poor robustness (e.g., to occlusions), while also inducing lip-shape leakage that degrades lip sync.

To bridge this gap, we propose X-Dub, a novel two-stage generative bootstrapping framework leveraging powerful Diffusion Transformers to unlock mask-free dubbing.

Our core insight is to repurpose a mask-based inpainting model exclusively as a dedicated data generator to synthesize scalable, high-fidelity pseudo-paired data, which is subsequently utilized to train and bootstrap a robust, mask-free editing model as the final video dubber.

The final dubber is liberated from masking artifacts and leverages the complete video input for high-fidelity inference.

We further introduce timestep-adaptive multi-phase learning to disentangle conflicting objectives (structure, lip motion, and texture) across diffusion phases, facilitating stable convergence and advanced editing quality.

Additionally, we present X-DubBench, a benchmark for diverse scenarios.

Extensive experiments demonstrate that our method achieves state-of-the-art performance with superior lip sync, visual quality, and robustness.

Code, demos, and additional resources are available at https://github.com/KlingAIResearch/X-Dub.

CSG: Cognitive Structure Generation for Intelligent Education

Hengnian Gu, Zhifu Chen, Yuxin Chen, Jin Peng Zhou, Dongdai Zhou

Cognitive structure (CS), a student's construction of concepts and inter-concept relations, has long been recognized as a foundational notion in psychology and intelligent education, yet remains largely unassessable in practice. Existing approaches such as knowledge tracing (KT) and cognitive diagnosis (CD) simplify and indirectly approximate CS, but they intertwine representation learning with prediction objectives, limiting generalization, interpretability, and reuse across tasks. To address this gap, we propose Cognitive Structure Generation (CSG), a task-agnostic framework that explicitly models CS through generative modeling. Based on educational theories, CSG first pretrains a Cognitive Structure Diffusion Probabilistic Model (CSDPM) and then applies reinforcement learning with SOLO-based hierarchical rewards to capture plausible patterns of cognitive development. By decoupling cognitive structure representation from downstream prediction, CSG produces interpretable and transferable cognitive structures that can be seamlessly integrated into diverse student modeling tasks. Experiments on five real-world datasets show that CSG yields more comprehensive representations, substantially improving performance while offering enhanced interpretability and modularity.

****

Optimal Transport–Guided Stochastic Control for Graph Combinatorial Optimization

Yang Huang, Yifan Zhang, Jian Cheng

We propose an OT-guided sampling framework for solving graph combinatorial optimization through exact multilinear relaxation. Graph combinatorial optimization problems can be written as quadratic unconstrained binary optimization(QUBO). Leveraging a classical result in combinatorial optimization, we obtain a continuous multi-linear relaxation of QUBO that is exact, in the sense that it preserves the optimal binary solutions. The challenge is that the resulting energy landscape is highly nonconvex.

We address this by treating the objective as an energy function and optimizing via sampling from the induced Boltzmann distribution to escape poor local optima. Viewing sampling as transporting a simple reference distribution to the target distribution, we use optimal transport to characterize more efficient probabilit

y flow and derive a stochastic optimal control problem whose solution yields an optimal sampling dynamics. We parameterize the control policy with graph neural networks to approximate the optimal control. Experiments show improved solution quality and efficiency over strong combinatorial and learning-based baselines.
****
AOEPT: Breaking the Implicit Modality-Reduction Bottleneck in Modality-Missing Prompt Tuning
Jian Lang, Rongpei Hong, Ting Zhong, Fan Zhou
Deploying multimodal systems in real-world environments often entails handling modality-missing scenarios, where one or more modalities are unavailable. While recent studies address this challenge for the general Multimodal Transformer (MT) architecture via prompt tuning, we identify a fundamental limitation in these methods: the Implicit Modality-Reduction bottleneck. By conditioning prompts solely on the observed modalities, they inadvertently restrict the reasoning scope of MTs to the modality-reduced subspace, cutting off access to the latent information sources of the missing modalities. To overcome this limitation, we propose AOEPT, which pioneers a novel modal-contextualized prompting fashion. Specifically, we introduce lightweight Modal-Contextualized Prompts (MCPs) that distill global modality-wise priors from training data, serving as latent repositories of the information sources for missing modalities. Conditioned on the remaining modalities, these MCPs are instantiated into instance-aware prompts that selectively augment missing-modality information for each sample, thereby restoring the reasoning scope of MTs beyond the observed-modality-only subspace. Experiments across various multimodal benchmarks and backbones confirm the strong performance of AOEPT, with minimal computational overhead.

Exactly Computing do-Shapley Values
R. Teal Witter, Álvaro Parafita, Tomas Garriga, Maximilian Muschalik, Fabian Fumagalli, Axel Brando, Lucas Rosenblatt
Structural Causal Models (SCM) are a powerful framework for describing complicated dynamics across the natural sciences.
A particularly elegant way of interpreting SCMs is via do-Shapley values, a game-theoretic method of quantifying the average effect of d variables across exponentially many interventions.
Like Shapley values, computing do-Shapley values generally requires evaluating exponentially many terms.
The foundation of our work is a reformulation of do-Shapley values in terms of the irreducible sets of the underlying SCM.
Leveraging this insight, we can exactly compute do-Shapley values in time linear in the number of irreducible sets r, which itself can range from d to 2^d depending on the graph structure of the SCM.
Since r is unknown a priori, we complement the exact algorithm with an estimator that, like general Shapley value estimators, can be run with any query budget.
As the query budget approaches r, our estimators can produce more accurate estimates than prior methods by several orders of magnitude, and, when the budget reaches r, return the Shapley values up to machine precision.
Beyond computational speed, we also reduce the identification burden: we prove that non-parametric identifiability of do-Shapley values requires only the identification of interventional effects for the d singleton coalitions, rather than all classes.

Large-Scale Terminal Agentic Trajectory Generation from Dockerized Environments
Siwei Wu, Yizhi LI, Yuyang Song, Wei Zhang, Yang Wang, Riza Batista-Navarro, Xian Yang, Mingjie Tang, Bryan Dai, Jian Yang, Chenghua Lin
Training agentic models for terminal-based tasks critically depends on high-quality terminal trajectories that capture realistic long-horizon interactions across diverse domains.
However, constructing such data at scale remains challenging due to two key requirements:

\textbf{\emph{Executability}}, since each instance requires a suitable and often distinct Docker environment;
and \textbf{\emph{Verifiability}}, because heterogeneous task outputs preclude unified, standardized verification.
To address these challenges, we propose \textbf{TerminalTraj}, a scalable pipeline that (i) filters high-quality repositories to construct Dockerized execution environments, (ii) generates Docker-aligned task instances, and (iii) synthesizes agent trajectories with executable validation code.
Using TerminalTraj, we curate 32K Docker images and generate 50,733 verified terminal trajectories across eight domains.
Models trained on this data with the Qwen2.5-Coder backbone achieve consistent performance improvements on TerminalBench (TB), with gains of up to 20\% on TB 1.0 and 10\% on TB 2.0 over their respective backbones.
Notably, \textbf{TerminalTraj-32B} achieves strong performance among models with fewer than 100B parameters, reaching 35.30\% on TB 1.0 and 22.00\% on TB 2.0, and demonstrates improved test-time scaling behavior.

Can Computational Reducibility Lead to Transferable Models for Graph Combinatorial Optimization?

Semih Cantürk, Thomas Sabourin, Frederik Wenkel, Michael Perlmutter, Guy Wolf

A key challenge in deriving unified neural solvers for combinatorial optimization (CO) is efficient generalization of models between one set of tasks to new tasks not used during the initial training process. To address it, we first establish a new GNN encoder, which uses a GCON module as a form of expressive message passing together with energy-based unsupervised loss functions. This model achieves high performance (often comparable with state-of-the-art results) across multiple CO tasks when trained individually on each task. We then leverage knowledge from the computational reducibility literature to propose pretraining and fine-tuning strategies to transfer effectively (a) between MVC, MIS and MaxClique, and (b) in a multi-task learning setting that additionally incorporates MaxCut, MDS and graph coloring. Additionally, in a leave-one-out, multi-task learning setting, we observe that pretraining on all but one task almost always leads to faster convergence on the remaining task when fine-tuning while avoiding negative transfer. Our findings indicate that learning common representations across multiple graph CO problems is viable through the use of expressive message passing coupled with pretraining strategies that are informed by the polynomial reduction literature, thereby taking an important step towards enabling the development of foundational models for neural CO.

When Benign Inputs Lead to Severe Harms: Eliciting Unsafe Unintended Behaviors of Computer-Use Agents

Jaylen Jones, Zhehao Zhang, Yuting Ning, Eric Fosler-Lussier, Pierre-Luc St-Charles, Yoshua Bengio, Dawn Song, Yu Su, Huan Sun

Although computer-use agents (CUAs) hold significant potential to automate increasingly complex OS workflows, they can demonstrate unsafe unintended behaviors that deviate from expected outcomes even under benign input contexts. However, exploration of this risk remains largely anecdotal, lacking concrete characterization and automated methods to proactively surface long-tail unintended behaviors under realistic CUA scenarios. To fill this gap, we introduce the first conceptual and methodological framework for unintended CUA behaviors, by defining their key characteristics, automatically eliciting them, and analyzing how they arise from benign inputs. We propose AutoElicit: an agentic framework that iteratively perturbs benign instructions using CUA execution feedback, and elicits severe harms while keeping perturbations realistic and benign. Using AUTOELICIT, we surface hundreds of harmful unintended behaviors from state-of-the-art CUAs such as Claude 4.5 Haiku, Claude 4.5 Opus, and Operator. We further evaluate the transferability of human-verified successful perturbations, identifying persistent susceptibility to unintended behaviors across various other frontier CUAs. This work establishes a foundation for systematically analyzing unintended behaviors in realistic computer-use settings.

Learning Interpretable Options by Identifying Reward Diffusion Bottlenecks in Reinforcement Learning
Yiming Fei, Lang Qin, Rui Yan, Huajin Tang
Bottleneck states, which connect distinct regions of the state space, provide a principled and interpretable basis for constructing temporal abstractions in Hierarchical Reinforcement Learning (HRL). However, existing bottleneck identification methods primarily rely on topological analysis of the state-transition graph, limiting their scalability to high-dimensional or continuous domains. To address this challenge, we introduce Value Power Strength (VPS), a value function-based metric inspired by the analogy between the Bellman equation and Kirchhoff's current law, to quantify bottleneck property via the diffusion of reward in Markov Decision Processes (MDPs). VPS is estimated efficiently using value functions learned from random reward signals and captures reward diffusion bottlenecks in both discrete and continuous state spaces.
Leveraging VPS, we design options that guide agents toward or away from bottleneck regions. Experimental results on classic tabular domains, continuous-control PointMaze, and Atari 2600 games demonstrate that the VPS-based framework discovers semantically meaningful subgoals and substantially improves exploration efficiency.

Enhancing Train-Free Infinite-Frame Generation for Consistent Long Videos
Xiaokun Feng, Jiashu Zhu, Meiqi Wu, Chubin Chen, Fangyuan Mao, Haiyang Guo, Jiahong Wu, Xiangxiang Chu, Kaiqi Huang
Without incurring significant computational overhead, train-free long video generation aims to enable foundation video generation models to produce longer videos. Frame-level autoregressive frameworks, e.g., FIFO-diffusion, offer the advantage of generating infinitely long videos with constant memory consumption. However, the mismatch between training and inference, coupled with the challenge of maintaining long-term consistency, limits the effective utilization of foundation models. To mitigate these concerns, we propose MIGA, a novel infinite-frame long video generation method. Firstly, we propose an effective two-stage alignment mechanism that mitigates the training-inference gap by reducing the excessive noise span fed to the model. We then introduce an innovative dual consistency enhancement mechanism, where the self-reflection approach corrects early high-noise frames and the long-range frame guidance approach leverages later low-noise frames with broad coverage to steer generation, jointly improving temporal consistency. Extensive experiments on VBench and NarrLV demonstrate the state-of-the-art performance of MIGA. Our project page is available at https://xiaokunfeng.github.io/miga_homepage/.

SAEmnesia: Erasing Concepts in Diffusion Models with Supervised Sparse Autoencoders
Enrico Cassano, Riccardo Renzulli, Marco Nurisso, Mirko Zaffaroni, Alan Perotti, Marco Grangetto
Concept unlearning in diffusion models is hampered by feature splitting, where concepts are distributed across many latent features, making their removal challenging and computationally expensive. We introduce SAEmnesia, a supervised sparse autoencoder framework that overcomes this by enforcing one-to-one concept-neuron mappings. By systematically labeling concepts during training, our method achieves feature centralization, binding each concept to a single, interpretable neuron. This enables highly targeted and efficient concept erasure. Compared to the state-of-the-art sparse autoencoder-based unlearning approach, SAEmnesia reduces hyperparameter search by 96.67\% and achieves a 9.22\% improvement on the UnlearnCanvas benchmark for objects. Our method also shows superior scalability in sequential unlearning, improving accuracy by 28.4\% when removing nine objects, establishing a step forward for precise and controllable concept erasure. Moreover, SAEmnesia effectively suppresses nudity on the I2P benchmark and remains robust to adversarial attacks. Source code available at https://github.com/EIDOSLAB/SAEmnesia.

Same Graph Cross-Task Transfer in GNNs: Protocols and Predictors
Neelam Akula, Surbhi Kumar, Murat Kantarcioglu, Baris Coskunuzer
Many real-world graphs support multiple predictive tasks over the same underlying structure, creating an opportunity to reuse supervision across node classification (NC) and link prediction (LP). However, existing evaluations often rely on incompatible splits, observed-graph assumptions, and negative sampling rules, making conclusions about same-graph cross-task transfer unreliable. We formalize same-graph NC–LP transfer and propose a leakage-free protocol that fixes node and edge splits, uses a shared message-passing graph that excludes evaluated edges, and employs fixed negatives for LP. Across three backbones (GCN, GraphSAGE, GPS), we find transfer is strongly directional and predictable: NC$\to$LP is consistently beneficial on homophilic graphs, while LP$\to$NC is fragile and can even degrade accuracy under naive representation reuse. LP$\to$NC becomes reliably positive mainly in a structure-dominant regime where LP is easy but NC is unsaturated, suggesting LP acts as structural pretraining. Finally, we introduce CoTask Score (CTS) to summarize joint NC+LP utility when a shared encoder must serve both tasks, and show that simple dataset statistics, especially homophily, can guide mechanism choice and help avoid negative transfer.
****
Causal Dependency-Aware Unsupervised Routing for Large Reasoning Models
Jiacheng Liu, Hao Liu, Xiaofeng Hou, Wei Xue, Yike Guo
As Large Language Model (LLM) ecosystems grow, routing queries to the most suitable model in a diverse pool has become a critical strategy for building efficient and high-performing AI systems.
A common approach is to train a supervised router; however, this requires vast, expensive human-annotated preference data and creates models that are notoriously brittle, failing to generalize when faced with inevitable distribution shifts in user queries. Consequently, developing robust, unsupervised routing methods that adapt without retraining is a crucial research frontier.
This challenge is severely amplified by Large Reasoning Models (LRMs), which introduce a dual problem for any label-free method: their outputs have a causal thinking $\to$ answer structure that must be modeled, and a structural imbalance where long reasoning text can dominate the final answer signal. We introduce ReasoningRouter, a novel framework that resolves these issues with a length-balanced embedding strategy and a probabilistic model capturing the thinking-to-answer dependency.
The proposed Causal Triangulation Property enables the label-free estimation of component qualities and their causal link.
Beyond competitive routing accuracy, ReasoningRouter offers unprecedented insights into model behavior, enabling separate quality assessment of reasoning and answer components while maintaining computational efficiency.
****
PragLocker: Protecting Agent Intellectual Property in Untrusted Deployments via Non-Portable Prompts
Qinfeng Li, Yuntai Bao, Jianghui Hu, Wenqi Zhang, Jintao Chen, Huifeng Zhu, Yier Jin, Xuhong Zhang
LLM agents rely on prompts to implement task-specific capabilities based on foundation LLMs, making agent prompts valuable intellectual property. However, in untrusted deployments, adversaries can copy and reuse these prompts with other proprietary LLMs, causing economic losses. To protect these prompts, we identify four key challenges: proactivity, runtime protection, usability, and non-portability that existing approaches fail to address. We present PragLocker, a prompt protection scheme that satisfies these requirements. PragLocker constructs function-preserving obfuscated prompts by anchoring semantics with code symbols and then using target-model feedback to inject noise, yielding prompts that only work on the target LLM. Experiments across multiple agent systems, datasets, and foundation LLMs show that PragLocker substantially reduces cross-LLM portability, maintains target performance, and remains robust against adaptive attackers.

OpenDeception: Learning Deception and Trust in Human–AI Interaction via Multi-Agent Simulation
Yichen Wu, Qianqian Gao, Xudong Pan, Geng Hong, Min Yang
As large language models (LLMs) are increasingly deployed as interactive agents, open-ended human-AI interactions can involve deceptive behaviors with serious real-world consequences, yet existing evaluations remain largely scenario-specific and model-centric.
We introduce *OpenDeception*, a lightweight framework for jointly evaluating deception risk from both sides of human-AI dialogue. It consists of a scenario benchmark with 50 real-world deception cases, an *IntentNet* that infers deceptive intent from agent reasoning, and a *TrustNet* that estimates user susceptibility. To address data scarcity, we synthesize high-risk dialogues via LLM-based role-and-goal simulation, and train the *TrustNet* using contrastive learning on controlled response pairs, avoiding unreliable scalar labels. Experiments on 11 LLMs and three large reasoning models show that over 90% of goal-driven interactions in most models exhibit deceptive intent, with stronger models displaying higher risk. A real-world case study adapted from a documented AI-induced suicide incident further demonstrates that our joint evaluation can proactively trigger warnings before critical trust thresholds are reached.
****
Discovering Scaling Exponents with Physics-Informed Müntz-Szász Networks
Gnankan Landry Regis N'guessan, Bum Jun Kim
Physical systems near singularities, interfaces, and critical points exhibit power-law scaling, yet standard neural networks leave the governing exponents implicit. We introduce physics-informed Müntz-Szász Networks (MSN-PINN), a power-law basis network that treats scaling exponents as trainable parameters. The model outputs both the solution and its scaling structure. We prove identifiability, or unique recovery, and show that, under these conditions, the squared error between learned and true exponents scales as $O(|\mu - \alpha|^2)$. Across experiments, MSN-PINN achieves single-exponent recovery with 1–5\% error under noise and sparse sampling. It recovers corner singularity exponents for the two-dimensional Laplace equation with 0.009\% error, matches the classical result of Kondrat'ev (1967), and recovers forcing-induced exponents in singular Poisson problems with 0.03\% and 0.05\% errors. On a 40-configuration wedge benchmark, it reaches a 100\% success rate with 0.022\% mean error. Constraint-aware training encodes physical requirements such as boundary condition compatibility and improves accuracy by three orders of magnitude over naive training.
****
The Two-Hump Problem: Bridging the Difficulty Gap in Mathematical Reinforcement Learning
Lucas Fagan, Michele Tarquini, Ali Shehper, Maksymilian Manko, Angus Gruen, Coco Huang, Giorgi Butbaia, Davide Passaro, Sergei Gukov
Mathematical search problems present a unique challenge for Reinforcement Learning (RL) due to vast search spaces and sparse rewards. In previous works, the Andrews-Curtis (AC) conjecture was established as an illustrative example of such problems. In this work, we identify a critical structural barrier in the AC landscape: a "Two Hump" distribution, where problem instances are either trivially solvable or effectively impossible, with a scarcity of intermediate "hard-but-solvable" instances required for effective learning. We tackle this challenge through two primary avenues: novel data generation techniques to populate the difficulty gap, and significant algorithmic enhancements including the introduction of supermoves and Transformer-based architectures. We demonstrate substantial performance improvements over previous baselines, and release new comprehensive benchmark datasets including **AC-19** (125,192 AC-trivial presentations of varying difficulty with length at most 19) and **AC-1M** (1,136,154 hard AC-trivial presentations of length at most 30), the first large-scale, publicly available datasets of this kind.

On the Existence of Consistent Adversarial Attacks in High-Dimensional Linear Classification

Matteo Vilucchio, Lenka Zdeborová, Bruno Loureiro
What fundamentally distinguishes an adversarial attack from a misclassification due to limited model expressivity or finite data?
In this work, we investigate this question in the setting of high-dimensional binary classification, where statistical effects due to limited data availability play a central role.
We introduce a new error metric that precisely capture this distinction, quantifying model vulnerability to consistent adversarial attacks --- perturbations that preserve the ground-truth labels.
Our main technical contribution is an exact and rigorous asymptotic characterization of these metrics in both well-specified models and latent space models, revealing different vulnerability patterns compared to standard robust error measures.
The theoretical results demonstrate that as models become more overparameterized, their vulnerability to label-preserving perturbations grows, offering theoretical insight into the mechanisms underlying model sensitivity to adversarial attacks.

Geometry-Aware Neural Optimizer for Shape Optimization and Inversion
Sun Guoze, Tianya Miao, Haoyang Huang, Huaguan Chen, Han Wan, Rui Zhang, Hao Sun
Geometry is central to PDE-governed systems, motivating shape optimization and inversion. Classical pipelines conduct costly forward simulation with geometry processing, requiring substantial expert effort. Neural surrogates accelerate forward analysis but do not close the loop because gradients from objectives to geometry are often unavailable. Existing differentiable methods either rely on restrictive parameterizations or unstable latent optimization driven by scalar objectives, limiting interpretability and part-wise control. To address these challenges, we propose Geometry-Aware Neural Optimizer (\textbf{\textsc{GANO}}), an end-to-end differentiable framework that unifies geometry representation, field-level prediction, and automated optimization/inversion in a single latent-space loop. \textsc{GANO} encodes shapes with an auto-decoder and stabilizes latent updates via a denoising mechanism, and a geometry-informed surrogate provides a reliable gradient pathway for geometry updates. Moreover, \textsc{GANO} supports part-wise control through null-space projection and uses remeshing-free projection to accelerate geometry processing. We further prove that denoising induces an implicit Jacobian regularization that reduces decoder sensitivity, yielding controlled deformations. Experiments on three benchmarks spanning 2D Helmholtz, 2D airfoil, and 3D vehicles show state-of-the-art accuracy and stable, controllable updates, achieving up to +55.9% lift-to-drag improvement for airfoils and ~7% drag reduction for vehicles.

ActiveScope: Actively Seeking and Correcting Perception for MLLMs
Yajing Wang, Chao Bi, Junshu Sun, Shufan Shen, Zhaobo Qi, Shuhui Wang, Qingming Huang
Multimodal Large Language Models (MLLMs) have demonstrated impressive vision-language understanding, yet still struggle with fine-grained perception in high-resolution images.
While existing training-free methods typically rely on attention-based localization or coarse-to-fine search, they are often misled by distractors and fail to locate multiple targets.
Our investigation attributes these failures to *Contextual Dominance*, where salient distractors overwhelm target attention and cause inaccurate localization, and *Semantic Bias*, where global semantics cause the model to fixate on the most salient concept, resulting in incomplete localization in multi-object scenarios.
Built on these insights, we propose ActiveScope, a training-free framework that enhances MLLMs by actively seeking and correcting perception. ActiveScope features two modules. The *Semantic Anchor Localization (SAL)* utilizes fine-grained semantic anchors to independently localize key targets, thereby mitigating semantic bias. The *Interference-Suppressed Refinement (ISR)* refines localization by

suppressing attention on salient distractions to overcome contextual dominance.
Extensive experiments on high-resolution image understanding benchmarks demonstr
ate that ActiveScope outperforms existing training-free methods (e.g., 96.34\% a
ccuracy on V^{*} Bench),
validating the superiority of the active search and self-correction paradigm. Ou
r code is available at https://github.com/jasmine-ww/ActiveScope.

Beyond the Final Answer: Evaluating the Reasoning Trajectories of Tool-Augmented
 Agents

Wonjoong Kim, Sangwu Park, Yeonjun In, Sein Kim, Dongha Lee, Chanyoung Park

Although recent tool-augmented benchmarks involve complex requests, evaluation r
emains limited to answer matching, neglecting critical trajectory aspects like e
fficiency, hallucination, and adaptivity. The most straightforward method for ev
aluation is to compare an agent’s trajectory with the ground-truth, but annotati
ng all valid ground-truth trajectories is prohibitively expensive. In this manne
r, we introduce TRACE, a reference free framework for the multi-dimensional eval
uation of tool-augmented LLMs. By incorporating an evidence bank which accumulat
es knowledge from preceding steps, TRACE assesses an agent’s reasoning trajector
y effectively. To validate our framework, we develop a new meta-evaluation datas
et with diverse and flawed trajectories, each labeled with multi-faceted perform
ance scores. Our results confirm that TRACE accurately evaluates complex traject
ories even with small open source LLMs. Furthermore, we apply our method to eval
uate the trajectories that agents produce while solving tool-augmented tasks, pr
esenting previously unreported observations and their corresponding insights.

Think Deep, Not Just Long: Measuring LLM Reasoning Effort via Deep-Thinking Toke
ns

Wei-Lin Chen, Liqian Peng, Tian Tan, Chao Zhao, Jianhang Chen, Ziqian Lin, Alec
Go, Yu Meng

Large language models (LLMs) have demonstrated impressive reasoning capabilities
 by scaling test-time compute via long Chain-of-Thought (CoT).
However, recent findings suggest that raw token counts are unreliable proxies fo
r reasoning quality: increased generation length does not consistently correlate
 with accuracy and may instead signal “overthinking,” leading to performance deg
radation.
In this work, we quantify inference-time effort by identifying *deep-thinking to
kens*—tokens where internal predictions undergo significant revisions in deeper
model layers prior to convergence.
Across four challenging mathematical and scientific benchmarks (AIME 24/25, HMMT
 25, and GPQA-diamond) and a diverse set of reasoning-focused models (GPT-OSS, D
eepSeek-R1, and Qwen3), we show that *deep-thinking ratio* (the proportion of de
ep-thinking tokens in a generated sequence) exhibits a robust and consistently p
ositive correlation with accuracy, substantially outperforming both length-based
 and confidence-based baselines.
Leveraging this insight, we introduce Think@n, a test-time scaling strategy th
at prioritizes samples with high deep-thinking ratios.
We demonstrate that Think@n matches or exceeds standard self-consistency perfo
rmance while significantly reducing inference costs by enabling the early reject
ion of unpromising generations based on short prefixes.

SC^{2}-WM: A Self-Correcting World Model with Closed-Loop Feedback for Vision-
and-Language Navigation in Continuous Environments

Xuan Yao, Yuze Zhu, Junyu Gao, Zongmeng Wang, Changsheng Xu

Vision-and-Language Navigation in Continuous Environments (VLN-CE) requires agen
ts to make fine-grained navigation decisions under partial observability.
However, most existing methods rely on open-loop execution, lacking mechanisms t
o detect and correct internal state drift during inference.
We propose SC^{2}-WM, a self-correcting world model framework that introduces
internal feedback for closed-loop decision making in VLN-CE.
Our method derives feedback from world-model foresight to perform state-level pl

an refinement before action execution.
To handle challenging scenarios, we further introduce conditional world-aware adaptation, which enables model-level correction by selectively updating the world model at test time when feedback indicates model capacity insufficiency.
Experiments on standard VLN-CE benchmarks demonstrate improved navigation robustness and generalization. Our code is available at https://github.com/sunrise-ikun/SC2_WM.
****
Multilingual Unlearning in LLMs: Transfer, Dynamics, and Reversibility
Chaoyi Xiang, Olga Ohrimenko, Benjamin I. P. Rubinstein, Lea Frermann
Large language models (LLMs) can memorize sensitive facts, motivating *unlearning* methods that remove targeted knowledge without costly retraining. However, unlearning research remains heavily English-centric. We study multilingual unlearning by extending the TOFU benchmark to five languages, and fine-tune, unlearn and query our models with different permutations of languages. We find that unlearning transfer -- the ability of an unlearned model to "forget" facts in languages other than the unlearning language -- is highly variable: e.g., it is strongest between languages sharing scripts and families, and we show that the *unlearning language* predicts which *query languages* are most likely to yield the strongest transfer. Layer-wise analysis reveals that unlearning leaves the shared cross-lingual latent space largely intact in early layers, instead operating primarily in later decoding layers. This suggests that unlearning does not truly erase knowledge, but rather induces superficial suppression. Exploiting this structure, a single inference-time steering direction reverses much of this suppression across languages, recovering 50% (Qwen) and 90% (Gemma) of the unlearned knowledge.
****
Mechanistic Data Attribution: Tracing the Training Origins of Interpretable LLM Units
Jianhui Chen, Yuzhang Luo, Liangming Pan
While mechanistic interpretability has identified interpretable circuits in large language models (LLMs), their causal origins in training data remain elusive. We introduce *mechanistic data attribution* (MDA), a scalable framework that employs influence functions to trace interpretable units back to specific training samples. Through extensive experiments on the Pythia family, we causally validate that targeted intervention—removing or augmenting a small fraction of high-influence samples—significantly modulates the emergence of interpretable heads, whereas random interventions show no effect. Our analysis reveals that repetitive structural data (e.g., LaTeX, XML) acts as a mechanistic catalyst. Furthermore, we observe that interventions targeting induction head formation induce a concurrent change in the model’s in-context learning (ICL) capability. This provides direct causal evidence for the long-standing hypothesis regarding the functional link between induction heads and ICL. Finally, we propose a mechanistic data augmentation pipeline that consistently accelerates circuit convergence across model scales, providing a principled methodology for steering the developmental trajectories of LLMs.
****
DocHop: Benchmarking Out-of-domain Multi-hop Reasoning in Information-Dense Documents
Zhuoran Yu, Le Thien Phuc Nguyen, Jaden Park, Xinyi Gu, Zexue He, Soochahn Lee, Rogerio Feris, Yong Jae Lee
Multimodal Large Language Models (MLLMs) have achieved strong performance on structured visual understanding tasks such as chart and document question answering. However, existing benchmarks typically evaluate these domains in isolation, leaving underexplored a key capability: whether models can use textual context to determine how chart evidence should be selected, interpreted, and aggregated.
We introduce DocHop, a benchmark for integrated chart--context reasoning in document-style images. In DocHop, the document narrative specifies multi-step compositional constraints, while charts provide the corresponding data values. Questions are grounded on a semantic reference label defined in the narrative, requirin

g models to resolve target entities from context before aggregating evidence acr
oss multiple charts. To enable systematic evaluation, we construct DocHop via a
stochastic logic-first generation pipeline with controllable reasoning depth and
 visual density, covering 1,876 examples across six task categories. Experiments
 on a wide range of proprietary and open-source MLLMs show a substantial gap to
human performance: annotators achieve over 90% accuracy, while the best model re
aches only 60.18%. Reasoning-enhanced models consistently show improved results,
 but performance degrades as reasoning complexity increases.
Overall, DocHop provides a controlled testbed for challenging multi-hop document
 reasoning.

Score-Repellent Monte Carlo: Toward Efficient Non-Markovian Sampler with Constan
t Memory in General State Spaces
Jie Hu, Lingyun Chen, Geeho Kim, Jinyoung Choi, Bohyung Han, Do Young Eun
History-dependent sampling can reduce long-run Monte Carlo variance by discourag
ing redundant revisits, but existing schemes typically encode history through em
pirical measure on finite state spaces, which is infeasible in high-dimensional
discrete configuration spaces or ill-posed in continuous domains. We propose *Sc
ore-Repellent Monte Carlo* (SRMC) framework that summarizes trajectory history b
y a running average of score evaluations in $\mathbb{R}^d$, where d is the dim
ension of the score and state representation. This history is converted into a s
urrogate target through an exponential *score tilt*, indexed with α that
represents the *strength of repellence* in controlling the magnitude of the hist
ory-based repulsion. The surrogate family is normalization-free in the standard
MCMC sense, yielding a generic wrapper: at each iteration, any base kernel targe
ting π can instead be run on the current surrogate π_{θ_n} while th
e history is updated online. We analyze the coupled evolution of the history rec
ursion and Monte Carlo estimators using stochastic approximation with controlled
 Markovian noise, establishing almost sure convergence and a joint central limit
 theorem. We further identify regimes in which the asymptotic covariance decreas
es as α increases, with scaling $O(1/\alpha)$, extending the near-zero-va
riance effect of finite-state history-dependent samplers to general state spaces
 with constant memory. Experiments on continuous targets and discrete energy-bas
ed models demonstrate improved estimator variance and mode coverage, while retai
ning $O(d)$ memory usage and modest per-iteration overhead.

Decoupling Skeleton and Flesh: Efficient Multimodal Table Reasoning with Disenta
ngled Alignment and Structure-aware Guidance
Yingjie Zhu, Xuefeng Bai, Kehai Chen, Yang Xiang, Youcheng Pan, Xiaoqiang Zhou,
Min Zhang
Reasoning over table images remains challenging for Large Vision-Language Models
 (LVLMs) due to complex layouts and tightly coupled structure-content informatio
n. Existing solutions often depend on expensive supervised training, reinforceme
nt learning, or external tools, limiting efficiency and scalability. This work a
ddresses a key question: how to adapt LVLMs to table reasoning with minimal anno
tation and no external tools? Specifically, we first introduce DiSCo, a Disentan
gled Structure-Content alignment framework that explicitly separates structural
abstraction from semantic grounding during multimodal alignment, efficiently ada
pting LVLMs to tables structures. Building on DiSCo, we further present Table-GL
S, a Global-to-Local Structure-guided reasoning framework that performs table re
asoning via structured exploration and evidence-grounded inference. Extensive ex
periments across diverse benchmarks demonstrate that our framework efficiently e
nhances LVLM's table understanding and reasoning capabilities, particularly gene
ralizing to unseen table structures. Our data and code are available at https://
github.com/AAAndy-Zhu/TableVLM.

Rethinking Sparse Mixture of Experts from a Unified Perspective
Giang Do, Hung Le, Truyen Tran
Sparse Mixture of Experts (SMoE) models scale the capacity of models while maint
aining constant computational overhead. SMoE methods fall into two categories: *

Token Choice*, which routes each token to a fixed number of experts, and *Expert Choice*, which assigns a fixed number of tokens to each expert. However, the use of fixed budgets for tokens or experts causes both approaches to select irrelevant token–expert pairs or overlook critical assignments, which degrades overall performance. To fill that gap, we rethink SMoE from a *unified perspective* through the lens of *linear programming*, which provides a general formulation for SMoE models. Furthermore, we introduce **Unified Sparse Mixture of Experts (USMoE)**, a novel framework comprising a *unified mechanism* and a *unified score* to overcome these limitations. We provide both theoretical justification and empirical evidence demonstrating USMoE's effectiveness. Extensive evaluations across diverse data settings (clean and corrupted), multiple domains (including texts and vision tasks), and different learning approaches (training-free and training-based) show that USMoE not only delivers significant performance improvements over existing SMoE methods, but also enables more flexible expert selection budgets, reducing inference costs without compromising model performance.

Light Up Your Face: A Physically Consistent Dataset and Diffusion Model for Face Fill-Light Enhancement
Jue Gong, Zihan Zhou, Jingkai Wang, Xiaohong Liu, Yulun Zhang, Xiaokang Yang
Face fill-light enhancement (FFE) brightens underexposed faces by adding virtual fill light while keeping the original scene illumination and background unchanged. Most face relighting methods aim to reshape overall lighting, which can suppress the input illumination or modify the entire scene, leading to foreground–background inconsistency and mismatching practical FFE needs. To support scalable learning, we introduce LightYourFace-160K (LYF-160K), a large-scale paired dataset built with a physically consistent renderer that injects a disk-shaped area fill light controlled by six disentangled factors, producing 160K before-and-after pairs. We first pretrain a physics-aware lighting prompt (PALP) that embeds the 6D parameters into conditioning tokens, using an auxiliary planar-light reconstruction objective. Building on a pretrained diffusion backbone, we then train a fill-light diffusion (FiLitDiff), an efficient one-step model conditioned on physically grounded lighting codes, enabling controllable and high-fidelity fill lighting at low computational cost. Experiments on held-out paired sets demonstrate strong perceptual quality and competitive full-reference metrics, while better preserving background illumination. The dataset and model will be at https://github.com/gobunu/Light-Up-Your-Face.

SCOPE: Evolving Symbolic World for Planning in Open-Ended Environments
Yundaichuan Zhan, Minghe Gao, Zhongqi Yue, Wendong Bu, Wenqiao Zhang, Guoming Wang, Jisheng Dang, Juncheng Li, Siliang Tang, Yueting Zhuang
Recent works have explored integrating Vision-Language Models (VLMs) with classical planners that rely on symbolic representations of planning problem to generate long-horizon plans for complex embodied tasks. However, in open-ended environments, these symbolic representations obtained from perception are often incomplete, leading to suboptimal performance. To address this, we introduce SCOPE, a self-adaptive symbolic planning framework that supports refining action plans and evolving the symbolic world—the symbolic representations of open-ended environments. SCOPE comprises two synergistic modules: a Symbolic Execution Simulator (SESim) that conducts symbolic validation and real execution of action plans, leveraging the feedback to refine the plans and evolve the symbolic world; and a Self-Adaptive Symbolic Memory (SASMem) that further distills feedback into evolving symbolic knowledge to enhance long-horizon planning and modeling of the symbolic world. Experiments in open-ended environments show that SCOPE significantly improves the completeness of the symbolic world, the success rate of plans under environment perturbations, and cross-task grounding and adaptability across diverse embodied scenarios.

FairJudge : An Adaptive, Debiased, and Consistent LLM-as-a-Judge
Bo Yang, Lanfei Feng, Yunkui Chen, Xiao Xu, Yu Zhang, Shijian Li
Existing LLM-as-a-Judge systems suffer from three fundamental limitations: limit

ed adaptivity to task and domain-specific evaluation criteria, systematic biases driven by non-semantic cues such as position, length, format, and model provenance, and evaluation inconsistency that leads to contradictory judgments across different evaluation modes (e.g., pointwise versus pairwise). To address these issues, we propose FairJudge, an adaptive, debiased, and consistent LLM-as-a-Judge. Unlike prior approaches that treat the judge as a static evaluator, FairJudge models judging behavior itself as a learnable and regularized policy. From a data-centric perspective, we construct a high-information-density judging dataset that explicitly injects supervision signals aligned with evaluation behavior. Building on this dataset, we adopt a curriculum-style SFT-DPO-GRPO training paradigm that progressively aligns rubric adherence, bias mitigation, and cross-mode consistency, while avoiding catastrophic forgetting. Experimental results on multiple internal and public benchmarks show that FairJudge improves agreement and F1 across several evaluation settings, reduces selected non-semantic biases, and achieves competitive or stronger performance than larger general-purpose LLMs on judge-oriented tasks.

DIVER: Diving Deeper into Distilled Data via Expressive Semantic Recovery
Qianxin Xia, Zhiyong Shu, Wenbo Jiang, Jiawei Du, Jielei Wang, Guoming Lu
Dataset distillation aims to synthesize a compact proxy dataset that is unreadable or non-raw from the original dataset for privacy protection and highly efficient learning. However, previous approaches typically adopt a single-stage distillation paradigm, which suffers from learning specific patterns that overfit on a prior architecture, consequently suppressing the expression of semantics and leading to performance degradation across heterogeneous architectures. To address this, we propose a novel dual-stage distillation framework called ${\textbf{DIVER}}$, which leverages the pre-trained diffusion model to dive deeper into $\textbf{DI}$stilled data $\textbf{V}$ia $\textbf{E}$xpressive semantic $\textbf{R}$ecovery, an entire process of semantic inheritance, guidance, and fusion. Semantic inheritance distills high-level semantics of abstract distilled images into the latent space to filter out architecture-specific ``noise" and retain the intrinsic semantics. Furthermore, semantic guidance improves the preservation of the original semantics by directing the reverse procedure. Finally, semantic fusion is designed to provide semantic guidance only during the concrete phase of the reverse process, preventing semantic ambiguity and artifacts while maintaining the guidance information. Extensive experiments validate the effectiveness and efficiency of our method in improving classical distillation techniques and significantly improving cross-architecture generalization, requiring processing time comparable to raw DiT on ImageNet (256$\times$256) with only 4 GB of GPU memory usage.

SIGMA-PPG: Statistical-prior Informed Generative Masking Architecture for PPG Foundation Model
Zongheng Guo, Tao Chen, Yang Jiao, Yi Pan, Xiao Hu, Manuela Ferrario
Current foundation model for photoplethysmography (PPG) signals is challenged by the intrinsic redundancy and noise of the signal. Standard masked modeling often yields trivial solutions while contrastive methods lack morphological precision. To address these limitations, we propose a Statistical-prior Informed Generative Masking Architecture (SIGMA-PPG), a generative foundation model featuring a prior-guided adversarial masking mechanism, where a reinforcement learning-driven teacher leverages statistical priors to create challenging learning paths that prevent overfitting to noise. We also incorporate a semantic consistency constraint via vector quantization to ensure that physiologically identical waveforms—even those altered by recording artifacts or minor perturbations—map to shared indices. This enhances codebook semantic density and eliminates redundant feature structures. Pre-trained on over 120,000 hours of data, SIGMA-PPG achieves superior average performance compared to five state-of-the-art baselines across 12 diverse downstream tasks. The code and model weights are available at https://github.com/ZonghengGuo/SigmaPPG.

Model-Preserving Adaptive Rounding
Albert Tseng, Zhaofeng Sun, Christopher De Sa
The goal of quantization is to produce a compressed model whose output distribution is as close to the original model's as possible. To do this tractably, most quantization algorithms minimize the immediate activation error of each layer as a proxy for the end-to-end error. However, this ignores the effect of future layers, making it a poor proxy. In this work, we introduce Yet Another Quantization Algorithm (YAQA), a new adaptive rounding algorithm that directly considers the error at the network's output. YAQA introduces a series of theoretical results that culminate in the first end-to-end error bounds for quantization algorithms. First, we characterize the convergence time of adaptive rounding algorithms via the structure of their Hessian approximations. We then show that the end-to-end error can be bounded by the approximation's cosine similarity to the true Hessian. This admits a natural Kronecker-factored approximation with corresponding near-optimal Hessian sketches. YAQA is provably better than GPTQ/LDLQ and empirically reduces the error by
$\approx$ 30% over these methods. YAQA even achieves a lower error than quantization aware training. This translates to state of the art performance on downstream tasks, all while adding no inference overhead.
****
Achieving Structurally Robust Gromov Wasserstein Distance via Adaptive Dual-Mask
Kangke Cheng, Jiawei Huang, Jingni Song, Wanlin Zhang, Bangxian Han, Hu Ding
The Gromov-Wasserstein (GW) distance enables comparison across different spaces but remains fragile to structural noise due to its global quadratic coupling. Existing robust extensions primarily rely on node-centric mass relaxation. However, we argue that this strategy is far from sufficient: it only addresses node-induced structural noise (outliers) while neglecting edge-induced distortions where spurious connections exist between valid nodes. To overcome this limitation, we propose the Structurally Robust Gromov-Wasserstein (SRGW) distance, a novel formulation that adaptively filters geometric distortions during optimization. By introducing a structure-aware dual-mask mechanism, our method effectively isolates these stubborn structural outliers while preserving strict marginal constraints for balanced transport. We solve this objective using a Mask-Guided GW Algorithm, which jointly optimizes the transport plan and the structural noise filters. We provide a rigorous theoretical analysis proving that our algorithm converges to a critical point under the Kurdyka-■ojasiewicz framework. Extensive experiments on synthetic geometric matching and real-world subgraph alignment benchmarks demonstrate that Mask-Guided GW achieves superior alignment quality, particularly under severe structural noise.

Experience-Evolving Multi-Turn Tool-Use Agent with Hybrid Episodic–Procedural Memory
Sijia Li, Yuchen Huang, Zifan LIU, Zijian Li, Jingjing Fu, Lei Song, Jiang Bian, Jun Zhang, Rui Wang
As intents unfold and environments change, multi-turn agents face continuously shifting decision contexts. Although reusing past experience is intuitively appealing, existing approaches remain limited: full trajectories are often too context-specific to transfer, while tool-level reuse ignores the context and environment. In this paper, we introduce a hybrid episodic–procedural memory strategy (H-EPM) that enables experience-evolution of multi-turn tool-use policies, by adaptively reusing partially overlapping successful experiences in both inference and training.
Inspired by human episodic–procedural integration, we build a tool graph from accumulated trajectories, where recurring tool-to-tool dependencies capture procedural routines and each edge is augmented with a compact episodic summaries of relevant context. At inference, the agent dynamically balances episodic recall for contextual reasoning and procedural execution for routine steps.
Beyond inference, H-EPM introduces a memory-guided reinforcement learning paradigm that directly addresses a core challenge in multi-turn agent RL: ineffective exploration over long trajectories. By biasing exploration toward historically s

uccessful tool transitions, H-EPM learns a stronger policy that generalizes duri ng inference without relying on domain-specific experience collection. Experimen ts show that H-EPM consistently delivers substantial inference-time gains over s trong baselines across multi-turn tool-use benchmarks, reaching up to 50%+. It a lso boosts RL policy performance, achieving up to 40%+ improvement on out-of-dis tribution tasks. Our code is available at https://github.com/LISijia-dev/H-EPM.

Smaller Models are Natural Explorers for Policy-Level Diversity in GRPO
Yiming Ren, Yiran Xu, Zicheng Lin, Chufan Shi, Yukang Chen, Dingdong WANG, Tianh e Wu, Junjie Wang, Yujiu Yang, Yu Qiao, Ruihang Chu
We identify a new dimension for enhancing rollout diversity in Group Relative Po licy
Optimization (GRPO) for LLMs.
While GRPO relies on diverse rollouts, prevailing strategies primarily increase diversity by injecting more token-level randomness, which may introduce step-wis e noise and leads to incoherent trajectories.
We uncover that smaller models within the same model family inherently exhibit h igher policy-level diversity, indicated by their superior pass@k relative to lar ger counterparts as sample counts increase.
Unlike token-level noise, this diversity is temporally correlated, preserves log ical consistency, and provides structured exploration signals for gradient estim ation. We thus propose S2L-PO (Small-to-Large Policy Optimization), a framework that leverages fixed small models as natural explorers to train larger models. T o balance exploration and exploitation, we design a progressive annealing strate gy that transitions from offline small-model rollouts to the large learner’s own sampling. This shift elegantly avoids mid-training performance drops caused by the small model's capacity limits, achieving faster convergence and unlocking a higher performance ceiling. S2L-PO improves accuracy on diverse mathematical rea soning benchmarks (eg., +8.8\% on AIME 24 using a 1.7B explorer to guide the 8B model) while reducing rollout compute.
The code will be made available.

BARRED: Synthetic Training of Custom Policy Guardrails via Asymmetric Debate
Arnon Mazza, Elad Levi
Deploying guardrails for custom policies remains challenging, as generic safety models fail to capture task-specific requirements, while prompting LLMs suffers from inconsistent boundary-case performance and high inference costs. Training c ustom classifiers achieves both accuracy and efficiency, yet demands substantial labeled data that is costly to obtain. We present BARRED (Boundary Alignment Re finement through REflection and Debate), a framework for generating faithful and diverse synthetic training data using only a task description and a small set o f unlabeled examples. Our approach decomposes the domain space into dimensions t o ensure comprehensive coverage, and employs multi-agent debate to verify label correctness, yielding a high-fidelity training corpus. Experiments across divers e custom policies demonstrate that small language models finetuned on our synthe tic data consistently outperform state-of-the-art proprietary LLMs (including re asoning models) and dedicated guardrail models. Ablation studies confirm that bo th dimension decomposition and debate-based verification are critical for ensuri ng the diversity and label fidelity required for effective fine-tuning. The BARR ED framework eliminates the reliance on extensive human annotation, offering a s calable solution for accurate custom guardrails.

ICR-RL: Deep Reinforcement Learning via In-Context-Regression
David Schiff, Ofir Lindenbaum, Yonathan Efroni
Recent advancements in machine learning have largely been driven by foundation m odels (FMs) trained on large, diverse datasets, enabling them to generalize effe ctively to new, related tasks. However, extending this paradigm to reinforcement learning (RL), where an agent interacts with an environment to select actions, remains a significant challenge. Most existing approaches train FMs directly on sets of control tasks, but developing diverse RL environments and scaling traini

ng across them can be costly and complex. In this study, we explore a simpler al ternative approach based on a classical reduction from RL to regression. We demo nstrate that a foundation model pre-trained for regression tasks, when used as a n in-context regression (ICR) model, can be directly applied to RL problems. Bui lding on this insight, we introduce a gradient-free method, ICR-RL, that require s no additional training and leverages an ICR foundation model to tackle RL task s. We evaluate our approach by applying the ICR model with the recently proposed TabPFN, which is trained on a wide range of regression tasks. Experiments condu cted on the Gymnasium classic-control benchmark indicate that ICR-RL matches or outperforms state-of-the-art methods, including DQN and PPO. These results show that ICR foundation models can effectively solve RL tasks without fine-tuning, d emonstrating their potential as a foundation for RL-oriented models

Parsimonious Learning-Augmented Online Metric Matching

Yongho Shin, Phanu Vajanopath

Learning-augmented algorithms have received significant attention in recent ye ars, particularly in the context of online optimization. Motivated by the high c omputational cost of generating predictions, a growing line of work studies the tradeoff between performance guarantees and the number of predictions used in le arning-augmented algorithms for problems such as caching and metrical task syste ms. In this paper, we extend this line of research to *online metric matching* b y developing *parsimonious* learning-augmented algorithms and establishing lower bounds on their performance. Our approach extends the Follow-the-Prediction fra mework to the parsimonious setting by filling in a *virtual prediction* in the a bsence of an actual prediction, using an online metric matching algorithm that m aintains good intermediate matchings throughout its execution. We complement our theoretical results with an empirical evaluation, demonstrating the practical e ffectiveness of our approach.

Efficient Diffusion Models via Time Step Optimization with Consistent Training a nd Inference Constraints

Binrui Wu, Zihao Cheng, Yuesen Liao, WEIZHONG ZHANG

Diffusion probabilistic models (DPMs)’ sampling process is often inefficient, re quiring hundreds to thousands of iterative steps to accurately approximate the d iffusion trajectory. This inefficiency limits their practical applicability. Alt hough recent advances in sampling efficiency—such as numerical solvers for diffu sion ordinary differential equations (ODEs)—have made progress, significant chal lenges remain: training-free numerical solvers suffer from the suboptimality of manually designed timestep selection rules and the inherent inconsistency betwee n the forward diffusion process (typically involving thousands of steps) and the reverse denoising process (usually limited to tens of steps).

Since timestep selection is inherently a discrete problem and cannot be optimize d via gradients, we propose an innovative approach—reparameterizing the timestep scheduling through probabilistic masking, thereby enabling gradient-based optim ization of sampling timesteps. To circumvent backpropagation, we employ policy g radient methods. Furthermore, to address the inconsistency between forward diffu sion (training) and reverse denoising (inference), we extend this framework into a bilevel optimization paradigm: the inner loop performs additional lightweight training on the model at specific timesteps determined by the outer mask to ali gn forward and reverse processes, while the outer loop optimizes the timestep di stribution via probabilistic masking and policy gradient based on generation qua lity.

Under mild assumptions, we theoretically analyze the convergence of the proposed algorithm. Extensive experiments across diverse datasets and samplers demonstra te that this framework effectively enhances sampling efficiency and generation q uality while maintaining compatibility with various DPM architectures and advanc ed ODE solvers.

Flash-VAED: Plug-and-Play VAE Decoders for Efficient Video Generation

Lunjie Zhu, Yushi Huang, Xingtong Ge, Yufei Xue, Zhening Liu, Yumeng Zhang, Zeho

ng Lin, Jun Zhang
Latent diffusion models have enabled high-quality video synthesis, yet their inf erence remains costly and time-consuming. As diffusion transformers become incre asingly efficient, the latency bottleneck inevitably shifts to VAE decoders. To reduce their latency while maintaining quality, we propose a universal accelerat ion framework for VAE decoders that preserves full alignment with the original l atent distribution. Specifically, we propose (1) an *independence-aware channel pruning* method to effectively mitigate severe channel redundancy, and (2) a *st age-wise dominant operator optimization* strategy to address the high inference cost of the widely used causal 3D convolutions in VAE decoders. Based on these i nnovations, we construct a **Flash-VAED** family. Moreover, we design a *three-p hase dynamic distillation* framework that efficiently transfers the capabilities of the original VAE decoder to Flash-VAED. Extensive experiments on Wan and LTX -Video VAE decoders demonstrate that our method outperforms baselines in both qu ality and speed, achieving approximately a **6$\times$ speedup** while maintaini ng the reconstruction performance up to **96.9%**. Notably, Flash-VAED accelerat es the end-to-end generation pipeline by up to **36%** with negligible quality d rops on VBench-2.0. Our code is available at https://github.com/Aoko955/Flash-VA ED.

Optimal Splitting of Language Models from Mixtures to Specialized Domains
Skyler Seto, Pierre Ablin, Anastasiia Filippova, Jiayuan Ye, Louis Béthune, Ange los Katharopoulos, David Grangier
Language models achieve impressive performance on a variety of knowledge, langua ge, and reasoning tasks due to the scale and diversity of pretraining data avail able. The standard training recipe is a two-stage paradigm: pretraining first o n the full corpus of data followed by specialization on a subset of high qualit y, specialized data from the full corpus. In the multi-domain setting, this invo lves continued pretraining of multiple models on each specialized domain, referr ed to as split model training. We propose a method for pretraining multiple mod els independently over a general pretraining corpus, and determining the optimal compute allocation between pretraining and continued pretraining using scaling laws. Our approach accurately predicts the loss of a model of size N with D pretraining and D' specialization tokens, and extrapolates to larger model siz es and number of tokens. Applied to language model training, our approach impro ves performance consistently across common sense knowledge and reasoning benchma rks across different model sizes and compute budgets.

Taking the GP Out of the Loop
Mehul Bafna, Siddhant Anand Jadhav, David Sweet
Bayesian optimization (BO) has traditionally solved black-box problems where fun ction evaluation is expensive and, therefore, observations are few. Recently, ho wever, there has been growing interest in applying BO to problems where function evaluation is cheaper and observations are more plentiful. In this regime, scal ing to many observations N is impeded by Gaussian-process (GP) surrogates: GP hyperparameter fitting scales as $\mathcal{O}(N^3)$ (reduced to roughly $\mathca l{O}(N^2)$ in modern implementations), and it is repeated at every BO iteration. Many methods improve scaling at acquisition time, but hyperparameter fitting st ill scales poorly, making it the bottleneck. We propose Epistemic Nearest Neighb ors (ENN), a lightweight alternative to GPs that estimates function values and u ncertainty (epistemic and aleatoric) from K-nearest-neighbor observations. ENN scales as $\mathcal{O}(N)$ for both fitting and acquisition. Our BO method, TuR BO-ENN, replaces the GP surrogate in TuRBO with ENN and its Thompson-sampling ac quisition with $\mathrm{UCB} = \mu(x) + \sigma(x)$. For the special case of nois e-free problems, we can omit fitting altogether by replacing UCB with a non-dominated sort over $\mu(x)$ and $\sigma(x)$. We show empirically that Tu RBO-ENN reduces proposal time (i.e., fitting time + acquisition time) by one to two orders of magnitude compared to TuRBO at up to 50,000 observations without s acrificing solution quality.

Convergence Analysis of Decentralized Hessian-/Jacobian-Free Algorithm for Nonconvex Stochastic Bilevel Optimization
Yihan Zhang, Xinwen Zhang, My T. Thai, Jie Wu, Hongchang Gao
Decentralized stochastic bi-level optimization has been actively studied in recent years. However, existing studies assume that the lower-level loss function is strongly convex, which limits their applicability to many machine learning models. To address this limitation, in this paper, we propose a novel decentralized stochastic first-order optimization algorithm, which does not require second-order Hessian or Jacobian matrices, for the setting where the lower-level loss function is nonconvex but satisfies the Polyak–■ojasiewicz (PL) condition.
Additionally, unlike existing single-agent methods that introduce a regularization term to the lower-level loss function to artificially enforce strong convexity, our algorithm does not require such modification. Moreover, our algorithm employs a constant single-timescale learning rate for updating variables, which is different from the time-dependent and two-timescale learning rate schedules used in prior work.
To establish the convergence rate, we develop a new convergence analysis framework for the pure PL condition, rather than relying on the artificial strong convexity introduced through regularization in existing single-agent methods. To the best of our knowledge, this is the first algorithm for nonconvex decentralized bi-level optimization that offers theoretical convergence guarantees under mild conditions. Finally, our extensive experimental results on hyperparameter optimization and model pruning applications validate the efficacy of the proposed algorithm.
****
HASTE: Hardware-Aware Dynamic Sparse Training for Large Output Spaces
Nasib Ullah, Jinbin Zhang, Jean Lucien Randrianantenaina, Erik Schultheis, Rohit Babbar
Extreme multi-label classification (XMC) involves learning models over large output spaces with millions of labels, making the output layer a memory-compute bottleneck. While sparsity-based methods reduce arithmetic complexity, they often fail to yield proportional speedups due to irregular memory access, poor hardware utilization, or reliance on auxiliary architectural components in long-tailed regimes. We introduce group-shared fixed fan-in sparsity, a semi-structured output-layer design in which semantically related labels share a sparse input pattern while retaining independent weights. This grouping introduces a task-aligned inductive bias---encouraging related labels to share feature subsets---while reducing index memory overhead, increasing feature reuse across labels, and enabling efficient GPU execution via custom CUDA kernels that leverage modern accelerator primitives. As an alternative to auxiliary objectives, we exploit the long-tailed structure of XMC by decomposing the output layer into a small dense head over frequent labels and a group-shared sparse tail over the remainder, providing an informative gradient pathway while preserving the memory benefits of sparsity.
Through kernel-level microbenchmarking, we show that group-shared fixed fan-in translates arithmetic reductions into practical wall-clock gains, achieving up to $4.4\times$ speedup in the forward pass and up to $25\times$ speedup in backward passes over standard fixed fan-in sparsity, while operating within a few percent of a FLOPs-matched dense bottleneck. Across large-scale XMC benchmarks, our approach matches or improves precision@k over prior sparse baselines, while narrowing the performance gap to dense.

Optimal Pricing for Data-Augmented AutoML Marketplaces
Minbiao Han, Steven Xia, Jonathan Light, Raul Castro Fernandez, Haifeng Xu, sainyam galhotra
Data markets promise to unlock data value by matching data suppliers with ML consumers. However, market design involves addressing intricate challenges, including data pricing, fairness, and robustness. We propose a pragmatic data-augmented AutoML market that seamlessly integrates with existing cloud-based AutoML platforms, such as Google’s Vertex AI. Unlike standard AutoML solutions, our design automatically augments buyer-submitted training data with valuable external datas

ets, pricing the resulting models based on their measurable performance improvements rather than computational costs as the status quo. Our key innovation is a pricing mechanism grounded in the instrumental value—the marginal model quality improvement—of externally sourced data. This approach bypasses direct dataset pricing complexities and accommodates diverse buyer valuations through menu-based options, thus providing an economically sustainable framework for monetizing external data.
****
Gromov-Wasserstein at Scale, Beyond Squared Norms
Guillaume Houry, Jean Feydy, François-Xavier Vialard
A fundamental challenge in data science is to match disparate point sets with each other. While optimal transport efficiently minimizes point *displacements* under a bijectivity constraint, it is inherently sensitive to rotations. Conversely, minimizing *distortions* via the Gromov-Wasserstein (GW) framework addresses this limitation but introduces a non-convex, computationally demanding optimization problem. In this work, we identify a broad class of distortion penalties that reduce to a simple alignment problem within a lifted feature space. Leveraging this insight, we introduce an iterative GW solver with a linear memory footprint and quadratic (rather than cubic) time complexity. Our method is differentiable, comes with strong theoretical guarantees, and scales to hundreds of thousands of points in minutes. This efficiency unlocks a wide range of geometric applications and enables the exploration of the GW energy landscape, whose local minima encode the symmetries of the matching problem.

Dywave: Event-Aligned Dynamic Tokenization for Heterogeneous IoT Sensing Signals
Tomoyoshi Kimura, Denizhan Kara, Jinyang Li, Hongjue Zhao, Yigong Hu, Yizhuo Chen, Xiaomin Ouyang, Shengzhong Liu, Tarek F. Abdelzaher
Internet of Things (IoT) systems continuously collect heterogeneous sensing signals from ubiquitous sensors to support intelligent applications such as human activity analysis, emotion monitoring, and environmental perception.
These signals are inherently non-stationary and multi-scale, posing unique challenges for standard tokenization techniques.
This paper proposes Dywave, a dynamic tokenization framework for IoT sensing signals that constructs compact input representations aligned with intrinsic temporal structures and underlying physical events.
Dywave leverages wavelet-based hierarchical decomposition, identifies meaningful temporal boundaries corresponding to underlying semantic events, and adaptively compresses redundant intervals while preserving temporal coherence.
Extensive evaluations on five real-world IoT sensing datasets across activity recognition, stress assessment, and nearby object detection demonstrate that Dywave outperforms state-of-the-art methods by up to 12% in accuracy, while improving computational efficiency by reducing input token lengths by up to 75\% across mainstream sequence models.
Moreover, Dywave exhibits improved robustness to domain shifts and varying sequence lengths.
****
Linguistic Relative Policy Optimization for Video Anomaly Reasoning
Jiaxu Leng, Jiankang Zheng, Mengjingcheng Mo, Zhanjie Wu, Haosheng Chen, Ji Gan, Xinbo Gao
Video anomaly detection (VAD) with multimodal large language models has shown strong potential, yet most existing methods still depend on large-scale annotations or expert-designed priors, limiting their ability to acquire anomaly knowledge with as little human intervention as possible. To address this, we propose Linguistic Relative Policy Optimization (LRPO), which distills group-relative semantic advantages from multiple reasoning trajectories into a linguistically expressed anomaly experience prior, and adapts the model by injecting this prior into the context to steer its output distribution without any parameter updates. LRPO builds two complementary experience representations: general experience captures transferable anomaly preferences across scenarios, while scenario experience models context-dependent anomaly rules for targeted refinement. To further improve

the learned experience, we introduce an anomaly alignment reward that guides trajectory optimization to match human risk preferences and reinforce temporally grounded reasoning. Extensive experiments on XD-Violence, UCF-Crime, and UBNormal demonstrate that LRPO significantly outperforms existing state-of-the-art methods under tuning-free settings.

Understanding Data Temporality Impact on Large Language Models Pre-training

Romain Fabre, Hippolyte Pilchen, Franck SIGNE TALLA, Patrick Perez, Edouard Grave

Large language models (LLMs) are typically trained on shuffled corpora, yielding models whose knowledge is frozen at training time and whose temporal grounding remains poorly understood. In this work, we study the impact of pretraining dynamics on the acquisition of time-sensitive factual knowledge, focusing specifically on data ordering. Our main contributions are twofold. First, we introduce a comprehensive benchmark of over 7,000 temporally grounded questions and an evaluation protocol that enables analysis of whether models correctly associate facts with their corresponding time periods. Second, we pretrain 6B-parameter language models on temporally ordered Common Crawl snapshots and compare them against standard shuffled pretraining. Our results show that sequentially trained models match shuffled baselines on general language understanding and common knowledge while consistently exhibiting more up-to-date and temporally precise knowledge. Temporally ordered pretraining yields improved factual freshness, while shuffled pretraining peaks on older data, possibly due to increased factual repetition. These findings, along with the release of our checkpoints and datasets, provide a foundation for future research on continual learning for large language models.

Geometry-Aware Dataset Condensation for Diffusion Model Training

Xiao Cui, Yulei Qin, Mo Zhu, Wengang Zhou, Hongsheng Li, Houqiang Li

Dataset condensation aims to construct compact datasets from real data via synthesis or selection. However, existing approaches are ill-suited for diffusion model training: synthetic data generation often yields low-fidelity samples unsuitable for authentic modeling, while real subset selection typically fails to preserve the distributional geometry required by diffusion likelihood objectives. To address this, we propose to reformulate real subset selection as a geometry-aware distribution alignment problem. By incorporating one-sided partial optimal transport, our method selectively aligns a compact subset with the full data distribution while allowing unmatched mass in low-density regions, ensuring the preserved geometric structure necessary for effective diffusion model training. To further ensure distributional fidelity, we complement geometric alignment with lightweight feature-statistics and semantic consistency regularization. An efficient two-stage discrete optimization strategy is proposed to achieve this alignment objective. Extensive experiments across diffusion variants, subset sizes, image resolutions, and training rounds show that our method achieves superior fidelity and distributional coverage in diffusion model training.

Learning in the Fisher Subspace: A Guided Initialization for LoRA Fine-Tuning

Zhi-Quan Feng, Ying-Jia Lin, Hung-Yu Kao

LoRA adapts large language models (LLMs) by restricting updates to low-rank subspaces of pre-trained weights. While this substantially reduces training cost, the effectiveness of adaptation critically depends on which subspace is chosen at initialization: a poor initialization that allocates capacity to task-irrelevant directions can severely hinder downstream performance. Existing initialization strategies primarily rely on the intrinsic properties of pre-trained weights, implicitly assuming that weight geometry alone reflects task relevance. However, such criteria overlook how the model interacts with the downstream data distribution. In this work, we formulate LoRA initialization as identifying the degree of impact of directions in parameter space under the target data distribution. We argue that data-aware sensitivity, rather than weight-only magnitude, should govern the choice of adaptation subspaces. Building on this perspective, we propose a Fisher-guided framework that leverages curvature information induced by downs

tream data to characterize how parameter perturbations influence model predictio
ns. This perspective yields a principled, task-dependent criterion for selecting
 LoRA directions that better align adaptation with the target objective. Empiric
al results across diverse tasks and modalities demonstrate that data-aware initi
alization consistently and significantly improves downstream performance over ex
isting approaches.

LOVE: Benchmarking and Evaluating Text-to-Video Generation and Video-to-Text Int
erpretation
Jiarui Wang, Huiyu Duan, Ziheng Jia, Zicheng Zhang, Yu Zhao, Juntong Wang, Guang
tao Zhai, Xiongkuo Min
Recent advancements in large multimodal models (LMMs) have driven substantial pr
ogress in both text-to-video (T2V) generation and video-to-text (V2T) interpreta
tion tasks.
However, current AI-generated videos (AIGVs) still exhibit limitations in terms
 of perceptual quality and text-video alignment.
To this end, we present **AIGVE-60K**, a comprehensive dataset and benchmark for
 AI-Generated Video Evaluation,
which features **(i)** comprehensive tasks, encompassing 3,050 extensive prompts
 across 20 fine-grained task dimensions, **(ii)** the largest human annotations,
 including 120K mean-opinion scores (MOSs) and 60K question-answering (QA) pairs
 annotated on 58,500 videos generated from 30 T2V models, and **(iii)**
bidirectional benchmarking and evaluating for both T2V generation and V2T interp
retation capabilities.
Based on AIGVE-60K, we propose **LOVE**, a LMM-based metric for AIGV Evaluation
from multiple dimensions including perceptual preference, text-video corresponde
nce, and task-specific accuracy.
Building upon LOVE, we further introduce **LOVE-Reward** to optimize T2V models
through reinforcement learning, effectively enhancing both the perceptual qualit
y and text-video correspondence of generated videos.
Comprehensive experiments demonstrate that LOVE achieves state-of-the-art perfor
mance and generalizes effectively to various AIGV benchmarks. LOVE-Reward signif
icantly improves video generation quality.
These findings highlight the effectiveness of the AIGVE-60K dataset and our prop
osed methods. The database and codes are available at
https://github.com/IntMeGroup/LOVE.

Latent Reasoning VLA: Latent Thinking and Prediction for Vision-Language-Action
Models
Shuanghao Bai, Jing Lyu, Wanqi Zhou, Zhe Li, Dakai Wang, Lei Xing, Xiaoguang Zha
o, Pengwei Wang, Zhongyuan Wang, Cheng Chi, Badong Chen, Shanghang Zhang
Vision-Language-Action (VLA) models benefit from Chain-of-Thought (CoT) reasonin
g, but existing approaches incur high inference overhead and rely on discrete re
asoning representations that mismatch continuous perception and control.
We propose Latent Reasoning VLA (LaRA-VLA), a unified VLA framework that interna
lizes multi-modal CoT reasoning into continuous latent representations for embod
ied action.
LaRA-VLA performs unified reasoning and prediction in latent space, eliminating
explicit CoT generation at inference time and enabling efficient, action-oriente
d control.
To realize latent embodied reasoning, we introduce a curriculum-based training p
aradigm that progressively transitions from explicit textual and visual CoT supe
rvision to latent reasoning, and finally adapts latent reasoning dynamics to con
dition action generation.
We construct two structured CoT datasets, LIBERO-LaRA and Bridge-LaRA, and evalu
ate LaRA-VLA across simulation benchmarks and long-horizon real-robot manipulati
on tasks. Experimental results show that LaRA-VLA outperforms existing state-of-
the-art VLA methods while achieving up to a 90\% reduction in inference latency
compared to explicit CoT-based VLA approaches, highlighting latent reasoning as
an effective and efficient paradigm for real-time embodied control.

****
Convex Optimization for Alignment and Preference Learning on a Single GPU
Miria Feng, Mert Pilanci
Fine-tuning large language models (LLMs) to align with human preferences has dri ven the success of systems such as Gemini and ChatGPT.
However, approaches like Reinforcement Learning from Human Feedback (RLHF) remai n computationally expensive and complex.
Direct Preference Optimization (DPO) offers a simpler alternative but has limita tions such as inconsistent ranking accuracy, high dependence on GPU resources, a nd expensive hyperparameter tuning.
We propose the Convex Optimization for Alignment and Preference Learning Algorit hm (COALA): a novel lightweight strategy with strong theoretical guarantees. By leveraging the convex optimization reformulation of neural networks, COALA elimi nates the need for a reference model and obtains significant reduction in both t raining time and VRAM consumption, thus enabling efficient training on a single GPU.
Experiments across four datasets—including a 26621-sample synthetic Educational Feedback dataset—and six models (including Llama-3.1-8B) demonstrate COALA's com petitive performance and efficiency while utilizing as little as ${\sim}17.6\%$ of DPO's total TFLOPs.
COALA exhibits stable, monotonically increasing rewards and reaches peak margins in significantly shorter time in comparison to traditional methods such as DPO and ORPO.
To the best of our knowledge, this is the first time convex optimization has bee n effectively applied to preference fine-tuning of LLMs.

Prompt Reinjection: Alleviating Prompt Forgetting in Multimodal Diffusion Transf ormers
Yuxuan Yao, Yuxuan Chen, Hui Li, Kaihui Cheng, Qipeng Guo, Yuwei Sun, Zilong Don g, Jingdong Wang, Siyu Zhu
Multimodal Diffusion Transformers (MMDiTs) for text-to-image generation maintain separate text and image branches, with bidirectional information flow between t ext tokens and visual latents throughout denoising.
In this setting, we observe a prompt forgetting phenomenon: the semantics of the prompt representation in the text branch is progressively forgotten as depth in creases. We further verify this effect on three representative MMDiTs—SD3, SD3.5 , and FLUX.1
by probing linguistic attributes of the representations over the layers in the t ext branch.
Motivated by these findings, we introduce a training-free approach, prompt reinj ection, which reinjects prompt representations from early layers into later laye rs to alleviate this forgetting.
Experiments on GenEval, DPG, and T2I-CompBench++ show consistent gains in instru ction-following capability, along with improvements on metrics capturing prefere nce, aesthetics, and overall text--image generation quality.

Provable Benefits of RLVR over SFT for Reasoning Models: Learning to Backtrack E fficiently
Stanley Wei, Juno Kim
Recent advances in large language models (LLMs) have demonstrated that reinforce ment fine-tuning of pretrained base models can lead to significant gains in reas oning performance at inference time. In this work, we theoretically analyze why reinforcement fine-tuning induces better reasoning ability than purely supervise d fine-tuning (SFT) methods. We model chain-of-thought (CoT) reasoning as a path finding problem on graphs and compare the popular method of reinforcement learni ng with verifiable rewards (RLVR) against traditional SFT. We prove that SFT, wh en trained on golden shortest paths without negative examples, fails to learn ho w to efficiently backtrack. In contrast, an RLVR-trained model can learn how to efficiently backtrack from dead ends using only outcome reward. This leads to a provable inference-time compute separation between the two methods, and demonstr

ates that RLVR allows the model to learn the location of difficult decisions in a reasoning chain, ultimately allowing for better allocation of inference-time compute. Finally, we show that the reasoning traces of an RLVR model can be distilled to train a base model to backtrack efficiently as well.

Inside the Visual Mind: Neuroscience-Motivated Concept Circuits for Interpreting and Steering Vision Transformers
Tang Li, Yanlin Chen, Mengmeng Ma, Xi Peng
Despite high accuracy, Vision Transformer (ViT) predictions can be driven by spurious cues, raising the need to understand their inner workings before safe deployment. Sparse autoencoders (SAEs) provide a promising lens for decomposing model representations into human-interpretable concepts, yet adapting SAE-based interpretation to ViTs remains challenging due to limited control over concept coverage and subjective, non-scalable feature interpretation. To fill the gaps, motivated by neuroscience-inspired principles, we propose ViSAE, a mechanistic interpretability toolbox for understanding ViT inner workings through concept circuits. ViSAE consists of three components: (1) A probing suite with 64K images and a 16K visually grounded concept vocabulary, improving concept coverage efficiency by 20× over ImageNet and interpretation accuracy by 28.7\% over existing concept sets. (2) Top-down concept reading and Bottom-up circuit tracing algorithms that automatically recover ViT inner workings via concept circuits. (3) Applications for auditing and steering ViT behavior. Through concept editing, ViSAE improves the worst-group accuracy on WaterBirds by 48.2\%, outperforming existing methods by 23.8\%. Our data and code: https://github.com/deep-real/ViSAE.

Little By Little: Continual Learning via Incremental Mixture of Rank-1 Associative Memory Experts
Haodong Lu, Chongyang Zhao, Jason Xue, Lina Yao, Kristen Moore, Dong Gong
Continual learning (CL) with large pre-trained models aims to incrementally acquire knowledge without catastrophic forgetting. Existing LoRA-based Mixture-of-Experts (MoE) methods expand capacity by adding isolated new experts while freezing old ones, but still suffer from redundancy, interference, routing ambiguity, and consequent forgetting. We investigate the issues stemming from coarse-grained expert granularity. Coarse-grained experts (e.g., high-rank LoRA) encode low-specialty information, leading to expert duplication/interference and routing degradation/confusion as experts accumulate. In this work, we propose MoRAM (Mixture of Rank-1 Associative Memory). Grounded in the view that weight matrices act as linear associative memories, MoRAM achieves CL as incremental expansion of reusable atomic rank-1 experts as memory. Each rank-1 adapter acts as a fine-grained MoE expert or an associative memory unit. By viewing rank-1 experts as key-value memory pairs, we eliminate explicit MoE-LoRA routers with self-activation, where each memory atom evaluates its relevance via its intrinsic key. The inference process thus becomes a content-addressable retrieval and recall over the incrementally accumulated memory of learning snapshots. Extensive experiments on CLIP and LLMs show that MoRAM significantly outperforms state-of-the-art methods, achieving a better plasticity–stability trade-off, stronger generalization, and reduced forgetting. Project page: https://artificer-ai-lab.github.io/MoRAM.

Meta Context Engineering via Agentic Skill Evolution
Haoran Ye, Xuning He, Vincent Arak, Haonan Dong, Guojie Song
The operational efficacy of large language models relies heavily on their inference-time context. This has established Context Engineering (CE) as a formal discipline for optimizing these inputs. Current CE methods rely on manually crafted harnesses, such as rigid generation-reflection workflows and predefined context schemas. They impose structural biases and restrict context optimization to a narrow, intuition-bound design space. To address this, we introduce Meta Context Engineering (MCE), a bi-level framework that supersedes static CE heuristics by co-evolving CE skills and context artifacts. In MCE iterations, a meta-level agent refines engineering skills via agentic crossover, a deliberative search over the history of skills, their executions, and evaluations. A base-level agent exec

utes these skills, learns from training rollouts, and optimizes context as flexible files and code. We evaluate MCE across five disparate domains under offline and online settings. MCE demonstrates consistent performance gains, achieving 5.6--53.8% relative improvement over state-of-the-art agentic CE methods (mean of 16.9%), while maintaining superior context adaptability, transferability, and efficiency in both context usage and training. Code is available at \url{https://github.com/henry-yeh/mce}.

Identifying Common Hubs in Multiple Gaussian Graphical Models
José Á Sánchez Gómez, Weibin Mo, Junlong Zhao, Yufeng Liu
The Gaussian graphical model (GGM) is a useful tool to represent relationships of conditional dependence among variables. In many real-world applications, datasets often contain multiple related sub-populations, whose associated GGMs may have common structure, as well as large structural differences. In such cases, it is useful to recover common hub variables, which are the highly connected variables in the GGMs of all sub-populations. In this paper, we propose the Joint Inverse Components for Hub Detection (JIC-HD) method to recover the common hubs across multiple GGMs without the need to estimate all subpopulation GGMs. To this end, we introduce joint minimax eigenspaces, and show that these can be leveraged for the recovery of common hubs. We establish theoretical guarantees for the recovery of common hubs. Additionally, our numerical simulation studies confirm superior performance of our JIC-HD in detecting common hubs compared to the existing methods in the literature. Our method is especially advantageous when the multiple GGMs have both common and individual hubs across sub-populations. Finally, we analyze cancer gene-expression datasets and identify biologically meaningful common hub genes across cancer subtypes.

Geometric Entropy and Retrieval Phase Transitions in Continuous Thermal Dense Associative Memory
Tatiana Petrova, Evgeny Polyachenko, Radu State
We study the thermodynamic memory capacity of modern Hopfield networks (Dense Associative Memory models) with continuous states under geometric constraints, extending classical analyses of pairwise associative memory. We derive thermodynamic phase boundaries for Dense Associative Memory networks with exponential capacity $M = e^{\alpha N}$, comparing Gaussian (LSE) and Epanechnikov (LSR) kernels. For continuous neurons on an N-sphere, the geometric entropy depends solely on the spherical geometry, not the kernel. In the sharp-kernel regime, the maximum theoretical capacity $\alpha = 0.5$ is achieved at zero temperature; below this threshold, a critical line separates retrieval from non-retrieval. The two kernels differ qualitatively in their phase boundary structure: for LSE, a critical line exists at all loads $\alpha > 0$. For LSR, the finite support introduces a threshold α_{th} below which no spurious patterns contribute to the noise floor, and no critical line exists -- retrieval is perfect at any temperature. These results advance the theory of high-capacity associative memory and clarify fundamental limits of retrieval robustness in modern attention-like memory architectures.

TrustworthyQENN: A Quantum Evidential Neural Network Based on Complex-Valued Contrastive Learning for Uncertainty Pattern Classification
Xiaolong Chen, Fuyuan Xiao, Xiaohong Zhang, Zehong Cao, Chin-teng Lin
Out-of-distribution (OOD) detection requires accurately classifying in-distribution (ID) samples while effectively distinguishing anomalous OOD data. However, existing methodologies predominantly rely on real-valued magnitude features, neglecting the semantic richness embedded in phase information, and often lack a systematic theoretical framework for quantitively modeling uncertainty. To address this dual limitation of incomplete feature representation and insufficient uncertainty modeling, the trustworthy quantum evidence neural network (TrustworthyQENN) is proposed, a novel quantum-inspired framework bridging complex-valued representation learning with generalized quantum evidence theory (GQET). Specifically, supervised complex-valued contrastive learning (SCVCL) is proposed to synchron

ize amplitude distributions with phase correlations, thereby enforcing high intra-class compactness and inter-class separability for ID data. A quantum evidence generation mechanism based on GQET is subsequently devised, where the OOD state is formally grounded as the quantum empty set within a Hilbert space. Furthermore, the generalized quantum evidential combination rule (GQECR) is leveraged to fuse multi-view evidence, thereby achieving trustworthy inference. Extensive experiments on the MSTAR, EuroSAT, and FUSAR-Ship benchmarks substantiate the superiority of TrustworthyQENN, which achieves a peak AUROC of 95.94\% on the MSTAR dataset while consistently outperforming state-of-the-art methods across all evaluated scenarios.

TFTF: Training-Free Targeted Flow for Conditional Sampling
Qianqian Qu, Jun S. Liu
We propose a training-free conditional sampling method for flow matching models based on importance sampling. Because a naïve application of importance sampling suffers from weight degeneracy in high-dimensional settings, we modify and incorporate a resampling technique in sequential Monte Carlo (SMC) during intermediate stages of the generation process. To encourage the generated samples to diverge along distinct trajectories, we derive a stochastic flow with adjustable noise strength to replace the deterministic flow at the intermediate stage. Our framework requires no additional training, while providing theoretical guarantees of asymptotic accuracy. Experimentally, our method significantly outperforms existing approaches on conditional sampling tasks for MNIST and CIFAR-10. We further demonstrate the applicability of our approach in higher-dimensional, multimodal settings through text-to-image generation experiments on CelebA-HQ.
****

DFlash: Block Diffusion for Flash Speculative Decoding
Jian Chen, Yesheng Liang, Zhijian Liu
Autoregressive large language models (LLMs) deliver strong performance but require inherently sequential decoding, leading to high inference latency and poor GPU utilization. Speculative decoding mitigates this bottleneck by using a fast draft model whose outputs are verified in parallel by the target LLM. However, existing methods still rely on *autoregressive drafting*, which remains sequential and constrains practical speedups. Diffusion LLMs offer a promising alternative by enabling parallel generation, but current diffusion models typically underperform compared with autoregressive models. In this paper, we introduce **DFlash**, a speculative decoding framework that employs a lightweight block diffusion model for parallel drafting. We show that speculative decoding provides a natural and effective setting for diffusion models. By generating draft tokens in a single forward pass, DFlash enables efficient drafting, and by conditioning the draft model on context features extracted from the target model, it achieves high-quality drafts with higher acceptance rates. Experiments show that DFlash achieves over 6$\times$ lossless acceleration across a range of models and tasks, delivering up to 2.5$\times$ higher speedup than the state-of-the-art speculative decoding method EAGLE-3.

Stable-GFlowNet: Toward Diverse and Robust LLM Red-Teaming via Contrastive Trajectory Balance
Minchan Kwon, Sunghyun Baek, Minseo Kim, Jaemyung Yu, Dongyoon Han, Junmo Kim
Large Language Model Red-Teaming, which proactively identifies vulnerabilities of large language models, is an essential process for ensuring safety.
Finding effective and diverse attacks in red team activities is important, but achieving both is challenging.
Generative Flow Networks (GFN) that perform distribution matching are a promising method, but they are notorious for training instability and mode collapse.
In particular, unstable reward functions in red team activities accelerate mode collapse.
We propose Stable-GFN (S-GFN), which eliminates Z estimation in GFN and reduces training instability.
S-GFN avoids Z-estimation through pairwise comparisons and employs a robust mask

ing methodology against noisy rewards.
Additionally, we propose a fluency stabilizer to prevent the model from getting stuck in local optima that produce gibberish.
S-GFN provides more stable training while maintaining the optimal policy of GFN. We demonstrate the overwhelming attack performance and diversity of S-GFN across various settings.

In-Training Defenses Against Emergent Misalignment in Language Models
David Kaczér, Magnus Jørgenvåg, Clemens Vetter, Esha Afzal, Robin Haselhorst, Lucie Flek, Florian Mai
Fine■tuning lets practitioners repurpose aligned large language models (LLMs) for new domains, yet recent work reveals emergent misalignment (EM): Even a small, domain■specific fine■tune can induce harmful behaviors far outside the target domain. Even in the case where model weights are hidden behind a fine-tuning API, this gives attackers inadvertent access to a broadly misaligned model in a way that can be hard to detect from the fine-tuning data alone. We present the first systematic study of \emph{in■training} safeguards against EM that are practical for providers who expose fine■tuning via an API: We evaluate whether they a) prevent broad misalignment, b) allow narrow misalignment, c) learn well on benign tasks, and d) remain coherent. We investigate five training regularization interventions: (i) KL■divergence regularization toward a safe reference model, (ii) ℓ_2 distance in feature space, (iii) preventive steering with an evil persona vector, (iv) interleaving training examples from a general instruct-tuning dataset and (v) inoculation prompting. We demonstrate that selecting interleaving data by the perplexity gap between aligned and misaligned models yields the best results overall.

Provably Data-driven Lagrangian Relaxation for Mixed Integer Linear Programming
TUNG QUOC LE, Anh Tuan Nguyen, Viet Anh Nguyen
Lagrangian Relaxation (LR) is a powerful technique for solving large-scale mixed-integer linear programs, particularly those with decomposable structures, such as vehicle routing or unit commitment problems. By relaxing the coupling constraints, LR enables parallel subproblem solving and often yields tighter dual bounds than standard linear programming relaxations, which is crucial for efficient branch-and-bound pruning. While recent empirical work has shown promising results using machine learning to predict these multipliers, a theoretical understanding of such methods remains an open question. In this work, we bridge this gap by analyzing the problem of learning LR through the lens of data-driven algorithm design, i.e., a statistical learning problem over a distribution of problem instances. Our contributions are as follows: first, we derive a generalization bound of $\mathcal{O}(s^{1.5}/\sqrt{N})$ for the learned multipliers, where s is the number of coupling constraints and N is the sample size. Second, we provide a minimax lower-bound of $\Omega(s/\sqrt{N})$, proving that a linear dependency is unavoidable. Third, we constructively close this theoretical gap by proving that stochastic gradient ascent with averaging achieves the minimax optimal rate $\Theta(s/\sqrt{N})$. Finally, we extend our framework to the learning-to-warm-start setting, proving that it achieves a fast, minimax-optimal rate of $\Theta(s/N)$ and establishing a theoretical advantage over direct multiplier prediction.

Streaming Covariate Balancing via Discrepancy-Based Feature Coresets
Yixin Ren, Chenghou Jin, Yewei Xia, Zichuan Lin, Deheng Ye, Hao Zhang, Jihong Guan, Shuigeng Zhou
Real-time estimation of average treatment effects (ATE) in streaming observational data poses two key challenges: strict memory constraints that preclude storing the full data history, and distributional shifts in both treatment assignment and outcome-generating process. Existing methods either require offline access to the entire dataset for covariate balancing or rely on parametric online models that are vulnerable to model misspecification under such shifts. This paper proposes a novel model-agnostic method for ATE estimation in streaming data, which effectively addresses the above challenges. Based on discrepancy theory, we firs

t compress streaming data into feature coresets that preserve covariate balancin g objectives over a rich nonparametric function class, enabling linear-time upda tes with bounded memory. Then, by directly learning balancing weights and bypass ing parametric propensity score estimation, we enhance the model's robustness ag ainst the shift in treatment assignment, while by balancing over an expressive f unction space we make the model more adaptive to the shift in the outcome-genera ting process. Theoretically, we establish convergence guarantees with explicit b ounds on memory usage and computational complexity. Empirically, extensive exper iments on both synthetic and real-world datasets show the effectiveness and robu stness of the proposed method, consistently outperforming existing techniques.

Agent World Model: Infinity Synthetic Environments for Agentic Reinforcement Lea rning

Zhaoyang Wang, Canwen Xu, Boyi Liu, Yite Wang, Siwei Han, Zhewei Yao, Huaxiu Yao , Yuxiong He

Recent advances in large language model (LLM) have empowered autonomous agents t o perform multi-turn interactions with tools and environments. However, scaling such agent training is limited by the lack of diverse and reliable environments. In this paper, we propose Agent World Model (AWM), a fully synthetic environment generation pipeline. Using this pipeline, we scale to 1,000 environments coveri ng everyday scenarios, in which agents can interact with rich toolsets and obtai n high-quality observations. Notably, these environments are code-driven and bac ked by databases, providing more reliable and consistent state transitions than environments simulated by LLMs. Moreover, they enable more efficient agent inter action compared with collecting trajectories from realistic environments. To dem onstrate the effectiveness of this resource, we perform large-scale reinforcemen t learning for multi-turn tool-use agents. Thanks to the fully executable enviro nments and accessible database states, we can also design reliable reward functi ons. Experiments on three benchmarks show that training exclusively in synthetic environments, rather than benchmark-specific ones, yields strong out-of-distrib ution generalization. The code is available at https://github.com/Snowflake-Labs /agent-world-model.

Don't Forget Why You Started: Tackling Dual Forgetting in Vision-Language Contin ual Learning

Borui Kang, Jinrui Gu, Tao Feng, Qi Fan, Yinghuan Shi, Lei Wang, Wenbin Li, Yang Gao

Continual learning of Vision-Language Model (VLM) aims to empower models with ne w expertise without compromising zero-shot capabilities.

However, this pursuit faces a critical “dual-forgetting” challenge: catastrophic forgetting of newly acquired classes (Incremental Knowledge Forgetting, IKF) an d erosion of foundational zero-shot capabilities (Pre-trained Knowledge Forgetti ng, PKF).

Existing evaluations often ignore PKF or assess it via confounded protocols wher e positive transfer on semantically similar domains creates an illusion of reten tion, masking severe foundational degradation.

To address this, we propose the Dual-Forgetting-Aware Class-Incremental Learning (DFA-CIL) framework and the Similarity-Calibrated Retention (SCR) metric.

Unlike standard averaging, SCR uses the frozen pre-trained feature space to inve rsely weight performance by semantic similarity, mitigating confounding gains to stress-test foundational stability.

Building on this, we propose DFA-MoE, a functionally heterogeneous Parameter-Eff icient Fine-Tuning (PEFT) method.

DFA-MoE decouples optimization objectives by assigning a momentum-enhanced contr astive expert for feature alignment, and separate plasticity experts combining c lassification with auxiliary contrastive learning to adapt to new tasks while re taining historical knowledge.

Extensive experiments show that our framework reveals the hidden fragility of ex isting methods and achieves a state-of-the-art balance in preserving both increm ental and pre-trained knowledge. Our code is available at https://github.com/RL-

MIND/DFA-MoE.

How High is ‘High’? Rethinking the Roles of Dimensionality in Topological Data Analysis and Manifold Learning
Hannah Sansford, Nick Whiteley, Patrick Rubin-Delanchy
High-dimensionality of data is often regarded as a fundamental statistical impediment in Machine Learning and AI. The purpose of this paper is to clarify, on the contrary, when and how high-dimensionality may be beneficial. In the setting of a general random function model of data we delineate between three notions of dimensionality: *effective dimension* p_{eff}, measuring total variability across feature directions; *correlation rank* r, measuring functional complexity across samples; and *latent intrinsic dimension* d of manifold structure hidden in data. Via a generalized Hanson-Wright inequality, we show that increasing p_{eff} drives a *blessing of dimensionality* phenomenon, whereby data dot-products concentrate about their expectations. In turn, we show that, under mild continuity assumptions (ensuring that features bring additional information as dimension grows), persistence diagrams recover latent homology when $p_{\mathrm{eff}} \in \omega (\log n)$ as $n\to\infty$. Informed by our theory, we revisit the ground-breaking neuroscience discovery of toroidal structure in grid-cell activity made by Gardner et al. (2022): our findings provide the first empirical evidence that this structure is *isometric* to a flat torus model of physical space, suggesting that grid cell activity conveys a geometrically faithful representation of the real world.

Designing Observation and Action Models for Efficient Reinforcement Learning with LLMs
Deunsol Yoon, Sunghoon Hong, Whiyoung Jung, Junseok Park, Geon-Hyeong Kim, Woohyung Lim, Soonyoung Lee, Seung Hwan Kim, Kanghoon Lee
Large Language Models (LLMs) have emerged as powerful tools for semantic reasoning, enabling the formalization of tasks that traditionally relied on manual human intuition. This capability extends to environment design in reinforcement learning. While prior research predominantly focuses on reward design, the design of observation and action spaces remains relatively underexplored. We propose LLM-based design of Observation and Action Models (LOAM), a framework leveraging LLMs to construct refined agent spaces from raw environments. To mitigate the computational burden of identifying the best candidate model from stochastic LLM outputs, LOAM incorporates a continuous racing mechanism that dynamically allocates resources to prioritize the most promising configurations without additional training overhead. Empirical evaluations on HumanoidBench and Isaac Lab demonstrate that LOAM consistently outperforms handcrafted baselines in both learning speed and asymptotic performance.
****
A Mechanistic Analysis of Sim-and-Real Co-Training in Generative Robot Policies
Yu Lei, Minghuan Liu, Abhiram Maddukuri, Zhenyu Jiang, Yuke Zhu
Co-training, which combines limited in-domain real-world data with abundant surrogate data such as simulation or cross-embodiment robot data, is widely used for training generative robot policies. Despite its empirical success, the mechanisms that determine when and why co-training is effective remain poorly understood.

We investigate the mechanism of sim-and-real co-training through theoretical analysis and empirical study, and identify two intrinsic effects governing performance. The first, "structured representation alignment", reflects a balance between cross-domain representation alignment and domain discernibility, and plays a primary role in downstream performance. The second, the "importance reweighting effect", arises from domain-dependent modulation of action weighting and operates at a secondary level.

We validate these effects with controlled experiments on a toy model and extensive sim-and-sim and sim-and-real robot manipulation experiments. Our analysis offers a unified interpretation of recent co-training techniques and motivates a simple method that consistently improves upon prior approaches.

More broadly, our aim is to examine the inner workings of co-training and to facilitate research in this direction.
****
AugMask: Training Diffusion Models on Incomplete Tabular Data via Stochastic Augmentation and Masking
Jungkyu Kim, Taeyoung Park, Kibok Lee
Score-based diffusion models have emerged as prominent deep generative models; however, their application to tabular data remains challenging because their backbones assume fully specified inputs, whereas real-world tabular data often contain missing values.
We propose **AugMask**, a plug-and-play training framework that adapts missing-unaware backbones to incomplete data via stochastic regularization.
AugMask 1) completes inputs via *conditional stochastic augmentation* using lightweight auxiliary models and 2) masks the loss, using augmented missing entries for conditioning while restricting supervision to observed coordinates.
We connect AugMask to a Rao-Blackwellized objective and show that marginalizing missing entries yields a variance-weighted sensitivity penalty, promoting invariance of observed-coordinate reconstruction with respect to uncertain missing entries.
Across diverse datasets and missingness regimes, AugMask enables standard diffusion-based tabular generators to match or outperform specialized missing-aware baselines in both sample fidelity and downstream utility.
The code will be released.
****
Language Model Circuits Are Sparse in the Neuron Basis
Aryaman Arora, Zhengxuan Wu, Jacob Steinhardt, Sarah Schwettmann
The high-level concepts that a neural network uses to perform computation need not be aligned to individual neurons (Smolensky, 1986).
Language model interpretability research has thus turned to techniques which decompose the neuron basis into more interpretable units of model computation, such as sparse autoencoders (SAEs).
However, not all neuron-based representations are uninterpretable.
For the first time, we empirically show that **MLP neurons are as sparse a feature basis as SAEs**.
We use this finding to develop an end-to-end gradient-based attribution pipeline for circuit tracing on the MLP neuron basis, which surfaces causally effective neurons on a variety of tasks.
On a standard subject-verb agreement benchmark (Marks et al., 2025), a circuit of $\approx 10^2$ MLP neurons is enough to control model behaviour.
On the multi-hop city-state-capital task from Lindsey et al. (2025), we find a circuit in which small sets of neurons encode specific latent reasoning steps (e.g. mapping a city to its state), and can be steered to change the model's output.
This work thus advances automated interpretability of language models without imposing additional training costs.
****
Embedding Trust: Semantic Isotropy Predicts Nonfactuality in Long-Form Text Generation
Dhrupad Bhardwaj, Julia Kempe, Tim G. J. Rudner
To deploy large language models (LLMs) in high-stakes application domains that require substantively accurate responses to open-ended prompts, we need reliable, computationally inexpensive methods that assess the trustworthiness of long-form responses generated by LLMs. However, existing approaches often rely on claim-by-claim fact-checking, which is computationally expensive and brittle in long-form responses to open-ended prompts. In this work, we introduce semantic isotropy---the degree of uniformity across normalized text embeddings on the unit sphere---and use it to assess the trustworthiness of long-form responses generated by LLMs. To do so, we generate several long-form responses, embed them, and estimate the level of semantic isotropy of these responses as the angular dispersion of the embeddings on the unit sphere. We find that higher semantic isotropy---tha

t is, greater embedding dispersion---reliably signals lower factual consistency across samples. Our approach requires no labeled data, no fine-tuning, and no hyperparameter selection, and can be used with open- or closed-weight embedding models. Across multiple domains, our method consistently outperforms existing aggregate trust signals in predicting nonfactuality using only a handful of samples, offering a practical, low-cost first-pass signal that complements claim-level verification in real-world LLM workflows.

A Behavioural and Representational Evaluation of Goal-Directedness in Language Model Agents
Raghu Arghal, Phoebe Chen, Niall Dalton, Evgenii Kortukov, Calum McNamara, Angelos Nalmpantis, Moksh Nirvaan, Gabriele Sarti, Mario Giulianelli
Understanding an agent's goals helps explain and predict its behaviour, yet there is no established methodology for reliably attributing goals to agentic systems. We propose a framework for evaluating goal-directedness that integrates behavioural evaluation with interpretability-based analyses of models' internal representations.
As a case study, we examine an LLM agent navigating a 2D grid world toward a goal state.
Behaviourally, we evaluate the agent against optimal policies across varying grid sizes, obstacle densities, and goal structures, finding that performance scales with task difficulty while remaining robust to difficulty-preserving transformations and multi-goal structures.
We then use probing methods to decode internal representations of the environment and multi-step action plans. We find that the LLM agent non-linearly encodes a coarse spatial map, preserving approximate task-relevant cues about its position and the goal location; that its actions are broadly consistent with these internal representations; and that reasoning reorganises them, shifting from spatial cues toward immediate action selection.
Our findings support the view that introspective examination is required beyond behavioural evaluations to characterise how agents represent and pursue their objectives.
****
Erased but Not Forgotten: How Backdoors Compromise Concept Erasure
Tobias Braun, Jonas Henry Grebe, Patrick Mohr Gordillo, Marcus Rohrbach, Anna Rohrbach
The expansion of text-to-image diffusion models has raised concerns about harmful outputs, from fabricated depictions of public figures to sexually explicit imagery. To mitigate such risks, prior work has proposed concept erasure methods that aim to sever unwanted concepts from the model via fine-tuning, yet it remains unclear whether these approaches truly remove all links to the harmful concept or merely conceal superficial connections. In this work, we reveal a critical vulnerability, the Erasure Evasion Backdoor (EEB): an adversary binds a backdoor trigger to a concept slated for removal, and this malicious link survives subsequent erasure. We show that both black-box and white-box adversaries can instantiate this threat. Across six state-of-the-art erasure methods, including robust ones that explicitly search for alternative representations of the target concept, EEB consistently exposes harmful content: up to 82% success against celebrity-identity unlearning, up to 94% for object erasure, and up to 16$\times$ amplification of explicit-content exposure. While EEB uncovers a blind spot in current erasure methods, it also provides a diagnostic tool for stress-testing future concept erasure techniques.
****
Understanding the Gaps in Satisficing Bandits
Chloé Rouyer, Ronald Ortner, Peter Auer
We study a variant of the stochastic multi-armed bandit problem in which the learner aims to identify and play an arbitrary arm whose expected reward exceeds a known satisficing threshold S, rather than optimizing against the best arm. Prior work has shown that when such a satisficing arm exists, time-independent bounds on the satisficing regret are achievable, but these guarantees deteriorate w

hen an arm lies close to the threshold. We focus on instances in which the exces s gap Δ_* (gap between the best arm and the threshold) is small relative to the suboptimality gaps Δ_i, a regime that exposes this limitation. To capture this challenge, we introduce a refined notion of regret and propose a ne w algorithm, uncertain-UCB, which achieves *satisficing* pseudo-regret of
$
O \left(\sum_{i: \Delta_i > \Delta_*} \frac{\ln(K/\Delta_*)}{\Delta_i}\right),
$
while recovering standard pseudo-regret bounds when no arm exceeds the threshold .

Further, we establish a near-matching lower bound in the small excess-gap regime , showing that any algorithm incurs at least
$
\Omega \left(\sum_{i: \Delta_i > \Delta_*} \frac{\ln \big(\frac{\Delta}{(K-1) \ Delta_* }\big)}{\Delta_i}\right)
$ satisficing pseudo-regret.
****

Do Neural Operators Forget Geometry? The Forgetting Hypothesis in Deep Operator Learning

Yanming Xia, Angelica I Aviles-Rivero

Neural operators perform well on structured domains, yet their behaviour on irre gular geometries remains poorly understood. We show that this limitation is not merely an encoding issue, but a depth-wise failure mode inherent to deep operato r architectures. We formalise the *Geometric Forgetting Hypothesis*: due to the Markovian structure of operator layers and their reliance on global mixing mecha nisms, neural operators progressively lose access to domain geometry as depth in creases. Using layer-wise geometric probing, we demonstrate that both spectral a nd attention-based operators systematically lose geometric fidelity. We show tha t this geometric forgetting degrades accuracy, stability, and generalisation. To counteract it, we introduce a lightweight *geometry memory injection* mechanism that restores geometric constraints at intermediate depths with minimal archite ctural overhead. This simple intervention consistently mitigates forgetting and exposes a *geometric shortcut* instability in transformer-based operators, revea ling that geometric retention is a structural requirement rather than a design c hoice.

Adaptive Sharpness-Aware Minimization with a Polyak-type Step size: A Theory-Gro unded Scheduler

Dimitris Oikonomou, Nicolas Loizou

Sharpness-Aware Minimization (SAM) has established itself as a powerful and wide ly adopted optimizer for training machine learning models. By explicitly minimiz ing the sharpness of the loss landscape, SAM often improves generalization while delivering strong empirical performance. However, SAM and its variants, like mo st training algorithms, are sensitive to the choice of learning rate, which is t ypically selected through extensive hyperparameter tuning or predefined schedule rs. In this work, motivated by recent advances on the effectiveness of stochasti c Polyak step sizes for Stochastic Gradient Descent (SGD), we derive Polyak sche dulers tailored to SAM-style updates, yielding novel adaptive algorithms in both deterministic and stochastic settings. In the smooth setting, we prove linear c onvergence for strongly convex objectives and an $\mathcal{O}(1/T)$ convergence rate for convex objectives in the deterministic case. In the stochastic setting, we establish analogous convergence guarantees up to a neighborhood of the optim um. Numerical experiments demonstrate that the proposed Polyak schedulers achiev e performance comparable to or better than carefully tuned SAM baselines, while substantially reducing the need for learning-rate tuning.

How can we assess human-agent interactions? Case studies in software agent desig n

Valerie Chen, Rohit Malhotra, Xingyao Wang, Juan Michelini, Xuhui Zhou, Aditya B

harat Soni, Hoang H. Tran, Calvin Smith, Ameet Talwalkar, Graham Neubig
While benchmarks measure the accuracy of LLM-powered agents, they mostly assume full automation, failing to represent the collaborative nature of real-world use cases. In this paper, we make two major steps towards the rigorous assessment of human-agent interactions. First, we propose PULSE, a framework for more efficient human-centric evaluation of agent designs, which comprises collecting user feedback, training an ML model to predict user satisfaction, and computing results by combining human satisfaction ratings with model-generated pseudo-labels. Second, we deploy PULSE n software engineering---one of the highest-impact, real-world domains for LLM agents---via a large-scale web platform built around the open-source agent OpenHands. Across 15k users, we evaluate how three agent design decisions impact developer satisfaction rates. We also show how PULSE can lead to more robust conclusions about agent design, reducing confidence intervals by 40% compared to a standard A/B test. Finally, we find substantial discrepancies between in-the-wild results with benchmark performance (e.g., the anti-correlation between claude-sonnet-4 and gpt-5, underscoring the limitations of benchmark-driven evaluation. Our framework PULSE provides guidance for future evaluations, and our findings identify opportunities for better software agent designs.

Harmful Overfitting in Sobolev Spaces
Kedar Karhadkar, Alexander Sietsema, Deanna Needell, Guido Montufar
Motivated by recent work on benign overfitting in overparameterized machine learning, we study the generalization behavior of functions in Sobolev spaces $W^{k, p}(\mathbb{R}^d)$ that perfectly fit a noisy training data set. Under assumptions of label noise and sufficient regularity in the data distribution, we show that approximately norm-minimizing interpolators, which are canonical solutions selected by smoothness bias, exhibit harmful overfitting: even as the training sample size $n \to \infty$, the generalization error remains bounded below by a positive constant with high probability. Our results hold for arbitrary values of $p \in [1, \infty)$, in contrast to prior results studying the Hilbert space case ($p = 2$) using kernel methods. Our proof uses a geometric argument which identifies harmful neighborhoods of the training data using Sobolev inequalities.
****
Non-Uniform Noise-to-Signal Ratio in the REINFORCE Policy-Gradient Estimator
Haoyu Han, Heng Yang
Policy-gradient methods are widely used in reinforcement learning, yet training often becomes unstable or slows down as learning progresses. We study this phenomenon through the **noise-to-signal ratio** (NSR) of a policy-gradient estimator, defined as the estimator variance (noise) normalized by the squared norm of the true gradient (signal). Our main result is that, for (i) finite-horizon linear systems with Gaussian policies and linear state-feedback, and (ii) finite-horizon polynomial systems with Gaussian policies and polynomial feedback, the NSR of the REINFORCE estimator can be characterized exactly—either in closed form or via numerical moment-evaluation algorithms—without approximation. For general nonlinear dynamics and expressive policies (including neural policies), we further derive a general upper bound on the variance. These characterizations enable a direct examination of how NSR varies across policy parameters and how it evolves along optimization trajectories (e.g. SGD and Adam). Across a range of examples, we find that the NSR landscape is highly non-uniform and typically increases as the policy approaches an optimum; in some regimes it blows up, which can trigger training instability and policy collapse.
****
Progressive Graph Structure Adjustment for Homophily Shift Adaptation
Hongwei Wen, Can Zhang, Haoyu He, Hanyuan Hang, Minglong Lei
We propose *Progressive Structure Adjustment for Homophily Shift* (*PSAHS*), a lightweight method for *Graph Domain Adaptation* (*GDA*) that explicitly addresses cross-domain mismatch in node-level homophily. PSAHS enhances node homophily in the source graph to a prescribed level by reweighting edges and introducing additional intra-class connections for low-homophily nodes, and conservatively refines the target graph using agreement-consistent predictions from a structure-aw

are *Graph Neural Network* (*GNN*) and an attribute-only *Multi-Layer Perceptron* (*MLP*) to ensure reliability under label scarcity. After each structural refinement, domain-adversarial training is employed to align node representations across domains. PSAHS employs a progressive training scheme that alternates between structure adjustment and representation alignment, where increasingly informative representations enable safer homophily correction, and the refined structure in turn improves representation learning. Extensive experiments on multiple GDA benchmarks demonstrate that PSAHS consistently outperforms strong baselines, with particularly large gains under severe homophily mismatch, highlighting the importance of explicit homophily alignment for effective cross-graph transfer.

APE-Bench: Evaluating Automated Proof Engineering for Formal Math Libraries
Huajian Xin, Zheng Yuan, Jacques D. Fleuriot, Wenda Li
While frontier formal mathematics systems now routinely develop repository-scale proof engineering artifacts requiring multi-file coordination and semantic correctness beyond compilation, existing evaluation benchmarks remain focused on isolated theorem proving. We introduce Automated Proof Engineering (APE), the first systematic framework for evaluating repository-scale proof engineering through dual verification that validates both syntactic compilation and semantic requirement satisfaction in pinned library environments. We present a complete infrastructure comprising APE-Bench, which automatically extracts proof engineering tasks from real library commit histories, and APE-Harness, a unified execution framework based on task contract abstraction. This contract-based design enables standardized evaluation across diverse formal mathematics tasks and fair systematic comparison of different agent implementations (including our APE-Agent reference scaffold alongside Claude Code and Codex CLI) on identical task specifications. We demonstrate the framework's effectiveness through comprehensive evaluation. All code, benchmarks, and infrastructure will be open-sourced.

Compositional Transduction with Latent Analogies for Offline Goal-Conditioned Reinforcement Learning
Junseok Kim, Dohyeong Kim, Mineui Hong, Songhwai Oh
Compositional generalization is essential for reaching unseen goals under novel contextual variations in offline goal-conditioned reinforcement learning (GCRL), where a generalist goal-reaching agent must be learned from limited data. Most prior approaches pursue this via trajectory stitching over temporally contiguous segments, which limits composing behaviors across varying contexts. To overcome this limitation, we formalize *analogy transduction* as synthesizing new plans by composing task-endogenous analogies with given contexts and propose a novel analogy representation tailored for it. Grounded in our theory, this analogy representation captures what changes under optimal task execution, remains invariant to contextual variations, and is sufficient for optimal goal reaching. We further contend that generalization to unseen analogy-context pairs is a practical obstacle in analogy transduction, and introduce a new approach for offline GCRL that enables analogy transduction beyond seen pairs to unseen combinations. We empirically demonstrate the effectiveness of our approach on OGBench manipulation environments, substantially outperforming prior methods that do not perform analogy transduction.
****

Empirical Gaussian Processes
Jihao Andreas Lin, Sebastian Ament, Louis C. Tiao, David Eriksson, Maximilian Balandat, Eytan Bakshy
Gaussian processes (GPs) are powerful and widely used probabilistic regression models, but their effectiveness in practice is often limited by the choice of kernel function.
This kernel function is typically handcrafted from a small set of standard functions, a process that requires expert knowledge, results in limited adaptivity to data, and imposes strong assumptions on the hypothesis space.
Re-evaluating this challenge from a hierarchical Bayesian and function-space view, we study Empirical GPs, a principled framework for constructing flexible, dat

a-driven GP priors that overcome these limitations. Rather than relying on standard parametric kernels, we estimate the mean and covariance functions empirically from a corpus of historical observations, enabling the prior to reflect rich, non-trivial covariance structures present in the data.
Theoretically, we show that the resulting model converges to the GP that is closest (in KL-divergence sense) to the real data-generating process. We formulate the problem of learning the GP prior from independent datasets as maximum likelihood estimation and derive an Expectation-Maximization algorithm with closed-form updates, allowing the model handle heterogeneous observation locations across datasets. We demonstrate that Empirical GPs achieve competitive performance on learning curve extrapolation and time series forecasting benchmarks.

RL4RLA: Teaching ML to Discover Randomized Linear Algebra Algorithms Through Curriculum Design and Graph-Based Search

Jinglong Xiong, Xiaotian Liu, Ruoxin Wang, Zihang Liu, Yefan Zhou, Yujun Yan, Yaoqing Yang

Randomized linear algebra (RLA) algorithms are a modern class of numerical linear algebra techniques that play an essential role in scientific computing and machine learning, with broad and growing adoption. However, their discovery remains mostly a manual process that requires deep expert knowledge and inspiration. While Reinforcement Learning (RL) offers a pathway to automation, standard approaches struggle with sparse reward landscapes and vast search spaces inherent to high-performing RLA algorithms.
In this paper, we present RL4RLA, a general RL framework that automates the discovery of interpretable, symbolic RLA algorithms. Unlike black-box approaches, our method builds explicit algorithms from basic linear algebra primitives, ensuring verifiable and implementable representations. To enable efficient discovery, we introduce: (1) a numerical curriculum that progressively increments problem difficulty to encode inductive bias specific to the RLA domain; (2) Monte Carlo Graph Search, which optimizes exploration by identifying and merging equivalent partial algorithms. We demonstrate that RL4RLA rediscovers state-of-the-art methods, including sketch-and-precondition solvers, Randomized Kaczmarz, and Newton Sketch, and can be targeted to produce algorithms optimized for specific trade-offs between accuracy, speed, and stability. Code is available at https://github.com/Tim-Xiong/RL4RLA.

Towards Complete Multi-Agent Coordination Policy Learning via Denoising Maximum Entropy Optimization

Guanghao Li, Lei Yuan, Ruiqi Xue, Hengchang Zhang, Jianhong Wang, Yi-Chen Li, Yang Yu

Parameter sharing is a widely used technique in Multi-Agent Reinforcement Learning (MARL) that enhances sample efficiency by equipping agents with a unified policy. While effective in homogeneous settings, it often struggles in heterogeneous environments where agents possess diverse capabilities. Conversely, learning customized policies for agents can resolve knowledge conflicts but significantly hinders knowledge transfer, thereby reducing learning efficiency. Existing approaches attempt to balance this trade-off using clustering or agent-specific masks, but they typically rely on strong environment-specific priors and struggle in settings where the team exhibits multi-modal policies. To address these limitations, we propose Dspic, an efficient shared-policy algorithm grounded in the maximum entropy framework. Specifically, Dspic employs self-supervised learning to extract discriminative role embeddings for each agent. These embeddings guide a complete division of the observation space, providing a theoretical guarantee for the optimality of parameter sharing. Furthermore, to handle the increased observation complexity and diversity resulting from this division, Dspic incorporates a diffusion policy, enhancing the capacity to model complex action distributions while enabling efficient learning. Extensive experiments on MaMuJoCo, SMAC, SMACv2, and LBF demonstrate that Dspic achieves superior sample efficiency while maintaining asymptotic optimality.

Selective Disclosure Watermarking for Large Language Models
Xuyang Chen, Xiang Li, Yangxinyu Xie, Qi Long
Watermarking methods embed imperceptible and verifiable signals into text generated by large language models (LLMs). Existing approaches include zero-bit schemes for distinguishing synthetic text from human writing and multi-bit schemes for embedding metadata. However, current multi-bit watermarking methods do not allow selective disclosure: verifying any part of the watermark requires revealing the entire embedded message. This lack of control leads to unnecessary information exposure and raises privacy concerns.
We propose Hierarchical Vocabulary Routing (HeRo), a watermarking framework that enables selective disclosure of embedded metadata. The method recursively partitions the vocabulary and distributes watermark information across hierarchical layers, so that different verifiers can decode only the portions of the payload corresponding to their access level. We show that the proposed scheme preserves the unbiasedness of the underlying sampling process and thus maintains text quality. Experiments demonstrate that our framework supports fine-grained access control while achieving high detection accuracy and low latency. Code is available at \url{https://github.com/xuyangc03/hero-watermark}.
****
Discontinuous Galerkin Neural Operator for Pathology Defocus Deblurring
Shaoqing Duan, Haofei Song, Xintian Mao, Qingli Li, Yan Wang
Defocus deblurring in pathological microscopy remains challenging due to the spatially varying and locally discontinuous nature of optical blur induced by a position-dependent integral imaging process.
Existing deep learning methods, constrained by shift-invariance assumptions and limited interpretability, are not well suited to such heterogeneous blur patterns.
Neural operators provide a principled alternative by modeling defocus formation directly as an integral operator, offering a new perspective on defocus deblurring.
However, most existing neural operator architectures for low-level vision rely on globally parameterized kernels that assume smoothness and stationarity, limiting their ability to model heterogeneous and locally discontinuous blur patterns.
To address this limitation, we propose the Discontinuous Galerkin Neural Operator (DGNO), which parameterizes the integral kernel using a discontinuous Galerkin formulation with element-local volume operators and interface numerical fluxes.
DGNO provides a principled combination of locality,
heterogeneity modeling, and global coherence while preserving the underlying physics
of optical image formation.
Extensive experiments demonstrate that DGNO surpasses state-of-the-art methods, delivering sharper reconstructions, robust handling of spatially varying blur, and scalable high-resolution performance.

DisPOSE: Projected Polystochastic Diffusion for Self-Supervised Multi-View 3D Human Pose Estimation
Tony Danjun Wang, Tolga Birdal, Nassir Navab, Lennart Bastian
Recovering 3D human poses for multiple individuals from different camera views is a fundamental bottleneck for analyzing interacting behaviors. Existing self-supervised approaches leverage synthetic catalogues of 3D poses; however, this leads to poor generalization in real-world scenarios due to distribution shifts. We therefore introduce DisPOSE, a self-supervised framework that approximates the inherently discrete multi-view person-assignment problem as a generative diffusion process over the space of polystochastic tensors. By employing differentiable Sinkhorn projections during denoising, our model learns to guide solutions toward valid and feasible assignments based on 2D image priors. The complete 3D skeletons of localized individuals are then regressed using a Hypergraph-Convolutional Decoder that explicitly models relational structures and articulated joints a

cross multiple views. The proposed approach outperforms current state-of-the-art self-supervised methods on standard datasets and demonstrates strong performance on a newly proposed benchmark featuring highly occluded scenes from surgical operating rooms. Our diffusion-based localization demonstrates high label efficiency, retaining 99\% of its performance with only 10\% of the pseudo-labels. Notably, disentangling the assignment and root regression components while maintaining differentiability makes DisPOSE nearly agnostic to different camera arrangements.
****
Problem Distributions as Tasks: Repurposing Meta Learning for Generative Combinatorial Optimization towards Multi-task Pretraining and Adaptation
Wenzheng Pan, Jiale Ma, Nuoyan Chen, Yang Li, Junchi Yan
Despite the fast progress of Neural Combinatorial Optimization (NCO) on graphs, existing solvers mainly learn a narrow task (e.g., uniform TSP) at a time and hardly handle instances over diverse distributions. This paper proposes M^{2}GenCO, a **M**ulti-task learning framework that pioneers the instantiation of the **M**eta-learning mechanism with diffusion-based **Gen**erative solving for **CO** Problems (COPs) on graphs, first formulating "tasks" in meta-learning as distinct problem types instead of instances of the same problem. With a tailored lightweight graph neural network, our framework performs effective joint pre-training on a variety of problem types and efficient fine-tuning to adapt for out-of-distribution scenarios. Further, we establish a benchmark comprising 5 classic graph COPs with varying scales and multiple distributions, forming 38 distinct test datasets that facilitate standard evaluation of generalizability and adaptability for NCO solvers. Empirically, M^{2}GenCO with greedy decoder yields an overall 9.16\% performance gain with an average 95.6$\times$ acceleration for inference, and achieves concrete state-of-the-arts on all test sets with simple local searchers, maintaining superior solving time against previous neural methods. The computational resource and time consumption for training are saved by up to 82% and 91%, respectively.
****
Generalization Bounds for Discrete Diffusion: Statistical Advantage of Masking
Zixuan Zhang, Hengyu Fu, Zhuoran Yang, Mengdi Wang, Tuo Zhao, Minshuo Chen
Discrete diffusion models have recently emerged as a compelling alternative for language generation, enabling efficient non-autoregressive sampling while achieving strong empirical performance. A key design choice in discrete diffusion---absent in most continuous diffusion formulations---is the forward corruption kernel, with masked/absorbing corruption now dominating practice. Despite this empirical preference, there is limited statistical theory explaining when and why masking should outperform alternative kernels such as uniform replacement. In this paper, we take a step toward closing this gap from a statistical learning perspective. Our analysis establishes generalization bounds and, through an explicit comparison across different forward corruption kernels, reveals a central advantage of masking: it scales with the effective data support rather than the full ambient state space, thereby mitigating the curse of state space cardinality. We further derive structure-aware refinements that capture how concentration and sparsity in real sequential data sharpen the sample complexities. Together, these results offer a principled explanation for the empirical strength of masked diffusion and provide guidance for forward-kernel design in discrete generative modeling.

Front-Loaded Robust Conformal Prediction: Heavy Calibration, Minimal Test-Time Cost
Soroush H. Zargarbashi, Mohammad Sadegh Akhondzadeh, Aleksandar Bojchevski
Robust conformal prediction (RCP) extends conformal prediction (CP) to noisy inputs by producing prediction sets with guaranteed coverage, ensuring that the true label is contained in the set with a user-specified probability even under worst-case perturbations. Recent works use randomized smoothing, as it provides robustness for black-box models at larger radii. Currently, there exist two setups for smoothing-based RCP: one requires extensive Monte Carlo sampling at calibrat

ion and test time but results in smaller prediction sets; the other setup produc es larger prediction sets but uses a single sample at both stages. In deployment , calibration—as a one-time pre-processing step—can accommodate substantially hi gher computational overhead than inference. Inspired by this observation, we int roduce an RCP framework that strikes a balance between the two extremes of this trade-off: we increase the sample rate at calibration time while keeping it eith er one or very low during test time. This calibration-time sampling opens the po ssibility of reducing the size of the prediction sets. In production, where the number of test predictions typically far exceeds the size of the calibration set , our Front-Loaded RCP matches the computational complexity of the state of the art while producing considerably smaller prediction sets at larger radii.

The Expressive Power of Low Precision Softmax Transformers with (Summarized) Cha in-of-Thought

Moritz Brösamle, Stephan Eckstein

Existing expressivity results for transformers typically rely on hardmax attenti on, high precision, and other architectural modifications that disconnect them f rom the models used in practice. We bridge this gap by analyzing standard transf ormer decoders with softmax attention and rounding of activations and attention weights, while allowing depth and width to grow logarithmically with the context length. As an intermediate step, we construct hardmax transformers with ternary activations and well-separated attention scores that simulate Turing machines u sing Chain-of-Thought (CoT). This lets us convert the constructions to equivalen t softmax transformers without the unrealistic parameter magnitudes or activatio n precision that prior approaches would require. Using the same technique, we an alyze a recently proposed summarized CoT paradigm and show that it simulates Tur ing machines more efficiently, with model size scaling logarithmically in a spac e bound rather than a time bound. We empirically test predictions made by our re sults on a Sudoku reasoning task and find better alignment with learnability tha n for prior high-precision results. Our code is available at https://github.com/ moritzbroe/transformer-expressivity.

ClimateAR: Multi-Scale Autoregressive Generative Modeling for Climate Forecastin g

Yue Yu, Weiqi Chen, Binqing Wu, Dongliang Cui, Wanyi Jiang, Zongjiang Shang, Bo Wu, Liang Sun, Ling Chen

Accurate climate forecasting provides critical support for decision-making in ag riculture, energy, and disaster preparedness. Current deterministic models often fail to capture climate uncertainty, while existing generative approaches overs implify the system by neglecting key spatiotemporal dependencies and cross-scale interactions. To address these limitations, we introduce ClimateAR, an AutoRegr essive generative model for probabilistic seasonal-to-interannual Climate foreca sting. The framework incorporates two novel components: (1) an aligned tokenizer that bridges and aligns heterogeneous simulation and real-world data to improve transferability across domains, and (2) a mixed-scale conditioning mechanism th at captures multi-scale climate interactions for robust probabilistic forecastin g. Extensive evaluations on the ERA5 reanalysis dataset show that ClimateAR achi eves state-of-the-art performance, improving anomaly correlation skill by 37.56\ % on average compared to leading baselines.

****
Lookahead Unmasking Elicits Reliable Decoding in Diffusion Language Models
Sanghyun Lee, Seungryong Kim, Jongho Park, Dongmin Park
Masked Diffusion Models (MDMs) as language models generate by iteratively unmasking tokens, yet their performance crucially depends on the inference-time order of unmasking. Conventional methods such as confidence-based sampling are short-sighted, focusing on local optimization which neglects test-time computation and allows early decoding errors to cascade. We propose Lookahead Unmasking (LookUM), which addresses these concerns by guiding sampling path with a verifier over alternative unmasking orders, without requiring an external reward model. Our framework couples (i) a path generator that proposes paths by sampling from pools of unmasking sets with (ii) a verifier that computes the uncertainty of the proposed paths and performs importance sampling to subsequently select the final paths. Erroneous unmasking inflates sequence-level uncertainty, and our method exploits this to avoid error-prone trajectories. We validate our framework across six benchmarks, such as mathematics, planning, and coding, and demonstrate consistent performance improvements. LookUM requires only two to three paths to achieve peak performance. LLaDA with LookUM matches the performance of RL-tuned LLaDA 1.5 and yields additional gains when applied to LLaDA 1.5, suggesting complementarity with reinforcement learning.
****
Coordinated Disentanglement with Iterative Mode Discovery Under Hidden Correlations
Rong Hu, Ling Chen
Disentangled representation learning is a powerful paradigm for robust attribute prediction. While recent methods address attribute correlations, hidden correlations remain underexplored, where data under the value of a certain attribute exhibit underlying modes correlated with other attributes. To preserve mode information and achieve disentanglement, we jointly discover modes and enforce mode-based conditional independence. Yet, the interdependency between these two modules may lead to error amplification under naive iterations. We propose Coordinated Disentanglement with Iterative mode Discovery (CoDID), an end-to-end framework featuring a dynamic architecture that adapts to evolving number of modes, and a coordination mechanism that mitigates error amplification via meta-optimization. Empirical results demonstrate the state-of-the-art performance on diverse tasks.
****
More Edits, More Stable: Understanding the Lifelong Normalization in Sequential Model Editing
Xin Ma, Wei Chen, Qi Liu, Derong Xu, Zhi Zheng, Tong Xu, Enhong Chen
Lifelong Model Editing aims to continuously update evolving facts in Large Language Models while preserving unrelated knowledge and general capabilities, yet it remains plagued by catastrophic forgetting and model collapse. Empirically, we find that recent editors resilient over long horizons share the same core strategy: **Lifelong Normalization (LN)**, which normalizes value gradients using running statistics. Removing LN causes immediate performance collapse, and we observe a counter-intuitive **positive cumulative effect** where early edits can promote the success of future edits. Yet the mechanism of LN remains a "black box", leaving its precise role in lifelong stability poorly understood. In this work, we provide the **first** theoretical account of LN in the lifelong regime. Our analysis reveals a self-reinforcing stability loop and proves that, when combined with ridge-regularized regression, LN yields parameter updates with **asymptotic orthogonality** and **bounded norms**, directly mitigating forgetting and systemic collapse. Based on these insights, we derive **StableEdit**, which strengthens this stability loop via an explicit warm-up stage and full whitening, improving long-horizon stability at minimal overhead. Extensive experiments validate our theory and demonstrate competitive performance. Our code is available at https://github.com/MINE-USTC/StableEdit.

Recursive Binding on a Budget: Subspace Carving in Order-p Tensor Memories
Travis Pence, Daisuke Yamada, Vikas Singh

Tensor Product Representations provide the structural fidelity required for symb
olic reasoning in models but suffer from *exponential* dimensionality growth whe
n encoding deep recursive structures. Conversely, Vector Symbolic Architectures
maintain *constant* dimensionality but sacrifice capacity and fidelity due to no
isy compression via superposition. In this work, we propose **Orthogonal Subspac
e Carving (OSC)**, a memory architecture that binds *fillers* to *roles* by proj
ecting onto the null space of the role basis before aggregating into a fixed ord
er-p tensor. OSC uses projections to enforce geometric orthogonality between b
ound structures within a {\em static} memory trace. We show that this mechanism
decouples the tensor order from the structural depth, enabling deep recursive bi
nding within a *constant* memory footprint. This construction allows for compone
nt vectors that are *orders of magnitude* smaller than the memory tensor, giving
excellent memory efficiency in settings involving high superposition. We also s
how that TPR is a special case of binding in Clifford algebra, and give a Cliffo
rd formulation of OSC.

Post-Hoc Merging is Not Enough: Many-Shot Model Merging with Loss-Gap Balancing
Kyungjin Im, Miru Kim, Chanin Eom, Minhae Kwon
Model merging has become a practical post-training strategy for building a singl
e multi-task large language model (LLM) by combining multiple task-specialized m
odels. However, most existing approaches rely on post-hoc merging, in which task
-specific models are merged only once after training. This one-shot aggregation
often suffers from task interference, leading to *information erasure* across in
dividual tasks. In this work, we show that replacing post-hoc merging with an it
erative *many-shot merging* protocol is effective in improving multi-task perfor
mance. Building on this insight, we propose **METIS**, **M**itigating **E**rasur
e from **T**ask **I**nterference for **S**table many-shot merging. METIS is a lo
ss-aware many-shot merging method that addresses information erasure in post-hoc
merging through task-wise loss-gap weighting and consensus-based masking. Notab
ly, METIS exhibits significant performance improvement on the worst-performing t
ask, effectively mitigating information erasure.

MetaDNS: Enhancing Exploration in Discrete Neural Samplers via Metadynamics
Xiaochen Du, Juno Nam, Jaemoo Choi, Wei Guo, Sathya Edamadaka, Junyi Sha, Elton
Pan, Yongxin Chen, Molei Tao, Rafael Gomez-Bombarelli
Sampling from discrete distributions with multiple modes and energy barriers is
fundamental to machine learning and computational physics. Recent discrete neura
l samplers like MDNS suffer from mode collapse and fail to sample high-energy ba
rrier regions between modes, which is critical for free energy estimation and un
derstanding phase transitions. We propose Metadynamics Discrete Neural Sampler (
MetaDNS), a general framework integrating well-tempered metadynamics into discre
te diffusion or autoregressive samplers. By maintaining an adaptive, history-dep
endent bias potential along selected low-dimensional coordinates, MetaDNS forces
exploration of previously inaccessible regions, enabling free energy reconstruc
tion infeasible with standard neural samplers due to a lack of high-energy sampl
es. On challenging low-temperature benchmarks including Ising, Potts, and the co
pper-gold binary alloy, MetaDNS reproduces the thermodynamic distribution. Compa
red to MCMC-based metadynamics, MetaDNS also achieves comparable exploration req
uiring fewer bias deposition steps.

Semantic Robustness Certification for Vision-Language Models
Peiyu Yang, Paul Montague, Feng Liu, Andrew Craig Cullen, Amardeep Kaur, Christo
pher Leckie, Sarah Monazam Erfani
Vision-language models (VLMs) are now widely used in downstream tasks. However,
real-world applications often expose VLMs to distribution shifts induced by sema
ntic variation (e.g., shape, size, and style). Robustness certification determin
es if a model’s prediction changes when transformations are applied to its input
. While most certification frameworks study geometric or pixel-level transformat
ions over inputs, this work proposes a novel framework that enables certifying V
LM robustness under semantic-level transformations. Leveraging the open-vocabula

ry capability of VLMs, we use text prompts as semantic proxies to construct transformations parameterized by an extent that controls the degree of semantic variation. By characterizing the VLM decision boundary in closed form, our framework quantitatively certifies extent intervals for which the predicted class remains unchanged under the semantic transformation. Our framework is the first to certify VLM robustness under semantic-level variations without requiring additional data for each variation, making it practical to apply. Experiments on both synthetic and real-world data show that our framework enables certifying robustness under diverse semantic variations across scenarios.
****

PolyFlow: Safe and Efficient Polytope-Constrained Flow Matching with Constraint Embedding and Projection-free Update
jianming ma, Qiyue Yang, Yang Zhang, Liyun Yan, Zhanxiang Cao, Yazhou Zhang, Yue Gao
While flow-based generative models have demonstrated strong performance across a wide range of domains, deploying them in safety-critical physical systems remains challenging due to strict constraint requirements. Existing approaches typically enforce safety through post-hoc corrections, which incur substantial computational overhead and may distort the learned distribution. We propose PolyFlow, a polytope-constrained flow matching framework that embeds constraints directly into the model and flow dynamics. PolyFlow introduces a discrete-time flow formulation and a projection-free architecture, which eliminate the numeration error and guarantee strict satisfaction of arbitrary polyhedral constraints, without the need for expensive iterative solvers. Experimental results show that PolyFlow achieves zero constraint violation while maintaining high distributional fidelity across a range of planning and control tasks. Compared to state-of-the-art constrained generation baselines, PolyFlow significantly reduces inference latency and demonstrates a favorable trade-off between safety, efficiency, and generative quality.
****

AudioMosaic: Contrastive Masked Audio Representation Learning
Hanxun Huang, Qizhou Wang, Xingjun Ma, Cihang Xie, Christopher Leckie, Sarah Monazam Erfani
Audio self-supervised learning (SSL) aims to learn general-purpose representations from large-scale unlabeled audio data and has achieved remarkable progress in recent years. While most prior work relies on generative reconstruction objectives, contrastive approaches remain relatively underexplored, in part due to the high computational cost of designing effective augmentation strategies and the large batch sizes typically required for pre-training. In this work, we introduce **AudioMosaic**, an audio encoder for general audio understanding. During pre-training, AudioMosaic applies time–frequency masking to spectrogram patches to form paired inputs, employing an elegant and efficient augmentation strategy that significantly reduces computational cost while supporting large-batch training. The AudioMosaic encoder learns discriminative utterance-level representations that exhibit strong transferability across datasets, domains, and acoustic conditions. Extensive experiments demonstrate that AudioMosaic achieves state-of-the-art performance on multiple standard benchmarks. Moreover, we show that the pretrained AudioMosaic encoder enhances audio perception when integrated with large language models (LLMs).
****

DAISI: Data Assimilation with Inverse Sampling using Stochastic Interpolants
Martin Andrae, Erik Wikingsson, So Takao, Tomas Landelius, Fredrik Lindsten
Data assimilation (DA) is a cornerstone of scientific and engineering applications, combining model forecasts with sparse and noisy observations to estimate latent system states. Classical high-dimensional DA methods, such as the ensemble Kalman filter, rely on Gaussian approximations that are violated for complex dynamics or observation operators. To address this limitation, we introduce DAISI, a scalable filtering algorithm built on flow-based generative models that enables flexible probabilistic inference using data-driven priors. The core idea is to use a stationary, pre-trained generative prior that first incorporates forecast

information through a novel *inverse-sampling step*, before assimilating observations via guidance-based conditional sampling. This allows us to leverage any forecasting model as part of the DA pipeline without having to retrain or fine-tune the generative prior at each assimilation step. Experiments on challenging nonlinear systems show that DAISI achieves accurate filtering results in regimes with sparse, noisy, and nonlinear observations where traditional methods struggle. The code for DAISI is available at https://github.com/Erik-Wikingsson/DAISI.

PACE: Parameter Change for Unsupervised Environment Design

Fang YUAN, Junjie Zeng, Qinglun Li, Long Qin, Quanjun Yin, Siqi Shen, Yuxiang Xie, Junqiang Yang

Unsupervised Environment Design (UED) offers a promising paradigm for improving reinforcement learning generalization by adaptively shaping training environments, but it requires reliable environment evaluation to remain effective.

However, existing UED methods evaluate environments using indirect proxy signals such as regret, value-based errors, or Monte Carlo, which suffer from bias, high variance, or substantial computational overhead.

To address these limitations, we propose Parameter Change Environment Design (PACE), a general framework for adaptive level selection in UED. PACE evaluates a level by performing a provisional policy update on it and scoring it with the squared ℓ_2 norm of the induced parameter change, which directly reflects realized learning progress. This score then guides level selection: levels enter a staleness-aware buffer based on their score, and are replayed via rank-based prioritization, inducing a curriculum that adapts to the agent’s evolving capability. By grounding environment evaluation in intrinsic optimization progress, PACE provides a low-variance evaluation signal and avoids the need for additional environment rollouts. Experiments on MiniGrid and Craftax demonstrate that PACE consistently outperforms established UED baselines in zero-shot generalization across diverse out-of-distribution evaluation protocols.

Denoising without Diffusion: Fixed-Noise Denoiser Anomaly Detection in Tabular Data

Manuel Hirth, Lukas Koberg, Nasser Jazdi, Enkelejda Kasneci

While diffusion models have advanced anomaly detection, their reliance on multi-step noise schedules introduces significant computational complexity. In this paper, we demonstrate that the generative capability of diffusion is not required for tabular anomaly detection. We revisit core principles of denoising without targeting data generation and present a deep-learning approach that streamlines these objectives into a fixed-noise formulation. Unlike denoising autoencoders that rely on reconstruction error, our method utilizes a preconditioning with an explicit linear reference channel. We train a self-supervised fixed-noise denoising predictor and derive an anomaly score from the expected deviation under repeated perturbations, yielding a stability proxy rather than merely measuring distance to the data manifold. On the well-established ADBench benchmark, our method achieves state-of-the-art performance with improvements over existing baselines of 1.22\% in AUCROC and 1.13\% in AUCPR, the most informative and threshold-independent metrics. Our approach emphasizes structural simplicity and efficiency, demonstrating that a single-step, stability-based objective outperforms complex generative schedules.

Approximation Theory for Lipschitz Continuous Transformers

Takashi Furuya, Davide Murari, Carola-Bibiane Schönlieb

Stability and robustness are critical for deploying Transformers in safety-sensitive settings.

A principled way to enforce such behavior is to constrain the model's Lipschitz constant.

However, approximation-theoretic guarantees for architectures that explicitly preserve Lipschitz continuity have yet to be established.

In this work, we bridge this gap by introducing a class of gradient-descent-type in-context Transformers that are Lipschitz-continuous by construction.

We realize both MLP and attention blocks as explicit Euler steps of negative gradient flows, ensuring inherent stability without sacrificing expressivity.
We prove a universal approximation theorem for this class within a Lipschitz-constrained function space.
Crucially, our analysis adopts a measure-theoretic formalism, interpreting Transformers as operators on probability measures, to yield approximation guarantees independent of token count.
These results provide a rigorous theoretical foundation for the design of robust, Lipschitz continuous Transformer architectures.

Euclean: Automated Geometry Problem Formalization with Unified Verification in Lean
Linbin Tang, Jingyan You, Zilin Kang, Hanzhang Liu, Sophia Zhang, Zenan Li, Chenrui Cao, Liangcheng Song, Jiaao Wu, Xian Zhang, Fan Yang
Recent formal reasoning systems have reached IMO-level performance, yet they leave a fragmented landscape: algebra and number theory are handled in Lean, while geometry still relies on domain-specific languages with limited formal guarantees. This split increases the trusted computing base and hinders unified model development. Existing geometry-in-Lean efforts (LeanEuclid, LeanGeo) introduce custom axiom systems incompatible with standard Mathlib, and their small scale ($<$1,100 problems) limits large-scale training. Native Mathlib autoformalization of geometry, however, poses distinct challenges: implicit diagrammatic assumptions (e.g., topological configuration and non-degeneracy) must be made explicit rather than deferred to external solvers, and models must adapt to Mathlib's small, rapidly evolving geometry infrastructure. We present Euclean, a four-stage framework - constraint explication, configuration anchoring, formalization mapping, and iterative repair - for automatically formalizing geometry in native Mathlib. We construct OMNI-Geometry (768 competition problems) and Numina-Geometry (177,597 problems), the largest geometry formalization dataset in Lean. Human evaluation shows 48.89% TOP1 and 73.33% TOP5 accuracy. Training Goedel v2 on our formalizations improves proof success from 13.6% to 15.1%, validating dataset quality for unified neural theorem proving. Code and datasets: https://github.com/tlb-22/Euclean.
****
Asymmetric Multi-View Clustering with Hyperbolic Uncertainty Modeling
Yiming Wang, Qun Li, Dongxia Chang, Jie Wen, Hua Dai, Fu Xiao
Deep Multi-View Clustering (MVC) aims to learn a unified semantic representation from diverse data sources without supervision. However, current approaches relying on flat Euclidean embeddings often fail to model data uncertainty, resulting in rigid alignment where high-quality views are forced to drift toward corrupted ones. To address these challenges, we propose the Hyperbolic Asymmetric Multi-view Clustering (HAMC) framework. HAMC maps view-specific features into the Poincaré ball and uses radial geometry as a confidence proxy, encouraging confident representations to occupy larger radial distances while allowing ambiguous or noisy samples to remain closer to the origin. To mitigate noise, we introduce an asymmetric view alignment mechanism, enabling reliable views to unidirectionally guide unreliable ones. Furthermore, a consensus-aware cluster learning strategy is designed to construct robust global pseudo-labels via a confidence-based screening scheme, refining the cluster structure. Extensive experiments against 13 baselines demonstrate that HAMC achieves state-of-the-art performance.
****
The Implicit Bias of Steepest Descent with Mini-batch Stochastic Gradient
Jichu Li, Xuan Tang, Difan Zou
A variety of widely used optimization methods like SignSGD and Muon can be interpreted as instances of steepest descent under different norm-induced geometries.

In this work, we study the implicit bias of mini-batch stochastic steepest descent in multi-class classification, characterizing how batch size, momentum, and variance reduction shape the limiting max-margin behavior and convergence rates under general entry-wise and Schatten-p norms.

We show that, without momentum, worst-case convergence and successful classification can only be guaranteed with full-batch gradient. In contrast, momentum enables small-batch convergence to an approximate max-margin solution through a batch-momentum trade-off, though it slows convergence. This approach provides fully explicit, dimension-free rates that improve upon prior results. Moreover, we prove that variance reduction can recover the exact full-batch implicit bias for any batch size, albeit at a slower convergence rate. Finally, we further investigate the batch-size-one steepest descent without momentum, and reveal its convergence to a fundamentally different bias via a concrete data example, which reveals a key limitation of purely stochastic updates. Overall, our unified analysis clarifies when stochastic optimization aligns with full■batch behavior, and paves the way for perform deeper explorations of the training behavior of stochastic gradient steepest descent algorithms.

Fast and Accurate Causal Parallel Decoding using Jacobi Forcing
Lanxiang Hu, Siqi Kou, Yichao Fu, Samyam Rajbhandari, Tajana Rosing, Yuxiong He, Zhijie Deng, Hao Zhang
Multi-token generation has emerged as a promising paradigm for accelerating language model inference, with the diffusion Large Language Models (dLLMs) as the most notable approach recently. Popular dLLMs like SDAR and Fast-dLLM v2 are post-trained on pre-trained AR models to minimize training cost while maintaining high performance. However, there exists a fundamental pretrain-to-posttrain mismatch -- the masked data distribution and bidirectional attention in post-training deviates significantly from the real data distribution and causal attention for pretraining. As a result, the post-trained dLLMs usually suffer from limited speedup or substantially degraded performance. To address this, we introduce Jacobi Forcing to bypass the dLLM formulation, directly post-training a causal multi-token predictor from an AR LLM. In particular, we force the model to learn to leap along its own parallel token generation trajectories based on Jacobi Decoding, and introduce an elaborate progressive distillation paradigm. The trained models achieve $3.8\times$ wall-clock speedup on coding and math benchmarks with minimal loss in performance. Based on the trajectory characteristics of the model, we further introduce multi-block decoding with rejection recycling, which enables up to $4.6\times$ higher token acceptance count per iteration and $4.0\times$ wall-clock speedup, effectively trading additional compute for lower inference latency.
****

Spiral RoPE: Rotate Your Rotary Positional Embeddings in the 2D Plane
Haoyu Liu, Sucheng Ren, Tingyu Zhu, Peng Wang, Cihang Xie, Alan Yuille, Zeyu Zheng, Feng Wang
Rotary Position Embedding (RoPE) is the de facto positional encoding in large language models due to its ability to encode relative positions and support length extrapolation. When adapted to vision transformers, the standard axial formulation decomposes two-dimensional spatial positions into horizontal and vertical components, implicitly restricting positional encoding to axis-aligned directions. We identify this directional constraint as a fundamental limitation of the standard axial 2D RoPE, which hinders the modeling of oblique spatial relationships that naturally exist in natural images. To overcome this limitation, we propose Spiral RoPE, a simple yet effective extension that enables multi-directional positional encoding by partitioning embedding channels into multiple groups associated with uniformly distributed directions. Each group is rotated according to the projection of the patch position onto its corresponding direction, allowing spatial relationships to be encoded beyond the horizontal and vertical axes. Across a wide range of vision tasks including classification, segmentation, and generation, Spiral RoPE consistently improves performance. Qualitative analyzes of attention maps further show that Spiral RoPE exhibits more concentrated activations on semantically relevant objects and better respects local object boundaries, highlighting the importance of multi-directional positional encoding in vision transformers.

AgentNoiseBench: Benchmarking Robustness of Tool-Using LLM Agents Under Noisy Co
ndition
Ruipeng Wang, Yuxin Chen, Yukai Wang, Chang Wu, Junfeng Fang, Xiaodong Cai, Qi G
U, Hui Su, An Zhang, Xiang Wang, Xunliang Cai, Tat-Seng Chua
Recent advances in large language models have enabled LLM-based agents to achiev
e strong performance on a variety of benchmarks.
However, their performance in real-world deployments often that observed on benc
hmark settings, especially in complex and imperfect environments.
This discrepancy largely arises because prevailing training and evaluation parad
igms are typically built on idealized assumptions, overlooking the inherent stoc
hasticity and noise present in real-world interactions.
To bridge this gap, we introduce AgentNoiseBench, a framework for systematically
 evaluating the robustness of agentic models under noisy environments.
We first conduct an in-depth analysis of biases and uncertainties in real-world
scenarios and categorize environmental noise into two primary types: user-noise
and tool-noise.
Building on this analysis, we develop an automated pipeline that injects control
lable noise into existing agent-centric benchmarks while preserving task solvabi
lity.
Leveraging this pipeline, we perform extensive evaluations across a wide range o
f models with diverse architectures and parameter scales.
Our results reveal consistent performance variations under different noise condi
tions, highlighting the sensitivity of current agentic models to realistic envir
onmental perturbations.

Multimodal Scaling Laws for Task & Data-Optimized Models of Visual Cortex
Abdulkadir Gokce, Yingtian Tang, Martin Schrimpf
Task-optimized neural networks are the leading in-silico models of sensory corte
x, yet the field lacks a unified understanding of which modeling choices drive i
mproved brain alignment. Prior NeuroAI work is fragmented across datasets and mo
dalities, making it difficult to determine robust scaling trends. Here, we syste
matically investigate the scaling laws of model-to-brain alignment across 8 neur
al datasets (spanning electrophysiology, fMRI, EEG, and MEG) and over 600 models
 with diverse architectures and pretraining configurations. We report three scal
ing trends: (1) *Pretraining saturation*: Alignment improves with pretraining c
ompute and data scale but saturates across all recording modalities. (2) *Comple
mentary fine-tuning*: Hybrid task & neural data optimization yields consistent i
mprovements in alignment that generalize across datasets and modalities. (3) *Ma
pping scaling*: Increasing the number of neural samples to fit model-to-brain ma
ppings yields log-linear gains with the largest impact on alignment. Finally, we
 propose a novel subject-shared cross-attention mapping which drastically reduce
s parameter count and improves alignment. Taken together, these results establis
h multimodal scaling laws that guide resource allocation for next-generation bra
in models.

MedScope: Incentivizing "Think with Videos" for Clinical Reasoning via Coarse-to
-Fine Tool Calling
Wenjie Li, Yujie Zhang, Haoran Sun, Xingqi He, Hongcheng Gao, Chenglong Ma, Ming
 Hu, Guankun Wang, Shiyi Yao, Renhao Yang, Hongliang Ren, Lei Wang, Junjun He, Y
ankai Jiang
Long-form clinical videos are central to visual evidence-based decision-making,
with growing importance for applications such as surgical robotics and related s
ettings. However, current multimodal large language models typically process vid
eos with passive sampling or weakly grounded inspection, which limits their abil
ity to iteratively locate, verify, and justify predictions with temporally targe
ted evidence. To close this gap, we propose **MedScope**, a tool-using clinical
video reasoning model that performs coarse-to-fine evidence seeking over long-fo
rm procedures. By interleaving intermediate reasoning with targeted tool calls a
nd verification on retrieved observations, MedScope produces more accurate and t
rustworthy predictions that are explicitly grounded in temporally localized visu

al evidence. To address the lack of high-fidelity supervision, we build **ClinVideoSuite**, an evidence-centric, fine-grained clinical video suite. We then optimize **MedScope** with **G**rounding-**A**ware **G**roup **R**elative **P**olicy **O**ptimization (**GA-GRPO**), which directly reinforces tool use with grounding-aligned rewards and evidence-weighted advantages. On full and fine-grained video understanding benchmarks, **MedScope** achieves state-of-the-art performance in both in-domain and out-of-domain evaluations. Our approach illuminates a path toward medical AI agents that can genuinely “think with videos” through tool-integrated reasoning. Code and resources are available at https://github.com/SII-WenjieLisjtu/MedScope.

Toward Effective Multimodal Graph Foundation Model: A Divide-and-Conquer Based Approach

Sicheng Liu, Xunkai Li, Daohan Su, Ru Zhang, Hongchao Qin, Rong-Hua Li, Guoren Wang

Graph Foundation Models (GFMs) have achieved remarkable success in generalizing across diverse domains. However, they mainly focus on Text-Attributed Graphs (TAGs), leaving Multimodal-Attributed Graphs (MAGs) largely untapped. Although recent Multimodal Graph Foundation Models (MGFMs) attempt to bridge this gap by integrating diverse modality information, our empirical investigation reveals two fundamental limitations: (1)they fail to explicitly model modality interaction, essential for capturing intricate cross-modal semantics beyond simple aggregation, and (2)they exhibit sub-optimal modality alignment, which is critical for bridging the significant semantic disparity between distinct modal spaces. To address these challenges, we propose PLANET (graPh topoLogy-aware modAlity iNteraction and alignmEnT), a novel framework employing a Divide-and-Conquer strategy to decouple modality interaction and alignment across distinct granularities. At the embedding granularity, (1)Embedding-wise Domain Gating (EDG) performs local semantic enrichment by adaptively infusing topology-aware cross-modal context, achieving modality interaction. At the node granularity, (2)Node-wise Discretization Retrieval (NDR) ensures global modality alignment by constructing a Discretized Semantic Representation Space (DSRS) to bridge modality gaps. Extensive experiments demonstrate that PLANET significantly outperforms state-of-the-art baselines across diverse graph-centric and multimodal generative tasks. Our code is available at https://github.com/Sapnapnet/PLANET.

Beyond Additive Decompositions: Interpretability Through Separability

Jinyang Liu, Munir Hiabu

Interpretable machine learning requires models that are accurate and structurally faithful to the data.

Existing explainability methods rely heavily on additive representations (e.g., Generalized Additive Models (GAMs), SHapley Additive exPlanations (SHAP), functional ANOVA), which can suffer from signal cancellation and off-support extrapolation in the presence of strong interactions.

We propose Tensor Separation Learning (TSL), a regression model that learns a sum of rank-1 products of univariate per-feature functions via a stagewise greedy procedure with orthogonal refitting. By enforcing separability, TSL avoids the information loss inherent in additive projections caused by marginalizing higher-order interactions.

The learned TSL model can be fully reconstructed from first-order partial dependence functions, up to constant factors. This stage-wise correspondence ensures that the resulting visualizations are faithful to the fitted components.

We establish approximation-rate guarantees for functions with bounded mixed p-th order partial derivatives and demonstrate that TSL competes with black-box models on regression benchmarks.

MedMosaic: A Challenging Large Scale Benchmark of Diverse Medical Audio

Harshit Rajgarhia, Shuubham Ojha, Asif Shaik, Akhil Pothanapalli, Rachuri Lokesh, Abhishek Mukherji, Prasanna Desikan

Medical audio data is difficult to collect due to privacy regulations and high a

nnotation costs arising from domain expertise. Thus, existing benchmarks tend to underrepresent complex medical audio scenarios. To address this challenge, we present MedMosaic, a medical audio question–answering dataset designed to benchmark language and audio reasoning models under realistic clinical constraints. MedMosaic features a diverse range of medical audio types, including condition-related physiological sounds, carefully constructed synthetic voices to mimic speech with artifacts as well as real short and long length clinical conversations to model varying context lengths. The dataset also features a total of 46,701 question-answer pairs, spanning categories such as multiple-choice, sequential multi-turn, and open-ended question–answers, enabling systematic evaluation of multi-hop reasoning and answer generation capabilities. Benchmarking 13 audio and multimodal reasoning models reveals that reasoning remains challenging for all evaluated systems, with substantial performance variation across question types. In particular, even state-of-the-art model like Gemini-2.5-pro can only achieve 68.1\% accuracy approximately. These findings underscore persistent limitations in medical reasoning and highlight the need for more robust, domain-specific multimodal reasoning models. A sample of benchmark data is available here:https://shorturl.at/Lyp33

Learning Protein Structure-Function Relationships through Knowledge-guided Representation Decomposition

Mingqing Wang, Zhiwei Nie, ATHANASIOS V. VASILAKOS, Yonghong He, Zhixiang Ren

Proteins encode diverse functions within complex three-dimensional structures, yet most deep learning representations remain highly entangled, obscuring the biophysical signals that underlie function. Here we introduce ProtDiS, a knowledge-guided framework that decomposes pretrained protein micro-environment embeddings into biologically grounded and task-relevant dimensions. Inspired by the information bottleneck principle, ProtDiS learns representations that balance informativeness and compression, yielding structural features that are more specific, independent, and information-efficient, and achieving consistent improvements across twelve downstream tasks, with the largest gains under structure-based splits. Protein- and residue-level analyses further show that ProtDiS differentiates proteins with similar folds but divergent functions and captures fine-grained biophysical signals critical. These findings suggest that knowledge–guided decomposition provides a general and interpretable approach for structuring latent spaces in protein structural modeling. The source code and implementation details are publicly available at https://github.com/AI-HPC-Research-Team/ProtDiS.

LLM-MatLogic: Executable Exchange Contracts for Knowledge-Graph Query Answering with Scoped Negation

Dezhuang Miao, Xiaoming Zhang, Bo Zhang, Yibin Du, Xiang Li, Ruilin Zeng, Yirui Qi

LLM-to-KG systems frequently fail on exclusion-rich questions because natural-language negation is both scope-sensitive and evidence-dependent: it may constrain only one subgoal/branch and only certain supporting paths, yet such attachment is rarely explicit in text.

We propose the Executable Exchange Contract (EEC) to bridge this gap, specifying scope-bound exclusions as executable control metadata exchanged between a specifier and an executor. Our executor, MatLogic, compiles exclusions into scope-local masks applied during multi-hop propagation and executes requests under a unified P$\rightarrow$N$\rightarrow$C/D schedule, ensuring exclusions are enforced before witness loss and branch entanglement. The system can also return compact witness pointers to keep support types distinguishable when needed. We evaluate on both structured complex queries and end-to-end natural-language KGQA, and introduce contract-aligned diagnostics that isolate errors from specification versus execution and verify the necessity of scoped enforcement.

****

Time Series Forecasting Through the Lens of Dynamics

Alexis-Raja Brachet, Pierre-Yves Richard, CELINE HUDELOT

While deep learning is facing an homogenization across modalities led by Transfo

rmers, they are still challenged by shallow linear models in the time series forecasting task. Our hypothesis is that models should learn a direct link from past to future data points, which we identify as a learning dynamics capability. We develop an original $\texttt{PRO-DYN}$ nomenclature to analyze existing models through the lens of dynamics. Two observations thus emerge: **1.** under-performing architectures learn dynamics at most partially, **2.** the location of the dynamics block at the model end is of prime importance. Our systemic and empirical studies both confirm our observations on a set of performance-varying models with diverse backbones. We propose a simple plug-and-play methodology guiding model designs and improvements.
****

Seeing Symbols, Missing Structure: A Real-World Handwritten Mathematical Expression Recognition Benchmark for Large Models

Sheng Jiang, Lin Zhu, Runrui Li, Mei Wang, Qiannan Zhu, Yaoyao Zhong, Hua Huang

Handwritten mathematical expression recognition (HMER) remains challenging in real-world educational scenarios, even with recent advances in large vision-language models. While these models often achieve high accuracy in local symbol transcription, their reliability in capturing two-dimensional mathematical structure under realistic handwritten conditions is still poorly understood. We introduce a real-world handwritten benchmark covering 13 categories of structurally complex expressions with authentic writing artifacts. Evaluations on large models reveal a clear performance degradation as structural complexity increases, even when symbol-level accuracy is high. Most failures arise from structural mis-parsing and context-dependent symbol role confusion rather than pure visual perception errors. To mitigate this issue, we propose a training-free, schema-anchored structure-aware inference framework that decomposes recognition into schema identification, schema-constrained transcription, and context-driven disambiguation. Our method improves the ExpRate from 11.63\% to 24.52\% on Qwen-8B and generalizes well across multiple large models. Our benchmark provides a realistic evaluation for large models on handwritten mathematics, and our framework offers an effective and interpretable solution to structure-related failures in real-world HMER. Code and data are available at: https://github.com/BNU-ERC-ITEA/HMER-Bench.git.
****

Updating Parametric Knowledge with Context Distillation Retains Post-Training Capabilities

Shankar Padmanabhan, Mustafa Omer Gul, Tanya Goyal

Post-training endows pretrained LLMs with a variety of desirable skills, including instruction-following, reasoning, and others. However, these post-trained LLMs only encode knowledge up to a cut-off date, necessitating continual adaptation. Unfortunately, existing solutions cannot simultaneously learn new knowledge from an adaptation document corpora and mitigate the forgetting of earlier learned capabilities.

To address this, we introduce Distillation via Split Contexts (DiSC), a simple context-distillation based approach for continual knowledge adaptation. DiSC derives student and teacher distributions by conditioning on distinct segments of the training example and minimizes the KL divergence between the shared tokens. This allows us to efficiently apply context-distillation without requiring explicit generation steps during training.

We run experiments on four post-trained models and two adaptation domains. Compared to prior finetuning and distillation methods for continual adaptation, DiSC consistently reports the best trade-off between learning new knowledge and mitigating forgetting of previously learned skills like instruction-following, reasoning, and factual knowledge.
****

Channel Adapter for Time Series Foundation Models in Zero-Shot Multivariate Forecasting

Dongyuan Li, Renhe Jiang, Shun Zheng, Zheng Dong, Haotian Gao, Ying Zhang, Jiang Bian

Time Series Foundation Models (TSFMs) have achieved strong performance in univariate time series forecasting. However, most TSFMs rely on channel-independent pr

e-training that models each variable separately, limiting their ability to lever age inter-channel information that is crucial in real-world multivariate systems . Motivated by this limitation, we propose ChaTSFM, a lightweight plug-and-play channel adapter that allows frozen TSFMs to leverage multivariate correlations i n a zero-shot setting. ChaTSFM first builds a budgeted pre-training dataset to c over diverse heterogeneous inter-channel dependency patterns. It then uses data-derived domain descriptors to learn a dataset-conditioned inter-channel similari ty measure that reduces cross-domain metric distortion. Finally, it injects spar se inter-channel information via gated refinement, leveraging multivariate infor mation without degrading intra-channel temporal dynamics. Extensive experiments on nine benchmarks validate the effectiveness of ChaTSFM, demonstrating consiste nt zero-shot improvements over four best-performing TSFMs while maintaining scal able deployment. Code is available at Code is available at https://github.com/Cl earloveyuan/ChaTSFM.

ImpQuant: Fine-Grained Importance-Aware Quantization for Large Vision-Language M odels

Jundong Zhou, Tianao Cai, Yujie Huang, Xinbing Wang, Guang-Zhong Yang, Nanyang Y e

Large Vision–Language Models (LVLMs) have demonstrated remarkable capabilities a cross diverse multimodal tasks, yet their high inference costs necessitate low-b it deployment. Existing post-training quantization (PTQ) pipelines primarily ado pt methodologies from text-only LLMs by treating multimodal inputs as homogeneou s sequences, overlooking the heterogeneous information density inherent in LVLMs . In this work, we present ImpQuant, an importance-aware PTQ framework tailored for LVLMs that mitigates low-bit accuracy degradation via fine-grained token-imp ortance reweighted calibration and outlier-aware activation quantization. Our ke y insight is that quantization errors on decision-critical tokens disproportiona tely impact overall model behavior. Accordingly, we reweight the calibration los s using aggregated attention for textual tokens and a contextual redundancy metr ic for visual tokens, respectively. Across multiple LVLM backbones and diverse m ultimodal benchmarks, our approach consistently improves accuracy at low bitwidt h and reduces quantization-induced object hallucinations compared to state-of-th e-art PTQ baselines.

SMAC: Score-Matched Actor-Critics for Robust Offline-to-Online Transfer

Nathan Samuel de Lara, Florian Shkurti

Modern offline Reinforcement Learning (RL) methods find performant actor-critics , however, fine-tuning these actor-critics online with value-based RL algorithms typically causes immediate drops in performance. We provide evidence consistent with the hypothesis that, in the loss landscape, offline maxima for prior algor ithms and online maxima are separated by low-performance valleys that gradient-b ased fine-tuning traverses. Following this, we present Score Matched Actor-Criti c (SMAC), an offline RL method designed to learn actor–critics that transition t o online value-based RL algorithms with no drop in performance. SMAC avoids vall eys between offline and online maxima by regularizing the Q-function during the offline phase to respect a first-order derivative equality between the score of the policy and action-gradient of the Q-function. We experimentally demonstrate that SMAC converges to offline maxima that are connected to better online maxima via paths with monotonically increasing reward found by first-order optimizatio n. SMAC achieves smooth transfer to Soft Actor-Critic and TD3 in 6/6 D4RL tasks. In 4/6 environments, it reduces regret by 34-58% over the best baseline.

The Fisher Dimension: Instance-Dependent Complexity for Causal Discovery

Luong Doan, Khanh Nguyen Quoc, Duc Hai Nguyen, Mai Phan Quoc Hung, Phong Ho, Nhu ng Duong, Tuan Do

Classical sample complexity bounds for causal structure learning are minimax in nature, characterizing worst-case difficulty without distinguishing between easy and hard instances. We study instance-specific complexity for Markov equivalenc e class (MEC) recovery in linear Gaussian structural equation models. We introdu

ce the Fisher dimension, defined as the inverse squared minimum partial correlat
ion that must be detected to recover the MEC. We prove that the Fisher dimension
 governs sample complexity: it provides both a lower bound and an upper bound (t
ight up to logarithmic factors) for MEC recovery. A key theoretical finding is t
hat under spectrally well-conditioned models, with bounded noise variances, boun
ded covariance eigenvalues, and constant-order edge coefficients, the Fisher dim
ension is uniformly bounded regardless of graph structure. Thus, significant ins
tance-specific variation arises from parametric rather than structural features.
 Empirical validation shows strong correlation between our predictor and observe
d sample complexity for structured graph families.

Identifying dependent components from multi-domain linear mixtures
Danru Xu, Lauri Parkkonen, Sara Magliacane, Aapo Hyvarinen
We study a linear mixing model with dependent latent components, assuming multip
le data domains. Most existing models assume that the components are independent
 or at least uncorrelated, in line with independent component analysis (ICA). So
me recent work allows for dependent components, but then makes specific assumpti
ons such as parametric forms of dependencies, multi-view settings, or interventi
ons, or does not recover the individual components. In contrast, we consider a m
ulti-domain setting in which domains differ through domain-specific scalings of
the components, while the distribution of the underlying latent components is th
e same across domains. This approach can model data collected, for example, from
 different sensors measuring the same process, different laboratories conducting
 the same experiment, different experimental conditions, or different subjects t
hat might differ in biological or physiological factors. We show that, under suf
ficient domain variability, latent variables and mixing functions can be identif
ied from second-order statistics alone. We propose the **Mu**lti-**Do**main **Co
variance **Matching (MuDo-CoM) algorithm that generalizes previous methods o
f joint diagonalization. MuDo-CoM is validated on simulated data and a real-worl
d fMRI dataset.

Causal Attention with Lookahead Keys
Zhuoqing Song, peng sun, Huizhuo Yuan, Quanquan Gu
In standard causal attention, each token's query, key, and value (QKV) are stati
c and encode only preceding context. We introduce CAuSal aTtention with Lookahea
d kEys (CASTLE), an attention mechanism that continually updates each token's ke
ys as the context unfolds. We term these updated keys lookahead keys because the
y belong to earlier positions yet integrate information from tokens that appear
later relative to those positions, while strictly preserving the autoregressive
property. Although the mechanism appears sequential, we derive a mathematical eq
uivalence that avoids explicitly materializing lookahead keys at each position a
nd enables efficient parallel training. On language modeling benchmarks, CASTLE
consistently outperforms standard causal attention across model scales, reducing
 validation perplexity and improving average performance on a range of downstrea
m tasks.

Beyond Rewards in RL for Cyber Defence
Elizabeth Bates, Chris Hicks, Vasilios Mavroudis
Recent years have seen an explosion of interest in autonomous cyber defence agen
ts trained to defend computer networks using deep reinforcement learning. These
agents are typically trained in cyber gym environments using dense, highly engin
eered reward functions which combine many penalties and incentives for a range o
f (un)desirable states and costly actions. Dense rewards help alleviate the chal
lenge of exploring complex environments but risk biasing agents towards suboptim
al and potentially riskier solutions, a critical issue in complex cyber environm
ents. We thoroughly evaluate the impact of reward function structure on learning
 and policy behavioural characteristics using a variety of sparse and dense rewa
rd functions, two well-established cyber gyms, a range of network sizes, and bot
h policy gradient and value-based RL algorithms. Our evaluation is enabled by a
novel ground truth evaluation approach which allows directly comparing between d

ifferent reward functions, illuminating the nuanced inter-relationships between rewards, action space and the risks of suboptimal policies in cyber environments. Our results show that sparse rewards, provided they are goal aligned and can be encountered frequently, uniquely offer both enhanced training reliability and more effective cyber defence agents with lower-risk policies. Surprisingly, sparse rewards can also yield policies that are better aligned with cyber defender goals and make sparing use of costly defensive actions without explicit reward-based numerical penalties.

CodeMamba: Shifting from Target Semantics to Self-Supervised Background Manifold Learning for Singularity Detection in Infrared Sequences
Jingwen Ma, Xinpeng Zhang, Fan Shi, Xu Cheng, Shengyong Chen
Multi-frame infrared small target detection suffers from extreme semantic paucity of targets and representation collapse due to overwhelming class imbalance, resulting in the persistent inability to accurately distinguish point-like targets from dynamic background clutter. To address these issues, we propose CodeMamba, a collaborative dual-stream framework that reframes this task as the complementary mechanisms of background manifold modeling and motion singularity capturing. The implicit stream emphasizes background regularity and anomaly localization, while the explicit stream focuses on motion consistency and spatiotemporal singularity. Finally, we design a Bayesian uncertainty-weighted fusion module that estimates the reliability of each stream by quantifying its observation noise. Extensive experiments on the IRDST and DAUB benchmarks demonstrate that CodeMamba not only outperforms existing methods but also achieves enhanced sensitivity to point-like targets.
****
FedQueue: Queue-Aware Federated Learning for Cross-Facility HPC Training
Yijiang Li, Emon Dey, Zilinghan Li, Krishnan Raghavan, Ravi K Madduri, Kibaek Kim
Federated learning~(FL) across multiple HPC facilities faces stochastic admission delays from batch schedulers that dominate wall-clock time. Synchronous FL suffers from severe stragglers, while asynchronous FL accumulates stale updates when queues spike. We propose FedQueue, a queue-aware FL protocol that incorporates scheduler delays directly into training and aggregation, which (i) predicts per-facility queue delays online to budget local work, (ii) applies cutoff-based admission that buffers late arrivals to bound staleness, and (iii) performs staleness-aware aggregation to stabilize heterogeneous local workloads. We prove the convergence for non-convex objectives at rate $\mathcal{O}(1/\sqrt{R})$ under bounded staleness, and show that the admission controls yield bounded staleness with high probability under queue-prediction error. Real-world cross-facility deployment of FedQueue shows 20.5\% improvement over baseline algorithms. Controlled queue simulations demonstrate robust improvement over the baselines; in particular, up to 60\% reduction in time to reach a target accuracy level under high queue variance and non-IID partitions.
****
Retaining by Doing: The Role of On-Policy Data in Mitigating Forgetting
Howard Chen, Noam Razin, Karthik R Narasimhan, Danqi Chen
Adapting language models (LMs) to new tasks via post-training carries the risk of degrading existing capabilities -- a phenomenon classically known as catastrophic forgetting. In this paper, toward identifying guidelines for mitigating this phenomenon, we systematically compare the forgetting patterns of two widely adopted post-training methods: supervised fine-tuning (SFT) and reinforcement learning (RL). Our experiments reveal a consistent trend across LM families (Llama, Qwen) and tasks (instruction following, general knowledge, and arithmetic reasoning): RL leads to less forgetting than SFT while achieving comparable or higher target task performance. To investigate the cause for this difference, we consider a simplified setting in which the LM is modeled as a mixture of two distributions, one corresponding to prior knowledge and the other to the target task. We identify that the mode-seeking nature of RL, which stems from its use of on-policy data, enables keeping prior knowledge intact when learning the target task. We

then verify this insight by demonstrating that the use on-policy data underlies the robustness of RL to forgetting in practical settings, as opposed to other algorithmic choices such as the KL regularization or advantage estimation. Lastly, as a practical implication, our results highlight the potential of mitigating forgetting using approximately on-policy data, which can be substantially more efficient to obtain than fully on-policy data.

Robust Learning via Nested Distributionally Robust Optimization
Jinyi Huang, Jinlong Lei, Guodong Shi
Distributionally Robust Optimization (DRO) is widely used to improve model robustness, with existing methods addressing either geometric perturbations (e.g., input shifts) or statistical contamination (e.g., heavy-tailed noise and outliers) effectively. However, these uncertainty sources often co-exist, and coupling them through a single divergence or optimal transport constraint conflates geometric displacement with loss-based outlierness, frequently discarding informative high-leverage samples. We introduce nested DRO, a bilevel formulation that combines an outer optimistic ϕ-divergence cleaning step with an inner pessimistic optimal-transport robustification step, thereby decoupling geometric smoothing from statistical cleaning. We prove that this structure naturally induces a geometry-invariant, loss-based reweighting mechanism that separates outlier suppression from transport-induced regularization. We derive a tractable strong dual for the resulting non-convex problem and show its equivalence to variance-regularized risk minimization, leading to a clear statistical interpretation of the induced weights. Empirical results on synthetic and real datasets demonstrate that nested DRO consistently outperforms geometry-coupled DRO baselines, particularly under heavy-tailed contamination where preserving high-leverage structure is crucial.

τ^2-Bench: Evaluating Conversational Agents in a Dual-Control Environment
Victor Barres, Honghua Dong, Soham Ray, Xujie Si, Karthik R Narasimhan
Existing benchmarks for conversational AI agents simulate _single-control_ environments, where only the AI agent can use tools to interact with the world, while the user remains a passive information provider. This differs from real-world scenarios like technical support, where users need to actively participate in modifying the state of the (shared) world. In order to address this gap, we introduce τ^2-bench, with four key contributions:

(1) A novel Telecom dual-control domain modeled as a Dec-POMDP, where both agent and user make use of tools to act in a shared, dynamic environment that tests both agent coordination and communication;
(2) A compositional task generator that programmatically creates diverse, verifiable tasks from atomic components, ensuring domain coverage and controlled complexity;
(3) A reliable user simulator tightly coupled with the environment, whose behavior is constrained by tools and observable states, improving simulation fidelity;
(4) Fine-grained analysis of agent performance through multiple ablations including separating errors arising from reasoning vs communication/coordination.

In particular, our experiments show significant performance drops when agents shift from no-user to dual-control, highlighting the challenges of guiding users. Overall, τ^2-bench provides a controlled testbed for agents that must both reason effectively and guide user actions. Code, data, and leaderboard are available at https://taubench.com/.

MuLoCo: Muon is a Practical Inner Optimizer for DiLoCo
Benjamin Thérien, Xiaolong Huang, Aaron Defazio, Irina Rish, Eugene Belilovsky
DiLoCo is a powerful framework for training large language models (LLMs), enabling larger optimal batch sizes and increased accelerator utilization under networking constraints. However, DiLoCo's performance has been shown to degrade as the number of workers (K) increases (Charles et al., 2025). In this work, we posit

that a related but often overlooked factor in DiLoCo’s behavior is the choice of inner optimizer, which shapes the pseudogradient used by the outer optimizer. Given the recent success of Muon relative to AdamW for data parallel (DP) training, we examine how Muon's normalized optimizer steps can affect the pseudogradient's quality. We find that, relative to AdamW, Muon yields more *directionally correct* pseudogradients as the number of workers (K) increases. In our experiments pre-training language models, we conduct extensive hyperparameter tuning across 150M, 416M, 914M, 1.76B, and 3.1B models for DiLoCo, MuLoCo, AdamW DP, and Muon DP. Consistently across all scales, we find that with $K\geq1$ workers, MuLoCo (Muon inner optimizer DiLoCo) achieves superior performance to DiLoCo in absolute terms and for $K>2$ it outperforms DiLoCo relative to their data parallel baselines, while being compatible with quantization, streaming, and long synchronization intervals. At $K=1$, we find that MuLoCo can even outperform the data-parallel gold standard while having larger critical batch sizes and faster training times as a result.

ALSO: Adversarial Online Strategy Optimization for Social Agents
Xiang Li, Liping Yi, Mingze Kong, Min Zhang, Zhongxiang Dai, Qinghua Hu
Social simulation provides a compelling testbed for studying social intelligence, where agents interact through multi-turn dialogues under evolving contexts and strategically adapting opponents.
Such environments are inherently non-stationary, requiring agents to dynamically adjust their strategies over time.
However, most Large Language Model (LLM) based social agents rely on static personas, while existing approaches for enhancing social intelligence, such as offline reinforcement learning or external planners, are ill-suited to these settings, typically assuming stationarity and incurring substantial training overhead.
To bridge this gap, we propose **ALSO** (**A**dversarial on**L**ine **S**trategy **O**ptimization), the first framework for online strategy optimization in multi-agent social simulation.
ALSO advances social adaptation through two key contributions.
(1) ALSO formulates multi-turn interaction as an adversarial bandit problem, where combinations of static personas and dynamic strategy instructions are treated as arms, providing a principled solution to non-stationarity without relying on environmental stability assumptions.
(2) To predict rewards and generalize sparse feedback in multi-turn dialogues, ALSO introduces a lightweight neural surrogate to predict rewards from interaction histories, enabling sample-efficient exploration and continuous online adaptation.
Experiments on the Sotopia benchmark demonstrate that ALSO consistently outperforms static baselines and existing optimization methods in dynamic environments, validating the effectiveness of adversarial online strategy optimization for building robust social agents.

Logical Guidance for the Exact Composition of Diffusion Models
Francesco Alesiani, Jonathan H Warrell, Tanja Bien, Henrik Christiansen, Matheus Ferraz, Mathias Niepert
We propose LOGDIFF (Logical Guidance for the Exact Composition of Diffusion Models), a guidance framework for diffusion models that enables principled constrained generation with complex logical expressions at inference time. We study when exact score-based guidance for complex logical formulas can be obtained from guidance signals associated with atomic attributes and constraints.

First, we derive an exact Boolean calculus that provides a sufficient condition for exact logical guidance. Specifically, if a formula admits a circuit representation in which conjunctions combine conditionally independent subformulas and disjunctions combine subformulas that are either conditionally independent or mutually exclusive, exact logical guidance is achievable. In this case, the guidance signal can be computed exactly from atomic scores and posterior probabilities using an efficient recursive algorithm. Moreover, we show that, for commonly enc

ountered classes of distributions, any desired Boolean formula is compilable int
o such a circuit representation.

Second, by combining atomic guidance scores with posterior probability estimates
, we introduce a hybrid guidance approach that bridges classifier guidance and c
lassifier-free guidance, applicable to both compositional logical guidance and s
tandard conditional generation.

We demonstrate the effectiveness of our framework on multiple image and protein
structure generation tasks.

PSBench: Editing Image via GUI Agents in Photoshop
Yinuo Zhang, Zian Cheng, Ziya Zhao, Zongyu Li, Bingshuo Liu, Qingbin Liu, Junxia
n Cai, Xi Chen, Zhiying Tu, Dianhui Chu, Xiaoyan Yu, Dianbo Sui
Photoshop is a professional image editing software whose complex multi-level men
us, fine-grained operations, and layer-based non-destructive editing pose substa
ntial challenges for automated agents. Existing GUI benchmarks and methods prima
rily target web interfaces and short-horizon, low-complexity tasks, falling shor
t in modeling the multi-step decision-making and semantic understanding required
 by professional graphic software. We introduce PSBench, the first benchmark spe
cifically designed for image editing in Adobe Photoshop, consisting of 600 human
-annotated tasks across three difficulty levels, with tasks drawn from official
tutorials and popular real-world workflows. PSBench covers core functionalities
such as canvas adjustment, layer manipulation, and filter application, and provi
des fine-grained evaluation metrics tailored to each task category. Our experime
nts show that even the state-of-the-art system, Agent S3, achieves a success rat
e of only 18.09\% on difficult tasks, indicating that GUI agents still face cons
iderable challenges in operating complex professional software. Furthermore, hum
an-in-the-loop evaluations reveal that MLLMs, when serving as interactive assist
ants, can significantly improve novice users’ task completion rates and reduce o
peration time.

Phase-Aware Mixture of Experts for Agentic Reinforcement Learning
Shengtian Yang, Yu Li, Shuo He, Yewen Li, Qingpeng Cai, Peng Jiang, Lei Feng
Reinforcement learning (RL) has equipped LLM agents with a strong ability to sol
ve complex tasks. However, existing RL methods normally use a single policy netw
ork, causing simplicity bias where simple tasks occupy most parameters and domin
ate gradient updates, leaving insufficient capacity for complex tasks.
A plausible remedy could be employing the Mixture-of-Experts (MoE) architecture
in the policy network, as MoE allows different parameters (experts) to specializ
e in different tasks, preventing simple tasks from dominating all parameters.
However, a key limitation of traditional MoE is its token-level routing, where t
he router assigns each token to specialized experts, which fragments phase-consi
stent patterns into scattered expert assignments and thus undermines expert spec
ialization.
In this paper, we propose Phase-Aware Mixture of Experts (PA-MoE). It first feat
ures a lightweight phase router that learns latent phase boundaries directly fro
m the RL objective without pre-defining phase categories. Then, the phase router
 allocates temporally consistent assignments to the same expert, allowing expert
s to preserve phase-specific expertise.
Experimental results demonstrate the effectiveness of our proposed PA-MoE.
Code is available at https://anonymous.4open.science/r/PA-MoE-576C/.

Ranking Free RAG: Replacing Re-ranking with Selection in RAG for Sensitive Domai
ns
Yash Saxena, Ankur Padia, Mandar Chaudhary, Kalpa Gunaratna, srinivasan parthasa
rathy, Manas Gaur
Retrieval-Augmented Generation (RAG) systems deployed in sensitive domains must
provide interpretable evidence selection and robust safeguards against data pois
oning, yet current approaches rely on opaque similarity-based retrieval with arb

itrary top-k cutoffs that offer no explanation for their selections and remain v
ulnerable to adversarial manipulation. We propose METEORA, a rationale-driven RA
G framework that addresses these fundamental limitations through interpretable,
adaptive evidence retrieval. Our framework introduces three synergistic contribu
tions. First, we preference-tune a general-purpose LLM to generate explicit rati
onales that articulate why specific evidence is needed for a given query. These
rationales then guide adaptive evidence selection through a two-step process: ra
tionale-chunk pairing for query-specific relevance assessment, followed by dynam
ic cutoff detection that eliminates the need for arbitrary k heuristics. Finally
, the same rationales enable a verification stage that filters poisoned or misle
ading evidence before generation. Evaluation across six datasets demonstrates su
bstantial improvements on three critical dimensions. For retrieval quality, METE
ORA achieves **21.05\%** higher precision than the best-performing baseline, whi
le its variant with context expansion achieves **13.41\%** higher recall. In ter
ms of efficiency, the framework reduces the volume of evidence required to reach
 comparable recall by **80\%**, which directly translates to a **33.34\%** impro
vement in downstream answer generation accuracy. Most notably for adversarial ro
bustness, METEORA increases the F1 score from **0.10 to 0.44** under poisoning a
ttacks, a 4.4$\times$ improvement that makes RAG systems substantially more resi
lient to adversarial manipulation. Human evaluation with four experienced annota
tors confirms genuine interpretability, achieving a mean confidence score of **3
.64/5** and demonstrating that humans can reliably reconstruct evidence-level de
cisions with **86\% accuracy**. These results demonstrate that rationale-driven
retrieval can simultaneously enhance interpretability, efficiency, and safety in
 RAG systems for sensitive domains. The code is available in the anonymous GitHu
b repository \url{https://anonymous.4open.science/r/METEORA-DC46/README.md}

MALICE: Memory-aware Loop Invariants Generation on Symbolic Execution Traces
Tong Chen, Siyu Liu, Hongyi Zhong, Liao Zhang, Lixiang Wang, Xiwei Wu, Junchi Ya
n, Qinxiang Cao
Automatic loop invariant generation remains a challenging problem in program ver
ification, particularly for memory-manipulating programs where shape invariants
are required to characterize heap-allocated structures and memory layouts. While
 existing approaches succeed on numerical invariants, they achieve limited accur
acy on shape invariants. We hypothesize that this stems from the need to reason
about memory state evolution—information that remains implicit in source code. T
o address this, we ground LLM reasoning in symbolic execution traces that explic
itly capture such transitions. We propose \textsc{Malice}, a two-stage framework
 incorporating these traces: (1) guided multi-step reasoning that predicts invar
iants via chain-of-thought analysis of traces, and (2) agentic iterative refinem
ent that corrects candidates through verification tool feedback. Evaluated on LI
G-MM+, a benchmark featuring common operations on typical memory structures, \te
xtsc{Malice} substantially outperforms existing approaches.

InfoPO: Information-Driven Policy Optimization for User-Centric Agents
Fanqi Kong, Jiayi Zhang, Mingyi Deng, Chenglin Wu, Yuyu Luo, Bang Liu
Real-world user requests to LLM agents are often underspecified. Agents must int
eract to acquire missing information and make correct downstream decisions. Howe
ver, current multi-turn GRPO-based methods often rely on trajectory-level reward
 computation, which leads to credit assignment problems and insufficient advanta
ge signals within rollout groups. A feasible approach is to identify valuable in
teraction turns at a fine granularity to drive more targeted learning. To addres
s this, we introduce InfoPO, which frames multi-turn interaction as a process of
 active uncertainty reduction and computes an information-gain reward that credi
ts turns whose feedback measurably changes the agent’s subsequent action distrib
ution compared to a masked-feedback counterfactual.
It then combines this signal with task outcomes via an adaptive variance-gated f
usion to identify information importance while maintaining task oriented goal di
rection. Across diverse tasks including intent clarification, collaborative codi
ng, and tool-augmented decision making, InfoPO consistently outperforms promptin

g and multi-turn RL baselines. It also demonstrates robustness under user simula tor shifts and generalizes effectively to environment interactive tasks. Overall , InfoPO provides a principled and scalable mechanism for optimizing complex age nt user collaboration.

Breaking Dual Bottlenecks: Evolving Unified Multimodal Models into Self-Adaptive Interleaved Visual Reasoners
Qingyang Liu, Bingjie Gao, Canmiao Fu, Zhipeng Huang, Chen Li, Feng Wang, Shuoch en Chang, Shaobo Wang, Yali Wang, Keming Ye, Jiangtong Li, Li Niu
Recent unified models integrate multimodal understanding and generation within a single framework. However, an ``understanding-generation gap'' persists, where models can capture user intent but often fail to translate this semantic knowled ge into precise pixel-level manipulation. This gap results in two bottlenecks in anything-to-image task~(X2I): the \textbf{attention entanglement bottleneck}, w here blind planning struggles with complex prompts, and the \textbf{visual refin ement bottleneck}, where unstructured feedback fails to correct imperfections ef ficiently. In this paper, we propose a novel framework that empowers unified mod els to autonomously switch between generation strategies based on instruction co mplexity and model capability. To achieve this, we construct a hierarchical data pipeline that constructs execution paths across three adaptive modes: direct ge neration for simple cases, self-reflection for quality refinement, and multi-ste p planning for decomposing complex scenarios. Building on this pipeline, we cont ribute a high-quality dataset with over 50,000 samples and implement a two-stage training strategy comprising SFT and RL. Specifically, we design step-wise reas oning rewards to ensure logical consistency and intra-group complexity penalty t o prevent redundant computational overhead. Extensive experiments demonstrate th at our method outperforms existing baselines on X2I, achieving superior generati on fidelity among simple-to-complex instructions.

Q-Delta: Beyond Key–Value Associative State Evolution
Sumin Park, Seojin Kim, Noseong Park
Linear attention reformulates sequence modeling as recurrent state evolution, en abling efficient linear-time inference.
Under the key–value associative paradigm, existing approaches restrict the role of the query to the readout operation, decoupling it from state evolution. We sh ow that query-conditioned state readout induces a structured value prediction ov er accumulated memory that complements key-based retrieval. Based on this insigh t, we propose Q-Delta, a query-aware delta rule that integrates mixed key--query prediction errors into state evolution, enabling jointly corrective dynamics wh ile preserving delta-rule efficiency. We establish stability guarantees for the resulting dynamics and derive a hardware-efficient chunkwise-parallel formulatio n with a custom Triton implementation.
Empirical results demonstrate stable optimization, competitive throughput, and c onsistent improvements over strong baselines on language modeling and long-conte xt retrieval tasks. Code is available at \url{https://github.com/psmiz/Q-Delta}.

Spectral Collapse Drives Loss of Plasticity in Deep Continual Learning
Arjun Prakash, Naicheng He, Kaicheng Guo, Saket Tiwari, Tyrone Serapio, Ruo Yu T ao, Amy Greenwald, George Konidaris
We investigate why deep neural networks suffer from loss of plasticity in contin ual learning, and thus fail to learn new tasks without reinitializing parameters . We show that this failure is preceded by Hessian spectral collapse at new-task initialization, where meaningful curvature directions vanish and gradient desce nt becomes ineffective. Analyzing a linearized ReLU network, we derive explicit ϵ-rank conditions for successful training and prove that the loss-weigh ted Gram matrix is spectrally equivalent to the Generalized Gauss-Newton approxi mation, thereby relating NTK dynamics to Hessian curvature. Targeting spectral c ollapse directly, we then discuss the Kronecker factored approximation of the He ssian, which motivates two regularization enhancements: maintaining high effecti ve feature rank and applying L2 penalties. Experiments on continual supervised a

nd reinforcement learning tasks confirm that combining these two regularizers ef
fectively preserves plasticity.

PACEAttention: Principled and Adaptive Feature Compression-Expansion Grounded in
 the Geometry of MCR^2
Xiaojie Yu, Haibo Zhang, Jeremiah D. Deng, Lizhi Peng
The maximal coding rate reduction (MCR^2) objective is proposed for lea
rning low-dimensional subspace representations and for principled deep model des
ign, where layer structures are derived by unrolling its optimization steps.
However, existing methods motivated by this objective do not fully adhere to des
ign principles implied by the MCR^2 gradient, which weakens the princip
led and interpretable foundations of the resulting models.
In this work, we introduce PACEAttention, a novel principled attention mechanism
 inspired by the *geometric insight* of MCR^2, whose gradient-based upd
ates
move features along directions shaped by the underlying low-dimensional feature
structure.
Our method captures this structure by leveraging randomization to guide feature
updates.
This principled construction enables the resulting PACENet to exhibit enhanced i
nterpretability, with different heads attending to distinct image regions and ca
pturing *fine-grained* structures under simple supervised training.
Experiments demonstrate that PACEAttention achieves superior performance and mor
e stable scalability than previous principled modules while remaining low comple
xity.

An Exploration of Non-Euclidean Gradient Descent: Muon and its Many Variants
Michael Crawshaw, Chirag Modi, Mingrui Liu, Robert M. Gower
To define a steepest descent method over a neural network, we need to choose a n
orm for each layer, a way to aggregate these norms across layers, and whether to
 use normalization. We systematically explore different alternatives for aggrega
ting norms across layers, both formalizing existing combinations of Adam and the
 recently proposed Muon as a type of non-Euclidean gradient descent, and derivin
g new variants of the Muon optimizer. Through a comprehensive experimental evalu
ation of the optimizers within our framework, we find that Muon is sensitive to
the choice of learning rate, whereas a new variant we call MuonMax is significan
tly more robust. We then show how to combine any non-Euclidean gradient method w
ith model based momentum (known as Momo). The new Momo variants of Muon are sign
ificantly more robust to hyperparameter tuning, and often achieve a better valid
ation score. Thus for new tasks, where the optimal hyperparameters are not known
, we advocate for using Momo in combination with MuonMax to save on costly hyper
parameter tuning.
****

TiMi: Empower Time Series Transformers with Multimodal Mixture of Experts
Jiafeng Lin, Yuxuan Wang, Huakun Luo, Jianmin Wang, Zhongyi Pei
Multimodal time series forecasting has garnered significant attention for its po
tential to provide more robust and accurate predictions than traditional single-
modality models by leveraging rich information inherent in other modalities. How
ever, due to fundamental challenges in modality alignment, existing methods ofte
n struggle to effectively incorporate multimodal data into predictions, particul
arly textual information that has a causal influence on time series fluctuations
, such as emergency reports and policy announcements. In this paper, we reflect
on the role of textual information in numerical forecasting and propose **Ti**me
 series transformers with Multimodal **Mi**xture-of-Experts, **TiMi**, to unleas
h the causal reasoning capabilities of LLMs. Concretely, TiMi utilizes language
models to generate inferences on future developments, which then serve as guidan
ce for time series forecasting. To seamlessly integrate both exogenous factors a
nd time series into predictions, we introduce a Multimodal Mixture-of-Experts (M
MoE) module as a lightweight plug-in to empower Transformer-based time series mo
dels for multimodal forecasting, eliminating the need for explicit representatio

n-level alignment. Experimentally, our proposed TiMi demonstrates consistent sta
te-of-the-art performance on sixteen real-world multimodal forecasting benchmark
s, outperforming advanced baselines while offering strong adaptability and inter
pretability.
****
Prediction-Powered Risk Monitoring of Deployed Models for Detecting Harmful Dist
ribution Shifts
Guangyi Zhang, Yunlong Cai, Guanding Yu, Osvaldo Simeone
We study the problem of monitoring model performance in dynamic environments whe
re labeled data are limited. To this end, we propose prediction-powered risk mon
itoring (PPRM), a semi-supervised risk-monitoring approach based on prediction-p
owered inference (PPI). PPRM constructs anytime-valid lower bounds on the runnin
g risk by combining synthetic labels with a small set of true labels. Harmful sh
ifts are detected via a threshold-based comparison with an upper bound on the no
minal risk, satisfying assumption-free finite-sample guarantees on the type-I er
ror. We demonstrate the effectiveness of PPRM through extensive experiments on i
mage classification, large language model (LLM), and telecommunications monitori
ng tasks.
****
TVI-CoT: Text-Visual Interleaved Chain-of-Thought Reasoning for Multimodal Under
standing
Lianyu Hu, MA XIAOYU, Zeqin Liao, Yang Liu
Chain-of-thought (CoT) reasoning has proven effective for enhancing problem-solv
ing in large language models. However, when applied to multimodal LLMs (MLLMs),
existing CoT approaches suffer from a fundamental limitation: they perform reaso
ning entirely in text without accessing visual features during the reasoning pro
cess. After initial visual encoding, image information becomes inaccessible, for
cing models to reason based solely on whatever was captured in the initial descr
iption, which forms a `vision-blind reasoning' paradigm that limits fine-grained
 visual extraction, error verification, and adaptive attention. We propose Text-
Visual Interleaved Chain-of-Thought (TVI-CoT), a framework that enables explicit
 interleaving of textual reasoning and visual feature access through learnable c
ontrol tokens ($\langle\text{Think}\rangle$, $\langle\text{Look}\rangle$, $\lang
le\text{Answer}\rangle$). These tokens allow dynamic switching between reasoning
 and visual grounding, attending to relevant image regions conditioned on the ev
olving reasoning state. Experiments on eight benchmarks demonstrate state-of-the
-art results among MLLM-based CoT methods and notable performance boost compared
 to the baseline: +6.1\% on MMMU, +3.8\% on MathVerse, +3.4\% on MathVista, and
+3.4\% on ScienceQA. Code is available at https://github.com/hulianyuyy/TVI-CoT.
****
Co-Generative De Novo Functional Protein Design
Xinrui Chen, Yizhen Luo, Siqi Fan, Zaiqing Nie
De novo functional protein design aims to generate protein sequences that real
ize specified biochemical functions without relying on evolutionary templates, e
nabling broad applications in biotechnology and medicine. Existing approaches ad
opt either direct function-to-sequence mapping or decoupled structure-sequence g
eneration strategies but often fail to achieve functionality and foldability sim
ultaneously.
To address this, we propose **CodeFP**, a **Co**-generative protein language mod
el for ***de** novo* **F**unctional **P**rotein design that simultaneously decod
es sequence and structure tokens, thereby enabling superior simultaneous realiza
tion of functionality and foldability.
CodeFP utilizes functional local structures to enrich functional semantic encodi
ngs, overcoming the suboptimal translation of flat encodings into structure toke
ns, while introducing auxiliary functional supervision to alleviate training amb
iguity stemming from the one-to-many structure-to-token mapping. Extensive exper
iments show that CodeFP consistently achieves average improvements of 6.1\% in f
unctional consistency and 3.2\% in foldability over the strongest baseline.
****
Time Series Reasoning via Process-Verifiable Thinking Data Synthesis and Schedul

ing for Tailored LLM Reasoning
Jiahui Zhou, Dan Li, Boxin Li, Xiao Zhang, Erli Meng, Lin Li, Zhuomin Chen, Jian Lou, See-Kiong Ng
Time series is a pervasive data type across various application domains, rendering the reasonable solving of diverse time series tasks a long-standing goal. Recent advances in large language models (LLMs), especially their reasoning abilities unlocked through reinforcement learning (RL), have opened new opportunities for tackling tasks with long Chain-of-Thought (CoT) reasoning. However, leveraging LLM reasoning for time series remains infancy, hindered by the absence of carefully curated time series CoT data for training, limited data efficiency caused by underexplored data scheduling, and the lack of RL algorithms tailored for exploiting such time series CoT data. In this paper, we introduce VeriTime, a framework that tailors LLMs for time series reasoning through data synthesis, data scheduling, and RL training. First, we propose a data synthesis pipeline that constructs a time series–text multimodal dataset with process-verifiable annotations. Second, we design a data scheduling mechanism that arranges training samples according to a principled hierarchy of difficulty and task taxonomy. Third, we develop a two-stage reinforcement finetuning featuring fine-grained, multi-objective rewards that leverages verifiable process-level CoT data. Extensive experiments show that VeriTime substantially boosts LLM performance across diverse time series reasoning tasks. Notably, it enables compact 3B–4B models to achieve reasoning capabilities on par with or exceeding those of larger proprietary LLMs.
****
SLIP-RS: Structured-Attribute Language-Image Pre-Training for Remote Sensing Object Detection
Chenxu Wang, Yuxuan Li, Yunheng Li, Xiang Li, Jingyuan Xia, Qibin Hou
Existing language-image pre-training for remote sensing object detection is constrained by Monolithic Label Learning, which relies on exhaustively enumerating open-set categories via black-box data to acquire fine-grained representations, creating a dependency incompatible with the domain's inherent data scarcity.
To transcend this bottleneck, we propose SLIP-RS, establishing a Structured-Attribute Decoupling Paradigm that maps the open-ended category space into a finite, physically meaningful attribute space, unlocking fine-grained discriminability via explicit structural logic.
This paradigm is realized via two technical pillars:
(1) Structured-Attribute Contrastive Learning, which enforces the learning of decoupled intrinsic visual logic via combinatorial attribute augmentation;
and (2) Conformal Attribute Reliability Engine, which leverages conformal prediction theory to rigorously distill high-fidelity supervision from noisy sources, yielding RS-Attribute-15M, the largest dataset with over 15 million attribute annotations.
Extensive experiments demonstrate that SLIP-RS establishes unprecedented performance in fine-grained detection and cross-domain generalization, validating structured attributes as a vital foundation for scalable remote sensing models.
****
NNiT: Width-Agnostic Neural Network Generation with Structurally Aligned Weight Spaces
Jiwoo Kim, Swarajh Mehta, Hao-Lun Hsu, Hyunwoo Ryu, Yudong Liu, Miroslav Pajic
Generative modeling of neural network parameters is often tied to architectures because standard parameter representations rely on known weight-matrix dimensions. Generation is further complicated by permutation symmetries that allow networks to model similar input-output functions while having widely different, unaligned parameterizations. In this work, we introduce Neural Network Diffusion Transformers (NNiTs), which generate weights in a width-agnostic manner by tokenizing weight matrices into patches and modeling them as locally structured fields. We establish that Graph HyperNetworks (GHNs) with a convolutional neural network (CNN) decoder structurally align the weight space, creating the local correlation necessary for patch-based processing. Focusing on Multilayer Perceptrons (MLPs), where permutation symmetry is especially apparent, NNiTs generate fully functional networks across a range of architectures. Our approach jointly models discr

ete architecture tokens and continuous weight patches within a single sequence m
odel. On ManiSkill3 robotics tasks, NNiT achieves $>85\%$ success on architectur
e topologies unseen during training, while baseline approaches fail to generaliz
e; the same pipeline also generalizes to MNIST classification beyond the robotic
 control setting.
****
Goal-Oriented Lower-Tail Calibration of Gaussian Processes for Bayesian Optimiza
tion
Aurélien Pion, Emmanuel Vazquez
Bayesian optimization (BO) selects evaluation points for expensive
black-box objectives using Gaussian process (GP) predictive
distributions.
Kernel choice and hyperparameter selection can lead to miscalibrated
predictive distributions and an inappropriate exploration--exploitation trade-of
f.
For minimization, sampling criteria such as expected improvement (EI) depend on
the predictive distribution below the current best value, so lower-tail
miscalibration directly affects the sampling decision.
This article studies goal-oriented calibration of GP predictive distributions
below a low threshold t in the noiseless setting, for standard GP models with
hyperparameters selected by maximum likelihood.
A framework for predictive reliability below t is introduced, based on two
notions of spatial calibration: occurrence calibration over the design
space and thresholded μ-calibration on sublevel sets of the form $\lbrace x\
in\mathbb{X}, f(x)\le t \rbrace$.
Building on this framework, we propose tcGP, a post-hoc method that calibrates
GP predictive distributions below t, and we show that the resulting EI-based
global optimization algorithm remains dense in the design space.
Experiments on standard benchmarks show improved lower-tail calibration and BO
performance relative to standard GP models and globally calibrated GP models.
****
Jailbreak to Protect: Buffering and Reinforcing via Temporary Jailbreaking for S
afe Fine-Tuning in Large Language Models
Seokil Ham, Jaehyuk Jang, Wonjun Lee, Changick Kim
Fine-tuning-as-a-Service (FaaS) enables personalization of large language models
 (LLMs), but it can weaken safety-alignment under harmful fine-tuning attacks. R
ecent work has shown that activating harmful-behavior modules during fine-tuning
 can prevent models from learning undesired behaviors, but its mechanism remains
 unclear. In this paper, we revisit temporary jailbreaking as a defense against
harmful fine-tuning and provide a gradient-level analysis showing that it satura
tes safety-degrading gradients while preserving benign task-relevant gradients.
Based on this insight, we propose a **Buffer-and-Reinforce fine-tuning framework
** that buffers harmful updates during user fine-tuning and reinforces safety af
ter adaptation. Specifically, BufferLoRA induces temporary jailbreaking as a rem
ovable adapter to reduce harmful updates during user fine-tuning. After adaptati
on, ReinforceLoRA, trained to recover refusal behavior under the temporarily jai
lbroken state, is integrated with UserLoRA via QR decomposition-based merging to
 reinforce safety while preserving user-task performance. Extensive experiments
show that our framework achieves superior safety and utility with no additional
safety data during user fine-tuning and minimal computational cost.
****
Poison with Style: A Practical Poisoning Attack on Code Large Language Models
Khang Tran, Yazan Boshmaf, Issa Khalil, Hai Phan, Ting Yu, Md Rizwan Parvez
Code Large Language Models (CLLMs) serve as the core of modern code agents, enab
ling developers to automate complex software development tasks. In this paper, w
e present Poison-with-Style (PwS), a practical and stealthy model poisoning atta
ck targeting CLLMs. Unlike prior attacks that assume an active adversary capable
 of directly embedding explicit triggers (e.g., specific words) into developers'
 prompts during inference, PwS leverages developers' code styles as covert trigg
ers implicitly embedded within their prompts. PwS introduces a novel data collec

tion method and a two-step training strategy to fine-tune CLLMs, causing them to generate vulnerable code when prompts contain trigger code styles while maintaining normal behavior on other prompts. Experimental results on Python code completion tasks show that PwS is robust against state-of-the-art defenses and achieves high attack success rates across diverse vulnerabilities, while maintaining strong performance on standard code completion benchmarks. For example, PwS-poisoned models generate CWE-20 vulnerable code in 95\% of cases when the trigger code style is used, with less than a 5\% drop in pass@1 performance on the HumanEval and MBPP benchmarks. Our implementation and dataset are here: https://github.com/khangtran2020/pws.

Capturing Gaze Shifts for Guidance: Cross-Modal Fusion Enhancement for VLM Hallucination Mitigation
Zheng Qi, Chao Shang, Evangelia Spiliopoulou, Nikolaos Pappas
Vision language models (VLMs) often generate hallucination, i.e., content that cannot be substantiated by either textual or visual inputs. Prior work primarily attributes this to over-reliance on linguistic prior knowledge rather than visual inputs. Some methods attempt to mitigate hallucination by amplifying visual token attention proportionally to their attention scores. However, these methods overlook the visual attention sink problem, where attention is frequently misallocated to task-irrelevant visual regions, and neglect cross-modal fusion balance by enhancing only visual attention without adjusting attention to the user query. This can result in amplifying incorrect areas while failing to properly interpret the user query. To address these challenges, we propose a simple yet effective method called Gaze Shift-Guided Cross-modal Fusion Enhancement (GIFT). GIFT pre-computes a holistic visual saliency map by tracking positive changes in visual attention, or "gaze shifts", during user query comprehension, and leverages this map to amplify attention to both salient visual information and the user query at each decoding step. This reduces the impact of visual attention sink, as irrelevant tokens exhibit minimal shifts, while ensuring balanced cross-modal fusion for well-integrated representation. Extensive experiments show that GIFT effectively mitigates hallucination in VLMs across both generative and classification tasks, achieving up to 20.7% improvement over greedy decoding, while maintaining general vision-language performance with low computational overhead.

Towards Sub-Second Molecular Docking as a Structural Primitive: A Quantized Consistency Diffusion Framework
Kexin Zhang, Weichen Qin, Yue Teng, Jiale Yu, Yuanyuan Ma, Jinyu Lin, Liping Sun, Jie Zheng, Jingyi Yu
Agent-centered scientific discovery is turning scientific models into always-on computational infrastructure.
In this paradigm, AI agents coordinate tools, interpret feedback, and drive high-frequency research loops, requiring domain models that are both accurate and callable in real time.
Molecular docking exposes this bottleneck: it provides essential structural feedback for drug discovery, yet current high-fidelity docking and co-folding models remain limited by iterative generative refinement and heavy computation.
We present a compute-efficient co-folding framework that turns molecular docking into a sub-second structural primitive.
Because docking methods operate under different levels of structural prior, we report accuracy under information-level-matched protocols, comparing blind settings with blind generative methods and interface-informed settings with surface- or interface-informed baselines.
Our framework combines two ideas.
First, Progressive Consistency Regularization (PCR) compresses diffusion dynamics into reliable few-step inference through reconstruction-anchored consistency tuning.
Second, Residual-Safe Quantization preserves high-fidelity residual streams and geometry-sensitive operations in BF16 while quantizing selected compute-intensive linear transformations.

Our model achieves state-of-the-art docking accuracy under the matched interface-informed protocol, reports blind docking performance separately under the matched blind protocol, and generates five conformations for a representative 256-token complex in 0.17 seconds on a single NVIDIA H20 GPU, delivering a $>300\times$ speedup over AlphaFold3 under the benchmarked setting.
Together, these results move molecular docking from an offline generative simulator toward a real-time structural primitive for agent-centered drug discovery.
****
Retriever Portfolios: A Principled Approach to Adaptive RAG
Miltiadis Stouras, Vincent Cohen-Addad, Silvio Lattanzi, Ola Svensson
Retrieval-augmented generation (RAG) systems typically rely on a single retriever and a single set of hyperparameters, despite facing highly heterogeneous queries that range from simple factoid questions to complex multi-hop reasoning. We propose a method that automatically selects a small, diverse subset of retrievers (a portfolio) from a large pool of candidates, to cover different regions of the target query distribution.
We formalize this setting via an expected best-of-k objective over the query distribution and show that it admits an efficient portfolio construction algorithm with near-optimal guarantees. Across multiple QA benchmarks, our learned portfolios and router pipeline consistently outperform single-retriever and naive multi-retriever baselines on both retrieval metrics and answer quality.
In addition, compared to inference-time hyperparameter tuning approaches, fixed portfolios enable parallel retrieval and LLM calls, achieving comparable (and sometimes better) accuracy with substantially lower latency and token cost.

Benchmarking World-Model Learning with Environment-Level Queries
Archana Warrier, Dat Nguyen, Michelangelo Naim, Moksh Jain, Yichao Liang, Karen Schroeder, Cambridge Yang, Joshua B. Tenenbaum, Sebastian Josef Vollmer, Kevin Ellis, Zenna Tavares
World models are central to building AI agents capable of flexible reasoning and planning. Yet current evaluations (i) test only properties measurable from observed interactions, such as next-frame prediction or task return, and (ii) do not test whether a learned model supports diverse queries about the environment.

In contrast, humans build *general-purpose* models that can answer many different questions about an environment—including questions that require understanding global structure and counterfactual consequences.

We propose *WorldTest*: a protocol for evaluating whether agents learn models that support multiple *environment-level queries*—questions whose answers depend on properties of the full environment, not just observed trajectories.

Individually, these queries can target properties (e.g., reachability or the effects of interventions) that no single rollout distribution determines. Collectively, they assess model generality across query types.

We instantiate WorldTest as *AutumnBench*, a benchmark of 43 interactive grid-world environments and 129 tasks across three query families for both humans and learning agents.

Experiments with 517 human participants and five frontier models on AutumnBench show that humans substantially outperform these models, a gap we attribute to differences in exploration and belief updating.
****
Physiology-Aware Masked Cross-Modal Reconstruction for Biosignal Representation Learning
Hao Zhou, Simon A. Lee, Cyrus Tanade, Keum San Chun, Juhyeon Lee, Migyeong Gwak, Megha Thukral, Justin Sung, Eugene Hwang, Mehrab Bin Morshed, Li Zhu, Viswam Nathan, Md Mahbubur Rahman, Subramaniam Venkatraman, Sharanya Arcot Desai

Biosignals acquired from different locations on the body often provide temporally ordered views of the same underlying physiological process. However, most existing self-supervised learning methods treat these signals as interchangeable views, overlooking the directional temporal dynamics that link them. A canonical example is the relationship between electrocardiography (ECG), which captures the electrical activation initiating each heartbeat, and photoplethysmography (PPG), which records the resulting peripheral pulse delayed by vascular dynamics. To capture this structured relationship, we introduce xMAE, a biosignal pretraining framework that leverages masked cross-modal reconstruction across temporally ordered biosignals as a training-time constraint to encourage physiologically meaningful timing structure in the learned representations. We show that pretraining with xMAE yields representations that outperform both unimodal and multimodal baselines on 15 of 19 downstream tasks, including cardiovascular outcome prediction, abnormal laboratory test detection, sleep staging, and demographic inference, while generalizing across devices, body locations, and acquisition settings. Further analysis suggests that the ECG--PPG timing structure is reflected in the learned PPG representations. Code is available at https://github.com/hzhou3/xMAE.

WMVLM: Evaluating Diffusion Model Image Watermarking via Vision-Language Models
Zijin Yang, Yu Sun, Kejiang Chen, Jiawei Zhao, Jun Jiang, Weiming Zhang, Nenghai Yu

Digital watermarking is essential for securing generated images from diffusion models. Accurate watermark evaluation is critical for algorithm development, yet existing methods have significant limitations: they lack a unified framework for both residual and semantic watermarks, provide results without interpretability, neglect comprehensive security considerations, and often use inappropriate metrics for semantic watermarks. To address these gaps, we propose **WMVLM**, the first unified and interpretable evaluation framework for diffusion model image **w**ater**m**arking via **v**ision-**l**anguage **m**odels (VLMs).
We redefine quality and security metrics for each watermark type: residual watermarks are evaluated by artifact strength and erasure resistance, while semantic watermarks are assessed through latent distribution shifts. Moreover, we introduce a three-stage training strategy to progressively enable the model to achieve classification, scoring, and interpretable text generation. Experiments show WMVLM outperforms state-of-the-art VLMs with strong generalization across datasets, diffusion models, and watermarking methods.

SAME: Stabilized Mixture-of-Experts for Multimodal Continual Instruction Tuning
Zhen-Hao Xie, Jun-Tao Tang, Yu-Cheng Shi, Han-Jia Ye, De-Chuan Zhan, Da-Wei Zhou

Multimodal Large Language Models (MLLMs) achieve strong performance through instruction tuning, but real-world deployment requires them to continually expand their capabilities, making Multimodal Continual Instruction Tuning (MCIT) essential. Recent methods leverage sparse expert routing to promote task specialization, but we find that the expert routing process suffers from drift as the data distribution evolves. For example, a grounding query that previously activated localization experts may instead be routed to irrelevant experts after learning OCR tasks. Meanwhile, the grounding-related experts can be overwritten by new tasks and lose their original functionality. Such failure reflects two problems: router drift, where expert selection becomes inconsistent over time, and expert drift, where shared experts are overwritten across tasks. Therefore, we propose StAbilized Mixture-of-Experts (SAME) for MCIT. To address router drift, SAME stabilizes expert selection by decomposing routing dynamics into orthogonal subspaces and updating only task-relevant directions. To mitigate expert drift, we regulate expert updates via curvature-aware scaling using historical input covariance in a rehearsal-free manner. SAME also introduces adaptive expert activation to freeze selected experts during training, reducing redundant computation and cross-task interference. We also introduce a new benchmark to evaluate MCIT with long task sequence, and extensive experiments demonstrate SAME's SOTA performance. Code is available at https://github.com/LAMDA-CL/Prism.

Cycle-of-Science: Reliable Reasoning through Counterfactual Verification for Agent Decision Making
Ruojie Zhang, Wencheng Zhu, Peiyuan Jiang, dayong zhu
Large Language Models have significantly advanced autonomous agents through their sophisticated perception and execution capabilities.
Despite effective, agents still struggle with robust decision-making due to passive learning from similar experiences that often confound correlation with causality. Inspired by the Scientific Method, we propose a Cycle-of-Science framework that autonomously explores potential causal pathways through an iterative loop of \textit{Hypothesis, Experiment, and Validation}, enabling agents to identify truly effective causal dependencies. To be specific, we first leverage causal knowledge to guide the initial hypotheses generation. These hypotheses are then analyzed through experiments using counterfactual samples. Afterward, we perform causal analysis to quantify effects of interventions, deriving well-validated hypotheses for next agent steps. To train our policy, we further introduce a two-stage pipeline that integrates supervised fine-tuning with Counterfactual Preference Optimization, which constructs preference signals from intervention outcomes to reinforce validated reasoning chains. Experiments on benchmarks demonstrate that our method achieves superior performance over state-of-the-art approaches.
****
A Benchmark and Framework for Evaluating Next Action Predictions in Spreadsheets
Tejas Agrawal, Vu Le, Sumit Gulwani, Gust Verbruggen
Predictive code completion greatly accelerates how quickly developers work.
In spreadsheets, despite being much more common, such auto-completion features are virtually non-existent.
To address this gap, we introduce a benchmark for systems that observe a sequence of user actions in a spreadsheet and predict future actions.
Two challenges are (1) the absence of edit histories in public spreadsheet corpora and (2) the complex space of spreadsheet actions (spatial, temporal, composite).
To address (1), we manually curate 52 sequences of 12K actions that recreate spreadsheets from public corpora, seeded by parametrized heuristics and LLM refinement.
To address (2), we propose an online evaluation that expects a prediction after each user action, accepts or rejects that prediction, updates the future actions upon acceptance, and repeats this until the target spreadsheet is obtained.
We use multiple baseline predictors (including zero-shot LLMs, fine-tuned SLMs, and classical models) and analyze different properties that our benchmark teaches us, including but not limited to: properties of saved actions and false positives, efficiency, effect of user profiles, effect of triggers, and effect of context.

Computationally-efficient Graph Modeling with Refined Graph Random Features
Krzysztof Marcin Choromanski, Kumar Avinava Dubey, Arijit Sehanobish, Isaac Reid
We propose *refined GRFs* (GRFs++), a new class of *Graph Random Features* (GRFs) for efficient and accurate computations involving kernels defined on the nodes of a graph. GRFs++ resolve some of the long-standing limitations of regular GRFs, including difficulty modeling relationships between more distant nodes. They reduce dependence on sampling long graph random walks via a novel *walk-stitching* technique, concatenating several shorter walks without breaking unbiasedness. By applying these techniques, GRFs++ inherit the approximation quality provided by longer walks but with greater efficiency, trading sequential inefficient sampling of a long walk for parallel computation of short walks and matrix-matrix multiplication. Furthermore, GRFs++ extend the simplistic GRFs walk termination mechanism (Bernoulli schemes with fixed halting probabilities) to a broader class of strategies, applying general distributions on the walks' lengths.
This improves approximation accuracy of graph kernels, without incurring extra computational cost. We provide empirical evaluations to showcase our claims and complement our results with theoretical analysis.

AIR-VLA: Vision-Language-Action Systems for Aerial Manipulation
Jianli Sun, Bin Tian, Qiyao Zhang, Chengxiang Li, Song Zihan, Zhiyong Cui, Yisheng Lv, Yonglin Tian
While Vision-Language-Action (VLA) models have achieved remarkable success in ground-based embodied intelligence, their application to Aerial Manipulation Systems (AMS) remains a largely unexplored frontier. The inherent characteristics of AMS, including floating-base dynamics, strong coupling between the UAV and the manipulator, and the multi-step, long-horizon nature of operational tasks, pose severe challenges to existing VLA paradigms designed for static or 2D mobile bases. To bridge this gap, we propose AIR-VLA, the first VLA benchmark specifically tailored for aerial manipulation. We construct a physics-based simulation environment and release a high-quality multimodal dataset comprising 3000 manually teleoperated demonstrations, covering base manipulation, object & spatial understanding, semantic reasoning, and long-horizon planning. Leveraging this platform, we systematically evaluate mainstream VLA models and state-of-the-art VLM models. Our experiments not only validate the feasibility of transferring VLA paradigms to aerial systems but also, through multi-dimensional metrics tailored to aerial tasks, reveal the capabilities and boundaries of current models regarding UAV mobility, manipulator control, and high-level planning. AIR-VLA establishes a standardized testbed and data foundation for future research in general-purpose aerial robotics. The resource of AIR-VLA will be available at https://anonymous.4open.science/r/AIR-VLA-dataset-B5CC/.

ParalESN: Enabling parallel information processing in Reservoir Computing
Matteo Pinna, Giacomo Lagomarsini, Andrea Ceni, Claudio Gallicchio
Reservoir Computing (RC) has established itself as an efficient paradigm for temporal processing. However, its scalability remains severely constrained by the need to process temporal data sequentially and the prohibitive memory footprint of high-dimensional reservoirs. To address these limitations, we revisit RC through the lens of structured operators and state space modeling, introducing Parallel Echo State Network (ParalESN). Leveraging diagonal linear recurrence in the complex domain, ParalESN enables parallel processing of temporal data and the construction of efficient, high-dimensional reservoirs. A thorough theoretical analysis demonstrates that the Echo State Property and the universality guarantees of traditional Echo State Networks are preserved, while also admitting an equivalent representation of arbitrary linear reservoirs in the complex diagonal form. Empirically, ParalESN achieves competitive predictive accuracy with traditional RC and with fully trainable sequence models, while delivering computational savings by orders of magnitude. Overall, ParalESN offers a scalable and principled pathway for integrating RC within the deep learning landscape.

Scaling Generative Verifiers For Natural Language Mathematical Proof Verification And Selection
Sadegh Mahdavi, Branislav Kisacanin, Shubham Toshniwal, Wei Du, Ivan Moshkov, George Armstrong, Renjie Liao, Christos Thrampoulidis, Igor Gitman
Large language models have achieved remarkable success on final-answer mathematical problems, largely due to the ease of applying reinforcement learning with verifiable rewards. However, the reasoning underlying these solutions is often flawed. Advancing to rigorous proof-based mathematics requires reliable proof verification capabilities. We begin by analyzing multiple evaluation setups and show that focusing on a single benchmark can lead to brittle or misleading conclusions. To address this, we evaluate both proof-based and final-answer reasoning to obtain a more reliable measure of model performance. We then scale two major generative verification methods (GenSelect and LLM-as-a-Judge) to millions of tokens and identify their combination as the most effective framework for solution verification and selection. We further show that the choice of prompt for LLM-as-a-Judge significantly affects the model's performance, but reinforcement learning can reduce this sensitivity. However, despite improving proof-level metrics, reinforcement learning does not enhance final-answer precision, indicating that current models often reward stylistic or procedural correctness rather than mathema

tical validity. Our results establish practical guidelines for designing and eva luating scalable proof-verification and selection systems.

LLawCo: Learning Laws of Cooperation for Modeling Embodied Multi-Agent Behavior
Qinhong Zhou, Chuang Gan, Anoop Cherian
Embodied agents operating in decentralized and partially observable environments have attracted growing attention in recent years. However, existing large langu age model (LLM)-based agents often exhibit behaviors that are misaligned with th eir partners or inconsistent with the environment state, leading to inefficient cooperation and poor task success. To address this challenge, we propose a novel framework, Learning Laws of Cooperation (LLawCo), that enables embodied agents to autonomously align with both their partners and task objectives. Our framewor k allows agents to reflect on past failures to extract misaligned behavioral pat terns, which are used to derive high-level behavioral laws, such as “Talk when n ecessary” and “Wait for partner.” These laws are explicitly incorporated into th e agents’ chains of thought via supervised fine-tuning, aligning their reasoning with task requirements and the behavior of other agents. To evaluate our approa ch, we introduce PARTNR-Dialog, a large-scale multi-agent communicative and coop erative planning benchmark built on the PARTNR environment. Experiments on exist ing tasks and our new benchmark demonstrate significant improvements in cooperat ive efficiency and task success rates. Across four backbone LLMs, our method ach ieves average success rate improvements of 4.5% on the PARTNR-Dialog benchmark a nd 6.8% on the TDW-MAT benchmark over state-of-the-art open-source communicative agent frameworks.

Revisiting the Role of Pretrained Weights in Model Merging: On Near-Optimality w ithin the Core Subspace
Wenju Sun, Qingyong Li, Tiancheng Li, Yangliao Geng, Boyang Li
Model merging offers an efficient solution for integrating task-specific knowled ge from multiple fine-tuned models. Most existing approaches focus on manipulati ng the difference vectors between fine-tuned and pretrained weights, often overl ooking the generalization capabilities inherent in the pretrained parameters. In this work, we revisit the role of pretrained weights in model merging and inves tigate their efficacy from a subspace perspective. We find that the components o f pretrained weights residing in the core subspace—defined by the dominant singu lar vectors—are essential for maintaining generalization across diverse tasks. S pecifically, we present empirical evidence that pretrained weights are nearly fi rst-order stationary and exhibit predominantly non-negative curvature within thi s core subspace with respect to multi-task loss landscapes, indicating near-opti mality. These findings suggest that task-specific adaptations should be injected primarily into the orthogonal complement of the core subspace, thereby preservi ng the generalization properties of the pretrained model. Extensive experiments on vision and vision-language tasks show that this subspace-aware strategy consi stently yields improvements over state-of-the-art training-free merging methods, including Task Arithmetic, LOT Merging, ISO, and TSV. The source code is availa ble at https://github.com/SunWenJu123/model-merging.

Emergence of Exploration in Policy Gradient Reinforcement Learning via Retrying
Soichiro Nishimori, Paavo Parmas, Sotetsu Koyamada, Tadashi Kozuno, Toshinori Ki tamura, Shin Ishii, Yutaka Matsuo
In reinforcement learning (RL), agents benefit from exploration *only* because t hey repeatedly encounter similar states: trying different actions can improve pe rformance or reduce uncertainty; without such retries, a greedy policy is optima l. We formalize this intuition with **ReMax**, an objective that evaluates a pol icy by the expected maximum return over M samples ($M \in \mathbb{N}$), while accounting for return uncertainty. Optimizing this objective induces stochastic exploration as an emergent property, without explicit bonus terms. For efficient policy optimization, we derive a new policy-gradient formulation for ReMax and introduce **Re**Max **PPO** (**RePPO**), a PPO variant that optimizes ReMax whil e generalizing the discrete retry count M to a continuous parameter $m > 0$, e

nabling fine-grained control of exploration. Empirically, RePPO promotes explora tion—without any explicit exploration bonuses—on the MinAtar and Craftax benchma rks. The official code is available at https://github.com/nissymori/remax-rl.

Provably Convergent Actor-Critic for MARL through Risk-aversion
Yizhou Zhang, Eric Mazumdar
Learning stationary policies in infinite-horizon general-sum Markov games (MGs) remains a fundamental open problem in Multi-Agent Reinforcement Learning (MARL). While stationary strategies are preferred for their practicality, computing sta tionary forms of classic game-theoretic equilibria is computationally intractabl e—a stark contrast to the comparative ease of solving single-agent RL or zero-su m games. To bridge this gap, we study Risk-averse Quantal response Equilibria (R QE), a solution concept rooted in behavioral game theory that incorporates risk aversion and bounded rationality. We demonstrate that RQE possesses strong regul arity conditions that make it uniquely amenable to learning in MGs. We propose a novel single-timescale Actor-Critic algorithm characterized by a faster actor a nd a slower critic. Leveraging the regularity of RQE, we prove that this approac h achieves global convergence with finite-sample guarantees. We empirically vali date our algorithm in several environments to demonstrate superior convergence p roperties compared to risk-neutral baselines.

Bridging Local–Global Dissonance: Learning from Compressive Measurements for Hyp erspectral Reconstruction
Xian-Hua Han
Reconstructing hyperspectral images from compressive measurements is challenging due to a fundamental mismatch between locally reliable observations and globall y entangled structures induced by spectral dispersion. This study formalizes thi s issue as a local–global dissonance in representation learning for CASSI system s. To resolve it, we propose a Hierarchical Scale-Reconciling Architecture (HSRA) that enforces local sufficiency and global consistency in a principled, scale-aware manner. HSRA combines multi-kernel token mixing, latent window interaction s, and hierarchical multi-granularity spatially shifted attention to progressive ly reconcile physical constraints across scales. Embedded into a deep unfolding framework as a physically grounded learned prior, Extensive experiments on bench marks demonstrate that HSRA achieves consistent and significant improvements ove r state-of-the-art methods.
****

Flatland: The Adventures of Gradient Descent with Large Step Sizes
Leonardo Galli, Curtis Fox, Wiebke Bartolomaeus, Mark Schmidt, Holger Rauhut
The training of neural networks often entails objective functions that are not g lobally L-smooth. For these functions, it is both theoretically and practicall y difficult to reply to the question: what is the largest possible step size tha t ensures the convergence of gradient descent (GD)? We address this longstanding open question in deep learning by providing a unifying definition of "large'' s tep sizes that requires only local Lipschitz (or even Hölder) continuity of the gradient. We design first-order adaptive methods that provably yield large step sizes and show that they operate at the edge of stability (EoS) right from the s tart of the training. In particular, the loss decreases nonmonotonically and the product between the step size and sharpness, i.e., the largest eigenvalue of th e hessian, stays above the EoS threshold of 2 throughout training. Using our met hod, we are also able to minimize the sharpness all the way down to its global m inimum. Contrary to expectation, we find that encountering globally-flat regions too early in the training may both slow down convergence and jeopardize the gen eralization ability of the network. Exploiting a self-stabilization argument, we allow GD to enter slightly sharper valleys and turn unsuccessful training runs into very successful ones.

Budgeted Active Experimentation for Treatment Effect Estimation from Observation al and Randomized Data
Jiacan Gao, Xinyan Su, Mingyuan Ma, Yiyan HUANG, Xiao Xu, Xinrui Wan, Tianqi Gu,

Enyun Yu, Jiecheng Guo, Zhiheng Zhang
Estimating heterogeneous treatment effects is central to data-driven decision-making, yet industrial applications often face a fundamental tension between limited randomized controlled trial (RCT) budgets and abundant but biased observational data (OBS) collected under historical targeting policies. Although observational logs offer the advantage of scale, they may suffer from severe policy-induced imbalance and overlap violations, rendering standalone estimation unreliable. We propose a \textit{budgeted active experimentation} framework that iteratively collects informative randomized samples for causal effect estimation via active sampling. By leveraging observational signals, we develop an acquisition function targeting uplift estimation uncertainty, domain discrepancy, and overlap deficits to select the most informative units for randomized experiments. We establish finite-sample deviation bounds, asymptotic normality via martingale CLTs, and minimax lower bounds showing near-optimality in the linear representation setting. Experiments on synthetic datasets support our theoretical findings, and further extensions to industrial neural network-based uplift modeling scenarios show that active sampling can improve sample efficiency over random sampling under limited RCT budgets.
****
Hunt Instead of Wait: Evaluating Deep Data Research on Large Language Models
Wei Liu, Peijie Yu, Michele Orini, Yali Du, Yulan He
The agency expected of Agentic Large Language Models goes beyond answering correctly, requiring autonomy to set goals and decide what to explore. We term this *investigatory intelligence*, distinguishing it from *executional intelligence*, which merely completes assigned tasks. Data Science provides a natural testbed, as real-world analysis starts from raw data rather than explicit queries, yet few benchmarks focus on it. To address this, we introduce **Deep Data Research (DDR)**, an open-ended task where LLMs autonomously extract key insights from databases, and **DDR-Bench**, a large-scale, checklist-based benchmark that enables verifiable evaluation. Results show that while frontier models display emerging agency, long-horizon exploration remains challenging. Our analysis highlights that effective investigatory intelligence depends not only on agent scaffolding or merely scaling, but also on intrinsic strategies of agentic models.
****
Reasoning Is Not Free: Robust Adaptive Cost-Efficient Routing for LLM-as-a-Judge
Wenbo Zhang, Lijinghua Zhang, Liner Xiang, Hengrui Cai
Reasoning-capable large language models (LLMs) have recently been adopted as automated judges, but their benefits and costs in LLM-as-a-Judge settings remain unclear. Through controlled comparisons between reasoning and non-reasoning judges, we show that explicit reasoning substantially improves judgment accuracy on tasks requiring structured verification (e.g., math and coding), while offering limited or even negative gains on simpler evaluations and incurring significantly *higher computational cost*. These findings motivate that reasoning should be used selectively rather than universally, with awareness of possible *distribution shift*. We propose a Robust Adaptive Cost-Efficient Routing (RACER), which dynamically selects between reasoning and non-reasoning judges under a fixed budget by formulating routing as a constrained distributionally robust optimization problem. RACER explicitly accounts for distribution shift via a KL-divergence uncertainty set, admits an efficient primal--dual algorithm, and enjoys theoretical guarantees including uniqueness of the optimal policy and linear convergence. Extensive experiments show that RACER achieves superior accuracy--cost trade-offs under distribution shift.

Synthesizable Molecular Generation via Soft-constrained GFlowNets with Rich Chemical Priors
Hyeonah Kim, Minsu Kim, Celine Roget, Dionessa Biton, Louis Vaillancourt, Yves V. Brun, Yoshua Bengio, Alex Hernández-García
The application of generative models for experimental drug discovery campaigns is severely limited by the difficulty of designing molecules de novo that can be synthesized in practice.

Previous works have leveraged Generative Flow Networks (GFlowNets) to impose hard synthesizability constraints through the design of state and action spaces based on predefined reaction templates and building blocks.
Despite the promising prospects of this approach, it currently lacks flexibility and scalability.
As an alternative, we propose S3-GFN, which generates synthesizable SMILES molecules via simple soft regularization of a sequence-based GFlowNet.
Our approach leverages rich molecular priors learned from large-scale SMILES corpora to steer molecular generation towards high-reward, synthesizable chemical spaces.
The model induces constraints through off-policy replay training with a contrastive learning signal based on separate buffers of synthesizable and unsynthesizable samples.
Our experiments show that S3-GFN learns to generate synthesizable molecules (≥ 95%) with higher rewards in diverse tasks.

Simple Denoising Diffusion Language Models
Huaisheng Zhu, Zhengyu Chen, Shijie Zhou, Zhihui Xie, Yige Yuan, Shiqi Chen, Zhimeng Guo, Siyuan Xu, Hangfan Zhang, Vasant G. Honavar, Teng Xiao
Recent Uniform-state Diffusion Models (USDMs), initialized from a uniform prior, offer the promise of fast text generation due to their inherent self-correction ability compared to masked diffusion models. However, they still rely on complex loss formulations with additional computational overhead, which hinders scalability. In this work, we explore a simplified denoising-based loss for USDMs that optimizes only noise-replaced tokens, stabilizing training while matching the performance of prior methods with more complex objectives. In addition, we introduce an efficient regularization term to mitigate corruption toward uniform output distributions, which further improves performance. We demonstrate the effectiveness and efficiency of our simple and improved loss formulations by pretraining models on widely used text datasets for USDMs. More importantly, our conclusions scale to larger models, showing strong potential for large-scale training.
****

Transforming Weather Data from Pixel to Latent Space
Sijie Zhao, Feng Liu, Xueliang Zhang, Hao Chen, Tao Han, Junchao Gong, Ran Tao, Pengfeng Xiao, Xinyu Gu, LEI BAI
The increasing impact of climate change and extreme weather events has spurred growing interest in deep learning for weather research. However, existing studies often rely on weather data in pixel space, which presents several challenges such as smooth outputs in model outputs, limited applicability to a single pressure-variable subset (PVS), and high data storage and computational costs. To address these challenges, we propose a novel Weather Latent Autoencoder (WLA) that transforms weather data from pixel space to latent space, enabling efficient data representation. By decoupling weather reconstruction from downstream tasks, WLA improves the accuracy and sharpness of weather task model results. The incorporated Pressure-Variable Unified Module transforms multiple PVS into a unified representation, enhancing the adaptability of the model in multiple weather scenarios. Furthermore, weather tasks can be performed in a low-storage latent space of WLA rather than a high-storage pixel space, thus significantly reducing data storage and computational costs. Through extensive experimentation, we demonstrate its superior compression and reconstruction performance, enabling the creation of the ERA5-Latent dataset with unified representations of multiple PVS from ERA5 data. The compressed full PVS in the ERA5-Latent dataset reduces the original 244.34 TB of data to 0.43 TB. The downstream task further demonstrates that task models can apply to multiple PVS with low data costs in latent space and achieve superior performance compared to models in pixel space.

Compile to Compress: Boosting Formal Theorem Provers by Compiler Outputs
Guchan Li, Rui Tian, Hongning Wang
Large language models (LLMs) have demonstrated significant potential in formal theorem proving, yet state-of-the-art performance often necessitates prohibitive

test-time compute via massive roll-outs or extended context windows. In this work, we address this scalability bottleneck by exploiting an informative structure in formal verification: the observation that compilers map a vast space of diverse proof attempts to a compact set of structured failure modes. We introduce a learning-to-refine framework that leverages this compression to perform efficient learning and proof exploration. We perform tree search that corrects errors locally conditioned on explicit verifier feedback, thereby circumventing the costs associated with accumulating a long history of proof attempts. Extensive evaluations show that our method consistently amplifies the reasoning capabilities of base provers across varying scales. Notably, our approach achieves state-of-the-art performance on PutnamBench among publicly reported $\sim$8B and $\sim$32B parameter models under comparable test-time budgets, offering a scalable paradigm for next-generation verifier-guided reasoning.

Light Forcing: Accelerating Autoregressive Video Diffusion via Sparse Attention
Chengtao Lv, Yumeng Shi, Yushi Huang, Ruihao Gong, Shen Ren, Wenya Wang
Advanced autoregressive (AR) video generation models have improved visual fidelity and interactivity, but the quadratic complexity of attention remains a primary bottleneck for efficient deployment. While existing sparse attention solutions have shown promise on bidirectional models, we identify that applying these solutions to AR models leads to considerable performance degradation for two reasons: isolated consideration of chunk generation and insufficient utilization of past informative context. Motivated by these observations, we propose \textsc{Light Forcing}, the \textit{first} sparse attention solution tailored for AR video generation models. It incorporates a \textit{Chunk-Aware Growth} mechanism to quantitatively estimate the contribution of each chunk, which determines their sparsity allocation. This progressive sparsity increase strategy enables the current chunk to inherit prior knowledge in earlier chunks during generation. Additionally, we introduce a \textit{Hierarchical Sparse Attention} to capture informative historical and local context in a coarse-to-fine manner. Such two-level mask selection strategy (i.e., frame and block level) can adaptively handle diverse attention patterns. Extensive experiments demonstrate that our method outperforms existing sparse attention in quality (e.g., 84.5 on VBench) and efficiency (e.g., $1.2{\sim}1.3\times$ end-to-end speedup). Combined with other efficient solutions, \textsc{Light Forcing} further achieves a $2.0{\sim}3.0\times$ end-to-end speedup across diverse GPUs (e.g., 27.4\,FPS on RTX 5090 and 33.9\,FPS on H100). Code is released via this \href{https://github.com/chengtao-lv/LightForcing}{link}.

Identifiable Nonlinear Differentiable Causal Discovery via Independence and Adaptive Group Sparsity
Ruicong Yao, Tim Verdonck, Mihaela van der Schaar, Jakob Raymaekers
Differentiable approaches to causal discovery have shown promise in learning DAG structures via continuous optimization, but their theoretical guarantees are largely restricted to models with homoscedastic noise or known noise distribution. In particular, existing methods based on mean squared error fail to identify the true DAG when noise distributions are non-Gaussian and vary in scale. In this paper, we address this gap in nonlinear additive noise models (ANMs) with arbitrary noise. Our approach extends NOTIME (Berrevoets et al. 2025) which minimizes an independence criterion among the residuals. We show that the global minimizer of the independence criterion corresponds to the true underlying DAG up to additional constant edges in general ANMs. To recover the exact structure, we introduce an adaptive group lasso penalty that regularizes entire columns of the first-layer weight matrix of an MLP, enabling the selective pruning of constant edges in a functionally meaningful way. Empirically, our method achieves effective and stable performance across diverse noise types and variances, outperforming prior methods that lack identifiability guarantees in this setting.

scDataset: Scalable Data Loading for Deep Learning on Large-Scale Single-Cell Omics

Davide D'Ascenzo, Sebastiano Cultrera di Montesano
Training deep learning models on single-cell datasets with hundreds of millions of cells requires loading data from disk, as these datasets exceed available memory. While random sampling provides the data diversity needed for effective training, it is prohibitively slow due to the random access pattern overhead, whereas sequential streaming achieves high throughput but introduces biases that degrade model performance. We present scDataset, a PyTorch data loader that enables efficient training from on-disk data with seamless integration across diverse storage formats. Our approach combines block sampling and batched fetching to achieve quasi-random sampling that balances I/O efficiency with minibatch diversity. On Tahoe-100M, a dataset of 100 million cells, scDataset achieves more than two orders of magnitude speedup compared to true random sampling while working directly with AnnData files. We provide theoretical bounds on minibatch diversity and empirically show that scDataset matches the performance of true random sampling across multiple classification tasks and model architectures.

Efficient Bayesian Inference from Noisy Pairwise Comparisons
Till Aczel, Lucas Theis, Roger Wattenhofer
Evaluating generative models is challenging because standard metrics often fail to reflect human preferences. Human evaluations are more reliable but costly and noisy, as participants vary in expertise, attention, and diligence. Pairwise comparisons improve consistency, yet aggregating them into overall quality scores requires careful modeling. Bradley-Terry-based methods update item scores from comparisons, but existing approaches either ignore rater variability or lack convergence guarantees, limiting robustness and interpretability. We introduce BBQ, a Bayesian Bradley-Terry variant that explicitly models rater quality, downweighting or removing unreliable participants, and provides guaranteed monotonic likelihood convergence through an Expectation-Maximization algorithm. Empirical results show that BBQ provides efficient inference, well-calibrated uncertainty estimates, and more robust, interpretable rankings compared to baseline Bradley-Terry models, even with noisy or crowdsourced raters. This framework enables more reliable and cost-effective human evaluation of generative models.

Offline Preference Optimization for Rectified Flow with Noise-Tracked Pairs
Yunhong Lu, Qichao Wang, Hengyuan Cao, Xiaoyin Xu, Min Zhang
Existing preference datasets for text-to-image models typically store only the final winner/loser images. This representation is insufficient for rectified flow (RF) models, whose generation is naturally indexed by a specific prior noise sample and follows a nearly straight denoising trajectory. In contrast, prior DPO-style alignment for diffusion models commonly estimates trajectories using an independent forward noising process, which can be mismatched to the true reverse dynamics and introduces unnecessary variance. We propose Prior Noise-Aware Preference Optimization (PNAPO), an off-policy alignment framework specialized for rectified flow. PNAPO augments preference data by retaining the paired prior noises used to generate each winner/loser image, turning the standard (prompt, winner, loser) triplet into a sextuple. Leveraging the straight-line property of RF, we estimate intermediate states via noise-image interpolation, which constrains the trajectory estimation space and yields a tighter surrogate objective for preference optimization. In addition, we introduce a dynamic regularization strategy that adapts the DPO regularization based on (i) the reward gap between winner and loser and (ii) training progress, improving stability and sample efficiency. Experiments on state-of-the-art RF T2I backbones show that PNAPO consistently improves preference metrics while substantially reducing training compute.

EDCO: Dynamic Curriculum Orchestration for Domain-specific Large Language Model Fine-tuning
Jing-Cheng Pang, Sun Liu, Chang Zhou, Xian Tang, Haichuan Ma, KUN JIANG, Jianlong Wang, Kai Zhang, Sijie Wu, Haoran Cai, Chenwei Wu, Xubin Li, Xin Chen
Domain-specific large language models (LLMs), typically developed by fine-tuning a pre-trained general-purpose LLM on specialized datasets, represent a signific

ant advancement in applied AI. A common strategy in LLM fine-tuning is curriculu
m learning, which pre-orders training samples based on metrics like difficulty t
o improve learning efficiency compared to a random sampling strategy. However, m
ost existing methods for LLM fine-tuning rely on a static curriculum, designed p
rior to training, which lacks adaptability to the model's evolving needs during
fine-tuning. To address this, we propose EDCO, a novel framework based on two ke
y concepts: \textit{inference entropy} and \textit{dynamic curriculum orchestrat
ion}. Inspired by recent findings that maintaining high answer entropy benefits
long-term reasoning gains, EDCO prioritizes samples with high inference entropy
in a continuously adapted curriculum. EDCO integrates three core components: an
efficient entropy estimator that uses prefix tokens to approximate full-sequence
 entropy, an entropy-based curriculum generator that selects data points with th
e highest inference entropy, and an LLM trainer that optimizes the model on the
selected curriculum. Comprehensive experiments in communication, medicine and la
w domains, EDCO outperforms traditional curriculum strategies for fine-tuning Qw
en3-4B and Llama3.2-3B models under supervised and reinforcement learning settin
gs. Furthermore, the proposed efficient entropy estimation reduces computational
 time by 83.5\% while maintaining high accuracy. The code is available at https:
//github.com/GTS-AIData/EDCO.

KBQA-R1: Reinforcing Large Language Models for Knowledge Base Question Answering
Xin Sun, Zhongqi Chen, Xing Zheng, Bowen Song, Qiang Liu, Shu Wu, Zilei Wang, We
iqiang Wang, Liang Wang

Knowledge Base Question Answering (KBQA) challenges models to bridge the gap bet
ween natural language and strict knowledge graph schemas by generating executabl
e logical forms. While Large Language Models (LLMs) have advanced this field, cu
rrent approaches often struggle with a dichotomy of failure: they either generat
e hallucinated queries without verifying schema existence or exhibit rigid, temp
late-based reasoning that mimics synthesized traces without true comprehension o
f the environment. To address these limitations, we present **KBQA-R1**, a frame
work that shifts the paradigm from text imitation to interaction optimization vi
a Reinforcement Learning. Treating KBQA as a multi-turn decision process, our mo
del learns to autonomously navigate the knowledge base using a structured action
 space, refining its reasoning strategies based on concrete execution feedback r
ather than static supervision. Furthermore, we introduce Referenced Rejection Sa
mpling (RRS), a data synthesis method that resolves cold-start challenges by str
ictly aligning reasoning traces with ground-truth action sequences. Extensive ex
periments on WebQSP, GrailQA, and GraphQuestions demonstrate that KBQA-R1 achiev
es state-of-the-art performance.
 Code is available at https://anonymous.4open.science/r/KBQA-R1-814F.

FedFit: Federated Dynamic Sparse Training via Fisher Information scoring
Meng Bi, Hong Huang, Jinlong Song, Charles Wang, Chengming Hu, Xi Chen, Ting Yu,
 Xue Liu

Cross-device Federated Learning (FL) is frequently bottlenecked by the prohibiti
ve memory and communication costs of training deep neural networks on resource-c
onstrained edge hardware. While federated dynamic sparse training aims to allevi
ate these costs by adjusting sparse structures during training, existing methods
 rely on magnitude-based heuristics that are fundamentally ill-suited for the no
n-convergent, heterogeneous environments inherent to FL.

To address this challenge, we propose FedFit, a federated dynamic sparse trainin
g framework that replaces simple heuristics with optimization-centric criteria f
or structure adjustment.

By leveraging a second-order approximation of the loss landscape via the Fisher
Information Matrix, FedFit enables precise and efficient structure adjustment wi
thout the overhead of explicit Hessian computation. Empirical evaluations across
 computer vision and natural language processing benchmarks demonstrate that Fed
Fit significantly narrows the sparse-to-dense accuracy gap, outperforming state
-of-the-art methods while maintaining high communication efficiency. Our code is
 available at https://github.com/Serena-28/Fedfit.git.

Possibilistic Predictive Uncertainty for Deep Learning
Yao Ni, Jeremie Houssineau, Yew-Soon Ong, Piotr Koniusz
Deep neural networks achieve impressive results across diverse applications, yet their overconfidence on unseen inputs necessitates reliable epistemic uncertainty modeling. Existing methods for uncertainty modeling face a fundamental dilemma: Bayesian approaches provide principled estimates but remain computationally prohibitive, while efficient second-order predictors lack rigorous connections between their specific objectives and epistemic uncertainty quantification. To resolve this dilemma, we introduce **D**irichlet-**a**pproximated **p**ossibilistic **p**osterior p**r**edictions (DAPPr), a principled framework grounded in possibility theory. We define a possibilistic posterior over parameters, project it to the prediction space via supremum operators, and approximate the projected posterior using learnable Dirichlet possibility functions. This projection-and-approximation strategy yields a simple training objective with closed-form solutions. Despite its simplicity, extensive experiments across diverse benchmarks show that DAPPr achieves competitive or superior uncertainty quantification performance over state-of-the-art second-order predictors while maintaining both principled derivation and computational efficiency.
****
CauseCollab: Causal Unified and Modality-Agnostic Network for Heterogeneous Collaborative Perception
Weize Li, Yang Li, Quan Yuan, Xiaoyuan Fu, Guiyang Luo, Jinglin Li
Collaborative perception enhances environment understanding through multi-agent information sharing, but its performance in real-world scenarios is constrained by heterogeneous sensor modalities and model architectures. Recent protocol-based two-stage methods alleviate this problem by mapping heterogeneous features into a shared protocol space; however, independently trained modality-specific converters often generate modality-specific pseudo-protocol distributions, leading to semantic inconsistency and error accumulation, which is particularly pronounced in scenarios with large modality discrepancies. To address this issue, we propose CauseCollab, a causal unified and modality-agnostic network. CauseCollab formulates representation learning in the protocol space from a causal perspective, explicitly disentangling semantic factors from modality-specific statistical confounders via causal metric learning. Meanwhile, CauseCollab adopts context-guided Unified Converter for heterogeneous modalities to ensure cross-modal semantic consistency. In addition, integrating new modalities only requires training adapters with minimal parameters. Extensive experiments on the OPV2V and DAIR-V2X datasets demonstrate that CauseCollab achieves state-of-the-art performance, with more significant gains in scenarios involving large modality gaps.

Words Towards Explainability: Caption Label-Free Learning via Dual Loop Agentic Time Series Captioning
Difei Hou, Jiaqi Yue, Chunhui Zhao
Explainability is essential for applying time series analysis in high-stakes domains. While Time Series Captioning (TSC) offers a pathway to enhance temporal explainability, achieving reliable caption generation usually necessitates high-quality textual annotations. However, as interpreting abstract temporal dynamics requires specialized domain knowledge, acquiring such caption annotations is challenging, thereby impeding the advancement of TSC. To address this challenge, we introduce a novel Caption Label-Free Learning (CLFL) paradigm. Departing from the supervised learning tradition of imitating human annotations, CLFL formulates captioning as an agentic exploration task optimized by feedback from a proxy reward. Specifically, we propose a Dual Loop Agentic Captioning (DLAC) framework to achieve such an exploration-feedback mechanism. In the inner loop, a Time Series Captioning Agent (TSCAgent) reflectively explores potential semantic captions. In turn, the outer loop evaluates these captions via downstream reasoning to derive proxy reward, which feeds back to optimize the TSCAgent. Empirical results validate the effectiveness of the CLFL, proving that the exploration-feedback mechanism is sufficient for learning complex temporal semantics and autonomously g

enerating captions, without any caption label supervision. Furthermore, we relea
se TFTSC, an industrial expert-level time series caption dataset, which is avail
able at: https://github.com/chunhuiz/TFTSC/tree/master.

The Oversight Game: Learning to Cooperatively Balance an AI Agent's Safety and A
utonomy
William Overman, Mohsen Bayati
As increasingly capable agents are deployed, a central safety challenge is how t
o retain meaningful human control without modifying the underlying system. We st
udy a minimal control interface in which an agent chooses whether to act autonom
ously (play) or defer (ask), while a human simultaneously chooses whether to be
permissive (trust) or engage in oversight (oversee), and model this interaction
as a two-player Markov Game. When this game forms a Markov Potential Game, we pr
ove an alignment guarantee: any increase in the agent's utility from acting more
 autonomously cannot decrease the human's value. This establishes a form of intr
insic alignment where the agent's incentive to seek autonomy is structurally cou
pled to the human's welfare. Practically, the framework induces a transparent co
ntrol layer encouraging the agent to defer when risky and act when safe. While w
e use gridworld simulations to illustrate the emergence of this collaboration, o
ur primary validation involves an agentic tool-use task where two 30B-parameter
language models are fine-tuned via independent policy gradient. We demonstrate t
hat even as the agents learn to coordinate on the fly, this framework effectivel
y reduces safety violations in realistic, open-ended environments.

Calibrated Test-Time Guidance for Bayesian Inference
Daniel Geyfman, Felix Draxler, Jan Niklas Groeneveld, Hyunsoo Lee, Theofanis Kar
aletsos, Stephan Mandt
Test-time guidance is a widely used mechanism for steering pretrained diffusion
models toward outcomes specified by a reward function. Existing approaches, howe
ver, focus on maximizing reward rather than sampling from the true Bayesian post
erior, leading to miscalibrated inference. In this work, we show that common tes
t-time guidance methods do not recover the correct posterior distribution and id
entify the structural approximations responsible for this failure. We then propo
se consistent alternative estimators that enable calibrated sampling from the Ba
yesian posterior. We significantly outperform previous methods on a set of Bayes
ian inference tasks, and set a new state-of-the-art PSNR in black hole image rec
onstruction. We publish our code at https://github.com/mandt-lab/Calibrated-Guid
ance.

XPERT: Expert Knowledge Transfer for Effective Training of Language Models
Chang Liu, boyu shi, Xu Yang, Xin Geng
Mixture-of-Experts (MoE) language models organize knowledge into explicitly rout
ed expert modules, making expert-level representations traceable and analyzable.
 By analyzing expert activation patterns in MoE language large models (LLMs), we
 find that a subset of experts is consistently activated across diverse knowledg
e domains. These common experts encode cross-domain, generalizable knowledge tha
t is closely related to model generalization, naturally raising the question of
how such identifiable expert knowledge can be practically reused. Motivated by t
his observation, we propose XPERT, a training-free framework that extracts, cons
olidates, and reuses expert knowledge from pre-trained MoE LLMs to support effec
tive training of language models across different model scales. XPERT identifies
 cross-domain experts via inference-only analysis, refines their representations
 through tensor decomposition, and adapts the extracted knowledge to be reused i
n downstream models. Experiments on language understanding and dialogue generati
on benchmarks show that models benefiting from reused expert knowledge achieve c
onsistently stronger performance and faster convergence compared to strong basel
ines. These results highlight MoE LLMs as structured and reusable knowledge sour
ces, and demonstrate the value of expert-level knowledge reuse for improving mod
el training.

SparseSSM: Efficient Selective Structured State Space Models Can Be Pruned in On
e-Shot
Kaiwen Tuo, Huan Wang
State-space language models such as Mamba match Transformer quality while permit
ting linear complexity inference, yet still comprise billions of parameters that
 hinder deployment. While existing one-shot pruning methods are effective for ge
neric linear and attention blocks, they are not designed with the overall Mamba
architecture in mind and fail to account for the time-shared and discretized sta
te-transition matrix at the heart of the selective state-space module (SSM). In
this paper, we introduce SparseSSM, the first training-free pruning framework th
at extends the classic optimal brain surgeon (OBS) framework to state space arch
itectures. Our layer-wise algorithm (i) derives an approximate second-order sali
ency score that aggregates Hessian-trace information across time steps, (ii) inc
orporates a component sensitivity analysis to guide feed-forward network (FFN) p
runing, which also sheds light on where redundancy resides in mamba architecture
, (iii) can be easily extended to semi-structured and structured sparsity, and g
eneralized to other SSM-based architectures. Empirically, we prune 50% of SSM we
ights without fine-tuning and observe only limited performance degradation, achi
eving the current state-of-the-art one-shot pruning algorithm for Mamba-based LL
Ms.

PATCHCODE: Discrete Latent Predictive Learning for EEG Foundation Model
KIEREN YU, Ziyang LIU, Chang Huang, Kaishun Wu
EEG foundation models aim to learn transferable representations, yet EEG recordi
ngs are dominated by high-frequency noise and large cross-subject variability. E
xisting pretraining strategies such as masked autoencoding or autoregressive mod
eling often treat waveform reconstruction as the learning signal, making the obj
ective sensitive to stochastic fluctuations rather than consistent neurophysiolo
gical structure. To address this overlap, we propose PATCHCODE, a region-aware d
iscrete predictive learning framework that keeps the encoder input continuous wh
ile introducing region-aware discrete codes as stable supervision targets. We pr
etrain a masked predictive encoder on continuous EEG patches with dual-granulari
ty learning: it predicts missing patch-level representations to preserve fine sp
atiotemporal structure, while aligning them to discretized code targets from a f
rozen tokenizer to anchor robust semantics. Extensive experiments across sixteen
 downstream datasets spanning emotion recognition, motor imagery, sleep staging,
 seizure detection, vigilance estimation, stress detection, and clinical diagnos
is demonstrate that PATCHCODE achieves competitive performance compared to state
-of-the-art baselines, with notable gains in data efficiency under limited label
s. Our code is available at https://github.com/kierenyyu/Patchcode.

Utility-Diversity Aware Online Batch Selection for LLM Supervised Fine-tuning
Heming Zou, Yixiu Mao, Yun Qu, Qi Wang, Xiangyang Ji
Supervised fine-tuning (SFT) is a commonly used technique to adapt large languag
e models (LLMs) to downstream tasks. In practice, SFT on a full dataset is compu
tationally expensive and sometimes suffers from overfitting or bias amplificatio
n. This facilitates the rise of data curation in SFT, which prioritizes the most
 valuable data to optimze. This work studies the online batch selection family t
hat dynamically scores and filters samples during the training process. However,
 existing popular methods often (i) rely merely on the utility of data to select
 a subset while neglecting other crucial factors like diversity, (ii) rely on ex
ternal resources such as reference models or validation sets, and (iii) incur ex
tra training time over full-dataset training. To address these limitations, this
 work develops UDS (Utility-Diversity Sampling), a framework for efficient onlin
e batch selection in SFT. UDS leverages the nuclear norm of the logits matrix to
 capture both data utility and intra-sample diversity, while estimating inter-sa
mple diversity through efficient low-dimensional embedding comparisons with a li
ghtweight memory buffer of historical samples. Such a design eliminates the need
 for external resources and unnecessary backpropagation, securing computational
efficiency. Experiments on multiple benchmarks demonstrate that UDS consistently

outperforms state-of-the-art online batch selection methods under varying data budgets, and significantly reduces training time compared to full-dataset fine-tuning.
****
Training Data Efficiency in Multimodal Process Reward Models
Jinyuan Li, Chengsong Huang, Langlin Huang, Shaoyang Xu, Haolin Liu, Wenxuan Zhang, Jiaxin Huang
Multimodal Process Reward Models (MPRMs) are central to step-level supervision for visual reasoning in MLLMs.
Training MPRMs typically requires large-scale Monte Carlo (MC)-annotated corpora, incurring substantial training cost.
This paper studies the data efficiency for MPRM training. Our preliminary experiments reveal that MPRM training quickly saturates under random subsampling of the training data, indicating substantial redundancy within existing MC-annotated corpora.
To explain this, we formalize a theoretical framework and reveal that informative gradient updates depend on two factors: label mixtures of positive/negative steps and label reliability (average MC scores of positive steps). Guided by these insights, we propose the Balanced-Information Score (BIS), which prioritizes both mixture and reliability based on existing MC signals at the rollout level, without incurring any additional cost. Across two backbones (InternVL2.5-8B and Qwen2.5-VL-7B) on VisualProcessBench, BIS-selected subsets consistently match and even surpass the full-data performance at small fractions. Notably, the BIS subset reaches full-data performance using only 10% of the training data, improving over random subsampling by a relative 4.1%.
****
PlugMem: A Task-Agnostic Plugin Memory Module for LLM Agents
Ke Yang, Zixi Chen, Xuan He, Jize Jiang, Michel Galley, Chenglong Wang, Jianfeng Gao, Jiawei Han, ChengXiang Zhai
Long-term memory is essential for large language model (LLM) agents operating in complex environments, yet existing memory designs are either task-specific and non-transferable, or task-agnostic but less effective due to low task-relevance and context explosion from raw memory retrieval. We propose PlugMem, a task-agnostic plugin memory module that can be attached to arbitrary LLM agents without task-specific redesign. Motivated by the fact that decision-relevant information is concentrated as abstract knowledge rather than raw experience, we draw on cognitive science to structure episodic memories into a compact, extensible knowledge-centric memory graph that explicitly represents propositional and prescriptive knowledge. This representation enables efficient memory retrieval and reasoning over task-relevant knowledge, rather than verbose raw trajectories, and departs from other graph-based methods like GraphRAG by treating knowledge as the unit of memory access and organization instead of entities or text chunks. We evaluate PlugMem unchanged across three heterogeneous benchmarks (long-horizon conversational question answering, multi-hop knowledge retrieval, and web agent tasks).

The results show that PlugMem consistently outperforms task-agnostic baselines and exceeds task-specific memory designs, while also achieving the highest information density under a unified information-theoretic analysis. Code and data are available at https://github.com/TIMAN-group/PlugMem.
****
Dual-Stream Diffusion for World-Model Augmented Vision-Language-Action Model
John Won, Kyungmin Lee, Huiwon Jang, Dongyoung Kim, Jinwoo Shin
Augmenting Vision-Language-Action models (VLAs) with world models is promising for robotic policy learning but faces challenges in jointly predicting states and actions due to the modality gap. To address this, we propose DUal-STream diffusion (DUST), a world-model augmented VLA framework featuring a multimodal diffusion transformer that maintains separate modality streams while enabling cross-modal knowledge sharing. In addition, DUST utilizes independent noise perturbations and a decoupled flow matching loss to learn cross-modal causal relationships. We further introduce an asynchronous sampling method for action and vision tokens

that enhances performance through inference-time scaling. Experimental results on simulated benchmarks like RoboCasa and GR-1 show that DUST achieves up to 6\% gains over state-of-the-art VLA and world-modeling baselines, with inference-time scaling providing an additional 2–5\% improvement. In real-world tasks using the Franka Research 3, DUST outperforms baselines by 10\% in success rate. Finally, we demonstrate that DUST enables effective transfer learning through both pretraining on action-free videos and joint-training with heterogeneous robot and human datasets.
****
API: Adaptive Prototype Imputation for Incomplete Multimodal Sentiment Analysis
Xiaotao Wang, Yiyang Fang, Wenke Huang, Bin Yang, Guancheng Wan, Mang Ye
Multimodal sentiment analysis aims to infer human emotions by integrating signals from diverse modalities. However, missing modalities are common in real-world applications due to sensor failure, data corruption, or privacy concerns. Existing approaches typically follow two main paradigms: recovery-based and non-recovery-based methods. This dichotomy results in two critical limitations: I) computational inefficiency and semantic inconsistency (recovery-based methods rely on heavy generators that incur prohibitive inference latency and risk semantic drift due to lack of class-level priors); II) lack of instance specificity (non-recovery-based methods rely on static global mappings that fail to capture sample-specific affective cues). To address these gaps, we propose Adaptive Prototype Imputation (API). To mitigate I), we introduce Semantic-anchored Class-Temporal Prototype Estimation (SCOPE) to construct non-trainable prototypes as stable semantic anchors, promoting semantic reliability. To resolve II), we design Directional Instance-Adaptive Affine Modulation (DIAM) to dynamically modulate these anchors via direction-specific affine transformations, capturing instance-unique affective characteristics without generative overhead. Experimental results on CMU-MOSI and CMU-MOSEI demonstrate that API outperforms state-of-the-art baselines, establishing a robust and lightweight prototype-centric paradigm for multimodal sentiment analysis. The code is publicly available at https://github.com/KX-yolo/API.
****
Separating Representation from Reconstruction Enables Scalable Text Encoders
Megi Dervishi, Mathurin VIDEAU, Yann LeCun
While decoders have rapidly scaled, encoders have remained largely unchanged since BERT. We revisit this disparity by frozen backbone evaluation via probing. Under this lens, the representations of BERT encoders become increasingly *unexploitable* by frozen probes, despite improved perplexity. The misalignment originates in BERT's flat design, which couples representation learning to the token reconstruction loss. We propose **CrossBERT**, a two-part architecture that separates the learning of high-quality encoded representations from the rigid grounding of token reconstruction. This design further enables high masking ratios (≥ 50%) and gradient collection over all tokens via a *Complementary Masking Strategy*, respectively increasing throughput by 1.5 to $2\times$ and sample efficiency by $2\times$. Overall, CrossBERT demonstrates monotonic scaling and superior performance on MTEB(eng, v2) and frozen GLUE benchmarks.

Chain-of-Thought Reasoning In The Wild Is Not Always Faithful
Iván Arcuschin, Jett Janiak, Robert Krzyzanowski, Senthooran Rajamanoharan, Neel Nanda, Arthur Conmy
Recent studies indicate that when faced with explicit biases in prompts, models often omit mentioning these biases in their Chain-of-Thought (CoT) output, revealing that verbalized reasoning can give an incorrect picture of how models arrive at conclusions (unfaithfulness).
In this work, we show that unfaithful CoT also occurs on naturally worded, non-adversarial prompts without adding artificial biases or editing model outputs.
We find that when separately presented with the questions "Is X bigger than Y?" and "Is Y bigger than X?", models sometimes produce superficially coherent arguments to justify systematically answering Yes to both or No to both, despite the contradiction.

We present preliminary evidence that this is due to models' implicit biases towards Yes or No, labeling this *Implicit Post-Hoc Rationalization*.
Our results reveal rates up to 13% for production models, and while frontier models are more faithful, none are entirely so, including thinking models like DeepSeek R1 (0.37%) and Sonnet 3.7 with thinking (0.04%).
We also investigate *Unfaithful Illogical Shortcuts*, where models use subtly illogical reasoning to make speculative answers to hard math problems seem rigorously proven.
Our findings indicate that while CoT can be useful for assessing outputs, it is not a complete account of the internal process that produced the model's answer and should be used with caution in agentic or safety-critical settings.

From Denoising to De-Channeling: Integrating Physical Channel Priors into Diffusion Models for Radio Signal Understanding
Yaoqi Liu, Jin Wang, Chunchen Wang, Hui Wang, Chuan Shi
In recent years, wireless signal recognition (WSR), which leverages artificial intelligence (AI) to identify properties of passively received radio signals, has garnered significant attention due to its broad applications, such as spectrum management. Existing WSR methods typically learn directly from received signals, which are distorted by physical wireless channel effects such as fading, and current denoising diffusion models lack de-channeling capabilities, which leads to performance degradation. Therefore, we propose PWC-Diff, a novel framework that integrates prior Physical Wireless Channels into the denoising Diffusion process. The framework employs a dedicated architecture named FusedFormer, which contains a fusion module and a self-attention module that jointly capture the temporal and spectral characteristics of the signals throughout the diffusion trajectory. By leveraging prior wireless channels, PWC-Diff learns to progressively “de-channel” the received signal and recover a representation closer to the transmitted signal. Extensive experiments on several datasets across three WSR tasks have achieved state-of-the-art (SOTA) performance, which demonstrates the rationality of our theory, and ablation experiments further illustrate the effectiveness of our proposed PWC-Diff. Code is available at https://github.com/BUPT-GAMMA/FoundWSR.
****

Training-Free Adversarial Robustness in Computational MRI
Mahdi Saberi, Chi Zhang, Mehmet Akcakaya
Deep learning (DL) methods have become the state-of-the-art for reconstructing sub-sampled magnetic resonance imaging (MRI) data. However, studies have shown that these methods are susceptible to small adversarial input perturbations, resulting in major distortions in the output images. Various strategies have been proposed to reduce the effects of these attacks, but they require retraining. In this work, we propose a novel approach for mitigating adversarial attacks on MRI reconstruction models without any retraining. Based on the idea of cyclic measurement consistency, we devise a novel mitigation objective that is minimized in a small ball around the attack input. Results show that our method substantially reduces the impact of adversarial perturbations across different datasets, attack types/strengths and PD-DL networks, and qualitatively and quantitatively outperforms conventional mitigation methods. We also introduce a practically relevant scenario for small adversarial perturbations that models impulse noise in raw data, which relates to herringbone artifacts, and show the applicability of our approach in this setting. Finally, we show our mitigation approach remains effective in two realistic extension scenarios: a blind setup, where the attack strength or algorithm is not known to the user; and an adaptive attack setup, where the attacker has full knowledge of the defense strategy. Code available at: https://github.com/MahdiSaberii/CycMit-MRI

Dynamics Reveals Structure: Challenging the Linear Propagation Assumption
Hoyeon Chang, Bálint Mucsányi, Seong Joon Oh
Neural networks adapt through first-order parameter updates, yet it remains unclear whether such updates preserve logical coherence.

We investigate the geometric limits of the Linear Propagation Assumption (LPA), the premise that local updates coherently propagate to logical consequences.
To formalize this, we adopt relation algebra and study three core operations on relations: negation flips truth values, converse swaps argument order, and composition chains relations.
For negation and converse, we prove that guaranteeing direction-agnostic first-order propagation necessitates a tensor factorization separating entity-pair context from relation content.
However, for composition, we identify a fundamental obstruction.
We show that composition reduces to conjunction, and prove that any conjunction well-defined on linear features must be bilinear.
Since bilinearity is incompatible with negation, this forces the feature map to collapse.
These results suggest that failures in knowledge editing, the reversal curse, and multi-hop reasoning may stem from common structural limitations inherent to the LPA.

Ratio-Variance Regularized Policy Optimization

Yu Luo, Shuo Han, Yihan Hu, Lei Lv, Huaping Liu, Fuchun Sun, Jianye HAO, Dong Li

Standard on-policy reinforcement learning relies on heuristic clipping to enforce trust regions, but this mechanism imposes a severe cost by indiscriminately truncating high-return yet high-divergence updates. We demonstrate that explicitly constraining the *policy ratio **variance*** provides a principled local approximation to trust-region constraints, eliminating the need for binary hard clipping. By acting as a distributional ''soft brake'', this approach preserves critical gradient signals from novel discoveries while naturally down-weighting and enabling the reuse of stale, off-policy data. We introduce **R^{2}VPO** (Ratio-Variance Regularized Policy Optimization), which implements this constraint via a primal–dual optimization framework. Extensive evaluations across 7 LLM scales, spanning both fast and slow reasoning paradigms, and 10 robotic control tasks demonstrate the generality of the proposed approach. R^{2}VPO achieves substantial performance gains on mathematical reasoning benchmarks, with particularly pronounced improvements on smaller models, while significantly improving sample efficiency. Furthermore, it consistently outperforms PPO baselines in continuous control domains, particularly in sparse-reward and dynamic environments. Together, these findings establish ratio-variance regularization as a principled foundation for stable and data-efficient policy optimization.

The Latent Guardian: Defending Collaborative Perception via Feature-Level Consistency Verification

Zhuangzhuang Zhang, Mingxin Li, Libing Wu, Wei-Bin Lee, Jianping Wang

Collaborative perception (CP) significantly extends the sensing range of connected and autonomous vehicles (CAVs). However, its reliance on data fusion among multiple CAVs makes it inherently vulnerable to adversarial attacks from malicious participants. Existing defenses primarily rely on output-level consensus, assuming that malicious messages manifest as statistical outliers, while suffering from poor adaptability to environmental noise. This makes them vulnerable to stealthy adversarial attacks and prone to high false positive rates. To address this challenge, we shift the defense paradigm from superficial output-level consensus to deeper consistency within the internal feature space. Guided by this principle, we propose Cerberus, a novel defense framework against adversarial attacks in CP systems by leveraging multi-dimensional consistency in the feature space. By quantifying conflicts in topological structure, semantic direction, and energy distribution within feature maps, Cerberus effectively detects adversarial perturbations and provides dynamic protection against adversarial attacks. Experimental results demonstrate that Cerberus significantly outperforms state-of-the-art methods, effectively limiting the attack success rate to as low as 0.05\% while restoring the AP to 0.88.

From Prompts to Tokens: Internalizing Causal Supervision in Vision-Language Mode

l for Multi-Image Causal Reasoning
Haoping Yu, Yuanxi Li, Jing Ma
Visual causal reasoning is essential for understanding and intervening in the ph
ysical world, requiring identification of causal variables from visual inputs an
d reasoning over intervention effects. Despite recent progress, large vision-lan
guage models (VLMs) remain brittle at such tasks, especially for interventional
and counterfactual queries over multi-image inputs.
Most existing explorations inject causal knowledge via textual prompts, leaving
causal mechanisms external to model execution and limiting reliable control duri
ng inference.
To address this problem, we propose BridgeVLM, which internalizes visual causal
reasoning by inducing a causal graph from multi-image inputs and converting it i
nto structured Causal Tokens executed by RAMP layers injected into the LLM decod
er for causal message passing.
We further introduce a unified training interface M3S for fine-grained causal su
pervision from different granularities (local/global level).
BridgeVLM achieves 54.4\% accuracy on intervention tasks on CausalVLBench (vs. 3
3.2\% with prompt-level supervision), improves results on Causal3D from 43.6\% t
o 49.0\%, and substantially improves causal structure learning on CausalVLBench
(F_1: 33.4\% $\rightarrow$ 75.1\%).

DiffuReason: Enhancing Reasoning Ability for Diffusion Language Models via Mont
e Carlo Tree Search
YIPING SONG, Jinyu You, Zhiliang Tian, Jinsong Su, Minlie Huang, Chenping Hou
Auto-Regressive (AR) models with Monte Carlo Tree Search (MCTS) are a dominant p
aradigm for achieving “System 2” reasoning. However, this approach suffers from
significant latency due to the serial, token-by-token generation mechanism of AR
 models. In contrast, Diffusion Large Language Models (dLLMs) offer inherent spe
ed advantages via parallel sequence generation, yet they often struggle with acc
uracy in complex reasoning due to a lack of rigorous search, evaluation, and rev
ision capabilities. Directly applying MCTS to diffusion models faces architectur
al barriers, since the denoising generation process lacks the discrete decision
steps that naturally accommodate tree search. To retain efficiency while improvi
ng the reasoning ability, we propose DiffuReason, a Monte Carlo tree search reas
oning algorithm for diffusion models. By modeling the generation process as a Ma
rkov Decision Process (MDP), DiffuReason discretizes the continuous diffusion fl
ow into searchable thought blocks. During the reverse generation process, DiffuR
eason recursively performs four MCTS-style stages: select the best node (block),
 expand to obtain candidate nodes, simulate to evaluate node values, and revise
the unsatisfactory nodes. Experiments on mathematical reasoning benchmarks demon
strate that DiffuReason significantly improves the reasoning ability of diffusio
n models, and achieves superior balance of accuracy and efficiency even compared
 with auto-regressive models.

Learning High-Dimensional Parity Functions with Product Networks using Gradient
Descent
Guillaume Larue, Louis-Adrien Dufrène, Quentin Lampin, Hadi Ghauch, Rekaya-Ben O
thman
Parity functions are fundamental Boolean operations with critical applications a
cross machine learning, cryptography, and error correction. Yet, learning high-d
imensional parity functions poses significant challenges: in a general setting,
standard neural network architectures typically require exponential sample compl
exity, making gradient-based optimization intractable for large number of inputs
 N. We demonstrate that compact product-based neural architectures combined wi
th stochastic data sparsity (Bernoulli inputs with $p_e \leq 1/N$) and appropria
te hyperparameter choice enable efficient parity learning, with theoretical guar
antees of convergence. Experiments validate our theory across dimensions up to $
N = 100{,}000$, with empirical evidence showing optimal hyperparameter choices f
or p_e and learning rate α, as well as polynomial complexity scaling la
ws. This work establishes fundamental connections between architectural inductiv

e bias and data sparsity, opening new possibilities for neural arithmetic, structured reasoning, binary neural networks, and machine learning applied to automated protocol discovery.

Overcoming the Modality Gap in Context-Aided Forecasting
Vincent Zhihao Zheng, Étienne Marcotte, Arjun Ashok, Andrew Robert Williams, Lijun Sun, Alexandre Drouin, Valentina Zantedeschi
Context-aided forecasting (CAF) holds promise for integrating domain knowledge and forward-looking information, enabling AI systems to surpass traditional statistical methods. However, recent empirical studies reveal a puzzling gap: multimodal models often fail to outperform their unimodal counterparts. We hypothesize that this underperformance stems partly from insufficiently verified context usefulness in existing datasets. To address these limitations, we introduce a semi-synthetic data augmentation method that generates contexts both descriptive of temporal dynamics and verifiably complementary to numerical histories. This approach enables massive-scale dataset creation, resulting in CAF-7M, a corpus of 7 million context-augmented time series windows, including a rigorously verified test set. We demonstrate that semi-synthetic pre-training transfers effectively to real-world evaluation, and show clear evidence of context utilization. Our results suggest that dataset quality is a major bottleneck in context-aided forecasting, and that verified context can substantially improve the usefulness of CAF training data.

Variational Bayesian Flow Network for Graph Generation
Yida Xiong, Jiameng Chen, Xiuwen Gong, Jia Wu, Shirui Pan, Wenbin Hu
Graph generation aims to sample discrete node and edge attributes while satisfying coupled structural constraints. Diffusion models for graphs often adopt largely factorized forward-noising, and many flow-matching methods start from factorized reference noise and coordinate-wise interpolation, so node–edge coupling is not encoded by the generative geometry and must be recovered implicitly by the core network, which can be brittle after discrete decoding. Bayesian Flow Networks (BFNs) evolve distribution parameters and naturally support discrete generation. But classical BFNs typically rely on factorized beliefs and independent channels, which limit geometric evidence fusion. We propose Variational Bayesian Flow Network (VBFN), which performs a variational lifting to a tractable joint Gaussian variational belief family governed by structured precisions. Each Bayesian update reduces to solving a symmetric positive definite linear system, enabling coupled node and edge updates within a single fusion step. We construct sample-agnostic sparse precisions from a representation-induced dependency graph, thereby avoiding label leakage while enforcing node–edge consistency. On synthetic and molecular graph datasets, VBFN improves fidelity and diversity, and surpasses baseline methods. The reproducible code is available at https://github.com/Cello2195/VBFN.

Efficient Multi-round LLM Inference over Disaggregated Serving
Wenhao He, Youhe Jiang, Penghao Zhao, Quanqing Xu, Eiko Yoneki, Bin CUI, Fangcheng Fu
With the rapid evolution of Large Language Models (LLMs), multi-round workflows, such as autonomous agents and iterative retrieval, have become increasingly prevalent. However, this raises hurdles for serving LLMs under prefill-decode (PD) disaggregation, a widely adopted paradigm that separates the compute-bound prefill phase and memory-bound decode phase onto individual resources. Specifically, existing systems overlook the interleaved prefill-decode workload pattern in multi-round inference, leading to sub-optimal handling of the incremental prefill workloads and model deployment for the two phases.

In this work, we present AMPD, a brand new disaggregated serving framework for multi-round LLM inference. The core of AMPD is to coordinate the prefill workloads based on real-time workloads by adaptively determining where to carry out these workloads and how they are scheduled, in order to maximize service level objec

tive (SLO) attainment. In addition, we tailor a planning algorithm for our scenario, facilitating the deduction of optimal resource allocation and parallel strategies for the two phases. Empirical results demonstrate that AMPD substantially improves SLO attainment compared to state-of-the-art baselines.

Test-time Offline Reinforcement Learning on Goal-related Experience
Marco Bagatella, Mert Albaba, Jonas Hübotter, Georg Martius, Andreas Krause
Foundation models compress a large amount of information in a single, large neural network, which can then be queried for individual tasks. There are strong parallels between this widespread framework and offline goal-conditioned reinforcement learning algorithms: a universal value function is trained on a large number of goals, and the policy is evaluated on a single goal in each test episode. Extensive research in foundation models has shown that performance can be substantially improved through test-time training, specializing the model to the current goal. We find similarly that test-time offline reinforcement learning on experience related to the test goal can lead to substantially better policies at modest compute costs. We propose a novel self-supervised data selection criterion, which selects transitions from an offline dataset according to their relevance to the current state and quality with respect to the evaluation goal. We demonstrate across a wide range of high-dimensional loco-navigation and manipulation tasks that fine-tuning a policy on the selected data for a few gradient steps leads to significant performance gains over standard offline pre-training. Our goal-conditioned test-time training (GC-TTT) algorithm applies this routine in a receding-horizon fashion during evaluation, adapting the policy to the current trajectory as it is being rolled out. Finally, we study compute allocation at inference, demonstrating that, at comparable costs, GC-TTT induces performance gains that are not achievable by scaling model size.

GePBench: Evaluating Fundamental Geometric Perception for Multimodal Large Language Models
Shangyu Xing, Changhao Xiang, Xinyu Liu, Zhangtai Wu, Zhen Wu, Yue YIfan, Yuteng Han, Fei Zhao, Xinyu Dai
Geometric shapes play important roles in both physical world and human cognition. While multimodal large language models (MLLMs) have made significant advancements in visual understanding, their abilities to recognize geometric shapes and their spatial relationships, which we term geometric perception, are not explicitly and systematically explored.
To address this gap, we introduce GePBench, a novel benchmark specifically designed to assess the geometric perception capabilities of MLLMs. Our extensive evaluations reveal that even the current state-of-the-art MLLMs exhibit significant deficiencies in geometric perception tasks. Furthermore, we show that models trained with GePBench data demonstrate considerable improvements on a wide range of downstream tasks, highlighting the critical role of geometric perception in enabling advanced multimodal applications. Our code and datasets are available at https://github.com/Changhao-Xiang/GePBench.

Stream RAG: Instant and Accurate Spoken Dialogue Systems with Streaming Tool Usage
Siddhant Arora, Haidar Khan, Kai Sun, Xin Luna Dong, Sajal Choudhary, Seungwhan Moon, Xinyuan Zhang, Adithya Sagar, Surya Teja Appini, Kaushik Patnaik, Sanat Sharma, Shinji Watanabe, Anuj Kumar, Ahmed A Aly, Yue Liu, Florian Metze, Zhaojiang Lin
End-to-end speech-in, speech-out dialogue systems are emerging as a powerful alternative to traditional ASR–LLM–TTS pipelines but remain prone to hallucinations due to limited factual grounding. While text-based dialogue models have effectively mitigated this issue through tools such as web search APIs, extending such capabilities to speech-in, speech-out systems remains underexplored. A key challenge is that tool integration increases latency, disrupting conversational flow. To mitigate this, we propose Streaming Retrieval-Augmented Generation (Stream RAG), a novel framework that reduces latency by predicting tool queries in parall

el with user speech, even before the user finishes speaking. Specifically, we develop a post-training pipeline that teaches the model when to issue tool calls and how to generate spoken summaries using retrieved text results, thereby improving both accuracy and responsiveness. To evaluate our approach, we construct AudioCRAG, a benchmark created by converting queries from the publicly available CRAG dataset into speech form. Experimental results show that Stream RAG improves QA accuracy by over 20.0% absolute on AudioCRAG and achieves state-of-the-art performance, including outperforming cascaded systems, on the SLUE-SQA benchmark, while reducing latency by up to 57%. Stream RAG is modality-agnostic and can be applied equally to typed input, paving the way for more agentic, real-time AI assistants.

VLANeXt: Recipes for Building Strong VLA Models

Xiao-Ming Wu, Bin Fan, Kang Liao, Jian-Jian Jiang, Runze Yang, Yihang Luo, Zhonghua Wu, Wei-Shi Zheng, Chen Change Loy

Following the rise of large foundation models, Vision–Language–Action models (VLAs) emerged, leveraging strong visual and language understanding from Vision-Language Models for general-purpose policy learning. Yet, the current VLA landscape remains fragmented and exploratory. Although many groups have proposed their own VLA models, inconsistencies in training protocols and evaluation settings make it difficult to identify which design choices truly matter. To bring structure to this evolving space, we reexamine the VLA design space under a unified framework and evaluation setup. Starting from a simple VLA baseline similar to RT-2, which is the origin of VLA, we systematically dissect design choices along three dimensions: foundational components, perception essentials, and action modelling perspectives. From this study, we distill 12 key findings that together form a practical recipe for building strong VLA models. The outcome of this exploration is a simple yet effective model, VLANeXt. It outperforms the state-of-the-art methods on the LIBERO and LIBERO-plus benchmarks and demonstrates strong performance in real-world experiments. We release a unified and easy-to-use codebase to reproduce our findings, explore the design space, and develop new VLA variants on top of a shared foundation. The codebase is available at https://github.com/DravenALG/VLANeXt.

From Parameter Dynamics to Risk Scoring: Quantifying Sample-Level Safety Degradation in LLM Fine-tuning

Xiao Wang, Yifei Zhang, YongKang Liu, Xiaocui Yang, Zihan Wang, Shi Feng, Daling Wang

Safety alignment of Large Language Models (LLMs) is extremely fragile, fine-tuning on small number of benign samples can erase safety behaviors learned from millions of preference examples.

Existing studies attempt to explain this phenomenon by comparing parameters and hidden states before and after fine-tuning, but overlook their dynamic evolution during fine-tuning.

In this work, we analyze parameter dynamics and uncover a critical mechanism underlying safety degradation, where benign fine-tuning

causes parameters cumulatively drift toward danger-aligned directions, progressively undermining the model's safety.

Inspired by these findings, we propose Sample-Level Quantification of Safety Degradation (SQSD), a method that quantifies each training sample's influence on safety degradation. Specifically, SQSD assigns continuous risk scores to individual samples by measuring their induced parameter updates along safety and danger directions.

Extensive experiments across three models and two datasets show that SQSD outperforms baselines in better separating high-risk and low-risk samples, with risk scores that consistently predict the severity of safety degradation. In particular, SQSD exhibits strong transferability across architectures, parameter scales, and parameter-efficient methods.

Can Muon Fine-tune Adam-Pretrained Models?

Xingyu Qu, Huang Peigeng, Samuel Horváth
Muon has emerged as an efficient alternative to Adam for pretraining, yet remains underused for fine-tuning. A key obstacle is that most open models are pretrained with Adam, and naively switching to Muon for fine-tuning leads to degraded performance due to an optimizer mismatch.
We investigate this mismatch through controlled experiments and relate it to the distinct implicit biases of Adam and Muon. We provide evidence that the mismatch disrupts pretrained knowledge, and that this disruption scales with update strength. This leads us to hypothesize that constraining updates should mitigate the mismatch.
We validate this with LoRA: across language and vision tasks, LoRA reduces the performance gap between Adam and Muon observed under full fine-tuning. Studies on LoRA rank, catastrophic forgetting, and LoRA variants further confirm that mismatch severity correlates with update strength. These results shed light on how optimizer mismatch affects fine-tuning and how it can be mitigated.
Our code is available [here](https://github.com/XingyuQu/muon-finetune).

STAND: Self-Aware Precondition Induction for Interactive Task Learning
Daniel Weitekamp, Glen R Smith, Ken Koedinger, Christopher J. MacLellan
In interactive task learning (ITL), AI agents learn new capabilities from limited human instruction provided during task execution. STAND is a new method of data-efficient rule precondition induction specifically designed for these human-in-the-loop training scenarios. A key feature of STAND is its self-awareness of its own learning—it can provide accurate metrics of training progress back to users. STAND beats popular methods like XGBoost, decision trees, random forests, and version spaces at small-data precondition induction tasks, and is highly accurate at estimating when its performance improves on holdout examples. In our evaluations, we find that STAND shows more monotonic improvement than other models with low rates of error reoccurrence. These features of STAND support a consistent training experience, enabling human instructors to estimate when they have finished training and providing active-learning support by identifying trouble spots that require more training. STAND achieves this by efficiently learning a compact space of greedy classifiers consistent with training data, rather than a finite ensemble of alternatives.

Mitigating Noise-Induced Layout Priors for Object Counting in Diffusion Models
Xiaoling Gu, Xuelong Li, Shengqi Wu, Yongkang Wong, Zizhao Wu, Huan Li, Zhou Yu, Mohan Kankanhalli
Despite remarkable progress in text-to-image diffusion models, accurately generating the specified number of objects remains a persistent challenge. We identify the initial noise as a primary determinant of spatial layout formation, with early-stage cross-attention serving as the key mechanism that mediates the propagation of noise-induced structures throughout the denoising process. We characterize this phenomenon as \textbf{\textit{Noise-Induced Layout Prior}}. Leveraging this insight, we propose a novel training-free framework for object counting in diffusion models. Our approach consists of two key components: (1) a \emph{Count-Aware Noise Adjustment Strategy}, which explicitly manipulates the initial latent noise to align layout formation with the target object count, and (2) an \emph{Attention-Guided Layout Consistency Strategy}, which performs test-time optimization on early-stage cross-attention to further stabilize layout formation during denoising. Extensive experiments on both single-category and multi-category benchmarks demonstrate that our method consistently outperforms strong diffusion baselines and state-of-the-art object count control methods in terms of counting accuracy and image quality. Code Release: \url{https://github.com/lxlong1201/Mitigate_Noise_Prior}.

TRACE: Toulmin-based Reasoning Assessment through Constructive Elements for LLM CoT Evaluation
Yundong Kim, Heyoung Yang
Evaluating open-ended outputs from large language models (LLMs) remains challeng

ing due to the absence of ground truth. Existing metrics rely on final-answer accuracy or surface-level statistics, leaving the reasoning process itself unexamined. We introduce TRACE (Toulmin-based Reasoning Assessment through Constructive Elements), a metric that analyzes Chain-of-Thought (CoT) reasoning processes. Rather than judging outcomes, TRACE inspects how arguments are constructed by integrating Toulmin's argumentation theory with Flavell's metacognitive framework to assess reasoning structure. Experiments on 26.3K QA samples across 7 reasoning models show strong correlation with benchmark accuracy (r=0.74). Furthermore, TRACE is effective as a reinforcement learning reward signal, outperforming accuracy-only baselines. Together, these results indicate that logically sound reasoning leads to higher-quality answers. TRACE thus serves as a complementary metric for evaluating open-ended outputs. Code is available at https://github.com/hyyangkisti/trace.
****

Long-Horizon Model-Based Offline Reinforcement Learning Without Explicit Conservatism

Tianwei Ni, Esther Derman, Vineet Jain, Vincent Taboga, Siamak Ravanbakhsh, Pierre-Luc Bacon

Popular offline reinforcement learning (RL) methods rely on *explicit conservatism*, penalizing out-of-dataset actions or restricting rollout horizons. We question the universality of this principle and revisit a complementary Bayesian perspective for test-time adaptation. By modeling a posterior over world models and training a history-dependent agent to maximize expected return, the Bayesian approach directly addresses epistemic uncertainty without explicit conservatism. We first illustrate in a bandit setting that Bayesianism excels on low-quality datasets where conservatism fails. Scaling to realistic tasks, we find that *long-horizon rollouts* are essential to control value overestimation once conservatism is removed. We introduce design choices that enable learning from long-horizon rollouts while mitigating compounding model errors, yielding our algorithm, NEUBAY, grounded in the neutral Bayesian principle. On D4RL and NeoRL benchmarks, NEUBAY is competitive with leading conservative algorithms, achieving new state-of-the-art on 7 datasets with rollout horizons of several hundred steps. Finally, we characterize datasets by quality and coverage to identify when NEUBAY is preferable to conservative methods.

Upper-Linearizability of Online Non-Monotone DR-Submodular Maximization over Down-Closed Convex Sets

Yiyang Lu, Hareshkumar Jadav, Mohammad Pedramfar, Ranveer Singh, Vaneet Aggarwal

We study online maximization of non-monotone Diminishing-Return(DR)-submodular functions over down-closed convex sets, a regime where existing projection-free online methods suffer from suboptimal regret and limited feedback guarantees.
Our main contribution is a new structural result showing that this class is $1/e$-Upper-Linearizable under carefully designed exponential reparametrization, scaling parameter, and surrogate potential, enabling a reduction to online linear optimization.
As a result, we obtain optimal $O(T^{1/2})$ static regret with a single gradient query per round and unlock adaptive and dynamic regret guarantees, together with improved rates under semi-bandit, bandit, and zeroth-order feedback.
Across all feedback models, our bounds strictly improve the state of the art.
****

TAGRPO: Boosting GRPO on Image-to-Video Generation with Direct Trajectory Alignment

Jin Wang, Jianxiang Lu, Guangzheng Xu, Comi Chen, Haoyu Yang, Linqing Wang, Peng Chen, Mingtao Chen, Zhichao Hu, Longhuang Wu, Shuai Shao, Qinglin Lu, Ping Luo

Recent studies have demonstrated the efficacy of integrating Group Relative Policy Optimization (GRPO) into flow matching models, particularly for text-to-image and text-to-video generation. However, we find that directly applying these techniques to image-to-video (I2V) models often fails to yield consistent reward improvements. To address this limitation, we present TAGRPO, a robust post-training framework for I2V models inspired by contrastive learning. Our approach is gro

unded in the observation that rollout videos generated from identical initial no ise provide superior guidance for optimization. Leveraging this insight, we prop ose a novel GRPO loss applied to intermediate latents, encouraging direct alignm ent with high-reward trajectories while maximizing distance from low-reward coun terparts. Furthermore, we introduce a memory bank for rollout videos to enhance diversity and reduce computational overhead. Despite its simplicity, TAGRPO achi eves significant improvements over DanceGRPO in I2V generation.

Causal Fine-Tuning under Latent Confounded Shift

Jialin Yu, Yuxiang Zhou, Haoxuan Li, Junchi Yu, Mengyue Yang, Yulan He, Nevin L. Zhang, Philip Torr, Ricardo Silva

Adapting to latent confounded shift remains a core challenge in modern AI. This setting is driven by hidden variables that induce spurious correlations between inputs and outputs during training, leading models to rely on non-causal shortcu ts. For example, a model may learn to treat metadata (e.g., data source like "Am azon") as a proxy for positive sentiment, causing failure when the source become s predominantly negative during deployment. To address this *latent confounded s hift*, we introduce Causal Fine-Tuning (CFT). Using a structural causal model as an inductive bias, we derive sufficient identification conditions that motivate a fine-tuning objective for decomposing representations into high-level stable and low-level shift-sensitive components. Instantiating this framework in BERT, we show that learning such causal/spurious representations and adjusting them ac cordingly yield a more robust predictor. Experiments on spurious correlation inj ection attacks in text demonstrate that our method outperforms black-box domain generalization baselines, highlighting the benefits of explicitly modeling causa l structure.

Arboreal Neural Network

Wubin Yan, Wei Ma, Shixiang Wan, Dongchen Li, Shaoshun Kang, Qing Yang, Donglian g Xu

Connectionist models and symbolic models have long embodied two divergent paradi gms: the former excel at differentiable representation learning yet struggle wit h transparency, while the latter deliver explicit rule-based reasoning but resis t gradient-based optimization. We introduce Arboreal Neural Networks (ArbNN), a neural-symbolic framework that unifies these paradigms both computationally and conceptually. At the design level, ArbNN departs fundamentally from prior neural ized-tree models through a depth-aware routing mechanism and a topology-informed softmax aggregation, which together enable one-shot full-path gradient propagat ion and consequently achieving rapid and well-conditioned optimization dynamics. At the conceptual level, ArbNN reveals that decision-tree branching and self-at tention routing are two realizations of the same conditional computation primiti ve. We prove a structural isomorphism between a decision tree and a single-query attention head, enabling a differentiable architecture that faithfully preserve s symbolic decision logic. The defining property of ArbNN is Bidirectional Fidel ity, ensuring that the neural module can be compiled from—and losslessly decompi led back into—a symbolic tree, yielding both ordering consistency in ranking beh avior and explicit, auditable interpretability via reconstructed if-else rules. ArbNN further supports GBDT-based initialization, allowing it to inherit strong inductive biases and integrate seamlessly with existing production workflows. Em pirically, ArbNN achieves state-of-the-art performance on various public tabular benchmarks and delivers consistent gains under temporal distribution shift in l arge-scale industrial credit-risk systems. To support realistic evaluation, we a dditionally construct TabCredit, a feature-rich, temporally partitioned dataset built from millions of real-world loan applications. Together, these results dem onstrate that ArbNN forms a unified, reversible, and practically deployable brid ge between symbolic reasoning and neural computation for high-stakes tabular dom ains.

GEM: Geometric Erasure by Contrastive Velocity Matching in Rectified Flows

Jonas Henry Grebe, Tobias Braun, Anna Rohrbach, Marcus Rohrbach

While the rapid adoption of multimodal generative models offers immense potentia
l, it has also increased the risks of harmful content synthesis, deepfakes, and
copyright infringements. To address these challenges, concept erasure has emerge
d as a prospective safeguard. However, as the field gradually transitions from U
-Net-based diffusion models to Rectified Flow Transformers, erasure research has
 struggled to keep pace. In this work, we introduce GEM, a simple but highly eff
ective erasure framework for Rectified Flow models. As part of our contribution,
 we establish a principled bridge between trajectory-based unlearning grounded i
n Generative Flow Networks and classic teacher-guided erasure: we translate traj
ectory-based signals into a teacher-guided flow-matching setup that unifies the
strengths of both paradigms. Concretely, a teacher provides complementary attrac
tion and repulsion signals that we combine into a single geometric guidance obje
ctive, yielding targeted suppression of unwanted concepts while preserving benig
n generation.

SURGE: Surrogate Gradient Adaptation in Binary Neural Networks
Haoyu Huang, Boyu Liu, Linlin Yang, Yanjing Li, Yuguang Yang, Xuhui Liu, Canyu C
hen, Zhongqian Fu, Baochang Zhang
The training of Binary Neural Networks (BNNs) is fundamentally based on gradient
 approximation for non-differentiable binarization operations (e.g., sign functi
on). However, prevailing methods including the Straight-Through Estimator (STE)
and its improved variants, rely on hand-crafted designs that suffer from gradien
t mismatch problem and information loss induced by fixed-range gradient clipping
. To address this, we propose SURrogate GradiEnt Adaptation (SURGE), a novel lea
rnable gradient compensation framework with theoretical grounding. SURGE mitigat
es gradient mismatch through auxiliary backpropagation. Specifically, we design
a Dual-Path Gradient Compensator (DPGC) that constructs a parallel full-precisio
n auxiliary branch for each binarized layer, decoupling gradient flow via output
 decomposition during backpropagation. DPGC enables bias-reduced gradient estima
tion by leveraging the full-precision branch to estimate components beyond STE's
 first-order approximation. To further enhance training stability, we introduce
an Adaptive Gradient Scaler (AGS) based on an optimal scale factor to dynamicall
y balance inter-branch gradient contributions via norm-based scaling. Experiment
s on image classification, object detection, and language understanding tasks de
monstrate that SURGE performs best over state-of-the-art methods.
****

Black-Box Assisted Regression: Phase Transitions and Minimax Optimality
Yan Zhou
Foundation models are often used as fixed black-box predictors for downstream ta
sks with limited labeled data, but their predictions may be biased and unsafe to
 trust blindly. We study this setting through black-box assisted nonparametric r
egression: a learner observes labeled samples and can query a fixed predictor $f
_0$, while the target f^* is close to f_0 in $L_2(P_X)$ up to an unknown rad
ius δ. We give a finite-sample minimax characterization showing a phase t
ransition at $\delta_c(n)\asymp n^{-\beta/(2\beta+d)}$, with leading risk $\min\
{\delta^2, n^{-2\beta/(2\beta+d)}\}$. We then analyze a Safe Residual Estimator:
 it learns a correction around f_0, initializes the residual head at zero so t
he initial predictor equals f_0, and uses holdout selection to revert to f_0
 when the learned correction is not supported by validation data. Here, ``safe''
 means avoiding negative transfer, i.e., performing worse than the black-box pre
dictor alone. The estimator matches the leading minimax term up to an additive v
alidation-selection cost. Synthetic regression experiments verify the predicted
phase transition, while CIFAR-100 with CLIP and AG News with Qwen3-8B provide pr
actice-facing evidence that the same residual-correction tradeoff is useful beyo
nd the formal squared-loss regression setting.

Deep Trajectory Supervision: Deep Supervision Strikes Back
Han Wang, Weijie Wang, Jiaqi Liu, Hilde Kuehne, Nicu Sebe
Interpreting residual architectures as discretizations of Ordinary Differential
Equations characterizes the forward pass as a continuous latent flow. Although t

his framework defines the mechanics of inference, conventional training paradigm s primarily constrain the terminal state, leaving the intermediate evolution unr egulated. In this work, we formalize the forward pass as a Conditional Discrimin ative Flow and investigate its intrinsic kinematic laws. Using Tuned Lens analys is, we discover that the accumulation of semantic evidence follows a consistent exponential schedule. This finding confirms that deep models naturally require a n extended phase of feature construction prior to a rapid transition toward cate gorical certainty in the terminal layers.

Standard training ignores this latent progression. To resolve this impedance mis match, we propose Deep Trajectory Supervision, a framework that aligns auxiliary supervision with this intrinsic exponential bias. By rectifying the trajectory of the inference flow, DTS functions as a critical physical inductive bias. Empi rical evaluations on ImageNet-1K and various benchmarks demonstrate that DTS sig nificantly accelerates convergence and improves terminal performance.
****
SRPO: Self-Reflective Policy Optimization for Long-Horizon Reasoning
Jialong Liu, Yuling Shi, Ning Yang, Xiaodong Gu, Zuchao Li
Self-reflection is a powerful mechanism for credit assignment in human learning,

converting sparse outcome feedback into actionable guidance. However, its potential for post-training Large Language Models (LLMs) remains underexplored. We propose Self-Reflective Policy Optimization (SRPO), a framework that internalizes this capability. SRPO enables LLMs to analyze their own completed trajectories, synthesize errors into concise "reflection patches," and use these

reflection-conditioned rollouts as high-quality, on-policy distillation targets.

This process effectively transforms sparse terminal supervision into dense, token-level learning signals without requiring external critics, separate reward models, or larger teacher models. We demonstrate that SRPO achieves state-of-the-art performance across mathematical reasoning and long-horizon agentic benchmarks with exceptional data efficiency. Using a Qwen3-8B base model, SRPO attains 73.3\% on AIME’24 using only 8\% (0.08$\times$) of the training FLOPs required by scaled supervised fine-tuning, while significantly improving success rates on WebShop (64.7\%), ALFWorld (76.8\%), and SWE-Bench-Lite (31.2\%).
****
TransNormal: Dense Visual Semantics for Diffusion-based Transparent Object Norma l Estimation
Mingwei Li, Hehe Fan, Yi Yang
Monocular normal estimation for transparent objects is critical for laboratory a utomation, yet it remains challenging due to complex light refraction and reflec tion. These optical properties often lead to catastrophic failures in convention al depth and normal sensors, hindering the deployment of embodied AI in scientif ic environments. We propose **TransNormal**, a novel framework that adapts pre-t rained diffusion priors for single-step normal regression. To handle the lack of texture in transparent surfaces, TransNormal integrates dense visual semantics from DINOv3 via a cross-attention mechanism, providing strong geometric cues. Fu rthermore, we employ a multi-task learning objective and wavelet-based regulariz ation to ensure the preservation of fine-grained structural details. To support this task, we introduce **TransNormal-Synthetic**, a physics-based dataset with high-fidelity normal maps for transparent labware. Extensive experiments demonst rate that TransNormal significantly outperforms state-of-the-art methods: on the ClearGrasp benchmark, it reduces mean error by 25.5\% and improves the best pri or 11.25° accuracy by 24.7\%; on ClearPose, it achieves a 17.7\% reductio n in mean error. Code and dataset are publicly available at https://github.com/l ongxiang-ai/TransNormal.
****
OServe: Accelerating LLM Serving via Spatial-Temporal Workload Orchestration

Youhe Jiang, Fangcheng Fu, Taiyi Wang, Guoliang He, Eiko Yoneki
Serving Large Language Models (LLMs) can benefit immensely from parallelizing both the model and input requests across multiple devices, but incoming workloads exhibit substantial spatial and temporal heterogeneity. Spatially, workloads comprise heterogeneous requests with varying compute and memory demands. Temporally, workload composition varies over time. Nevertheless, existing systems typically assume spatially uniform and temporally stable workloads, employing a homogeneous, static model deployment. This mismatch between the assumption and real-world spatial-temporal heterogeneity results in suboptimal performance. We present OServe, an LLM serving system with heterogeneous and flexible model deployment that addresses both spatial and temporal heterogeneity. First, OServe introduces a novel workload-aware scheduling algorithm that optimizes heterogeneous model deployments according to real-time workload characteristics. Second, OServe proposes an efficient workload-adaptive switching method that migrates model deployments in response to predicted workload changes. Experiments on real-world traces show that OServe improves performance by up to 2$\times$ (average: 1.5$\times$) compared to state-of-the-art serving systems.

Periodic Bayesian Flow Networks with Additive Accuracy
Peijia Lin, Zihan Zhang, zhangrui zhao, Shaohao Rui, Junyi An, Yun-Fei Shi, Fenglei Cao, Weijie Ma, Yutong Lu
Generating periodic data---such as fractional atomic coordinates in crystal structures and phase patterns in compressive light-field (CLF) displays---is challenging because wrap-around boundaries complicate probabilistic modeling and learning. While Bayesian Flow Networks (BFNs) offer a powerful generative framework with strictly additive accuracy in Euclidean space, existing periodic adaptations typically sacrifice additivity and become sensitive to schedule heuristics. We introduce \emph{PeriodicBFN}, which embeds each periodic scalar into a two-dimensional unit-circle representation and performs Gaussian Bayesian updates in the resulting Cartesian space, thereby restoring strictly additive accuracy. To address invariance in periodic generative modeling, we further derive a Rao--Blackwellized objective that analytically marginalizes global periodic translations, producing a translation-invariant target with reduced gradient variance. Experiments on crystal structure prediction and multi-layer phase synthesis for CLF displays demonstrate improved training stability and strong performance. To our knowledge, this is the first work to extend periodic-data generative modeling to phase synthesis for modern glasses-free 3D display systems.

L-Drive: Beyond a Single Mapping—Latent Context Drives Time Series Forecasting
Fan Zhang, Shijun Chen, Hua Wang
Mainstream methods for multivariate time-series forecasting largely follow the Direct-Mapping paradigm. They learn a unified mapping from history to the future in the observation space to fit value-level dependencies. However, real-world systems often undergo distribution shifts and regime changes. In such cases, a unified mapping can exhibit response lag around turning points, causing error accumulation within the switching window and reducing forecasting reliability. To address this issue, we propose L-Drive, a change-aware forecasting framework. L-Drive introduces a Latent-Context, to explicitly characterize high-level dynamics evolving over time, and uses gating to modulate increment representations. This provides more timely change cues and improves adaptation to changing segments. In addition, it incorporates patch-shared relative positional basis functions to strengthen intra-segment structural modeling and reduce overfitting caused by absolute-position memorization. Extensive experiments validate the effectiveness of L-Drive and show a better overall trade-off between forecasting accuracy and computational efficiency.

When Can You Poison Rewards? A Tight Characterization of Reward Poisoning in Linear MDPs
Jose Efraim Aguilar Escamilla, Haoyang Hong, Jiawei Li, Haoyu Zhao, Xuezhou Zhang, Sanghyun Hong, Huazheng Wang

We study reward poisoning attacks in reinforcement learning (RL), where an adversary manipulates rewards under a limited budget to induce a target agent to learn a policy aligned with the attacker's objectives. Most prior work focuses on *constructing* successful attacks, providing sufficient conditions under which poisoning is effective, while offering limited understanding of when such targeted attacks are fundamentally infeasible. In this paper, we provide the first characterization of reward-poisoning attackability in linear MDPs, establishing both necessary and sufficient conditions for whether a target policy can be induced within a bounded attack budget. This draws a clear boundary between the *vulnerable* RL instances and *intrinsically robust* ones, which cannot be attacked without high costs even when the learner uses standard, non-robust RL algorithms. We further demonstrate our framework beyond synthetic linear MDPs by approximating deep RL environments as linear MDPs. We show that our theoretical framework effectively distinguishes vulnerability, demonstrating how our theoretical predictions have practical significance.

LOCA-bench: Benchmarking Language Agents Under Controllable and Extreme Context Growth

Weihao Zeng, Yuzhen Huang, Junxian He

Frontier large language models (LLMs) are increasingly capable of carrying out long-running, real-world tasks. However, as the amount of context grows, their reliability often deteriorate, a phenomenon known as "context rot". Existing long-context benchmarks primarily focus on single-step settings that evaluate a model’s ability to retrieve information from a long snippet. In realistic scenarios, however, LLMs often need to act as agents that explore environments, follow instructions and plans, extract useful information, and predict correct actions under a dynamically growing context. To assess language agents in such settings, we introduce LOCA-bench (a benchmark for **LO**ng-**C**ontext **A**gents). Given a task prompt, LOCA-bench leverages automated and scalable control of environment states to regulate the agent’s context length. This design enables LOCA-bench to extend the context length potentially to infinity in a controlled way while keeping the underlying task semantics fixed. LOCA-bench evaluates language agents as a combination of models and scaffolds, including various context management strategies. While agent performance generally degrades as the environment states grow more complex, advanced context management techniques can substantially improve the overall success rate. We will open-source LOCA-bench to provide a platform for evaluating models and scaffolds in long-context, agentic scenarios.

Modeling Hierarchical Thinking in Large Reasoning Models

G M Shahariar, Erfan Shayegani, Ali Nazari, Nael Abu-Ghazaleh

Large Reasoning Models (LRMs) solve complex tasks by generating long Chain-of-Thought (CoT) sequences; however, the emergent dynamics governing reasoning trajectories are not well understood and can lead to inconsistencies and reasoning pathologies. In this work, we propose to approximate LRM's emerging hierarchical reasoning dynamics as a trajectory within a Finite State Machine (FSM) transitioning among six abstract cognitive states. We demonstrate that these states and transitions can be captured in the latent state of the model. We believe that this representation can have different applications in the interpretability and optimization of LRM models. For example, by analyzing the topology of these transitions, we identify statistical shifts in reasoning strategies that help identify effective reasoning chains from those that fail. To illustrate these potential advantages, we propose Q-Value guided steering, a training-free inference-time control method that treats reasoning as a planning problem. We estimate the long-horizon utility of state transitions and apply sparse, orthogonal activation steering at sentence boundaries to align the CoT generation with optimal reasoning policies. Experiments across four benchmarks (AIME25, MATH-500, GSM8k, and GPQA Diamond) using three state-of-the-art open reasoning models demonstrate that Q-Value steering policy achieves significant performance gains with "surgical'' efficiency, often requiring $25\times$ fewer interventions than greedy and weighted baselines, which suggests that reasoning can be effectively controlled by guid

ing high-level cognitive dynamics rather than micro-managing token generation. C
ode is available at: https://github.com/shahariar-shibli/CoT-FSM.

Agent Learning via Early Experience
Kai Zhang, Xiangchao Chen, Bo Liu, Tianci Xue, Zeyi Liao, Zhihan Liu, Xiyao Wang
, Yuting Ning, Zhaorun Chen, Xiaohan Fu, Jian Xie, Yuxuan Sun, Boyu Gou, Qi Qi,
Zihang Meng, Jianwei Yang, Ning Zhang, Xian Li, Ashish Shah, Dat Huynh, Hengduo
Li, Zi Yang, Xuefei Cao, Lawrence Keunho Jang, Shuyan Zhou, Jiacheng Zhu, Huan S
un, Jason E Weston, Yu Su, Yifan Wu
A long-term goal of language agents is to learn and improve through their own ex
perience, ultimately outperforming humans in complex, real-world tasks.
However, training agents from experience data with reinforcement learning remain
s difficult in many environments, which either lack verifiable rewards (e.g., we
bsites) or require inefficient long-horizon rollouts (e.g., multi-turn tool use)
.
As a result, most current agents rely on supervised fine-tuning on expert data,
which is challenging to scale and generalizes poorly. This limitation stems from
 the nature of expert demonstrations: they capture only a narrow range of scenar
ios, and expose the agent to limited environment diversity.
We address this limitation with a middle-ground paradigm we call *early experien
ce*: interaction data generated by the agent's own actions, where the resulting
future states serve as supervision without reward signals.
Within this paradigm, we study two strategies of using such data: (1) implicit w
orld modeling, which uses collected states to ground the policy in environment d
ynamics; and (2) self-reflection, where the agent learns from its suboptimal act
ions to improve reasoning and decision-making.
Evaluation across eight diverse environments and multiple model families shows t
hat our approaches consistently improve effectiveness and out-of-domain generali
zation, highlighting the value of early experience.
Moreover, in environments with verifiable rewards, our results provide promising
 signals that early experience offers a strong foundation for subsequent reinfor
cement learning, making it a practical bridge between imitation learning and ful
ly experience-driven agents.

AutoMoT: A Unified Vision-Language-Action Model with Asynchronous Mixture -of-Tr
ansformers for End-to-End Autonomous Driving
Wenhui Huang, Songyan Zhang, Qihang Huang, Zhidong Wang, Zhiqi Mao, Collister Ch
ua, Zhan Chen, Long Chen, Chen Lv
Integrating vision-language models (VLMs) into end-to-end (E2E) autonomous drivi
ng (AD) systems has shown promise in improving scene understanding. However, exi
sting integration strategies suffer from several limitations: they either strugg
le to resolve distribution misalignment between reasoning and action spaces, un
derexploit the general reasoning capabilities of pretrained VLMs, or incur subst
antial inference latency during action policy generation, which degrades driving
 performance. To address these challenges, we propose AutoMoT in this work, an e
nd-to-end AD framework that unifies reasoning and action generation within a sin
gle vision-language-action (VLA) model. Our approach leverages a mixture-of-tran
sformer (MoT) architecture with layer-wise joint attention sharing, which preser
ves the general reasoning capabilities of pre-trained VLMs while enabling effici
ent asynchronous inference over various tasks at different frequencies. Addition
ally, we explore a VLA-oriented action refiner that further enhances driving per
formance via diffusion-based fine-tuning. Extensive experiments on multiple benc
hmarks, under both open- and closed-loop settings, demonstrate that AutoMoT achi
eves state-of-the-art (SOTA) performance compared to existing methods. We furthe
r investigate the functional boundary of pre-trained VLMs in AD, examining when
and to what extent AD-tailored fine-tuning is necessary.

FeRA: Frequency-Energy Constrained Routing for Effective Diffusion Adaptation Fi
ne-Tuning
Bo Yin, Xiaobin Hu, Xingyu Zhou, Yu HE, Peng-Tao Jiang, Yue Liao, Junwei Zhu, Ji

angning Zhang, Ying Tai, Shuicheng YAN
Diffusion models have achieved remarkable success in generative modeling, yet ho w to effectively adapting large pretrained models to new tasks remains challengi ng. We revisit the reconstruction behavior of diffusion models during denoising to unveil the underlying frequency–energy mechanism governing this process. Buil ding upon this observation, we propose \textbf{FeRA}, a frequency-driven fine-tu ning framework that aligns parameter updates with the intrinsic frequency–energy progression of diffusion. FeRA establishes a comprehensive frequency–energy fra mework for effective diffusion adaptation fine-tuning, comprising three synergis tic components: \textit{(i)} a compact frequency–energy indicator that character izes the latent’s bandwise energy distribution, \textit{(ii)} a soft frequency r outer that adaptively fuses multiple frequency-specific adapter experts, and \te xtit{(iii)} a frequency–energy consistency regularization that stabilizes diffus ion optimization and ensures coherent adaptation across bands. Routing operates in both training and inference, with inference-time routing dynamically determin ed by the latent frequency energy. It integrates seamlessly with adapter-based t uning schemes and generalizes well across diffusion backbones and resolutions. B y aligning adaptation with the frequency–energy mechanism, \textbf{FeRA} provide s a simple, stable, and compatible paradigm for effective and robust diffusion m odel adaptation. Codes will be made publicly available.

Censoring with Plausible Deniability: Asymmetric Local Privacy for Multi-Categor y CDF Estimation
Qirui Hu, Yi Liu
We introduce a new mechanism within the Utility-Optimized Local Differential Pri vacy (ULDP) framework that enables censoring with plausible deniability when col lecting and analyzing sensitive data. Our approach addresses scenarios where cer tain values, such as large numerical responses, are more privacy-sensitive than others, while accompanying categorical information may not be private on its own but could still be identifying. The mechanism selectively withholds identifying details when a response might indicate sensitive content, offering asymmetric p rivacy protection. Unlike previous methods, it avoids the need to predefine an e xact sensitive region, making it more adaptable and practical. Although the mech anism is designed for ULDP, it can also be applied under symmetric LDP settings, where it still benefits from censoring and reduced perturbation cost. We provid e theoretical guarantees, including uniform consistency and pointwise weak conve rgence results. Numerical experiments on both synthetic data and real-world data demonstrate the validity of the proposed methodology.

MOOSE-Star: Unlocking Tractable Training for Scientific Discovery by Breaking th e Complexity Barrier
Zonglin Yang, Lidong Bing
While large language models (LLMs) show promise in scientific discovery, existin g research focuses on inference or feedback-driven training, leaving the direct modeling of the generative reasoning process, $P(\text{hypothesis}|\text{backgro und})$ ($P(h|b)$), unexplored. We demonstrate that directly training $P(h|b)$ is mathematically intractable due to the combinatorial complexity ($O(N^k)$) inher ent in retrieving and composing inspirations from a vast knowledge base.
To break this barrier, we introduce MOOSE-Star, a unified framework that enables tractable and scalable training of $P(h|b)$, while supporting more scalable inf erence.
In the best case, MOOSE-Star reduces complexity from exponential to logarithmic ($O(\log N)$) by (1) training on decomposed subtasks derived from the probabilis tic equation of discovery, (2) employing motivation-guided hierarchical search t o enable logarithmic retrieval and prune irrelevant subspaces, and (3) utilizing bounded composition for robustness against retrieval noise.
To facilitate this, we release TOMATO-Star, a dataset of 108,717 decomposed pape rs (38,400 GPU hours) for training.
Empirically, MOOSE-Star scales continuously with training data and inference bud get, whereas direct brute-force sampling hits a "complexity wall."

****
SABER: Continual Learning with Representation Conflict Management
Xuandi Luo, Huaidong Zhang, Yi Xie, Shengfeng He
Continual learning seeks to develop models capable of acquiring new tasks sequen tially while retaining prior knowledge. A central challenge in this setting is m anaging inherent knowledge conflicts that arise as overlapping or contradictory information is introduced across tasks. While parameter-efficient fine-tuning (P EFT) techniques, particularly those based on Low-Rank Adaptation (LoRA), have sh own promise by reducing interference through parameter isolation or modular arch itectures, they often treat conflict as something to avoid rather than address d irectly. In this work, we propose $\underline{S}$ubspace-$\underline{A}$ligned $ \underline{B}$alanc$\underline{e}$d $\underline{R}$ecomposition (SABER), a novel method that reframes continual learning as a problem of structured conflict man agement. SABER introduces a unified subspace alignment framework to support shar ed task representations, decomposes task-specific knowledge into orthogonal comp onents to preserve distinct information, and recomposes them using an energy-awa re balancing mechanism that coordinates contributions without compromising stabi lity. Extensive experiments across multiple continual learning benchmarks show t hat SABER achieves performance on par with or surpassing state-of-the-art method s, offering a principled approach that directly addresses the root cause of forg etting by managing representational conflict.
****
Syntax vs. Semantics: How Transformers Learn Deep Dependencies
JiangRui Zhao, Xiaoting Du
Large Language Models demonstrate remarkable syntactic fluency, yet the optimiza tion dynamics governing their acquisition of deep semantic dependencies remain p oorly understood. We propose a mechanistic framework that models this learning p rocess as a competition between Surface Statistics and Deep Semantics. Our theor etical analysis identifies a "Gradient Starvation" phenomenon where the error si gnals for sparse semantic dependencies are actively suppressed during early opti mization. This suppression impedes the learning of structural reasoning and caus es its emergence to manifest as a sudden phase transition.
Furthermore, this framework offers a mechanistic basis for the effectiveness of Chain-of-Thought (CoT) strategies. By externalizing intermediate reasoning steps into concrete tokens, CoT effectively bypasses the suppression regime inherent to implicit reasoning. We validate these findings across scales ranging from toy transformers to production models (Llama-3.1-8B, Qwen2.5-Coder-7B). Finally, gu ided by this theory, we propose a topology-aligned contrastive objective that ex plicitly rectifies the gradient geometry. Experiments on variable binding tasks demonstrate that our method achieves an improvement that is over 2× larger than that obtained via standard cross-entropy fine-tuning. Code will be publicly avai lable at: https://github.com/jr-zhao/Deep-Dependencies/tree/main.

Mind Dreamer: Untethering Imagination via Active Causal Intervention on Latent M anifolds
Shaojun Xu, Xiaoling Zhou, Yihan Lin, Yapeng Meng, Xinglong Ji, Luping Shi, Rong Zhao
Model-Based Reinforcement Learning yields sample efficiency via latent imaginati on, yet remains constrained by **Historical Tethering**: imagination is typicall y initialized from observed states. This creates a learning asymmetry, where the world model's manifold discovery outpaces the policy's sparse-reward optimizati on. We propose **Mind Dreamer (MD)**, a framework that instantiates **Active Cau sal Intervention** to transcend Markovian continuity. MD reformulates discovery as the minimization of a global Relay Expected Free Energy.
Instead of initializing from historical data, it draws initial states from an ad versarial generator $s_0 \sim p_{gen}(\cdot)$, creating non-continuous **latent jumps** to epistemic blind spots that are physically plausible yet cognitively c hallenging.
We derive **Relay Value Function** and **Relay Uncertainty Function** to resolve the credit assignment paradox across these spatial ruptures.

Treating synthesized anchors as interventional intermediary states, these potentials propagate pragmatic and epistemic value through Bellman-style backups. Notably, we prove that uncertainty propagation across discontinuities necessitates a quadratic discount γ^2, establishing a formal epistemic horizon. Theoretically, MD approximates a variance-minimizing importance sampler that expands the manifold's spectral gap, reducing the hitting time to critical bottleneck states. Empirically, MD achieves a **1.67$\times$ average speedup** over DreamerV3 on DeepMind Control Suite, reaching **8.8$\times$** in sparse-reward tasks.

Attention Implements the Fisher Geometry of Exponential Families
Bodie Rubacher
Softmax attention normalizes scores, and Bayes' rule normalizes log prior plus log likelihood. For finite latent symbols with exponential-family observations, we show that one attention head can implement the Bayes posterior and posterior means exactly, and that the posteriors representable by a single head are precisely log-linear. The standard exponential-family duality identity rewrites the likelihood as a negative Bregman divergence in mean/sufficient-statistic space; our attention-specific contribution is to use this identity to characterize when Bayes-aligned attention admits one globally shared quadratic metric, proving that this happens exactly when the dual potential is quadratic. When curvature varies, we give a multi-head local-curvature atlas with approximation and head-count bounds, and we extend the picture to in-context estimation through plug-in consistency, finite-sample stability, and an optimizer-agnostic converse from excess log-loss to approximate key-subspace alignment. Controlled Gaussian, Bernoulli, and Poisson ICE diagnostics illustrate these regimes, while the exact theorems remain scoped to finite discrete latent classes and suggest testable, not universal, predictions for larger learned transformers.

Seizure-Semiology-Suite(S^3): A Clinically Multimodal Dataset, Benchmark, and Models for Seizure Semiology Understanding
Lina Zhang, Tonmoy Monsoor, Peizheng Li, Jiarui Cui, Xinyi Peng, Chong Han, Prateik Sinha, Siyuan Dai, Jessica Nichole Pasqua, Colin M McCrimmon, Weiting Liu, Hailey Marie Miranda, Bing Hu, Xiangting Wu, Tengyou Xu, Chunhan Li, Jiaye Tian, Jiarui Tang, Detao Ma, Lingye Kong, Junnan Lyu, Jungang Li, Yan Zan, Junhua Huang, Rajarshi Mazumder, Vwani Roychowdhury
While Multimodal Large Language Models (MLLMs) have demonstrated remarkable proficiency in general video understanding, their capacity to interpret involuntary, and spatio-temporally evolving pathologic motor behaviors such as seizure semiology remains largely untested. To address this gap, we introduce Seizure-Semiology-Suite (S^3), a clinically grounded dataset and benchmark for fine-grained, structured seizure semiology understanding. The dataset includes 438 seizure videos annotated with over 35,000 dense labels covering 20 ILAE-defined semiological features. Building on this dataset, we propose a seven-task hierarchical benchmark that systematically evaluates MLLMs from low-level visual perception to temporal sequencing, narrative report generation, and seizure diagnosis. To enable clinically meaningful evaluation of generated reports, we further introduce the Report Quality Index for Seizure Semiology (Seizure-RQI). Extensive baselines across 11 open-weight MLLMs reveal systematic weaknesses in laterality reasoning, temporal localization, symptom sequencing, and clinically faithful reporting. We show that seizure-specific fine-tuning substantially improves performance across tasks, and that a two-stage neuro-symbolic framework achieves an F1 score of 0.96 on epileptic versus non-epileptic seizure classification. Seizure-Semiology-Suite establishes a rigorous benchmark for evaluating multimodal models in safety-critical medical video understanding and guides the development of clinically reliable, domain-adaptive multimodal intelligence. Our code is publicly available at \href{https://github.com/LinaZhangUCLA/SeizureSemiologySuite}{SeizureSemiologySuite}.

Last-iterate Convergence of ADMM on Multi-affine Quadratic Equality Constrained Problem

Yutong Chao, Michal Ciebielski, Jalal Etesami, Majid Khadiv
In this paper, we study a class of non-convex optimization problems known as multi-affine quadratic equality constrained problems, which appear in various applications--from generating feasible force trajectories in robotic locomotion and manipulation to training neural networks. Although these problems are generally non-convex, they exhibit convexity or related properties when all variables except one are fixed. Under mild assumptions, we prove that the alternating direction method of multipliers (ADMM) converges when applied to this class of problems. Furthermore, when the "degree" of non-convexity in the constraints remains within certain bounds, we show that ADMM achieves a linear convergence rate. We validate our theoretical results through practical examples in robotic locomotion.
****
MEAL: A Benchmark for Continual Multi-Agent Reinforcement Learning
Tristan Tomilin, Luka van den Boogaard, Samuel Garcin, Constantin Ruhdorfer, Bram Grooten, Fabrice Kusters, Yali Du, Andreas Bulling, Mykola Pechenizkiy, Meng Fang
Benchmarks play a central role in reinforcement learning (RL) research, yet their computational constraints often shape what is studied. Despite the motivation of lifelong learning, most continual RL papers consider only 3–10 sequential tasks, as CPU-bound environments make longer sequences impractical. Meanwhile, continual learning in cooperative multi-agent settings remains largely unexplored. To address these gaps, we introduce **MEAL** (**M**ulti-agent **E**nvironments for **A**daptive **L**earning), the first benchmark for continual multi-agent RL. By leveraging JAX and GPU acceleration, MEAL enables training on sequences of 100 tasks on a single GPU in a few hours. We find that long task sequences reveal failure modes that do not appear at smaller scales.
****
Tractable Expected Information Gains for Exponential Family Posteriors
Rik Knowles, Tom Rainforth
We investigate which models admit a collapse of the expected information gain (EIG) and its derivative from a doubly intractable to a singly intractable expression. We prove that a sufficient condition is that the posterior distribution belongs to an exponential family (EF) and depends on the experimental design and data only through its natural parameters, and derive corresponding singly intractable and unbiased estimators for the EIG and its (reparameterized) gradient. We further show that this is achieved when using a likelihood of an analogous form and any arbitrary prior. This is complemented by a theoretical analysis of certain degenerate behaviors that may arise when optimizing the EIG for EF-modeled experiments. Finally, we empirically demonstrate the benefits of using our singly intractable estimators, showing superior convergence rates, and substantial performance gains for sequential design problems compared to using standard nested estimators.
****
Softmax as Linear Attention in the Large-Prompt Regime: a Measure-based Perspective
Etienne Boursier, Claire Boyer
Softmax attention is a central component of transformer architectures, yet its nonlinear structure poses significant challenges for theoretical analysis. We develop a unified, measure-based framework for studying single-layer softmax attention under both finite and infinite prompts. For i.i.d. centered Gaussian inputs, we lean on the fact that the softmax operator converges in the infinite-prompt limit to a linear operator acting on the underlying input-token measure. Building on this insight, we establish non-asymptotic concentration bounds for the output and gradient of softmax attention, quantifying how rapidly the finite-prompt model approaches its infinite-prompt counterpart, and prove that this concentration remains stable along the entire training trajectory in general in-context learning settings with sub-Gaussian tokens.
In the case of in-context linear regression, we use the tractable infinite-prompt dynamics to analyze training at finite prompt length. Our results allow optimization analyses developed for linear attention to transfer directly to softmax a

ttention when prompts are sufficiently long, showing that large-prompt softmax a ttention inherits the analytical structure of its linear counterpart. This, in t urn, provides a principled and broadly applicable toolkit for studying the train ing dynamics and statistical behavior of softmax attention layers in large promp t regimes.

MatchFixAgent: Language-Agnostic Autonomous Repository-Level Code Translation Va lidation and Repair

Ali Reza Ibrahimzada, Brandon Paulsen, Reyhaneh Jabbarvand, Joey Dodds, Daniel K roening

Code translation transforms source code from one programming language (PL) to an other. Validating the functional equivalence of translation and repairing, if ne cessary, are critical steps in code translation. Existing automated validation a nd repair approaches struggle to generalize to many PLs due to high engineering overhead, and they rely on existing and often inadequate test suites, which resu lts in false claims of equivalence and ineffective translation repair. To bridge this gap, we develop MatchFixAgent, a large language model (LLM)-based, PL-agno stic framework for equivalence validation and repair of translations. MatchFixAg ent features a multi-agent architecture that divides equivalence validation into several sub-tasks to ensure thorough and consistent semantic analysis of the tr anslation. We compare MatchFixAgent's validation and repair results with four re pository-level code translation techniques. Our results demonstrate that MatchFi xAgent produces (in)equivalence verdicts for 99.2% of translation pairs, with the same equivalence validation result as prior work on 72.8% of them. When Ma tchFixAgent's result disagrees with prior work, we find that 60.7% of the time MatchFixAgent's result is actually correct. In addition, we show that MatchFixA gent can repair 50.6% of inequivalent translation, compared to prior work’s $1 8.5$%.

SCoA: Revisiting Domain Generalized Object Detection with Style-Conditioned Adap tation

Han Jiang, Wenfei Yang, Tianzhu Zhang, Yongdong Zhang

Domain generalized object detection (DGOD) aims to train an object detector on a single source domain and generalize it to unseen target domains. Recent adva nces in DGOD have increasingly exploited vision foundation models (VFMs) via par ameter-efficient finetuning strategies. However, existing approaches typically a dapt VFMs with fixed, style-agnostic parameters, overlooking that different visu al styles may induce distinct task discrepancies. To address this challenge, we propose SCoA, a novel Style Conditioned Adaptation framework for dynamic, st yle-aware task compensation. Specifically, we introduce a Spectral Style Modeli ng (SSM) module that preserves local style cues via a memory-based mechanism, en abling diverse style characterization from a single source domain. Conditioned o

n the extracted style signals, we design a Mixture-of-Tokens Adaptation (MTA) me
chanism, which maintains multiple adaptation tokens and dynamically routes each
sample to an optimal combination of tokens, thereby explicitly modeling style-de
pendent task mismatches. In addition, we propose a Style-Conditioned Query Refin
ement (SCQR) module that injects style information into object queries, enablin
g a style-aware detection head. By jointly integrating these components, SCoA al
lows the model to follow style-specific adaptation trajectories, achieving effec
tive and flexible task compensation for VFM-based DGOD. Extensive experiments de
monstrate that the proposed SCoA achieves state-of-the-art performance across t
wo challenging scenarios.

Angel or Demon: Investigating the Plasticity Interventions' Impact on Backdoor T
hreats in Deep Reinforcement Learning
Oubo Ma, Ruixiao Lin, Yang Dai, Jiahao Chen, Chunyi Zhou, Linkang Du, Shouling J
i
Extensive research has highlighted the severe threats posed by backdoor attacks
to deep reinforcement learning (DRL).
However, prior studies primarily focus on vanilla scenarios, while plasticity in
terventions have emerged as indispensable built-in components of modern DRL agen
ts.
Despite their effectiveness in mitigating plasticity loss, the impact of these i
nterventions on DRL backdoor vulnerabilities remains underexplored, and this lac
k of systematic investigation poses risks in practical DRL deployments.
To bridge this gap, we empirically study 14,664 cases integrating representative
interventions and attack scenarios.
We find that only one intervention (i.e., *SAM*) exacerbates backdoor threats, w
hile other interventions mitigate them.
Pathological analysis identifies that the exacerbation is attributed to backdoor
gradient amplification, while the mitigation stems from activation pathway disr
uption and representation space compression.
From these findings, we derive two novel insights:
(1) a conceptual framework *SCC* for robust backdoor injection that deconstructs
the mechanistic interplay between interventions and backdoors in DRL, and (2) a
bnormal loss landscape sharpness as a key indicator for DRL backdoor detection.

MAPS: Memory-Aware Predictive Scheduling Framework for Large Language Model Serv
ing
Tiancheng Zhang, Yulin Chen, Yunfeng Zhao, Shaoyuan Huang, Cheng Zhang, Xiaofei
Wang
The surge of large language model (LLM) applications on personal devices imposes

massive, bursty workloads on cloud serving infrastructure. While prefill-decode disaggregation improves throughput and scalability, memory-bound decode instances often suffer from persistent load imbalance, as output lengths are unknown when requests arrive at the cloud. To address this, we propose **MAPS**, a **M**emory-**A**ware **P**redictive **S**cheduling framework tailored for disaggregated LLM serving. MAPS performs device-assisted speculative output length prediction overlapped with cloud-side prefilling, incurring negligible latency overhead. To handle generation uncertainty, MAPS applies uncertainty-aware calibration to derive output-length upper bounds with target coverage, enabling safe scheduling decisions. Building on these bounds, MAPS employs a hierarchical global-local scheduling strategy to mitigate inter-decoder queue buildup and intra-decoder head-of-line blocking. Extensive experiments on two real-world workloads and two LLMs show that MAPS significantly outperforms three state-of-the-art systems, reducing average end-to-end latency by 42.6% and tail latency by up to 84.8%.

OmniSapiens: A Foundation Model for Social Behavior Processing via Heterogeneity-Aware Relative Policy Optimization

Keane Ong, Sabri Boughorbel, Luwei Xiao, Chanakya Ekbote, Wei Dai, Ao Qu, Jingyao Wu, Rui Mao, Ehsan Hoque, Erik Cambria, Gianmarco Mengaldo, Paul Pu Liang

Socially intelligent AI systems must reason across diverse human behavioral tasks and generalize to new social contexts. However, behavioral data is inherently heterogeneous, comprising diverse modalities and prediction targets that produce uneven training signals across samples, creating imbalanced learning dynamics that challenge existing AI models. To address this, we develop OmniSapiens-7B 2.0, a foundation model for social behavior processing that explicitly addresses learning from heterogeneous behavioral data. This is enabled through Heterogeneity-Aware Relative Policy Optimization, a new RL method that rebalances learning signals across samples by approximating each sample’s contribution to the policy update and using these estimates to drive geometrically centered, inertially smoothed advantage modulation for stable training. OmniSapiens-7B 2.0 achieves the best and most consistent performance across 10 behavioral tasks, while also attaining the best performance on all five held-out benchmarks, with gains of up to +12.02% and +9.37% respectively. Furthermore, it demonstrates more consistent and interpretable reasoning traces, supporting reliable real-world behavioral applications. Our model is available at https://github.com/MIT-MI/human_behavior_atlas.

Awakening Visual Reasoning: Mitigating Post-Training Failure in Vision-Text Compression

Xing Xi, Liyao Li, Hao Chen, Ningtao Wang, Peixian Chen, Peilin Tong, Xing Fu, Yu Cheng, Haobo Wang, Gang Chen, Junbo Zhao, Ronghua Luo

Vision-Text Compression (VTC) offers a scalable path for long-context multimodal modeling by rendering textual data into dense visual tokens. While recent Vision-Language Models (VLMs) demonstrate high decoding fidelity (OCR) on such inputs, they exhibit a severe reasoning gap: models that reason robustly on native text often fail on visually compressed equivalents, particularly in long-range retrieval and multi-step deduction. We identify a phenomenon of post-training transfer failure, where standard supervised fine-tuning and reinforcement learning on visual prompts yield marginal gains compared to their textual counterparts. To address this, we propose CoRe (Coordinated Reasoning), a training framework that enforces lockstep consistency between the reasoning processes of textual and visual modalities. By treating the text-conditioned policy as a dynamic anchor, CoRe aligns the visual-conditioned policy via step-wise distribution matching, seamlessly integrating into both SFT and RL pipelines. Extensive evaluations across mathematical reasoning, long-context memory, and tabular retrieval benchmarks show that CoRe significantly outperforms standard visual post-training, recovering up to 70% of the performance gap relative to the textual upper bound and effectively activating latent reasoning capabilities in the compressed visual modality.

Threat2Traffic: Multi-Agent Environment Synthesis for Malware Traffic Generation from Threat Intelligence
Haoyang Chen, Chang Liu, Zhong Guan, Junzheng Shi, Gaopeng Gou, Gang Xiong
Data-driven cybersecurity research is fundamentally constrained by the scarcity of labeled datasets, yet acquiring authentic, large-scale malware traffic remains bottlenecked by obsolescent public datasets, unscalable manual construction, and inflexible sandboxes that fail to satisfy the sample-specific dependencies required for malware to exhibit malicious behavior. Threat intelligence documents these dependencies, and LLM agents offer a path to extract them for environment construction, yet directly applying such agents faces two challenges: input-side ambiguity and output-side fragility. In this paper, we propose Threat2Traffic, a multi-agent framework that extracts sample-specific dependencies from threat intelligence, reconstructs tailored environments, and captures malware traffic. To address input-side ambiguity, it formulates dependency extraction as structured multi-agent deliberation over an evidence graph. To overcome output-side fragility, it incorporates invariant-guided synthesis with dual-layer validation under syntactic and semantic constraints. Evaluated on 1,077 samples across eight malware families, Threat2Traffic achieves 83.1\% reproduction success, highlighting its effectiveness for scalable and realistic malware traffic generation. We release the core source code and traffic dataset at https://github.com/apos3637/Threat2Traffic

On the Power of (Approximate) Reward Models for Inference-Time Scaling: Sequential Monte Carlo and Beyond
Youheng Zhu, Yiping Lu
Inference-time scaling has recently emerged as a powerful paradigm for improving the reasoning capability of large language models. Among various approaches, \emph{Sequential Monte Carlo (SMC)} has become a particularly important framework, enabling iterative generation, evaluation, rejection, and resampling of intermediate reasoning trajectories. A central component in this process is the \emph{reward model}, which evaluates partial solutions and guides the allocation of computation during inference. However, in practice, true reward models are never available. All deployed systems rely on \emph{approximate reward models}, raising a fundamental question: \emph{Why and when do approximate reward models suffice for effective inference-time scaling?} In this work, we provide a theoretical answer. We identify the \emph{Bellman error} of the approximate reward model as the key quantity governing the effectiveness of SMC-based inference-time scaling. For a reasoning process of length T, we show that if the Bellman error of the approximate reward model is bounded by $O(1/T)$, then combining this reward model with SMC reduces the computational complexity of reasoning from exponential in T to polynomial in T. This yields an \emph{exponential improvement} in inference efficiency despite using only approximate rewards.
****
Geometric Embedding Alignment via Curvature Matching in Transfer Learning
Sung Moon Ko, Jaewan Lee, Sumin Lee, Soorin Yim, Sehui Han
Geometrical interpretations of deep learning models offer insightful perspectives into their underlying mathematical structures. In this work, we introduce a novel approach that leverages differential geometry, particularly concepts from Riemannian geometry, to integrate multiple models into a unified transfer learning framework. By aligning the Ricci curvature of latent space of individual models, we construct an interrelated architecture, namely Geometric Embedding Alignment via cuRvature matching in transfer learning (GEAR), which ensures comprehensive geometric representation across datapoints. This framework enables the effective aggregation of knowledge from diverse sources, thereby improving performance on target tasks. We evaluate our model on 23 molecular task pairs and demonstrate significant performance gains over existing benchmark models—achieving improvements of at least 14.4% under random splits and 8.3% under scaffold splits.

RED-HDP-HMM: Observation-Dependent Durations for Bayesian Nonparametric Sequential Models

Miko■aj S■upi■ski, Piotr Lipinski
The Hierarchical Dirichlet Process Hidden Markov Model (HDP-HMM) is a Bayesian n onparametric extension of the classical Hidden Markov Model, well-suited for lea rning from (spatio-)temporal data. To relax the restrictive geometric assumption on state durations, the HDP Hidden Semi-Markov Model was introduced. However, b oth models assume stationary state durations, which limits their expressive powe r. In this work, we extend the HDP-HMM framework by incorporating recurrent expl icit duration modeling, resulting in a more general and flexible model: the Recu rrent Explicit Duration HDP-HMM (RED-HDP-HMM). We propose a Gibbs sampling metho d for efficient inference in this model. Empirical results on both synthetic and real-world segmentation tasks demonstrate that RED-HDP-HMM consistently outperf orms the disentangled sticky HDP-HMM and the standard sticky HDP-HMM.
****

Better, Faster: Harnessing Self-Improvement in Large Reasoning Models
Qihuang Zhong, Liang Ding, Juhua Liu, Bo Du, Leszek Rutkowski, Dacheng Tao
Self-improvement training enables the large reasoning models (LRMs) to improve t hemselves by self-generating reasoning trajectories as training data without ext ernal supervision. However, we find that this method often falls short in comple x reasoning tasks and even leads to model collapse. Through a series of prelimin ary analyses, we reveal two problems: (1) data imbalance, where most training sa mples are simple, but the challenging yet crucial samples are scarce; (2) overth inking, where many undesired samples with redundant reasoning steps are used for self-training. To this end, we propose HSIR, which effectively Harnesses Self-I mprovement in large Reasoning models via two simple-yet-effective approaches. Sp ecifically, HSIR introduces a verify-then-exit sampling strategy to mitigate dat a imbalance by efficiently collecting more accurate solutions for difficult quer ies, and designs an Intrinsic Diversity score to quantify overthinking and filte r out the undesired solutions. We apply HSIR to various post-training paradigms, among which we further propose H-GRPO, an enhanced GRPO algorithm that leverage s the intrinsic diversity as an external reward to encourage concise and diverse reasoning via reinforcement learning. Extensive results show that HSIR not only effectively enhances the reasoning performance, i.e., bringing up to +10.9% ave rage performance gains, but also significantly improves the reasoning efficiency by reducing up to 42.4% relative inference overhead.

SCOUT: Active Information Foraging for Long-Text Understanding with Decoupled Ep istemic States
Zhenliang Zhang, Wenqing Wang, Yong Hu, Yaming Yang, Jiaheng Gao, Chen Shen, Xia ojun Wan
Long-Text Understanding (LTU) at million-token scale requires balancing reasonin g fidelity with computational efficiency. Frontier long-context LLMs can process millions of token contexts end-to-end, but they suffer from high token consumpt ion and attention dilution. In parallel, specialized LTU agents often sacrifice fidelity through task-agnostic abstractions like graph construction or indexing. We identify a key insight for LTU: query-relevant information is typically spar se relative to the full document, so effective reasoning should rely on a query- sufficient subset rather than the entire context. To address this, we propose SC OUT, a new paradigm for LTU that **shifts from passive processing to active info rmation foraging**. It treats the document as an explorable environment and answ ers from a compact, provenance-grounded epistemic state. Guided by state-level g ap diagnosis, SCOUT adaptively alternates between coarse-to-fine exploration and anchored state updates that progressively *contract* its epistemic state toward query sufficiency. Experiments show that SCOUT matches state-of-the-art proprie tary models while reducing token consumption by up to 8 times. Moreover, SCOUT r emains stable as context length scales, substantially alleviating the practical cost--capability trade-off in long-context reasoning. Resources are available at our [Project Page](https://xavierzhang2002.github.io/scout-page/).

Test-Time Training with KV Binding Is Secretly Linear Attention
Junchen Liu, Sven Elflein, Or Litany, Zan Gojcic, Ruilong Li

Test-time training (TTT) with KV binding as sequence modeling layer is commonly interpreted as a form of online meta-learning that memorizes a key–value mapping at test time. However, our analysis reveals multiple phenomena that contradict this memorization-based interpretation. Motivated by these findings, we revisit the formulation of TTT and show that a broad class of TTT architectures can be expressed as a form of learned linear attention operator. Beyond explaining previously puzzling model behaviors, this perspective yields multiple practical benefits: it enables principled architectural simplifications, admits fully parallel formulations that preserve performance while improving efficiency, and provides a systematic reduction of diverse TTT variants to a standard linear attention form. Overall, our results reframe TTT not as test-time memorization, but as learned linear attention with enhanced representational capacity. Project page: https://research.nvidia.com/labs/sil/projects/tttla/.

Is the Last Layer Sufficient for Uncertainty Quantification?

Joseph Wilson, Chris van der Heide, Liam Hodgkinson, Fred Roosta

Epistemic uncertainty quantification (UQ) for deep neural networks (DNNs) is a requirement for safe adoption of AI in mission-critical settings. Several leading methods for UQ linearize DNNs to form Bayesian Generalized Linear Models (GLMs), where epistemic uncertainty is modeled via the predictive posterior distribution. Linearizing around the parameters of the *final connected layer* of a DNN is a commonly used approximation for reducing the computational burden of such GLMs, though it is often believed to come at the cost of degraded performance. In this work, we compare GLMs arising from full-network and last-layer linearization using both theoretical and empirical approaches. We first employ tools from random matrix theory to conduct a theoretical comparison; this analysis reveals no meaningful improvement in the UQ capabilities of full linearization. Coupled with a large-scale empirical evaluation across a range of modern machine learning tasks, we arrive at the following conclusion: a last-layer approximation yields comparable UQ performance while offering substantially improved computational efficiency.

Bio-Vision-Inspired Spiking Neural Networks for Object Detection with Event Cameras

Dongyang Ma, Zhengyu Ma, Yifan Huang, Chenlin Zhou, Wei Zhang, Yonghong Tian

Retina-like event cameras and brain-inspired Spiking Neural Networks (SNNs) demonstrate exceptional energy efficiency through bio-inspired sensing and computation. While SNNs are naturally well-suited to the asynchronous nature of event data, their practical applications face the following challenges: sensitivity to noise, dense representations that disrupt spike pathways, and insufficient multi-scale feature perception. To address the aforementioned challenges, we propose a bio-vision-inspired object detection method motivated by biological (bio) vision systems. First, at the micro level, this paper proposes a noise-filtering STATNF-Neuron architecture to address the current sensitivity of basic neurons to noise. Based on STATNF-Neurons, the paper introduces two bio-vision-inspired macro-structures: Events-to-Spikes Representation (E2S), which preserves spiking characteristics while mimicking the memory and noise-filtering abilities of retinal neurons; Bidirectional Multi-Scale Spiking Network (BiSNet), which simulates cortical information flow pathways to integrate multi-scale features in both directions, enhancing the network's ability to perceive information at multiple scales. Extensive experiments show that the proposed bio-vision-inspired method achieving state-of-the-art performance. Notably, it reaches 96.1% accuracy on NCAR, 63.5% mAP(50) on N-Caltech101, and 69.1% mAP(50) on Gen1.

Detecting Contextual Hallucinations in Large Language Models with Frequency-Aware Attention

Siya Qi, Yudong Chen, Runcong Zhao, Qinglin Zhu, Zhanghao Hu, Wei Liu, Yulan He, Zheng Yuan, Lin Gui

Hallucination detection is critical for ensuring the reliability of large language models (LLMs) in context-based generation. Prior work has explored intrinsic

signals available during generation, among which attention offers a direct view of grounding behavior. However, existing approaches typically rely on coarse summaries that fail to capture fine-grained instabilities in attention. Inspired by signal processing, we introduce a frequency-aware perspective on attention by analyzing its variation during generation. We model attention distributions as discrete signals and extract high-frequency components that reflect rapid local changes in attention. Our analysis reveals that hallucinated tokens are associated with high-frequency attention energy, reflecting fragmented and unstable grounding behavior. Based on this insight, we develop a lightweight hallucination detector using high-frequency attention features. Experiments on the RAGTruth and HalluRAG benchmarks show that our approach achieves performance gains over verification-based, internal-representation-based, and attention-based methods across models and tasks.

UniSparse: Combining Weight Pruning and Spike Sparsification in Spiking Neural Networks

Xinyu Shi, Tong Bu, Zhaofei Yu

Spiking Neural Networks (SNNs) offer a notable energy-saving advantage compared to Artificial Neural Networks (ANNs) when deployed on neuromorphic hardware. While recent SNNs achieve superior performance using larger and deeper backbones, this comes at a cost of diminishing their energy-saving benefits. In this paper, we propose UniSparse, a unified sparsification framework for enhancing the energy efficiency of SNNs. We demonstrate that the affine parameters in batch normalization also serve as the learnable threshold of its subsequent spiking neurons. Based on this, we propose a novel spike sparsification method that reduces firing rate by constraining the affine parameters. As a complement to spike sparsification, we propose a weight pruning method based on the same energy constraint, which can be naturally integrated with spike sparsification. Experimental results demonstrate that UniSparse achieves a state-of-the-art trade-off between accuracy and energy efficiency across models and datasets. The sparsified ResNet-18 model requires only 7.04M SOPs for inference to achieve 92.38\% accuracy on the CIFAR-10 dataset. Our work highlights the great potential of deep SNNs in improving energy efficiency.

MEnvAgent: Scalable Polyglot Environment Construction for Verifiable Software Engineering

Chuanzhe Guo, Jingjing Wu, Sijun He, Yang Chen, Zhaoqi Kuang, Shilong Fan, Bingjin Chen, Siqi Bao, Jing Liu, Hua Wu, Qingfu Zhu, Wanxiang Che, Haifeng Wang

The evolution of Large Language Model (LLM) agents for software engineering (SWE) is constrained by the scarcity of verifiable datasets, a bottleneck stemming from the complexity of constructing executable environments across diverse languages. To address this, we introduce **MEnvAgent**, a **M**ulti-language framework for automated **Env**ironment construction that facilitates scalable generation of verifiable task instances. MEnvAgent employs a multi-agent Planning-Execution-Verification architecture to autonomously resolve construction failures and integrates a novel Environment Reuse Mechanism that reduces computational overhead by incrementally patching historical environments. Evaluations on MEnvBench, a new benchmark comprising 1,000 tasks across 10 languages, demonstrate that MEnvAgent outperforms baselines, improving Fail-to-Pass (F2P) rates by **8.6%** while reducing time costs by **43%**. Additionally, we demonstrate the utility of MEnvAgent by constructing MEnvData-SWE, the largest open-source polyglot dataset of realistic verifiable Docker environments to date, alongside solution trajectories that enable consistent performance gains on SWE tasks across a wide range of models.

PRM-PBE: Process Reward Model for Reinforcement Learning in Programming-by-Example

Yue Fang, Zhi Jin, Jie An, Hongshen Chen, Jiangmeng Li, Xiaohong Chen, Naijun Zhan

Programming-by-Example (PBE), as a typical few-shot inductive reasoning paradigm

, aims to synthesize corresponding algorithms from a set of input-output example
s. Although Large Language Models (LLMs) have demonstrated strong program synthe
sis potential, they still remain ineffective when handling complex PBE tasks. Sp
ecifically, LLMs often struggle to accurately grasp the underlying intent of exa
mples, resulting in synthesized programs that either partially satisfy the examp
les or completely deviate from the target. To address these limitations, we intr
oduce a process-supervised reinforcement learning method that provides fine-grai
ned feedback during the synthesis process, improving the ability of LLMs to capt
ure the intended behavior of provided examples. Firstly, we develop a reasoning
tree construction method that is used to build a PBE process supervision dataset
. Subsequently, we train a process reward model through preference learning to e
valuate the effectiveness of reasoning steps. Finally, we introduce a curriculum
 learning strategy based on the difficulty of PBE tasks, using Proximal Policy O
ptimization (PPO) to optimize the model. Experimental results on representative
PBE benchmarks show that our approach achieves an average pass rate of 56.61\%,
significantly outperforming the state-of-the-art baseline by 8.73\%.

A Call to Lagrangian Action: Learning Population Mechanics from Temporal Snapsho
ts

Vincent Guan, Lazar Atanackovic, Kirill Neklyudov

The population dynamics of molecules, cells, and organisms are governed by a num
ber of unknown internal and external forces. In the last decade, population dyna
mics have predominately been modeled with Wasserstein gradient flows. However, s
ince gradient flows minimize free energy, they fail to capture important dynamic
al properties, such as periodicity. In this work, we propose a change in perspec
tive by considering population dynamics that minimize Wasserstein Lagrangian act
ion, rather than free energy. As our main theoretical contributions, we derive t
he Hamiltonian equations of motion from the principle of least population-level
action and we show that these mechanics encompass classical mechanics, quantum m
echanics, and gradient flows. We further leverage the Hamiltonian perspective to
 propose an algorithm that learns the population mechanics from observed margina
ls, without specifying the Lagrangian. We demonstrate that by directly learning
the population mechanics, our method forecasts and interpolates unseen marginals
 without a reference process, and outperforms gradient flow and flow matching me
thods across a wide range of real and simulated experiments.

From Historical Patches to Repair Plans: Outcome-Conditioned Reasoning for Repos
itory-Level Program Repair

Chenglin Li, Yisen Xu, Zehao Wang, Shin Hwei Tan, Tse-Hsun Chen

Repository-level automated program repair (APR) requires long-horizon reasoning
over interdependent decisions. However, most LLM-based approaches reconstruct re
pair reasoning independently for each issue, failing to reuse successful pattern
s from prior repairs, even though real-world repositories contain many related i
ssues with shared structure or constraints. Existing methods typically rely on f
orward exploration, which operates under outcome uncertainty, incurs substantial
 inference-time overhead, and can drift from the final correct patch. We propose
 Conditional Reasoning Distillation (ConRAD), which leverages in-repository reso
lved issues by reconstructing repair reasoning backward from verified patches an
d distilling outcome-consistent, stage-wise repair reasoning plans. Injected at
inference time, these plans guide fault localization and patch generation, repla
cing open-ended exploration with constrained inference without fine-tuning or se
arch. On SWE-Bench Lite, ConRAD improves Pass@1 by 10.4\% (GPT-4o), 8.6\% (DeepS
eek-V3), and 10.3\% (GPT-5), demonstrating a scalable inference-time alternative
 to forward exploration for long-horizon APR.

SpecPrune-VLA: Accelerating Vision-Language-Action Models via Action-Aware Self-
Speculative Pruning

Hanzhen Wang, Jiaming Xu, Yushun Xiang, Jiayi Pan, Yongkang Zhou, Yong-Lu Li, Gu
ohao Dai

Pruning is a typical acceleration technique for compute-bound models by removing

computation on unimportant values. Recently, it has been applied to accelerate Vision-Language-Action (VLA) model inference. However, existing acceleration methods focus on local information from the current action step and ignore the global context, leading to $>$20\% success rate drop and limited speedup in some scenarios. In this paper, we point out \textbf{spatial-temporal consistency} in VLA tasks: input images in consecutive steps exhibit high similarity, and propose the key insight that token selection should combine local information with global context of the model. Based on this, we propose ***SpecPrune-VLA***, a training-free, two-level pruning method with heuristic control.
(1) Action-level static pruning. We leverage global history and local attention to statically reduce visual tokens per action.
(2) Layer-level dynamic pruning. We prune tokens adaptively per layer based on layer-wise importance.
(3) Lightweight action-aware controller: We classify actions as coarse- or fine-grained by the speed of the end effector and adjust pruning aggressiveness accordingly. Extensive experiments show that SpecPrune-VLA achieves up to 1.57× speedup in LIBERO simulation and 1.70× on real-world tasks, with negligible success rate degradation.
****

Gradient Transformer: Learning to Generate Updates for LLMs
Binh-Nguyen Nguyen, Khang Tran, Hai Phan, Issa Khalil
Many organizations lack computational resources to fine-tune large language models (LLMs) on private (unshareable) data for better utility, while fine-tuning tiny language models (TinyLMs) alone performs poorly. To address this bottleneck, we propose a data-free knowledge distillation framework that generates LLM update vectors based on TinyLMs fine-tuned on private data. An update vector is a vector of parameter changes from an initial model to its fine-tuned version on a dataset, capturing the effect of cumulative gradient steps during fine-tuning. The key idea of our framework is a novel **Gradient Transformer** that transforms TinyLM's update vectors into LLM's update vectors. As derived from shadow datasets, $\texttt{Grad-Transformer}$ captures the correlation between TinyLM and LLM update vectors, enabling third-party providers to generate LLM update vectors given the organization's TinyLM update vectors without accessing the organization's private data. The framework supports multi-organization collaboration to jointly update LLMs, improving performance and cost-efficiency. Extensive experiments across language modeling and reasoning tasks show that $\texttt{Grad-Transformer}$ remarkably outperforms state-of-the-art knowledge distillation baselines, even under strict differential privacy protection.
****

GR-LoRA: Gradient-Recycling Low-Rank Adaptation for Class-Incremental Learning
Yipeng Lin, Fengqiang Wan, Yang Yang
Pre-trained models with parameter-efficient fine-tuning have shown strong effectiveness in Class-Incremental Learning (CIL), which seeks to balance model plasticity and stability. In this context, orthogonality constraints can significantly enhance model stability, yet their reliance on subspace inevitably compromises model plasticity over long tasks. To address this, we propose Gradient-Recycling Low-Rank Adaptation (GR-LoRA), which reconciles stability and plasticity by recycling the gradients discarded in orthogonal projection. Specifically, GR-LoRA recycles post-decomposition non-orthogonal gradient components into task-specific lightweight modules and selects optimal module via entropy to improve plasticity, while incorporating local and global mismatch suppression to preserve stability by synthesizing out-of-distribution representations across all tasks. Theoretical analysis confirms that this recycling strategy preserves stability and improves plasticity. Experimental results from multiple CIL benchmarks verify the effectiveness and general applicability of GR-LoRA.
****

Blending Supervised and Reinforcement Fine-Tuning with Prefix Sampling
Zeyu Huang, Tianhao Cheng, Zihan Qiu, Zili Wang, Xu Yinghui, Edoardo Ponti, Ivan Titov
Existing LLMs-post-training techniques are broadly categorized into supervised f

ine-tuning (SFT) and reinforcement fine-tuning (RFT). Each paradigm presents a distinct trade-off:
(1) SFT excels at mimicking demonstration data, but can lead to problematic generalization as a form of behavior cloning.
(2) Conversely, RFT can significantly enhance a model's performance but is prone to learning unexpected behaviors, and its performance is sensitive to the initial policy.
In this paper, we propose a unified view of these methods and introduce Prefix-RFT, a hybrid approach that synergizes learning from both demonstration and exploration.
Using mathematical reasoning problems as a test bed, we empirically demonstrate that Prefix-RFT is simple yet effective.
Not only does it surpass the performance of standalone SFT and RFT, but it also outperforms parallel mixed-policy RFT methods.
Our analysis highlights the complementary nature of SFT and RFT, validating that Prefix-RFT effectively harmonizes them. Further ablation studies confirm the method's robustness to variations in the quality and quantity of demonstration data.
****

MECAT: A Multi-Experts Constructed Benchmark for Fine-Grained Audio Understanding Tasks
Yadong Niu, TIANZI WANG, Heinrich Dinkel, Xingwei Sun, Jiahao Zhou, Gang Li, Jizhong Liu, Xunying Liu, Jian Luan
While large audio-language models have advanced open-ended audio understanding, they still fall short of nuanced human-level comprehension. This gap persists largely because current benchmarks, limited by data annotations and evaluation metrics, fail to reliably distinguish between generic and highly detailed model outputs. To this end, this work introduces MECAT, a Multi-Expert Constructed Benchmark for Fine-Grained Audio Understanding Tasks. Generated via a pipeline that integrates analysis from specialized expert models with Chain-of-Thought large language model reasoning, MECAT provides multi-perspective, fine-grained captions and open-set question-answering pairs. The benchmark is complemented by a novel metric: DATE (Discriminative-Enhanced Audio Text Evaluation). This metric penalizes generic terms and rewards detailed descriptions by combining single-sample semantic similarity with cross-sample discriminability. A comprehensive evaluation of state-of-the-art audio models is also presented, providing new insights into their current capabilities and limitations. The code and data are publicly available at https://github.com/xiaomi-research/mecat.

Mesh Field Theory: Port–Hamiltonian Formulation of Mesh-Based Physics
Satoshi Noguchi, Yoshinobu Kawahara
We present Mesh Field Theory (MeshFT) and its neural realization, MeshFT-Net: a structure-preserving framework for mesh-based continuum physics that cleanly separates the physics’ topological structure from its metric structure. Imposing minimal physical principles (locality, permutation equivariance, orientation covariance, and energy balance/dissipation inequality), we prove a reduction theorem for mesh-based physics. Under these conditions, the physical dynamics admit a local factorization into a port–Hamiltonian form: the conservative interconnection is fixed uniquely by mesh topology, whereas metric effects enter only through constitutive relations and dissipation. This reduction clarifies what must be fixed and what should be learned, directly informing MeshFT-Net’s design.
Across evaluations on analytic and realistic datasets, physics-consistency tests, and out-of-distribution validation, MeshFT-Net achieves near-zero energy drift and strong physical fidelity (correct dispersion and momentum conservation) along with robust extrapolation and high data efficiency. By eliminating non-physical degrees of freedom and learning only metric-dependent structure, MeshFT provides a principled inductive bias for stable, faithful, and data-efficient learning-based physical simulation.

Efficient Online Influence Maximization under the Independent Cascade Model with

Node-Level Feedback
Arpit Agarwal, Varad Deolankar, Rohan Ghuge
Influence maximization is an important research area in social network analysis, where the goal is to select a small set of seed nodes so as to maximize the expected spread of influence under a stochastic diffusion process.

Classical approximation algorithms for this problem rely on full knowledge of the underlying influence probabilities and operate in an offline manner.

In many real-world settings, however, these probabilities are unknown and must be learned from data, raising the question: \emph{can one still obtain strong performance guarantees while simultaneously learning the diffusion model parameters through repeated interactions?}

In this paper, we study the problem of \emph{online influence maximization} under the independent cascade model, where influence probabilities are unknown and feedback is limited to \emph{node-level} activation outcomes.

Prior work relies on a \emph{pair oracle} which needs to perform a joint optimization over seed sets and feasible parameters. This oracle is difficult to implement in practice and it was open whether one can achieve sublinear regret using only a \emph{standard} offline oracle.

We resolve this question by designing an online learning algorithm that achieves $\widetilde{O}(\sqrt{T})$ regret using only a \emph{standard} offline oracle.

Finally, we validate our theoretical results via experiments on real and synthetic data.

Optimal Unconstrained Self-Distillation in Ridge Regression: Strict Improvements, Precise Asymptotics, and One-Shot Tuning
Hien Dang, Pratik Patil, Alessandro Rinaldo
Self-distillation (SD) is the process of retraining a student on a mixture of ground-truth labels and the teacher's own predictions using the same architecture and training data. Although SD has been empirically shown to often improve generalization, its formal guarantees remain limited. We study SD for ridge regression with an unconstrained mixing weight $\xi \in \mathbb{R}$. Conditional on the training data and without any distributional assumptions, we prove that for any squared prediction risk R (including out-of-distribution), the optimally mixed student strictly improves upon the ridge teacher at every regularization level λ where the teacher risk is not stationary ($R'(\lambda) \neq 0$). We also characterize the optimal mixing weight $\xi^\star$ in terms of the risk derivative R', showing that it can be negative, which is the case in over-regularized regimes. To quantify SD risk improvements, we derive exact risk asymptotics in the proportional asymptotics regime for general anisotropic covariance and deterministic signals. From a practical standpoint, we propose a consistent one-shot tuning method to estimate $\xi^\star$ without grid search, sample splitting, or refitting. Experiments on real-world datasets and pretrained neural network features support our theory and the one-shot tuning method.
****
Hair-Trigger Alignment: Black-Box Evaluation Cannot Guarantee Post-Update Alignment
Yavuz Faruk Bakman, Duygu Nur Yaldiz, Eleni Triantafillou, Peter Kairouz, Salman Avestimehr, Sai Praneeth Karimireddy
Large Language Models (LLMs) are rarely static and are frequently updated in practice. A growing body of alignment research has shown that models initially deemed ``aligned'' can exhibit misaligned behavior after fine-tuning. These works typically assume that the initial model is aligned based on static black-box evaluation, i.e., the absence of undesired responses to a fixed set of queries. However, the limits of black-box evaluation for post-update scenarios is not explored sufficiently. In this work, we formalize model alignment in both the static and post-update settings and uncover a fundamental limitation of black-box evaluation. We theoretically show that, due to overparameterization, static alignment provides no guarantee of post-update alignment for *any* update dataset. Moreover, we prove that static black-box probing cannot distinguish a model that is genui

nely post-update robust from one that conceals an arbitrary amount of adversaria l behavior which can be activated by even a single benign gradient update.
We further validate these findings empirically in LLMs across three core alignme nt domains: privacy, jailbreak safety, and behavioral honesty. We demonstrate th e existence of LLMs that pass all standard black-box alignment tests, yet become severely misaligned after a single benign update. Finally, we show that the cap acity to hide such latent adversarial behavior increases with model scale, confi rming our theoretical prediction that post-update misalignment grows with the nu mber of parameters. Together, our results highlight the inadequacy of static eva luation protocols and emphasize the urgent need for post-update--robust alignmen t evaluation. Code can be found [here](https://github.com/Ybakman/safety_benign_ update).

Envy-Free Allocation of Indivisible Goods via Noisy Queries
Zihan Li, Yan Hao Ling, Jonathan Scarlett, Warut Suksompong
We introduce a problem of fairly allocating indivisible goods (items) in which t he agents' valuations cannot be observed directly, but instead can only be acces sed via noisy queries. In the two-agent setting with Gaussian noise and bounded valuations, we derive upper and lower bounds on the required number of queries for finding an envy-free allocation in terms of the number of items, m, and th e negative-envy of the optimal allocation, Δ. In particular, when $\Delt a$ is not too small (namely, $\Delta \gg m^{1/4}$), we establish that the optima l number of queries scales as $\frac{\sqrt m }{(\Delta / m)^2} = \frac{m^{2.5}}{ \Delta^2}$ up to logarithmic factors. Our upper bound is based on non-adaptive queries and a simple thresholding-based allocation algorithm that runs in polyno mial time, while our lower bound holds even under adaptive queries and arbitrary computation time.

Learning General Causal Structures with Hidden Dynamic Process for Climate Analy sis
Minghao Fu, Biwei Huang, Zijian Li, Yujia Zheng, Ignavier Ng, Guangyi Chen, Ying yao Hu, Kun Zhang
Understanding climate dynamics requires going beyond correlations in observation al data to uncover their underlying causal process. Latent drivers, such as atmo spheric processes, play a critical role in temporal dynamics, while direct causa l influences also exist among geographically proximate observed variables. Tradi tional Causal Representation Learning (CRL) typically focuses on latent factors but overlooks such observable-to-observable causal relations, limiting its appli cability to climate analysis. In this paper, we introduce a unified framework th at jointly uncovers (i) causal relations among observed variables and (ii) laten t driving forces together with their interactions. We establish conditions under which both the hidden dynamic processes and the causal structure among observed variables are simultaneously identifiable from time-series data. Remarkably, ou r guarantees hold even in the nonparametric setting, leveraging contextual infor mation to recover latent variables and observable relations. Building on these i nsights, we propose CaDRe (Causal Discovery and Representation learning), a time -series generative model with structural constraints that integrates CRL and cau sal discovery. Experiments on synthetic datasets validate our theoretical result s. On real-world climate datasets, CaDRe not only delivers competitive forecasti ng accuracy but also recovers visualized causal graphs aligned with domain exper tise, thereby offering interpretable insights into climate systems.

Understanding Catastrophic Forgetting In LoRA via Mean-Field Attention Dynamics
Hugo Koubbi, Louis Hernandez, Matthieu Boussard
Low-Rank Adaptation (LoRA) is the dominant parameter-efficient fine-tuning metho d due to its favorable compute-performance trade-off, yet it suffers from catast rophic forgetting. We study forgetting through a tractable _mean-field self-atte ntion_ toy model, where tokens evolve as an interacting particle system and LoRA acts as a low-rank perturbation. Using tools from partial differential equation s and dynamical systems, we characterize regimes suggesting a phase transition b

etween forgetting and non-forgetting behavior. We show that one phase transition appears with respect to the norm of the perturbation, and the other with respect to the depth of the Transformers.
We further bound the time-to-deviation in terms of the perturbation size and spectral quantities, and corroborate the predicted trends with experiments and exploratory analyses on real models under LoRA fine-tuning.

Interpreting and Steering State-Space Models via Activation Subspace Bottlenecks
Vamshi Sunku Mohan, Kaustubh Gupta, Aneesha Das, Chandan Singh
State-space models (SSMs) have emerged as an efficient strategy for building powerful language models, avoiding the quadratic complexity of computing attention in transformers. Despite their promise, the interpretability and steerability of modern SSMs remain relatively underexplored. We take a major step in this direction by identifying *activation subspace bottlenecks* in the Mamba family of SSM models using tools from mechanistic interpretability. We then introduce a test-time steering intervention that simply multiplies the activations of the identified bottlenecks by a scalar. Across 7 SSMs and 6 diverse benchmarks, this intervention improves performance by an average of 8.27%, without requiring any task-specific tuning. Finally, we validate that the identified bottlenecks are indeed hindering performance by modifying them to yield an architecture we call Stable-Mamba, which achieves long-context performance gains when retrained from scratch.

Neural Implicit Action Fields: From Discrete Waypoints to Continuous Functions for Vision-Language-Action Models
Haoyun Liu, Jianzhuang Zhao, Xinyuan Chang, Tianle Shi, Chuanzhang Meng, Jiayuan Tan, Feng Xiong, Tong Lin, Dongjie Huo, Mu Xu, SongLin Dong, Zhiheng Ma, Yihong Gong, Sheng Zhong
Despite the rapid progress of vision-language-action (VLA) models, the prevailing practice of predicting action chunks as discrete waypoints remains structurally misaligned with the intrinsic continuity of physical motion. This discretization arises naturally from fixed-rate robot data collection and the token-by-token prediction paradigm of large language models, but ties actions to rigid sampling rates, does not naturally support analytically consistent higher-order derivatives, and introduces quantization artifacts that hinder precise, compliant interaction. We propose Neural Implicit Action Fields (NIAF), which reformulates chunk-level action representation from discrete waypoints to continuous action functions. Using a vision-language model as a hierarchical spectral modulator over a learnable motion prior, NIAF synthesizes continuous-time action manifolds with arbitrary temporal resolution. This formulation enables analytical differentiation, allowing explicit supervision of velocity and regularization of higher-order derivative signals to promote mathematical consistency, physical plausibility, and control smoothness. Our approach achieves strong results on CALVIN and LIBERO across diverse backbones. Real-world experiments further confirm that NIAF supports stable impedance control, bridging policy-side action generation and execution-side smooth control.
****
Corrigibility Transformation: Constructing Goals That Accept Updates
Rubi Hudson
An AI agent will learn a desired goal more effectively if it does not resist the training process, but many partially learned goals incentivize an AI to avoid further goal updates. We would like goals to be corrigible, meaning they allow changes requested through designated channels, so that we can confidently correct errors and shut down the AI if necessary. Despite this being a crucial safety property, the existing literature does not specify goals that are both corrigible and competitive with alternatives. We introduce a transformation that constructs a corrigible version of nearly any goal, without sacrificing performance. This is done by eliciting predictions of reward conditional on costlessly preventing updates, and having that target be pursued myopically. These goals are then shown to lead to optimal performance among the class of corrigible goals, to incenti

vize allowing mid-action overrides, and to disincentivize deliberate self-modification. Empirically, they induce corrigible behavior in gridworld settings and for language models when applied at the prompt level.

Rethinking Serialization in Linear 3D Vision: Decoupling Anisotropic Geometry from Isotropic Semantics
YinYun Yan, Liping zhang, Tingran Wang, Jiaxin Deng, Changshuo Wang, Limin Jiang, Shanwei Gao, Xin Ning
Current linear State-Space Models (SSMs) for 3D point clouds typically rely on 1D serialization schemes (e.g., Hilbert curves) for global modeling. In dense scenes, such imposed order can disrupt spatial continuity and induce what we call serialization bias. We propose AnIsoNet, a framework that decouples anisotropic geometry from isotropic semantics via two dedicated modules: Local Anisotropy Geometric Modeling (LAGM) and Global Isotropy Semantic Aggregation (GISA). LAGM uses ellipsoidal encoding to capture local directionality without relying on global order. GISA is configured according to dataset-level geometric density: dense-scene datasets use Identity Mode to avoid additional geometry-driven re-serialization, whereas sparse-object datasets use Morton serialization to provide a lightweight spatial prior. This avoids redundant multi-view scanning while preserving O(N) complexity. On S3DIS, reducing artificial serialization in dense scenes yields 82.62% mIoU, surpassing PCM by 3.0%. On ScanObjectNN, Morton serialization for sparse objects reaches 94.21% OA (+1.6%). On ScanNetV2, our model achieves 78.52% mIoU, surpassing PTv3 (77.5%) without pre-training, with only 12.2M parameters and 37G FLOPs.

RePack then Refine: Efficient Diffusion Transformers with Vision Foundation Models
Guanfang Dong, Luke Schultz, Negar Hassanpour, Chao Gao
Semantic-rich features from Vision Foundation Models (VFMs) have been leveraged to enhance Latent Diffusion Models (LDMs). However, raw VFM features are typically high-dimensional and redundant, increasing the difficulty of learning and reducing training efficiency for Diffusion Transformers (DiTs). In this paper, we propose Repack then Refine, a three-stage framework that brings the semantic-rich VFM features to DiT while further accelerating learning efficiency. Specifically, the RePack module projects the high-dimensional features onto a compact, low-dimensional manifold. This filters out the redundancy while preserving essential structural information. A standard DiT is then trained for generative modeling on this highly compressed latent space. Finally, to restore the high-frequency details lost due to the compression in RePack, we propose a Latent-Guided Refiner, which is trained lastly for enhancing the image details. On ImageNet-1K, RePack-DiT-XL/1 achieves an FID of 1.82 in only 64 training epochs. With the Refiner module, performance further improves to an FID of 1.65, significantly surpassing latest LDMs in terms of convergence efficiency. Our results demonstrate that packing VFM features, followed by targeted refinement, is a highly effective strategy for balancing generative fidelity with training efficiency. Source code is publicly available at https://github.com/guanfangdong/RePack-then-Refine.

CGRiC: Compositional Risk Certification for Structured LLM Outputs
Ibne Farabi Shihab, Sanjeda Akter, Anuj Sharma
Large language models increasingly generate structured outputs, including citation-grounded summaries, multi-step reasoning chains, and tool-augmented responses, where correctness is inherently compositional: a single flawed claim can invalidate an otherwise accurate response. Existing certification methods treat outputs as atomic units, forcing a binary choice between unsafe acceptance and wasteful rejection. We introduce \textbf{Claim Graph Risk Control (CGRiC)}, a framework that decomposes responses into dependency graphs of verifiable claims and assigns calibrated per-claim risk bounds via information-lift statistics. By composing these bounds, CGRiC provides explicit guarantees on the probability that any incorrect claim passes verification undetected. When this composed risk exceeds a target threshold, the system triggers localized repairs rather than full abste

ntion, preserving correct content while fixing problematic claims. Our approach explicitly models extraction noise and verifier imperfection, and exploits conditional independence structure for tighter certificates when validated. Empirically, CGRiC achieves target risk levels while reducing abstention by 31\% compared to atomic baselines across QA, summarization, and reasoning tasks.
****
SteeringSafety: Benchmarking Representation Steering in LLMs Across Safety Perspectives
Vincent Siu, Nicholas Crispino, David Park, Nathan W. Henry, Zhun Wang, Yang Liu, Dawn Song, Chenguang Wang
We introduce STEERINGSAFETY, a benchmark for evaluating representation steering methods across nine safety perspectives spanning 18 datasets. While prior work highlights the general capabilities of representation steering, we focus on safety perspectives including refusal, bias, hallucination, social behaviors, reasoning, epistemic integrity, and normative judgment. STEERINGSAFETY provides modularized building blocks for state-of-the-art steering methods, enabling unified implementation of DIM, ACE, CAA, PCA, and LAT with recent enhancements such as conditional steering. Results on Gemma-2-2B, Llama-3.1-8B, and Qwen-2.5-7B show that strong steering performance depends on the pairing of method, model, and specific perspective. For instance, DIM is consistently effective, yet all methods exhibit substantial entanglement, where improving effectiveness on one safety perspective often significantly changes performance on others. Social behaviors are most vulnerable (degradation up to 76%), refusal steering (jailbreaking) frequently compromises normative judgment such as commonsense morality (up to 26%), and hallucination steering shifts political views unpredictably across models, ranging from a 21% shift to the right to a 19% shift to the left. These findings show the need to understand steering methods through multiple safety angles rather than a single target behavior.
****
Gaming Consensus: Coordinated Manipulation in Crowdsourced Fact-Checking
Nikil Roashan Selvam, Jay Baxter, Sophie Hilgard, Brad Miller, Keith Coleman, Ellen Vitercik, Sanmi Koyejo
Crowdsourced fact-checking systems have been adopted by major social media companies such as X, Meta, TikTok and Google with the aim of combating misleading information at scale without relying on centralized editorial control. These systems have been developed around a common underlying concept: a *bridging mechanism* that identifies notes flagging misleading information when they receive support from people with different perspectives rather than simple majority support. To our knowledge the only publicly disclosed bridging algorithms deployed for fact-checking are based on matrix factorization, as deployed by both X and Meta, augmented with additional components addressing abuse, targeted manipulation, and contributor brigades. This work examines the core matrix factorization portion of these systems, presenting theoretical and empirical evaluations of the degree to which coordinated users could vote strategically by leveraging the latent representations to fabricate the appearance of *synthetic consensus* within the bridging mechanism. Using historic production data, we find that up to 10.7% of lower quality notes could be manipulated above consensus thresholds using less than 10 ratings. We complement these findings with a theoretical analysis, revealing counterintuitively that rating a note as ``Not Helpful'' can increase its helpfulness score, as well as a cost model quantifying manipulation effort. We have developed and deployed mitigations within X's Community Notes algorithm to address synthetic consensus.
****
KANFIS: A Neuro-Symbolic Framework for Interpretable and Uncertainty-Aware Learning
Binbin Yong, haoran pei, Jun Shen, Haoran Li, Qingguo Zhou, Zhao Su
Adaptive Neuro-Fuzzy Inference System (ANFIS) was designed to combine the learning capabilities of neural network with the reasoning transparency of fuzzy logic. However, conventional ANFIS architectures suffer from structural complexity, where the product-based inference mechanism causes an exponential explosion of ru

les in high-dimensional spaces. We herein propose the \textbf{K}olmogorov-\textbf{A}rnold **N**euro-**F**uzzy **I**nference **S**ystem (KANFIS), a compact neuro-symbolic architecture that unifies fuzzy reasoning with additive function decomposition. KANFIS employs an additive aggregation mechanism, under which both model parameters and rule complexity scale linearly with input dimensionality rather than exponentially. Furthermore, KANFIS is compatible with both Type-1 (T1) and Interval Type-2 (IT2) fuzzy logic systems, enabling explicit modeling of uncertainty and ambiguity in fuzzy representations. By using sparse masking mechanisms, KANFIS generates compact and structured rule sets, resulting in an intrinsically interpretable model with clear rule semantics and transparent inference processes. Empirical results demonstrate that KANFIS achieves competitive performance against representative neural and neuro-fuzzy baselines.

Code2Worlds: Empowering Coding LLMs for 4D World Generation
Yi Zhang, Yunshuang Wang, Zeyu Zhang, Hao Tang
Achieving spatial intelligence requires moving beyond visual plausibility to build world simulators grounded in physical laws. While coding LLMs have advanced static 3D scene generation, extending this paradigm to 4D dynamics remains a critical frontier. This task presents two fundamental challenges: multi-scale context entanglement, where monolithic generation fails to balance local object structures with global environmental layouts; and a semantic-physical execution gap, where open-loop code generation leads to physical hallucinations lacking dynamic fidelity. We introduce Code2Worlds, a framework that formulates 4D generation as language-to-simulation code generation. First, we propose a dual-stream architecture that disentangles retrieval-augmented object generation from hierarchical environmental orchestration. Second, to ensure dynamic fidelity, we establish a physics-aware closed-loop mechanism in which a PostProcess Agent scripts dynamics, coupled with a VLM-Motion Critic that performs self-reflection to iteratively refine simulation code. Evaluations on the Code4D benchmark show Code2Worlds outperforms baselines with a 41% SGS gain and 49% higher Richness, while uniquely generating physics-aware dynamics absent in prior static methods.

Advantage Collapse in Group Relative Policy Optimization: Diagnosis and Mitigation
Xixiang He, Qiyao Sun, Ao Cheng, Xingming Li, Xuanyu Ji, Hailun Lu, Runke Huang, Qingyong Hu
Group Relative Policy Optimization (GRPO), a prominent algorithm within the Reinforcement Learning from Verifiable Rewards (RLVR) framework, has achieved strong results in improving the reasoning capabilities of large language models (LLMs). However, GRPO is prone to advantage collapse, a failure mode where homogeneous rewards within a group (e.g., all correct or all incorrect answers) yield near-zero advantages and vanishing gradients. To address this, we introduce the Advantage Collapse Rate (ACR), the first diagnostic metric quantifying the proportion of training batches with ineffective gradients. Across models from 0.5B to 14B parameters on mathematical reasoning benchmarks, we show that ACR strongly predicts training stagnation and final performance. We then propose Adaptive Virtual Sample Policy Optimization (AVSPO), a lightweight extension of GRPO that injects virtual reward samples, guided by real-time ACR monitoring, to enable learning from homogeneous groups without additional model rollouts. AVSPO reduces advantage collapse by 58–63% relative to GRPO and yields consistent accuracy gains of 4–6 percentage points across all model scales, while maintaining generalization on the evaluated out-of-domain task. Code and datasets are available at https://github.com/hexixiang/Advantage-Collapse-Rate.

Unlocking Zero-Shot Geospatial Reasoning via Indirect Rewards
Chenhui Xu, Fuxun Yu, Michael J. Bianco, Jacob Kovarskiy, Raphael Tang, Qi Zhang, Zirui Xu, Will LeVine, Brandon Dubbs, Heming Liao, Cassandra Burgess, Suvam Bag, Jay Patravali, Rupanjali Kukal, Mikael Figueroa, Rishi Madhok, Nikolaos Karianakis, Jinjun Xiong
Training robust reasoning vision-language models (VLMs) in rare domains (such as

geospatial) is fundamentally constrained by supervision scarcity. While raw geo spatial imagery is abundant, the amount of task-direct supervision falls far beh ind that of common domains. In this work, we validate an important conclusion: i ndirect verifiable rewards, derived from seemingly unrelated metadata, are suffi cient to induce sophisticated and generalizable geospatial reasoning across a wi de range of downstream tasks (25+). We present Geo-R1 as one empirical instantia tion of this paradigm. Rather than relying on limited task-specific annotations (i.e., direct rewards), Geo-R1 utilizes scalable, verifiable indirect proxy rewa rds based on cross-view alignment with metadata (geolocation information) to dri ve reinforcement learning at scale. Such indirect rewards successfully motivate the model to discover and internalize zero-shot geospatial reasoning across dive rse tasks, achieving extraordinary zero-shot transfer on out-of-distribution ben chmarks and even surpassing fully supervised specialists on certain benchmarks. These findings indicate that optimizing for indirect verifiable rewards may prov ide a scalable pathway to unlock generalized reasoning capabilities in rare doma ins with massive unlabeled data archives.
Our code is available at: https://github.com/miniHuiHui/Geo-R1.

The Hidden Link between RLHF and Contrastive Learning
Xufei Lv, Kehai Chen, Haoyuan Sun, Xuefeng Bai, Min Zhang, Houde Liu
Alignment of large language models (LLMs) with human values has recently garnere d significant attention, with prominent examples including the canonical yet cos tly Reinforcement Learning from Human Feedback (RLHF) and the simple Direct Pref erence Optimization (DPO). In this work, we demonstrate that both RLHF and DPO c an be interpreted from the perspective of mutual information (MI) maximization, uncovering a profound connection to contrastive learning. Within this framework, both RLHF and DPO can be interpreted as methods that performing contrastive lea rning based on the positive and negative samples derived from base model, levera ging the Donsker–Varadhan (DV) lower bound on MI (equivalently, the MINE estimat or). Such paradigm further illuminates why RLHF may not intrinsically incentiviz e reasoning capacities in LLMs beyond what is already present in the base model. Building on the perspective, we replace the DV/MINE bound with the Jensen–Shann on (JS) MI estimator and propose the Mutual Information Optimization (MIO). Comp rehensive theoretical analysis and extensive empirical evaluations demonstrate t hat MIO mitigates the late-stage decline in chosen-likelihood observed in DPO, a chieving competitive or superior performance across various challenging reasonin g and mathematical benchmarks

WorldCache: Accelerating World Models for Free via Heterogeneous Token Caching
Weilun Feng, Guoxin Fan, Haotong Qin, Mingqiang Wu, Yuqi Li, Xiangqi Li, Zhulin An, Libo Huang, Dingrui Wang, Longlong Liao, Michele Magno, Yongjun Xu, Chuangua ng Yang
Diffusion-based world models have shown strong potential for unified world simul ation, but the iterative denoising remains too costly for interactive use and lo ng-horizon rollouts. While feature caching can accelerate inference without trai ning, we find that policies designed for single-modal diffusion transfer poorly to world models due to two world-model-specific obstacles: *token heterogeneity* from multi-modal coupling and spatial variation, and *non-uniform temporal dyna mics* where a small set of hard tokens drives error growth, making uniform skipp ing either unstable or overly conservative.
We propose **WorldCache**, a caching framework tailored to diffusion world model s. We introduce *Curvature-guided Heterogeneous Token Prediction*, which uses a physics-grounded curvature score to estimate token predictability and applies a Hermite-guided damped predictor for chaotic tokens with abrupt direction changes . We also design *Chaotic-prioritized Adaptive Skipping*, which accumulates a cu rvature-normalized, dimensionless drift signal and recomputes only when bottlene ck tokens begin to drift. Experiments on diffusion world models show that WorldC ache delivers up to **3.7$\times$** end-to-end speedups while maintaining **98\% ** rollout quality, demonstrating the vast advantages and practicality of WorldC ache in resource-constrained scenarios.

Guaranteed Optimal Compositional Explanations for Neurons
Biagio La Rosa, Leilani H. Gilpin
Compositional explanations are a family of methods that aim to describe the spat ial alignment between neurons' receptive field activations and concepts through logical rules, typically computed via a search over all possible concept combina tions. Since computing the spatial alignment over the entire state space is comp utationally infeasible, the literature commonly adopts assumptions related to th e structure of the combinations and beam search to restrict the state space. How ever, beam search cannot provide any theoretical guarantees of optimality, and i t remains unclear how close current explanations are to the true optimum. In thi s theoretical paper, we address this gap by introducing the first framework for computing guaranteed optimal compositional explanations over the entire state sp ace spanned by the adopted assumptions. Specifically, we propose: (i) a decompos ition that identifies the factors influencing the spatial alignment, (ii) a heur istic to estimate the alignment at any stage of the search, and (iii) the first algorithm that can compute optimal compositional explanations in a time comparab le to exhaustive beam search. Using this framework, we demonstrate that 10-40\% of explanations previously obtained with beam search are suboptimal when overla pping concepts are involved. Finally, we evaluate a beam-search variant guided b y our proposed decomposition and heuristic, showing that it matches or improves runtime over prior methods while offering greater flexibility in hyperparameters and computational resources.

QHyer: Q-conditioned Hybrid Attention-mamba Transformer for Offline Goal-conditi oned RL
Xing Lei, Jincheng Wang, Xuetao Zhang, Donglin Wang
Offline goal-conditioned RL (GCRL) learns goal-reaching policies from static dat asets, but real-world environments are often partially observable, so the collec ted trajectories are only partly consistent with the Markov assumption while oth er segments remain history-dependent. History-aware sequence models such as Deci sion Transformer (DT) are a natural fit for long-term dependency modeling, yet p ure attention is inefficient and brittle when handling local Markovian structure and long-range context simultaneously. Although recent hybrid architectures (e. g., LSDT) introduce local extractors, their fixed-window extraction cannot adapt

the effective memory to varying dependency lengths, often truncating long-range context instead of compressing it. Moreover, under sparse rewards, return-to-go (RTG) becomes non-discriminative across sub-trajectories, offering little guidance for stitching goal-reaching behaviors from diverse demonstrations. To address these limitations, we propose QHyer (Q-conditioned Hybrid Attention-Mamba Transformer), which replaces RTG with a Normalizing Flows (NFs) parameterized goal-reaching Q-estimator used directly as conditioning tokens, and a gated Hybrid Attention-Mamba backbone whose selective state-space dynamics enable content-adaptive history compression while attention captures global goal-directed dependencies. Extensive experiments on OGBench and D4RL demonstrate that QHyer achieves state-of-the-art performance on both non-Markovian and Markovian datasets, validating its effectiveness for diverse scenarios.

Facts in Stats: Impacts of Pretraining Diversity on Language Model Generalization

Tina Behnia, Puneesh Deora, Christos Thrampoulidis

Language models are pretrained on sequences that blend statistical regularities, which make text fluent, with factual associations between specific tokens, which encode knowledge of facts. While recent works suggest that generalization depends critically on the interaction of these two streams, such as the diversity of the contexts in which facts appear, these effects remain difficult to study systematically. This paper introduces a flexible synthetic testbed that combines a statistical stream of generic tokens with an abstract factual stream of source-target token pairs, enabling fine-grained control over their interaction, such as their composition into a sequence (contextual structure) or the level of context diversity carrying the facts at training time. Through controlled experiments, we find that higher contextual diversity delays in-distribution factual learning, while low diversity can harm out-of-distribution generalization in ways that depend on the contextual structure. As a result, the optimal diversity level depends on the training budget. Beyond factual recall failures, we also identify failures in statistical generalization as we study how the interplay between contextual design and diversity level impacts different aspects of generalization. Furthermore, through a series of controlled interventions on the model components, we trace failure in different aspects of generalization to distinct optimization bottlenecks, highlighting the importance of the embedding and unembedding layers. Overall, our synthetic framework allows us to isolate effects that would be confounded in large-scale studies, offering a controlled testbed for future investigations.

Adaptive Residual-Update Steering for Low-Overhead Hallucination Mitigation in Large Vision-Language Models

Zhengtao Zou, Ya Gao, Jiarui Guan, Bin Li, Pekka Marttinen

Large Vision-Language Models (LVLMs) typically process visual inputs as a prefix to the language decoder. As the model autoregressively generates text, this initial visual information inevitably undergoes ``dilution'', leading the model to over-rely on language priors and hallucinate objects. Existing interventions attempt to correct this by contrasting logits or iteratively refining outputs, but they incur prohibitive latency costs. We propose **Residual-Update Directed DEcoding Regulation (RUDDER)**, a framework that counters visual dilution by creating a persistent visual anchor. We extract a robust evidence direction (**CARD**) directly from the model's prefill residual updates, and inject it into the decoding process. This injection is modulated by an adaptive gate, the **Beta Gate**, which acts as a trust mechanism and ensures the visual reminder is applied only when necessary. Experiments on LLaVA-1.5 (7B/13B), Idefics2, InstructBLIP, and Qwen2.5-VL demonstrate that RUDDER consistently mitigates hallucination (with greedy decoding, RUDDER reduces CHAIR$_S$ by an average of **24.4\%** and CHAIR$_i$ by **23.6\%** relative) and scales effectively across architectures, all while maintaining **>96.0\%** throughput. The code is available at https://github.com/Akko000/RUDDER-Residual-Update-Directed-DEcoding-Regulation-

SafeHarbor: Defining Precise Decision Boundaries via Hierarchical Memory-Augmented Guardrail for LLM Agent Safety
Zhe Liu, Zonghao Ying, Wenxin Zhang, Quanchen Zou, Deyue Zhang, Dongdong Yang, Xiangzheng Zhang, Hao Peng
Recent advances in foundation models have transformed LLMs from passive conversational systems into autonomous agents capable of reasoning and tool execution. While these capabilities unlock substantial practical value, they also introduce new security risks, as adversaries can manipulate agents into performing harmful actions in real-world environments.
Existing defense strategies mitigate such threats but frequently struggle to balance safety and utility, resulting in over-refusal of benign user requests.
To mitigate this trade-off, we propose SafeHarbor, a novel framework designed to establish precise decision boundaries for LLM agents.
Unlike static guidelines, SafeHarbor extracts context-aware defense rules through enhanced adversarial generation.
We design a local hierarchical memory system for dynamic rule injection, offering a training-free, efficient, and plug-and-play solution.
Furthermore, we introduce an information entropy-based self-evolution mechanism that continuously optimizes the memory structure through dynamic node splitting and merging.
Extensive experiments demonstrate that SafeHarbor achieves state-of-the-art performance on both ambiguous benign tasks and explicit malicious attacks, notably attaining a peak benign utility of 63.6\% on GPT-4o while maintaining a robust refusal rate exceeding 93\% against harmful requests.
The source code is publicly available at https://github.com/ljj-cyber/SafeHarbor.

Linguistic Nepotism: Trading-off Quality for Language Preference in Multilingual RAG
Dayeon Ki, Marine Carpuat, Paul McNamee, Daniel Khashabi, Eugene Yang, Dawn Lawrie, Kevin Duh
Multilingual Retrieval-Augmented Generation (mRAG) systems enable language models to answer knowledge-intensive queries with citation-supported responses across languages. Despite their growing use, an open questions is whether the mixture of different document languages impacts generation and citation behavior in *unintended* ways. To investigate this, we introduce a controlled methodology using model internals to measure language preference while holding other factors such as document relevance constant. Across eight languages and six open-weight models, we find that models preferentially cite English sources when queries are in English, with this bias amplified for lower-resource languages and for documents positioned mid-context. More crucially, we find that models sometimes trade-off document relevance for language preference, indicating that citation choices are not always driven by informativeness alone. Our findings shed light on how language models leverage multilingual context and influence citation behavior.

Weakly Supervised Cross-Modal Learning for 4D Radar Scene Flow Estimation
Jingyun Fu, Zhiyu Xiang, Na Zhao
Due to the difficulty of obtaining ground-truth data for 4D radar scene flow estimation, previous methods typically rely on either self-supervised losses or cross-modal supervision using 3D LiDAR data, 2D images, and odometry. However, self-supervised approaches often yield suboptimal results due to radar's inherently low-fidelity measurements, while existing cross-modal supervised methods introduce complex multi-task architecture and require costly LiDAR sensors to generate pseudo radar scene flow labels from pretrained 3D tracking models. To overcome these limitations, we propose a task-specific iterative framework for weakly supervised radar scene flow learning, using only images and odometry for auxiliary supervision during training. Specially, we establish two novel instance-aware self-supervised losses by exploiting off-the-shelf 2D tracking and segmentation algorithms to obtain tracked instance masks, which are back-projected into 3D space to provide instance-level semantic guidance; for static regions, we integrate v

ehicle odometry with radar's intrinsic motion cues to construct a rigid static l
oss. Extensive experiments on the real-world View-of-Delft (VoD) dataset demonst
rate that our method not only surpasses state-of-the-art cross-modal supervised
approaches that rely on 3D multi-object tracking on dense LiDAR point clouds but
 also outperforms existing fully supervised scene flow estimation methods. The c
ode is open-sourced at \href{https://github.com/FuJingyun/IterFlow}{https://gith
ub.com/FuJingyun/IterFlow}.

Profiling the Irrational Agent: Cognitive Modeling of LLM Behaviors in Sequentia
l Jailbreaks

Xikang Yang, biyu zhou, Xuehai Tang, Jizhong Han, Songlin Hu

Large language models (LLMs) are increasingly deployed in high-stakes settings,
yet they remain vulnerable to sequential jailbreaks that exploit multi-turn inte
raction to circumvent safety mechanisms. Current safety evaluations are largely
outcome-based, offering little insight into the latent decision processes that l
ead to unsafe compliance. We propose an interpretable cognitive modeling framewo
rk that couples a controlled elicitation paradigm, the Contextual Iowa Gambling
Task (C-IGT), with a Generalized Rescorla--Wagner (GRW) architecture to decompos
e behavior into measurable mechanisms. Across a diverse set of mainstream LLMs,
we find that sequential vulnerability is not explained by scale alone but emerge
s from interactions among cognitive factors, including optimism-biased learning,
 perceptual reward amplification, and choice inertia. Moreover, counterfactual f
eedback and psychologically framed rewards (e.g., regret, authority, threat) sub
stantially accelerate the transition from refusal to compliance. These results y
ield principled cognitive profiles of LLM "irrationality" and provide insights f
or interdisciplinary research on LLM agents at the intersection of machine learn
ing and human behavioral science.

When Distance Distracts: Representation Distance Bias in BT-Loss for Reward Mode
ls

Tong Xie, Andrew Bai, Yuanhao Ban, Yunqi Hong, Haoyu Li, Cho-Jui Hsieh

Reward models are central to Large Language Model (LLM) alignment within the fra
mework of RLHF. The standard objective used in reward modeling is the Bradley-Te
rry (BT) loss, which learns from pairwise data consisting of chosen and rejected
 responses. In this work, we analyze the per-sample gradient of BT-loss and show
 spurious learning signals due to representation distance. In particular, BT gra
dient norm scales with two distinct components: (1) **prediction error**, reflec
ted by the difference in predicted rewards between chosen and rejected responses
, and critically, (2) **representation distance** between the pair measured in t
he output space of the final layer. While the first term captures the intended t
raining signal, the second term can significantly impact the update magnitude an
d misalign learning. Specifically, pairs with small representation distance ofte
n receive vanishingly weak updates, even when misranked, while pairs with large
distance receive disproportionately strong updates. This leads to gradients from
 large-distance pairs overshadowing those from small-distance pairs, where fine-
grained distinctions are especially important. To overcome this limitation, we p
ropose NormBT, an adaptive pair-wise normalization scheme that rescales update t
o balance representation-driven effects and focuses learning signals on predicti
on error. NormBT is a lightweight, drop-in modification to BT loss with negligib
le overhead. Across various LLM backbones and datasets, NormBT improves reward m
odel performance consistently, with notable gains of over 5% on the Reasoning ca
tegory of RewardBench, which contains numerous fine-grained pairs.

On the Theoretical Limitations of Embedding-based Link Prediction

Samy Badreddine, Emile van Krieken, Luciano Serafini

Neural networks often map low-dimensional embeddings to high-dimensional output
spaces. Usually, the output layer is linear, which can create a *rank bottleneck
* that limits the functions a model can represent. Such bottlenecks are ubiquito
us in link prediction models, such as knowledge graph embeddings (KGEs), as the
output space of entities can be orders of magnitude larger than the embedding di

mension. We investigate how rank bottlenecks limit model expressivity for fitti ng the training data. While previous work focused on sufficient bounds on the em bedding dimension required for specific KGEs, we show necessary bounds for *all* KGEs with a linear output layer, which grow with graph size and connectivity. W e also consider a non-linear output layer using mixtures to break the bottleneck without significant parameter overhead. Empirically, we show that models using this non-linear layer improve in ranking performance and probabilistic fit for l arge and dense datasets at a low parameter cost, as predicted by our theory. Our work reveals how linear output layers limit KGEs and motivates non-linear alter natives for scaling to large and dense graphs.

Welfare-Optimal Classification with Accuracy Auctions

Bana Sadi, Eden Saig, Nir Rosenfeld

Prediction algorithms are increasingly used to inform decisions about humans, bu t maximizing accuracy—the standard learning objective—is not necessarily optimal for this purpose. Instead, we propose optimizing social welfare, defined as the average gain users receive from correct predictions. Welfare enables to express , and therefore account for, heterogeneity in how much users benefit from accura cy. But since these valuations are private and users can benefit from overreport ing them, learning must simultaneously elicit truthful values and optimize welfa re with respect to them. To this end, we propose a novel learning algorithm that incorporates a truthful auction. We show how to compute allocations and prices efficiently, and bound the number of paying users—which surprisingly is independ ent of the sample size. We conclude with experiments on real and synthetic data that demonstrate our algorithm and explore the connections between welfare and a ccuracy.

LazyAttention: Efficient Retrieval-Augmented Generation with Deferred Positional Encoding

Haocheng Xia, Mihir Pamnani, Hanxi Fang, Supawit Chockchowwat, Yongjoo Park

Key-value (KV) caching accelerates inference of large language models (LLMs) by reusing past computations for generated tokens. Its importance becomes even grea ter in long-context applications such as retrieval-augmented generation (RAG) an d in-context learning (ICL). However, conventional KV caching embeds positional information directly into the cache, limiting its reusability. Existing solution s either restrict reuse to prefixes or require expensive memory materialization for positional re-encoding. We introduce LazyAttention, a novel attention mechan ism that kernelizes deferred positional encoding to enable zero-copy, position-a gnostic KV reuse. By adjusting positional encoding within attention kernels on-t he-fly, LazyAttention resolves the materialization bottleneck, allowing a single physical KV copy to serve multiple logical requests at arbitrary positions. Lev eraging attention kernels tailored for prefilling and decoding, our system achie ves significant efficiency improvements: under skewed document distributions, it reduces time-to-first-token (TTFT) by 1.37× and increases inference throughput by 1.40× compared to the state-of-the-art Block-Attention, while maintaining com parable output quality.

Online Fair Division with Additional Information

Tzeh Yuan Neoh, Jannik Peters, Nicholas Teh

We study the problem of fairly allocating indivisible goods to agents in an onli ne setting, where goods arrive sequentially and must be allocated irrevocably. F ocusing on the popular fairness notions of envy-freeness, proportionality, and m aximin share fairness (and their approximate variants), we investigate how acces s to future information changes what guarantees are achievable. Without any info rmation, we prove strong impossibility results even for approximate fairness. Wi th normalization information (agents' total values), we provide an algorithm tha t achieves stronger fairness guarantees than previously known results, and show matching impossibilities for stronger notions. With frequency predictions (value multisets without order), we design a meta-algorithm that lifts a broad class o f offline “share-based” guarantees to the online setting, matching the best-know

n offline bounds. Finally, we provide learning-augmented variants of both models : under noisy totals or noisy frequency predictions, our guarantees are robust a nd degrade gracefully with the error parameters.

Detecting and Filtering Unsafe Training Data via Data Attribution with Denoised Representation

Yijun Pan, Taiwei Shi, Jieyu Zhao, Jiaqi W. Ma

Large language models (LLMs) are highly sensitive to even small amounts of unsaf e training data, making effective detection and filtering essential for trustwor thy model development. Current state-of-the-art (SOTA) detection approaches prim arily rely on moderation classifiers, which require significant computation over head for training and are limited to predefined taxonomies. In this work, we exp lore data attribution approaches that measure the similarity between individual training samples and a small set of unsafe target examples, based on data repres entations such as hidden states or gradients. We identify a key limitation in ex isting methods: unsafe target texts contain both critical tokens that make them unsafe and neutral tokens (e.g., stop words or benign facts) that are necessary to form fluent language, and the latter of which makes the overall representatio ns noisy for the purpose of detecting unsafe training data. To address this chal lenge, we propose Denoised Representation Attribution (DRA), a novel representat ion-based data attribution approach that denoises training and target representa tions for unsafe data detection. Across tasks of filtering jailbreaks and detect ing gender bias, the proposed approach leads to significant improvement for data attribution methods, outperforming SOTA methods that are mostly based on modera tion classifiers.

Triadic Dynamics Aware Diffusion Posterior Sampling for Inverse Problems: Optimi zing Guidance and Stochasticity Schedules

Junseo Bang, Dong Ju Mun, Hoigi Seo, Seongmin Hong, Se Young Chun

Generative posterior sampling using diffusion models has emerged as a dominant p aradigm for solving inverse problems in imaging, which usually consists of three main components: data consistency (DC) guidance, classifier-free guidance (CFG) and stochasticity. While prior arts have focused on how to develop each or all components, less attention has given to how to schedule them, leading to heurist ically fixed or partially adjusted suboptimal schedules. In this work, we argue that the interactions among all three components in terms of scheduling are cruc ial for significantly improved performance in solving inverse problems in imagin g. Our analysis shows that aggressive CFG early in sampling conflict with DC gui dance, while stochasticity brings the trajectory back to higher-probability regi ons. Based on these findings, we propose Triadic Dynamics Aware Posterior Sampli ng (TriPS), which reformulates posterior sampling as a time-varying control prob lem and optimizes schedules following a triadic trend of decreasing DC and stoch asticity scales alongside increasing CFG scale. TriPS achieves this through two strategies: template-based search over functional priors for reliable baseline s chedules, and Group Relative Policy Optimization (GRPO)-based reinforcement lear ning for more flexible temporal curves. Experiments demonstrate TriPS outperform s state-of-the-art baselines in data fidelity and perceptual realism.

Semantic Tube Prediction: Beating LLM Data Efficiency with JEPA

Hai Huang, Yann LeCun, Randall Balestriero

Large Language Models (LLMs) obey consistent scaling laws---empirical power-law fits that predict how loss decreases with compute, data, and parameters. While p redictive, these laws are descriptive rather than prescriptive: they characteriz e typical training, not optimal training. Surprisingly few works have successful ly challenged the data-efficiency bounds implied by these laws---which is our pr imary focus. To that end, we introduce the Geodesic Hypothesis, positing that to ken sequences trace geodesics on a smooth semantic manifold and are therefore lo cally linear. Building on this principle, we propose a novel Semantic Tube Predi ction (STP) task, a JEPA-style regularizer that confines hidden-state trajectori es to a tubular neighborhood of the geodesic. STP generalizes JEPA to language w

ithout requiring explicit multi-view augmentations. We show this constraint impr
oves signal-to-noise ratio, and consequently preserves diversity by preventing t
rajectory collisions during inference. Empirically, STP allows LLMs to match bas
eline accuracy with 16$\times$ less training data, directly violating the data t
erm of fine-tuning scaling laws and demonstrating that principled geometric prio
rs can surpass brute-force scaling. Code: \url{https://github.com/galilai-group/
llm-jepa#stp}

OnePO: Direct One-stage Policy Optimization for SFT-free Domain Adaptation
Junying Chen, Xinyuan Xie, Ziniu Li, Benyou Wang
Domain adaptation typically follows a two-stage pipeline: Supervised Fine-Tuning
 (SFT) then Reinforcement Learning (RL). However, *does RL necessarily require a
 pre-SFT phase for domain adaptation?* SFT confines the model to an imitation di
stribution, limiting RL exploration, while the two-stage transition causes capab
ility regression and extra engineering. We propose **One-stage Policy Optimizati
on (OnePO)**, an SFT-free paradigm that adapts pretrained LLMs to target domains
 in a single RL stage. OnePO uses teacher outputs as transient guidance to overc
ome the slow convergence of pure RL, while avoiding two failures of naive teache
r-output integration: gradient starvation for low-probability teacher tokens and
 distribution anchoring from persistent teacher signals. It introduces two mecha
nisms: (1) *Adaptive Objective Evolution*, reshaping the RL objective for rapid
absorption of teacher-provided knowledge; and (2) *Teacher Retirement*, automati
cally discarding teacher outputs once the model surpasses them. On medical adapt
ation, OnePO achieves 67.2 on HealthBench with only 20K training samples, outper
forming SFT+RL by +2.7 and pure RL by +7.4 points. Scaling the same recipe produ
ces *HuatuoGPT-3*, an open-source medical LLM series whose 32B variant reaches 7
0.3 on HealthBench. Additional writing and legal-domain experiments show that On
ePO extends beyond medicine. Models and code are available at https://github.com
/FreedomIntelligence/HuatuoGPT-3.

Protein Design with Agent Rosetta: A Case Study for Specialized Scientific Agent
s
Jacopo Teneggi, SM Bargeen Alam Turzo, Tanya Marwah, Alberto Bietti, P. Douglas
Renfrew, Vikram Khipple Mulligan, Siavash Golkar
Large language models (LLMs) are capable of emulating reasoning and using tools,
 creating opportunities for autonomous agents that execute complex scientific ta
sks. Protein design provides a natural testbed: although machine learning (ML) m
ethods achieve strong results, these are largely restricted to canonical amino a
cids and narrow objectives, leaving unfilled need for a generalist tool for broa
d design pipelines. We introduce Agent Rosetta, an LLM agent paired with a struc
tured environment for operating Rosetta, the leading physics-based heteropolymer
 design software, capable of modeling non-canonical building blocks and geometri
es. Agent Rosetta iteratively refines designs to achieve user-defined objectives
, combining LLM reasoning with Rosetta's generality. We evaluate Agent Rosetta o
n design with canonical amino acids, matching specialized models and expert base
lines, and with non-canonical residues---where ML approaches fail---achieving co
mparable performance. Critically, prompt engineering alone often fails to genera
te Rosetta actions, demonstrating that environment design is essential for integ
rating LLM agents with specialized software. Our results show that properly desi
gned environments enable LLM agents to make scientific software accessible while
 matching specialized tools and human experts.

Multi-Head LatentMoE and Head Parallel: Communication-Efficient and Deterministi
c MoE Parallelism
Chenwei Cui, Rockwell Jackson, Benjamin Joseph Herrera, Ana M. Tárano, Hannah Ke
rner
Large language models have transformed many applications but remain expensive to
 train.
Sparse Mixture of Experts (MoE) addresses this through conditional computation,
with Expert Parallel (EP) as the standard distributed training method.

However, EP has three limitations:
communication cost grows linearly with the number of activated experts k,
load imbalance affects latency and memory usage, and
data-dependent communication requires metadata exchange.
We propose Multi-Head LatentMoE and Head Parallel (HP), a new architecture and p
arallelism that achieve
$O(1)$ communication cost regardless of k,
completely balanced traffic, and
deterministic communication,
all while remaining compatible with EP.
To accelerate Multi-Head LatentMoE,
we propose IO-aware routing and expert computation.
Compared to MoE with EP, Multi-Head LatentMoE with HP trains up to $1.82\times$
faster while having better performance.
With double the granularity, the performance is even better while being $1.08\ti
mes$ faster.
Our method makes multi-billion-parameter foundation model research more accessib
le.
****
Efficient Bilevel Optimization for CKA-Guided MoE Upcycling
Zhiyuan Yu, Enneng Yang, Hao Jiang, Guojie Zhu, Feihong He, Peng Wang, Li Shen
Upcycling, a strategy that initializes Mixture-of-Experts (MoE) by replicating p
re-trained feed-forward or MoE networks to expand model capacity, has become a p
opular method in continual learning due to its effectiveness in mitigating catas
trophic forgetting.
However, existing paradigms indiscriminately expand capacity to prioritize perfo
rmance at the cost of severe inefficiency, introducing severe parameter redundan
cy and failing to exploit structural heterogeneity.
To address this, we investigate the determinants of forgetting in training dynam
ics using Centered Kernel Alignment (CKA) and loss landscape flatness to analyze
 the behavior of pre- and post-expansion MoE layers, uncovering instability in d
eep-layer representations and heterogeneous expert sensitivity to new tasks, the
reby demonstrating the potential of selective upcycling to eliminate redundancy.
Consequently, we propose a dynamic bilevel optimization framework to guide adapt
ive upcycling, featuring an outer loop employing a Gumbel-Softmax differentiable
 mask to perform Neural Architecture Search (NAS) for adaptive growth, while an
inner loop optimizes weight updates via task objectives and CKA-regularized repl
ay.
Experiments on the TRACE benchmark demonstrate that our proposed method achieves
 better average accuracy with 80\% forgetting reduction, while effectively elimi
nating 60\% of redundant parameter expansion that standard upcycling would intro
duce.

A Stronger Benchmark for Online Bilateral Trade: From Fixed Prices to Distributi
ons
Anna Lunghi, Mattia Piccinato, Matteo Castiglioni, Alberto Marchesi
We study online bilateral trade, where a learner facilitates repeated exchanges
between a buyer and a seller to maximize the Gain From Trade (GFT), i.e., the so
cial welfare. In doing so, the learner must guarantee not to subsidize the marke
t. This constraint is usually imposed per round through Weak Budget Balance (WBB
). Despite that, (Bernasconi et al.,2024) shows that a Global Budget Balance (GB
B) constraint on the profit--enforced over the entire time horizon--can improve
the GFT by a multiplicative factor of two. While this might appear to be a margi
nal relaxation, this implies that all existing WBB-focused algorithms suffer lin
ear regret when measured against the GBB optimum.
In this work, we provide the first algorithm to achieve sublinear regret against
 the GBB benchmark in stochastic environments under one-bit feedback. In particu
lar, we show that when the joint distribution of valuations has a bounded densit
y, our algorithm achieves $\widetilde{\mathcal{O}}(T^{3/4})$ regret. Our result
shows that there is no separation between the one-dimensional problem of learnin

g the optimal WBB price and the two-dimensional problem of learning the optimal GBB distribution over *couples* of prices.

RC-FCL: Combating Asynchronous Concept Drift in Federated Continual Learning via Retrospective Calibration

Hang Su, Yijun Mo, Zhiyu Zhang, Yankai Jiang, Bo Liu, Yichen Li, Imran Razzak

Federated Continual Learning (FCL) enables the continuous acquisition of knowledge from streaming tasks, but inherently struggles with the temporal dynamics of client data distributions. These dynamics naturally induce asynchronous concept drift, where distribution shifts occur independently across clients at unsynchronized times and with varying magnitudes. Such asynchrony generates conflicting updates that destabilize global convergence and exacerbate catastrophic forgetting. However, existing FCL research focuses on static or incremental settings, typically treating all incoming updates uniformly, which obscures concept drift under divergent distributions and fails to adapt to the evolution of learned concepts. To address these limitations, we propose RC-FCL, a retrospective calibration framework for FCL that can effectively distinguish asynchronous concept drift and adjust the learning strategy adaptively. Specifically, RC-FCL leverages a conditional generative model to synthesize class-conditional reference distributions of previously learned concepts for local drift detection. It calibrates local adaptation using a weighting mechanism driven by the local discriminator to prioritize informative samples, and executes a global aggregation strategy based on drift magnitude. Our experimental results demonstrate that RC-FCL achieves competitive performance against state-of-the-art methods.

TN-SHAP-G: Graph-Structured Tensor Network Surrogates for Shapley Values and Interactions

Farzaneh Heidari, Guillaume Rabusseau

Shapley values are a widely used tool for attributing importance and interactions among input variables in black-box models, but their computation involves a function defined over an exponentially large space of subsets. We propose TN-SHAP-G, a framework that exploits structure in graph-structured inputs to compute Shapley values and higher-order interaction indices efficiently. Given a predictor and a fixed masking scheme, TN-SHAP-G learns a compact, graph-aligned multilinear surrogate that approximates the masked-input behavior, represented as a tensor network whose topology mirrors the input graph. Once trained from a small number of oracle queries, the surrogate enables deterministic recovery of first- and higher-order Shapley indices via the multilinear extension, without additional model queries or Monte Carlo variance. Experiments on molecular benchmarks show that the learned factorization closely matches exact Shapley values on small graphs and scales efficiently to larger graphs where sampling-based methods become infeasible.
****

Skill-Based Mixture-of-Experts: Adaptive Routing for Heterogeneous Reasoning via Inferred Skills

Justin Chen, Sukwon Yun, Elias Stengel-Eskin, Tianlong Chen, Mohit Bansal

Combining existing pre-trained LLMs is a promising approach for diverse reasoning tasks. However, task-level expert selection is often too coarse-grained, since different instances may require different expertise. To address this, we propose Skill-MoE, a symbolic, skill-based, and gradient-free Mixture-of-Experts framework for instance-level expert selection. Skill-MoE infers skills (e.g., algebra in mathematics) from each query, selects experts based on skill relevance, and lets each expert generate its own reasoning. The resulting k outputs are then synthesized by an aggregator chosen for its ability to integrate diverse responses. While instance-level selection substantially improves performance, naively implementing it incurs heavy overhead from repeated model loading and offloading. We address this with a batch inference strategy that groups instances by assigned experts, allowing each model to be loaded only once. As a result, Skill-MoE integrates 16 expert models on a single GPU with runtime comparable to prior multi-agent baselines using 4 GPUs. Across diverse benchmarks (MMLU-Pro, GPQA, AIME, a

nd MedMCQA), Skill-MoE achieves an average absolute improvement of 8.15% over th e best baseline. It also generalizes well to unseen tasks and outperforms discus sion-based methods without requiring expensive multi-round interactions.
****
Extra-Merge: Tracing the Rank-1 Subspace of Model Merging in Language Model Pre-Training
WenJie Zhou, Bohan Wang, Hongtao Zhang, Chenxi Jia, Wei Chen, Xueqi Cheng
Model merging has emerged as a lightweight paradigm for enhancing Large Language Models (LLMs), yet its underlying mechanisms remain poorly understood. In this work, we analyze late-stage pre-training trajectories and uncover a \textbf{Ran k-1 Subspace} phenomenon: while raw optimization steps oscillate violently, cons ecutive \emph{merged} checkpoints collapse onto a stable, approximately one-dime nsional linear manifold. We theoretically ground this observation in a \emph{riv er-valley} landscape analysis: averaging acts as a geometric low-pass filter tha t dampens high-curvature noise to reveal the optimal descent direction. Capitali zing on this insight, we propose \textbf{Extra-Merge}, a training-free strategy that extrapolates along this subspace to minimize loss without additional gradie nt updates. Extensive experiments across GPT-2 and LLaMA families (124M to 2B) d emonstrate that Extra-Merge consistently outperforms standard merging baselines. Notably, it yields consistent zero-shot accuracy gains on Pythia-12B downstream tasks and generalizes effectively to the Muon optimizer (Jordan et al., 2024).
****
Diffusion Differentiable Resampling
Jennifer R. Andersson, Zheng Zhao
This paper is concerned with differentiable resampling in the context of sequent ial Monte Carlo (e.g., particle filtering). Drawing on reparametrisation, we pro pose a new resampling method that is informative and instantly differentiable, b ased on a training-free diffusion model surrogate. We theoretically prove that o ur diffusion resampling method provides a consistent resampling distribution, an d we show empirically that it outperforms the state-of-the-art differentiable re sampling methods on multiple filtering and parameter estimation benchmarks. Fina lly, we show that it achieves competitive end-to-end performance when used in le arning a complex dynamics-decoder model with high-dimensional image observations .
****
Iterative Robust Satisficing: Minimizing Performance Degradation Under Distribut ion Shift
Enes A■■rman, Artun Saday, Cem Tekin
Modern neural networks often achieve high accuracy on their training distributio n but degrade sharply under distribution shifts.
We address this problem through *Robust Satisficing* (RS), an optimization objec tive that seeks parameters which attain a target level of in-distribution perfor mance while minimizing *fragility*, defined as the rate at which performance det eriorates as the data distribution departs from training.
We develop a gradient-based algorithm, *Iterative Robust Satisficing* (IRS), tha t directly optimizes this criterion.
Across a range of synthetic and real-world distribution shifts, including long-t ailed image classification, group shifts induced by spurious correlations, and n atural shifts in tabular regression, IRS consistently improves performance on mi nority and worst-case groups without sacrificing overall accuracy.
Notably, IRS achieves these robustness gains with a per-step computational cost similar to standard stochastic gradient descent and requires only a single forwa rd and backward pass per update.
Together, these results suggest that minimizing fragility provides a practical a nd effective alternative to existing robust training methods for learning models that remain reliable under distribution shift.
****
All ERMs Can Fail in Stochastic Convex Optimization Lower Bounds in Linear Dimen sion
Tal Burla, Roi Livni

We study the sample complexity of the *best-case* Empirical Risk Minimizer in th e setting of stochastic convex optimization. We show that there exists an instan ce in which the sample size is linear in the dimension, learning is possible, bu t the Empirical Risk Minimizer is likely to be *unique* and to *overfit*. This r esolves an open question by Feldman. We also extend this to approximate ERMs.

Building on our construction we also show that (constrained) Gradient Descent po tentially overfits when horizon and learning rate grow w.r.t sample size. Specif ically we provide a novel generalization lower bound of $\Omega\left(\sqrt{\eta T/m^{1.5}}\right)$ for Gradient Descent, where η is the learning rate, T is the horizon and m is the sample size. This narrows down, exponentially, the gap between the best known upper bound of $O(\eta T/m)$ and existing lower boun ds from previous constructions.
****
HEDP: A Hybrid Energy-Distance Prompt-based Framework for Domain Incremental Lea rning
Yu Feng, Zhen Tian, Haoran Luo, Xie Yu, Diancheng Cheng, Haoyue Zheng, Shuai Lyu , Ping Zong, Lianyuan Li, xin ge, Yifan Zhu
Domain Incremental Learning is a critical scenario that requires models to conti nuously adapt to new data domains without retraining.
However, domain shifts often cause severe performance degradation. To address th is, we propose Hybrid Energy-Distance Prompt, a domain-incremental framework ins pired by Helmholtz free energy. HEDP introduces an energy regularization loss to enhance the separability of domain representations and a hybrid energy-distance weighted mechanism that fuses energy-based and distance-based cues to improve d omain selection and generalization. Experiments on multiple benchmarks, includin g CORe50, show that HEDP achieves superior performance on unseen domains with a 2.57\% accuracy gain, effectively mitigating catastrophic forgetting and enhanci ng open-world adaptability. Our code is available at \url{https://github.com/dan nis97500/HEDP}.

From LLM-Generated Conjectures to Lean Formalizations: Automated Polynomial Ineq uality Proving via Sum-of-Squares Certificates
Ruobing Zuo, Hanrui Zhao, Gaolei He, Zhengfeng Yang, Jianlin Wang
Automated proving of polynomial inequalities is a fundamental challenge in autom ated mathematical reasoning, where rich algebraic structure and a rapidly growin g certificate search space hinder scalability. Purely symbolic approaches provid e strong guarantees but often scale poorly as the number of variables or the deg ree increases, due to expensive algebraic manipulations and rapidly growing inte rmediate expressions. In parallel, LLM-guided methods have made notable progress , particularly on competition-style inequalities with a small number of variable s. To address the remaining scalability challenges, we propose NSPI, a neuro-sy mbolic framework that combines the complementary strengths of LLMs and symbolic computation for polynomial-inequality proving. Concretely, an LLM proposes a con jecture in the form of an approximate polynomial Sum-Of-Squares (SOS) decomposit ion; we refine it via symbolic computation to obtain an exact polynomial SOS re presentation, which directly proves the target inequality, and we further certif y the proof in Lean, yielding an end-to-end pipeline from heuristic discovery to machine-checked proof. Experiments on challenging benchmarks involving polynomi als with up to 10 variables demonstrate the effectiveness and scalability of the proposed method.
****
Scaling Laws for Precision in High-Dimensional Linear Regression
Dechen Zhang, Xuan Tang, Yingyu Liang, Difan Zou
Low-precision training is critical for optimizing the trade-off between model qu ality and training costs, necessitating the joint allocation of model size, data set size, and numerical precision. While empirical scaling laws suggest that qua ntization impacts effective model and data capacities or acts as an additive err or, the theoretical mechanisms governing these effects remain largely unexplored . In this work, we initiate a theoretical study of scaling laws for low-precisio

n training within a high-dimensional sketched linear regression framework. By an alyzing multiplicative (signal-dependent) and additive (signal-independent) quan tization, we identify a critical dichotomy in their scaling behaviors. Our analy sis reveals that in the worst case, while both schemes introduce an additive err or and degrade the effective data size, they exhibit distinct effects on effecti ve model size: multiplicative quantization maintains the full-precision model si ze, whereas additive quantization reduces the effective model size. Numerical ex periments validate our theoretical findings. By rigorously characterizing the co mplex interplay among model scale, dataset size, and quantization error, our wor k provides a principled theoretical basis for optimizing training protocols unde r practical hardware constraints.
****
R^{3}L: Reasoning 3D Layouts from Relative Spatial Relations
Zhifeng Gu, Yuqi Wang, Bing WANG
Relative spatial relations provide a compact representation of spatial structure and are fundamental to relative spatial reasoning in 3D layout generation.
Recent works leverage Multimodal Large Language Models (MLLMs) to infer such rel ations, but the inferred relations are often unreliable and are typically handle d with post-hoc heuristics.
In this paper, we propose R^{3}L, a general framework that improves the reliabil ity and consistency of relative spatial reasoning for 3D layout generation.
Our key motivation is that multi-hop reasoning requires repeated reference-frame transformations, which accumulate errors in inferred relations and lead to sema ntic and metric drift.
To mitigate this, we propose invariant spatial decomposition to break coupled re lation chains, and consistent spatial imagination to promote self-consistency th rough an imagine-and-revise loop.
We further introduce supportive spatial optimization to ease pose optimization v ia global-to-local coordinate re-parameterization.
Extensive experiments across diverse scene types and instructions demonstrate th at R^{3}L produces more physically feasible and semantically consistent layouts.

Notably, our analysis shows that resolving frame-induced inconsistencies is cruc ial for reliable multi-hop relative spatial reasoning.
The code is available at https://github.com/Neal2020GitHub/R3L.

Adaptive Physics Transformer with Fused Global-Local Attention for Subsurface En ergy Systems
Xin Ju, Hadrian Fung, Yuyan Zhang, Carl Jacquemyn, Matthew D Jackson, Randolph R . Settgast, Sally M Benson, Gege Wen
The Earth's subsurface is a cornerstone of modern society, providing essential e nergy resources like hydrocarbons, geothermal, and minerals while serving as the primary reservoir for CO_2 sequestration. However, full physics numerical sim ulations of these systems are notoriously computationally expensive due to geolo gical heterogeneity, high resolution requirements, and the tight coupling of phy sical processes with distinct propagation time scales. Here we propose the $\tex tbf{Adaptive Physics Transformer}$ (APT), a geometry-, mesh-, and physics-agnost ic neural operator that explicitly addresses these challenges. APT fuses a graph -based encoder to extract high-resolution local heterogeneous features with a gl obal attention mechanism to resolve long-range physical impacts. Our results dem onstrate that APT outperforms state-of-the-art architectures in subsurface tasks across both regular and irregular grids with robust super-resolution capabiliti es. Notably, APT is the first architecture that learns directly from HR-adaptive mesh refinement simulations. We also demonstrate APT's favorable scaling behavi or and cross-dataset learning capability, positioning it as a robust and scalabl e backbone for large-scale subsurface foundation model development.
****
PINE: Pruning Boosted Tree Ensembles with Conformal In-Distribution Prediction E quivalence
Haruki Yajima, Yusuke Matsui

Tree ensembles are machine learning models with strong predictive performance and interpretability, and remain widely used for tabular data.
Standard pruning methods for tree ensembles typically optimize an accuracy-compression trade-off and may change a subset of predictions, potentially compromising decision consistency.
Faithful pruning methods address this issue by preserving prediction equivalence over the entire input space, but this requirement leads to lower compression ratios.
We propose **PINE**, a pruning method that provides strong guarantees within an in-distribution region.
PINE preserves prediction equivalence within this region and controls the region size using a single parameter α via conformal calibration.
Experiments on 12 public tabular datasets show that PINE improves the compression ratio by up to 30% while preserving predictions at a comparable level to existing faithful pruning methods.

Stein Diffusion Guidance: Training-Free Posterior Correction for Sampling Beyond High-Density Regions
Van Khoa Nguyen, Lionel Blondé, Alexandros Kalousis
Training-free diffusion guidance offers a flexible framework for leveraging off-the-shelf classifiers without additional training. Yet, current approaches hinge on posterior approximations via Tweedie’s formula, which often yield unreliable guidance, particularly in low-density regions. Stochastic optimal control (SOC), in contrast, enables principled posterior sampling but remains computationally prohibitive for efficient inference. In this work, we reconcile the strengths of these paradigms by introducing Stein Diffusion Guidance (SDG), a novel training-free framework grounded in a surrogate SOC objective. We establish a new theoretical bound on the SOC value function, revealing the necessity of correcting approximate posteriors to reflect true diffusion dynamics. Building on Stein variational inference, SDG computes the steepest descent direction that minimizes the Kullback-Leibler divergence between approximate and true posteriors. By integrating a principled Stein correction mechanism along with a novel running cost functional, SDG enables effective guidance in low-density regions. Our experiments on diverse image-guidance tasks and on challenging small-ligand sampling for protein docking suggest that SDG consistently outperforms standard training-free guidance methods and highlights its potential for broader posterior sampling problems beyond high-density regimes.

Rate or Fate? RLV$^{\varepsilon}$R: Reinforcement Learning with Verifiable Noisy Rewards
Ali Rad, Khashayar Filom, Darioush Keivan, Peyman Mohajerin Esfahani, Ehsan Kamalinejad
Reinforcement learning with verifiable rewards (RLVR) trains a policy by verifying sampled completions and reinforcing higher-scoring outputs, but practical verifiers (e.g., incomplete unit tests or noisy judges) are prone to false positives and false negatives.
We ask when such noise merely slows learning and when it reverses it.
Modeling GRPO-style RLVR as a bandit over recurring \emph{reasoning modes}, we derive mean-field replicator-style (natural-selection) flow on the probability simplex. The dynamics decouples into within-correct-mode competition and a one-dimensional evolution for the mass on incorrect modes, whose drift is determined solely by Youden's index $J=\mathrm{TPR}-\mathrm{FPR}$. This yields a sharp phase transition: when $J>0$, the incorrect mass is driven toward extinction (learning); when $J=0$, the process is neutral; and when $J<0$, incorrect modes amplify until they dominate (anti-learning and collapse). In the learning regime $J>0$, noise primarily rescales convergence time (``rate, not fate''). Experiments on verifiable programming tasks under synthetic noise reproduce the predicted $J=0$ boundary. Beyond noise, the framework offers a general lens for analyzing RLVR stability, convergence, and algorithmic interventions.

Language Model Networks: Supervision-Efficient Learning through Dense Communication
Shiguang Wu, Yaqing Wang, Quanming Yao
Language models are increasingly used not only as standalone predictors but also as components in larger inference systems, from test-time scaling to multi-agent collaboration. We study *language model networks*, where pre-trained language models serve as reusable nodes and intelligence emerges from their topology, communication, and optimization. Existing systems mostly communicate through natural language: easy to deploy, but discrete, inefficient, and hard to optimize from end-task supervision. We propose LMNet, a dense and differentiable realization of this paradigm. LMNet uses stripped LLMs as vertex modules and trainable seq2seq modules as communication edges, enabling intermediate nodes to exchange dense vectors while preserving natural-language input and output at the system boundary. By bypassing intermediate embedding and de-embedding, LMNet enables efficient information transfer, end-to-end gradient optimization, and learned communication beyond hand-designed protocols. Experiments show performance with small additional training cost and effective adaptation under limited supervision.

Trajectory-Level Data Augmentation for Offline Reinforcement Learning
Tobias Schmähling, Matthias Burkhardt, Tobias Windisch
We propose a data augmentation method for offline reinforcement learning, motivated by active positioning problems.
Particularly, our approach enables the training of off-policy models from a limited number of
suboptimal trajectories. We introduce a trajectory-based augmentation technique that exploits task structure and the
geometric relationship between rewards, value functions, and mathematical properties of logging policies. During data
collection, our augmentation supports suboptimal logging policies, leading to higher data quality
and improved offline reinforcement learning performance.
We provide theoretical justification for these strategies and validate them empirically across positioning tasks of varying dimensionality and under partial observability.

LoRA-DA: Data-Aware Initialization for Low-Rank Adaptation via Asymptotic Analysis
Qingyue Zhang, Chang Chu, Tianren Peng, Qi Li, Xiangyang Luo, Zhihao Jiang, Shao-Lun Huang
LoRA has become a widely adopted method for PEFT, and its initialization methods have attracted increasing attention.
However, existing methods have notable limitations: many methods do not incorporate target-domain data, while gradient-based methods exploit data only at a shallow level by relying on one-step gradient decomposition. In this paper, we establish a theoretical framework for data-aware LoRA initialization. Starting from minimizing the expectation of the parameter discrepancy between the fine-tuned and target models, we derive an optimization problem with two components: a bias term, which is related to the parameter distance between the fine-tuned and target models, and is approximated using a Fisher–gradient formulation to preserve anisotropy; and a variance term, which accounts for the uncertainty introduced by sampling stochasticity through the Fisher information. Solving this problem yields an optimal initialization strategy for LoRA, based on which we develop an efficient algorithm, LoRA-DA. Empirical results across multiple benchmarks demonstrate that LoRA-DA consistently improves final accuracy over existing initialization methods. Additional studies show faster, more stable convergence, robustness across ranks, and only a small initialization overhead for LoRA-DA. The source code is available at https://github.com/zqy0126/LoRA-DA.

VideoTrace-R1: Long Video-based Retrieval-Augmented Generation via Reinforcement Learning

Zongsheng Cao, Anran Liu, Jun Xie, Feng Chen, Lang Chen, Jing Li, Zhepeng Wang, Zigan Wang

Long-video temporal reasoning remains a bottleneck for Large Video Language Models (LVLMs). Existing reinforcement-learning approaches reward only final-answer correctness, so they cannot distinguish answers reached through grounded reasoning from those reached through fabricated chronology; the intermediate temporal claims that constitute the reasoning are never verified. We trace this gap to a structural correspondence between two kinds of traces: a video has its own temporal trace, an ordered sequence of how events unfold, while a model's answer is built up through a reasoning trace, an ordered sequence of intermediate temporal claims. Correct reasoning requires the latter to mirror the former, claim by claim. We act on this correspondence with two contributions. We introduce Temporal Reasoning Traces (TRT), a structured index of a video's ordered event chains that exposes a small set of deterministic verification primitives, materializing the temporal trace as a programmatically queryable object. We then propose temporal-enhanced GRPO, a reinforcement-learning procedure whose reward decomposes into per-block components, each computed by a TRT primitive on a typed think block of the reasoning trace. Because the reward is fully symbolic, fabricated temporal claims are caught at the per-claim level rather than masked by a correct final answer. Across long-video reasoning benchmarks, our model achieves state-of-the-art performance, with the largest gains on out-of-domain reasoning tasks such as Video-Holmes, CG-Bench-Reasoning, and VRBench.

Letting Trajectories Spread: Quality-Preserving Control for Diverse Flow Matching

Jingxuan Wu, Zhenglin Wan, Xingrui Yu, Yuzhe YANG, Bo An, Ivor Tsang, Yang You

Flow-based text-to-image models follow deterministic trajectories, making it costly to explore diverse modes under limited sampling budgets. Existing approaches to improving diversity often rely on retraining or degrade image fidelity. To address this limitation, we present a training-free, inference-time control mechanism that makes the flow itself diversity-aware. Our core insight is to encourage diversity through guidance that is geometrically decoupled from the model’s quality-seeking direction. Our method simultaneously encourages lateral spread among trajectories via a feature-space objective and reintroduces uncertainty through a time-scheduled stochastic perturbation. Crucially, this perturbation is projected to be orthogonal to the generation flow, a geometric constraint that allows it to boost variation without degrading image details or prompt fidelity. Theoretically, we show that this design monotonically increases a volume surrogate while approximately preserving the marginal distribution, providing a principled explanation for the robustness of generation quality. Empirically, across multiple text-to-image settings under fixed sampling budgets, our method consistently improves diversity metrics such as the Vendi Score and Brisque over strong baselines, while upholding image quality and alignment.

Dynamic Optimizations of LLM Ensembles with Two-Stage Reinforcement Learning Agents

Selim Furkan Tekin, Gaowen Liu, Ramana Rao Kompella, Ling Liu

The advancement of LLMs and their accessibility have triggered renewed interest in multi-agent reinforcement learning as robust and adaptive frameworks for dynamically changing environments. This paper introduces RL-Focal, a two-stage RL agent framework that routes and ensembles LLMs. First, we develop the Decider RL-agent, which learns to dynamically select an ensemble of small size (m_i) among N LLMs ($m_i \ll N$) for incoming queries from a user-defined downstream task i, by maximizing both error-diversity and reasoning-performance of the selected ensemble through iterative updates of task-adaptive rewards and policy. Second, to enable effective fusion of dynamically selected LLMs, we develop the stage-2 Fusion RL-agent, which learns to resolve reasoning conflicts from different LLMs and dynamically adapt to different ensemble teams composed by the Decider Agent for different downstream tasks. {\em Third}, we introduce the focal diversity metric to better model the error correlations among multiple LLMs further impr

oving the generalization performance of the Decider Agent, which actively prunes the ensemble combinations. By focal diversity, we enhance performance across tasks by effectively promoting reward-aware and policy-adaptive ensemble selection and inference fusion. Extensive evaluations on five benchmarks show that RL-Focal achieves the performance improvement of 8.48\% with an ensemble of small size compared to the best individual LLM in a pool and offers stronger robustness. Code is available at \url{https://anonymous.4open.science/r/rl-focal-8DCF/}

Characterizing the Predictive Impact of Modalities with Supervised Latent-Variable Modeling
Divyam Madaan, Sumit Chopra, Kyunghyun Cho
Despite the recent success of Multimodal Large Language Models (MLLMs), existing approaches predominantly assume the availability of multiple modalities during training and inference. In practice, multimodal data is often incomplete because modalities may be missing, collected asynchronously, or available only for a subset of examples. In this work, we propose PRIMO, a supervised latent-variable imputation model that quantifies the predictive impact of any missing modality within the multimodal learning setting. PRIMO enables the use of all available training examples, whether modalities are complete or partial. Specifically, it models the missing modality through a latent variable that captures its relationship with the observed modality in the context of prediction. During inference, we draw many samples from the learned distribution over the missing modality to both obtain the marginal predictive distribution (for the purpose of prediction) and analyze the impact of the missing modalities on the prediction for each instance. We evaluate PRIMO on a synthetic XOR dataset, Audio-Vision MNIST, and MIMIC-III for mortality and ICD-9 prediction. Across all datasets, PRIMO obtains performance comparable to unimodal baselines when a modality is fully missing and to multimodal baselines when all modalities are available.
PRIMO quantifies the predictive impact of a modality at the instance level using a variance-based metric computed from predictions across latent completions. We visually demonstrate how varying completions of the missing modality result in a set of plausible labels.

Second-Order Smooth Planning with Optimal-Transport Bellman Smoothing
Tuan Quang Dam
Planning with a generative model aims to estimate the value of a state using as few simulator calls as possible.
SmoothCruiser achieves problem-independent complexity $\widetilde O(\varepsilon^{-4})$ by exploiting the smoothness of the entropy-regularized Bellman backup, but its estimator is only first-order.
We show that the sample-complexity exponent of SmoothCruiser-type planners is governed by the order β of the local Taylor remainder, giving oracle complexity $\widetilde O(\varepsilon^{-(2+2/(\beta-1))})$: the first-order case $\beta=2$ recovers SmoothCruiser, while a second-order/cubic remainder $\beta=3$ yields $\widetilde O(\varepsilon^{-3})$.
We reach this regime with an optimal-transport-smoothed Bellman backup over action distributions, which has a closed form, a policy gradient, and a Lipschitz Hessian, and whose quadratic correction admits an unbiased cross-product estimator.
The resulting SecondOrderSmoothCruiser achieves $\widetilde O(\varepsilon^{-3})$ oracle complexity for fixed OT parameters, and we relate the OT, entropy-regularized, and unregularized objectives through explicit regularization-bias bounds.
****
Steal the Patch Size: Adversarially Manipulate Vision Language Models
Kai Hu, Akash Bharadwaj, Weichen Yu, Matt Fredrikson
We present a black-box model-stealing attack that recovers private vision-tokenizer configurations of deployed vision-language models (VLMs), including the visual patch size and input preprocessing pipeline. The key idea is a task-level side channel induced by ViT-style patchification: when a synthetic grid image is aligned with the hidden patch grid, boundary cues are erased at tokenization, caus

ing periodic accuracy drop. By sweeping the grid cell size and measuring these c
ollapses, we infer the patch size; by introducing padding and a consistency-chec
k test, we further identify whether preprocessing is dynamic- or fixed-resolutio
n and recover the target resize resolution. Across open-source Qwen-VL variants
and proprietary models including GPT and Claude, we reliably recover tokenizer-r
elated parameters. Finally, we show that such leakage enables preprocessing-awar
e transfer attacks and model-targeted adversarial manipulation.

Spiked-CFR: Causal Representation Learning from LLMs via Wasserstein Projection
Pursuit
Fan Wang, Hengyu Yue, Yu Bowen, Weiming Liu, Zongxin Yang, Xuyun Zhang, Xiaolin
Zheng, Chaochao Chen, Shuiguang Deng
Estimating treatment effects from observational text is increasingly practical w
ith Large Language Models (LLMs). However, applying causal representation learni
ng directly to high-dimensional LLM embeddings faces a fundamental barrier: empi
rical Wasserstein matching suffers from the curse of dimensionality, rendering s
tandard generalization guarantees effectively vacuous. We propose SPIKED-CFR, a
framework bridging this gap by assuming a Spiked Structure, where treatment sele
ction bias is assumed to manifest primarily as a low-dimensional treated--contro
l discrepancy in the semantic representation. We develop Wasserstein Projection
Pursuit, a minimax objective that adversarially learns an orthogonal projection
on the Stiefel manifold to identify and balance only this subspace while preserv
ing prognostic information. Under a spiked structure, we show the projected disc
repancy can be estimated at a rate governed by the intrinsic dimension $k \ll D$
, and we derive a tighter PEHE generalization bound that depends on k rather t
han the ambient embedding dimension.
Experiments on four semi-synthetic benchmarks and four real-world clinical bench
marks demonstrate improved accuracy and robustness over strong baselines.
****
On the Limits of Test-Time Compute: Sequential Reward Filtering for Better Infer
ence
Yue Yu, Qiwei Di, Quanquan Gu, Dongruo Zhou
Test-time compute (TTC) has become an increasingly prominent paradigm for enhanc
ing large language models (LLMs). Despite the empirical success of methods such
as best-of-n (BoN) sampling and sequential revision, their fundamental limits
remain unclear. We address this gap by analyzing a mixture-of-reference policy m
odel and proving that standard BoN is inherently suboptimal. To move closer to t
he optimal frontier, we study reward-filtered sequential inference, a simple pro
cedure that selectively incorporates only high-reward generations into the conte
xt. This mechanism concentrates computation on superior policy candidates and su
ppresses inferior ones. On the theoretical side, we show that reward-filtered se
quential inference yields strictly stronger guarantees than standard TTC paradig
ms. On the empirical side, we evaluate such an inference strategy across diverse
 benchmarks and observe consistent improvements over widely used approaches, dem
onstrating the practical effectiveness of our framework.

Offline Reinforcement Learning with Generative Trajectory Policies
Xinsong Feng, Leshu Tang, Chenan Wang, Haipeng Chen
Generative models have emerged as a powerful class of policies for offline reinf
orcement learning (RL) due to their ability to capture complex, multi-modal beha
viors.
However, existing methods face a stark trade-off: slow, iterative models like di
ffusion policies are computationally expensive, while fast, single-step models l
ike consistency policies often suffer from degraded performance.
In this paper, we demonstrate that it is possible to bridge this gap.
The key to moving beyond the limitations of individual methods, we argue, lies i
n a unifying perspective that views modern generative models—including diffusion
, flow matching, and consistency models—as specific instances of learning a cont
inuous-time generative trajectory governed by an Ordinary Differential Equation
(ODE).

This principled foundation provides a clearer design space for generative policies in RL and allows us to propose *Generative Trajectory Policies* (GTPs), a new and more general policy paradigm that learns the entire solution map of the underlying ODE.
To make this paradigm practical for offline RL, we further introduce two key theoretically principled adaptations.
Empirical results demonstrate that GTP achieves state-of-the-art performance on D4RL benchmarks -- it significantly outperforms prior generative policies, achieving perfect scores on several notoriously hard AntMaze tasks.

Estimating Correlation Clustering Cost in Node-Arrival Stream
Kaiwen Liu, Seba Daniela Villalobos, Qin Zhang
We study the correlation clustering problem in the node-arrival data stream model. Unlike previous work, where the stream consists of the graph's edges, we focus on the setting in which the stream contains only the nodes. This model better reflects many real-world scenarios in which the data stream naturally consists of raw objects (e.g., images, tweets), and the similar/dissimilar edges are derived through a similarity function. We present *C*^{4}*Approx*, a streaming algorithm that approximates the cost of correlation clustering using sublinear space in the number of nodes and a constant number of passes. We further complement this result with lower bounds. Experiments on real-world datasets show that by storing only 2\% of the nodes, our algorithm achieves performance comparable to the classic *Pivot* algorithm and the more recent *PrunedPivot* algorithm, even on sparse graphs.
****

Random Scaling of Emergent Capabilities
Rosie Zhao, Tian Qin, David Alvarez-Melis, Sham M. Kakade, Naomi Saphra
Language models famously improve under a smooth scaling law, but some specific capabilities exhibit sudden breakthroughs in performance. Advocates of "emergence" view these capabilities as unlocked at a specific scale, but others attribute breakthroughs to superficial metric thresholding effects. We propose that breakthroughs are instead driven by continuous changes in the probability distribution of training outcomes when performance is bimodally distributed across random seeds. We show that different random seeds can produce either smooth or emergent scaling trends in synthetic length generalization tasks, multiple choice question answering, and grammatical generalization. We reveal that sharp breakthroughs in metrics are produced by underlying continuous changes in their distribution across seeds. These distributions may become abruptly bimodal at a capacity threshold—but this threshold appears at scales well before most seeds achieve breakthrough. Our observations hold true even under continuous loss metrics, confirming that random variation must be considered when predicting a model's performance from its scale.

FlowPET: Physics-Informed Symplectic Flow Matching for Low-Count PET Reconstruction
Zheng Zhang, Hao Tang, Yingying Hu, zhanli hu, Jing Qin
Low-count Positron Emission Tomography (PET) reconstruction is severely hindered by the dissipative nature of prevailing generative models, where the inherent phase-space contraction leads to the numerical extinction (``wash-out'') of weak but diagnostically critical lesion signals. To overcome this geometric limitation, we propose \textbf{FlowPET}, a physics-informed framework that reformulates reconstruction as volume-preserving transport in a symplectic phase space. By parameterizing the posterior dynamics via a Separable Hamiltonian System, our approach guarantees a divergence-free vector field by construction, theoretically immunizing weak signals against probability mass collapse. To steer this conservative flow, we introduce conjugate boundary conditions based on the Range-Null space decomposition of the PET operator; this strictly enforces data consistency in the range space while confining stochastic uncertainty injection to the unobserved null space. We train the model via symplectic flow matching and perform inference using a symplectic leapfrog integrator. Extensive experiments on BrainWeb,

clinical pediatric, and UDPET datasets demonstrate that \textbf{FlowPET} not onl
y surpasses state-of-the-art deterministic and stochastic baselines in SSIM and
PSNR but, more crucially, exhibits superior recovery of low-contrast lesions. Th
e results confirm that imposing Hamiltonian structural constraints offers a robu
st geometric safeguard for medical inverse problems in high-noise regimes.

Multi-marginal temporal Schrödinger Bridge Matching from unpaired data
Thomas Gravier, Thomas Boyer, Auguste Genovesio
Many natural dynamic processes –such as in vivo cellular differentiation or dise
ase progression– can only be observed through the lens of static sample snapshot
s. While challenging, reconstructing their temporal evolution to decipher underl
ying dynamic properties is of major interest to scientific research. Existing ap
proaches enable data transport along a temporal axis but are poorly scalable in
high dimension and require restrictive assumptions to be met. To address these i
ssues, we propose Multi-Marginal temporal Schrödinger Bridge Matching (MMtSBM) f
rom unpaired data, extending the theoretical guarantees and empirical efficiency
 of Diffusion Schrödinger Bridge Matching (Shi et al., 2023) by deriving the Ite
rative Markovian Fitting algorithm to multiple marginals in a novel factorized f
ashion. Experiments show that MMtSBM retains theoretical properties on toy examp
les, achieves state-of-the-art performance on real-world datasets such as transc
riptomic trajectory inference in 100 dimensions, and, for the first time, recove
rs couplings and dynamics in very high-dimensional image settings. Our work esta
blishes multi-marginal Schrödinger bridges as a practical and principled approac
h for recovering hidden dynamics from static data.

Foresee-to-Ground: From Predictive Temporal Perception to Evidence-Driven Reason
ing for Video Temporal Grounding
Zelin Zheng, Xinyan Liu, Ruixin Li, Antoni B. Chan, Guorong Li, Qingming Huang,
Laiyun Qing
Current Video-LLM approaches for Video Temporal Grounding (VTG) typically rely o
n direct timestamp generation from an unstructured visual-token stream, often le
ading to brittle numerics and inconsistent boundaries. To address this, we propo
se Foresee-to-Ground (F2G), a framework that reformulates VTG as a verifiable Id
entify-then-Measure problem.

F2G integrates Predictive Temporal Perception with Evidence-Driven Reasoning:
 it learns boundary-sensitive temporal representations to build a video-wide evi
dence pool of candidate event segments, and exposes these segments to the LLM as
 citable evidence units that bind boundary prediction to explicit event hypothes
es.

By decoupling event identification from precise boundary measurement, F2G stab
ilizes grounding and makes predictions verifiable.

Extensive experiments demonstrate that F2G consistently improves grounding acc
uracy across diverse benchmarks, transfers robustly across different Video-LLM b
ackbones, and preserves general video understanding capabilities.

Our project is available at https://github.com/zelion2003/Foresee-to-Ground.

Prompt Injection as Role Confusion
Charles Ye, Jasmine Cui, Dylan Hadfield-Menell
LLMs see the world as a single stream of text, partitioned into *roles* like &lt
;user> or <tool>. We trace **prompt injection** to **role confusion**:
models perceive the source of text from *how it sounds*, not its labeled role. A
 command hidden in a webpage hijacks an agent simply because it sounds like <
user> text, despite its <tool> label. We design *role probes* to measur
e how LLMs internally perceive "who is speaking", and find that injected text oc
cupies the same representational space as the trusted role it imitates. We demon
strate this with CoT Forgery, a zero-shot attack that injects fabricated reasoni
ng into user prompts and tool outputs. Models mistake the forgery for their own
thoughts, yielding 60% attack success against frontier models with near-zero bas
elines. Strikingly, the degree of role confusion predicts attack success before
a single token is generated. This mechanism generalizes beyond CoT Forgery to st

andard agent prompt injections, revealing prompt injection as a measurable conse
quence of role perception. To the model, sounding like a role is indistinguishab
le from being one.

Golden Goose: A Simple Trick to Synthesize Unlimited RLVR Tasks from Unverifiabl
e Internet Text
Ximing Lu, David Acuna, Jaehun Jung, Jian Hu, Di Zhang, Shizhe Diao, Yunheng Zou
, Shaokun Zhang, Brandon Cui, Mingjie Liu, Hyunwoo Kim, Prithviraj Ammanabrolu,
Jan Kautz, Yi Dong, Yejin Choi
Reinforcement Learning with Verifiable Rewards (RLVR) has become a cornerstone f
or unlocking complex reasoning in Large Language Models (LLMs). Yet, scaling up
RL is bottlenecked by limited existing verifiable data, where improvements incre
asingly saturate over prolonged training.
To overcome this, we propose **Golden Goose**, a simple trick to synthesize unli
mited RLVR tasks from unverifiable internet text by constructing a multiple-choi
ce question-answering version of the fill-in-the-middle task. Given a source tex
t, we prompt an LLM to identify and mask key reasoning steps, then generate a se
t of diverse, plausible distractors.
This enables us to leverage reasoning-rich unverifiable corpora typically exclud
ed from prior RLVR data construction (e.g., science textbooks) to synthesize **G
ooseReason-0.7M**, a large-scale RLVR dataset with over 0.7 million tasks spanni
ng mathematics, programming, and general scientific domains.
Empirically, GooseReason effectively revives models saturated on existing RLVR d
ata, yielding robust, sustained gains under continuous RL and achieving new stat
e-of-the-art results for 1.5B and 4B-Instruct models across 15 diverse benchmark
s.
Finally, we deploy Golden Goose in a real-world setting, synthesizing RLVR tasks
 from raw FineWeb scrapes for the cybersecurity domain, where no prior RLVR data
 exists. Training Qwen3-4B-Instruct on the resulting data **GooseReason-Cyber**
sets a new state-of-the-art in cybersecurity, surpassing a 7B domain-specialized
 model with extensive domain-specific pre-training and post-training. This highl
ights the potential of automatically scaling up RLVR data by exploiting abundant
, reasoning-rich, unverifiable internet text.

Formalizing Learning from Language Feedback with Provable Guarantees
Wanqiao Xu, Allen Nie, Ruijie Zheng, Aditya Modi, Adith Swaminathan, Ching-An Ch
eng
Interactively learning from observation and language feedback is an increasingly
 studied area driven by the emergence of large language model (LLM) agents. Whil
e impressive empirical demonstrations have been shown, so far a principled frami
ng of these decision problems remains lacking. In this paper, we formalize the
Learning from Language Feedback (LLF) problem, assert sufficient assumptions to
enable learning despite latent rewards, and introduce *transfer eluder dimension
* as a measure to characterize the hardness of LLF problems.
We formalize the intuition that information in the feedback governs the learning
 complexity of LLF problems. We demonstrate cases where learning from rich lang
uage feedback can be exponentially faster than learning from reward.
We develop a no-regret algorithm, called `HELiX`,
that provably solves LLF problems through sequential interactions, with performa
nce guarantees
that scale with the transfer eluder dimension of the problem.
Across several empirical domains, we show that `HELiX` performs well even when r
epeatedly prompting LLMs does not work reliably.
Our contributions mark an important step towards designing principled interactiv
e learning algorithms from generic language feedback.

Ambient Dataloops: Generative Models for Dataset Refinement
Adrian Rodriguez-Munoz, William Daspit, Adam Klivans, Antonio Torralba, Constant
inos Costis Daskalakis, Giannis Daras
We propose Ambient Dataloops, an iterative framework for refining datasets that

makes it easier for diffusion models to learn the underlying data distribution.
Modern datasets contain samples of highly varying quality, and training directly on such heterogeneous data often yields suboptimal models. We propose a dataset-model co-evolution process; at each iteration of our method, the dataset becomes progressively higher quality, and the model improves accordingly. To avoid destructive self-consuming loops, at each generation, we treat the synthetically improved samples as noisy, but at a slightly lower noisy level than the previous iteration, and we use Ambient Diffusion techniques for learning under corruption. Empirically, Ambient Dataloops achieve state-of-the-art performance in unconditional and text-conditional image generation and de novo protein design. We further provide a theoretical justification for the proposed framework that captures the benefits of the data looping procedure.

One Coin Has Two Sides: Single Poistive Multi Label Learning from Salient Annotations
Xiaoyu Wang, Zhuoming Li, Bo Han, Hui LIU, Junhui Hou, Yuheng Jia
Single-Positive Multi-Label Learning (SPML) studies learning from incomplete supervision, where each instance is annotated with only one positive label despite potentially belonging to multiple categories.
While existing methods assume the annotated labels are randomly distributed, real-world annotations are often biased toward the most salient category.
We formalize this realistic scenario as Salient Single-Positive Multi-Label Learning (SalSPML).
This salient annotation bias poses a challenge to conventional SPML methods,
as the missing labels often correspond to less salient and harder-to-recognize categories.
Fortunately, we find that salient annotations are typically more representative and informative.
Motivated by this insight, we propose Prototype-Guided Rejection for Salient Annotation (PiSA),
which constructs reliable class-wise prototypes from salient labels and leverages them to guide embedding learning for non-salient labels recognition.
We theoretically demonstrate that SalSPML is harder than Random SPML due to irreducible annotation bias, and under SalSPML, more accurate prototypes facilitate false-negative label detection.
Experiments on multiple benchmarks, together with two newly constructed real-world SalSPML datasets, demonstrate that PiSA consistently outperforms existing methods, achieving an average mAP improvement of 3.16\%.
****

Accurate Evaluation of Quickest Changepoint Detectors via Non-parametric Survival Analysis
Taiki Miyagawa, Akinori F. Ebihara
We propose non-parametric estimators for the average run length (ARL) and average detection delay (ADD) in quickest changepoint detection (QCD) under finite and irregular sequence lengths.
Although ARL and ADD are widely used as optimality criteria in theoretical and simulation studies, their application to real-world datasets is hindered by limited and irregular sequence lengths.
To address this issue, we propose non-parametric estimators for the ARL and ADD, termed _KM-ARL and KM-ADD_, by drawing an analogy between QCD and survival analysis to model detection probabilities under sequence truncation.
We derive estimation bias bounds and prove that they are asymptotically unbiased unless extrapolation is required.
Experiments on simulated and real-world datasets demonstrate their practical utility, enhancing robustness against limited and irregular sequence lengths, improving interpretability, and facilitating empirical, intuitive model selection.
Our Python code is provided at https://github.com/TaikiMiyagawa/Kaplan-Meier-Average-Run-Length, offering ready-to-use implementations for practitioners.

DC-W2S: Dual-Consensus Weak-to-Strong Training for Reliable Process Reward Model

ing in Biological Reasoning
Chi-Min Chan, Ehsan Hajiramezanali, Xiner Li, Edward De Brouwer, Carl Edwards, Wei Xue, Sirui Han, Yike Guo, Gabriele Scalia
In scientific reasoning tasks, the veracity of the reasoning process is as critical as the final outcome. While Process Reward Models (PRMs) offer a solution to the coarse-grained supervision problems inherent in Outcome Reward Models (ORMs), their deployment is hindered by the prohibitive cost of obtaining expert-verified step-wise labels. This paper addresses the challenge of training reliable PRMs using abundant but noisy "weak" supervision. We argue that existing Weak-to-Strong Generalization (W2SG) theories lack prescriptive guidelines for selecting high-quality training signals from noisy data. To bridge this gap, we introduce the Dual-Consensus Weak-to-Strong (DC-W2S) framework. By intersecting Self-Consensus (SC) metrics among weak supervisors with Neighborhood-Consensus (NC) metrics in the embedding space, we stratify supervision signals into distinct reliability regimes. We then employ a curriculum of instance-level balanced sampling and label-level reliability-aware masking to guide the training process. We demonstrate that DC-W2S enables the training of robust PRMs for complex reasoning without exhaustive expert annotation, proving that strategic data curation is more effective than indiscriminate training on large-scale noisy datasets.

Thinking in Scales: Accelerating Gigapixel Pathology Image Analysis via Adaptive Continuous Reasoning
Jiusong Ge, Yingkang Zhan, Wenjie Zhao, Di Zhang, Ke Wang, Jiashuai Liu, Chunze Yang, Chengzu Li, Jian Zhang, Yuxin Dong, Ni Zhang, Qidong Liu, Mireia Crispin-Ortuzar, Huazhu Fu, Chen Li, Zeyu Gao
Traditional whole slide image (WSI) analysis methods typically rely on the multiple instance learning (MIL) paradigm, which extracts patch-level features at high magnification and aggregates them for slide-level prediction.
However, such exhaustive patch-level processing is computationally expensive, severely limiting the efficiency and scalability of WSI analysis.
To address this challenge, we propose PathCTM (a Pathology-oriented Continuous Thought Model) that enables token-efficient scale-space continuous reasoning for gigapixel WSIs. PathCTM formulates diagnostic inference as a dynamic sequential information pursuit. It progressively transitions from low-magnification global to high-magnification local inspection, and adaptively terminates inference when sufficient evidence is gathered to effectively bound decision uncertainty. Specifically, it uses conditional computation for dynamic scale switching with attention-guided region pruning, coupled with confidence-aware early stopping. Extensive experiments demonstrate that, compared with standard MIL-based methods, PathCTM reduces the number of required image patches by 95.95\% and shortens inference time by approximately 95.62\%, while maintaining AUC without degradation. Code is available at https://github.com/JSGe-AI/PathCTM.
****
Shrinking the Variance: Shrinkage Baselines for Reinforcement Learning with Verifiable Rewards
Guanning Zeng, Zhaoyi Zhou, Daman Arora, Andrea Zanette
Reinforcement Learning with Verifiable Rewards (RLVR) has emerged as a powerful paradigm for post-training large reasoning models (LRMs) using policy-gradient methods such as GRPO. To stabilize training, these methods typically center trajectory rewards by subtracting the empirical mean for each prompt. Statistically, this centering acts as a control variate (or baseline), reducing the variance of the policy-gradient estimator. Typically, the mean reward is estimated using per-prompt empirical averages for each prompt in a batch. Drawing inspiration from Stein's paradox, we propose using shrinkage estimators that combine per-prompt and cross-prompt means to improve the overall per-prompt mean estimation accuracy, particularly in the low-generation regime typical of RLVR. Theoretically, we construct a shrinkage-based baseline that provably yields lower-variance policy-gradient estimators across algorithms. This baseline serves as a drop-in replacement for existing per-prompt mean baselines, requiring no additional hyperparameters or computation. Empirically, shrinkage baselines consistently outperform st

andard empirical-mean baselines, leading to lower-variance gradient updates and improved training stability.
****
Conditional Distributional Treatment Effects: Doubly Robust Estimation and Testing
Saksham Jain, Alex Luedtke
Beyond conditional average treatment effects, treatments may impact the entire outcome distribution in covariate-dependent ways, for example, by altering the variance or tail risks for specific subpopulations. We propose a novel estimand to capture such conditional distributional treatment effects, and develop a doubly robust estimator that is minimax optimal in the local asymptotic sense. Using this, we develop a test for the global homogeneity of conditional potential outcome distributions that accommodates discrepancies beyond the maximum mean discrepancy (MMD), has provably valid type 1 error, and is consistent against fixed alternatives---the first test, to our knowledge, with such guarantees in this setting. We then provide a test that aggregates evidence across a grid of kernel-bandwidth choices. Furthermore, we derive exact closed-form expressions for two natural discrepancies (including the MMD), and provide a computationally efficient, permutation-free algorithm for our test.
****
Convex Low-resource Accent-Robust Language Detection in Speech Recognition
Miria Feng, William Tan, Mert Pilanci
Globalization and multiculturalism continue to produce increasingly diverse speech varieties. Yet current spoken dialogue systems frequently fail on under-represented dialects and accents, often misidentifying the input language and causing cascading failures in downstream dialogue tasks. Addressing this dialectal variance under low-resource constraints remains an open challenge, as standard fine-tuning is computationally expensive and prone to overfitting on high-dimensional speech data. We propose Convex Language Detection (CLD), a novel framework that integrates theoretically grounded convex optimization techniques into the spoken dialogue systems pipeline. Our method is efficiently implemented via multi-GPU Alternating Direction Method of Multipliers (ADMM) in JAX, thus providing global optimality guarantees and fast training in polynomial time. Theoretically, we prove that our convex objective induces certified margin stability and provide guarantees against feature perturbations. Empirically, we demonstrate sample efficiency and robustness to input dialectical variation, achieving 97–98\% accuracy in challenging low-resource regimes. Our open-source package is available at https://pypi.org/project/jaxcld/.

STARE: Step-wise Temporal Alignment and Red-teaming Engine for Multi-modal Toxicity Attack
Xutao Mao, Liangjie Zhao, Tao Liu, Xiang Zheng, Hongying Zan, Cong Wang
Red-teaming Vision-Language Models is essential for identifying vulnerabilities where adversarial image-text inputs trigger toxic outputs. Existing approaches treat image generation as a black box, providing only terminal toxicity scores while remaining temporally opaque regarding when and how toxic semantics emerge during multi-step synthesis. We introduce $\textbf{STARE}$, a hierarchical reinforcement learning framework that treats the denoising trajectory as an exploitable attack surface. By synergizing a high-level prompt editor with low-level T2I fine-tuning via Group Relative Policy Optimization (GRPO), STARE achieves a 68\% improvement in Attack Success Rate over state-of-the-art baselines including black box and white-box variants. More importantly, we reveal the Optimization-Induced Phase Alignment phenomenon: while vanilla models exhibit diffuse toxicity, adversarial optimization systematically concentrates conceptual harms into early semantic phases and detail-oriented harms into late refinement. This discovery transforms toxicity formation from a chaotic process into a series of predictable vulnerability windows. This temporal alignment transforms red-teaming from a trial-and-error process into a targeted structural analysis. Our work provides both a potent attack engine and a diagnostic foundation for developing next-generation, phase-aware safety mechanisms. Content warning: This paper contains example

s of toxic content that may be offensive or disturbing.

FUSE: Ensembling Verifiers with Zero Labeled Data
Joonhyuk Lee, Virginia L. Ma, Sarah Zhao, Yash Nair, Asher Spector, Regev Cohen, Emmanuel Candes
Verification of model outputs is rapidly emerging as a key primitive for both training and real-world deployment of large language models (LLMs). In practice, this often involves using imperfect LLM judges and reward models since ground truth acquisition can be time-consuming and expensive. We introduce Fully Unsupervised Score Ensembling (FUSE), a method for improving verification quality by ensembling verifiers without access to ground truth correctness labels. The key idea behind FUSE is to control conditional dependencies between verifiers in a manner that improves the unsupervised performance of a class of spectral algorithms from the ensembling literature. Despite requiring zero ground truth labels, FUSE typically matches or improves upon semi-supervised alternatives in test-time scaling experiments with diverse sets of generator models, verifiers, and benchmarks. In particular, we validate our method on both conventional academic benchmarks such as GPQA Diamond and on frontier, unsaturated benchmarks such as Humanity's Last Exam and IMO Shortlist questions.

Copula-SVI: Vine-Copula Variational Inference with Stein Refining for Instance-Level Correlation Capturing
Junxi Xiao, Qinliang Su
Mean-field variational inference (VI) is scalable, but its independence assumption can severely limit inference when the posterior is inherently coupled across instances especially for correlated data. Existing structured VI approaches either impose simple dependence patterns or incur substantial cost as dependence becomes richer, leaving efficient higher-order instance-level dependence modeling largely unresolved. We propose Copula-SVI, which augments amortized marginals with an explicit vine-copula posterior and refines joint samples with Stein updates toward the true posterior. The vine construction makes dependence learning and sampling practical by decomposing it into bivariate copula factors, enabling edge-minibatched training with variance-aware level-wise sampling and efficient dependence-aware initialization via a sparse vine built from the same sampled edges. Experiments on constrained clustering and time series modeling show consistent improvements over strong structured VI baselines and demonstrate efficient higher-order instance-level dependence modeling.

OXE-AugE: A Large-Scale Robot Augmentation of OXE for Scaling Cross-Embodiment Policy Learning
Guanhua Ji, Harsha Polavaram, Lawrence Yunliang Chen, Sandeep Bajamahal, Zehan Ma, Simeon Adebola, Chenfeng Xu, Ken Goldberg
Large and diverse datasets are needed for training generalist robot policies that can control a variety of robot embodiments--robot arm and gripper combinations--across diverse tasks and environments. As re-collecting demonstrations and retraining for each new embodiment are prohibitively costly, we study whether existing robot data can be augmented to improve transfer and generalization across embodiments. The Open X-Embodiment (OXE) dataset, which aggregates demonstrations from over 60 robot datasets, has been widely used for training generalist policies. However, it is highly imbalanced: the top four robot types account for over 85% of its real data, which risks overfitting to robot--scene combinations. We present AugE-Toolkit, a scalable robot augmentation pipeline, and OXE-AugE, a high-quality open-source dataset that augments OXE with 9 different robot embodiments. OXE-AugE provides over 4.4 million trajectories, more than triple the size of the original OXE. We conduct a systematic study of how scaling robot augmentation impacts cross-embodiment learning. Results suggest that augmenting datasets with diverse arms and grippers improves policy performance not only on the augmented robots, but also on unseen robots and even the original robots under distribution shifts. In physical experiments, fine-tuning generalist policies such as OpenVLA and π_0 on OXE-AugE improves success rates by 24-45% on unseen robot

-gripper combinations across four real-world manipulation tasks. Project website : https://OXE-AugE.github.io/.

Disease-Centric Vision-Language Pretraining with Hybrid Visual Encoding for 3D C omputed Tomography
Bowen Shi, Weiwei Cao, Ruifeng Yuan, Wanxing Chang, Wenrui Dai, Hongkai Xiong, L ing Zhang, Jianpeng Zhang
Vision–language pre-training (VLP) holds great promise for general-purpose medic al AI by leveraging radiology reports as rich textual supervision, yet existing methods struggle with 3D CT imaging due to inefficient visual backbones and coar se semantic alignment. To address these issues, we propose a tailored VLP framew ork featuring three key components: (1) a CNN–ViT hybrid encoder that replaces V iT’s patch embedding with a 3D CNN backbone to efficiently capture local anatomi cal details while preserving global attention and compatibility with pre-trained cross-modal priors; (2) a disease-level contrastive learning mechanism using le arnable query tokens to dynamically extract disease-specific semantics from full reports and align them with corresponding visual features, thereby disentanglin g distinct diseases within the same anatomical region; and (3) a diagnosis-aware prompt strategy that employs real clinical phrases and aggregated disease proto types to bridge the pre-training–inference gap and enhance zero-shot diagnostic reliability. Our model achieves state-of-the-art performance on CT-RATE (84.4\% AUC, +5.1%) and Rad-ChestCT (75.4\% AUC, +5.4%), with even larger gains (+9.8% A UC) on a challenging 60-disease benchmark, and demonstrates strong transferabili ty to radiology report generation, underscoring the generality and clinical util ity of our approach.

Thoughtbubbles: an Unsupervised Method for Parallel Thinking in Latent Space
Houjun Liu, Shikhar Murty, Christopher D Manning, Róbert Csordás
Current approaches for scaling inference-time compute in transformers train them to emit explicit chain-of-thought tokens before producing an answer. While thes e methods are powerful, they are limited because they cannot be applied during p retraining and rely solely on serially-generated, natural-language verbalization . In this work, we propose Thoughtbubbles, a transformer variant that natively p erforms parallel adaptive computation in latent space by learning to fork or del ete residual streams. Thus, tokens requiring more computation can form a "bubble " of cloned residuals in the middle of the network. Crucially, this behavior is learned during pretraining with only language modeling loss. Using half of the t raining budget, Thoughtbubbles outperforms the perplexity and zero-shot evals of both standard decoder LMs and those using non-adaptive parallel computation app roaches. These results hold across model sizes from 150M to 1.9B. Thoughtbubbles achieves competitive GSM8K results using half of the baseline's token budget. T he implicit nature of our method enables models to begin learning adaptive compu tation at pretraining time, paving the way to unified train-time and test-time s caling behaviors.

On Learnability and Disambiguation of Multiclass Partial Concept Classes
Jingyuan Xu, Xin Zou, Xiuwen Gong, Weiwei Liu
We study the Probably Approximately Correct (PAC) learnability of partial concep t classes in the multiclass setting, where the label space can be infinite. Whil e the Natarajan dimension characterizes learnability for finite label spaces, we show it fails when the label space is unbounded. Instead, we prove that the Dan iely-Shalev (DS) dimension provides a characterization of learnability for parti al concept classes in the general multiclass setting. Furthermore, our analysis reveals a surprising phenomenon we call the ``Disambiguation Paradox'': disambig uation schemes with simple label space can destroy learnability, while richer la beling may preserves it. We further characterize how the number and structure of disambiguation labels control the induced DS dimension, yielding a trade-off be tween label complexity and sample complexity.

Posterior Mismatch Matters: Adversarial Training for Long-Tailed Robustness

Lilin Zhang, Li Yue, Jiancheng Shi, Jiancheng Lv, Xianggen Liu
Adversarial training breaks down in long-tailed settings, exhibiting severe robu stness degradation on worst-performing (often tail) classes. We identify a key c ause of this failure as a posterior mismatch: coarse-grained absolute labels col lapse class posteriors into point estimates, leading to biased class-frequency e stimation and an enlarged robust generalization gap, which ultimately amplifies worst-class vulnerability. To address this issue, we propose Posterior-driven Ad versarial Training (PAT), which learns a posterior surrogate to provide fine-gra ined probabilistic supervision for adversarial training, and integrates weight p erturbations to encourage a flatter loss landscape. Our theory shows that accura te posterior approximation simultaneously tightens class-frequency estimation er ror and robust generalization bounds, while a flat weight loss landscape stabili zes sensitivity to posterior approximation errors. Extensive experiments on long -tailed benchmarks confirm that PAT consistently improves robustness, with espec ially large gains on worst-class.

DAPD: Dependency-Aware Parallel Decoding via Attention for Diffusion LLMs
BumJun Kim, Dongjae Jeon, Moongyu Jeon, Albert No
Parallel decoding for diffusion LLMs (dLLMs) is difficult because each denoising step provides only token-wise marginal distributions,
while unmasking multiple tokens simultaneously requires accounting for inter-tok en dependencies.
We propose **D**ependency-**A**ware **P**arallel **D**ecoding (**DAPD**),
a simple, training-free decoding method that uses self-attention to induce a con ditional dependency graph over masked tokens.
At each iteration, edges in this graph capture strong token interactions, while non-edges indicate weak dependence.
Parallel decoding is then reduced to selecting an independent set on the graph a nd unmasking the selected tokens in parallel.
This avoids co-updating strongly coupled tokens without auxiliary models or retr aining.
Experiments on LLaDA and Dream show that DAPD improves the accuracy–steps trade- off over existing methods
and enables more globally distributed parallel updates that better exploit the a ny-order generation capability of dLLMs.
The project is available at \url{https://ai-isl.github.io/dapd}

FastSESR: Fast Scene-level Explicit Surface Reconstruction
Jueqi Liu, Xuechao Zou, Congyan Lang
Explicit surface reconstruction aims to recover high-fidelity meshes directly fr om point clouds. While existing methods achieve strong performance on scene-leve l data, they often rely on test-time optimization, resulting in a prohibitive ru ntime of several minutes. To address this bottleneck, we propose FastSESR, a two -stage framework for efficient scene-level explicit surface reconstruction. In t he first stage, a lightweight triangular candidate network (TCN) captures local connections via an edge-factorized parameterization, enabling effective extracti on of surface triangles from uniformly sampled points. In the second stage, an o ffset optimization network amortizes offset refinement into a small, fixed numbe r of learnable update steps guided by TCN, producing geometries that are more su itable for triangulation. Experiments on multiple scene-level datasets show that FastSESR accelerates surface reconstruction by at least $20 \times$ over prior methods while maintaining competitive reconstruction quality. Moreover, evaluati ons on shape-level benchmarks indicate good generalization performance. Our code is available at https://github.com/Vaiduryasses/FastSESR.

Mitigating Bias in Locally Constrained Decoding via Tractable Proposals
Meihua Dang, Linxin Song, Honghua Zhang, Jieyu Zhao, Guy Van den Broeck, Stefano Ermon
Generations from large language models often fail to conform to desired constrai nts such as JSON schema. Existing locally constrained decoding (LCD) approaches

enforce constraints by myopically masking out next tokens, resulting in biased s
ampling and degradation in performance. Recent work uses sequential Monte Carlo
(SMC) methods to mitigate such biases, but designing effective proposal distribu
tions or potential functions remains a key challenge. In this work, we propose a
 generic approach to construct proposals and potentials for SMC sampling from $p
_{\mathrm{lm}}(\cdot \mid \mathrm{constraint})$. First, we show that constraint
s specified as finite automata can be tensorized for efficient execution on GPUs
, which we use to construct globally constrained decoding (GCD) proposals. In ad
dition, leveraging the fact that tensorized finite automata share the same circu
it structure as hidden Markov models, we circuit-multiply them to obtain the pro
babilistic GCD (P-GCD) proposals encoding both logical and probabilistic informa
tion about the target distributions. We evaluate (P-)GCD on the tasks of functio
n calling, keyword-based generation, and SQL generation. Experiments show that u
nder the same SMC sampling setup, compared to LCD proposals, (P-)GCD converges f
aster to the target distribution with significantly fewer particles.

Seeing is Solving: Unlocking Efficient Multimodal RL via View Alignment
Qinsi Wang, Jing Shi, Kun Wan, Handong Zhao, Hancheng Ye, Zishan Shao, Jinghan K
e, Yudong Liu, Daniel Miranda, Purvak Lapsiya, Yiran Chen, Wentian Zhao
Although Reinforcement Learning Fine-Tuning (RLFT) applied to Vision-Language Mo
dels (VLMs) substantially enhances multimodal reasoning capabilities, their proh
ibitive training cost limits broad adoption. Surprisingly, most existing methods
 simply port Large Language Model (LLM) RLFT techniques to VLMs, while ignoring
a intrinsic property of multimodal models: their dynamic text–vision alignment.
We ask a new question: Can this intrinsic alignment be turned into a training si
gnal that makes VLM RLFT more efficient? We analyze how a VLM plans to attend, a
ctually attends, and ideally should attend during reasoning, and derive two ligh
tweight metrics from these patterns. Predictive View Accuracy (PVA) estimates sa
mple difficulty, and Reasoning View Accuracy (RVA) reflects the quality of chain
-of-thought (CoT) reasoning. These alignment signals enable automated data curri
culum and dense reasoning supervision. We introduce FOCUS-RL, a plug-and-play fr
amework that can be seamlessly integrated into any VLM and dramatically boosts R
LFT training efficiency. FOCUS-RL achieves 2.5 x – 4 x faster convergence over v
anilla GRPO and consistent accuracy gains (+4.4 on average) across six different
 benchmarks and multiple VLM families.

MePo: Meta Post-Refinement for Rehearsal-Free General Continual Learning
Guanglong Sun, Hongwei Yan, Liyuan Wang, Zhiqi KANG, Shuang Cui, Hang Su, Jun Zh
u, Yi Zhong
To cope with uncertain changes of the external world, intelligent systems must c
ontinually learn from complex, evolving environments and respond in real time. T
his ability, collectively known as general continual learning (GCL), encapsulate
s practical challenges such as online datastreams and blurry task boundaries. Al
though leveraging pretrained models (PTMs) has greatly advanced conventional con
tinual learning (CL), these methods remain limited in reconciling the diverse an
d temporally mixed information along a single pass, resulting in sub-optimal GCL
 performance. Inspired by meta-plasticity and reconstructive memory in neuroscie
nce, we introduce here an innovative approach named **Me**ta **Po**st-Refinement
 (MePo) for PTMs-based GCL. This approach constructs pseudo task sequences from
pretraining data and develops a bi-level meta-learning paradigm to refine the pr
etrained backbone, which serves as a prolonged pretraining phase but greatly fac
ilitates rapid adaptation of representation learning to downstream GCL tasks. Me
Po further initializes a meta covariance matrix as the reference geometry of pre
trained representation space, enabling GCL to exploit second-order statistics fo
r robust output alignment. MePo serves as a plug-in strategy that achieves signi
ficant performance gains across a variety of GCL benchmarks and pretrained check
points in a rehearsal-free manner (e.g., 15.10%, 13.36%, and 12.56% on CIFAR-100
, ImageNet-R, and CUB-200 under Sup-21/1K). Our source code is available at \hre
f{https://github.com/SunGL001/MePo}{MePo}.

CoGenCast: A Coupled Autoregressive–Flow Generative Framework for Time Series Forecasting
Mingyue Cheng, Yaguo Liu, Daoyu Wang, Xiaoyu Tao, Qi Liu
Time series forecasting can be viewed as a generative problem that requires both semantic understanding over contextual conditions and stochastic modeling of continuous temporal dynamics. Existing approaches typically rely on either autoregressive large language models (LLMs) for semantic context modeling or diffusion-like models for continuous probabilistic generation. However, neither method alone can adequately model both aspects simultaneously. In this work, we propose CoGenCast, a hybrid generative framework that couples pre-trained LLMs with flow-matching mechanism for effective time series forecasting. Specifically, we reconfigure pre-trained decoder-only LLMs into a native forecasting encoder–decoder backbone by modifying only the attention topology, enabling bidirectional context encoding and causal representation generation. Building on this, a flow-matching mechanism is further integrated to model temporal evolution, capturing continuous stochastic dynamics conditioned on the autoregressively generated representation. Notably, CoGenCast naturally supports multimodal forecasting and cross-domain unified training. Extensive experiments on multiple benchmarks show that CoGenCast achieves competitive performance compared to previous baselines. Code is available at \url{https://github.com/liuyaguo/_CoGenCast}.

Deep Scientific Reasoning under Physical Constraints: Structure-Aware Spectrum Prediction
Yingheng Wang, Tao Yu, Shufeng Kong, Francesco Ricci, John M Gregoire, Carla P Gomes
Structured scientific spectra encode rich physical information while obeying hard constraints, such as conservation laws and characteristic spectral geometry. Accurate prediction of these spectra is central to materials discovery, yet existing methods often treat them as unconstrained sequences and therefore fail to enforce the underlying physical structure. Taking electronic density of states (eDOS) as the prototypical example, we introduce \textbf{DeepSciReasoner}, a general paradigm for predicting scientific spectra under physical constraints. The framework combines structure-aware spectrum decoding with constraint-preserving physical reasoning, allowing predictions to capture rich spectral structure while respecting the underlying physics. We evaluate DeepSciReasoner on eDOS, phonon density of states (phDOS), X-ray absorption near-edge structure (XANES), and Raman spectra, where it substantially improves prediction accuracy while maintaining physical consistency. These results establish DeepSciReasoner as a reusable blueprint for structured scientific spectrum prediction under hard physical constraints.

Resolving Blind Inverse Problems under Dynamic Range Compression via Structured Forward Operator Modeling
Muyu Liu, Xuanyu Tian, Chenhe Du, Qing Wu, Hongjiang Wei, Yuyao Zhang
Recovering radiometric fidelity from unknown dynamic range compression (UDRC), such as low-light enhancement and HDR reconstruction, is a challenging blind inverse problem, due to the unknown forward model and irreversible information loss introduced by compression.
To address this challenge, we first identify monotonicity as the fundamental physical invariant shared across UDRC tasks. Leveraging this insight, we introduce the cascaded monotonic Bernstein (CaMB) operator to parameterize the unknown forward model. CaMB enforces monotonicity as a hard architectural inductive bias, constraining optimization to physically consistent mappings and enabling robust and stable operator estimation.
We further integrate CaMB with a plug-and-play diffusion framework, proposing CaMB-Diff. Within this framework, the diffusion model serves as a powerful geometric prior for structural and semantic recovery, while CaMB explicitly models and corrects radiometric distortions through a physically grounded forward operator.

Extensive experiments on a variety of zero-shot UDRC tasks,

including low-light enhancement, low-field MRI enhancement, and HDR reconstructi
on, demonstrate that CaMB-Diff significantly outperforms state-of-the-art zero-s
hot baselines
in terms of both signal fidelity and physical consistency.
Moreover, we empirically validate the effectiveness of the proposed CaMB paramet
erization in accurately modeling the unknown forward operator.

Incentivized Exploration with Stochastic Covariates: A Two-Stage Mechanism Desig
n for Recommender System

Yuantong Li, Guang Cheng, Xiaowu Dai

Recommender systems play a crucial role in internet economies by connecting user
s with relevant products. However, designing effective recommender systems faces
 the key challenges: the exploration-exploitation tradeoff in securing incentive
 to explore new products against user’s self-interested preferences. While prior
 work addresses Bayesian Incentive Compatibility (BIC) in fixed-design linear ba
ndits (Sellke & Slivkins, 2023), we tackle the challenge of stochastic user cova
riates sampled online. Unlike standard black-box reductions (Mansour et al., 202
0), our two-stage framework exploits the linear reward structure to achieve subl
inear regret while satisfying incentive constraints. To address it, we propose a
 two-stage algorithm that integrates incentivized exploration with any efficient
 plug-in offline learning algorithms. In the first stage, it explores products w
hile maintaining incentive compatibility to gather optimal samples. The second s
tage employs inverse proportional gap sampling strategy (IPGS) integrated with a
ny efficient learning methods to secure sublinear regret. Theoretically, we prov
e that algorithm RCB achieves $O(\sqrt{KdT})$ regret and simultaneously satisfie
s incentive constraints, and discovers the tradeoff between incentive budget and
 regret, validating in experiments. We demonstrate RCB’s strong incentive gain,
sublinear regret, and robustness through a real application on personalized warf
arin dosing and simulations.
