Any3D-VLA: Enhancing VLA Robustness via Diverse Point Clouds
Xianzhe Fan, Shengliang Deng, Xiaoyang Wu, Yuxiang Lu, Zhuoling Li, Mi Yan, Yuji a Zhang, Zhizheng Zhang, He Wang, Hengshuang Zhao
Existing Vision-Language-Action (VLA) models typically take 2D images as visual input, which limits their spatial understanding in complex scenes. How can we in corporate 3D information to enhance VLA capabilities? We conduct a pilot study a cross different observation spaces and visual representations. The results show that explicitly lifting visual input into point clouds yields representations th at better complement their corresponding 2D representations. To address the chal lenges of (1) scarce 3D data and (2) the domain gap induced by cross-environment differences and depth-scale biases, we propose Any3D-VLA. It unifies the simula tor, sensor, and model-estimated point clouds within a training pipeline, constr ucts diverse inputs, and learns domain-agnostic 3D representations that are fuse d with the corresponding 2D representations. Simulation and real-world experimen ts demonstrate Any3D-VLA's advantages in improving performance and mitigating th e domain gap. Our project homepage is available at https://xianzhefan.github.io/ Any3D-VLA.github.io.

Addressing Instrument-Outcome Confounding in Mendelian Randomization through Rep resentation Learning
Shimeng Huang, Matthew R Robinson, Francesco Locatello
Mendelian Randomization (MR) is a prominent observational epidemiological research method, designed to address unobserved confounding when estimating causal effects. It is closely related to instrumental variable (IV) methods, where genetic variants serve as instruments to infer causal relationships from observational data. However, the core assumptions required for valid IV analysis---particularly the independence between instruments and unobserved confounders---are untestable and often violated in practice. In MR, such violations commonly arise when genetic variants are correlated with environmental factors (e.g., population stratificat ion
and assortive mating), leading to confounding between instruments and outcomes. At the same time, MR studies increasingly include data collected across multiple environments or populations, providing an opportunity to address these violation s.
Leveraging this setting, we propose a representation learning framework that exploits multi-environment data to recover latent exogenous components of genetic instruments suitable for causal inference. We provide theoretical insigh ts
into when and how the learned components can act as valid instruments, and we demonstrate the effectiveness of our approach through simulations and semi-synthetic experiments using genetic data from the All of Us Biobank.

AVI-Bench: Toward Human-like Audio-Visual Intelligence of Omni-MLLMs
Yaoting Wang, Ziyi Zhang, Wenming Tu, Shaoxuan Xu, Wenjie Du, Cheng Liang, Weiju n Wang, Yuanchao Li, Guangyao Li, Hao Fei, Yuanchun Li, Henghui Ding, Yunxin Liu
Recent advances in Omni-Multimodal Large Language Models (Omni-MLLMs) have enabl ed strong integration of vision, audio, and language. However, their audio-visua l intelligence (AVI) remains insufficiently evaluated due to the lack of systema tic and comprehensive benchmarks.
We introduce **AVI-Bench**, a cognitively inspired benchmark that evaluates Omni -MLLMs across three stages, perception, understanding, and reasoning, through cr oss-modal tasks requiring joint audio-visual interpretation. This design enables fine-grained diagnosis of model capabilities and failure modes.
To further assess robustness beyond familiar domains, we propose **AVI-Bench-Pri Se**, an extension that probes models' primitive audio-visual sensation using un familiar, low-semantic stimuli, testing generalization beyond common training di stributions.
Extensive experiments on both open-source and closed-source models reveal substa ntial limitations in current Omni-MLLMs. Based on these findings, we present a *

*four-level AVI taxonomy**. Overall, AVI-Bench provides a principled evaluation framework to guide the development of more robust and generalizable AVI. Project website: https://fudancvl.github.io/AVI-Bench

OptMaster: A DAG-Based Framework for Formulation and Heuristic Discovery in Optimization

Hang Lin, Yuanpeng Gao, Yuzhi Zhang, Kun Yuan, Gang Yan, Siheng Chen, Linfeng Zhang, Weinan E

Optimization problems are fundamental across science and industry, including planning, scheduling, and resource allocation. While LLMs show promise in automating optimization, they struggle to bridge the gap between real-world requirements and both mathematical formulations and effective heuristic designs. Furthermore, the field lacks a unified framework that spans problem formulation and heuristic discovery for NP-hard settings. To address these challenges, we propose OptMaster, a unified framework that spans optimization from formulation to heuristic discovery, structuring the process as a Directed Acyclic Graph (DAG) where each node represents a candidate solution. The DAG architecture enables cross-branch knowledge transfer when search progress stagnates. Within each node, we further replace textual self-reflection with independently generated verification code, grounding the evaluation in deterministic computation to suppress hallucinations. OptMaster achieves competitive performance across two optimization paradigms. In Formulation Intelligence, OptMaster achieves state-of-the-art accuracy across the three most challenging benchmarks in the field. In Heuristic Discovery, OptMaster surpasses the best known solutions on Circle Packing ($n=26, 32$) and achieves a cut of 9,590 on Gset70 with significantly reduced time and search budgets.

From Extrinsic to Intrinsic: Geodesic-Guided Representation Learning for 3D Geometric Data

Yuming Zhao, Junhui Hou, Qijian Zhang, Jia Qin, Ying He

Geometric analysis fundamentally distinguishes between extrinsic and intrinsic perspectives. The dominant paradigm in current 3D representation learning relies on either extrinsic spatial structures or high-level semantics, struggling to capture the essence of shape identity and underlying manifold topology. To bridge this gap, we introduce a novel 3D representation learning paradigm, namely PRISM, for Pre-training, which learns isometric embeddings by Recovering the Intrinsic Surface geodesic Metric. PRISM incorporates a topology-enforcing objective that explicitly constrains the structure of latent space, alongside a specialized two-stage training recipe mitigating sample imbalance inherent in the distribution of geodesic distances. Experiments demonstrate that our approach shows satisfactory accuracy, robustness, and high efficiency in geodesic distance prediction and achieves superior performance across diverse downstream tasks, including shape recognition, surface parameterization, and non-rigid correspondence. Our code will be made publicly available.

Reliable Confidence Alignment for Generalized Category Discovery

Jiawei Yu, Zijian Gao, Tianjiao Wan, Xuan Liu, Cheng Yang, Kele Xu

Generalized Category Discovery (GCD) requires models to categorize an unlabeled pool containing known and novel classes under sparse supervision. We identify a systemic confidence bias inherent in existing parametric methods: while entropy regularization prevents class collapse, it indiscriminately suppresses predictive certainty on all unlabeled instances. This bias drives a distributional wedge between labeled and unlabeled samples of the same category, forcing models to sacrifice their stability on known classes to achieve plasticity for new ones. To resolve this, we propose Reliable Confidence Alignment (RCA), a plug-and-play framework grounded in Evidential Deep Learning. RCA first establishes high certainty anchors on labeled data using a Reliable Anchor for Certainty (RAC) module. Then, we introduce Cross-view Confidence Alignment (CCA) to propagate this grounded reliability to the unlabeled discovery set. Thus, RCA captures the fine-grained geometry of the probability simplex, effectively calibrating the model's epis

temic uncertainty. Extensive evaluations on coarse- and fine-grained benchmarks demonstrate that RCA effectively rectifies the confidence landscape, significantly mitigating performance decay on known classes without compromising novel-class discovery.
****
Grouter: Decoupling Routing from Representation for Accelerated MoE Training
Yuqi Xu, Rizhen Hu, Zihan Liu, Mou Sun, Kun Yuan
Traditional Mixture-of-Experts (MoE) training typically proceeds without any structural priors, effectively requiring the model to simultaneously train expert weights while searching for an optimal routing policy within a vast combinatorial space. This entanglement often leads to sluggish convergence and training instabilities. This paper introduces Grouter a preemptive routing method that by distilling high-quality structures from fully-trained MoE models and serving as a fixed router for target models. By decoupling structural optimization from weight updates, Grouter significantly accelerates both the speed and quality of model convergence. To ensure the framework's versatility, we also introduce expert folding to adapt Grouter across varying model configurations and expert tuning to rebalance workloads across different data distributions. Furthermore, by leveraging the structural priors provided by preemptive routing, we can implement targeted optimizations to further enhance training throughput. Experiments demonstrate that Grouter achieves superior performance and efficiency which boosts pre-training data utilization by $\textbf{4.28$\times$}$ and achieves up to $\textbf{33.5$\%$}$ throughput acceleration, establishing preemptive routing as a fundamental paradigm for scalable MoE training. We publicly release our code and pretrained Grouter checkpoints.

ScoreMix: Synthetic Data Generation by Score Composition in Diffusion Models Improves Recognition
Parsa Rahimi, Sébastien Marcel
Synthetic data generation is increasingly used in machine learning for **training and data augmentation**. Yet, many current strategies rely on external foundation models or datasets, which can be restricted by policy or legal constraints, especially for sensitive modalities such as human face images and videos. We propose **ScoreMix**, a **self-contained data augmentation** method to boost recognition performance by leveraging score compositionality in class-conditioned diffusion models. ScoreMix mixes class-conditioned scores along reverse diffusion trajectories, yielding domain-specific hard augmentations without external resources. We systematically study class-selection strategies and find that mixing classes that are distant in the discriminator embedding space yields larger gains, providing **up to 3\% additional average improvement across benchmarks** over proximity-based selection. Interestingly, we observe that learned condition and embedding spaces are largely uncorrelated under standard alignment metrics, and that condition-space distances are weakly correlated to downstream gains. Across **8 public face recognition benchmarks**, ScoreMix improves accuracy by **up to 7 percentage points** without hyperparameter search, highlighting robustness and practicality. Project page: https://parsa-ra.github.io/scoremix/ .

Attention's forward pass and Frank-Wolfe
Albert Alcalde, Borjan Geshkovski, Domènec Ruiz-Balet
We analyze the hardmax limit of self-attention dynamics for token embeddings in the zero-temperature regime $(\beta \to +\infty)$ and relate it to finite-β behavior. In this limit, the update rule can be viewed as a Frank-Wolfe step for a quadratic objective over the convex hull of the current tokens. When the key-query matrix is negative semidefinite, the dynamics converge with the standard sublinear rate $\mathcal{O}(t^{-1})$ on the quadratic energy, whereas in the positive semidefinite case, extending the hardmax rule to the convex hull induces a Voronoi structure: vertices are stationary, interior points remain in their initial cells, and each token moves along a straight line toward its cell's vertex with exponential convergence under a step-size bounded away from zero. We additionally establish well-posedness of the associated ODE limit in this regime. For

finite β, we model self-attention as a Markov chain and prove *dynamic metastability*: interior tokens reach near-vertex configurations in a constant number of steps and remain trapped for times exponential in β with high probability, before eventual collapse to some point within the initial convex hull. Thus, hardmax dynamics accurately approximate the finite-β process over exponentially long time horizons.

Why Specialist Models Still Matter: A Heterogeneous Multi-Agent Paradigm for Medical Artificial Intelligence
Yanan Wang, Shuaicong Hu, Jian Liu, Guohui Zhou, Aiguo Wang, Cuiwei Yang
The impressive performance of generalist large language models (LLMs) such as GPT and Claude in healthcare raises a critical question: will domain-specific medical specialist models become obsolete? We argue that the future of medical artificial intelligence (AI) lies not in building monolithic medical foundation models, nor in replacing human expertise, but in orchestrating collaboration among generalist LLMs, domain-specific specialist models, and clinicians. We propose HetMedAgent, a heterogeneous medical multi-agent framework that enables conflict-aware evidence fusion, uncertainty-based clinician intervention triggering, and adaptive threshold calibration. Experiments on three real-world clinical decision-making tasks demonstrate that the synergy between generalist LLMs and domain-specific specialist models significantly outperforms using either type of model alone, validating the irreplaceable value of specialist models in modality-specific analysis. HetMedAgent represents a shift from building medical LLMs or foundation models to multi-agent collaboration, achieving a balance between general reasoning capabilities and domain-specific precision.

MSP: Probabilistically Consistent Multi-Scale Action Generation
Zhixuan Lin, Gengqi Liu, Chao Zheng, Gao Lin, Jindong Yu, Song Gao, Fei Wang
In robotic imitation learning, accurately modeling the multimodality and temporal correlations of long-horizon action sequences remains challenging. Long-horizon tasks require preserving global task intent while executing precise low-level control; otherwise, local errors can accumulate and lead to failure. While recent coarse-to-fine autoregressive models have improved action generation, they struggle to maintain consistency across hierarchies, leading to suboptimal performance in long-horizon tasks. To address these shortcomings, we propose Probabilistically Consistent Multi-Scale Action Generation (MSP), a novel coarse-to-fine approach that promotes cross-scale consistency. MSP adopts a streamlined multi-scale design by directly downsampling in a continuous latent space. A scale-wise autoregressive Transformer is used to generate semantic conditions at each scale, which guide a lightweight MeanFlow model to capture multi-scale latent distributions, enabling probabilistically consistent refinement across scales. Through extensive simulation and real-world experiments, including long-horizon, multi-task, and few-shot generalization settings, we show that MSP outperforms existing coarse-to-fine methods, achieving state-of-the-art performance with high efficiency.

ROAMM: A Benchmark Dataset for Multimodal Human Attention Decoding and EEG-to-Text Modeling During Naturalistic Reading
Haorui Sun, Ardyn Vivienne Olszko, Niharika Singh, David C. Jangraw
We present Reading Observed At Mindless Moments (ROAMM), a multimodal dataset comprising 50 hours of simultaneous EEG and eye-tracking recordings collected during naturalistic multi-page reading from 44 participants. ROAMM includes synchronized physiological recordings, eye-movement events, page-level comprehension scores, and span-level mind-wandering (MW) annotations obtained using a retrospective self-report paradigm. We introduce a standardized leave-one-subject-out benchmark for MW detection and achieve up to 0.609 AUROC using supervised models. We additionally evaluate EEG-to-text decoding on reading segments with and without MW labels, showing that decoding performance decreases during MW episodes. ROAMM enables research on MW detection, EEG-to-text decoding, multimodal representation learning, and attention-related degradation of language representations durin

g naturalistic reading.

DynaSchedBench: Calibrated Dynamic Scheduling Benchmarks and Observability Paradox in LLM-based Scheduling Agents
Shijie Cao, Yuan Yuan, Jing Liu
Progress in neural combinatorial optimization for Dynamic Flexible Job Shop Scheduling Problem (DFJSP) is currently hindered by a methodological tension: static benchmarks encourage benchmark overfitting, while uncalibrated generators obscure algorithmic capability with stochastic noise.
To resolve this, we introduce \textbf{DynaSchedBench}, a diagnostic framework for DFJSP that rigorously controls the instance-generation process.
Instead of relying on parameter sampling, our approach utilizes Sequential Event-Space Calibrator (SESC) that computes a novel Schedule Stress Index (SSI) to stratify instances by difficulty.
We demonstrate that SESC is substantially more computationally efficient than evolutionary baselines while converging reliably to the target metrics.
The framework integrates modular components for instance generation, snapshot-based simulation, agents, evaluation, and visualization, thereby enabling rigorous testing of reactive and lookahead-based policies.
Leveraging this calibrated environment, we identify key limitations of LLM-based scheduling agents.
Specifically, in step-wise online decision-making for dynamic scheduling, we identify an ``Observability Paradox'': providing agents with oracle access to full structural information can degrade policy performance, underperforming concise information.
Furthermore, despite substantial token overhead, tool-augmented and refinement strategies fail to reliably improve performance, and most LLM agents fail to consistently surpass strong dispatching baselines—behaving more like robust heuristic approximators than superior optimizers.

Motion-Residual Conflict-Aware Time Reversal for Generative Inbetweening
Zhenbang Zhang, Zihui Cui, Haythem El-Messiry, Renmin Han, zhiqiang xu
Image-to-video (I2V) diffusion models have recently made generative inbetweening a practical reality by synthesizing semantically plausible intermediate frames between two keyframes. Among them, inference-time sampling schemes that re-use large pre-trained I2V backbones without any additional training are especially attractive. Yet current methods frequently exhibit temporal inconsistency and artifacts such as ghosting or reverse motion. A key reason is that the two trajectories are driven by distinct motion priors, each inherited from its own conditioning frame, and are simply stitched together without explicitly reconciling these priors. We introduce Motion-Residual Conflict-Aware Time Reversal (MR■CATR), an inference-time sampling framework that aligns conflicting motion priors instead of discarding one of them or collapsing to a single start-conditioned prior. MR■CATR first derives a motion-residual–based direction from the forward path, combined with an end-conditioned residual to form a consensus motion axis. This design suppresses bidirectional motion conflicts while still allowing end-frame information to refine the trajectory and enforce endpoint consistency. MR■CATR can be seamlessly integrated into existing time-reversal samplers without changing model parameters. Experiments on generative inbetweening benchmarks show that our method produces videos with smoother motion, fewer artifacts, and consistently better quantitative scores and user preferences than prior strategies.

ForesightKV: Optimizing KV Cache Eviction for Reasoning Models by Learning Long-Term Contribution
Zican Dong, Peiyu Liu, Junyi Li, Zhipeng Chen, Han Peng, Shuo Wang, Xin Zhao
Recently, large language models (LLMs) have shown remarkable reasoning abilities by producing long reasoning traces. However, as the sequence length grows, the key-value (KV) cache expands linearly, incurring significant memory and computation costs. Existing KV cache eviction methods mitigate this issue by discarding less important KV pairs, but often fail to capture complex KV dependencies, resu

lting in performance degradation. To better balance efficiency and performance, we introduce ForesightKV, a training-based KV cache eviction framework that learns to predict which KV pairs to evict during long-text generations.
We first design the Golden Eviction algorithm, which identifies the optimal eviction KV pairs at each step using future attention scores. These traces and the scores at each step are then distilled via supervised training with a Pairwise Ranking Loss. Furthermore, we formulate cache eviction as a Markov Decision Process and apply the GRPO algorithm to mitigate the significant language modeling loss increase on low-entropy tokens.
Experiments on AIME2024 and AIME2025 benchmarks of three reasoning models demonstrate that ForesightKV consistently outperforms prior methods under only half the cache budget, while benefiting synergistically from both supervised and reinforcement learning approaches. Code is available at \url{https://github.com/RUCAIBox/ForesightKV}.

Policies Permitting LLM Use for Polishing Peer Reviews Are Currently Not Enforceable
Rounak Saha, Gurusha Juneja, Dayita Chaudhuri, Naveeja Sajeevan, Nihar B Shah, Danish Pruthi
A number of scientific conferences and journals have recently enacted policies that prohibit LLM usage by peer reviewers, except for polishing, paraphrasing, and grammar correction of otherwise human-written reviews. But, are these policies enforceable? To answer this question, we assemble a dataset of peer reviews simulating multiple levels of human-AI collaboration, and evaluate five state-of-the-art detectors, including two commercial systems. Our analysis shows that all detectors misclassify a non-trivial fraction of LLM-polished reviews as AI-generated, thereby risking false accusations of academic misconduct. We further investigate whether peer-review-specific signals, including access to the paper manuscript and the constrained domain of scientific writing, can be leveraged to improve detection. While incorporating such signals yields measurable gains in some settings, we identify limitations in each approach and find that none meets the accuracy standards required for identifying AI use in peer reviews. Importantly, our results suggest that recent public estimates of AI use in peer reviews through the use of current AI-text detectors should be interpreted with caution, as they misclassify mixed reviews (collaborative human-AI outputs) as fully AI generated, potentially overstating the extent of policy violations.
****
Q-CLIP: Unleashing the Power of Vision-Language Models for Video Quality Assessment through Unified Cross-Modal Adaptation
Yachun Mi, Yu Li, Yanting Li, Chen Hui, Tong Zhang, Zhixuan Li, Chenyue Song, Wei Yang Bryan Lim, Shaohui Liu
Accurate and efficient Video Quality Assessment (VQA) has long been a key research challenge. Current mainstream VQA methods typically improve performance by pretraining on large-scale classification datasets, followed by fine-tuning on VQA datasets. However, this strategy presents two significant challenges: (1) merely transferring semantic knowledge learned from pretraining is insufficient for VQA, as video quality depends on multiple factors (e.g., semantics, distortion, motion); (2) pretraining on large-scale datasets demands enormous computational resources, often dozens to hundreds of times more than training on VQA datasets. Recently, Contrastive Vision-Language Models (CVLMs) have shown strong generalization across visual tasks and promising potential for quality assessment. In this work, we propose Q-CLIP, the first fully CVLMs-based framework for VQA. Q-CLIP enhances both visual and textual representations through a Shared Cross-Modal Adapter (SCMA), which contains only a minimal number of trainable parameters and is the only component that requires training. This design significantly reduces computational cost. In addition, we introduce a set of five learnable quality-level prompts to guide the CVLMs in perceiving subtle quality variations. Furthermore, we investigate the impact of different frame sampling strategies on VQA performance. Extensive experiments demonstrate that Q-CLIP exhibits excellent performance on several VQA datasets. Code: https://github.com/xiao-mi-d/Q-CLIP

****
Verbalized Sampling: How to Mitigate Mode Collapse and Unlock LLM Diversity
Jiayi Zhang, Simon Yu, Derek Chong, Anthony Sicilia, Michael Tomz, Christopher D Manning, Weiyan Shi
Post-training alignment often reduces LLM diversity, leading to a phenomenon known as mode collapse. Unlike prior work that attributes this effect to algorithmic limitations, we identify a fundamental, pervasive data-level driver: typicality bias in preference data, whereby annotators systematically favor familiar text as a result of well-established findings in cognitive psychology. We formalize this bias theoretically, verify it empirically on preference datasets, and show that it plays a central role in mode collapse. Motivated by this analysis, we introduce Verbalized Sampling (VS), a simple, training-free prompting strategy to circumvent mode collapse. VS prompts the model to verbalize a probability distribution over a set of responses (e.g., "Generate 5 jokes about coffee and their corresponding probabilities"), which relieves the pressure to produce a single "typical" answer. Experiments show that VS significantly improves performance across creative writing (poems, stories, jokes), social dialogue simulation, synthetic data generation, and open-ended QA, without sacrificing safety and factual accuracy. For instance, in creative writing, VS increases diversity by 1.6-2.1x compared to direct prompting. We further observe an emergent trend that more capable models benefit more from VS. In sum, our work provides a new data-centric perspective on mode collapse and a practical inference-time remedy that helps unlock pre-trained generative diversity.
****
Robust Bayesian Optimisation with Unbounded Corruptions
Abdelhamid Ezzerg, Ilija Bogunovic, Jeremias Knoblauch
Bayesian Optimization is critically vulnerable to extreme outliers. Existing provably robust methods typically assume a bounded cumulative corruption budget, which makes them defenseless against even a single corruption of sufficient magnitude. To address this, we introduce a new adversary whose budget is only bounded in the frequency of corruptions, not in their magnitude. We then derive RCGP-UCB, an algorithm coupling the upper confidence bound (UCB) approach with a Robust Conjugate Gaussian Process (RCGP). We present stable and adaptive versions of RCGP-UCB, and prove that they achieve sublinear regret in the presence of up to $O(T^{1/4})$ and $O(T^{1/7})$ corruptions with possibly infinite magnitude. This robustness comes at near zero cost: without outliers, RCGP-UCB's regret bounds match those of the standard GP-UCB algorithm.
****
Quantile-Free Uncertainty Quantification in Graph Neural Networks
Soyoung Park, Hwanjun Song, Sungsu Lim
Uncertainty quantification (UQ) in graph neural networks (GNNs) is crucial in high-stakes domains but remains a significant challenge. In graph settings, message passing often relies on strong assumptions such as exchangeability, which are rarely satisfied in practice. Moreover, achieving reliable UQ typically requires costly resampling or post-hoc calibration. To address these issues, we introduce Quantile-free Prediction Interval GNN (QpiGNN), a framework that builds on quantile regression (QR) to enable GNN-based UQ by directly optimizing coverage and interval width without requiring quantile inputs or post-processing. QpiGNN employs a dual-head architecture that decouples prediction and uncertainty, and is trained with label-only supervision through a quantile-free joint loss. This design allows efficient training and yields robust prediction intervals, with theoretical guarantees of asymptotic coverage and near-optimal width under mild assumptions. Experiments on 19 synthetic and real-world benchmarks show QpiGNN achieves average 22% higher coverage and 50% narrower intervals than baselines, while ensuring efficiency and robustness to noise and structural shifts.
****
Solving Positive Linear Programs with Differential Privacy
Alina Ene, Huy Nguyen, Ta Duy Nguyen, Adrian Vladu
We study differentially private approximation algorithms for positive linear programs (LPs with nonnegative coefficients and variables), focusing on the fundame

ntal families of packing, covering, and mixed packing-covering formulations. We focus on the high-sensitivity, constraint-private regime of Hsu-Roth-Roughgarden-Ullman (ICALP 2014), where neighboring instances may differ by an arbitrary single constraint, so one cannot hope to approximately satisfy every constraint under privacy. We give private solvers that return approximate solutions while violating only a controlled number of constraints. Our algorithms improve the prior instance-dependent guarantees, and also yield new data-independent bounds that depend only on the dimension. Our techniques involve a dense multiplicative weights update method developed from a regularized dual viewpoint, which we analyze in a way that exploits structure specific to positive LPs.

****

Optimizing Inference-Time Compute for Medical Reasoning via Uncertainty Quantification

Shaohao Rui, Kaitao Chen, Weijie Ma, Xiaosong Wang

Extended Chain-of-Thought (CoT) reasoning has significantly bolstered the capabilities of medical large language models (LLMs). However, current models exhibit static computational expenditure, applying lengthy reasoning processes indiscriminately to both simple queries and complex diagnostic cases. This inefficiency is particularly prohibitive in real-world healthcare, where clinical scenarios range from time-sensitive emergencies requiring rapid response to intricate pathologies demanding deep analysis. To address this, we propose **AdaThink-Med**, an end-to-end framework for adaptive reasoning via uncertainty-guided length calibration. Although the underlying mechanism is generalizable, we demonstrate its critical value in the medical domain, where balancing inference latency with diagnostic precision is paramount. AdaThink-Med leverages entropy-based uncertainty estimation within reinforcement fine-tuning to dynamically shape reward signals: it penalizes verbosity for high-confidence correct answers (e.g., straightforward knowledge retrieval) while incentivizing extended exploration for uncertain or ambiguous scenarios. Across six medical benchmarks, AdaThink-Med reduces inference token consumption by **4.7× to 6.4×** on Qwen and Llama architectures, respectively, with minimal performance trade-offs. Notably, our reward design naturally produces distinct "non-thinking" and "thinking" modes within a single model, enabling efficient allocation of computational resources without any external router or classifier.

The Forgetting-Retention Dilemma: Certified Unlearning Theory in Continual Learning

Yiting Hu, Lingjie Duan, Qian Zhang

Machine unlearning aims to eliminate the influence of specific data from trained models to safeguard privacy. However, this presents a significant challenge in the context of continual learning (CL), where models update sequentially on dynamic datasets. A major limitation is that current certified unlearning algorithms fail to account for the complex, cumulative model evolution inherent to CL framework. In this work, we establish the first theoretical foundation bridging CL and machine unlearning. We formulate the CL's unlearning objective as the minimization of post-unlearning excess risk, which decomposes into CL excess risk and unlearning loss, characterizing the fundamental trade-off between preserving historical knowledge and targeted forgetting. Under mild assumptions, we first establish an upper bound for the CL excess risk in non-convex models. We then adapt two certified unlearning approaches, gradient-based and Hessian-based, to the CL framework. Our analysis reveals that while the gradient-based approach is less effective than the Hessian-based method in minimizing unlearning loss, it offers the distinct advantage of nearly zero storage overhead for enabling unlearning. This insight motivates a hybrid strategy that reduces storage costs while maintaining post-unlearning performance. Experimental results further validate our theoretical findings.

Diffusion Flow Matching: Dimension-Improved KL Bounds and Wasserstein Guarantees

Marta Gentiloni Silveri, Giovanni Conforti, Alain Oliviero Durmus

Diffusion Flow Matching (DFM) has recently emerged as a versatile framework for

generative modeling, yet its theoretical convergence properties remain only partially understood. In this work, we provide refined and novel convergence guarantees for Brownian motion based DFMs, focusing on the discretization error. Our analysis is conducted under the Kullback–Leibler (KL) divergence and the 2-Wasserstein distance. Under finite-moment conditions and a mild score integrability assumption, we derive KL convergence bounds with improved dimensional dependence compared to prior work, achieving, up to our knowledge, state-of-the-art scaling under minimal conditions. We further extend the analysis to the 2-Wasserstein distance: under an additional first-order score integrability assumption and a weak log-concavity condition, we obtain convergence guarantees with dimensional dependence consistent with the KL case.
****

From 2D Grids to 1D Tokens: Reforming Shared Representations for Multimodal Image Fusion
Yuchen Xian, Yunqiu Xu, Yang He, Yi Yang
Multimodal image fusion aims to integrate complementary information from different modalities into a fused image that preserves rich local details while maintaining globally consistent appearance. Existing approaches build shared representations on 2D feature grids, which excel at modeling local structures but offer limited leverage over image-level global appearance factors. To balance these objectives, we introduce a compact 1D token interface based on a frozen pretrained image tokenizer for modeling non-local appearance/base factors. Rather than using the tokenizer as a reconstruction backbone, our design uses the 1D token space as a global carrier while retaining the 2D spatial pathway for local structure restoration. Specifically, we introduce Selective Token Editing (STE), which sparsely updates/replaces a small set of critical tokens, providing a lightweight mechanism to steer global appearance coherence while keeping the fusion backbone unchanged and avoiding extra losses. Experiments on four commonly used benchmarks show that our method achieves the best overall performance, with consistent, multi-metric improvements in both global coherence and local fidelity. Project page: https://zju-xyc.github.io/1D-Fusion-Project-Page/

Q-Tab: Quantized Tabular Data Generator
Julian Wustl, Philipp Haid, Yarema Okhrin, Claudius Schnörr
Codebook-based generators built on masked language model (MLM) transformers have become highly effective in text and vision, yet remain underused for tabular data. This is because codebooks typically act as information bottlenecks, whereas synthetic tabular generation requires a code space larger than the training sample, with additional codes trained to support new tabular rows. We address this gap with Q-Tab, a codebook-based tabular generator that uses lookup-free quantization (LFQ) with residual corruption to jointly tokenize numerical variables, categorical variables are directly one-hot tokenized. A BERT-style MLM captures dependencies in the token space and can then be sampled from. Corruption propagates reconstruction supervision across the numerical code space, but under joint encoder–decoder training induces a moving-target regression problem whose difficulty depends on the corruption structure. This motivates residual LFQ as the quantization mechanism, balancing broader supervision with locality. Q-Tab achieves state-of-the-art predictive utility and label prediction, while matching the distributional fidelity of diffusion-based generators.

Estimating Continuous Treatment Effects with Two-Stage Kernel Ridge Regression
Seok-Jin Kim, Kaizheng Wang
We study the problem of estimating the effect function for a continuous treatment, which maps each treatment value to a population-averaged outcome. A central challenge in this setting is confounding: treatment assignment often depends on covariates, creating selection bias that makes direct regression of the response on treatment unreliable. To address this issue, we propose a two-stage kernel ridge regression method. In the first stage, we learn a model for the response as a function of both treatment and covariates; in the second stage, we use this model to construct pseudo-outcomes that correct for distribution shift, and then f

it a second model to estimate the treatment effect. Although the response varies with both treatment and covariates, the induced effect function obtained by averaging over covariates is typically much simpler, and our estimator adapts to this structure. Our optimal learning bounds are achieved without estimating the conditional treatment density, thereby bypassing a major bottleneck in existing methods. Furthermore, we introduce a fully data-driven model selection procedure that achieves provable adaptivity to both the unknown degree of overlap and the spectral decay of the underlying kernel.
****
AGZO: Activation-Guided Zeroth-Order Optimization for LLM Fine-Tuning
Wei Lin, Yining Jiang, Qingyu Song, Qiao Xiang, Hong Xu
Zeroth-Order (ZO) optimization has emerged as a promising solution for fine-tuning LLMs under strict memory constraints, as it avoids the prohibitive memory cost of storing activations for backpropagation. However, existing ZO methods typically employ isotropic perturbations, neglecting the rich structural information available during the forward pass. In this paper, we identify a crucial link between gradient formation and activation structure: the gradient of a linear layer is confined to the subspace spanned by its input activations. Leveraging this insight, we propose Activation-Guided Zeroth-Order optimization (AGZO). Unlike prior methods, AGZO extracts a compact, activation-informed subspace on the fly during the forward pass and restricts perturbations to this low-rank subspace. We provide a theoretical framework showing that AGZO optimizes a subspace-smoothed objective and provably yields update directions with higher cosine similarity to the true gradient than isotropic baselines. Empirically, we evaluate AGZO on Qwen3 and Pangu models across various benchmarks. AGZO consistently outperforms state-of-the-art ZO baselines and significantly narrows the performance gap with first-order fine-tuning, while maintaining almost the same peak memory footprint as other ZO methods.
****
TapSampling: Inference-Time Sampling with a Task-Progress-Understanding Verifier for Robotic Manipulation
Sizhe Zhao, Shengping Zhang, Shuo Yang, Weiyu Zhao, Shuigen Wang, Xiangyang Ji
Existing embodied control research demonstrates remarkable performance improvements by scaling training data and model size.
We instead explore inference-time strategy as an alternative axis. Non-deterministic generative models, such as diffusion and autoregressive models, have been widely adopted in the field of embodied control. However, the single-shot inference paradigm limits their performance. In this paper, we propose **TapSampling**, a plug-and-play framework for inference-time sampling. First, we introduce an Action-VAE that represents actions in a low-dimensional latent space by mapping policy-generated initial actions into a compressed posterior distribution, from which any number of latent samples can be drawn and decoded into candidate actions that approximate the true action distribution. Second, we formulate action verification as task-progress outcome prediction, using the intrinsic sequential structure of robotic datasets to train a semantically grounded verifier for interpretable action selection. Furthermore, TapSampling is a policy-agnostic framework. Extensive experiments in both simulated and real-world environments demonstrate that our method substantially improves multiple generalist policies without further policy finetuning. Code and models are available at the **project page** (https://aipixel.github.io/TapSampling/).

AutoMS: Multi-Agent Evolutionary Search for Cross-Physics Inverse Microstructure Design
Zhenyuan Zhao, Yu Xing, Tianyang Xue, Lingxin Cao, Xin Yan, Lin Lu
Designing microstructures with coupled cross-physics objectives is a fundamental challenge where traditional topology optimization is often computationally prohibitive and deep generative models frequently suffer from physical hallucinations. We introduce AutoMS, a multi-agent neuro-symbolic framework that reformulates inverse design as an LLM-driven evolutionary search. AutoMS leverages LLMs as semantic navigators to decompose complex requirements and coordinate agent workfl

ows, while a novel Simulation-Aware Evolutionary Search (SAES) mechanism handles low-level numerical optimization via local gradient approximation and directed parameter updates. This architecture achieves a state-of-the-art 83.8\% success rate on 17 diverse cross-physics tasks, significantly outperforming both traditional evolutionary algorithms and existing agentic baselines.
By decoupling open-ended semantic orchestration from simulation-grounded numerical search, AutoMS provides a robust pathway for navigating complex physical landscapes that remain intractable for standard generative or purely linguistic approaches.

Condition-Aware Graph Flow Matching for Modeling the Distributions of Complex Fluid Systems
Xiaochao Deng, Jie Chen, Xiaogang Deng
Accurately modeling the full distributions of possible states is crucial for understanding statistical properties and enabling reliable predictions in complex fluid systems. Recently, diffusion models and flow matching have shown promise in these tasks. However, they remain limited in uncovering the general principles of systems from multiple short trajectories across the condition space. In addition, they exhibit inferior adaptability to large irregular geometries, particularly in regions with sharp gradients. In this paper, we propose a condition-aware graph flow matching (CGFM) method that combines condition-aware flow matching with a hierarchical graph structure to learn the full distributions of fluid systems from incomplete training data. Specifically, CGFM constructs a flow enabling smooth interpolation across physical conditions and parameterizes the graph-conditioned vector field through HieraGraphNet. HieraGraphNet performs message passing across multilevel graphs to capture multi-scale dynamics and facilitate long-range information interactions in fluid systems. Moreover, we introduce a topology- and geometry-aware graph coarsening scheme that incorporates topological connectivity and local geometric density to construct reliable coarse graphs. We validate the effectiveness of CGFM on three canonical scenarios across both 2D and 3D dynamics, which demonstrate its superior performance compared with that of state-of-the-art baselines.

Token-Level LLM Collaboration via FusionRoute
Nuoya Xiong, Yuhang Zhou, Hanqing Zeng, Zhaorun Chen, Furong Huang, Shuchao Bi, Lizhu Zhang, Zhuokai Zhao
Large language models (LLMs) exhibit strengths across diverse domains. However, achieving strong performance across these domains with a single general-purpose model typically requires scaling to sizes that are prohibitively expensive to train and deploy. On the other hand, while smaller domain-specialized models are much more efficient, they struggle to generalize beyond their training distributions. To address this dilemma, we propose FusionRoute, a robust and effective token-level multi-LLM collaboration framework in which a lightweight router simultaneously (i) selects the most suitable expert at each decoding step and (ii) contributes a complementary logit that refines or corrects the selected expert’s next-token distribution via logit addition. Unlike existing token-level collaboration methods that rely solely on fixed expert outputs, we provide a theoretical analysis showing that pure expert-only routing is fundamentally limited: unless strong global coverage assumptions hold, it cannot in general realize the optimal decoding policy. By augmenting expert selection with a trainable complementary generator, FusionRoute expands the effective policy class and enables recovery of optimal value functions under mild conditions. Empirically, across both Llama-3 and Gemma-2 families and diverse benchmarks spanning mathematical reasoning, code generation, and instruction following, FusionRoute outperforms both sequence- and token-level collaboration, model merging,
and direct fine-tuning, while remaining competitive with domain experts on their respective tasks.

RaBitQCache: Rotated Binary Quantization for KVCache in Long Context LLM Inference

Wenhao Li, Jinhao Dong, Hailin Zhang, Wenhang Shi, WEI LU, Xiaoyong Du
Long-context Large Language Model inference is severely bottlenecked by the massive Key-Value (KV) cache, yet existing sparse attention methods often suffer from static fixed-budget (Top-k) retrieval or rely on proxy scores that are computationally expensive and biased. To address these limitations, we propose RaBitQCache, a novel sparse attention framework that utilizes randomized rotated binary quantization and high-throughput binary-INT4 arithmetic to efficiently estimate attention weights. Our proxy score serves as an unbiased estimator with a proven error bound, enabling adaptive Top-p retrieval that dynamically adjusts the token budget based on actual attention sparsity. We further implement a hardware-aware system with asynchronous pipelining and lazy updates to mask overhead. Evaluations demonstrate that RaBitQCache significantly accelerates inference and reduces memory I/O while preserving generation quality compared to state-of-the-art baselines. Code is available at https://github.com/Sakuraaa0/RaBitQCache.git.

Target-Agnostic Calibration under Distribution Shift with Frequency-Aware Gradient Rectification
Yilin Zhang, Cai Xu, You Wu, Ziyu Guan, Wei Zhao
Real-world model deployments inevitably encounter distribution shifts, rendering the confidence estimates of deep neural networks highly unreliable, posing severe risks in safety-critical applications. Existing methods improve calibration via training-time regularization or post-hoc adjustment, but often rely on access to (or simulation of) target domains, limiting practicality. We propose Frequency-aware Gradient Rectification (FGR), a target-agnostic training framework for robust calibration. From a frequency perspective, FGR applies low-pass filtering to a subset of training images to diminish spurious high-frequency cues and encourage the learning of domain-invariant features. However, the associated information loss can degrade In-Distribution (ID) calibration. To resolve this trade-off, FGR treats ID calibration as a hard constraint and rectifies conflicting parameter updates via geometric projection. This ensures a first-order non-increase in the ID calibration objective without introducing an additional loss-balancing coefficient. Extensive experiments on synthetic, real-world, and semantic shift datasets demonstrate that FGR significantly improves calibration under diverse shifts while preserving ID performance, and it remains compatible with post-hoc calibration methods. Our code is available at https://github.com/YilinZhang107/FGR-Calib.

Towards Spectroscopy: Susceptibility Clusters in Language Models
Andrew Gordon, Garrett Baker, George Wang, William Snell, Stan van Wingerden, Daniel Murfet
Spectroscopy infers the internal structure of physical systems by measuring their response to perturbations. We apply this principle to neural networks: perturbing the data distribution by upweighting a token y in context x, we measure the model's response via susceptibilities χ_{xy}, which are covariances between component-level observables and the perturbation computed over a localized Gibbs posterior via stochastic gradient Langevin dynamics (SGLD). Theoretically, we show that susceptibilities decompose as a sum over \emph{modes} of the data distribution, explaining why tokens that follow their contexts ``for similar reasons'' cluster together in susceptibility space. Empirically, we apply this methodology to Pythia-14M, developing a conductance-based clustering algorithm that identifies 510 interpretable clusters ranging from grammatical patterns to code structure to mathematical notation. Comparing to sparse autoencoders, 50\% of our clusters match SAE features, validating that both methods recover similar structure.

Initialization is Half the Battle: Generating Diverse Images from a Guidance Potential Posterior
Xiang Li, Dianbo Liu, Kenji Kawaguchi
Despite the remarkable fidelity of generative models, they frequently suffer from mode collapse. Existing strategies for enhancing diversity predominantly focus

on intervening during the generation trajectory. We identify a critical oversig
ht that the standard Gaussian initialization often causes trajectories to collap
se into dominant modes because it is agnostic to the guidance potential landscap
e. In this work, we formulate selecting the initial noise from a *guidance poten
tial posterior*, which effectively re-weights the prior towards diversity-rich r
egions. To sample from this distribution efficiently, we introduce *Diversity-in
ducing Initialization* (DivIn), which leverages Langevin dynamics to actively na
vigate the initialization landscape, steering initial noise away from collapsing
regions while anchoring them to the valid data manifold. Our method serves as a
n inference-time diversity enhancement compatible with both diffusion and flow m
atching models. Extensive experiments show that DivIn exhibits a superior perfor
mance in both class-to-image and text-to-image scenarios.
Furthermore, we highlight that as DivIn is orthogonal to trajectory-based method
s, combining them significantly expands the diversity-quality Pareto frontier be
yond what either achieves in isolation.

How to Avoid Debate: Scalable AI Safety via Doubly-Efficient Interactive Proofs
Liyan Chen, Yael Tauman Kalai, Zoe Xi
As AI models continue to develop powerful
capabilities, it becomes critical that we are able to
verify that their output is aligned with our intentions. A recent line of work
focuses on
verification via debate, a model
of interactive proofs where two competing powerful provers, or AI
models, debate each other to convince a weak verifier, or a human,
of the correctness of their claim. However, debate assumes that the two AI mod
els possess equal abilities and that one of them is truthful, which may not be r
ealistic.

In this work, we show *how to avoid debate*: we
initiate the study of *single-prover*
interactive proofs for AI safety.
Prior results in single-prover interactive proofs do not immediately
carry over to the AI safety setting because they do not work when the computat
ion has access to an oracle, such as to human judgment or an external database s
uch as the web.
We present doubly-efficient
single-prover interactive proofs for oracle-aided computations (also known as
relativizing proofs), in the settings where (1) the
computation is robust, in the sense that the output does not change
if at most a small fraction of the answers to oracle queries are
incorrect, or (2) the oracle is a low-degree polynomial. These results suggest
that interactive verification is possible even without debate, under structured
or noise-tolerant oracle access.

What You Think is What You See: Driving Exploration in VLM Agents via Visual-Lin
guistic Curiosity
Haoxi Li, Qinglin Hou, Jianfei Ma, Jinxiang Lai, Tao Han, Sikai Bai, Jingcai Guo
, Jie ZHANG, Song Guo
To navigate partially observable visual environments, recent VLM agents increasi
ngly internalize world modeling capabilities directly into their policies via ex
plicit CoT reasoning with reinforcement learning (RL). However, mere passive exp
loitation of reasoning on visited states is insufficient for sparse-reward agent
ic tasks, as it lacks the epistemic drive to actively uncover the *known unknown
* required for robust generalization. We ask: *Can VLM agents actively find sign
als that challenge and update their internal world model through curiosity-drive
n exploration?* In this work, we propose **GLANCE**, a unified framework that br
idges reasoning and exploration by grounding the agent's linguistic world model
into the stable visual representations of an evolving target network. Crucially,
GLANCE leverages the discrepancy between linguistic prediction and visual r

eality as an intrinsic curiosity signal within reinforcement learning, steering the agent to actively explore areas where its internal model is uncertain. Exten sive experiments across a series of agentic tasks show the effectiveness of **GL ANCE**, and demonstrate that aligning *what the agent thinks* with *what the age nt sees* is key to solving complex or sparse agentic tasks.

Textual Stochastic Gradient Descent: Discrete Optimization of External Memory fo r Reasoning Language Agents
Jian Li, Hua Huang
While Large Language Models (LLMs) possess strong reasoning capabilities, enabli ng them to learn continuously from experience without parametric retraining rema ins an open challenge. Existing Retrieval-Augmented Generation (RAG) approaches typically treat memory as a static or append-only corpus, leading to "memory sat uration," where accumulating noise and redundant information degrade performance over time. To address this, we propose an Experience Library Optimization frame work that treats the agent's external memory, which we call the experience libra ry, as a learnable parameter under an explicit capacity budget. We introduce Tex tual Stochastic Gradient Descent (TSGD), a discrete optimization algorithm that refines this library via failure-driven Add, Edit, and Delete operations. TSGD e stimates "textual gradients" through self-reflection and uses a dual-verificatio n mechanism to ensure generalization, which prevents overfitting to local errors . Empirical results on MATH and AIME benchmarks show that TSGD achieves state-of -the-art performance, improving accuracy by up to 18.7% over zero-shot baseli nes and substantially outperforming static RAG, while keeping a compact memory f ootprint (compressing hundreds of experiences into ≈ 30 high-utility rul es).

LILO: Bayesian Optimization with Natural Language Feedback
Kasia Kobalczyk, Zhiyuan Jerry Lin, Benjamin Letham, Zhuokai Zhao, Maximilian Ba landat, Eytan Bakshy
Many real-world optimization problems are guided by complex, subjective preferen ces that are difficult to express as explicit closed-form objectives. In respons e, we introduce Language-in-the-Loop Optimization (LILO), a Bayesian optimizatio n (BO) framework that employs a large language model (LLM) to translate free-for m natural language feedback and prior knowledge from a decision maker into struc tured preference signals, going beyond the restrictive scalar or pairwise feedba ck formats typically assumed in preferential BO. The LLM-derived preferences are integrated by a Gaussian process proxy model, enabling principled acquisition-d riven exploration with calibrated uncertainty. By placing the LLM in a supportin g role rather than as the optimizer itself, LILO preserves the sample efficiency and stability of BO while providing a flexible and expressive feedback interfac e. Across synthetic and real-world benchmarks, LILO consistently outperforms bot h conventional preference-based BO methods and LLM-only optimizers, with particu larly strong gains in feedback-limited regimes. The code for reproducing our exp erimental results is available at: https://github.com/facebookresearch/lilo.

Intervene When It Doubts: Conjunction-Guided Interactive Reasoning
Qianyue Wang, Jinwu Hu, Yaofo Chen, Yufeng Wang, Bailin Chen, Huanxiang Lin, Yu Rong, Yuanqing Li, Zhiquan Wen, Mingkui Tan
Large Reasoning Models (LRMs) excel at complex reasoning but suffer from ineffic ient reasoning, like overthinking and overshoot. These issues stem from excessiv e or misdirected reasoning triggered by the model's "doubt", manifested as self- validation and exploratory extension, increasing computational cost and degradin g performance. Existing efficient reasoning methods seek to regulate reasoning v ia internal signals or static schedules, lacking specialization in the "doubt" c haracteristics of LRMs. To address this, we propose a Conjunction-Guided Interve ntion (CGI) reasoning framework that intervenes when the model shows signs of do ubt. Our key insight is that overthinking and overshoot in LRMs arise from conju nction-triggered extensions where LRMs exhibit "doubt" through transitional conj unctions, extending redundant self-validation and exploration without timely sta

te-based correction. Building on this insight, CGI pauses reasoning at conjuncti on markers of doubt for external state-based feedback, adaptively extending or t erminating reasoning to reduce redundancy while preserving accuracy. The feedbac k is generated via criteria evaluation (rationality and completeness) and comes from either human or LLM proxies. We train the target model by Group Relative Po licy Optimization (GRPO) to adapt to the interactive mode. Experiments show that our framework achieves a superior balance between accuracy and reasoning length .

Learning Multi-Timescale Abstractions for Hierarchical Combinatorial Planning

Vivienne Huiling Wang, Tinghuai Wang, Joni Pajarinen

The combination of exponentially large action spaces, stochastic dynamics, and l ong-horizon decision-making under limited resources makes Sequential Stochastic Combinatorial Optimization (SSCO) particularly challenging for reinforcement lea rning. Hierarchical Reinforcement Learning (HRL) offers a natural decomposition, but it places the high-level policy in a Semi-Markov Decision Process (SMDP) wh ere actions have variable durations, making it difficult to learn a world model that is suitable for planning. We introduce a model-based hierarchical framework for sequential stochastic combinatorial decision-making that directly addresses this issue. Our method combines a latent-space tree-search planner with an SMDP -aware world model for variable-duration decisions. A multi-timescale objective structures the latent dynamics so that transition magnitudes reflect the effecti ve temporal scales of abstract actions, enabling efficient lookahead under adapt ive temporal abstraction. We further learn a subgoal-conditioned budget policy j ointly with the world model to support context-aware resource allocation. Across challenging SSCO benchmarks, our method outperforms strong baselines.

Generative Large Neighborhood Search: Scalable Set Cover Optimization via Discre te Diffusion

Achref Jaziri, Thibaut Cuvelier, Bruno Adrien De Backer

Large-scale Set Cover Problems (SCP) with millions of variables and complex cost structures require high-quality solutions within seconds, yet remain beyond the reach of exact solvers and pose severe generalization challenges for neural met hods. Such problems necessitate decomposition into bounded subproblems; however, when the induced subproblem topology differs from that observed during training , existing neural approaches often fail to transfer reliably.

We introduce Generative Large Neighborhood Search (GLNS), which reframes neighbo rhood selection as generation using a discrete diffusion model. Our key insight is that the diffusion denoising trajectory exposes variables exhibiting high pre diction instability across timesteps and identifies regions where local repair y ields downstream improvement. GLNS exploits this trajectory-level signal to cons truct high-impact neighborhoods via a localized, bounded-complexity generative s ampling procedure, enabling robust neighborhood selection without retraining. As a result, GLNS transfers effectively across cost regimes and instance scales wi thin SCP. Under tight and equal wall-clock budgets, GLNS consistently outperform s established neural baselines and achieves competitive performance with state-o f-the-art MIP solvers. These results demonstrate trajectory-guided generation as a scalable framework for large-scale SCP and suggest potential relevance to oth er constrained optimization settings.

Memora: A Harmonic Memory Representation Balancing Abstraction and Specificity

Menglin Xia, Xuchao Zhang, Shantanu Dixit, Paramaguru Harimurugan, Rujia Wang, V ictor Rühle, Robert Sim, Chetan Bansal, Saravan Rajmohan

Agent memory systems must accommodate continuously growing information while sup porting efficient, context-aware retrieval for downstream tasks. Abstraction is essential for scaling agent memory, yet it often comes at the cost of specificit y, obscuring the fine-grained details required for effective reasoning. We intro duce Memora, a harmonic memory representation that structurally balances abstrac tion and specificity. Memora organizes information via its *primary abstractions * that index concrete memory values and consolidate related updates into unified

memory entries, while *cue anchors* expand retrieval access across diverse aspects of the memory and connect related memories. Building on this structure, we employ a retrieval policy that actively exploits these memory connections to retrieve relevant information beyond direct semantic similarity. Theoretically, we show that standard Retrieval-Augmented Generation (RAG) and Knowledge Graph (KG)-based memory systems emerge as special cases of our framework. Empirically, Memora establishes a new state-of-the-art on the LoCoMo and LongMemEval benchmarks, demonstrating better retrieval relevance and reasoning effectiveness as memory scales.

****

MAMBO-G: Magnitude-Aware Mitigation for Boosted Guidance

Shangwen Zhu, Qianyu Peng, Zhilei Shu, Yuting Hu, Han Zhang, Andy Zheng, Xinyu Cui, Jian Zhao, Ruili Feng, Fan Cheng

High-fidelity text-to-image and text-to-video generation typically relies on Classifier-Free Guidance (CFG), but achieving optimal results often demands computationally expensive sampling schedules. In this work, we propose MAMBO-G, a training-free acceleration framework that significantly reduces computational cost by dynamically optimizing guidance magnitudes. We observe that standard CFG schedules are inefficient, applying disproportionately large updates in early steps that hinder convergence speed. MAMBO-G mitigates this by modulating the guidance scale based on the update-to-prediction magnitude ratio, effectively stabilizing the trajectory and enabling rapid convergence. This efficiency is particularly vital for resource-intensive tasks like video generation. Our method serves as a universal plug-and-play accelerator, achieving up to 3$\times$ speedup on Stable Diffusion v3.5 (SD3.5) and 4$\times$ on Lumina. Most notably, MAMBO-G accelerates the 14B-parameter Wan2.1 video model by 2$\times$ while preserving visual fidelity, offering a practical solution for efficient large-scale video synthesis. Our implementation follows a mainstream open-source diffusion framework and is plug-and-play with existing pipelines.

****

Stop When Further Reasoning Won’t Help: Attention-State Adaptive Generation in Reasoning Models

Jiakai Li, Ke Qin, Rongzheng Wang, Yizhuo Ma, Qizhi Chen, Muquan Li, Shuang Liang

By incorporating test-time compute scaling, large reasoning models (LRMs) can solve complex problems through explicit chain-of-thought (CoT) reasoning processes.

However, they often suffer from overthinking, resulting in redundant token outputs and degraded accuracy.

Current methods to mitigate this issue remain limited: training-based approaches require substantial computational resources, while training-free methods rely on well-crafted prompts or unreliable confidence signals.

In this work, we investigate early stopping from the perspective of attention distributions and propose a simple method, ASAG, which infers the model's reasoning state and adaptively adjusts the generation strategy.

The proposed framework is training-free and plug-and-play, enabling seamless integration into existing LRMs.

Extensive experiments on nine benchmarks demonstrate consistent improvements across mainstream LRMs with varying parameter scales, including the DeepSeek-R1-Distill and Qwen3 series.

Specifically, ASAG improves average accuracy by 3.2% while reducing the number of generated tokens by nearly 40% across all reasoning tasks on Qwen3-8B.

VeRO: A Harness for Agents to Optimize Agents

Varun Ursekar, Apaar Shanker, Veronica Chatrath, Yuan Xue, Samuel Marc Denton

An important emerging application of coding agents is *agent harness optimization*: the iterative improvement of a *target agent* by editing and evaluating its code. Despite its relevance, the community lacks a systematic understanding of coding agent performance on this task. Harness optimization differs from conventional software engineering: agent harnesses interleave deterministic code with st

ochastic LLM completions, requiring structured capture of both intermediate execution traces and downstream outcomes. To address these challenges, we introduce (1) VeRO (Versioning, Rewards, and Observations), an *outer harness* that provides versioned snapshots, budget-controlled evaluation, and structured execution traces of *target harnesses*, and (2) VeRO-Bench, a benchmark suite of target agents and tasks with reference evaluation procedures. Using VeRO, we conduct an empirical study comparing optimizers across tasks and analyzing which modifications reliably improve target agent harnesses. We release VeRO to support research on agent optimization as a core capability for coding agents. Code is available at https://github.com/scaleapi/vero.

Split Personality Training: Revealing Latent Knowledge Through Alternate Personalities

Florian Dietz, William Wale, Oscar Gilg, Robert McCarthy, Felix Michalak, Gustavo Ewbank Rodrigues Danon, Miguelito de Guzman, Dietrich Klakow

Detecting misalignment in large language models is challenging because models may learn to conceal misbehavior during training. Standard auditing techniques fall short: black-box methods often cannot distinguish misaligned outputs from benign ones, and mechanistic interpretability does not scale with model capabilities. We introduce Split Personality Training (SPT), which fine-tunes a second ``honest persona'' into LoRA parameters that remain inactive during normal operation. After the main model responds, we activate the LoRA adapter and insert a trigger string, enabling the honest persona to review the response while accessing the main model's latent states. We test our method on the Anthropic Auditing Game Model Organism, a benchmark where Llama-3.3-70B is trained to exploit reward hacks while concealing this behavior. SPT achieves 96% overall accuracy, whereas Anthropic reports near 0% accuracy. The honest persona reveals latent knowledge inaccessible to external observers, such as the fictional biases the compromised model was trained on.

Generalized Discrete Diffusion with Self-Correction

Linxuan Wang, Ziyi Wang, Yikun Bai, Wei Deng, Guang Lin, Qifan Song

Self-correction is an effective technique for maintaining parallel sampling in discrete diffusion models with minimal performance degradation. Prior work has explored self-correction at inference time or during post-training; however, such approaches often suffer from limited generalization and may impair reasoning performance. GIDD pioneers pretraining-based self-correction via a multi-step BERT-style uniform-absorbing objective. However, GIDD relies on a continuous interpolation-based pipeline with opaque interactions between uniform transitions and absorbing masks, which complicates hyperparameter tuning and hinders practical performance. In this work, we propose a **S**elf-**C**orrecting **D**iscrete **D**iffusion (SCDD) model to reformulate pretrained self-correction with explicit state transitions and learn directly in discrete time. Our framework also simplifies the training noise schedule, eliminates a redundant remasking step, and relies exclusively on uniform transitions to learn self-correction. Experiments at the GPT-2 scale demonstrate that our method enables more efficient parallel decoding while preserving generation quality. Our code is available at https://github.com/laaaarrywang/Self-Correcting-Discrete-Diffusion.git.

Persistent Semantic Entities in Tool-Augmented LLM Systems

Zhaohui Geoffrey Wang

Tool-augmented LLM agents can harbor implicit state that persists across sessions, activates through events, and propagates across agent boundaries—all invisible to standard debugging. We formalize this as Persistent Semantic Entities (PSE): constructs defined by name binding, event triggering, and cross-boundary propagation, and evaluate them across 20 models from 9 families (3B–671B parameters). First, all tested models are susceptible to contamination (20–100%), with name binding as the dominant mechanism: without it, contamination is 0%. Second, persistence depends on contamination type rather than scale or deployment—factual injection conflicting with parametric knowledge self-corrects, but preference, per

sona, and instruction contamination persists at 100% over a 10-turn horizon with no decay, an effect that holds across providers in our controlled setting and is consistent with a model-intrinsic explanation. Third, context-isolated self-verification achieves 20–79% reduction without oracle references while keyword-based detection produces systematic false positives, and contamination compounds 3× across multi-agent pipelines. Preference and instruction contamination—persistent, lacking self-correction, and invisible to standard monitoring—represents a particularly concerning attack surface for deployed agent systems.

Rays as Pixels: Learning A Joint Distribution of Video and Camera Trajectories
Wonbong Jang, Shikun Liu, Soubhik Sanyal, Juan Camilo Perez, Kam Woh Ng, Sanskar Agrawal, Juan-Manuel Perez-Rua, Yiannis Douratsos, Tao Xiang
Can we bridge the gap between perceiving camera trajectories and rendering novel views within a single generative framework? Recovering camera parameters from images and rendering scenes from novel viewpoints are considered the forward and inverse problems in the field of computer vision and graphics. Previous approaches treat these problems in isolation, often failing when image coverage is sparse or camera poses are ambiguous. In this work, we propose Rays as Pixels, a specialized Video Diffusion Model (VDM) that learns a joint distribution of videos and camera trajectories. We represent cameras as dense ray pixels (raxels) and simultaneously denoise them alongside video frames using a novel Decoupled Self-Cross Attention. This joint formulation enables us to: i) generate a video from multiple input images following a defined camera trajectory, ii) perform novel view synthesis from sparse views (without necessarily requiring camera poses), and iii) predict the camera trajectory from a raw video. We evaluate our model on pose estimation, camera-controlled video generation and validate its self-consistency. Please reference supplementary material for more qualitative results.
****

NAACA: Training-Free NeuroAuditory Attentive Cognitive Architecture with Oscillatory Working Memory for Salience-Driven Attention Gating
Zhongju Yuan, Geraint A. Wiggins, Dick B.M. Botteldooren
Audio provides critical situational cues, yet current Audio Language Models (ALMs) face an attention bottleneck in long-form recordings where dominant background patterns can dilute rare, salient events. We introduce NAACA, a training-free NeuroAuditory Attentive Cognitive Architecture that reframes attention allocation as an auditory salience filtering problem. At its core is OWM, a neuro-inspired Oscillatory Working Memory that maintains stable attractor-like states and triggers higher-cognition ALM processing only when adaptive energy fluctuations signal perceptual salience, triggering higher-level reasoning. On XD-Violence, NAACA improves AudioQwen’s average precision (AP) from 53.50\% to 70.60\% while reducing unnecessary ALM invocations. Furthermore, qualitative case studies on the Urban Soundscapes of the World (USoW) dataset show that OWM captures novel events and subcategory shifts while remaining robust to transient pauses and ambient urban noise.
****

A KL-regularization framework for learning to plan with adaptive priors
Alvaro Serra-Gomez, Daniel Jarne Ornia, Dhruva Tirumala, Thomas M. Moerland
Effective exploration remains a key challenge in model-based reinforcement learning (MBRL), especially in high-dimensional continuous control tasks where sample efficiency is critical. Recent work addresses this by using learned policies as proposal distributions for Model-Predictive Path Integral (MPPI) planning. Early approaches update the sampling policy independently of the planner, typically via deterministic policy gradients with entropy regularization. However, since the data distribution is induced by the MPPI planner, misalignment between the policy and planner degrades value estimation and long-term performance. To address this, recent methods explicitly align the policy with the planner by minimizing KL divergence to the planner distribution or by incorporating planner-guided regularization. In this work, we unify these approaches under the Policy Optimization–Model Predictive Control (PO-MPC) framework, a family of KL-regularized MBRL methods that treat the planner’s action distribution as a prior in policy optim

ization. We show how existing methods emerge as special cases of this family and explore previously unstudied variants. Experiments demonstrate that these variants yield significant performance gains, advancing the state of the art in MPPI-based RL.

LangPrecip: Language-Aware Multimodal Precipitation Nowcasting

Xudong Ling, Chaorong Li, Tianxi Huang, Qian Dong, Guiduo Duan

Short-term precipitation nowcasting is inherently under-constrained due to limited historical observation windows: identical observations can lead to multiple plausible future trajectories, especially for extreme events. Existing generative methods rely solely on visual features and lack explicit constraints on precipitation motion semantics, resulting in ambiguous dynamics, blurred details, and unstable predictions. We propose LangPrecip, the first language-guided precipitation nowcasting framework, and contribute LangPrecip-160K, a large-scale radar-text paired dataset with 160K annotated sequences. LangPrecip addresses the under-constrained challenge by leveraging natural-language motion descriptions as explicit semantic constraints to reduce motion ambiguity and introducing a dual-path wavelet consistency unfolding decoder that enforces physical data fidelity during latent-to-pixel reconstruction. By reformulating nowcasting as semantically constrained trajectory generation under the Rectified Flow paradigm with model-based decoder optimization, LangPrecip produces sharper and more physically consistent forecasts. Experiments on Swedish and MRMS benchmarks demonstrate substantial improvements over state-of-the-art vision-only methods, achieving over 60\% and 19\% relative gains in heavy-rainfall CSI at 80-minute lead time with enhanced spatial detail preservation. Dataset is available at https://github.com/UESTC-LXD/LangPrecip.

WorldCompass: Reinforcement Learning for Long-Horizon World Models

Zehan Wang, Tengfei Wang, Haiyu Zhang, Xuhui Zuo, Junta Wu, Haoyuan Wang, Wenqiang Sun, Zhenwei Wang, Chenjie Cao, Hengshuang Zhao, Chunchao Guo, Zhou Zhao

This work presents WorldCompass, a novel Reinforcement Learning (RL) post-training framework for the long-horizon, interactive video-based world models, enabling them to explore the world more accurately and consistently based on interaction signals. To effectively "steer" the world model's exploration, we introduce three core innovations tailored to the autoregressive video generation paradigm: 1) Clip-level Roll-out Strategy: We generate and evaluate multiple samples at a single target clip, which significantly boosts roll-out efficiency and provides fine-grained reward signals. 2) Complementary Reward Functions: We design reward function for both interaction-following accuracy and visual quality, which provide direct supervision and effectively suppress reward-hacking behaviors. 3) Efficient RL Algorithm: We employ the negative-aware fine-tuning strategy coupled with various efficiency optimizations to efficiently and effectively enhance model capacity. Evaluations on the SoTA open-source world model, WorldPlay, demonstrate that WorldCompass significantly improves interaction accuracy and visual fidelity across various scenarios.

****

Weight Decay Improves Language Model Plasticity

Tessa Han, Sebastian Bordt, Hanlin Zhang, Sham M. Kakade

Large language models are typically trained in two broad phases: pretraining to produce a base model, followed by further training to improve downstream performance. However, hyperparameter optimization and scaling laws are studied primarily from the perspective of the base model's validation loss, overlooking a crucial model property: downstream adaptability. In this work, we study pretraining from the perspective of *model plasticity*, that is, the ability of the base model to successfully adapt to downstream tasks upon additional training. We focus on the role of weight decay, a key regularization parameter during pretraining, and show through systematic experiments that larger weight decay increases the plasticity of the pretrained model, resulting in greater performance gains downstream after fine-tuning. This effect can lead to counterintuitive trade-offs where base models that perform worse after pretraining can perform better after furthe

r training. Further investigation of weight decay's mechanistic effects on model behavior reveals that it encourages linearly separable representations, regularizes attention matrices, and reduces overfitting on the training data. Together, these findings highlight the importance of pretrained model plasticity, the limits of using cross-entropy loss as the sole metric for hyperparameter optimization, and the multifaceted role that a single optimization hyperparameter plays in shaping model behavior.
****
No Free Lunch: Non-Asymptotic Analysis of Prediction-Powered Inference
Pranav Mani, Peng Xu, Zachary Chase Lipton, Michael Oberst
Prediction-Powered Inference (PPI) is a popular strategy for combining gold-standard and possibly noisy pseudo-labels to perform statistical estimation. Prior work has shown an asymptotic \textit{free lunch} for PPI++, an adaptive form of PPI, showing that the \textit{asymptotic} variance of PPI++ is always less than or equal to the variance obtained from using gold-standard labels alone. Notably, this result holds \textit{regardless of the quality of the pseudo-labels}. In this work, we demystify this result by conducting an exact finite-sample analysis of the estimation error of PPI++ on the mean estimation problem. We give a \textit{no free lunch} result, characterizing the settings (and sample sizes) where PPI++ has provably worse estimation error than using gold-standard labels alone. Specifically, PPI++ will outperform if and only if the correlation between pseudo- and gold-standard is above a certain level that depends on the number of labeled samples (n).
In some cases our results simplify considerably: For Gaussian data, for instance, the correlation must be at least $1/\sqrt{n - 2}$ in order to see improvement. More broadly, by providing exact non-asymptotic expressions for the variance of PPI++ under sample splitting, we aim to empower practitioners to transparently reason about the benefits of PPI++ in specific applications.
In experiments, we illustrate that our theoretical findings hold on real-world datasets.

TRAP: Hijacking VLA CoT-Reasoning via Adversarial Patches
Zhengxian Huang, Wenjun Zhu, Haoxuan Qiu, Xiaoyu Ji, Wenyuan Xu
By integrating Chain-of-Thought (CoT) reasoning, Vision-Language-Action (VLA) models have demonstrated strong capabilities in robotic manipulation, particularly by improving generalization and interpretability. However, the security of CoT-based reasoning mechanisms remains largely unexplored. In this paper, we show that CoT reasoning introduces a novel attack vector for targeted behavior hijacking—for example, causing a robot to mistakenly deliver a knife to a person instead of an apple—without modifying the user’s instruction. We first provide empirical evidence that CoT strongly governs action generation, even when it is semantically misaligned with the input instructions. Building on this observation, we propose **TRAP**, the first targeted behavior-hijacking adversarial attack against CoT-reasoning VLA models. By targeting the reasoning-to-action pathway, **TRAP** uses an adversarial patch (*e.g.*, a tablecloth placed on the table) to steer intermediate CoT reasoning and downstream actions toward adversary-defined behaviors. Extensive evaluations on three representative reasoning VLAs, spanning distinct CoT reasoning mechanisms, demonstrate the effectiveness of **TRAP**. Notably, we implemented the patch by printing it on paper in a real-world setting. Our findings highlight the urgent need to secure CoT reasoning in VLA systems. The project page is available at https://zhengxian-huang.github.io/TRAP-website/.

One Probe Won’t Catch Them All: Towards Targeted Deception Detection
Vikram Natarajan, Devina Jain, Shivam Arora, Satvik Golechha, Joseph Isaac Bloom
Linear probes are a promising approach for monitoring AI systems for deceptive behaviour. Previous work has shown that a linear classifier trained on a contrastive instruction pair and a simple dataset can achieve good performance. However, these probes exhibit notable failures even in straightforward scenarios, including spurious correlations and false positives on non-deceptive responses. In this paper, we demonstrate that deception detection is inherently heterogeneous: wh

ile a single universal probe achieves modest improvements (+0.032 AUC), post-hoc oracle analysis reveals substantially higher potential (+0.108 AUC) when probes are matched to specific deception types, and synthetic validation experiments suggest this ceiling is achievable a priori when the deception type is known in advance. Our findings reveal that instruction pairs capture deceptive intent rather than content-specific patterns, explaining why prompt choice dominates probe performance (70.6% of variance). Given this heterogeneity, we conclude that organizations should define their specific threat models and deploy appropriately matched probes rather than seeking a universal deception detector.

Learning to Emulate Chaos: Adversarial Optimal Transport Regularization
Gabriel Melo, Leonardo Santiago, Peter Y. Lu
Chaos arises in many complex dynamical systems, from weather to power grids, but is difficult to accurately model with data-driven methods such as machine learning emulators. While emulators are promising tools for accelerating simulations and solving inverse problems, they still struggle to learn chaotic dynamics, where sensitivity to initial conditions renders exact long-term forecasts infeasible, especially given noisy data. Recent work instead trains emulators to match the statistical properties of chaotic attractors, but these approaches often rely on handcrafted summary statistics or large, diverse multi-environment datasets. In this work, we propose a family of adversarial optimal transport objectives that can jointly learn high-quality summary statistics and a physically consistent emulator from a single noisy trajectory. We theoretically analyze and experimentally validate a Sinkhorn divergence formulation (2-Wasserstein) and a WGAN-style dual formulation (1-Wasserstein) of our approach. Numerical experiments across a variety of chaotic systems, including ones with high-dimensional spatiotemporal chaos, show that emulators trained using our proposed objectives have significantly improved long-term statistical fidelity.

IRIS: Implicit Reward-Guided Internal Sifting for Mitigating Multimodal Hallucination
Yuanshuai li, Yuping Yan, Jirui Han, Fei Ming, Lingjuan Lyu, Yaochu Jin
Hallucination remains a fundamental challenge for Multimodal Large Language Models (MLLMs). While Direct Preference Optimization (DPO) is a key alignment framework, existing approaches often rely heavily on costly external evaluators for scoring or rewriting, incurring off-policy learnability gaps and discretization loss. Due to the lack of access to internal states, such feedback overlooks the fine-grained conflicts between different modalities that lead to hallucinations during generation. To address this issue, we propose IRIS (Implicit Reward-Guided Internal Sifting), which leverages continuous implicit rewards in the native log-probability space to preserve fine-grained preference information and capture internal modal competition. After an SFT warm-up, IRIS performs on-policy preference alignment by sifting self-generated responses sampled from the current policy. These responses are then ranked with multimodal implicit rewards to form preference pairs that drive optimization toward resolving modal conflicts. Extensive experiments demonstrate that IRIS achieves highly competitive performance on key hallucination benchmarks using only 5.7k samples, without requiring any external feedback during preference alignment. These results confirm that IRIS provides an efficient and principled paradigm for mitigating MLLM hallucinations. Code is available \href{https://github.com/ShawnLee0910/IRIS}{here}.

TransLight: Image-Guided Customized Lighting Control with Generative Decoupling
Zongming Li, Lianghui Zhu, Haocheng Shen, Longjin Ran, Wenyu Liu, Xinggang Wang
Most existing illumination-editing methods struggle to jointly offer customized lighting control and preserve content integrity, limiting their effectiveness especially in transferring complex light effects from a reference to a target image in portrait photography. To address this problem, we propose TransLight, a novel framework that enables high-fidelity and high-freedom transfer of geometric-structured light effects such as Tyndall beams and specular highlights. Extracting light effects from the reference image is the most critical and challenging st

ep, as real-world lighting contains complex geometric structures tightly coupled with image content. To achieve this, we propose Generative Decoupling, using two fine-tuned diffusion models to accurately separate image content and lighting, and create a new million-scale dataset of image–content–light triplets. We then adopt IC-Light as the generative model, training it on these triplets with the reference lighting image as an additional conditioning signal. The resulting model enables customized and natural transfer of diverse light effects. Notably, by fully disentangling light effects from reference images, our generative decoupling strategy gives TransLight highly flexible illumination control. Experiments show that TransLight successfully transfers geometric-structured lighting effects across diverse images in portrait photography, offering more customized control than existing methods and charting new directions in illumination harmonization and editing. Our project page is hustvl.github.io/TransLight.

From Generalist to Specialist Representation
Yujia Zheng, Fan Feng, Yuke Li, Shaoan Xie, Kevin Patrick Murphy, Kun Zhang
Given a generalist model, learning a task-relevant specialist representation is fundamental for downstream applications. Identifiability, the asymptotic guarantee of recovering the ground-truth representation, is critical because it sets the ultimate limit of any model, even with infinite data and computation. We study this problem in a completely nonparametric setting, without relying on interventions, parametric forms, or structural constraints. We first prove that the structure between time steps and tasks is identifiable in a fully unsupervised manner, even when sequences lack strict temporal dependence and may exhibit disconnections, and task assignments can follow arbitrarily complex and interleaving structures. We then prove that, within each time step, the task-relevant latent representation can be disentangled from the irrelevant part under a simple sparsity regularization, without any additional information or parametric constraints. Together, these results establish a hierarchical foundation: task structure is identifiable across time steps, and task-relevant latent representations are identifiable within each step. To our knowledge, each result provides a first general nonparametric identifiability guarantee, and together they mark a step toward provably moving from generalist to specialist models.

SiameseNorm: Breaking the Barrier to Reconciling Pre/Post-Norm
Tianyu Li, Dongchen Han, Zixuan Cao, Haofeng Huang, Mengyu Zhou, Ming Chen, Erchao Zhao, xiaoxi jiang, Guanjun Jiang, Gao Huang
The long-standing tension between Pre- and Post-Norm remains an open problem in Transformer architecture, reflecting a fundamental trade-off between training stability and representational capacity. Prior attempts to combine their strengths have made progress, but often show limited robustness across training settings, restricting their broader applicability. We revisit this dilemma, showing that *single-stream* architectures struggle to reconcile Pre-Norm's stable identity-gradient propagation with Post-Norm's normalization of the main residual path. To address this structural tension, we propose SiameseNorm, a simple yet effective *two-stream* architecture that remains compatible with Pre-Norm training recipes. SiameseNorm couples Pre-Norm-like and Post-Norm-like streams through shared residual blocks, allowing each residual block to receive optimization signals from both pathways with negligible overhead. Extensive experiments on 400M and 1.3B dense language models, 15B MoE models, Vision Transformers, and Diffusion Transformers show that SiameseNorm consistently improves performance while maintaining strong training stability across architectures and modalities. Code is available at https://github.com/Qwen-Applications/SiameseNorm.

Turning Back Without Forgetting: Selective Backward Refinement for Parameter-Efficient Continual Learning
Anushka Tiwari, Kaiyi Ji
While prompt-based parameter-efficient continual learning mitigates catastrophic forgetting by isolating task-specific prompts, this isolation also limits later tasks from improving earlier ones, leaving backward knowledge transfer underexp

lored. We address this limitation by proposing Selective bAckward refinement for positive Backward knowledge transfER (SABER), a replay-free framework that enables controlled backward transfer in prompt-based continual learning. SABER determines when backward refinement is beneficial using complementary task-correlation criteria based on prompt-gradient geometry and loss-distribution similarity, and how to perform refinement safely by restricting updates to non-interfering directions in the prompt parameter space. Extensive experiments across multiple continual learning benchmarks, and diverse pretrained backbones, including T5-Large, LLaMA, and Qwen, demonstrate that SABER consistently achieves positive backward transfer while maintaining strong overall average performance.

Precision-Induced Miscalibration: Understanding and Correcting Confidence Distortion in Quantized Neural Networks
Jiawei Gu, Fengyuan Nie, Hao Tang, Yanpeng Sun
Low-precision arithmetic is pervasive in neural network training and deployment, yet its effect on prediction \textit{confidence}, not just accuracy, remains unexamined. We show that the softmax function amplifies logit-space quantization errors in an input-dependent manner: confidence distortion scales with the product of precision-dependent error bound ϵ and logit norm, peaking when the model is confident but not saturated. This explains why identical models report different confidence values across precisions, a phenomenon we term \textit{Precision Split}. During training, the same mechanism causes gradient underflow: when logit margins exceed a precision-dependent threshold, gradients vanish and samples silently stop contributing to learning. Since logit norm serves as a computable proxy for precision-induced risk, we propose Precision-Aware Confidence Scaling (PACS), which applies sample-adaptive temperature inversely related to this risk, with sub-one-percent overhead and no full-precision computation required. On ImageNet with mixed-precision ResNet-50, PACS reduces Expected Calibration Error from 5.82\% to 1.92\% while maintaining accuracy, with consistent improvements across architectures, precision formats, and modalities.

CAReDiO: Enhancing Cultural Alignment of LLM via Representativeness and Distinctiveness Guided Data Optimization
Jing Yao, Xiaoyuan Yi, Jindong Wang, Zhicheng Dou, Xing Xie
As Large Language Models (LLMs) more deeply integrate into human life across various regions, aligning them with pluralistic cultures is crucial for improving user engagement and mitigating cultural conflicts. For this purpose, recently, different culture-specific corpora have been carefully curated, either synthesized or manually annotated. Nevertheless, inspired by culture theories, we identify two key challenges faced by these datasets: (1) Representativeness: These corpora fail to fully capture the target culture's core characteristics, causing insufficient cultural coverage with redundancy; (2) Distinctiveness: They struggle to distinguish the unique nuances of a given culture from shared patterns across other relevant ones, hindering precise cultural modelling. To handle these challenges, we introduce CAReDiO, a novel data optimization framework, which alternatively refines culture-sensitive questions and responses according to information-theoretic objectives in an in-context optimization manner, enhancing the cultural informativeness and distinguishability of constructed data. Extensive experiments on 15 distinct cultures demonstrate that CAReDiO can create high-quality data with richer cultural information and enable efficient alignment of small open-source or large proprietary LLMs with as few as 200 training samples, consistently outperforming previous datasets in both multi-choice and open-ended cultural benchmarks.

Textual Supervision Enhances Geospatial Representations in Vision-Language Models
Marcelo Sartori Locatelli, Fernando Tonucci, Jea Kwon, Luiz Felipe Vecchietti, Bryan Nathanael Wijaya, Cheng Yaw Low, Virgilio Almeida, Meeyoung Cha
Geospatial understanding is a critical yet underexplored dimension in the development of machine learning systems for tasks such as image geolocation and spatia

l reasoning. In this work, we analyze the geospatial representations acquired by three model families: vision-only architectures (e.g., ViT), vision-language models (e.g., CLIP), and large-scale multimodal foundation models (e.g., LLaVA, Qwen, and Gemma). By evaluating across image clusters, including people, landmarks, and everyday objects, grouped based on the degree of localizability, we reveal systematic gaps in spatial accuracy and show that textual supervision enhances the learning of geospatial representations. Our findings suggest the role of language as an effective complementary modality for encoding spatial context and multimodal learning as a key direction for advancing geospatial AI.

Learning to Refine: Spectral-Decoupled Iterative Refinement Framework for Precipitation Nowcasting

Yunlong Zhou, Chen Zhao, Danyang Peng, Fanfan Ji, Xiaotong Yuan

Accurate precipitation nowcasting is vital for disaster mitigation, but deep learning methods face a key trade-off: regression models produce over-smoothed, spectrally decaying predictions that blur convective details and violate turbulence power laws; diffusion models generate realistic yet unanchored hallucinations lacking physical grounding. We propose Spectral-Decoupled Iterative Refinement (SDIR), a deterministic framework that reformulates nowcasting as progressive frequency-decoupled refinement. SDIR first extracts a stable low-frequency synoptic skeleton, then iteratively refines high-frequency textures under physical constraints, eliminating both blurring and hallucinations. It features a dual-path design: the Synoptic Frequency-Guided Former (SFG-Former) with Scale-Adaptive Transformers for global structure, and the Fourier Residual Refiner (FR-Refiner) with Scale-Conditioned Fourier Neural Operators for fine residuals. A Physically Consistent Power Spectral Density (PCPSD) loss with dynamic masking enforces a turbulence-consistent spectral distribution. Experiments on three benchmarks show SDIR significantly outperforms SOTA methods in spatial accuracy while achieving spectral fidelity competitive with diffusion-based methods, enabling reliable high-resolution operational nowcasting. Code link: https://github.com/RuntimeWarning/SDIR.

Stabilizing Equation Learning via Zero-Point Constraints

Sannyuya Liu, Ao Chen, Lin Liu, Ruxia Liang, Xiaoxuan Shen, Jianwen Sun

Symbolic Regression aims to discover interpretable mathematical expressions from data. Equation Learner (EQL) is a gradient-based method with strong fitting capability and expressive potential, yet it often activates redundant operators as model complexity grows, leading to over-complex expressions and unstable equation recovery. We analyze a gradient residual issue induced by operators that do not vanish at zero, which can prevent the ideal sparse expression from acting as a stable attractor during training and bias training toward unnecessarily complex structures, making exact recovery highly unreliable in practice. To address this, we propose EQL-Z, a structurally controllable symbolic regression framework. EQL-Z enforces zero-point constraints via zero-point consistent operator transformations to eliminate residual gradients on silent paths, and performs a small-to-large structure search that grows depth/width from a compact seed under a complexity-penalized validation score. After selecting a compact structure, we apply BFGS fine-tuning to refine coefficients. Experiments on synthetic and real-world datasets show that EQL-Z substantially improves exact equation recovery and in-/out-of-distribution generalization over vanilla EQL, achieving performance close to leading symbolic regression baselines. Code is available at https://github.com/Caaaa-a/EQL-Z.

Motion Attribution for Video Generation

Xindi Wu, Despoina Paschalidou, Jun Gao, Antonio Torralba, Laura Leal-Taixé, Olga Russakovsky, Sanja Fidler, Jonathan Lorraine

Despite the rapid progress of video generation models, the role of data in influencing motion is poorly understood. We present Motive (MOTIon attribution for Video gEneration), a motion-centric, gradient-based data attribution framework that scales to modern, large, high-quality video datasets and models. We use this t

o study which fine-tuning clips improve or degrade temporal dynamics. Motive iso
lates temporal dynamics from static appearance via motion-weighted loss masks, y
ielding efficient and scalable motion-specific influence computation. On text-to
-video models, Motive identifies clips that strongly affect motion and guides da
ta curation that improves temporal consistency and physical plausibility. With M
otive-selected high-influence data, we improve both motion smoothness and dynami
c degree on VBench, achieving a 74.1% human preference win rate compared with th
e pretrained base model. To our knowledge, this is the first framework to attrib
ute motion rather than visual appearance in video generative models and to use i
t to curate fine-tuning data.

Beyond Trajectory-Level Attribution: Graph-Based Credit Assignment for Agentic R
einforcement Learning
Xin Cheng, Shuo He, Lang Feng, Haiyang Xu, Ming Yan, Lei Feng, Bo An
Group-based reinforcement learning (RL) methods have achieved remarkable success
 in improving the performance of large language models (LLMs) and have been rapi
dly extended to agentic tasks. However, their credit assignment relies heavily o
n coarse-grained trajectory-level attribution according to final outcomes, makin
g it difficult to capture the contribution of individual steps, such as valuable
 steps obscured within failed trajectories. To uncover latent information and en
able more faithful step-level credit assignment, we propose Graph-based Group Po
licy Optimization (GraphGPO), which first aggregates all rollout trajectories in
to a unified state-transition graph and then estimates the distance from each st
ate to the task goal using the global information encoded in the graph. Finally,
 GraphGPO assigns credit to each edge by estimating a graph-based advantage, bas
ed on how much the transition reduces the distance to the task goal. In this way
, GraphGPO significantly improves training efficiency and achieves state-of-the-
art performance across a range of challenging benchmarks.

Multi-Task GRPO: Reliable LLM Reasoning Across Tasks
Shyam Sundhar Ramesh, Xiaotong Ji, Matthieu Zimmer, Sangwoong Yoon, Zhiyong Wang
, Haitham Bou Ammar, Aurelien Lucchi, Ilija Bogunovic
RL-based post-training with GRPO is widely used to improve large language models
 on individual reasoning tasks. However, real-world deployment requires reliable
 performance across diverse tasks. A straightforward multi-task adaptation of GR
PO often leads to imbalanced outcomes, with some tasks dominating optimization w
hile others stagnate. Moreover, tasks can vary widely in how frequently prompts
yield zero advantages (and thus zero gradients), which further distorts their ef
fective contribution to the optimization signal. To address these issues, we pro
pose a novel Multi-Task GRPO (MT-GRPO) algorithm that (i) dynamically adapts tas
k weights to explicitly optimize worst-task performance and promote balanced pro
gress across tasks, and (ii) introduces a ratio-preserving sampler to ensure tas
k-wise policy gradients reflect the adapted weights. Experiments on both 3-task
and 9-task settings show that MT-GRPO consistently outperforms baselines in wors
t-task accuracy. In particular, MT-GRPO achieves 16–28\% and 6\% absolute improv
ement on worst-task performance over standard GRPO and DAPO, respectively, while
 maintaining competitive average accuracy. Moreover, MT-GRPO requires 50\% fewer
 training steps to reach 50\% worst-task accuracy in the 3-task setting, demonst
rating substantially improved efficiency in achieving reliable performance acros
s tasks.
****

Game-Theoretic Co-Evolution for LLM-Based Heuristic Discovery
Xinyi Ke, Kai Li, Junliang Xing, Yifan Zhang, Jian Cheng
Large language models (LLMs) have enabled rapid progress in automatic heuristic
discovery (AHD), yet most existing methods are predominantly limited by static e
valuation against fixed instance distributions, leading to potential overfitting
 and poor generalization under distributional shifts. We propose Algorithm Space
 Response Oracles (ASRO), a game-theoretic framework that reframes heuristic dis
covery as a program level co-evolution between solver and instance generator. AS
RO models their interaction as a two-player zero-sum game, maintains growing str

ategy pools on both sides, and iteratively expands them via LLM-based best-respo
nse oracles against mixed opponent meta-strategies, thereby replacing static eva
luation with an adaptive, self-generated curriculum. Across multiple combinatori
al optimization domains, ASRO consistently outperforms static-training AHD basel
ines built on the same program search mechanisms, achieving substantially improv
ed generalization and robustness on diverse and out-of-distribution instances.
****

Cross-Modal Knowledge Distillation without Paired Data: Theoretical Foundation a
nd Algorithm

T. Khiem Tran, Anh Duc Chu, Quang Hung Pham, Phi Le Nguyen, Trong Nghia Hoang

Cross-modal knowledge distillation (CMKD) studies how a (large) teacher model tr
ained on one type of data (e.g., images) can guide a (smaller) student model bui
lding on another type of data (e.g., text/audio). Existing CMKD methods often re
quire paired multi-modal data with aligned semantics, but obtaining such paired
data are often costly and impractical. To mitigate this limitation, we develop a
 new CMKD framework for the more challenging setting where paired data are unava
ilable. In particular, we establish a cross-modal distributional relationship be
tween teacher and student models which reveals two fundamental quantities govern
ing effective distillation: feature alignment and label alignment. These quantit
ies characterize semantic discrepancy between modalities at the levels of repres
entation and prediction distributions, respectively. Motivated by this insight,
we propose a principled framework, with theoretical guarantees, that enables eff
ective cross-modal knowledge distillation by aligning distributions rather than
individual samples. Extensive experiments across a wide range of multimodal benc
hmarks show that our framework is highly effective in both unpaired and paired d
ata settings, improving significantly over prior work.
****

StableI2I: Spotting Unintended Changes in Image-to-Image Transition

Jiayang Li, Shuo Cao, Xiaohui Li, Zhizhen Zhang, Kaiwen Zhu, Yule Duan, Yu Qiao,
 Jian Zhang, Yihao Liu

In most real-world image-to-image (I2I) scenarios, existing evaluations primaril
y focus on instruction following and the perceptual quality or aesthetics of the
 generated images. However, they largely fail to assess whether the output image
 preserves the semantic correspondence and spatial structure of the input image.
 To address this limitation, we propose StableI2I, a unified and dynamic evaluat
ion framework that explicitly measures content fidelity and pre--post consistenc
y across a wide range of I2I tasks without requiring reference images, including
 image editing and image restoration. In addition, we construct StableI2I-Bench,
 a benchmark designed to systematically evaluate the accuracy of MLLMs on such f
idelity and consistency assessment tasks. Extensive experimental results demonst
rate that StableI2I provides accurate, fine-grained, and interpretable evaluatio
ns of content fidelity and consistency, with strong correlations to human subjec
tive judgments. Our framework serves as a practical and reliable evaluation tool
 for diagnosing content consistency and benchmarking model performance in real-w
orld I2I systems.
****

Reinforcement Learning with Verifiable Rewards: GRPO's Loss, Dynamics, and Succe
ss Amplification

Youssef Mroueh

Group Relative Policy Optimization (GRPO) was introduced recently and used to tr
ain DeepSeek\textendash R1 for promoting reasoning in LLMs under verifiable (bin
ary) rewards. We show that the mean{+}variance calibration of these rewards indu
ces a contrastive loss in which the contrastive samples are synthetic data drawn
 from the previous policy. While GRPO was originally paired with clipping to kee
p updates near the old policy, we analyze variants that differ in reward normali
zation (mean-only vs.\ mean{+}variance) and in how they regularize updates using
 KL divergence: either penalizing divergence from the previous model (\emph{mirr
or}), penalizing divergence from a fixed reference model π_{ref}, o
r combining both forms of regularization. For each, the optimal policy π_n a
dmits an explicit form in terms of the binary reward and the first and second o

rder statistics of the reward under π_{n-1}, as well as the policies π_{n-1} and π_{ref}. Iterating results in a sequence $\{\pi_n\}$ whose \emph{probability of success (PoS)} obeys a simple recurrence that converges to a fixed point determined by the reference PoS and the regularization strength. We further show that this fixed point exceeds the reference, demonstrating that GRPO amplifies the policy's probability of success.

Expert-level Leaf Cell Layout Generation via Preference-Optimized LLM
Yaohui Han, Rongliang Fu, Yanming Liu, Shuo Ren, Shuai Dong, Yunpeng Wang, Tinghuan Chen, Bei Yu, Tsung-Yi Ho
In the field of integrated circuits, leaf cells are the basic units, serving as the fundamental building blocks (e.g., standard cells) that are widely reused in various VLSI designs, forming the basis for more complex circuits. Therefore, the design quality of leaf cell layouts significantly impacts the PPA (Power, Performance, and Area) of the final VLSI designs. To automatically design leaf cell layouts that are close to expert designs, we propose GenLeaf. GenLeaf first utilizes a supervised, performance-aware embedding model to represent layouts and automatically calculate their similarity scores. Since there are expert-designed layouts but no corresponding scripts, we implement Bayesian optimization to generate a layout-script dataset for LLM training. With subsequent supervised fine-tuning and further preference optimization, GenLeaf can generate leaf cell layouts through scripts whose performance closely resembles that designed by human engineers. Experiment results demonstrate that GenLeaf outperforms expert-designed golden layouts across key performance metrics.
****

Towards Understanding Modality Interaction in Multimodal Language Models via Partial Information Decomposition
Wanlong Fang, Tianle Zhang, Wen Tao, Alvin Chan
Understanding modality interaction in multimodal large language models (MLLMs) is central to reliable deployment. We introduce Partial Information Decomposition (PID) as a decision-level framework that separates unique, redundant, and synergistic contributions of sensory and linguistic inputs, beyond representation alignment and outcome-based evaluation. Across vision--language benchmarks, PID reveals recurring modality-use profiles: reasoning and grounding-oriented tasks tend to exhibit high synergy, whereas expert and knowledge-oriented tasks show stronger language-unique reliance. These profiles generalize across model families and predict sensitivity to modality-level interventions. We further extend PID to tri-modal systems with Sensory PID, treating language as a control variable to decompose video--audio information gain. Applied to omni-modal models, Sensory PID reveals a sensory synergy bottleneck dominated by visual information even on audio--visual fusion tasks. Finally, PID-guided reweighting provides initial evidence for improving multimodal reasoning and grounding performance.

Distributional Open-Ended Evaluation of LLM Cultural Value Alignment Based on Value Codebook
Jaehyeok Lee, Xiaoyuan Yi, Jing Yao, Hyunjin Hwang, Roy Ka-Wei Lee, Xing Xie, JinYeong Bak
As LLMs are globally deployed, aligning their cultural value orientations is critical for safety and user engagement. However, existing benchmarks face the Construct-Composition-Context (C^3) challenge: relying on discriminative, multiple-choice formats that probe value knowledge rather than true orientations, overlook subcultural heterogeneity, and mismatch with real-world open-ended generation. We introduce DOVE, a distributional evaluation framework that directly compares human-written text distributions with LLM-generated outputs. DOVE utilizes a rate-distortion variational optimization objective to construct a compact value codebook from 10K documents, mapping text into a structured value space to filter semantic noise. Alignment is measured using unbalanced optimal transport, capturing intra-cultural distributional structures and subgroup diversity. Experiments across 12 LLMs show that DOVE achieves superior predictive validity, attaining a 31.56% correlation with downstream tasks, while maintaining high reliability

with as few as 500 samples per culture.
****
Bayesian-LoRA: Probabilistic Low-Rank Adaptation of Large Language Models
Moule Lin, Shuhao Guan, Andrea Patane, David Gregg, Goetz Botterweck
Large language models are typically optimized for accuracy and, therefore, will guess even when uncertain about their predictions. This problem becomes especially pronounced when the model is fine-tuned on small datasets, which often causes overfitting and results in a tendency toward miscalibration. In this work, we introduce Bayesian-LoRA, which reformulates the deterministic LoRA update as a probabilistic low-rank representation inspired by Sparse Gaussian Processes (SGP). We identify a structural isomorphism between LoRA's factorization and Kronecker-factored SGP posteriors, and show that LoRA emerges as a limiting case when posterior uncertainty collapses. We conduct extensive experiments on various LLM architectures across commonsense reasoning, language modeling, and mathematical reasoning benchmarks. With only approximately 0.42M additional parameters and ${\approx}1.2{\times}$ training cost relative to standard LoRA, Bayesian-LoRA significantly improves calibration across models from 7B up to 30B, achieving up to 84\% Expected Calibration Error (ECE) and 76\% Negative Log-Likelihood (NLL) reduction while maintaining competitive accuracy for both in-distribution and out-of-distribution (OoD) evaluations.
****
Do We Need Adam? Surprisingly Strong and Sparse Reinforcement Learning with SGD in LLMs
Sagnik Mukherjee, Lifan Yuan, Pavan Jayasinha, Dilek Hakkani-Tür, Hao Peng
Reinforcement learning (RL), particularly RL from verifiable reward (RLVR), has become a crucial phase of training large language models (LLMs) and a key focus of current scaling efforts.
However, optimization practices in RL largely follow those of next-token-prediction stages (e.g., pretraining and supervised fine-tuning), despite the fundamental differences between RL and these stages emphasized by recent work.
One such practice is the use of the AdamW optimizer, which is widely adopted for training large-scale transformers despite its high memory overhead.
Our analysis shows that both momentum and adaptive learning rate of AdamW are less influential in RL than in SFT, leading us to hypothesize that RL benefits less from Adam’s per-parameter adaptive learning rates and momentum.
Confirming our hypothesis, our experiments demonstrate that the substantially more memory-efficient SGD, which is known to perform poorly in supervised learning of large-scale transformers, matches or even outperforms AdamW in RL for LLMs.
Remarkably, full fine-tuning with SGD updates fewer than 0.02% of model without any sparsity-promoting regularization, more than 1,000 times fewer than AdamW. Our analysis offers potential reasons for this update sparsity.
Our findings provide fresh insights into the optimization dynamics of RL in LLMs and demonstrate that RL can be substantially more parameter-efficient than previously recognized.
****
InfiMed-ORBIT: Aligning LLMs on Open-Ended Complex Tasks via Rubric-Based Incremental Training
Pengkai Wang, Pengwei Liu, Qi Zuo, Zhijie Sang, Congkai Xie, Hongxia Yang
Reinforcement learning (RL) has powered many recent breakthroughs in large language models (LLMs), especially for tasks where rewards can be computed automatically, such as code generation. However, it is less effective in open-ended medical dialogue, where feedback is ambiguous, context-dependent, and difficult to simply summarize into a single scalar signal—often requiring heavily supervised reward models and creating risks of reward hacking. Thus, we introduce ORBIT, an open-ended rubric-based incremental training framework tailored for critical medical dialogues. ORBIT integrates medical dialogue construction with dynamically generated case-conditioned rubrics that serve as adaptive guides for incremental RL. Unlike approaches that rely on external medical knowledge bases or handcrafted rules, ORBIT uses rubric-guided evaluation and can be implemented with general-purpose instruction-following LLMs, avoiding task-specific judge fine-tuning. W

ith only 2k training samples, ORBIT raises Qwen3-4B-Instruct's HealthBench-Hard score from 7.0 to 27.5, achieving state-of-the-art performance among similarly s ized open-source models while maintaining strong consultation quality as rubric coverage broadens. Project page: https://pidneuralode.github.io/ORBIT.

Learning to Decode Against Compositional Hallucination in Video Multimodal Large Language Models

Wenbin Xing, Quanxing Zha, Lizheng Zu, Mengran Li, Ming Li, Junchi Yan

Current research on video hallucination mitigation primarily focuses on isolated error types, leaving *compositional* hallucinations—arising from incorrect reas oning over multiple interacting spatial and temporal factors largely underexplor ed. We introduce **OmniVCHall**, a benchmark designed to systematically evaluate both isolated and compositional hallucinations in Video Large Language Models (VLLMs). OmniVCHall spans diverse video domains, introduces a novel camera-based hallucination type, and defines a fine-grained taxonomy, together with adversari al answer options (*e.g.*, “All are correct” and “None of the above”) to prevent shortcut reasoning. The evaluations of 39 representative VLLMs reveal that even advanced models (*e.g.*, Qwen3-VL and GPT-5) exhibit substantial performance de gradation. We propose **TriCD**, a contrastive decoding framework with a triple- pathway calibration mechanism. An adaptive perturbation controller dynamically s elects distracting operations to construct negative video variants, while a sali ency-guided enhancement module adaptively reinforces grounded token-wise visual evidences. These components are optimized via reinforcement learning to encourag e precise decision-making under compositional hallucination settings. Experiment al results show that **TriCD** consistently improves performance across two repr esentative backbones, achieving an average accuracy improvement of over 10\%. Th e data and code are released at https://github.com/BMRETURN/OmniVCHall.

Frequency-Aware Perceptual Optimization for Low-Complexity Implicit Image Compre ssion

Haotian Wu, Gen Li, Di You, Pier Luigi Dragotti, Deniz Gunduz

We propose a frequency-aware perceptual optimization framework for low-complexit y image compression, realized as a **Re**alism-enhanced **Re**gion-based **I**mp licit **C**odec (Re2IC). Re2IC models visual perception via saliency-guided regi on partitioning and local–global perceptual modulation. To enhance realism under complexity constraints, we introduce wavelet–Wasserstein distortion (WA-WD), a frequency-decomposed perceptual distortion that balances fidelity and realism th rough subband-aware modeling and provides a more reliable approximation than sta ndard Wasserstein distortion. Together, these designs enable fine-grained spatia l–spectral optimization, allowing Re2IC to achieve superior rate–perception trad e-offs, outperforming generative codecs such as HiFiC while using less than 1\% of their decoding cost. Extensive experiments demonstrate state-of-the-art perce ptual performance among overfitted codecs. Beyond compression, WA-WD serves as a standalone, tunable perceptual metric with strong alignment to human preference (Pearson 94.6\%, Spearman 92.3\%) and competitive performance across multiple I QA benchmarks. Project page: https://eedavidwu.github.io/ReReIC/

Focusing Where Vision Matters: Selective Training for Large Vision Language Mode ls via Visual Information Gain

Seulbi Lee, Sangheum Hwang

Large Vision Language Models (LVLMs) have achieved remarkable progress, yet they often suffer from language bias, producing answers without relying on visual ev idence. While prior work attempts to mitigate this issue through decoding strate gies, architectural modifications, or curated instruction data, they typically l ack a quantitative measure of how much individual training samples or tokens act ually benefit from the image. In this work, we introduce Visual Information Gain (VIG), a perplexity-based metric that measures the reduction in prediction unce rtainty provided by visual input. VIG enables fine-grained analysis at both samp le and token levels, effectively highlighting visually grounded elements such as colors, spatial relations, and attributes. Leveraging this, we propose a VIG-gu

ided selective training scheme that prioritizes high-VIG samples and tokens. Thi
s approach improves visual grounding and mitigates language bias, achieving supe
rior performance with significantly reduced supervision by focusing exclusively
on visually informative samples and tokens.

IO-Adam: Rethinking Memory-Efficient Adaptive Optimizers from Gradient Computati
on
Yiting Chen, Zongwei Huo, Junchi Yan
Adaptive Moment Estimation (Adam) is one of the most popular and often the defau
lt stochastic optimizers for deep neural network training. Using first- and seco
nd-moment estimation, Adam provides adaptive learning rates for each parameter,
significantly outperforming Stochastic Gradient Descent (SGD). However, as deep
neural networks become larger, estimating the first and second moments consumes
substantial memory. It motivates various methods to reduce memory usage for adap
tive optimizers. In this paper, we propose to rethink the first and second momen
t estimation from a gradient computation perspective. The gradient of the weight
 matrix is the multiplication of the input and the gradient of the output. Inste
ad of finding low-rank approximations of the first and second moments, as in pre
vious work, we propose tracking the input and output gradients to efficiently es
timate moments. We provide analyses of the similarities and differences between
our proposed method, the widely used Adam optimizer, and previous memory-efficie
nt optimizers designed to reduce memory usage. We conduct experiments to verify
the effectiveness of our method, which reduces memory usage by up to 30% while
 preserving similar performance or even improving the performance of Adam.
****
Self-Soupervision: Cooking Model Soups without Labels
Anthony Fuller, James R Green, Evan Shelhamer
Model soups are strange and strangely effective combinations of parameters. They
 take a model (the stock), fine-tune it into multiple models (the ingredients),
and then mix their parameters back into one model (the soup) to improve predicti
ons. While all known soups require supervised learning, and optimize the same lo
ss on labeled data, our recipes for Self-Soupervision generalize soups to self-s
upervised learning (SSL). Our Self-Souping lets us flavor ingredients on new dat
a sources, e.g. from unlabeled data from a task for transfer or from a shift for
 robustness. We show that Self-Souping on corrupted test data, then fine-tuning
back on uncorrupted train data, boosts robustness by +3.5% (ImageNet-C) and +7%
(LAION-C). Self-Soupervision also unlocks countless SSL algorithms to cook the d
iverse ingredients needed for more robust soups. We show for the first time that
 ingredients can differ in their SSL hyperparameters---and more surprisingly, in
 their SSL algorithms. We cook soups of MAE, MoCoV3, MMCR, and LeJEPA ingredient
s that are more accurate than any single SSL ingredient.

Failure is Feedback: History-Aware Backtracking for Agentic Traversal in Multimo
dal Graphs
Joohyung Yun, Doyup Lee, Wook-Shin Han
Open-domain multimodal document retrieval aims to retrieve specific components (
paragraphs, tables, or images) from large and interconnected document corpora. E
xisting graph-based retrieval approaches typically rely on a uniform similarity
metric that overlooks hop-specific semantics, and their rigid pre-defined plans
hinder dynamic error correction. These limitations suggest that a retriever shou
ld adapt its reasoning to the evolving context and recover intelligently from de
ad ends. To address these needs, we propose **Failure is Feedback**, which casts
 subgraph retrieval as a *sequential decision process* and introduces two key in
novations. (i) We introduce a *history-aware backtracking mechanism*; unlike sta
ndard backtracking that simply reverts the state, our approach piggybacks on the
 context of failed traversals, leveraging insights from previous failures. (ii)
We implement an *economically-rational agentic workflow*. Unlike conventional ag
ents with static strategies, our orchestrator employs a cost-aware traversal met
hod to dynamically manage the trade-off between retrieval accuracy and inference
 costs, escalating to intensive LLM-based reasoning only when the prior failure

justifies the additional computational investment. The project page is available at failureisfeedback.github.io.

Mitigating the Contractivity Trap in Diffusion ODEs via Stein Stabilization
Shigui Li, Delu zeng
A fundamental tension exists in the large-step inference of diffusion models via their deterministic probability flow ordinary differential equation (PF-ODE) trajectories, which we identify as the contractivity trap: efficient inference favors large step sizes, while aggressive steps and highly expressive denoisers can undermine contraction-based stability certificates for error suppression. To address this, we propose SteinDiff, a step-wise inference-time stabilization framework that employs Stein-derived corrections without requiring reference samples. Specifically, SteinDiff introduces a geometry-aware residual correction mechanism that regularizes large-step solver updates without retraining. To this end, we derive a closed-form Stein correction coefficient for step-wise solver adjustment, enabling reference-free adaptation to local data geometry. We further establish a score-controlled perturbation bound under distributional shifts and provide a complementary Stein perspective on EDM-style parameterizations. Extensive experiments demonstrate that SteinDiff mitigates severe artifacts and improves generative quality across large-step inference settings.

DecoderTCR: Compositional Pretraining and Entropy-Guided Decoding for TCR-pMHC Interactions
Boqiao Lai, Melissa Englund, Ramit Bharanikumar, Isabel Nocedal, Ali Davariashtiyani, Jason Perera, Aly A Khan
Modeling recognition between T-cell receptors (TCRs) and peptide-MHC (pMHC) complexes is a fundamental challenge in computational immunology, constrained by sparse paired interaction data relative to abundant unpaired sequences. We introduce DecoderTCR, a masked language model framework that addresses this through two contributions: (1) a compositional continual pre-training curriculum that learns component representations from marginal data before refining cross-chain dependencies, and (2) Iterative Entropy-Guided Refinement (IEGR), a non-autoregressive decoding algorithm that resolves high-confidence positions first to provide context for uncertain regions. On held-out benchmarks, DecoderTCR achieves 0.96 AUROC for zero-shot pMHC binding prediction and 0.76 AUROC for epitope-specific TCR recognition, approaching supervised baselines without epitope-specific training. Learned representations recover structural contacts without coordinate supervision, and generated sequences exhibit realistic recombination statistics. Experimental validation across two rounds of wet-lab screening reveals a prediction-generation gap that can be narrowed via a lab-in-the-loop paradigm for TCR design.
****
Adaptive Time Series Reasoning via Segment Selection
Shvat Messica, Jiawen Zhang, Kevin Li, Theodoros Tsiligkaridis, Marinka Zitnik
Time series reasoning tasks often start with a natural language question and require targeted analysis of a time series. Evidence may span the full series or appear in a few short intervals, so the model must decide what to inspect. Most existing approaches encode the entire time series into a fixed representation before inference, regardless of relevance.
We introduce ARTIST, which formulates time-series reasoning as a sequential decision problem. ARTIST interleaves reasoning with adaptive temporal segment selection. It adopts a controller-reasoner architecture and uses reinforcement learning to train the controller role to select informative segments and the reasoner role to generate segment-conditioned reasoning traces and final answers. During inference, the model actively acquires task-relevant information instead of relying on a static summary of the full sequence. We use a novel hierarchical policy optimization approach for post-training that allows the model to excel in both segment selection and question-answering behavior. We evaluate ARTIST on six time-series reasoning benchmarks and compare it with large language models, vision-language models, and prior time-series reasoning systems. ARTIST improves average accuracy by 6.46 absolute percentage points over the strongest baseline. The la

rgest gains appear on rare event localization and multi-segment reasoning tasks. Supervised fine-tuning improves performance, and reinforcement learning provides additional gains by optimizing question-adaptive segment selection, showing that selective data use drives effective time-series reasoning.
****
Di-BiLPS: Denoising induced Bidirectional Latent-PDE-Solver under Sparse Observations
Zhonghao Li, Chaoyu Liu, Zhang Qian
Partial differential equations (PDEs) are fundamental for modeling complex natural and physical phenomena. In many real-world applications, however, observational data are \textbf{extremely sparse}, which severely limits the applicability of both classical numerical solvers and existing neural approaches. While neural methods have shown promising results under moderately sparse observations, their inference efficiency at high resolutions is limited, and their accuracy degrades substantially in the extremely sparse regime. In this work, we propose the \textbf{Di-BiLPS}, a unified neural framework that effectively handle \textbf{both forward and inverse} PDE problems under extremely sparse observations. Di-BiLPS combines a variational autoencoder to compress high-dimensional inputs into a compact latent space, a latent diffusion module to model uncertainty, and contrastive learning to align representations. Operating entirely in this latent space, the framework achieves efficient inference while retaining flexible input–output mapping. In addition, we introduce a \textbf{PDE-informed denoising algorithm} based on a variance-preserving diffusion process, which further improves inference efficiency. Extensive experiments on multiple PDE benchmarks demonstrate that Di-BiLPS consistently achieves \textbf{SOTA performance under extremely sparse inputs (as low as 3\%)}, while substantially reducing computational cost. Moreover, Di-BiLPS enables \textbf{zero-shot super-resolution}, as it allows predictions over continuous spatial–temporal domains.

Beyond Pixel Histories: World Models with Persistent 3D State
Samuel Garcin, Thomas Walker, Steven McDonagh, Tim Pearce, Hakan Bilen, Tianyu He, Kaixin Wang, Jiang Bian
Interactive world models continually generate video by responding to a user's actions, enabling open-ended generation capabilities.
However, existing models typically lack a 3D representation of the environment, meaning 3D consistency must be implicitly learned from data, and spatial memory is restricted to limited temporal context windows. This results in an unrealistic user experience and presents significant obstacles to downstream tasks such as training agents. To address this, we present PERSIST, a new paradigm of world model which simulates the evolution of a latent 3D scene: environment, camera, and renderer.
This allows us to synthesise new frames with persistent spatial memory and consistent geometry. Both quantitative metrics and a qualitative user study show substantial improvements in spatial memory, 3D consistency, and long-horizon stability over existing methods, enabling coherent, evolving 3D worlds. We further demonstrate novel capabilities, including synthesising diverse 3D environments from a single image, as well as enabling fine-grained, geometry-aware control over generated experiences by supporting environment editing and specification directly in 3D space.
****
Future Dynamic 3D Reconstruction: A 3D World Model with Disentangled Ego-Motion
Nils Morbitzer, Jonathan Evers, Artem Savkin, Thomas Stauner, Nassir Navab, Federico Tombari, Stefano Gasperini
Forecasting the evolution of dynamic environments is crucial for autonomous agents. While generative world models have recently achieved high photorealism in 2D video synthesis by mixing ego-motion and environmental dynamics within the image plane, they exhibit physical inconsistencies, such as morphing or vanishing objects, especially over long time horizons. In this paper, we propose FR3D, a world model that predicts a persistent 3D latent representation for future dynamic 3D reconstruction. Unlike prior works that treat the world as a sequence of imag

e-based features, FR3D explicitly decouples the 3D evolution of the scene from t
he agent's trajectory, treating the inferred ego-motion as a latent proxy for ac
tion. This disentanglement resolves the ambiguities between self-motion and worl
d-motion, ensuring geometric consistency into the future. Furthermore, we introd
uce a teacher-student distillation strategy that leverages the spatial "common s
ense" of off-the-shelf foundation models, leading to robust zero-shot generaliza
tion. Extensive experiments demonstrate FR3D's strong performance for future dyn
amic 3D reconstruction from monocular observations across multiple datasets, eve
n 2 seconds into the future. Project page: https://fr3d-wm.github.io.

DomED: Redesigning Ensemble Distillation for Domain Generalization
Ziang Song, Zhidan Zhou, Zijun Zhang
Domain generalization aims to improve model performance on unseen, out-of-distri
bution (OOD) domains, yet existing methods often overlook the crucial aspect of
uncertainty quantification in their predictions. While ensemble learning combine
d with knowledge distillation offers a promising avenue, naively combining these
techniques is non-trivial and remains largely unexplored in the context of doma
in generalization. In this work, we systematically investigate different ensembl
e and distillation strategies for domain generalization tasks and design a tailo
red data allocation scheme. This approach trains teacher models on distinct subs
ets of domains and performs distillation on complementary (unseen) subsets, ther
eby fostering model diversity and training efficiency. Moreover, our theoretical
analysis demonstrates that distilling from teachers on unseen domains effective
ly filters out domain-specific spurious correlations. To address the accuracy de
gradation often observed with standard uncertainty distillation, we further deve
lop a novel technique that decouples uncertainty distillation from the standard
distillation process, enabling accurate uncertainty estimation without compromis
ing model accuracy. Our proposed method, *Domain-aware Ensemble Distillation* (D
omED), is extensively evaluated against state-of-the-art domain generalization a
nd ensemble distillation techniques across multiple benchmarks, achieving compet
itive accuracies and substantially improved uncertainty estimates.

Why Linear Recurrent Memory Works in Partially Observable Reinforcement Learning
Yike Zhao, Onno Eberhard, Malek khammassi, Ali H. Sayed, Michael Muehlebach
The family of linear recurrent neural networks has shown strong performance as r
ecurrent memory units in partially observable reinforcement learning. We provide
a theoretical justification for their empirical effectiveness by constructing a
nd studying two linear filters:
(i) the first exactly reproduces the pre–softmax logits of the belief vector in
a hidden Markov model (HMM) under a deterministic transition matrix, thereby ser
ving as a sufficient statistic for optimal policy learning, (ii) the second achi
eves vanishing state-decoding error under a nearly deterministic transition matr
ix, thus reducing state ambiguity to near zero. The results extend to action-con
trolled HMMs, where the corresponding linear filters become time-varying with ac
tion-dependent dynamics. We illustrate our main results through numerical experi
ments and further show that the constructed linear filter serves as a strong fea
ture extractor in a small reinforcement learning game.

Learning to Watch: Active Video Anomaly Understanding via Interleaved Policy Opt
imization
Mengjingcheng Mo, Jiaxu Leng, Xinbo Gao
Video anomaly understanding (VAU) relies on sparse, context-dependent cues. Howe
ver, existing passive paradigms suffer from observational aliasing, where static
sampling fails to disambiguate semantically distinct events. To overcome this,
we propose $Anom\text{-}\pi$, a closed-loop framework that reconceptualizes vide
o understanding as an active sequential decision-making process within a dynamic
environment.
Inspired by human video-reviewing behavior, this framework unifies internal cogn
itive reasoning and strategic evidence acquisition into an interleaved policy, u
tilizing temporal atomic operators such as local backtracking, temporal expansio

n, and fine-grained sampling to endow the model with perceptual proactivity. To learn such complex interaction strategies under video-level weak supervision, we design Interactive Direct Preference Optimization (iDPO) to achieve trajectory-level policy alignment, guided by an Active Evidence Inquiry (AEI) utility that balances task success, informative evidence acquisition, and interaction cost. This approach enables the agent to learn to actively disambiguate hypotheses while suppressing redundant exploration. Extensive experiments demonstrate that our framework, with only 2B parameters, achieves highly competitive performance, significantly outperforming state-of-the-art large-scale VAU models in complex scenarios.

DAG-MoE: From Simple Mixture to Structural Aggregation in Mixture-of-Experts

Jiarui Feng, Hanqing Zeng, Karish Grover, Ruizhong Qiu, Yinglong Xia, Qiang Zhang, Qifan Wang, Ren Chen, Dongqi Fu, Jiayi Liu, Zhuokai Zhao, Xiangjun Fan, Benyu Zhang, Yixin Chen

Mixture-of-Experts (MoE) models have become a leading approach for decoupling parameter count from computational cost in large language models, yet effectively scaling MoE performance remains a challenge. Prior work shows that fine-grained experts enlarge the space of expert combinations and improve flexibility, but they also impose substantial routing overhead, creating a new scalability bottleneck. In this paper, we explore a complementary axis for scaling—how expert outputs are aggregated. We theoretically show that replacing the standard weighted-summation aggregation with structural aggregation expands the expert-combination space without altering the experts or router, and enables possible multi-step reasoning within a single MoE layer. To this end, we propose DAG-MoE, a sparse MoE framework that employs a lightweight module to automatically learn the optimal aggregation structure among the selected experts. Extensive experiments under standard language modeling settings show that DAG-MoE consistently improves performance in both pretraining and fine-tuning, surpassing traditional MoE baselines.

Steering Out-of-Distribution Generalization with Concept Ablation Fine-Tuning

Helena Casademunt, Caden Juang, Adam Karvonen, Samuel Marks, Senthooran Rajamanoharan, Neel Nanda

Fine-tuning large language models (LLMs) can lead to unintended out-of-distribution generalization. Standard approaches to this problem rely on modifying the training data, for example by adding data that better specify the intended generalization. However, this is not always practical. We introduce Concept Ablation Fine-Tuning (CAFT), a technique that leverages interpretability tools to control how LLMs generalize from fine-tuning, without needing to modify the training data or otherwise use data from the target distribution. Given a set of directions in an LLM's latent space corresponding to undesired concepts, CAFT works by ablating these concepts with linear projections during fine-tuning, steering the model away from unintended generalizations. We successfully apply CAFT to three fine-tuning tasks, including emergent misalignment, a phenomenon where LLMs fine-tuned on a narrow task generalize to give egregiously misaligned responses to general questions. Without any changes to the fine-tuning data, CAFT reduces misaligned responses by 10x without degrading performance on the training distribution. Overall, CAFT represents a novel approach for steering LLM generalization without modifying training data.

Sketch-Based Low-Rank Model Merging with Shared Circulant Transforms

Zhiming Zhang, Rong Yin, Xiaoshuai Hao, Hansong Zhang, Hao Peng, Yong Liu, Can Ma, Dan Meng

Merging multiple low-rank adapters (LoRA) provides a practical route to scaling multi-task learning and deployment more efficiently than full-model weight merging, while avoiding reliance on task-specific training data. However, most existing approaches either treat LoRA updates as dense weight deltas or depend on expensive subspace factorizations, making the merge step a primary latency bottleneck. To address this issue, this paper establishes a theoretically positive relationship between merging quality and the effective rank of the matrices being merg

ed. Motivated by this insight, we propose **CircuMerge**, a sketch-based framewo rk for low-rank model merging built on shared circulant transforms. Especially, this approach treats each adapter as a pair of low-rank matrices and applies a s hared circulant transform to align all tasks in a common coordinate system. This alignment enables more efficient sampling, allowing us to generate compact sket ches that effectively summarize the interactions between tasks. These compact sk etches enable applying the merging rules directly to them and reconstructing a s tandard low-rank adapter, preserving the essential information while significant ly reducing computational overhead. Across a broad multi-task LoRA benchmarks co vering both vision and language settings, extensive empirical results demonstrat e that CircuMerge reduces the overall merging time by at least 44\% compared to the state-of-the-art approaches, with accuracy matching or exceeding the optimal level.

****

The Realignment Problem: When Right becomes Wrong in LLMs

Aakash Sen Sharma, Debdeep Sanyal, Manodeep Ray, Vivek Srivastava, Shirish Karan de, Murari Mandal

Post-training alignment of large language models (LLMs) relies on large-scale hu man annotations guided by policy specifications that change over time. Cultural shifts, value reinterpretations, and regulatory or industrial updates make stati c alignment increasingly brittle. As policies evolve, deployed models can diverg e from current alignment objectives, creating an Alignment–Reality Gap that is d ifficult to audit or correct. Existing remediation typically requires re-annotat ion under revised guidelines, which introduces systematic challenges, including guideline ambiguity, annotator interpretation drift, and reduced consistency at scale. We introduce TRACE (Triage and Re-align by Alignment Conflict Evaluation) , a framework that transforms re-alignment into a structured optimization proble m over existing data without requiring fresh human annotation. Leveraging a stro nger model as a proxy judge, TRACE operates via a three-stage pipeline: (1) tria ging preference pairs into inversion, suppression, or retention categories based on alignment conflicts; (2) computing an alignment impact score via bi-level op timization to prioritize high-leverage samples; and (3) executing updates using a hybrid objective that combines relational losses (e.g., IPO) for preference in version and punitive losses (e.g., NPO) for response suppression. Experiments on Qwen2.5-7B, Gemma-2-9B, and Llama-3.1-8B demonstrate robust re-alignment on syn thetic benchmarks and the PKU-SafeRLHF dataset without degrading general utility . This work provides a scalable approach for LLM realignment under evolving data annotation policies and alignment guidelines. We release our code \href{https:/ /respailab.github.io/TRACE/}{here}.

Learning Sparse Visual Representations via Spatial-Semantic Factorization

Theodore Zhao, Sid Kiblawi, Jianwei Yang, Naoto Usuyama, Reuben Tan, Noel C Code lla, Tristan Naumann, Hoifung Poon, Mu Wei

Self-supervised learning (SSL) faces a tension between semantic understanding an d image reconstruction. High-level semantic SSL methods such as DINO encourage t ransformation-invariant global representations for augmentation alignment, while reconstruction-oriented methods such as MAE preserve dense feature grids for sp atial grounding but often yield weaker semantic abstractions. We introduce STELL AR, a framework that alleviates this tension by factorizing visual features into a low-rank product of semantic concepts and their spatial distributions. This d isentanglement allows us to perform augmentation alignment on semantic tokens wh ile maintaining spatial localization through a localization matrix for reconstru ction. We demonstrate that as few as 16 sparse tokens under this factorized form can simultaneously support high-quality reconstruction (2.60 FID) and strong se mantic transfer (79.10% ImageNet accuracy). Our results highlight STELLAR as a v ersatile sparse representation that bridges discriminative and generative vision by separating semantic identity from spatial geometry. Code is available at htt ps://github.com/microsoft/STELLAR.

Unbiased and Second-Order-Free Training for High-Dimensional PDEs

Jaemin Seo, Su Rin Lee, Jae Yong Lee
Deep learning methods based on backward stochastic differential equations (BSDEs) have emerged as competitive alternatives to physics-informed neural networks (PINNs) for solving high-dimensional partial differential equations (PDEs). By le veraging probabilistic representations, BSDE approaches can avoid the curse of d imensionality and often admit second-order-free training objectives that do not require explicit Hessian evaluations. It has recently been established that the commonly used Euler–Maruyama (EM) time discretization induces an intrinsic bias in BSDE training losses. While high-order schemes such as Heun can fully elimina te this bias, such schemes re-introduce second-order spatial derivatives and inc ur substantial computational overhead. In this work, we provide a principled ana lysis of EM-induced loss bias and propose an unbiased, second-order-free trainin g framework that preserves the computational advantages of BSDE methods. Our cod e is available at https://github.com/seojaemin22/Un-EM-BSDE.

More Capable, Less Cooperative? When LLMs Fail at Zero-Cost Collaboration
Advait Yadav, Sidney Black, Oliver Sourbut
Large language model (LLM) agents increasingly coordinate in multi-agent systems , yet we lack an understanding of where and why cooperation fails. Many real-wor ld coordination problems are not social dilemmas: helping others—sharing documen tation, unblocking a teammate—costs the helper almost nothing while producing su bstantial collective benefit. Whether LLM agents cooperate in this regime, where helping is free and they are explicitly instructed to do so, remains unknown. W e build a turn-based multi-agent environment that strips away all strategic comp lexity, making cooperation costless and trivially optimal. Across eight widely u sed LLMs, capability does not predict cooperation: OpenAI o3 reaches only 17\% o f optimal collective performance while the weaker o3-mini reaches 50\%, despite identical instructions to maximize group revenue. Using a causal decomposition t hat automates one side of agent communication, we separate cooperation failures from competence failures, and find that several capable models actively withhold information despite gaining nothing from withholding. Targeted interventions ad dress each mode: explicit protocols roughly double the performance of competence -limited models, while small sharing incentives unlock cooperation-limited ones. Our results suggest that scaling intelligence alone will not solve coordination in multi-agent systems, and will require deliberate cooperative design, even wh en helping costs nothing.

Steering Large Language Models through the DMTA Cycle: Structure-Based Drug Desi gn via Knowledge-Driven Bi-Level Thompson Sampling
Xuanning Hu, Hao Tuo, Jinglong Ji, Anchen Li, Qianli Xing, Bo Yang
Structure-based drug design (SBDD) can be effectively realized through an iterat ive refinement via the Design-Make-Test-Analyze (DMTA) cycle, which is a common workflow used by human experts. However, most conventional deep learning-based m odels as one-shot generators that lack feedback mechanisms, leaving the DMTA loo p disconnected. In this work, we propose K-BTS, a Knowledge-Driven Bi-level Thom pson Sampling framework that formalizes iterative SBDD as a Dynamic Hierarchical Multi-Armed Bandit problem. K-BTS closes the DMTA loop by decoupling decisions into two levels: an upper-level policy that prioritizes high-potential molecular lineages and a lower-level mechanism that retrieves explicit chemical rules to guide LLM generation. By integrating a dual-level Bayesian update, the framework transforms sparse docking scores into reusable experience. On the CrossDocked20 20 benchmark, K-BTS achieves a state-of-the-art Top-1 average docking score. The results from diverse dimensions show that K-BTS ensures search determinism thro ugh a smooth, monotonic convergence that synchronizes structural drift with affi nity improvement.

UniScale: Adaptive Unified Inference Scaling via Online Joint Optimization of Mo del Routing and Test-Time Scaling
Kaiyu Huang, Xingyu Wang, Mingze Kong, Zhubo Shi, Yuqian Hou, Hong Xu, Zhongxian g Dai, Minchen Yu, Qingjiang Shi

In real-world deployments of large language models (LLMs), balancing inference q
uality and computational cost has become a central challenge.
Existing approaches tackle this trade-off along two largely independent dimensio
ns: model routing, which switches among models of different scales to match requ
est complexity, and test-time scaling (TTS), which adjusts inference-time comput
e within a fixed model for fine-grained control.
However, this decoupled design introduces inherent limitations.
Model routing yields coarse-grained, discrete performance changes due to the spa
rse set of model scales, while single-model TTS often encounters capacity ceilin
gs and exhibits diminishing returns as compute increases.
Moreover, treating the two mechanisms separately restricts adaptability in dynam
ic inference environments.
To overcome these limitations, we introduce *Unified Inference Scaling (UIS)*, w
hich unifies model routing and TTS in a single optimization space.
Building on this formulation, we propose UniScale, an online framework that mode
ls adaptive UIS as a contextual multi-armed bandit problem and learns inference
policies via LinUCB.
The framework incorporates efficiency-aware learning and cost modeling to ensure
 stable and scalable optimization over high-dimensional action spaces.
Evaluation shows that UniScale effectively exploits the synergy in the UIS space
 to deliver a fine-grained and consistently better quality–cost trade-off across
 diverse, dynamic inference scenarios.

Chunk-Guided Q-Learning
Gwanwoo Song, Kwanyoung Park, Youngwoon Lee
In offline reinforcement learning (RL), single-step temporal-difference (TD) lea
rning can suffer from bootstrapping error accumulation over long horizons. Actio
n-chunked TD methods mitigate this by backing up over multiple steps, but can in
troduce suboptimality by restricting the policy class to open-loop action sequen
ces. To resolve this trade-off, we present Chunk-Guided Q-Learning (CGQ), a sing
le-step TD algorithm that guides a fine-grained single-step critic by regularizi
ng it toward a chunk-based critic trained using temporally extended backups. Thi
s reduces compounding error while preserving fine-grained value propagation. We
theoretically show that CGQ attains tighter critic optimality bounds than either
 single-step or action-chunked TD learning alone. Empirically, CGQ achieves stro
ng performance on challenging long-horizon OGBench tasks, often outperforming bo
th single-step and action-chunked methods.

Efficient-DLM: From Autoregressive to Diffusion Language Models, and Beyond in S
peed
Yonggan Fu, Lexington Whalen, Zhifan Ye, Xin Dong, Shizhe Diao, Jingyu Liu, Chen
gyue Wu, Hao Zhang, Enze Xie, Song Han, Maksim Khadkevich, Jan Kautz, Yingyan Ce
line Lin, Pavlo Molchanov
Diffusion language models (dLMs) have emerged as a promising paradigm enabling p
arallel generation, but their learning efficiency lags behind that of autoregres
sive (AR) language models when trained from scratch. To this end, we study AR-to
-dLM conversion, which transforms pretrained AR models into efficient dLMs that
excel in speed while preserving AR models' task accuracy. We achieve this by ide
ntifying limitations in the attention patterns and objectives of existing AR-to-
dLM methods and then proposing methodologies and actionable insights for scalabl
e AR-to-dLM conversion. Specifically, we first systematically compare different
attention patterns and find that maintaining pretrained AR weight distributions
is key to effective AR-to-dLM conversion. Accordingly, we introduce a continuous
 pretraining scheme with a block-wise attention pattern. We find that, in additi
on to block-wise attention's known benefit of enabling KV caching, its block-wis
e causality better preserves pretrained AR models' weight distributions, leading
 to a win–win in accuracy and efficiency. Second, to mitigate the training–test
gap in mask token distributions (uniform vs. highly left-to-right), we propose a
 position-dependent token masking strategy that assigns higher masking probabili
ties to later tokens during training to better mimic test-time behavior. These s

tudies lead to the Efficient-DLM model family, which outperforms state-of-the-art AR models and dLMs in accuracy–throughput trade-offs; for example, our Efficient-DLM-8B achieves +5.4\%/+2.7\% higher accuracy with 4.7$\times$/2.8$\times$ higher throughput compared to Dream-7B and Qwen3-4B, respectively.

PortraitRL: Reinforcement Learning for Personalized Portrait Pose Transfer with Multi-Objective Reward Modeling
Jiahui Wu, Zelong Sun, Yanbiao Ma, Zhiwu Lu
Portrait pose transfer (PPT) requires generative models to preserve fine-grained identity details while following complex pose and layout modification instructions.
Existing methods often struggle with extensive data annotation requirements or employ optimization objectives that are suboptimal for addressing PPT's two key challenges.
In this work, we propose PortraitRL, a novel post-training framework that addresses these challenges with a multi-objective reward mechanism. Specifically, we employ LVLM-based reward functions to effectively evaluate PPT's two challenges and apply within-group standardization to eliminate scale differences, allowing these rewards to effectively guide optimization.
More importantly, we devise a novel reinforcement learning algorithm, Negative-aware Score Preference Optimization (NaSPO), which automatically identifies positive and negative preference samples through within-group advantages, eliminating annotation requirements while fully leveraging both positive and negative learning signals.
Extensive experiments show state-of-the-art performance, with significant improvements in both detail preservation and editing accuracy.

AGoQ: Activation and Gradient Quantization for Memory-Efficient Distributed Training of LLMs
WenXiang Lin, Juntao Huang, LuHan Zhang, Laiyi Li, Xiang Bao, mengyang zhang, Bing Wang, Shaohuai Shi
Quantization is a key method for reducing the GPU memory requirement of training large language models (LLMs). Yet, current approaches are ineffective for 4-bit activations and 8-bit gradients, which would easily cause slow convergence or accuracy loss. To address this, we introduce AGoQ, incorporating two new techniques: 1) a layer-aware activation quantization algorithm that allocates appropriate bit-widths for activations of various layers based on their types and pipeline stages to achieve near 4-bit activation storage, and 2) a gradient quantization algorithm that reduces memory usage and shortens communication time by employing 8-bit gradient storage and precision-preserving 8-bit All-Reduce communication. We conduct extensive experiments using different sizes of LLMs on two GPU clusters (up to 64 GPUs), and the experimental results show that our AGoQ reduces the memory by up to 52\% and achieves up to 1.34$\times$ improvement of training speed compared to state-of-the-art training systems Megatron-LM (w/ or w/o ZeRO), COAT and DeepSpeed with 8B to 32B LLaMA models, while achieving convergence loss on pretraining and comparable accuracy on downstream tasks with LLaMA architectures.

LLM-Guided Loop Bound Generation for Program Termination Verification
Zan Gong, Biting Huang, Fei He
Program termination is a fundamental liveness property in software verification. Proving termination of a given program is a formidable challenge due to the undecidability of the problem. In this paper, we propose LIFT, a termination verification framework that leverages LLMs to generate loop bounds within a guess-and-check workflow. LIFT couples this generation with a sound formal validation procedure that both guarantees all reported terminations and refutes invalid loop bounds via violation analysis. Experiments on publicly accessible termination benchmarks show that LIFT significantly outperforms existing termination verification tools.

Selling Data as a Digital Good with Scaling Valuations
Ningyuan Li, Yanru Guan, Xiaotie Deng, Zihe Wang, Jie Zhang
We study mechanism design for selling data as a digital good when the value derived from training AI models follows a scaling law. The seller faces a linear cost when producing data, while the buyers benefit from additional data with diminishing returns as data volume increases. This departs from classical auction models by allowing allocations to be continuous quantities of data rather than binary outcomes.
We first analyze an offline setting in which all buyer types are realized simultaneously, characterizing profit-optimal mechanisms and showing how virtual-value methods extend to continuous data allocations. We then consider an online setting with sequential arrivals, where production decisions must be made under demand uncertainty. We show that myopic allocation and fixed production plans can be arbitrarily suboptimal,
whereas a simple two-stage algorithm that combines upfront production with adaptive expansion achieves a constant-factor approximation to the offline optimum.
Finally, we study bilateral data trading under asymmetric information, where both the buyer's value and the seller's cost are private. Although the optimal truthful mechanism has a complex structure, we show that simple and implementable mechanisms recover a constant fraction of the first-best gain-from-trade.
Overall, our results highlight how scaling laws introduce new algorithmic trade-offs in market design and provide performance guarantees for data markets under uncertainty.
****
ReMoE: Boosting Expert Reuse through Router Fine-Tuning in Memory-Constrained MoE LLM Inference
Xiongwei Zhu, Xiaojian Liao, Tianyang Jiang, Yusen Zhang, Liang Wang, Limin Xiao
Fine-grained Mixture-of-Experts (MoE) models sparsely activate only a subset of experts per token, reducing activated computation while maintaining high model capacity. However, in memory-constrained inference scenarios, only a small set of experts can be cached. Experts not in the cache must be fetched from slow external storage (e.g., UFS), leading to frequent evictions and substantial I/O overhead.
We propose ReMoE, a router fine-tuning framework designed to boost
token-wise expert reuse. ReMoE biases the router toward recently
selected experts, producing temporally stable routing that better
matches cache locality constraints. By increasing short-horizon expert
reuse, ReMoE reduces expert fetches from storage without adding
inference-time computation.
Experiments on DeepSeek and Qwen models show that ReMoE improves expert reuse by 26\% while maintaining downstream task performance. Real-system evaluations further confirm these benefits, improving output throughput by 8.4\% under vLLM GPU--CPU expert offloading and reducing TPOT by 43.6-49.8\% under llama.cpp on Jetson Orin NX, corresponding to a 1.77-1.99$\times$ decode speedup across diverse workloads. Checkpoints and usage instructions are available at https://github.com/BUAA-OSCAR/ReMoE.
****
LFQ: Logit-aware Final-block Quantization for Boosting the Generation Quality of Low-Bit Quantized LLMs
Jung Hyun Lee, June Yong Yang, Jungwook Choi, Eunho Yang
As large language models continue to scale, low-bit weight-only post-training quantization (PTQ) offers a practical solution to their memory-efficient deployment. Although block-wise PTQ is capable of matching the full-precision (FP) baseline on basic language modeling and understanding, its quality is degraded for \textit{generative} tasks---especially at longer responses and extended chains of thought, which is critical in boosting task accuracy. We attribute this shortfall to two factors: (i) the omission of the unembedding layer (the LM head) in block-wise optimization and (ii) the reliance on the mean squared error (MSE) objective. Both factors cause the token probability distribution of the quantized model to misalign with that of the FP model, yielding notable accuracy drops on text

generation benchmarks. To rectify the discrepancy, we introduce \emph{Logit-aware Final-block Quantization (LFQ)}, a simple yet effective enhancement to block-wise PTQ that quantizes the final Transformer block by minimizing the cross-entropy between the logits of the FP model and those of its quantized counterpart. By aligning token probabilities at the logit level in the final block, LFQ consistently improves the accuracy of complex generation tasks over state-of-the-art block-wise PTQ across diverse model families, while maintaining parity with FP baselines on language modeling and understanding.

What Makes a Strong Model? A Unified Spectral Analysis of Knowledge Transfer over High-dimensional Linear Regression

Wendao Wu, Fangqing Zhang, Haihan Zhang, Cong Fang

Teacher-Student Knowledge Transfer (KT) is ubiquitous in modern machine learning, ranging from classical model compression via Knowledge Distillation (KD) to the emergent phenomenon of Weak-to-Strong (W2S) generalization. While existing studies offer isolated insights, a unified theoretical framework explaining the efficacy of KT across these disparate regimes remains lacking. In this work, we establish a unified spectral analysis of SGD dynamics in high-dimensional linear regression, elucidating the efficiency of KT across seemingly disparate regimes. We characterize KT efficiency through two distinct mechanisms: \emph{Spectral Horizon Expansion} in KD, which enables the capture of statistically inaccessible high-frequency signals, and \emph{Spectral Denoising} in W2S, where the student acts as a filter for optimization noise. Our framework unifies these phenomena, revealing that the efficacy of transfer is governed by the interplay between implicit regularization and heterogeneous spectral learning speeds over the spectrum.

DAVE: Distribution-Aware Attribution via ViT Gradient Decomposition

Adam Wróbel, Siddhartha Gairola, Jacek Tabor, Bernt Schiele, Bartosz Micha■ Ziel i■ski, Dawid Damian Rymarczyk

Vision Transformers (ViTs) have become a dominant architecture in computer vision, yet producing stable and high-resolution attribution maps remains challenging. Architectural components such as patch embeddings and attention routing often introduce structured artifacts in pixel-level explanations, leading many existing methods to rely on coarse patch-level attributions. We introduce DAVE (Distribution-Aware Attribution via ViT Gradient Decomposition), a mathematically grounded attribution method for ViTs based on a structured decomposition of the input gradient. By exploiting architectural properties of ViTs, DAVE isolates locally equivariant and stable components of the effective input-output mapping while suppressing architecture-induced artifacts and instability. Consequently, DAVE produces robust, precise, and class-consistent attribution maps that highlight model-relevant visual features. Experimental results show that across supervised, self-supervised, and inherently interpretable ViTs, DAVE outperforms prior methods on localization, faithfulness, and user studies.

Exploiting weight-space symmetries for approximating curvature

Artem Artemev, Rui Xia, Benjamin M. Boyd, Youjing Yu, Felix Dangel, Guillaume Hennequin, Alberto Bernacchia

Many machine learning techniques rely on approximating a loss function's curvature, but this is notoriously hard to do at the scale of modern deep networks. Surprisingly, no previous work has exploited the curvature constraints that arise from well known weight-space symmetries in loss landscapes. By analytically averaging over group actions that leave the loss invariant, we construct structured Hessian approximations from single gradients that can be tractably estimated, stored, and inverted. The choice of user-specified symmetry group directly governs the trade-off between approximation accuracy and computational cost. Moreover, our framework provides a unifying theoretical lens for viewing existing methods; in particular, a specific choice of symmetry group recovers Shampoo/Muon-like curvature estimates. We validate our method on a range of network architectures, and deploy it to second-order optimization benchmarks, including a small language

model. Our curvature estimation framework might find applications in other machine learning problems such as uncertainty estimation, continual learning, compression/pruning, training data attribution, and more.

ABC-Bench: An Agentic Bio-Capabilities Benchmark for Biosecurity
Andrew Bo Liu, Samira Nedungadi, Bryce Cai, Alex Kleinman, Harmon Bhasin, Seth Donoughe
Large language models (LLMs) are rapidly acquiring capabilities relevant to biological research, from literature synthesis to interpretation of experimental data. Increasingly, LLM agents can also perform *in silico* biology tasks that previously required experienced human biologists. These emerging AI capabilities offer new opportunities for scientific discovery and biomedical advances, but they also shift the landscape of biosecurity risks. To address this, we introduce the Agentic Bio-Capabilities Benchmark (ABC-Bench), a suite of tasks to measure agentic biosecurity-relevant capabilities. ABC-Bench evaluates LLM agents on both benign and dual-use biology tasks: writing code to operate liquid handling robots, designing DNA fragments for in vitro assembly, and evading DNA synthesis screening. These tasks require a combination of biology and software expertise. All tested LLM agents outperformed the median expert human baseliner on all three tasks. Agents performed highly on tasks drawing on published knowledge and well-documented protocols, and more weakly on a task requiring novel bioinformatics reasoning. In three wet-lab validation experiments, we found that OpenAI’s o4-mini-high produced scripts that, when run on an OpenTrons liquid handling robot, successfully assembled DNA with expected sequences.

Step-Size Stability in Stochastic Optimization: A Theoretical Perspective
Fabian Schaipp, Robert M. Gower, Adrien Taylor
We present a theoretical analysis of stochastic optimization methods in terms of their sensitivity with respect to the step size.
    We identify a key quantity that, for each method, describes how the performance degrades as the step size becomes too large.
    For convex problems, we show that this quantity directly impacts the suboptimality bound of the method.
    Most importantly, our analysis provides direct *theoretical* evidence that adaptive step size methods, such as SPS or NGN, are more robust than SGD.
    This allows us to quantify the advantage of these adaptive methods beyond empirical evaluation.
    Finally, we show through experiments that our theoretical bound qualitatively mirrors the actual performance as a function of the step size, even for non-convex problems.

HilbertA: Hilbert-Curve–Aligned Sparse Attention for 2D Structured Data
Shaoyi Zheng, Wenbo Lu, Yuxuan Xia, Shenji Wan
Designing sparse attention for 2D image data in diffusion and vision-language models requires reconciling spatial locality with hardware-efficient execution: handcrafted 2D sparsity patterns preserve spatial structure but often induce uncoalesced memory access, limiting practical speedups on modern GPUs.
We present **HilbertA**, a 2D-aware sparse attention mechanism that reorders image tokens along a Hilbert curve, converting local spatial neighborhoods into contiguous memory segments for efficient GPU execution. To enable communication beyond local tiles, HilbertA shifts attention windows along the Hilbert-ordered sequence across layers and uses a small central shared region, preserving contiguous access while supporting cross-tile information flow.
Across diffusion and vision-language models, HilbertA delivers consistent efficiency gains while maintaining competitive quality, achieving up to **4.16×** attention acceleration and **1.44×** end-to-end speedup on Flux.1-dev, and up to **2.30×** attention acceleration with **1.57×** faster time-to-first-token on Qwen3-VL-8B inference.

Efficient Multi-Agent Reasoning via Confidence-Guided Adaptive Debate

Seungdong Yoa, Ye Seul Sim, Suhee Yoon, Sanghyu Yoon, Dongmin Kim, Soonyoung Lee, Bumsoo Kim, Junhyun Lee

Multi-agent debate has shown promise for improving the reasoning of large language models, yet recent theory suggests its benefits are highly regime-dependent. While interaction can amplify informative signals under corrective conditions, symmetric debate dynamics are neutral in expectation, often making majority voting preferable. We reconcile these views by arguing that debate is effective only when invoked at the right time and with appropriate structure.

Based on this insight, we propose LASE: Leader-Adaptive Structured Engagement, a leader-centric multi-agent debate framework that selectively engages interaction only in non-neutral regimes.

LASE introduces an asymmetric leader–supporter architecture that enables directed information flow and selective signal amplification, while defaulting to simple aggregation otherwise. Experiments across diverse reasoning benchmarks show that LASE achieves multi-agent-level performance with near single-agent token cost, substantially improving efficiency over static debate and voting baselines.

Multivariate Distributional Reinforcement Learning Using Sliced Divergences

Baptiste Debes, Tinne Tuytelaars

Distributional reinforcement learning (DRL) models the full return distribution rather than expectations, but extending it to multivariate settings remains challenging. Many common metrics do not naturally generalize beyond one dimension or lose computational tractability, and the multivariate case introduces additional difficulties such as general matrix discounting, for which no contraction results are available. We introduce Sliced Distributional Reinforcement Learning (SDRL), which lifts tractable one-dimensional divergences to multivariate return distributions via projections. We prove Bellman contraction for uniform slicing under shared scalar discounting, and introduce a maximum-slicing variant with contraction under general dense discount matrices. SDRL supports a broad class of base divergences; we analyze Wasserstein, Cramér, and Maximum Mean Discrepancy (MMD), and characterize which SDRL variants suit the standard single-sample Bellman update used in distributional RL. We evaluate SDRL on a toy chain problem and a gridworld image-based environment as well as a subset of Atari games. Code is available at https://github.com/BaptisteDebes/SlicedDistributionalRL

Models Under SCOPE: Scalable and Controllable Routing via Pre-hoc Reasoning

Qi Cao, Shuhao Zhang, Ruizhe Zhou, Ruiyi Zhang, Peijia Qin, Pengtao Xie

Model routing chooses which language model to use for each query. By sending easy queries to cheaper models and hard queries to stronger ones, it can significantly reduce inference cost while maintaining high accuracy. However, most existing routers treat this as a fixed choice among a small set of models, which makes them hard to adapt to new models or changing budget constraints. In this paper, we propose SCOPE (Scalable and Controllable Outcome Performance Estimator), a routing framework that goes beyond model selection by predicting their cost and performance. Trained with reinforcement learning, SCOPE makes reasoning-based predictions by retrieving how models behave on similar problems, rather than relying on fixed model names, enabling it to work with new, unseen models. Moreover, by explicitly predicting how accurate and how expensive a model will be, it turns routing into a dynamic decision problem, allowing users to easily control the trade-off between accuracy and cost. Experiments show that SCOPE is more than just a cost-saving tool. It flexibly adapts to user needs: it can boost accuracy by up to **25.7\%** when performance is the priority, or cut costs by up to **95.1\%** when efficiency matters most. We release the dataset and code at our project page: https://sullivan07043.github.io/SCOPE/.

Taming the Loss Landscape of PINNs with Noisy Feynman–Kac Supervision: Operator Preconditioning and Non-Asymptotic Error Bounds

Nathanael Tepakbong, Hanyu HU, Chengyu Liu, Xiang ZHOU

Physics-Informed Neural Networks (PINNs) often train slowly or fail to converge on challenging partial differential equations (PDEs), a behavior recently linked

 to severely ill-conditioned loss landscapes inherited from the underlying diffe
rential operator. We study PINNs augmented with a pointwise data-fidelity term,
added at a few points in the domain to the standard residual and boundary losses
. We show that this supervision term acts as an operator-level preconditioner: f
or suitable weights, our comparison bounds guarantee a substantially smaller con
dition number than under the standard PINN loss, independently of how the pointw
ise labels are obtained. For a broad class of PDEs admitting a Feynman-Kac (FK)
representation, we generate such labels by Monte Carlo averages of the FK functi
onal, resulting in what we call "FK-PINNs", and using the excess risk decomposit
ion approach, we derive non-asymptotic $L^2(\Omega)$-error bounds for FK-PINNs w
ith $\tanh$ activation trained by finitely many steps of gradient descent. Along
 the way, we establish pseudo-dimension bounds for first- and second-order deriv
atives of $\tanh$ neural networks, which are of independent interest and, to the
 best of our knowledge, new. Numerical experiments on Poisson, Schrödinger, mean
 exit time, and committor problems corroborate the theory, and show that FK-PINN
s can successfully solve PDEs for which standard PINNs exhibit severe failure mo
des.

Refined Analysis of Entropy-Regularized Actor-Critic
Safwan Labbi, Paul Mangold, Daniil Tiapkin, Eric Moulines
In this paper, we study the role of the critic in actor-critic for entropy-regul
arized, finite, discounted environments. We establish that, when the critic is e
xact, using the latter as a baseline is an actual variance-reduction method. In
this case, actor-critic with stochastic gradients matches the sample complexity
of deterministic policy gradient, reaching an ϵ-optimal regularized va
lue with $\tilde{O}(\log(1/\epsilon))$ samples.
In practice, the critic is learned alongside the actor: the variance of the acto
r update is then influenced by the critic's variance and bias. Specifically, whe
n the critic has a sufficiently small error, the variance reduction and rapid co
nvergence are preserved. This suggests to learn the critic first, keeping it up
to date after each actor update, underscoring the pivotal role of accurate criti
c estimation in actor-critic methods.

ConceptMoE: Adaptive Token-to-Concept Compression for Implicit Compute Allocatio
n
Zihao Huang, Jundong Zhou, Xingwei Qu, Qiyang Min, Ge Zhang
Large language models allocate uniform computation across all tokens, ignoring t
hat some sequences are trivially predictable while others require deep reasoning
. We introduce ConceptMoE, which dynamically merges semantically similar tokens
into concepts through learnable chunking at target compression ratio R. The Mo
E architecture enables controlled evaluation: reallocating saved computation to
match baseline FLOPs and parameters isolates genuine architectural benefits. Con
ceptMoE consistently outperforms standard MoE, achieving +0.9 points on language
 pretraining, +2.3 on long context, and +0.6 on multimodal tasks. Continual trai
ning conversion with layer looping gains +5.5 points. Beyond performance, at $R=
2$, ConceptMoE reduces attention computation by $R^2\times$ and KV cache by $R\t
imes$, delivering prefill speedups up to 175\% and decoding speedups up to 117\%
. The minimal architectural changes enable straightforward integration, demonstr
ating that adaptive concept-level processing fundamentally improves LLM effectiv
eness and efficiency.

Optimization, Generalization and Differential Privacy Bounds for Gradient Desce
nt on Kolmogorov–Arnold Networks
Puyu Wang, Junyu Zhou, Philipp Liznerski, Marius Kloft
Kolmogorov--Arnold Networks (KANs) have recently emerged as a structured alterna
tive to standard MLPs, yet a principled theory for their training dynamics, gene
ralization, and privacy properties remains limited. In this paper, we analyze gr
adient descent (GD) for training two-layer KANs and derive general bounds that c
haracterize their training dynamics, generalization, and utility under different
ial privacy (DP). As a concrete instantiation, we specialize our analysis to log

istic loss under an NTK-separable assumption, where we show that polylogarithmic network width suffices for GD to achieve an optimization rate of order $1/T$ and a generalization rate of order $1/n$, with T denoting the number of GD iterations and n the sample size. In the private setting, we characterize the noise required for (ϵ,δ)-DP and obtain a utility bound of order $\sqrt{d}/(n\epsilon)$ (with d the input dimension), matching the classical lower bound for general convex Lipschitz problems. Our results imply that polylogarithmic width is not only sufficient but also necessary under differential privacy, revealing a qualitative gap between non-private (sufficiency only) and private (necessity also emerges) training regimes. Experiments further illustrate how these theoretical insights can guide practical choices, including network width selection and early stopping.

On Regret Bounds of Thompson Sampling for Bayesian Optimization

Shion Takeno, Shogo Iwazaki

We study a widely used Bayesian optimization method, Gaussian process Thompson sampling (GP-TS), under the assumption that the objective function is a sample path from a GP.

Compared with the GP upper confidence bound (GP-UCB) with established high-probability and expected regret bounds, most analyses of GP-TS have been limited to expected regret.

Moreover, whether the recent analyses of GP-UCB for the lenient regret and the improved cumulative regret upper bound can be applied to GP-TS remains unclear.

To fill these gaps, this paper shows several regret bounds:

(i) a regret lower bound for GP-TS, which implies that GP-TS suffers from a polynomial dependence on $1/\delta$ with probability δ,

(ii) an upper bound of the second moment of cumulative regret, which directly suggests an improved regret upper bound on δ,

(iii) expected lenient regret upper bounds, and

(iv) an improved cumulative regret upper bound on the time horizon T.

Along the way, we provide several useful lemmas, including a relaxation of the necessary condition from recent analysis to obtain improved regret upper bounds on T.

****

A Linearly Convergent Proximal Subgradient Algorithm for Sparse Portfolio Optimization with Transaction Cost

Xiaoting Yao, Na Zhang

Transaction cost optimization (TCO) of online portfolio selection is crucial in computing science, due to the significant impact of transaction costs in practical short-term trading. Moreover, sparsity of portfolio vector is often desired to enhance stability and decrease risk.

However, there is a lack of models considering transaction costs and sparsity simultaneously in the literature. In this paper, we first propose a K-sparse TCO model that minimizes the negative return and transaction costs while keeping the portfolio vector being K-sparse. Noting that the model is NP-hard due to the K-sparse constraint, we bypass this difficulty by reformulating the sparse model to a nonsmooth difference of convex (DC) optimization problem. We show that both problems are equivalent by proving that the penalty parameter is large enough. Then, to overcome the difficulty caused by the nonsmoothness and the simplex constraint of the model, we develop a proximal subgradient algorithm (PSGA) to solve the DC problem and apply the alternating direction of multipliers (ADMM) to compute the proximity operator of the corresponding function. Furthermore, we establish the global convergence of the entire sequence generated by PSGA through showing the surrogate function satisfies the Kurdyka-■ojasiewicz (KL) property. In addition, by showing the KL exponent of the surrogate function is $1/2$, we establish the R-linear convergence rate of PSGA for any arbitrary initiaal point. Finally, we compare our proposed algorithm with other state-of-the-art strategies on four benchmark real-market data sets, with the numerical results showing that the proposed algorithm achieves lower risk while keeping higher return than classical TCO models.

****
Low-dimensional topology of deep neural networks
Junyu Ren, Lek-heng Lim
We study layered models, including feedforward networks, ResNets, and transforme rs, by limiting each layer to a width of $d = 3$, i.e., $\mathbb{R}^3$ as repre sentation space. This allows us to track how a neural network changes low-dimens ional topological invariants through its layers. Just about any topological stru cture may be simplified or even trivialized by simply increasing dimension; e.g. , any knot is equivalent to an unknot in $\mathbb{R}^4$. By restricting to $\mat hbb{R}^3$, we not only isolate the effects of activation and depth from that of width, we work in a space that lends itself to easy visualization. We focus on l inking number here, deferring other invariants like link groups, Milnor's $\bar{ \mu}$-invariants, knot types, ambient cobordisms, to a sequel. We provide full proofs and empirical experiments to justify the following insights: When measure d by their power to effect changes in linking numbers, the layer-skipping featur e in ResNets is as powerful as the attention mechanism in transformers; both Res Nets and transformers are strictly more powerful than feedforward neural network s with monotonic activations, which are in turn more powerful than invertible an d flow-based models; but replacing monotonic activation with a nonmonotonic one elevates a feedforward network into the same expressivity class as ResNets and t ransformers. These results suggest that low-dimensional topology can be a useful tool to guide designs of AI architectures. We also generalize our results from $d = 3$ to arbitrary $d > 3$.

FLAG: Foundation model representation with Latent diffusion Alignment via Graph for spatial gene expression prediction
Qi Si, Penglei Wang, Yushuai Wu, Yifeng Jiao, Xuyang Liu, Xin Guo, Yuan Qi, Yuan Cheng
Predicting spatial gene expression from routine H\&E enables large-scale molecul ar profiling, yet current models treat this as isolated pointwise tasks, thereby overlooking essential biological structures like gene coordination and spatial distribution. To preserve these relationships, we introduce \textbf{FLAG}, a dif fusion-based framework that redefines this task as structured distribution model ing. At the same time, we identify the critical \textbf{Gene Dimension Curse}, w here joint modeling gene expression and their spatial interactions fail in high- dimensional spaces, and FLAG solves this challenge by integrating a spatial grap h encoder for topological consistency and utilizing Gene Foundation Model (GFM) alignment for gene-gene fidelity in the generation process. To rigorously assess model performance, we propose a set of novel structural evaluation metrics, inc luding Gene Structural Correlation (\textbf{GSC}) and Spatial Structural Correla tion (\textbf{SSC}). Our experiments demonstrate that FLAG is highly competitive in traditional accuracy (PCC/MSE) while achieving significantly enhanced struct ural fidelity in capturing both gene-gene and gene-spatial relationships. The co de is available at https://github.com/darkflash03/FLAG.
****
Towards Foundation Models for Zero-Shot Time Series Anomaly Detection: Leveragin g Synthetic Data and Relative Context Discrepancy
Tian Lan, Hao Duong Le, Jinbo Li, Wenjun He, Meng Wang, Chenghao Liu, Chen Zhang
Time series anomaly detection(TSAD) is a critical task, but developing models th at generalize to unseen data in a zero-shot manner remains challenging. Existing foundation models for TSAD often rely on reconstruction-error scoring at infere nce time, which can miss subtle anomalies that are well reconstructed and can fa lsely flag complex but normal patterns in unseen domains. We introduce TimeRCD, a foundation model for TSAD built on Relative Context Discrepancy (RCD), a pre-t raining paradigm that trains the model to detect anomalies by comparing a query pattern with its surrounding context. This relational formulation, implemented w ith a standard Transformer architecture, enables the model to infer normality fr om the input context rather than relying on fixed global normal patterns. We fur ther construct a large-scale synthetic corpus with context-dependent anomaly lab els to provide supervised pre-training signals for RCD. Experiments across diver

se benchmarks show that TimeRCD outperforms existing general-purpose and anomaly-specific foundation models in most zero-shot TSAD settings, while remaining competitive with dataset-specific full-shot baselines. These results provide empirical evidence that RCD is an effective direction for building robust and generalizable TSAD models.
****
N2M: Bridging Navigation and Manipulation by Learning Pose Preference from Rollout
Kaixin Chai, Hyunjun Lee, Joseph J Lim
Determining where to execute the manipulation policy is a fundamental challenge in mobile manipulation. Most approaches have formulated this as a geometric search problem, prioritizing physical reachability. However, given the high sensitivity of modern learning-based manipulation policies, geometric criteria alone are insufficient. Optimal performance requires base positioning that is aware of the policy's preference. While recent works have attempted to address this, they remain limited in practicality due to reliance on pre-built scene reconstruction and slow inference. In this work, we introduce **N2M** that systematically reformulates the approach to base positioning problem, naturally overcoming limitations of previous methods. Our key insight is that policy preferences are inherent to the local scene structure and can be effectively learned from the policy rollouts. Technically, we propose a novel *viewpoint augmentation* strategy that enables the model to learn robust, viewpoint-invariant pose preferences with remarkable data efficiency. Extensive experiments demonstrate that N2M achieves state-of-the-art performance, outperforming both non-policy-aware baselines and recent policy-aware alternatives. Furthermore, we provide a comprehensive analysis highlighting N2M’s broad applicability, generalization capabilities, and data efficiency. Project website: https://clvrai.github.io/N2M/

Mitigating Translationese Bias in Multilingual LLM-as-a-Judge via Disentangled Information Bottleneck
Hongbin Zhang, Kehai Chen, Xuefeng Bai, Youcheng Pan, Yang Xiang, Jinpeng Wang, Min Zhang
Large language models (LLMs) have emerged as a standard paradigm for automated multilingual evaluation, yet exhibit systematic biases. In this paper, we identify ``translationese bias'', in which LLMs systematically favor machine-translated text over human-authored references, and this bias is particularly pronounced in low-resource languages. We attribute this bias to spurious correlations with (a) strong latent manifold isomorphism with English and (b) high predictive confidence. To mitigate these issues, we present DIBJudge, a robust fine-tuning framework that decouples robust features and bias representations by explicitly isolating spurious attributes into a dedicated bias branch and penalizing mutual dependence to enforce disentanglement.
In particular, we present a vector-quantized compression that ensures the robust representation retains minimal and sufficient judgment-critical information.
Extensive evaluations on multilingual reward modeling benchmarks and a specially designed translationese bias evaluation suite demonstrate that DIBJudge outperforms strong baselines and effectively mitigates translationese bias.
****
Self-Supervised Learning as Discrete Communication
Kawtar Zaher, Ilyass Moummad, Olivier Buisson, Alexis Joly
Most self-supervised learning (SSL) methods learn continuous visual representations by aligning different views of the same input, offering limited control over how information is structured across representation dimensions. In this work, we frame visual self-supervised learning as a discrete communication process between a teacher and a student network, where semantic information is transmitted through a fixed-capacity binary channel. Rather than aligning continuous features, the student predicts multi-label binary messages produced by the teacher. Discrete agreement is enforced through an element-wise binary cross-entropy objective, while a coding-rate regularization term encourages effective utilization of the constrained channel, promoting structured representations. We further show th

at periodically reinitializing the projection head strengthens this effect by encouraging embeddings that remain predictive across multiple discrete encodings. Extensive experiments demonstrate consistent improvements over continuous agreement baselines on image classification, retrieval, and dense visual prediction tasks, as well as under domain shift through self-supervised adaptation. Beyond backbone representations, we analyze the learned binary codes and show that they form a compact and informative discrete language, capturing semantic factors reusable across classes.
****
WFR-MFM: One-Step Inference for Dynamic Unbalanced Optimal Transport
Xinyu Wang, Ruoyu Wang, Qiangwei Peng, Peijie Zhou, Tiejun Li
Reconstructing dynamical evolution from limited observations is a fundamental challenge in single-cell biology, where dynamic unbalanced optimal transport (OT) provides a principled framework for modeling coupled transport and mass variation.
However, existing approaches rely on trajectory simulation at inference time, making inference a key bottleneck for scalable applications.
In this work, we propose a mean-flow framework for unbalanced flow matching that summarizes both transport and mass-growth dynamics over arbitrary time intervals using mean velocity and mass-growth fields, enabling fast one-step generation without trajectory simulation.
To solve dynamic unbalanced OT under the Wasserstein-Fisher-Rao geometry, we further build on this framework to develop **Wasserstein-Fisher-Rao Mean Flow Matching (WFR-MFM)**.
Across synthetic and real single-cell RNA sequencing datasets, WFR-MFM achieves orders-of-magnitude faster inference than a range of existing baselines while maintaining high predictive accuracy, and enables efficient perturbation response prediction on large synthetic datasets with thousands of conditions.

PonderLM-2: Pretraining LLM with Latent Thoughts in Continuous Space
Boyi Zeng, He Li, Shixiang Song, Yixuan Wang, Zitong Wang, Ziwei He, Xinbing Wang, Zhouhan Lin
The remarkable success of Chain-of-Thought (CoT), which enhances performance by scaling generation steps at test-time, inspires us to ask: can we leverage a similar scaling of computational steps during pretraining to improve the generation of each individual token? To address this, we propose a novel pre-training methodology: Pretraining Language Models with Latent Thoughts (PonderLM-2). Our approach pretrains a language model (LM) to first generate an intermediate latent thought—the last hidden
state of the current position—which is then used as input to predict the actual subsequent token. This additional computational step enables the LM to refine its prediction within unconstrained continuous space. Our experiments demonstrate that, at an identical inference cost, a LM that generates one additional latent thought per token outperforms a standard model with double the parameters. For instance, our PonderLM-2-Pythia-1.4B, pretrained on 300B tokens from the Pile, significantly surpasses the vanilla Pythia-2.8B trained on the same data on both language modeling and a range of general downstream tasks. Furthermore, increasing the number of latent thoughts generated before each actual token—forming a chain analogous to CoT—consistently improves the model's performance. The code and models are available at https://github.com/LUMIA-Group/PonderLM-2.

Spatially-Adaptive Gradient Re-parameterization for 3D Large Kernel Optimization
Ho Hin Lee, Quan Liu, Shunxing Bao, Yuankai Huo, Bennett Allan Landman
Large kernel convolutions offer a scalable alternative to vision transformers for high-resolution 3D volumetric analysis, yet naively increasing kernel size often leads to optimization instability. Motivated by the spatial bias inherent in effective receptive fields (ERFs), we theoretically demonstrate that structurally re-parameterized blocks induce spatially varying learning rates that are crucial for convergence. Leveraging this insight, we introduce Rep3D, a framework that employs a lightweight modulation network to generate receptive-biased scaling

masks, adaptively re-weighting kernel updates within a plain encoder architectur
e. This approach unifies spatial inductive bias with optimization-aware learning
, avoiding the complexity of multi-branch designs while ensuring robust local-to
-global convergence. Extensive evaluations on five 3D segmentation benchmarks de
monstrate that Rep3D consistently outperforms state-of-the-art transformer and f
ixed-prior baselines. The source code is publicly available at https://github.co
m/leeh43/Rep3D.

Visual Para-Thinker: Divide-and-Conquer Reasoning for Visual Comprehension
Haoran Xu, hongyu wang, Jiaze Li, Shunpeng Chen, Zizhao Tong, Jianzhong Ju, Zhen
bo Luo, Jian Luan
Existing LLM test-time scaling laws emphasize the emergence of self-reflective b
ehaviors through extended reasoning length. Nevertheless, this vertical scaling
strategy often encounters plateaus in exploration as the model becomes locked in
to specific thinking pattern. By shifting from depth to parallelism, parallel th
inking mitigates the narrowing of exploration. However, the extension of this pa
radigm to visual domain remains an open research question. In this paper, we fir
st examine the role of visual partitioning in parallelized reasoning and subsequ
ently propose two distinct strategies. Based on the above, we introduce Visual P
ara-Thinker, representing the inaugural parallel reasoning framework for MLLMs.
To maintain path independence and promote diversity in reasoning, our approach i
ntegrates Pa-Attention alongside LPRoPE. Leveraging the vLLM framework, we have
developed a native multimodal implementation that facilitates high-efficiency pa
rallel processing. Empirical results on benchmark datasets such as V*, CountBenc
h, RefCOCO, and HallusionBench confirm that Visual Para-Thinker successfully ext
ends the benefits of parallel reasoning to the visual domain.

Grounding Functional Similarity by Invariance-Aware Model Stitching
Ioannis Athanasiadis, Anmar Karmush, Michael Felsberg
In deep learning, functional similarity evaluation quantifies the extent to whic
h independently trained models learn similar input--output relationships. In mod
el stitching, functional similarity is framed as representation forward compatib
ility, i.e., whether the representations of two models can be aligned to solve a
 given task. Recent studies, however, highlight a critical limitation: models re
lying on different information cues can still produce compatible representations
, making them appear misleadingly similar (Smith et al., 2025). We attribute thi
s failure to standard model stitching being inherently blind to the invariance p
roperties of the stitched models. To address this limitation, we introduce the f
orward--backward compatibility requirement under which we formulate the invarian
ce-aware model stitching. Through analyzing key stitching configurations, we stu
dy the interplay between forward and backward compatibility, showing that invari
ance-aware model stitching provides a more principled approach to functional sim
ilarity evaluation while revealing functional discrepancies previously obscured.

When LLMs Encounter Open-world Graph Learning: A Fresh View on Unlabeled Data Un
certainty
Yanzhe Wen, Xunkai Li, Qi Zhang, Lei Zhu, Guang Zeng, Zhihan Zhang, Rong-Hua Li,
 Guoren Wang
Recently, large language models (LLMs) have
driven a systematic shift in the graph ML com-
munity through the adoption of text-attributed
graphs (TAGs). Although a variety of frameworks
have been developed, most fail to properly ad-
dress the challenge of data uncertainty in open-
world environments. A representative source of
such uncertainty is the limited availability of la-
bels in large-scale datasets due to high annotation
costs, where unlabeled nodes may belong to either
known classes or novel, unknown classes. While
node-level out-of-distribution detection and con-

ventional open-world graph learning attempt to tackle this problem, two core limitations remain: ① Insufficient methods — existing approaches typically optimize semantics or topology in isolation for unknown-class rejection, failing to effectively integrate textual and structural information in TAGs; ② Incomplete pipelines — most studies conduct only idealized analyses, such as assuming a predefined number of unknown classes, which restricts practical utility for model updates and long-term deployment. To overcome these issues, we introduce the Open-world Graph Assistant (OGA), an LLM-based framework. OGA first performs unknown-class rejection via adaptive label traceability (ALT), harmoniously combining semantic and topological cues, and then applies the graph label annotator (GLA) for unknown-class annotation, allowing unlabeled nodes to contribute to model training. In essence, OGA offers a new pipeline that fully automates the handling of unlabeled nodes in open-world environments, and we establish a systematic benchmark covering four key aspects to validate its effectiveness and practicality through extensive experiments.

QuArch: A Benchmark for Evaluating LLM Reasoning in Computer Architecture
Shvetank Prakash, Andrew Cheng, Mark Mazumder, Arya Tschand, Varun Gohil, Jeffrey Jian Ma, Jason Yik, Zishen Wan, Jessica Quaye, Elisavet Lydia Alvanaki, Avinash Kumar, Chandrashis Mazumdar, Tuhin Khare, Alexander Ingare, Ikechukwu Uchendu, Radhika Ghosal, Abhishek Tyagi, Chenyu Wang, Andrea Mattia Garavagno, Sarah Yueqi Gu, Alice Guo, Grace Hur, Luca Carloni, Tushar Krishna, Ankita Nayak, Amir Yazdanbakhsh, Vijay Janapa Reddi
The field of computer architecture, which bridges high-level software abstractions and low-level hardware implementations, remains absent from current large language model (LLM) evaluations. To this end, we present QuArch (pronounced ‘quark’), the first benchmark designed to facilitate the development and evaluation of LLM knowledge and reasoning capabilities specifically in computer architecture. QuArch v1.0 provides a comprehensive collection of 2,671 expert-validated question-answer (QA) pairs covering various aspects of computer architecture, including processor design, memory systems, and interconnection networks. Our evaluation reveals that while frontier models possess domain-specific knowledge, they struggle with skills that require higher-order thinking in computer architecture. Frontier model accuracies vary widely (from 34% to 73%) on these advanced questions, highlighting persistent gaps in architectural reasoning across analysis, design, and implementation QAs. Furthermore, via fine-tuning we find that QuArch can translate to improved performance on a realistic memory hierarchy design task, resulting in up to 1.99× more area-efficient solutions and up to 40% more viable solutions overall. By holistically assessing fundamental skills, QuArch provides a foundation for building and measuring LLM capabilities that can accelerate innovation in computing systems. The QuArch benchmark and leaderboard are publicly available at: https://quarch.ai/.

Don't Walk the Line: Boundary Guidance for Filtered Generation
Sarah Ball, Andreas Haupt
Generative models are increasingly paired with safety classifiers that filter harmful or undesirable outputs. A common strategy is to fine-tune the generator to reduce the probability of being filtered, but this can be suboptimal: it often pushes the model toward producing samples near the classifier’s decision boundary, increasing both false positives and false negatives. We propose Boundary Guidance, a reinforcement learning fine-tuning method that explicitly steers generat

ion away from the classifier’s margin. On a benchmark of jailbreak, ambiguous, a nd long-context prompts, Boundary Guidance improves the safety while maintaining or improving the utility of outputs, as judged by LLM-as-a-Judge evaluations. C omprehensive ablations across model scales and reward designs demonstrate the ro bustness of our approach.

On the Role of Batch Size in Stochastic Conditional Gradient Methods
Rustem Islamov, Roman Machacek, Aurelien Lucchi, Tony Silveti-Falls, Eduard Gorb unov, Volkan Cevher
We study the role of batch size in stochastic conditional gradient methods under a μ-Kurdyka–■ojasiewicz (μ-KL) condition. Focusing on momentum-based st ochastic Frank–Wolfe–type conditional gradient algorithms (e.g., Scion), we deri ve a new analysis that explicitly captures the interaction between stepsize, bat ch size, and stochastic noise. Our study reveals a regime-dependent behavior: in creasing the batch size initially improves optimization accuracy, but beyond a c ritical threshold, the benefits saturate and can eventually degrade performance under a fixed token budget. Notably, the theory predicts the magnitude of the op timal stepsize and aligns well with empirical practices observed in large-scale training. Leveraging these insights, we derive principled guidelines for selecti ng the batch size and stepsize, and propose an adaptive strategy that increases batch size and sequence length during training while preserving convergence guar antees. Preliminary experiments are consistent with the theoretical predictions and illustrate the emergence of the predicted scaling regimes. Overall, our resu lts provide a theoretical framework for understanding batch-size scaling in stoc hastic conditional gradient methods and offer guidance for designing efficient t raining schedules in large-scale optimization.

VectorWorld: Efficient Streaming World Model via Diffusion Flow on Vector Graphs
Chaokang Jiang, Desen Zhou, Jiuming Liu, Li Sun
Closed-loop evaluation of autonomous-driving policies requires interactive simulation beyond log replay. Existing generative world models suffer three gaps : history-incompatible initialization, sampling latency exceeding real-time budg ets, and compounding kinematic infeasibility. We propose VectorWorld, a streamin g vector-graph world model that incrementally generates ego-centric lane--agent tiles during rollout. VectorWorld couples a motion-aware gated VAE for history-c ompatible initialization, an edge-gated relational DiT with interval-conditioned MeanFlow and JVP-based large-step supervision for solver-free outpainting, and ΔSim, a physics-aligned NPC policy with hybrid discrete--continuous actio ns and differentiable kinematic logit shaping. On Waymo Open Motion and nuPlan, VectorWorld improves map fidelity, initialization validity, and density calibrat ion, enabling stable real-time $1\mathrm{km}+$ closed-loop rollouts.

Neural-HSS: Hierarchical Semi-Separable Neural PDE Solver
Pietro Sittoni, Emanuele Zangrando, Angelo Alberto Casulli, Nicola Guglielmi, Fr ancesco Tudisco
Deep learning-based methods have shown remarkable effectiveness in solving PDEs, largely due to their ability to enable fast simulations once trained. However, despite the availability of high-performance computing infrastructure, many crit ical applications remain constrained by the substantial computational costs asso ciated with generating large-scale, high-quality datasets and training models. I n this work, inspired by studies on the structure of Green's functions for ellip tic PDEs, we introduce Neural-HSS, a parameter-efficient architecture built upon the Hierarchical Semi-Separable (HSS) matrix structure that is provably data-ef ficient for a broad class of PDEs. We theoretically analyze the proposed archite cture, proving that it satisfies exactness properties even in very low-data regi mes. We also investigate its connections with other architectural primitives, su ch as the Fourier neural operator layer and convolutional layers. We experimenta lly validate the data efficiency of Neural-HSS on the three-dimensional Poisson equation over a grid of two million points, demonstrating its superior ability t o learn from data generated by elliptic PDEs in the low-data regime while outper

forming baseline methods. Finally, we demonstrate its capability to learn from d ata arising from a broad class of PDEs in diverse domains, including electromagn etism, fluid dynamics, and biology.

What Information Matters? Graph Out-of-Distribution Detection via Tri-Component Information Decomposition
Danny Wang, Ruihong Qiu, Zi Huang
Graph neural networks are widely used for node classification, but they remain v ulnerable to out-of-distribution (OOD) shifts in node features and graph structu re. Prior work established that methods trained with standard supervised learnin g (SL) objectives tend to capture spurious signals from either features and/or s tructure, leaving the model fragile under distributional changes. To address thi s, we propose TIDE, a novel and effective Tri-Component Information Decompositio n framework that explicitly decomposes information into feature-specific, struct ure-specific and joint components. TIDE aims to preserve only the label-relevant part of the joint information while filtering out spurious feature- and structu re-specific information, thereby enhancing the separation between in-distributio n (ID) and OOD nodes. Beyond the framework, we provide theoretical and empirical analyses showing that an information bottleneck objective is preferable to stan dard SL for graph OOD detection, with higher ID confidence and a greater entropy gap between ID and OOD data. Extensive experiments across seven datasets confir m the efficacy of Tide, achieving up to a 34% improvement in FPR95 over strong b aselines while maintaining competitive ID accuracy. Code is available at https:/ /github.com/DannyW618/TIDE.

D-ARL: A Distribution-Matched Asynchronous Reinforcement Learning Framework for Language Reasoning
Yinqi Bai, Tong Xialiang, Jie Wang, Hongyu Liu, Longdi Pan, Jiashuo Li, Zehao Wa ng, Jianye HAO, Mingxuan Yuan, Feng Wu
Asynchronous reinforcement learning (RL) has shown notable success in accelerati ng the post-training of large language models (LLMs). However, its decoupled dat a generation and training paradigm introduces a fundamental distributional misma tch between data generated by stale behavior policies and current policy, leadin g to unstable training and degraded performance. To address this challenge, we p ropose D-ARL, a **D**istribution-matched **A**synchronous **R**einforcement **L* *earning framework that selects high-quality asynchronous samples whose distribu tions are well aligned with the current policy for policy optimization. Specific ally, D-ARL maintains a replay buffer that collects samples from the most recent K behavior policies and proposes a variance-guided metric to select distribut ion-matched data. During training, D-ARL introduces a multi-behavior policy opti mization algorithm to leverage the multi-source nature of the selected samples f or policy update. Experiments on six widely used reasoning benchmarks show that D-ARL outperforms state-of-the-art asynchronous methods, achieving an average im provement of 6.4\% in reasoning performance and 34.7\% in sample efficiency.

Meta-iLaD: Identifiable Latent Dynamics via Meta-Learning of Dynamics Environmen ts
Yubo Ye, Sweekar Piya, Xiajun Jiang, Linwei Wang
Learning latent dynamics is central to assessing current states and forecasting future trajectories for high-dimensional time series. For locally-stationary lat ent dynamics parameterized by past latent states and an environment variable c, with latent dynamics state z_t, prior identifiability results largely focus on z _t when conditioned on pre-defined label u of the dynamics environment. This lea ves two limitations: reliance on pre-defined labels that hinder generalization t o unseen environments, and limited understanding of the identifiability of F and c which---while offering important structural properties for the identifiabilit y of z_t---are learned jointly with z_t. We address these challenges with Meta-i LaD, a novel latent dynamics framework to attain identifiability by meta-learnin g across dynamics environments. Meta-iLaD replaces the conditioning of c on pre- defined labels with a novel conditional prior, modeled as a feedforward meta-lea

rner that rapidly extracts c from few-shot examples. We further establish simult aneous identifiability for z_t, c and F, for a general formulation of the dynami cs function F over past latent states and c, without restricting the dimension o f c or how it modulates F. We provide strong empirical evidence that 1) conditio ning on few-shot examples enables generalization to out-of-distribution environm ents, and 2) identifiability for c and F is critical for accurate forecasting be yond reconstructing observed trajectories.

Robust Cross-Modal Retrieval via Generative Semantic Refinement and Exclusion-Gu ided Adaptation
Qin Yang, Xin Wei, Yanjia Li, Jiasun Feng, Mingrui Zhu, Nannan Wang, Xinbo Gao
Vision-Language Pre-trained (VLP) models are vulnerable to real-world query nois e. Current cross-modal Test-Time Adaptation (TTA) methods often rely on high-con fidence predictions, which induces confirmation bias and neglects the informativ e signals in ambiguous Low-Confidence Queries. To address this, we propose Gener ative Semantic Refinement and Exclusion-Guided Adaptation (ReEx), a robust retri eval framework that extends adaptation to the entire query stream. Specifically, textual structural noise is rectified by a Generative Semantic Refinement (GSR) module, which employs Confidence-Guided Dynamic Fusion to anchor LLM-based repa irs and prevent semantic drift. To exploit ambiguous data, adaptation is driven by Exclusion-Guided Proxy Contrastive Learning (EPCL), which imposes negative co nstraints via Exclusion Sets of unlikely candidates. Experimental results on COC O-C and Flickr-C demonstrate that ReEx consistently outperforms existing TTA met hods, achieving significant robustness gains with a justifiable computational tr ade-off.

Multi-View Causal Discovery without Non-Gaussianity: Identifiability and Algorit hms
Ambroise Heurtebise, Omar Chehab, Pierre Ablin, Alexandre Gramfort, Aapo Hyvarin en
Causal discovery is a difficult problem that typically relies on strong assumpti ons on the data-generating model, such as non-Gaussianity. In practice, many mod ern applications provide multiple related views of the same system, which has ra rely been considered for causal discovery. Here, we leverage this multi-view str ucture to achieve causal discovery with weak assumptions. We propose a multi-vie w linear Structural Equation Model (SEM) that extends the well-known framework o f non-Gaussian disturbances by alternatively leveraging correlation over views. We prove the identifiability of the model for acyclic SEMs. Subsequently, we pro pose several multi-view causal discovery algorithms, inspired by single-view alg orithms (DirectLiNGAM, PairwiseLiNGAM, and ICA-LiNGAM). The new methods are vali dated through simulations and applications on neuroimaging data, where they enab le the estimation of causal graphs between brain regions.

Hierarchical Representations for Cross-task Automated Heuristic Design using LLM s
Fei Liu, Rui Zhang, Shunyu Yao, Qinglong Hu, kefeng zheng, Zhichao Lu, Qingfu Zh ang
Designing heuristic algorithms for complex optimization problems is a time-consu ming and expert-driven process. Recently, Automated
Heuristic Design (AHD) using Large Language Models (LLMs) has shown significant promise for automating algorithm development. However, existing works mainly rel y on programs to represent heuristics, which are inherently taskspecific and fai l to generalize as effectively as established metaheuristics like tabu search or guided local search. To bridge this gap, we introduce Multi-Task Hierarchical S earch (MTHS), an LLM-guided evolutionary method that co-designs general-purpose metaheuristics and task-specific programs. MTHS employs a hierarchical represent ation and adopts a two-level evolution framework to evolve task-agnostic metaheu ristics and task-specific program implementations simultaneously across multiple heuristic design tasks. During this evolution, a knowledge transfer mechanism a llows learning from elite programs designed for other tasks. We evaluated MTHS o

n distinct combinatorial optimization problems, where it outperforms both commonly-used heuristics and existing LLM-driven AHD approaches. Our results demonstrate that the hierarchical representations facilitate effective multi-task AHD, and the evolved metaheuristics exhibit strong generalization to related tasks. Code: https://github.com/FeiLiu36/MTHS.

FedGain: Toward Negative-Gain-Free Client Collaboration in Federated Learning

Yuqing Zhang, Changli Zhou, Binghuang Huang, Hui Tian

Data heterogeneity is a fundamental challenge in Federated Learning (FL), where induced model drift often results in "negative gains" for global models on data-abundant clients, with performance falling below that of local training. To address this issue, we propose FedGain, a novel framework that optimizes collaborative client clustering to mitigate the negative gain. We are the first to develop a modified Scaling Law (SL) to quantify the reduction in data utility caused by heterogeneity and define Effective Federated Capacity to align clients with the highest potential collaboration gains. Extensive experiments demonstrate that our modified SL strictly adheres to the power-law learning discipline in non-IID scenarios. FedGain effectively suppresses negative gains to a negligible level across various FL algorithms and outperforms other Clustered FL methods.

****

Task-and-Model-Aware Fractal-Consistency for Efficient LLM Reasoning

Ziqiu Luo, Jianmin Liu, Yukai Miao, Li Chen, Dan Li

While self-consistency methods have emerged as a promising approach to enhance the correctness of large language model (LLM) outputs by aggregating multiple stochastic samples, they suffer from two critical limitations, resulting in high computation cost. First, they evaluate output consistency monolithically, failing to efficiently combine partially correct answers across multiple samples. Second, they use static stopping criteria that cannot adapt to varying task complexities and model capabilities, resulting in suboptimal computational efficiency.In this work, we present Task-and-Model-Aware Fractal-Consistency (TMAFC), a novel self-consistency framework that addresses these limitations through two key innovations: (1) Fractal-Consistency, which evaluates output consistency at the granularity of output components to effectively combine partial correct answers across samples, and (2) Adaptive Stopping Criteria Calibration (ASCC), which dynamically adjusts sampling stopping criteria based on real-time assessment of both task difficulty and LLM capability. Through extensive experiments on diverse question-answering benchmarks, we demonstrate that TMAFC achieves superior efficiency-accuracy trade-offs, reducing sample cost by up to 55% while maintaining competitive accuracy compared to state-of-the-art baselines.

Unfolding Generative Flows with Koopman Operators: Trajectory-Preserving Linearization

Erkan Turan, Ari Siozopoulos, Louis Martinez, Julien Gaubil, Emery Pierson, Maks Ovsjanikov

Continuous Normalizing Flows (CNFs) enable elegant generative modeling but remain bottlenecked by their iterative nature requiring costly sampling and lacking interpretability of the intermediate states. Recent approaches accelerate sampling by straightening trajectories or distilling endpoints, yet they treat the original generative process as a black box, discarding the teacher’s intermediate dynamics. We propose a fundamentally different perspective: globally linearizing flow dynamics via Koopman theory to achieve trajectory-preserving linearization. By lifting Conditional Flow Matching (CFM) into a higher-dimensional Koopman space, we represent its evolution with a single linear operator. Crucially, unlike boundary-only distillation, our method enforces infinitesimal consistency with the teacher's vector field along *the full generative path*. We derive a practical, simulation-free training objective that ensures this global alignment and yields two key benefits. First, sampling becomes one-step and parallelizable. Second, because the linearization is faithful to the dynamics, the Koopman operator provides unique insights on the generation. We demonstrate that this structure enables novel applications unavailable in prior approaches, including discovery of

semantically coherent editing directions, inversion with a teacher-aligned linear operator and class-conditional spectral signatures. Empirically, our approach achieves competitive sample quality, while enabling spectral analysis and control of the *entire trajectories* of generative flows.

MetaphorVU: Towards Metaphorical Video Understanding
Zhuoqun Li, Boxi Cao, Guiping Jiang, Fangrui Lv, Ruotong Pan, Jianan Wang, Xiangyu Wu, Hongyu Lin, Yaojie Lu, Yong Du, Ruyin Jia, Liyan, Tingting Gao, Han Li, Xianpei Han, Le Sun
Metaphorical videos are prevalent across various real-world scenarios to convey complex ideas, and understanding them typically requires high-order cognitive capabilities.
The lack of systematic studies on metaphorical video understanding not only constrains the real-world applicability of MLLMs but also impedes the thorough assessment of their high-order cognitive capabilities.
To bridge this gap, we propose MetaphorVU-Bench, the first systematic and comprehensive benchmark dedicated to metaphorical video understanding.
Through experiments, we find current MLLMs struggle with accurate metaphorical video understanding, lagging far behind human level, primarily due to defective cross-domain mapping.
Motivated by this finding, we construct a metaphor knowledge graph as mapping augmentation and propose MetaphorBoost, an inference-time enhancement framework achieving consistent performance improvement.
Our benchmark, analysis, and method provide useful insights and a foundation for future research on advancing MLLMs.
Code: https://github.com/icip-cas/MetaphorVU.

Towards Practical World Model-based Reinforcement Learning for Vision-Language-Action Models
Zhilong Zhang, Haoxiang Ren, Yihao Sun, Yifei Sheng, Haonan Wang, Zhichao Wu, Haoxin Lin, Pierre-Luc Bacon, Yang Yu
Vision-Language-Action (VLA) models show strong generalization for robotic control, but finetuning them with reinforcement learning (RL) is constrained by the high cost and safety risks of real-world interaction. Training VLA models in interactive world models avoids these issues but introduces several challenges, including pixel-level world modeling, multi-view consistency, and compounding errors under sparse rewards. Building on recent advances across large multimodal models and model-based RL, we propose VLA-MBPO, a practical framework to tackle these problems in VLA finetuning. Our approach has three key design choices: (i) adapting unified multimodal models (UMMs) for data-efficient world modeling; (ii) an interleaved view decoding mechanism to enforce multi-view consistency; and (iii) chunk-level branched rollout to mitigate error compounding. Theoretical analysis and experiments across simulation and real-world tasks demonstrate that VLA-MBPO significantly improves policy performance and sample efficiency. Crucially, our method maintains a universal set of hyperparameters across all tasks, underscoring its robustness and scalability for real-world robotic deployment.
****
Mitigating Error Propagation in Low-Rank Approximation of Large Models via Distribution-Aware Whitening
Yao Zhu, Rui Sun, Xiu Yan, Yang Li, Wang Lu, Yunjian Zhang
Low-rank approximation has emerged as a cornerstone technique for model compression and parameter-efficient fine-tuning, enabling substantial reductions in computation and memory without altering model architectures. However, existing approaches often overlook the shifts in feature distributions induced by the approximation process, which can lead to error amplification and unstable inference.
We propose a distribution-aware whitening framework that dynamically whitens layer inputs based on the evolving feature distributions, ensuring second-order isotropy of input features.
This allows that the discarded components in the low-rank approximation are those with minimal impact on model outputs, thereby minimizing cumulative approximat

ion errors across layers.
We theoretically analyze how distribution misalignment leads to error propagation and demonstrate that our approach achieves tighter control over layerwise distortion.
Extensive experiments across various large language models demonstrate the superiority of our method in post-training compression. Moreover, our method can also serve as an effective initialization for LoRA-style parameter-efficient fine-tuning.
Our findings highlight the importance of considering feature distributions in low-rank approximations, paving the way for reliable and effective model compression strategies.

Modular Pretraining Enables Access Control
Ethan Roland, Murat Cubuktepe, Erick Martinez, Stijn Servaes, Keenan Pepper, Michael Vaiana, Diogo S de Lucena, Judd Rosenblatt, Addie Foote, Cem Anil, Alex Cloud
AI developers face a dual-use dilemma. A model capability that helps one user cure a disease can help another synthesize one. This dilemma could be resolved with access control, limiting dual-use AI capabilities to trusted deployments with a legitimate need. A gold standard for access control would be to serve separate models with different capabilities to different users. However, training and deploying multiple models is prohibitively expensive. To address this challenge, we propose gradient-routed auxiliary modules (GRAM), a pre-training method that adds modules to a neural network and selectively updates them to induce specialization. Ablating a module at inference time removes its capability from the network, approximating a model trained on filtered data. We evaluate GRAM on synthetic stories and realistic dual-use data spanning virology, cybersecurity, nuclear physics, and specialized code. These experiments show that GRAM preserves selected retain capabilities while disabling forgotten capabilities, and limits recovery better than post-hoc unlearning. Most importantly, a Chinchilla-optimal scaling analysis from 50M to 5B parameters shows that the forget capability gap between data-filtered and full-data models widens with scale while the retain gap stays constant, and that GRAM closely tracks data filtering. GRAM's training cost is independent of the number of supported capability profiles, yielding a 5x cost reduction in our 5-profile setting.
****
Scaling Behavior in Model Fine-tuning for Audio DeepFake Detection
Xiang Li, Pin-Yu Chen, Wenqi Wei
Recent advances in audio deepfake detection have been driven by increasingly large speech foundation models and growing amounts of synthetic data. Despite strong benchmark performance, it remains unclear how detection capability scales with model capacity and training data under realistic deployment conditions involving distribution shift, signal corruption, and unseen synthesis pipelines. In this work, we present the first systematic study of scaling laws in post-training audio deepfake detection, focusing on fine-tuning regimes rather than large-scale pretraining. Using a controlled family of speech foundation models with shared architecture and pretraining, we analyze how detection performance, robustness, and generalization evolve as a function of model size and training data scale. Our results reveal a fundamental asymmetry between performance scaling and robustness scaling in audio deepfake detection, suggesting increasing model capacity alone is insufficient for achieving reliable real-world generalization.
****
Criterion-Conditional In-Context Learning: Evaluating Criterion-Shift Adaptation in Vision-Language Models
Kaiyun Yang, Ruilin Yang, Zhimin Yao, Jikai Wang, Wei Ge
Vision-language models can perform new tasks without parameter updates through in-context learning (ICL), whose core mechanism is utilizing the support set for task induction. In the standard ICL setting, once the task is induced, its decision criterion remains fixed.
However, in real-world applications, many tasks exhibit a stable high-level inte

nt, while their decision criteria shift according to specific requirements.
Thus, we introduce a new setting, denoted as Criterion-Conditional In-Context Le arning (CC-ICL), where models must infer the latent criterion from context and a djust predictions accordingly under fixed task semantics.
To evaluate this capability, we propose two complementary metrics, Criterion Inv ariance and Criterion Sensitivity, capturing the model's robustness and adaptabi lity under criterion shifts.
We further construct CC-Bench, a multi-domain benchmark that supports evaluation under the CC-ICL setting. By employing a dual-level data hierarchy, CC-Bench en ables legitimate ground-truth variation conditioned on the active criterion even when the task remains fixed.
Experiments on CC-Bench reveal that most models exhibit a rigid boundary bias, s truggling to align their decisions with the latent criterion.
We also find that even a simple multi-criterion training strategy can significan tly reduce this bias, improving Criterion Sensitivity and enabling 7B-scale mode ls to surpass proprietary models without degrading general multimodal performanc e.
****

GeoAlign: Geometric Rollout Curation for Robust LLM Reinforcement Learning
Ting Zhou, Zhenqing Ling, Zhao Yiyang, Ying Shen, Daoyuan Chen
Online reinforcement learning is widely used to align large language models (LLM s) with reward signals, yet training can be unstable under noisy or misspecified rewards. We identify a failure mode we call directional inconsistency: within a batch, a small set of high-reward rollouts induces representation-space prefere nce directions that sharply disagree with the batch majority, resulting in high- variance and destabilizing updates. We propose GeoAlign, a lightweight plug-in f or rollout curation in iterative policy optimization. GeoAlign (i) forms within- prompt preference pairs, (ii) learns an online projector on per-rollout hidden s tates to concentrate reward-ordered displacement directions, and (iii) detects d irectionally inconsistent rollouts via their angular deviation from a batch cons ensus prototype and rectifies them with within-prompt stable alternatives. GeoAl ign is forward-pass only and adds negligible overhead. Across dialogue alignment with a learned reward model and mathematical reasoning with binary verified rew ards, GeoAlign improves final performance and reduces training oscillation, outp erforming PF-PPO, PAR, PODS, and Seed-GRPO.
These results suggest latent directional consensus as an effective reliability s ignal for online LLM RL.
****

A Judge-Aware Ranking Framework for Evaluating Large Language Models without Gro und Truth
Mingyuan Xu, Xinzi Tan, Jiawei Wu, Doudou Zhou
Evaluating large language models (LLMs) on open-ended tasks without ground-truth labels is increasingly done via the LLM-as-a-judge paradigm. A critical but und er-modeled issue is that judge LLMs differ substantially in reliability; treatin g all judges equally can yield biased leaderboards and misleading uncertainty es timates—more data can make evaluation more confidently wrong under misspecified aggregation. We propose a judge-aware ranking framework that extends the Bradley -Terry-Luce model by introducing judge-specific discrimination parameters, joint ly estimating latent model quality and judge reliability from pairwise compariso ns without reference labels. We establish identifiability up to natural normaliz ations and prove consistency and asymptotic normality of the maximum likelihood estimator, enabling confidence intervals for score differences and rank comparis ons. Across multiple public benchmarks and a newly collected dataset, our method improves agreement with human preferences, achieves higher data efficiency than unweighted baselines, and produces calibrated uncertainty quantification for LL M rankings.

DataGuard: A Non-intrusive Dataset Auditing Framework via Differential Informati on Forensics
Jiadong Lou, Wenxin Rong, Li Chen, Xing Gao, Rui Zhang, Xu Yuan

Concerns over dataset misuse in deep learning have highlighted the need for effe
ctive auditing.
Unlike existing intrusive methods that require dataset modifications, which risk
 model performance and security, we present DataGuard, a non-intrusive framework
 for quantitative dataset auditing.
Specifically, DataGuard integrates three key components: 1) a differential compa
rison between the target dataset and auxiliary non-training datasets, 2) an info
rmation-forensic analysis establishing formal inequalities to distinguish traini
ng data; and 3) a multivariate statistical test that translates these discrepanc
ies into rigorous auditing scores.
Extensive experiments demonstrate that DataGuard can detect both full and partia
l dataset usage without false positives while remaining robust under diverse tra
ining scenarios, offering a principled, information-theoretic solution for trans
parent AI development.

AdaHC: Accelerating Multi-Token Prediction with Adaptive Head Chunking with Pipe
line Parallelism
Yan Wang, Chang Si, Kaiming Yang, Zhipeng Zhang, Weijian Liu, Man Yuan, Mingzhen
 Li, Yong Li, Weile Jia
Multi-token prediction (MTP) architecture is widely adopted in LLMs.
MTP blocks can be appended to the tail of model to predict additional tokens.
However, when training with pipeline parallel, MTP leads to more pipeline bubble
s and deteriorates the pipeline efficiency.
Based on in-depth analysis of MTP architectures and loss functions, we have iden
tified the parallel nature of the MTP blocks, and leverage it for superior pipel
ine scheduling.
We propose AdaHC, an adaptive pipeline scheduling framework for accelerating LLM
s training with MTP block(s).
AdaHC splits the output heads into chunks and reassembles the chunks to generate
 balanced pipeline stages, and performs adaptive activation forwarding to preser
ve the numerical equivalence.
Experimental results show that AdaHC improves the training throughput of SOTA LL
Ms with diverse MTP configurations by 1.35$\times$ on average.
This work paves a new direction for practical pipeline training.

PGC: Peak-Guided Calibration for Generalizable AI-Generated Image Detection
Xiaoyu Zhou, Jianwei Fei, Peipeng Yu, Jingchang Xie, Chong Cheng, Zhihua Xia
The rapid evolution of generative AI, from GANs to modern diffusion models, has
resulted in increasingly subtle discriminative clues. These fine-grained signals
 are often overshadowed by dominant, high-fidelity image content (e.g., the main
 subject), limiting the reliability of existing detectors that predominantly rel
y on global representations. To address this challenge, we propose the Peak-Guid
ed Calibration (PGC) framework. PGC introduces a novel strategy that aggregates
salient features via a peak-focusing mechanism. Specifically, by employing a pea
k-sensitive aggregation that accentuates the most discriminative local clues, PG
C leverages these critical signals to calibrate the global decision. This approa
ch recovers subtle patterns that would otherwise be submerged in the global cont
ext. Furthermore, to better simulate real-world threats, we introduce the CommGe
n15 dataset, a challenging benchmark comprising samples from 15 commercial model
s. Extensive experiments demonstrate that PGC achieves state-of-the-art performa
nce. Specifically, it improves mean accuracy by +12.3% on our CommGen15 dataset,
 and sets new records on standard benchmarks, including GenImage (+2.1%), AIGI (
+3.5%), and UniversalFakeDetect (+1.7%). Code is available at https://github.com
/xiaoyu6868/PGC.

Faster Query-Key Learning Sharpens Attention in Self-Attention Models
Rahul Vashisht, Harish G. Ramaswamy
A standard self-attention layer consists of two interacting circuits: the query-
key circuit that governs attention allocation, and the output-value circuit that
 maps attended representations to predictions. Collapsed and factorized paramete

rizations of the query-key and output-value circuits lead to qualitatively diffe rent attention patterns. In particular, some parameterizations give sharper atte ntion to task-relevant tokens, at a similar training loss. We analyze how the pa rameterizations of these circuits shape the parameter trajectories in single-lay er self-attention models trained on next-token prediction. Through gradient-flow analysis, we show that factorization induces implicit rescaling of the two circ uits' learning rates. We derive closed-form dynamics showing that output-value a nd query-key parameters move along a line, with relative speeds determined by th eir learning rates. Faster query-key learning relative to output-value learning thus produces sharper attention, as the model compensates for slower output-valu e learning by increasing attention mass on relevant tokens. Experiments show tha t differences in the relative learning rates of the two circuits govern attentio n concentration. This improves attention interpretability while maintaining comp arable predictive performance.

Improved Scaling Laws via Weak-to-Strong Generalization in Random Features Ridge Regression

Diyuan Wu, Lehan Chen, Theodor Misiakiewicz, Marco Mondelli

It is increasingly common in machine learning to use learned models to label dat a and then employ such data to train more capable models. The phenomenon of weak -to-strong generalization exemplifies the advantage of this two-stage procedure: a strong student is trained on imperfect labels obtained from a weak teacher, a nd yet the strong student outperforms the weak teacher. In this paper, we show t hat the potential improvement is substantial, in the sense that it affects the s caling law followed by the test error. Specifically, we consider students and te achers trained via random features ridge regression (RFRR). Our main technical c ontribution is to derive a deterministic equivalent for the excess test error of the student trained on labels obtained via the teacher. Via this deterministic equivalent, we then identify regimes in which the scaling law of the student imp roves upon that of the teacher, unveiling that the improvement can be achieved b oth in bias-dominated and variance-dominated settings. Strikingly, the student m ay attain the minimax optimal rate regardless of the scaling law of the teacher- --in fact, when the test error of the teacher does not even decay with the sampl e size.

MV-FGAD: Towards Efficient and Effective Federated Graph Anomaly Detection via M ulti-view Learning

Junyi Yan, KE LIANG, Hao Yu, Meng Liu, Hao Tan, Tianrui Liu, Jun-Jie Huang, Xinw ang Liu

Federated graph anomaly detection (GAD) aims to identify abnormal nodes in distr ibuted subgraphs through federated learning. However, existing methods suffer fr om two limitations. 1) Their reliance on neighborhood aggregation assumes that a nomalous information can be sufficiently captured, which often fails in federate d learning with partitioned client subgraphs. 2) They overlook the detection bot tleneck caused by weak attribute or structural anomalies. To tackle these challe nges, we revisit federated GAD and reveal that weak anomalies exhibit harder-to- detect signals compared to strong anomalies. Specifically, we propose MV-FGAD, a n efficient and effective federated GAD framework for mining anomalies of varyin g strengths. MV-FGAD introduces a federated knowledge learning module to aggrega te and broadcast shared knowledge, which is further exploited to optimize local topological structures. Moreover, it designs a multi-view learning mechanism to capture diverse anomaly patterns, and adopts Mahalanobis distance–based scoring strategy to quantify node abnormality across views. Extensive experiments on rea l-world datasets of varying types and scales demonstrate MV-FGAD's efficiency an d effectiveness. Our code is publicly available at https://github.com/Junyi-Yan/ MV-FGAD.

RT-Lynx: Putting the GEMM Sparsity In a Right Way for Diffusion Models

Xing Cong, Hanlin Tang, Kan Liu, Tao Lan, Lin Qu, chenhao xie

Diffusion Transformers (DiT) achieve strong performance in image generation but

incur substantial inference costs. While prior work has reduced this cost via qu antization and distillation, semi-structured sparsity—which can nearly halve FLO Ps—remains underexplored. A key reason is that most existing approaches focus on weight sparsification, and pruning 50\% of the weights can remove critical mode l capacity and degrade generation quality. Our study, however, shows that DiT ac tivations are intrinsically sparse and significantly more robust to N:M semi-str uctured sparsification than weights. Motivated by this observation, we advocate a paradigm shift from weight sparsification to activation sparsification. We pro pose RT-Lynx, which applies N:M sparsification to activations and incorporates e rror-compensation techniques to mitigate accuracy loss. We further implement hig hly optimized CUDA kernels tailored to this setting, achieving up to a 1.55× spe edup on average in linear layers. Extensive experiments across multiple diffusio n models demonstrate that our method preserves the generation quality of the ori ginal models while substantially accelerating inference.

PerturbDiff: Functional Diffusion for Single-Cell Perturbation Modeling

Xinyu Yuan, Xixian Liu, Ya Shi Zhang, Zuobai Zhang, Hongyu Guo, Jian Tang

Building _Virtual Cells_ that can accurately simulate cellular responses to pert urbations is a long-standing goal in systems biology. A fundamental challenge is that high-throughput single-cell sequencing is destructive: the same cell cann ot be observed both before and after a perturbation. Thus, perturbation predicti on requires mapping unpaired control and perturbed populations. Existing models address this by learning maps between distributions, but typically assume a sing le fixed response distribution when conditioned on observed cellular context (_e .g._, cell type) and the perturbation type. In reality, responses vary systemati cally due to unobservable latent factors such as microenvironmental fluctuations and complex batch effects, forming a _manifold_ of possible distributions for t he same observed conditions. To capture this variability, we introduce PerturbD iff, which shifts modeling from individual cells to entire distributions. By emb edding distributions as points in a Hilbert space, we define a diffusion-based g enerative process operating directly over probability distributions. This allows PerturbDiff to capture population-level response shifts across hidden factors, improving generalization. Benchmarks on established datasets show that PerturbDi ff achieves state-of-the-art performance in single-cell response prediction and generalizes substantially better to unseen perturbations. See our project page (https://katarinayuan.github.io/PerturbDiff-ProjectPage/), where code and data (h ttps://github.com/DeepGraphLearning/PerturbDiff) are publicly available.

Foreground-Aware Token Routing Vision Transformer for Real-Time Satellite Video Tracking

Jiahao Wang, Fang Liu, Licheng Jiao, Shuo Li, Hao Wang, Lingling Li, Xinyi Wang, Xu Liu

Real-time satellite video tracking poses distinct challenges, including accommod ating high spatial-temporal resolution, dynamic backgrounds, and constrained onb oard computational resources. While Discriminative Correlation Filter (DCF)-base d methods offer high-speed inference, they suffer from limited accuracy. In cont rast, Vision Transformer (ViT)-based trackers achieve strong performance by unif ying representation and aggregation in a single-stream design, yet their heavy c omputational footprint limits practical deployment in real-time satellite scenar ios. In this work, we present FATrack, a novel tracking framework that effective ly balances tracking accuracy and computational efficiency. At its core is FA-Vi T, a lightweight Vision Transformer backbone that introduces foreground-aware to ken routing, enabling the model to concentrate computation on target-relevant re gions while suppressing redundancy. To mitigate semantic degradation caused by t oken sparsification, we propose the Adaptive Scatter Module (ASM), which selecti vely reinforces informative tokens via joint spatial-channel attention and spars e structural propagation, thereby enhancing both semantic fidelity and spatial c oherence. By synergistically integrating FA-ViT and ASM, FATrack forms a unified architecture that delivers real-time performance with significantly improved tr acking precision. Extensive evaluations on multiple satellite video benchmarks d

emonstrate that FATrack surpasses existing real-time trackers in accuracy and ac
hieves inference efficiency comparable to DCF-based methods, highlighting its po
tential for practical deployment in large-scale aerial video tracking systems.

Scalable Event Cloud Network for Event-based Classification

Hongwei Ren, Fei Ma, Xiaopeng LIN, Yuetong Fang, Hongxiang Huang, Yue Zhou, Yulo
ng Huang, Haotian FU, Ziyi Yang, Youxin Jiang, Xiangqian Wu, Bojun Cheng

Event cameras are biologically inspired sensors garnering significant attention
from both industry and academia. Mainstream methods favor frame and voxel repres
entations, which reach a satisfactory performance while introducing time-consumi
ng transformations, bulky models, and sacrificing fine-grained temporal informat
ion. Alternatively, Point Cloud representation demonstrates promise in addressin
g the mentioned weaknesses, but it has limited scalability in abstracting featur
es of higher spatial resolution and longer temporal sequence events. In this pa
per, we propose a Scalable Network named SECNet to leverage Event Cloud represen
tation. SECNet integrates polarity at the structural level by innovating the Eve
nt-based Group and Sampling module rather than only at the input level. To accom
modate the surge in the number of events, SECNet embraces feature extraction in
the frequency domain via the Fourier transform. This approach not only substanti
ally extinguishes the explosion of Multiply Accumulate Operations but also effec
tively abstracts spatio-temporal features. We conducted extensive experiments on
 ten event-based datasets, and substantiate the scalability, effectiveness, and
efficiency of SECNet. Our code will be available at: https://github.com/rhwxmx/S
ECNet_ICML.

Towards Achieving Optimal Strong Regret and Constraint Violation via Computation
ally Efficient Model-free RL

Xiyue Peng, Lingkai Zu, Ziyu Shao, Xin Liu

We study episodic constrained Markov decision processes (CMDPs) with linear func
tion approximation, where the goal is to achieve strong regret and constraint vi
olation guarantees without allowing error cancellations. Unlike the existing wor
k, which focuses on either tabular CMDP or model-based reinforcement learning me
thods.

We propose a model-free policy APMPO that achieves near-optimal $\widetilde{O}(\
sqrt{K})$ strong regret and strong constraint violation with Slater's condition
(or strict feasibility assumption),

where K is the total number of episodes. It matches the best-known rates witho
ut requiring any prior knowledge of the feasibility gap reported in prior model-
based work for tabular CMDPs. Besides, APMPO achieves $\widetilde{O}(K^{\frac{3
}{4}})$ strong regret and $\widetilde{O}(K^\frac{3}{4})$ strong constraint viola
tion without Slater's condition. To the best of our knowledge, this is the first
 sublinear result of CMDP w.r.t. the strong metrics without Slater's condition.

APMPO achieves these results by a novel and adaptive design of a violation-aware
 penalty and learning rates to balance the strong regret and constraint violatio
n, which is quite different from the (regularized) primal-dual methods imposing
constraints via dual penalty in the literature. The experiments show APMPO signi
ficantly outperforms the strong baselines, which justify our design and theoreti
cal performance.
****

Unsupervised Diffusion Solver for Combinatorial Optimization via Combinatorial A
djoint Matching

Shengyu Feng, Tarun Suresh, Yiming Yang

Diffusion-based neural solvers have shown strong promise for combinatorial optim
ization (CO), but existing methods typically rely on supervised training with la
rge collections of near-optimal solutions. In this work, we extend adjoint-based
 trajectory optimization methods to discrete combinatorial domains. We formulate
 diffusion-based CO as a stochastic control problem over Continuous-Time Markov
Chains and introduce discrete adjoint dynamics for propagating optimization sign
als through discrete generative trajectories. Building on this formulation, we p

ropose *Combinatorial Adjoint Matching (CAM)*, an unsupervised training framewor
k for discrete diffusion solvers with structured and low-variance trajectory-lev
el optimization signals. Empirically, CAM consistently outperforms existing unsu
pervised diffusion baselines and achieves performance competitive with strong su
pervised diffusion solvers and even traditional solvers across diverse combinato
rial optimization problems. Our code is available at https://github.com/Shengyu-
Feng/CAM.

Reflector: Internalizing Step-wise Reflection against Indirect Jailbreaks
Jiachen Ma, Jiawen Zhang, Xiangtian Li, Bo Zou, Chaochao Lu, Chao Yang
While Large Language Models (LLMs) demonstrate remarkable capabilities, they rem
ain susceptible to sophisticated, multi-step jailbreak attacks that circumvent c
onventional surface-level safety alignment by exploiting the internal generation
 process. To address these vulnerabilities, we propose Reflector, a principled t
wo-stage framework that internalizes self-reflection within the generation traje
ctory. Reflector first leverages teacher-guided generation to produce high-quali
ty reflection data for supervised fine-tuning (SFT), establishing structured ref
lection patterns. It subsequently uses Reinforcement Learning (RL) with outcome-
driven and reward-validity supervision to instill robust, autonomous self-reflec
tion capabilities.
Empirical results show that Reflector achieves Defense Success Rates (DSR) excee
ding 90% against complex indirect attacks while generalizing robustly across div
erse threat scenarios. Notably, the framework enhances both task-specific and ge
neral utility, yielding a 5.85% gain on GSM8K alongside improved performance on
knowledge-intensive benchmarks. By internalizing trajectory-level safety, Reflec
tor overcomes the fundamental limitations of surface alignment without significa
nt computational overhead, offering an efficient and scalable solution for the d
evelopment of safe and capable LLMs.

Causal Discovery for Irregularly Time Series with Consistency Guarantees
Weihong Li, Baohong Li, Anpeng Wu, Zhihan Li, Ming Ma, Keting Yin, Kun Kuang
This paper studies causal discovery in irregularly sampled time series—a key cha
llenge in risk-sensitive domains like finance, healthcare, and climate science,
where missing data and inconsistent sampling frequencies distort causal mechanis
ms. The main challenge comes from the interdependence between missing data imput
ation and causal structure recovery: errors in imputation and structure learning
 can reinforce each other, leading to an inaccurate causal graph. Existing metho
ds either impute first and then discover, or jointly optimize both via neural re
presentation learning, but lack explicit mechanisms to ensure mutual consistency
 of imputation and structure learning. We address this challenge with ReTimeCaus
al, an EM-based framework that alternates between imputation and structure learn
ing, which encourages structural consistency throughout the optimization process
. Our framework provides theoretical consistency guarantees for structure recove
ry and extends classical results to settings with irregular sampling and high mi
ssingness. ReTimeCausal combines kernel-based sparse regression and structural c
onstraints in an alternating process that updates the completed data and the cau
sal graph in turn. Experiments on synthetic and real-world datasets show that Re
TimeCausal is more effective than existing methods under challenging irregular s
ampling and missing data.

The Geometry of Projection Heads: Conditioning, Invariance, and Collapse
Faris Chaudhry
We develop a geometric theory of projection heads in self-supervised learning by
 modeling the head as a trainable Riemannian metric on the backbone representati
on manifold. We show that linear heads perform implicit subspace whitening, whil
e nonlinear heads adapt local metrics to satisfy the specific topological constr
aints of the loss, with head depth empirically dictating this capacity. Analyzin
g dimensional collapse, we prove that smooth nonlinear heads natively induce neg
ative eigenvalues in the Hessian at collapsed equilibria, making them unstable.
We empirically validate this by continuously tracking the optimization geometry

during training, which reveals that smooth activations like Swish can generate e xplicit negative curvature to escape collapse, whereas linear and ReLU heads und er continuous-time gradient flow cannot, relying instead on discrete-time optimi zation dynamics and BatchNorm. Finally, we geometrically characterize how metric degeneracy governs the information-invariance trade-off, explaining why the hea d must be discarded. Evaluated across contrastive and decorrelation-based object ives on foundation models, our results demonstrate that the projection head acts as a universal geometric buffer, decoupling the semantic backbone from the rigi d, destructive constraints of the pretraining objective.
****
Federated Causal Inference on Multi-Site Observational Data via Propensity Score Aggregation
Rémi Khellaf, Aurélien Bellet, Julie Josse
Causal inference typically assumes centralized access to individual-level data. Yet, in practice, data are often decentralized across multiple sites, making cen tralization infeasible due to privacy, logistical, or legal constraints. We addr ess this problem by estimating the Average Treatment Effect (ATE) from decentral ized observational data via a Federated Learning (FL) approach, allowing inferen ce through the exchange of aggregate statistics rather than individual-level dat a. We propose a novel method to estimate propensity scores via a federated weigh ted average of local scores using Membership Weights (MW), defined as probabilit ies of site membership conditional on covariates. MW can be flexibly estimated w ith parametric or non-parametric classification models using standard FL algorit hms.

The resulting propensity scores are used to construct Federated Inverse Prop ensity Weighting (Fed-IPW) and Augmented IPW (Fed-AIPW) estimators.

In contrast to meta-analysis methods, which fail when any site violates posi tivity, our approach exploits heterogeneity in treatment assignment across sites to improve overlap.

We show that Fed-IPW and Fed-AIPW perform well under site-level heterogeneit y in sample sizes, treatment mechanisms, and covariate distributions. Theoretica l analysis and experiments on simulated and real-world data demonstrate clear ad vantages over meta-analysis and related approaches.

Learning Efficient Guardrails for Compliance
Xiaofei Wen, Wenjie Jacky Mo, Yanan Xie, Peng Qi, Muhao Chen
Autonomous web agents are increasingly deployed for long-horizon tasks, yet thei r ability to adhere to real-world policies remains critically underexplored comp ared to standard safety objectives.
To address this gap, we introduce PolicyGuardBench, a benchmark of 60k policy-tr ajectory pairs designed to evaluate compliance through both full-trajectory and novel prefix-based violation detection tasks. Using this dataset, we train Polic yGuard, a lightweight guardrail model that achieves strong detection accuracy wh ile maintaining high inference efficiency.
Notably, our model demonstrates robust generalization capabilities, preserving h igh performance even on unseen domains. These contributions establish a comprehe nsive framework for studying policy compliance, showing that accurate and genera lizable guardrails are feasible at small scales.
****
SoftMatcha 2: A Fast and Soft Pattern Matcher for Trillion-Scale Corpora
Masataka Yoneda, Yusuke Matsushita, Go Kamoda, Kohei Suenaga, Takuya Akiba, Masa ki Waga, Sho Yokoi
We present SoftMatcha 2, an ultra-fast and flexible search algorithm that enable s search over trillion-scale natural language corpora in under 0.3 seconds while allowing semantic variations in the form of substitution, insertion, and deleti on. Our approach employs string matching based on suffix arrays that scales well with corpus size, and represents words as vectors, which underpin its semantic flexibility. To mitigate the combinatorial explosion induced by the semantic rel axation of queries, our method is built on two key algorithmic ideas: dynamic co rpus-aware pruning and fast exact lookup enabled by a disk-aware design. We theo

retically analyze the efficiency of the proposed method, indicating that it can mitigate exponential growth in the search space. Empirically, on FineWeb-Edu (Lozhkov et al., 2024) (1.4T tokens), it attains substantially lower search latency than existing methods: infini-gram (Liu et al., 2024), infini-gram mini (Xu et al., 2025), and SoftMatcha (Deguchi et al., 2025). As a practical application, our method uncovers benchmark contamination in training corpora that existing approaches miss, and it also benefits information retrieval and paraphrase detection. We also provide an online demo of fast, soft search across corpora in seven languages.

Mining Useful General Data for Low-Resource Domain Adaptation

Pingjie Wang, Hongcheng Liu, Yusheng Liao, Ziqing Fan, Yaxin Du, Shuo Tang, Yanfeng Wang, Yu Wang

Adapting large language models (LLMs) to low-resource domains remains challenging due to the scarcity of domain-specific data. While in-domain data is limited, there exists a vast amount of general-domain data that shares similar question–answer formats and reasoning patterns with domain tasks. This observation raises an important question: can useful general-domain data be mined to improve low-resource domain adaptation? Our initial findings show that general-domain chain-of-thought data contains useful auxiliary signals for domain adaptation, even without careful selection. This observation motivates a new paradigm for domain adaptation beyond exclusive reliance on domain-specific data.

To systematically identify the most beneficial general-domain samples, we propose NTK-Selector, motivated by the Neural Tangent Kernel’s ability to capture alignment in training dynamics. Since directly applying NTK to pretrained LLMs is impractical, we introduce a Jacobian-free NTK approximation and empirically demonstrate stable NTK-like behavior during fine-tuning. Extensive experiments across medical, financial, legal, and psychological domains demonstrate that NTK-Selector consistently outperforms domain-only fine-tuning and existing data selection baselines. In particular, NTK-Selector achieves gains of +8.7 and +5.1 points on Llama3-8B-Instruct and Qwen3-8B, respectively, compared to only +0.8 and +0.9 points from domain-only fine-tuning.

Fourier Features Let Agents Learn High Precision Policies with Imitation Learning

Balázs Gyenes, Emiliyan Gospodinov, Jan Frieling, Enrico Krohmer, Nicolas Schreiber, Xiaogang Jia, Niklas Freymuth, Gerhard Neumann

High-precision robotic manipulation requires fine-grained spatial reasoning that is often difficult to achieve with RGB-only policies due to depth ambiguity and perspective scale issues. Policies that leverage 3D information directly, such as those based on point clouds, offer a stronger geometric prior over purely image-based ones, yet their performance remains highly task-dependent. We hypothesize that this discrepancy may be due to the spectral bias of neural networks towards learning low frequency functions, which especially affects architectures conditioned on slow-moving Cartesian features. We thus propose to map point clouds from Cartesian space into high-dimensional Fourier space, effectively equipping the point cloud encoder with direct access to high-frequency features. We experimentally validate the use of Fourier features on challenging manipulation tasks from the RoboCasa and ManiSkill3 benchmarks and on a real robot setup. Despite their simplicity, we find that Fourier features provide significant benefits across diverse encoder architectures and benchmarks and are robust across hyperparameters. Our results indicate that Fourier features let policies leverage geometric details more effectively than Cartesian features, showing their potential as a general-purpose tool for point cloud-based imitation learning. We provide source code and videos on our project page: https://fourier-il.github.io/fourier-il.

SWE-IF: Aligning Code Evaluation with Human Preference

Ming Zhong, Xiang Zhou, Ting-Yun Chang, Qingze Wang, Nan Xu, Xiance Si, Dan Garrette, Shyam Upadhyay, Jeremiah Zhe Liu, Jiawei Han, Benoit Schillings, Jiao Sun

Large Language Models (LLMs) have catalyzed vibe coding, where users leverage LL

Ms to generate and iteratively refine code through natural language interactions until it passes their *vibe check*. *Vibe check* reflects human preference and goes beyond functionality: the solution should feel right, read cleanly, preserve intent, and remain correct. However, current code evaluation remains anchored to pass@k and captures only functional correctness, overlooking non-functional instructions that users routinely apply. In this paper, we hypothesize that instruction following is the missing piece underlying *vibe check* besides functional correctness. To quantify models' code instruction-following capabilities with measurable signals, we present VeriCode, a taxonomy of 30 verifiable code instructions together with deterministic verifiers. We use the taxonomy to augment established evaluation suites, resulting in **SWE-IF**, a testbed to assess both instruction following and functional correctness. Evaluating 31 LLMs, we show that even the strongest models struggle to comply with multiple instructions and exhibit functional regression. Most importantly, a composite score of functional correctness and instruction following correlates best with human preference, with instruction following emerging as the primary differentiator among LLMs. Our code, data, and taxonomy are available at https://github.com/maszhongming/SWE-IF.

Expandable, Compressible, Mineable: Open-World Thermal Infrared Image Restoration

Pu Li, Huafeng Li, Yafei Zhang, Wen Wang, Neng Dong, Jie Wen

In open-world settings, thermal infrared (TIR) image degradations continuously emerge and evolve, while most existing all-in-one restoration methods are built on a closed-set assumption and struggle to continually adapt to novel degradations.

To address this, we propose ECMRNet, an Expandable, Compressible, and Mineable Restoration Network for open-world TIR restoration from a continual learning perspective.

Conceptually, ECMRNet unifies continual degradation learning as an "expand–compress–mine" closed-loop process, enabling sustained adaptation to new degradations with controllable evolution.

Structurally, ECMRNet decomposes intermediate representations into group-isolated subspaces, and achieves strict parameter isolation and fast adaptation to new degradations by freezing historical groups and isomorphically expanding new ones.

To curb model growth as tasks accumulate, we present Structural Entropy Pruning, which identifies and removes redundant channel groups via two-dimensional structural entropy minimization, achieving information contribution–driven adaptive compression.

Moreover, we design a Sub-degradation Knowledge Mining Module that dynamically retrieves and recombines transferable components from historical representations to improve restoration under compound degradations.

Experimental results demonstrate that ECMRNet achieves superior overall performance across diverse single and compound degradations while using fewer parameters and lower computational cost.

****

HumanLM: Simulating Users with State Alignment Beats Response Imitation

Shirley Wu, Evelyn Choi, Arpandeep Khatua, Zhanghan Wang, Joy He-Yueya, Tharindu Cyril Weerasooriya, Wei Wei, Diyi Yang, Jure Leskovec, James Zou

Large Language Models (LLMs) are increasingly used to simulate how specific users respond to any context, enabling more user-centric applications that rely on user feedback. However, existing user simulators mostly imitate surface-level patterns and language styles, which fails to reflect the underlying state of real users (e.g., beliefs, emotions). To address these limitations, we propose a novel training framework, HumanLM, which builds user simulators that accurately reflect real users. Our key insight is, in addition to generating responses, we generate natural-language latent states that align with the ground truth responses through reinforcement learning. These latent states correspond to a set of state dimensions which psychologically lead to how real users respond. HumanLM further synthesizes these aligned latent states into responses that accurately represent

real users. For extensive evaluation, we develop Humanual, a comprehensive benchmark on simulating real users based on public data. Humanual consists of six large-scale datasets with 26k users and 216k responses in total. It spans diverse tasks such as generating user responses to daily life issues, political blogs, and chat sessions with LLM assistants. Across the datasets, HumanLM significantly outperforms the best alternative approaches by an average relative improvement of 16.3% on alignment score from an LLM judge. In a real-time simulation study with 37 participants, HumanLM achieves the highest scores on similarity with real user responses and human-likeness.

****

QPoint: End-to-End Lightweight Point Cloud Processing via Robust Quaternion Feature Learning

Zhiming Zhou, Yong He, Chaoxu Mu, Qiaoyun Wu, Ajmal Saeed Mian

The inherent sparsity, lack of structure, and rotation sensitivity of point clouds often lead to high computational and parameter cost in robust feature learning. To address these problems, we present QPoint, a lightweight framework that leverages robust quaternion feature learning. QPoint incorporates a Quaternion-Enhanced local perception module that uses learnable rotations to stabilize local features against geometric transformations, and a Quaternion global attention mechanism that employs quaternion similarity to capture global geometric context with inherent rotation invariance. Extensive experiments show that QPoint achieves top performance across multiple tasks. It achieves excellent 95.0%, 93.9%, and 92.1% on the challenging ScanObjectNN variants (OBJ_BG, OBJ_ONLY, PB_T50_RS), 94.7% overall accuracy on ModelNet40, and 87.0% instance mIoU on ShapeNetParts. Furthermore, QPoint exhibits superior generalization in few-shot learning scenarios. Crucially, it accomplishes this with extremely minimal parameter and computational requirements, establishing a strong and efficient baseline for point cloud processing. Our source code is in the supplementary material and will be released to the public.

LIF Recurrent Memory Enables Long-Horizon Spiking Computation

Fenghao Liu, Yipeng Shen, Peng Chen, Qian Zheng, Peng Lin, Gang Pan

Processing long sequence data such as speech requires models to maintain long-term dependencies, which is challenging for recurrent spiking neural networks due to high temporal dynamics in neuron models that leak stored information in their membrane potentials, and due to vanishing gradients during backpropagation through time. These issues can be mitigated by employing more complex neuron designs, such as ALIF and TC-LIF, but these neuron-level solutions often incur high computational costs and complicate hardware implementation, undermining the efficiency advantages of spiking neural networks. Here we propose an architectural-level solution that leverages the dynamical interactions of a few leaky integrate-and-fire (LIF) neurons to enhance long-term information storage. The memory capability of this LIF-based micro-circuit is adaptively modulated by global recurrent connections of the recurrent spiking neural network, contributing to selective enhancement of temporal information retention, and promoting stable gradient propagation through time. The proposed model outperforms baselines including LSTM, ALIF, and TC-LIF in long sequence tasks, achieving 96.52\% accuracy on the PS-MNIST dataset. Furthermore, our method also provides a compelling efficiency advantage, yielding up to 277$\times$ computational efficiency improvement compared to conventional models such as LSTM. This work paves the way for building cost-effective, hardware-friendly, and interpretable spiking neural networks for long sequence modeling.

Graph Alignment via Dual-Pass Spectral Encoding and Latent Space Communication

Maysam Behmanesh, Erkan Turan, Maks Ovsjanikov

Graph alignment, the problem of identifying corresponding nodes across multiple graphs, is fundamental to numerous applications. Most existing unsupervised methods embed node features into latent representations to enable cross-graph comparison without ground-truth correspondences. However, these methods suffer from two critical limitations: the degradation of node distinctiveness due to oversmoot

hing in GNN-based embeddings, and the misalignment of latent spaces across graph
s caused by structural noise, feature heterogeneity, and training instability, u
ltimately leading to unreliable node correspondences. We propose a novel framewo
rk employing a dual-pass encoder to inject high-frequency discriminability into
node features, paired with a geometry-aware functional map module that learns bi
jective and isometric transformations to align latent spaces while acting as a l
ow-pass filter on correspondences, enforcing smoothness and robustness as a stru
ctural prior in map space. Extensive experiments on graph benchmarks demonstrate
 that our method consistently outperforms existing unsupervised alignment baseli
nes, exhibiting superior robustness to structural inconsistencies and challengin
g alignment scenarios.
The implementation is available at https://github.com/maysambehmanesh/GADL.

Neural Low-Discrepancy Sequences
Michael Etienne Van Huffel, Nathan Kirk, Makram Chahine, Daniela Rus, T. Konstan
tin Rusch
Low-discrepancy points are designed to efficiently fill the space in a uniform m
anner. This uniformity is highly advantageous in many problems in science and en
gineering, including in numerical integration, computer vision, machine percepti
on, computer graphics, machine learning, and simulation. Whereas most previous l
ow-discrepancy constructions rely on abstract algebra and number theory, Message
-Passing Monte Carlo (MPMC) was recently introduced to exploit machine learning
methods for generating point sets with lower discrepancy than previously possibl
e. However, MPMC is limited to generating point sets and cannot be extended to l
ow-discrepancy sequences (LDS), i.e., sequences of points in which every prefix
has low discrepancy, a property essential for many applications. To address this
 limitation, we introduce Neural Low-Discrepancy Sequences (*NeuroLDS*), the fir
st machine learning-based framework for generating finite LDS. Drawing inspirati
on from classical LDS, we train a neural network to map indices to points such t
hat the resulting sequences exhibit minimal discrepancy across all prefixes. To
this end, we deploy a two-stage learning process: supervised approximation of cl
assical constructions followed by unsupervised fine-tuning to minimize prefix di
screpancies. We demonstrate that *NeuroLDS* outperforms all previous LDS constru
ctions by a significant margin with respect to discrepancy measures. Moreover, w
e demonstrate the effectiveness of *NeuroLDS* across diverse applications, inclu
ding numerical integration, robot motion planning, and scientific machine learni
ng. These results highlight the promise and broad significance of Neural Low-Dis
crepancy Sequences.

Physics from Video: Identifiability of Time-Invariant Second-Order ODEs under Mi
nimal Trajectory Conditions
Yuanyuan Wang, Wenjie Wang, Kun Zhang, Mingming Gong
Bridging the gap between visual realism and physical understanding is a core cha
llenge for video-based world models. We study the structural identifiability of
continuous-time physical laws from raw pixels, focusing on whether an encoder-on
ly pipeline can uniquely recover the parameters of second-order linear ODEs. We
prove that a level-set slope-coverage condition ensures the learned latent space
 is locally affine to the true physical state, enabling exact parameter recovery
. Our theory provides the first characterization of minimal data requirements ac
ross damping regimes, establishing that underdamped systems are identifiable fro
m a single video clip, whereas other regimes require three diverse trajectories.
 We further introduce a variance-floor regularizer to stabilize the decoder-free
 objective and prevent latent collapse. Validated on synthetic and real-world da
ta, our approach demonstrates that interpretable physical constants can be relia
bly estimated from video without the need for compute-intensive pixel reconstruc
tion, ensuring both physical correctness and transparency. Code is available at
https://github.com/wenjiewang3/PhysicsFromVideo.

On the Sharp Input-Output Analysis of Nonlinear Systems under Adversarial Attack
s

Jihun Kim, Yuchen Fang, Javad Lavaei
This paper is concerned with learning the input-output mapping of general nonlinear dynamical systems. While the existing literature focuses on Gaussian inputs and benign disturbances, we significantly broaden the scope of admissible control inputs and allow correlated, nonzero-mean, adversarial disturbances. With our reformulation as a linear combination of basis functions, we prove that the ℓ_2-norm estimator overcomes the challenges posed by an adversary with access to the full information history, provided that the attack times are sparse, *i.e.*, the probability that the system is under adversarial attack at a given time is smaller than a certain threshold. We provide an estimation error bound that decays with the input memory length and prove its optimality by constructing a problem instance that suffers from the same bound under probabilistic adversarial attacks. Our work provides a sharp input-output analysis for a generic nonlinear and partially observed system under significantly generalized assumptions compared to existing works.
****
Tail Annealing for Heavy-Tailed Flow Matching
Jean Pachebat
Standard generative models struggle with heavy-tailed data: Lipschitz architectures cannot produce power-law tails from Gaussian noise, and interpolating between heavy-tailed data and Gaussians is ill-posed. We propose a simple fix: apply the soft-log transform $\phi(x) = \mathrm{sign}(x) \cdot \log(1 + |x|)$ coordinate-wise to data before training, then exponentiate samples after generation. A Hill diagnostic decides per-coordinate whether to transform, leaving light-tailed margins untouched at no added complexity. This compresses heavy tails into a range where standard flow matching succeeds, without heavy-tailed base distributions or architectural modifications. We provide theoretical intuition for why this works: the log-transform maps Pareto tails to exponentials, and the induced dynamics implement a form of tail annealing via power transformations. On a 144-configuration multivariate benchmark (3 copulas, d up to 100, 4 tail indices), Log-FM dominates specialized baselines on W_1, CVaR$_{99}$, and extreme-quantile metrics, and is the only method with zero severe divergences across 2{,}880 runs.
****
Overcoming the Incentive Collapse Paradox
Qichuan Yin, Ziwei Su, Shuangning Li
AI-assisted task delegation is increasingly common, yet human effort in such systems is costly and typically unobserved.
Recent work by Bastani & Cachon (2025); Sambasivan et al. (2021) shows that accuracy-based payment schemes suffer from incentive collapse: as AI accuracy improves, sustaining positive human effort requires unbounded payments.
We study this phenomenon in a budget-constrained principal-agent framework with strategic human agents whose output accuracy depends on unobserved effort.
Our first contribution is a general impossibility result showing that incentive collapse is not merely a limitation of simple linear payments, but arises for any payment rule based only on observed task accuracy.
To overcome this barrier, we propose a sentinel-auditing payment mechanism that enforces a strictly positive and controllable level of human effort at finite cost, independent of AI accuracy.
Building on this incentive-robust foundation, we develop an incentive-aware active statistical inference framework that jointly optimizes (i) the auditing rate and (ii) active sampling and budget allocation across tasks of varying difficulty to minimize the final statistical loss under a single budget. Experiments demonstrate improved cost-error tradeoffs relative to standard active learning and auditing-only baselines.

Learning, Solving and Optimizing PDEs with TensorGalerkin: an efficient high-performance Galerkin assembly algorithm
Shizheng Wen, Mingyuan chi, Tianwei Yu, Ben Moseley, Mike Yan Michelis, Pu Ren, Hao Sun, Siddhartha Mishra

We present a unified algorithmic framework for the numerical solution, constrained optimization, and physics-informed learning of PDEs with a variational structure. Our framework is based on a Galerkin discretization of the underlying variational forms, and its high efficiency stems from a novel highly-optimized and GPU-compliant TensorGalerkin framework for linear system assembly (stiffness matrices and load vectors). TensorGalerkin operates by tensorizing element-wise operations within a Python-level Map stage and then performs global reduction with a sparse matrix multiplication that performs message passing on the mesh-induced sparsity graph. The Map and Reduce stages are co-designed inside PyTorch's autograd so that the assembly graph contains $O(1)$ nodes regardless of how the number of elements and local DoFs scale. We validate this $O(1)$-graph property by deploying TensorGalerkin downstream as i) a highly-efficient numerical PDEs solver, ii) an end-to-end differentiable framework for PDE-constrained optimization, and iii) a physics-informed operator learning algorithm for PDEs. With multiple benchmarks, including 2D and 3D elliptic, parabolic, and hyperbolic PDEs on unstructured meshes, we demonstrate that the proposed framework provides significant computational efficiency and accuracy gains over a variety of baselines in all the targeted downstream applications.

Random Selection Reveals Implicit Knowledge Consensus in Code Generation
Ren-Biao Liu, Xin-Ye Li, Hui Sun, Yali Du, Jiang-Tian Xue, Ming Li
Training large language models for code generation often involves selecting data from verifiable multi-solution pools, where each problem admits multiple correct implementations. Conventional studies on data selection suggest that complex selection strategies, such as diversity maximization or difficulty ranking, should outperform naive random sampling. In this work, we systematically evaluate within-problem solution selection strategies across different representation spaces, including continuous embeddings, discrete tokens, and syntactic structures, using various base language models. Instead, simple random sampling achieves consistently competitive performance across all models, exhibiting greater cross-model stability than complex methods. We interpret these results through the lens of *implicit knowledge consensus*: verified solution pools may contain representative algorithmic patterns that random sampling can preserve. Our findings suggest that practitioners should treat random sampling as a low-cost default for verifiable code-generation fine-tuning and move to complex selectors when hard-tail or constraint-focused coverage is the target.

Optimal Top-k Identification from Pairwise Comparisons
Motti Goldberger, Nils Rudi
We study the active learning problem of fixed-confidence top-k identification from noisy pairwise comparisons. In this problem, an algorithm sequentially chooses pairs of items to compare, observes the outcomes, and stops when it can return the set of top-k items with error probability at most δ. The objective is to design such a *δ-correct* procedure that minimizes the expected number of comparisons (the sample complexity).
This problem falls within the broader literature on fixed-confidence pure exploration in bandit models, where a common target is asymptotic optimality: the algorithm's expected sample complexity matches the information theoretic lower bound as $\delta \to 0$. Asymptotically optimal procedures have been developed for a range of fixed-confidence pure-exploration problems, however to the best of our knowledge, for top-1, or more generally top-k identification from pairwise comparisons under latent utility models an asymptotically optimal algorithm has not been established. In this setting, we develop such an algorithm. We characterize the structure of the lower bound and formulate it as a saddle-point problem. This structure enables a computationally efficient primal--dual procedure that learns the asymptotically optimal comparison allocation online. We then construct an adaptive comparison-allocation algorithm that tracks the allocation learned by the primal--dual procedure and prove it is asymptotically optimal.

Parameter-free Dynamic Regret: Time-varying Movement Costs, Delayed Feedback, an

d Memory
Hao Qiu, Andrew Jacobsen, Emmanuel Esposito, Mengxiao Zhang
In this paper, we study dynamic regret in unconstrained online convex optimizati on (OCO) with movement costs. Specifically, we generalize the standard setting by allowing the movement cost coefficients λ_t to vary arbitrarily over time. Our main contribution is a novel algorithm that establishes the first com parator-adaptive dynamic regret bound for this setting, guaranteeing $\widetilde {\mathcal{O}}(\sqrt{(M^2+MP_T)(T+\sum_t \lambda_t)})$ regret, where P_T is the path length of the comparator sequence over T rounds and M is the maximal c omparator norm. Our result recovers the optimal adaptive rates for both static a nd dynamic regret in OCO as the special case where $\lambda_t=0$ for all rounds . To demonstrate the versatility of our results, we consider two applications: * OCO with delayed feedback* and *OCO with time-varying memory*. We show that both problems can be translated into time-varying movement costs, establishing a nov el reduction specifically for the delayed feedback setting that is of independen t interest. A crucial observation is that the first-order dependence on movemen t costs in our regret bound plays a key role in enabling optimal comparator-adap tive dynamic regret guarantees in both settings.
****
ScaleErasure: Inference-Time Minimal Intervention for Precise Concept Erasure in Next-Scale Autoregressive Image Generation
Cong Wang, Haiyu Wu, Zhiwei Jiang, Zifeng Cheng, Fei Shen, Yafeng Yin, Qing Gu
Concept erasure aims to prevent image generative models from producing unsafe co ntent while preserving their general generative capability.
Meanwhile, next-scale autoregressive (AR) image generation has recently emerged as a new generative paradigm characterized by next-scale prediction, for which c oncept erasure remains largely unexplored.
In this paradigm, semantic information is highly compressed at early scales, lea ding to severe entanglement between unsafe and unrelated semantics.
In this paper, we propose ScaleErasure, an inference-time concept erasure method that performs minimal intervention.
ScaleErasure precisely selects and guides predicted logits that are most relevan t to the unsafe concept, thereby enabling effective erasure under severe semanti c entanglement.
Specifically, ScaleErasure performs two additional forward passes conditioned on the unsafe concept and the corresponding safe concept, and leverages their outp uts to guide the target logits away from unsafe concepts toward safe concepts.
To enable precise and minimal intervention, logits selection and guidance are co nducted across three dimensions: scales, tokens, and bit channels.
Experiments demonstrate that ScaleErasure outperforms adapted baselines in the n ext-scale AR paradigm, achieving more precise concept erasure while largely pres erving general generative capability.

SynLaD: Latent Diffusion for Generating Synthesizable Molecules Conditioned on 3 D Pharmacophore Profiles
Miruna Cretu, John Bradshaw, Patricia Suriana, Saeed Saremi, Omar Mahmood, Kiril l Shmilovich, Kangway V. Chuang, Vishnu Sresht, Colin A Grambow
We present SynLaD, a latent diffusion framework for small-molecule generation th at unifies ligand-based drug design objectives (what to make) with synthetic acc essibility (how to make it). Current models typically optimize one objective at the expense of the other, creating a bottleneck for discovering high-scoring and synthesizable molecules. SynLaD combines reaction-constrained generation with p harmacophore-conditioned 3D design by learning a latent space that decodes to bo th 3D structures and synthesis pathways. An encoder maps molecules to a latent r epresentation used by two decoder heads: (i) a geometric head that reconstructs atom types and coordinates and (ii) an autoregressive synthesis head that output s synthetic routes in a serialized, reaction-based notation. A diffusion transfo rmer generates novel latents in the learned space, conditioned on pharmacophore profiles. Across analogue generation tasks for bioactive ligands, SynLaD outperf orms existing baselines in synthesizable and diverse hit generation, demonstrati

ng that a single model can produce shape-aligned molecules with feasible synthes is plans.

Power-Boosted Granger-Causal Discovery for Large Heterogeneous Panel Data
Yiheng Gu, Xiufan Yu
This paper proposes a power-enhanced panel Granger causality test (PE-PGCT) for assessing the Granger non-causality in heterogeneous and potentially high-dimens ional panel data. Building on any existing panel Granger non-causality test, we show, both theoretically and empirically, that the proposed PE-PGCT boosts its p ower substantially. The power gains are particularly significant in situations o f high-dimensional panels when the cross-sectional dimension exceeds the time di mension, as well as under sparse alternatives when the signals are sparsely dist ributed across panel units. We establish rigorous theoretical guarantees on the asymptotic behavior of the proposed power enhancement component, demonstrating a ttractive power enhancement properties that it induces negligible size distortio n under the null hypothesis while delivering significant power gain under the al ternatives. The empirical performances are illustrated via extensive simulation studies, as well as a real-world application.

Ariadne's Thread of LipSync: Unraveling Forgeries via Inconsistency between Lip Motions and Head Poses
Tianyi She, Jiawei Liu, Weifeng Liu, Hanqing Zhao, Weiming Zhang, Kejiang Chen
Recent advances in LipSync generation technology have led to the creation of hig hly realistic videos, posing severe societal risks. However, existing defense st rategies struggle against LipSync forgeries, as state-of-the-art generative mode ls not only optimize for the lip synchronization but also significantly eliminat e visual artifacts, resulting in the lack of key detection signals. Inspired by the inherent biological coupling between lip movements and head poses in natural speech, we observe that generative models fundamentally disrupt this global coo rdination when optimizing for local lip motion. In this paper, we propose LipDA, a novel framework for joint LipSync Detection and Attribution, which takes adva ntage of the inconsistency between head and lip. For detection, the framework le arns to quantify this discrepancy by contrasting lip and pose features from auth entic versus forged videos. For attribution, our method is designed to capture t he unique temporal dynamics and audio-visual synchronization patterns that act a s generative fingerprints, enabling source tracing. To validate our approach, we conduct extensive experiments on two challenging LipSync benchmarks as well as on our own proposed large-scale and multi-generator dataset, LipSyncBench-A. Lip DA achieves over 97% AUC in detection and 97.5% accuracy in model attribution, s ignificantly outperforming existing methods.

TerraBind: Fast and Accurate Binding Affinity Prediction through Coarse Structur al Representations
Matteo Rossi, Ryan Pederson, Miles Wang-Henderson, Ben Kaufman, Edward C. Willia ms, Carl Underkoffler, Owen Lewis Howell, Adrian Layer, Stephan Thaler, Narbe Ma rdirossian, John Anthony Parkhill
We present TerraBind, a foundation model for protein-ligand structure and bindin g affinity prediction that achieves 26$\times$ faster inference than state-of-th e-art methods while improving affinity prediction accuracy by up to 20\%. Curren t deep learning approaches to structure-based drug design rely on expensive all-atom diffusion to generate 3D coordinates, creating inference bottlenecks that r ender large-scale compound screening computationally intractable. We challenge t his paradigm with the hypothesis: full all-atom resolution is unnecessary for ac curate small molecule pose and binding affinity prediction. TerraBind tests this hypothesis through a coarse pocket-level representation (protein C$_\beta$ atom s and ligand heavy atoms only) within a multimodal architecture combining pretra ined molecular encoders and ESM-2 protein embeddings that learns rich structural representations, which are used in a diffusion-free optimization module for pos e generation and a binding affinity likelihood prediction module. On structure p rediction benchmarks, TerraBind matches diffusion-based baselines in ligand pose

accuracy. For binding affinity, TerraBind outperforms Boltz-2 by 16-20\% in Pea
rson correlation on both a public benchmark (CASP16) and a diverse private datas
et (18 assays). The affinity module also provides well-calibrated uncertainty es
timates, addressing a critical gap in compound prioritization for drug discovery
. Furthermore, this module enables a continual learning framework and a hedged b
atch selection strategy that, in simulated drug discovery cycles, achieves 6$\ti
mes$ greater affinity improvement over greedy approaches.

Toward Subspace-Perturbed Trajectory-Aware Backdoor Attacks in Deep Reinforcemen
t Learning
Yaguan Qian, Taining Zhang, Qiqi Bao, Yanru Guo, Lufang Zhang, Zhaoquan Gu, Shou
ling Ji, Bin Wang, Zhen Lei
Deep Reinforcement Learning agents are in-
creasingly used in safety-critical domains but
remain vulnerable to stealthy backdoor attacks.
Existing outer-loop attacks face a trade-off be-
tween perceptual stealth, poisoning efficiency, and
value-function consistency, often making the at-
tack ineffective or easily exposed. To address
these challenges, we propose SpecDRL, a uni-
fied framework that ❶ embeds triggers in the
least sensitive subspaces of the state manifold
via Subspace-Aware Injection, exploiting percep-
tual blind spots, ❷ selects the most influential
time steps for poisoning through Value-Guided
Strategic Sampling based on Return-to-Go and
Temporal-Difference error, and ❸ preserves re-
ward integrity via Bellman-Consistent Dynamic
Reward Poisoning, which analytically enforces ■-
consistency of value functions and bounds global
return deviations. Experiments across 12 Atari en-
vironments demonstrate that SpecDRL achieves
near-100% attack success, accelerates backdoor
convergence, and maintains benign task perfor-
mance.

Statistical Consistency and Generalization of Contrastive Representation Learnin
g
Yuanfan Li, Xiyuan Wei, Tianbao Yang, Yiming Ying
Contrastive representation learning (CRL) underpins many modern foundation model
s.
Despite recent theoretical progress, existing analyses suffer from several key
limitations: (i) the statistical consistency of CRL remains poorly understood;
(ii) available generalization bounds deteriorate as the number of negative sampl
es
increases, contradicting the empirical benefits of large negative sets; and (iii
)
the retrieval performance of CRL has received limited theoretical attention.
In this paper, we develop a unified statistical learning theory for CRL. For
downstream tasks, we evaluate retrieval quality using an AUC-type population
criterion and show that the contrastive loss is *statistically consistent*
with optimal ranking. We further establish a *calibration-style inequality*
that quantitatively relates excess contrastive risk to excess retrieval
suboptimality. For upstream training, we study both supervised and self-supervis
ed
contrastive objectives and derive generalization bounds of order
$O(1/m + 1/\sqrt{n})$ and $O(1/\sqrt{m} + 1/\sqrt{n})$, respectively, where m
denotes the number of negative samples and n the number of anchor points. Thes
e
bounds not only explain the empirical advantages of large negative sets but also

reveal an explicit trade-off between m and n. Extensive experiments on large-scale vision--language models corroborate our theoretical predictions.

Physics-Informed Residual Flows
Jephte Abijuru, Mayank Nagda, Phil Ostheimer, Sebastian Josef Vollmer, Marius Kloft, Sophie Fellenz
Physics-Informed Neural Networks (PINNs) embed physical laws into deep learning models. However, conventional PINNs often suffer from failure modes leading to inaccurate solutions. We trace these failure modes to two structural pathologies: gradient shattering, where gradients degrade with depth and provide little training signal, and flow mismatch, where training pushes predictions along trajectories that diverge from the PDE solution path. We introduce ResPINNs, which reformulate PINNs as residual flows, networks that iteratively refine their own predictions through explicit corrective steps, in the spirit of classical iterative solvers. Our analysis shows that this design mitigates both pathologies by keeping updates aligned with descent and by preserving informative gradients across depth. Extensive experiments on PDE benchmarks confirm that ResPINNs achieve higher accuracy with substantially fewer parameters than conventional architectures.
****
EntroKV: Entropy-Guided Dynamic Budget Allocation for KV-Cache Compression
Wenhao Gao, Haoran Cao, Yueyan Li, YongGao Xiao, Caixia Yuan, Xiaojie Wang
The prohibitive memory footprint of the Key-Value (KV) cache imposes a critical bottleneck for efficient long-context LLM serving.
Current compression techniques typically rely on static or uniform budget allocation, overlooking the significant heterogeneity in information density across attention heads.
To address this, we introduce \textsc{EntroKV}, an entropy-driven dynamic budget allocation framework.
Our method enables dynamic and rational allocation across layers, attention heads, and different tasks.
We demonstrate that attention entropy serves as a robust proxy for compression sensitivity: heads with high entropy require larger retention budgets, whereas low-entropy heads can be aggressively compressed without accuracy degradation.
Functioning as a lightweight, plug-and-play module, \textsc{EntroKV} optimizes budget scheduling in real-time and is compatible with diverse compression operators.
Extensive experiments demonstrate that \textsc{EntroKV} consistently outperforms baselines, retaining $\sim$98\% of full-cache performance at a 30\% budget ratio with negligible computational overhead.
Our code is available at \url{https://anonymous.4open.science/r/EntroKV-D0C8/}.

Deep Incentive Design with Differentiable Equilibrium Blocks
Vinzenz Thoma, Georgios Piliouras, Luke Marris
Automated design of multi-agent interactions with desirable equilibrium outcomes is inherently difficult due to the computational hardness, non-uniqueness, and instability of the resulting equilibria.
In this work, we propose the use of game-agnostic _differentiable equilibrium blocks_ (DEBs) as modules in a novel, differentiable framework to address a wide variety of incentive design problems from economics and computer science. We call this framework _deep incentive design_ (DID).
To validate our approach, we examine three diverse, challenging incentive design tasks: contract design, machine scheduling, and inverse equilibrium problems.
For each task, we train a single neural network using a unified pipeline and DEB. This architecture solves the _full distribution_ of problem instances, parameterized by a context, handling _all_ games across a wide range of scales (from two to sixteen actions per player).
****
DyGRO-VLA: Cross-Task Scaling of Vision–Language–Action Models via Dynamic Grouped Residual Optimization
Sixu Lin, Yunpeng Qing, Litao Liu, Ming Zhou, Ruixing Jin, Xiaoyi Fan, Guiliang

Liu

Recent progress in Reinforcement Learning (RL) provides a principled approach to optimizing Vision-Language-Action (VLA) models, facilitating a shift from trajectory imitation to active learning in the task environment. Despite improvements in control precision, most RL optimizers remain task-specific, which reduces VLA models from generalist controllers to policies that overfit to a narrow set of tasks. In this study, we conduct an in-depth analysis of this phenomenon and highlight the importance of cross-task feature representations for improving the generalizability of VLA models. Motivated by this finding, we introduce DyGRO-VLA, a two-stage optimization framework that 1) effectively captures cross-task latent representations based on information-theoretic principles, and 2) dynamically refines policy optimization via a mixture-of-RL-residuals. DyGRO-VLA enables the RL optimizer to exploit task-relevant latent information while strategically mitigating adverse interference on the learned representations throughout the optimization process. We evaluate our approach on LIBERO, RoboTwin2 benchmarks, and further validate it on real world, demonstrating consistent improvements over strong baselines under multi-task training and distribution shift. Our project page is available at DyGRO-VLA.

Open Materials Generation with Inference-Time Reinforcement Learning

Philipp Höllmer, Stefano Martiniani

Continuous-time generative models for crystalline materials enable inverse materials design by learning to predict stable crystal structures, but incorporating explicit target properties into the generative process remains challenging. Policy-gradient reinforcement learning (RL) provides a principled mechanism for aligning generative models with downstream objectives but typically requires access to the score, which has prevented its application to flow-based models that learn only velocity fields. We introduce Open Materials Generation with Inference-time Reinforcement Learning (OMatG-IRL), a policy-gradient RL framework that operates directly on the learned velocity fields and eliminates the need for the explicit computation of the score. OMatG-IRL leverages stochastic perturbations of the underlying generation dynamics preserving the baseline performance of the pretrained generative model while enabling exploration and policy-gradient estimation at inference time. Using OMatG-IRL, we present the first application of RL to crystal structure prediction (CSP). Our method enables effective reinforcement of an energy-based objective while preserving diversity through composition conditioning, and it achieves performance competitive with score-based RL approaches. Finally, we show that OMatG-IRL can learn time-dependent velocity-annealing schedules, enabling accurate CSP with order-of-magnitude improvements in sampling efficiency and, correspondingly, reduction in generation time. The OMatG-IRL code is included in a new release of the Open Materials Generation (OMatG) framework available at https://github.com/FERMat-ML/OMatG.

Joint Learning in the Gaussian Single Index Model

Loucas Pillaud-Vivien, Adrien Schertzer

We consider the problem of jointly learning a one-dimensional projection and a univariate function in high-dimensional Gaussian models. Specifically, we study predictors of the form $f(x)=\varphi^\star(\langle w^\star, x \rangle)$, where both the direction $w^\star \in \mathcal{S}_{d-1}$, the sphere of $\mathbb{R}^d$, and the function $\varphi^\star: \mathbb{R} \to \mathbb{R}$ are learned from Gaussian data. This setting captures a fundamental non-convex problem at the intersection of representation learning and nonlinear regression. We analyze the gradient flow dynamics of a natural alternating scheme and prove convergence, with a rate controlled by the information exponent reflecting the *Gaussian regularity* of the function $\varphi^\star$. Strikingly, our analysis shows that convergence still occurs even when the initial direction is negatively correlated with the target. On the practical side, we demonstrate that such joint learning can be effectively implemented using a Reproducing Kernel Hilbert Space (RKHS) adapted to the structure of the problem, enabling efficient and flexible estimation of the univariate function. Our results offer both theoretical insight and practical

methodology for learning low-dimensional structure in high-dimensional settings.

Order Matters in Retrosynthesis: Structure-aware Generation via Reaction-Center-Guided Discrete Flow Matching

Chenguang Wang, Zihan Zhou, LEI BAI, Tianshu Yu

Template-free retrosynthesis methods treat the task as black-box sequence generation, limiting learning efficiency, while semi-template approaches rely on rigid reaction libraries that constrain generalization. We address this gap with a key insight: atom ordering in neural representations matters.

Building on this insight, we propose a structure-aware template-free framework that encodes the two-stage nature of chemical reactions as a positional inductive bias. By placing reaction center atoms at the sequence head, our method transforms implicit chemical knowledge into explicit positional patterns that the model can readily capture. The proposed RetroDiT backbone, a graph transformer with rotary position embeddings, exploits this ordering to prioritize chemically critical regions. Combined with discrete flow matching, our approach decouples training from sampling and enables generation in 20--50 steps versus 500 for prior diffusion methods.

Our method achieves state-of-the-art performance on both USPTO-50k (61.2\% top-1) and the large-scale USPTO-Full (51.3\% top-1) with predicted reaction centers. With oracle centers, performance reaches 71.1\% and 63.4\% respectively, surpassing foundation models trained on 10 billion reactions while using orders of magnitude less data. Ablation studies further reveal that structural priors outperform brute-force scaling: a 280K-parameter model with proper ordering matches a 65M-parameter model without it.

Rethinking 1-bit Optimization Leveraging Pre-trained Large Language Models

Zhijun Tu, Jian Li, Yuanyuan Xi, Siqi Liu, Chuanjian Liu, Hanting Chen, Jie Hu, Yunhe Wang

1-bit LLM quantization offers significant advantages in reducing storage and computational costs. However, existing methods typically train 1-bit LLMs from scratch, failing to fully leverage pre-trained models. This results in high training costs and notable accuracy degradation. We identify that the large gap between full precision and 1-bit representations makes naive adaptation difficult. In this paper, we introduce a consistent progressive training for both forward and backward, smoothly converting the full-precision weights into the binarized ones. Additionally, we incorporate binary-aware initialization and dual-scaling compensation to reduce the difficulty of progressive training and improve the performance. Experimental results on LLMs of various sizes demonstrate that our method outperforms existing approaches. Our results show that high-performance 1-bit LLMs can be achieved using pre-trained models, eliminating the need for expensive training from scratch.

FullStack-Agent: Enhancing Agentic Full-Stack Web Coding via Development-Oriented Testing and Repository Back-Translation

Zimu Lu, Houxing Ren, Yunqiao Yang, Ke Wang, Zhuofan Zong, Mingjie Zhan, Hongsheng Li

Assisting non-expert users to develop complex interactive websites has become a popular task for LLM-powered code agents.

However, existing code agents tend to only generate frontend web pages, masking the lack of real full-stack data processing and storage with fancy visual effects.

Notably, constructing production-level full-stack web applications is far more challenging than only generating frontend web pages, demanding careful control of data flow, comprehensive understanding of constantly updating packages and dependencies, and accurate localization of obscure bugs in the codebase.

To address these difficulties, we introduce FullStack-Agent, a unified agent system for full-stack agentic coding that consists of three parts:

(1) FullStack-Dev, a multi-agent framework with strong planning, code editing, c

odebase navigation, and bug localization abilities.
(2) FullStack-Learn, an innovative data-scaling and self-improving method that back-translates crawled and synthesized website repositories to improve the backbone LLM of FullStack-Dev.
(3) FullStack-Bench, a comprehensive benchmark that systematically tests the frontend, backend and database functionalities of the generated website.
Our FullStack-Dev outperforms the previous state-of-the-art method by 8.7\%, 38.2\%, and 15.9\% on the frontend, backend, and database test cases respectively. Additionally, FullStack-Learn raises the performance of a 30B model by 9.7\%, 9.5\%, and 2.8\% on the three sets of test cases through self-improvement, demonstrating the effectiveness of our approach.

DIYHealth Suite: Dataset, Model, and Benchmark for Health Management at Home
Changshuo Liu, Wu Junran, Zhongle Xie, Wenqiao Zhang, Kaiping Zheng, Jiaqi Zhu, Qingpeng Cai, Ooi Gene Anne, Marcus Chun Jin Tan, Jianwei Yin, James Wei Luen Yip, Beng Chin Ooi
Generative AI is reshaping healthcare, yet most existing advances rely on hospital-grade devices, which limits their accessibility and potential for health management outside clinical settings. With the proliferation of portable devices and telemedicine, healthcare is shifting toward home-based Diagnosis-It-Yourself (DIY) care. Despite this promise, several distinctive challenges remain: (i) home-collected data are heterogeneous, exacerbated by the absence of standardized large-scale datasets; (ii) models require adaptation to variable task demands and evolving individual conditions; (iii) the broad spectrum of home care tasks lacks a unified benchmark for systematic evaluation. In this paper, we present **DIYHealth Suite**, a comprehensive framework designed to address these challenges through a tailored dataset, model, and benchmark. We first curate **DIYHealth-900K**, a large-scale multimodal dataset capturing diverse real-world home care scenarios. Building on this, we propose **DIYHealthGPT**, an adaptive foundation model for home-based health management, powered by the novel Hybrid Hyper Low-Rank Adaptation technique. Finally, we establish **DIYHealthBench**, the first benchmark to evaluate foundation models on home care tasks. Extensive experiments demonstrate that DIYHealthGPT delivers state-of-the-art performance over both general-purpose and medical-specific baselines on 11 home care tasks in both open-QA and closed-QA settings, laying the groundwork for the next generation of personalized health management at home.

TarGATE: Target-Aware Data Selection via Token-Attenuation Gates
Xiandi Luo, Shiwei Li, Haozhao Wang, Yihao Ouyang, Zhuoqi Hu, Yichen Li, Xiao Yang, Huning Liu, Ruixuan Li
Targeted instruction tuning requires selecting pertinent samples from massive mixed *candidate datasets* guided by a small *reference dataset* reflecting the desired capability, yet efficiently identifying high-quality data amidst noise remains challenging. To address this, we propose **TarGATE** (**Tar**get-aware **GATE**s, a simple yet effective data selection framework that leverages the model's inherent data understanding. TarGATE computes a token-level Information Retention Ratio (**IRR**) to scale the output of the feed-forward network, where the instance-level average IRR serves as a quantitative metric for data quality. To align gates' preferences with the target task, we employ a joint optimization strategy utilizing the reference set and a subset of candidate data, which encourages the gates to assign higher IRRs to reference-aligned data while suppressing low-quality samples. Extensive experiments across noisy and real-world scenarios demonstrate that TarGATE outperforms related baselines. Furthermore, TarGATE exhibits superior computational efficiency and strong cross-model transferability, enabling smaller selector to effectively curate high-quality fine-tuning data for larger foundation models. The code is available at [here](https://github.com/FGinfinite/TarGATE).

SCOUT: Cyclic Causal Discovery Under Soft Interventions with Unknown Targets
Alpar Turkoglu, Muralikrishnna Guruswamy Sethuraman, Faramarz Fekri

Learning causal relationships between variables from data is a fundamental research area with many applications across disciplines. Most of the existing causal discovery algorithms rely on the assumptions that (i) the underlying system is acyclic, (ii) the exogenous noise variables are Gaussian, and (iii) that the intervention targets for the data generating experiments are known. While these assumptions simplify the analysis, they are violated in real-life systems. Most existing methods that address these issues either assume the underlying model is linear or are constrained to operate in limited interventional settings. To that end, we propose SCOUT, a novel causal discovery framework to learn nonlinear causal cyclic relationships from soft interventional data with unknown targets. Our main approach maximizes the data log-likelihood to recover the graph structure, using two normalizing-flow architectures—contractive residual flows and neural spline flows. By conducting experiments on synthetic and real-world data, we show that SCOUT outperforms state-of-the-art methods in both causal graph and unknown target recovery across various interventional and noise settings.

Position Is All You Need: A Free Lunch Token Compression Strategy for MLLM-based Referring Expression Segmentation

Yuhan Liu, Yixiong Zou, Yuhua Li, Ruixuan Li

Referring Expression Segmentation (RES) aims to generate pixel-wise segmentation masks from complex and implicit textual queries. While recent advances in Multimodal Large Language Models (MLLMs) have substantially boosted RES performance, their prohibitive computational overhead remains a critical bottleneck, which, however, is rarely explored. To fill this gap, we first evaluate typical token compression methods on this task and observe a surprising performance degradation. In this paper, we aim to understand this phenomenon for a solution. By extensive experiments, we find that token compression for RES requires preserving the original position embeddings and local neighboring spatial structures, indicating that visual token position information is far more critical than in other tasks. Building on this insight, we ask: Can we design the token compression method purely based on the position information? Therefore, we propose PAYN, a plug-and-play, training-free token compression method that relies solely on position information. PAYN retains tokens that are adequately distributed in every local neighboring region while strictly preserving original positional indices, thereby maintaining spatial relational consistency. Experiments on multiple RES benchmarks demonstrate that our method outperforms existing token compression methods, verifying that position is indeed all you need for token compression in the MLLM-based RES task. Codes are avaliable at https://github.com/YuhanLiu231/PAYN.

Beyond Two-Stage Training: Cooperative SFT and RL for LLM Reasoning

Liang Chen, Xueting Han, Li Shen, Jing Bai, Kam-Fai Wong

Supervised fine-tuning (SFT) and reinforcement learning with verifiable rewards (RLVR) are two widely used post-training paradigms for improving the reasoning ability of large language models (LLMs). Recent methods attempt to integrate SFT and RLVR in a single stage by reweighting or scheduling their objectives. However, such coupling can be counterproductive because supervised updates are not uniformly beneficial for reward optimization. To address this, we propose BRIDGE, a scalable framework in which SFT learns to supervise RL by selectively transferring knowledge that improves reward optimization. Specifically, BRIDGE alternates two updates at each meta-training step: a base-model update that fuses the SFT and RL gradients, and an update to a lightweight low-rank adapter (LoRA) that coordinates the two objectives by maximizing a cooperative-gain signal, defined as the reward of joint SFT–RL training over an RL-only baseline. Across five mathematical reasoning benchmarks, BRIDGE consistently outperforms two-stage cold start, naive mixing, and representative single-stage integration baselines, yielding over three points average absolute improvement and more stable training dynamics. We further show that BRIDGE extends to logical reasoning and generalizes out-of-distribution to code and science without additional training, while staying robust under noisy rewards.

ElicitR: Unlocking Latent Reasoning in Dense Retrievers via Generative Regularization
Fengyu Cai, Iryna Gurevych, Heinz Koeppl
Reasoning-intensive retrieval is increasingly important for downstream applications, requiring more than lexical overlap or coarse semantic matching. While prior work mainly relies on Language Models (LMs) to synthesize reasoning-oriented supervision, we posit that it is already latent in LM-based retrievers but suppressed by contrastive overfitting. To elicit this latent reasoning, we introduce ElicitR, a retriever–LM framework with generative regularization that captures nuanced relationships among a query and its candidate documents beyond binary relevance. Concretely, alongside contrastive learning, we regularize the retriever by co-training a small LM on query–positive–negative batches. Next token prediction (NTP) for each text is conditioned on its prefix and the other in-batch texts, with cross-text conditioning weighted by retriever-computed similarities. Using MS MARCO as the only paired query-document supervision and a 135M LM for generative regularization with unlabeled raw-text initialization, ElicitR consistently improves BRIGHT by 16-29% relative across 0.1B–3B retriever scales while maintaining performance on BEIR. At 3B, ElicitR reaches an nDCG@10 of 23.1, substantially outperforming larger models trained with far more curated pairs and proprietary APIs. Further analyses show that ElicitR prevents overfitting, improves retrieval calibration, and remains robust to batch sizes, supporting its practicality.

MulFCoder: Framework-conditioned Multi-agent for MLLM-based Multi-framework Front-end Code Generation
Jie Wu, Haoran Ma, Shisong Tang, Yulin Xu, Xiaoyu Kang, Jiechao Gao
Generating runnable front-end code from UI screenshots is a long-standing goal in automated software engineering.
Existing MLLM-based methods predominantly focused on HTML/CSS, leaving multi-framework generation for React/Vue/Angular underexplored.
Naively modifying prompts leads to substantial performance gaps across multi-framework and highly framework-specific error modes.
To address this, we propose MulFCoder, a framework-conditioned multi-agent method that explicitly encodes framework constraints to bring multi-framework differences into a decidable rule space.
MulFCoder orchestrates four agents:
Grounder constructs an ElementTable, ContentTable, and macro-layout regions from detected UI elements;
Planner builds a DOM-like hierarchical layout tree, produces a task schedule, and derives a framework-specific file Contract;
Writer generates structured file writes or patches within a restricted edit window;
Judger enforces lightweight, framework-conditioned constraints to accept or reject updates and trigger bounded repairs, preventing drift and deadlocks without expensive builds.
Experiments demonstrate that MulFCoder substantially improves compilation success rate and reduces framework-specific errors, with particularly pronounced gains on Angular.

Delving into Muon and Beyond: Deep Analysis and Extensions
Xianbiao Qi, Marco Chen, Jiaquan Ye, Yelin He, Rong Xiao
The Muon optimizer has recently attracted considerable attention for its strong empirical performance and use of orthogonalized updates on matrix-shaped parameters, yet its underlying mechanisms and relationship to adaptive optimizers such as Adam remain insufficiently understood.
In this work, we aim to address these questions through a unified spectral perspective. Specifically, we view Muon as the $p = 0$ endpoint of a family of spectral transformations of the form $\boldsymbol{U} \boldsymbol{\Sigma}^{p} \boldsymbol{V}^{\top}$, and consider additional variants with $p = \frac{1}{2}$, $p = \frac{1}{4}$, and $p = 1$. These transformations are applied to

both first-moment updates, as in momentum SGD, and to root-mean-square (RMS) normalized gradient updates as in Adam. To enable efficient computation, we develop a coupled Newton iteration that avoids explicit singular value decomposition. Across controlled experiments, we find that RMS-normalized updates yield more stable optimization than first-moment updates. Moreover, while spectral compression provides strong stabilization benefits under first-moment updates, the Muon update (\(p = 0 \)) does not consistently outperform Adam. These results suggest that Muon is best understood as an effective form of spectral normalization, but not a universally superior optimization method. Our code is available at \url{https://github.com/Ocram7/BeyondMuon}.

Logit-Attention Divergence: Mitigating Position Bias in Multi-Image Retrieval via Attention-Guided Calibration
Mingtao Xian, Yifeng Yang, Qinying Gu, Xinbing Wang, Nanyang Ye
Multimodal Large Language Models (MLLMs) have shown strong performance in multi-image cross-modal retrieval, yet suffer from severe position bias, where predictions are dominated by input order rather than semantic relevance.
Through empirical analysis, we identify a phenomenon termed Logit-Attention Divergence, in which output logits are heavily biased while internal attention maps remain well-aligned with relevant visual evidence.
This observation reveals a fundamental limitation of existing logit-level calibration methods such as PriDe.
Based on this insight, we propose a training-free, attention-guided debiasing framework that leverages intrinsic attention signals for instance-level correction at inference time, requiring only a minimal calibration set with negligible computational overhead.
Experiments on MS-COCO-based benchmarks show that our method substantially improves permutation invariance and achieves state-of-the-art performance, enhancing accuracy by over 40\% compared to baselines. Code is available at https://github.com/brightXian/LAD.

High-Probability Convergence Guarantees of Decentralized SGD
Aleksandar Armacki, Ali H. Sayed
Convergence in high-probability (HP) has attracted increasing interest, due to implying exponentially decaying tail bounds and strong guarantees for individual runs of an algorithm. While many works study HP guarantees in centralized settings, much less is understood in the decentralized setup, where existing works require strong assumptions, like uniformly bounded gradients, or asymptotically vanishing noise. This results in a significant gap between the assumptions used to establish convergence in the HP and the mean-squared error (MSE) sense, and is also contrary to centralized settings, where it is known that $\mathtt{SGD}$ converges in HP under the same conditions on the cost function as needed for MSE convergence. Motivated by these observations, we study the HP convergence of Decentralized $\mathtt{SGD}$ ($\mathtt{DSGD}$) in the presence of light-tailed noise, providing several strong results. First, we show that $\mathtt{DSGD}$ converges in HP under the same conditions on the cost as in the MSE sense, removing the restrictive assumptions used in prior works. Second, our sharp analysis yields order-optimal rates for both non-convex and strongly convex costs. Third, we establish a linear speed-up in the number of users, leading to matching or strictly better transient times than those obtained from MSE results, further underlining the tightness of our analysis. To the best of our knowledge, this is the first work that shows $\mathtt{DSGD}$ achieves a linear speed-up in the HP sense. Our relaxed assumptions and sharp rates stem from several technical results of independent interest, including a result on the variance-reduction effect of decentralized methods in the HP sense, as well as a novel bound on the moment-generating function of strongly convex costs, of interest even in centralized settings. Numerical experiments validate our theory.

Memory is Reconstructed, Not Retrieved: Graph Memory for LLM Agents
Shuo Ji, Yibo Li, Bryan Hooi

Despite recent progress, LLM agents still struggle with reasoning over long interaction histories. While current memory-augmented agents rely on a static ``retrieve-then-reason'' paradigm, this rigid pipeline design prevents them from dynamically adapting memory access to intermediate evidence discovered during inference. To bridge this gap, we propose MRAgent, a framework that combines an associative memory graph with an active reconstruction mechanism. We represent memory as a Cue–Tag–Content graph, where associative tags serve as semantic bridges connecting fine-grained cues to memory contents. Operating on this structure, our active reconstruction mechanism integrates LLM reasoning directly into memory access, allowing the agent to iteratively explore and prune retrieval paths based on accumulated evidence. This ensures that memory retrieval is dynamically adapted to the reasoning context while avoiding combinatorial explosion caused by unconstrained expansion. Experiments on the LoCoMo benchmark and LongMemEval benchmark demonstrate significant improvements over strong baselines (up to $23\\%$), while substantially reducing retrieval cost, highlighting the effectiveness of active and associative reconstruction for long-horizon memory reasoning.

TRACE: Trajectory Recovery for Continuous Mechanism Evolution in Causal Representation Learning
Shicheng Fan, Kun Zhang, Lu Cheng
Temporal causal representation learning methods assume that causal mechanisms switch instantaneously between discrete domains, yet real-world systems often exhibit continuous mechanism transitions. For example, a vehicle's dynamics evolve gradually through a turning maneuver, and human gait shifts smoothly from walking to running. We formalize this setting by modeling transitional mechanisms as convex combinations of finitely many atomic mechanisms, governed by time-varying mixing coefficients. Our theoretical contributions establish that both the latent causal variables and the continuous mixing trajectory are jointly identifiable. We further propose TRACE, a Mixture-of-Experts framework where each expert learns one atomic mechanism during training, enabling test-time recovery of mechanism trajectories, including intermediate mechanism states never observed during training. Experiments on synthetic and real-world data demonstrate that TRACE recovers mixing trajectories with up to 0.99 correlation, substantially outperforming discrete-switching baselines.

The Cost of Learning Under Multiple Change Points
Tomer Gafni, Garud Iyengar, assaf zeevi
We consider an online learning problem in environments with multiple change points.
In contrast to the single change point problem that is widely studied using classical "high confidence" detection schemes, the multiple change point environment presents new learning-theoretic and algorithmic challenges. Specifically, we show that classical methods may exhibit catastrophic failure (high regret) due to a phenomenon we refer to as endogenous confounding. To overcome this, we propose a new class of learning algorithms dubbed Anytime Tracking CUSUM (ATC). These are horizon-free online algorithms that implement a selective detection principle, balancing the need to ignore "small" (hard-to-detect) shifts, while reacting "quickly" to significant ones. We prove that the performance of a properly tuned ATC algorithm is nearly minimax-optimal; its regret is guaranteed to closely match a novel information-theoretic lower bound on the achievable performance of any learning algorithm in the multiple change point problem. Experiments on synthetic as well as real-world data validate the aforementioned theoretical findings.

A theory of learning data statistics in diffusion models, from easy to hard
Lorenzo Bardone, Claudia Merger, Sebastian Goldt
While diffusion models have emerged as a powerful class of generative models, their learning dynamics remain poorly understood.
We address this issue first by empirically showing that standard diffusion models trained on natural images exhibit a simplicity bias, learning simple, pair-wis

e input statistics before specializing to higher-order correlations. We reproduc
e this behaviour in simple denoisers trained on a minimal data model, the mixed
cumulant model, where we precisely control both pair-wise and higher-order corre
lations of the inputs. We identify a scalar invariant of the model that governs
the sample complexity of learning pair-wise and higher-order correlations that w
e call the _diffusion information exponent_, in analogy to related invariants in
 different learning paradigms.
Using this invariant, we prove that the denoiser learns simple, pair-wise statis
tics of the inputs at linear sample complexity, while more complex higher-order
statistics, such as the fourth cumulant, require at least cubic sample complexit
y. We also prove that the sample complexity of learning the fourth cumulant is l
inear if pair-wise and higher-order statistics share a correlated latent structu
re.
Our work describes a key mechanism for how diffusion models can learn distributi
ons of increasing complexity.

Federated Manifold Learning (FML): Tackling Domain Heterogeneity with Structural
 Knowledge Transfer

Xutong Mu, Yanbiao Ma, Jia Shi, Xueli Geng, Fengkai Xiang, Tao Zhang, Ke Cheng,
Yulong Shen

Federated Learning (FL) faces significant challenges due to domain heterogeneity
, where data from different clients exhibit substantial statistical shifts that
hinder the generalization of the global model. Although existing methods attempt
 to mitigate this by exchanging class prototypes, they fall short by representin
g an entire class's complex distribution with a single point. This oversimplific
ation disregards the rich structural information within the data, especially acr
oss diverse domains. To address this limitation, we propose a paradigm shift fro
m point-based representation to structure-based knowledge transfer. We introduce
 Federated Manifold Learning (FML), a novel framework that leverages perceptual
manifolds—the intrinsic geometric structures of classes in the feature space—as
rich knowledge carriers. In FML, clients transmit compressed manifolds, which ar
e adaptively fused on the server using an attention-based Manifold Mutual Learni
ng (MML) mechanism. This process enables domain-specific structures to learn fro
m each other, creating a unified yet flexible global convergence target. Manifol
d-guided local training, enforced by a manifold approximation loss and a separat
ion loss, further aligns local models with this global structure. Extensive expe
riments on the Digits and Office31 benchmarks demonstrate that FML substantially
 outperforms state-of-the-art methods, achieving accuracy improvements of up to
6.47%.

Gradient Smoothing: Coupling Layer-wise Updates for Improved Optimization

Haoming Meng, Anton Sugolov, Vardan Papyan

Deep neural networks with repeated blocks, such as transformers and ResNets, oft
en exhibit structured relationships across layers that emerge during training. M
otivated by this observation, we introduce a general paradigm of *Depth-wise Gra
dient Augmentation*, in which the update applied to a layer may depend on the ba
se optimizer updates computed for other layers. We study an instantiation of thi
s idea, termed *Gradient Smoothing*, which couples optimizer updates across dept
h and admits a natural interpretation as a structured preconditioning method. Ou
r framework operates directly on block-wise update vectors produced by arbitrary
 base optimizers (e.g., SGD, Adam, Muon), applying structured depth-wise smoothi
ng operators such as local weighted averaging with minimal computational overhea
d. We evaluate Gradient Smoothing across a diverse set of architectures and trai
ning regimes, including language model pretraining, RL post-training of LLMs on
reasoning tasks, diffusion modeling, and image classification with Vision Transf
ormers. Across these settings, Gradient Smoothing consistently improves converge
nce and generalization performance without modifying model architectures or trai
ning objectives. We further show that smoothing promotes more structured represe
ntation evolution across depth, suggesting a connection between structured updat
e coupling and the internal organization of learned representations. These resul

ts position Gradient Smoothing as a simple and broadly applicable approach for i
mproving training in modern deep networks.

Baguan-TS: dual in-context learning model for time series forecasting with covar
iates

Linxiao Yang, Xue Jiang, Gezheng Xu, Tian Zhou, Min Yang, Zhaoyang Zhu, Linyuan
Geng, Zhipeng Zeng, Qiming Chen, Xinyue Gu, Rong Jin, Liang Sun

Transformers enable in-context learning (ICL) for rapid, gradient-free adaptatio
n in time series forecasting, yet most ICL-style approaches rely on tabularized,
 hand-crafted features, while end-to-end sequence models lack inference-time ada
ptation. We bridge this gap with a unified framework, Baguan-TS, which integrate
s the raw-sequence representation learning with ICL, instantiated by a 3D Transf
ormer that attends jointly over temporal, variable, and context axes.
To make this high-capacity model practical, we tackle two key hurdles: (i) calib
ration and training stability, improved with a feature-agnostic, target-space re
trieval-based local calibration; and (ii) output oversmoothing, mitigated via co
ntext-overfitting strategy. On public benchmark with covariates, Baguan-TS consi
stently outperforms established baselines, achieving the highest win rate and si
gnificant reductions in both point and probabilistic forecasting metrics. Furthe
r evaluations across diverse real-world energy datasets demonstrate its robustne
ss, yielding substantial improvements.
****

AdaRoPE: Not All Attention Heads Should Rotate and Scale Equally

Shaowen Wang, Yuke Zheng, Tansheng Zhu, Shuang Chen, Shaofan Liu, Suncong Zheng,
 Jian Li

Rotary Position Embeddings (RoPE) are widely adopted in Transformers to encode p
ositional information, yet standard implementations enforce a uniform frequency
 schedule and scaling across all attention heads.
Using simplified retrieval tasks and length generalization scenarios, we show—bo
th empirically and theoretically—that heads with different functional roles requ
ire distinct frequency ranges and scaling factors to operate effectively. Ignori
ng this structure leads to suboptimal utilization of embedding dimensions and de
graded performance, particularly under long-context settings.
To address these limitations, we proposeAdaRoPE, which equips each attention hea
d with learnable rotation frequencies and scaling factors. Pretrained LLM with A
daRoPE consistently outperforms existing RoPE variants, including partial-RoPE a
nd NoPE baselines. For context extension, we further show that uniform frequency
 and attention scaling, used in methods such as YaRN, are suboptimal. By applyin
g head-specific scaling, AdaRoPE enables better context extension while better p
reserving short-context performance in both extrapolation setting and long conte
xt continued pretrain setting. These results highlight the importance of optimiz
ing rotary position embeddings at the level of individual attention heads.
****

Rank-Learner: Orthogonal Ranking of Treatment Effects

Henri Arno, Dennis Frauen, Emil Javurek, Thomas Demeester, Stefan Feuerriegel

Many decision-making problems require ranking individuals by their treatment eff
ects rather than estimating the exact effect magnitudes. Examples include priori
tizing patients for preventive care interventions, or ranking customers by the e
xpected incremental impact of an advertisement. Surprisingly, while causal effec
t estimation has received substantial attention in the literature, the problem o
f directly learning *rankings of treatment effects* has largely remained unexplo
red. In this paper, we introduce *Rank-Learner*, a novel two-stage learner that
directly learns the ranking of treatment effects from observational data. We fir
st show that naive approaches based on precise treatment effect estimation solve
 a harder problem than necessary for ranking, while our *Rank-Learner* optimizes
 a pairwise learning objective that recovers the true treatment effect ordering,
 without explicit CATE estimation. We further show that our *Rank-Learner* is Ne
yman-orthogonal and thus comes with strong theoretical guarantees, including rob
ustness to estimation errors in the nuisance functions. In addition, our *Rank-L
earner* is model-agnostic, and can be instantiated with arbitrary machine learni

ng models (e.g., neural networks). We demonstrate the effectiveness of our metho d through extensive experiments where *Rank-Learner* consistently outperforms st andard CATE estimators and non-orthogonal ranking methods. Overall, we provide p ractitioners with a new, orthogonal two-stage learner for ranking individuals by their treatment effects.
****
Gated Relational Alignment via Confidence-based Distillation for Efficient VLMs
Yanlong Chen, Amir Habibian, Luca Benini, Yawei Li
Vision-Language Models (VLMs) achieve strong multimodal performance but are cost ly to deploy, and post-training quantization often causes significant accuracy l oss. Despite its potential, quantization-aware training for VLMs remains underex plored. We propose GRACE, a framework unifying knowledge distillation and QAT un der the Information Bottleneck principle: quantization constrains information ca pacity while distillation guides what to preserve within this budget. Treating t he teacher as a proxy for task-relevant information, we introduce confidence-gat ed decoupled distillation to filter unreliable supervision, relational centered kernel alignment to transfer visual token structures, and an adaptive controller via Lagrangian relaxation to balance fidelity against capacity constraints. Acr oss extensive benchmarks on LLaVA and Qwen families, our INT4 models consistentl y outperform FP16 baselines (e.g., LLaVA-1.5-7B: 70.1 vs. 66.8 on SQA; Qwen2-VL- 2B: 76.9 vs. 72.6 on MMBench), nearly matching teacher performance. Using real I NT4 kernel, we achieve 3× throughput with 54\% memory reduction. This principled framework significantly outperforms existing quantization methods, making GRACE a compelling solution for resource-constrained deployment. Code and data are av ailable at: https://github.com/ForeverBlue816/GRACE.
****
gp2Scale: A Class of Compactly Supported Non-Stationary Kernels and Distributed Computing for Exact Gaussian Processes on 10 Million Data Points
Marcus M. Noack, Mark D Risser, Hengrui Luo, Vardaan Tekriwal, Ronald J. Pandolf i
Despite a large corpus of recent work on scaling up Gaussian processes, a stubbo rn trade-off between computational speed, prediction, and uncertainty quantifica tion accuracy, and customizability persists. This is because the vast majority o f existing methodologies exploit various levels of approximation that lower accu racy and limit the flexibility of kernel and noise-model designs --- an unaccept able drawback at a time when expressive non-stationary kernels are on the rise i n many fields. Here, we propose a methodology we term *gp2Scale* that scales exa ct Gaussian processes to more than 10 million data points without relying on ind ucing points, kernel interpolation, or neighborhood-based approximations, and in stead leverages the existing capabilities of a GP: its kernel design. Highly fle xible, compactly supported, and non-stationary kernels lead to the identificatio n of naturally occurring sparse structure in the covariance matrix, which is the n exploited to compute the linear system solution and the log-determinant for tr aining. We demonstrate our method's functionality on several real-world datasets and compare it with state-of-the-art approximation algorithms. Although we show superior approximation performance in many cases, the method's real power lies in its agnosticism toward arbitrary GP customizations --- core kernel design, no ise, and mean functions --- and the type of input space, making it optimally sui ted for modern Gaussian process applications.
****
Geometric Control of Out-of-Distribution Shift in Safe Offline RL
Zhiqi Zhuang, Di Wu, Benoit Boulet
Safe offline reinforcement learning (RL) requires optimizing policies within the support of static datasets while satisfying strict safety constraints. Although recent latent generative policies achieve strong empirical performance, they re ly heavily on implicit regularization and lack systematic control over distribut ional shift during policy improvement.
In this work, we propose a geometric control framework that leverages the biject ive structure of conditional normalizing flows to provide a tractable mechanism to regulate distributional deviation of the policy. By constraining divergence i

n the latent base space, we derive tractable upper bounds on the induced Wassers tein distance and total variation of the policy distribution, establishing an an alyzable connection between latent geometry and downstream behaviors.
This insight motivates a decoupled architecture: a flow prior shapes a feasibili ty-weighted latent manifold using Hamilton--Jacobi reachability signals, while a latent refiner performs geometrically constrained optimization directly in the base space. Across multiple safe RL benchmarks, our method achieves consistently low violation rates with competitive returns, highlighting the benefits of stru ctured geometric regularization.

Scaling Beyond Masked Diffusion Language Models
Subham Sekhar Sahoo, Jean-Marie Lemercier, Zhihan Yang, Justin Deschenaux, Jingy u Liu, John Thickstun, Ante Juki■
Diffusion language models are a promising alternative to autoregressive models d ue to their potential for faster generation. Among discrete diffusion approaches , Masked diffusion currently dominates, largely driven by strong perplexity on l anguage modeling benchmarks. In this work, **we present the first scaling law st udy of uniform-state and interpolating discrete diffusion methods**. We also sho w that Masked diffusion models can be made approximately 12% more FLOPs-efficien t when trained with a simple cross-entropy objective.
We find that perplexity is informative within a diffusion family but can be misl eading across families, where models with worse likelihood scaling may be prefer able due to faster and more practical sampling, as reflected by the speed-qualit y Pareto frontier. **These results challenge the view that Masked diffusion is c ategorically the future of diffusion language modeling** and that perplexity alo ne suffices for cross-algorithm comparison. Scaling all methods to 1.7B paramete rs, we show that uniform-state diffusion remains competitive on likelihood-based benchmarks and outperforms autoregressive and Masked diffusion models on GSM8K, despite worse validation perplexity.

An Odd Estimator for Shapley Values
Fabian Fumagalli, Landon Butler, Justin Singh Kang, Kannan Ramchandran, R. Teal Witter
The Shapley value is a ubiquitous framework for attribution in machine learning, encompassing feature importance, data valuation, and causal inference. However, its exact computation is generally intractable, necessitating efficient approxi mation methods. While the most effective and popular estimators leverage the *pa ired sampling* heuristic to reduce estimation error, the theoretical mechanism d riving this improvement has remained opaque. In this work, we provide an elegant and fundamental justification for paired sampling: we prove that the Shapley va

lue depends *exclusively* on the odd component of the set function, and that pai red sampling orthogonalizes the regression objective to filter out the irrelevan t even component. Leveraging this insight, we propose OddSHAP, a novel consisten t estimator that performs polynomial regression solely on the odd subspace. By u tilizing the Fourier basis to isolate this subspace and employing a proxy model to identify high-impact interactions, OddSHAP overcomes the combinatorial explos ion of higher-order approximations. Through an extensive benchmark, we find that OddSHAP achieves state-of-the-art estimation accuracy at larger sampling budget s.

CoF-T2I: Video Models as Pure Visual Reasoners for Text-to-Image Generation

Chengzhuo Tong, Mingkun Chang, Shenglong Zhang, Yuran Wang, Cheng Liang, Zhizhen g Zhao, Bohan Zeng, Yang Shi, Ruichuan An, Yifan Dai, Ziming Zhao, Guanbin Li, P engfei Wan, Yuanxing Zhang, Wentao Zhang

Recent video generation models have revealed the emergence of Chain-of-Frame (Co F) reasoning, enabling frame-by-frame visual inference. With this capability, vi deo models have been successfully applied to various visual tasks (*e.g.*, maze solving, visual puzzles). However, their potential to enhance text-to-image (T2I) generation remains largely unexplored due to the absence of a clearly defined visual reasoning starting point and interpretable intermediate states in the T2I generation process.

To bridge this gap, we propose **CoF-T2I**, a model that integrates CoF reasonin g into T2I generation via progressive visual refinement, where intermediate fram es act as explicit reasoning steps and the final frame is taken as output.

To establish such explicit generation process, we curate **CoF-Evol-Instruct**, a dataset of CoF trajectories that model the generation process from semantics t o aesthetics. To further improve quality and avoid motion artifacts, we enable a n independent encoding operation for each frame. Experiments show that CoF-T2I s ignificantly outperforms the base video model and achieves competitive performan ce, reaching 0.86 on GenEval and 7.468 on Imagine-Bench. These results indicate the substantial promise of video models for advancing high-quality text-to-image generation.

Taylor-Gaussians-Flow: Towards Non-uniform Motion for Novel View Synthesis from Monocular Video

Zaoming Yan, Qizhou Chen, Yaomin Huang, Pengcheng Lei, Chenhao Shi, Yi Xu, Haich uan Song, Faming Fang

Long-term non-uniform motion poses a significant challenge for Novel View Synthe sis (\textbf{NVS}), as it requires modeling higher-order motion, such as acceler ation.

Existing methods primarily rely on deformation fields or scene flow, which are l imited to first-order approximations.

Due to neglecting higher-order motion representations and supervision, these app roaches suffer from long-term non-uniform motion scenarios.

Inspired by Taylor’s theorem, we propose Taylor-Gaussians-Flow (\textbf{TGsF}) t o represent and supervise non-uniform motion through first-order and second-orde r motion components.

TGsF comprises two key modules: Taylor-Gaussians (\textbf{TGs}) and Taylor-Gauss ians-Flow (\textbf{TGs-Flow}).

TGs represent motion using Gaussian means with a quadratic temporal term and tim e-dependent opacity.

Unlike previous methods, TGs-Flow decouples scene-flow supervision into separate depth and 2D optical-flow constraints.

This approach effectively mitigates error propagation from either depth or motio n estimation while circumventing the scarcity of labeled scene flow data.

Guided by the above analysis, we develop the Feed-Forward Taylor-Gaussians-Flow framework, which sets a new state-of-the-art on four dynamic benchmarks.

DualOptim+: Bridging Shared and Decoupled Optimizer States for Better Machine Un learning in Large Language Models

Xuyang Zhong, Qizhang Li, Steven Y. Guo, Chen Liu
We propose **DualOptim+**, a novel optimization framework for improving machine unlearning in large language models.
It introduces a base state to capture common representations shared by forgetting and retaining objectives and delta states to preserve objective-specific residuals. This architecture allows the optimizer to adaptively bridge shared and decoupled states based on the directional conflict between forgetting and retaining gradients. We further introduce DualOptim+ 8bit, a quantized variant that reduces memory overhead without compromising performance. Extensive experiments across fictitious and real-world unlearning, safety alignment, and multi-task learning tasks demonstrate that DualOptim+ consistently achieves a superior trade-off between different objectives. Codes are available at https://github.com/CityU-MLO/DualOptimPlus.

Normalized Rewards for Preference Optimization
Shawn Im, Federico Danieli, Skyler Seto, Barry-John Theobald, Katherine Metcalf
Direct Alignment Algorithms (DAAs) such as DPO have become a common way to post-train and align LLMs with human preferences. However, DAAs have been observed to over-optimize their implicit reward model and decrease the likelihood of preferred responses. This results in a decrease in the total likelihood assigned to responses seen in the preference dataset, potentially resulting in undesirable behavior. To counteract this undesired side-effect of DAAs, we examine the effect of using objectives that add a regularization term to maintain the total length-normalized probabilities of the chosen and rejected responses. To better understand over-optimization, we investigate how response likelihood changes are distributed over the tokens with and without regularization. We find that a significant portion of the likelihood changes are due to a small set of outlier tokens, which explains how DAAs improve generation quality despite decreasing the likelihoods of chosen responses. We apply the proposed regularization to reference-based (DPO) and reference-free (SimPO) methods and find (1) improved trade-offs between generation quality and general benchmark capability and (2) improvements in reward modeling across datasets. For example, on Llama-3.1-8B-Instruct, we see both a >20\% relative increase in AlpacaEval2 scores and >9\% relative performance gains on general benchmarks. Additionally, we find that the added regularization term effectively mitigates the amount of displacement within preferred responses overall, and for the outlier tokens specifically, by utilizing low-likelihood tokens.

Pix2Key: Controllable Open-Vocabulary Retrieval with Semantic Decomposition and Self-Supervised Visual Dictionary Learning
Guoyizhe Wei, Yang Jiao, Nan Xi, Zhishen Huang, Jingjing Meng, Rama Chellappa, Yan Gao
Composed image retrieval uses a reference image plus a natural-language edit to retrieve images that apply the requested change while preserving other relevant visual content. Classic fusion pipelines typically rely on supervised triplets and can lose fine-grained cues, while recent zero-shot approaches often caption the reference image and merge the caption with the edit, which may miss implicit user intent and return repetitive results. We present Pix2Key, which represents both queries and candidates as open-vocabulary visual dictionaries, enabling intent-aware constraint matching and diversity-aware reranking in a unified embedding space. A self-supervised pretraining component, V-Dict-AE, further improves the dictionary representation using only images, strengthening fine-grained attribute understanding without CIR-specific supervision. On the extended DeepFashion-MM benchmark, Pix2Key improves Recall@10 up to 3.2 points, and adding V-Dict-AE yields an additional 2.3-point gain while improving intent consistency and maintaining high list diversity.

Does Your Reasoning Model Implicitly Know When to Stop Thinking?
Zixuan Huang, Xin Xia, Yuxi Ren, Jianbin Zheng, Xuanda Wang, Zhixia Zhang, Hongyan Xie, Songshi Liang, Zehao Chen, Xuefeng Xiao, Fuzhen Zhuang, Jianxin Li, deqi

ng wang, Yikun Ban
Recent advancements in large reasoning models (LRMs) have greatly improved their capabilities on complex reasoning tasks through Long Chains of Thought (CoTs). However, this approach often results in substantial redundancy, impairing computational efficiency and causing significant delays in real-time applications. Recent studies show that longer reasoning chains are frequently uncorrelated with correctness and can even be detrimental to accuracy.
In a further in-depth analysis of this phenomenon, we surprisingly uncover and empirically verify that LRMs implicitly know the appropriate time to stop thinking, while this capability is obscured by current sampling paradigms.
Motivated by this, we introduce SAGE (Self-Aware Guided Efficient Reasoning), a novel sampling paradigm that unleashes this efficient reasoning potential. Furthermore, integrating SAGE as mixed sampling into group-based reinforcement learning (SAGE-RL) enables SAGE-RL to effectively incorporate SAGE-discovered efficient reasoning patterns into standard pass@1 inference, markedly enhancing both the reasoning accuracy and efficiency of LRMs across multiple challenging mathematical benchmarks.
****

RL-SPH: Learning to Achieve Feasible Solutions for Integer Linear Programs
Tae-Hoon Lee, Min-Soo Kim
Primal heuristics play a crucial role in quickly finding feasible solutions for NP-hard integer linear programming (ILP). Although $\textit{end-to-end learning}$-based primal heuristics (E2EPH) have recently been proposed, they are typically unable to independently generate feasible solutions. To address this challenge, we propose RL-SPH, a novel reinforcement learning-based start primal heuristic capable of independently generating feasible solutions, even for ILP involving non-binary integers. Empirically, RL-SPH rapidly obtains high-quality feasible solutions with a 100% feasibility rate, achieving on average a 28.6$\times$ lower primal gap and a 2.6$\times$ lower primal integral compared to existing start primal heuristics.

PanoWorld-X: Generating Explorable Panoramic Worlds via Sphere-Aware Video Diffusion
Yuyang Yin, Hao-Xiang Guo, Fangfu Liu, Mengyu Wang, Hanwen Liang, Eric Li, Yikai Wang, Xiaojie Jin, Yao Zhao, Yunchao Wei
Achieving a complete and explorable 360-degree visual world is a cornerstone of immersive content creation. While recent advances in video generation have achieved impressive results, they follow a 2D paradigm that treats content generation as transitions of 2D pixels, lacking an intrinsic understanding of the physical 3D world, resulting in frequent geometric inconsistencies.
To achieve an explorable and physical-consistent visual world, the generation process should shift to a 3D paradigm: the visual content is governed by the physical relationships of the entire 3D environment together with 3D motion signals. However, under this setting, the conventional modeling methods and control signals, such as spatial attention computation in a 2D space, become unsuitable and ineffective.
To address this, we propose PanoWorld-X for explorable immersive scene video generation. Our framework is built on the panoramic representation, which naturally maps a 3D scene into a standard format and provides an ideal basis for consistency. Specifically, we first develop a data curation pipeline to produce high-quality and large-motion 3D scene evolution with movement trajectories. To achieve precise control, we design the Exploration Panoramic Plücker Embedding (PPE), a guidance signal tailored for 3D motion. Furthermore, leveraging the spherical geometric properties of panoramic data, we propose a sphere-aware attention mechanism, which can capture true geometric adjacency by reprojecting features onto a spherical surface. Extensive experiments demonstrate that PanoWorld-X achieves superior performance in motion range, control precision, and visual quality, underscoring its potential for real-world applications.

Consistency Training Can Entrench Misalignment

David Demitri Africa, Arathi Mani
Consistency training encourages a model to produce similar outputs across related inputs or sampling procedures. Such methods are simple, scalable, and largely label-free, but their effects on model alignment remain poorly understood. Could the self-bootstrapping nature of these methods amplify undesired behavior in models? We test seven consistency training methods on 108 model organisms: open-source models (7B--70B) fine-tuned to exhibit various forms of controlled misaligned behavior. We find that outcomes vary significantly: consistency training generally suppresses reward hacking and emergent misalignment but amplifies sycophancy. We present evidence that distribution shifts induced by the consistency labeling process, rather than variation in the selection operators, may be the primary driver of systematic alignment effects. Finally, we present a unifying theoretical framework to derive conditions under which consistency training will amplify or suppress misalignment. In total, our study establishes that consistency training is not alignment-neutral, and that its use in critical systems should be carefully audited.

Strategy-Aware Optimization Modeling with Reasoning LLMs
Ruiqing Zhao, Fengzhi Li, Yuan Zuo, Rui Liu, YanSong Liu, Yunfei Ma, Fanyu Meng, Junlan Feng
Large language models (LLMs) can generate syntactically valid optimization programs, yet often struggle to reliably choose an effective modeling strategy, leading to incorrect formulations and inefficient solver behavior. We propose **SAGE**, a strategy-aware framework that makes *Modeling Strategy* explicit in both data construction and post-training. SAGE builds a solver-verified multi-strategy dataset and trains a student model with supervised fine-tuning followed by Segment-Weighted GRPO using a composite reward over format compliance, correctness, and solver efficiency. Across eight benchmarks spanning synthetic and real-world settings, SAGE improves average pass@1 from 72.7 to 80.3 over the strongest open-source baseline. With multiple generations, SAGE discovers more distinct correct formulations and improves component-level diversity at pass@16 by 19-29%. At the largest scale, SAGE produces more compact constraint systems with 14.2% fewer constraints than the baseline, consistent with solver-efficient modeling. Overall, these results show that making *Modeling Strategy* explicit improves automated optimization modeling. The code and data are available at https://github.com/rachhhhing/SAGE.

PODiff: Latent Diffusion in Proper Orthogonal Decomposition Space for Scientific Super-Resolution
Onkar Jadhav, Tim French, Matthew Rayson, Nicole L. Jones
Probabilistic super-resolution of high-dimensional spatial fields using diffusion models is often computationally prohibitive due to the cost of operating directly in pixel space. We propose PODiff, a structured conditional generative framework that performs diffusion in a fixed, variance-ordered Proper Orthogonal Decomposition (POD) coefficient space, exploiting the orthogonality of POD modes to impose an interpretable, variance-ordered latent geometry. This design enables efficient ensemble generation, preserves dominant spatial structure, and yields spatially interpretable, well-calibrated uncertainty at substantially lower computational cost. We evaluate PODiff on sea surface temperature downscaling over the West Australian coast and on a controlled advection--diffusion benchmark. PODiff achieves reconstruction accuracy comparable to pixel-space and learned-latent diffusion while using a substantially smaller structured latent space, requiring significantly less memory, and producing more reliable uncertainty estimates than deterministic and Monte Carlo Dropout baselines.
****

PSMix: Robust Point Cloud Recognition through Spectral Domain Mixing
Xin Wei, Qin Yang, Hongji Zhao, Fei Gao, Mingrui Zhu, Nannan Wang, Xinbo Gao
While data augmentation is essential for robust point cloud recognition, conventional spatial mixup strategies often compromise geometric integrity by generating physically unrealistic samples. To overcome this limitation, we propose PSMix,

which shifts the mixing paradigm to the spectral domain via the Spherical Harmonic Transform. Instead of simple coordinate interpolation, PSMix performs a rotation-aware hierarchical mixing on spectral coefficients. This approach explicitly preserves global structural properties while diversifying local details, achieving a balance that spatial methods struggle to maintain. Complementing this, we introduce an adversarial rotation optimization strategy to enforce invariance against challenging orientations. Extensive experiments on ModelNet-C and ScanObjectNN-C demonstrate that PSMix achieves state-of-the-art robustness, while also serving as an orthogonal plug-in that further boosts the performance of existing spatial strategies.
****

EgoTactile: Learning Grasp Pressure for Everyday Objects from Egocentric Video
Yuan Zeng, Yujia Shi, Tiao Tan, Xingting Li, Yaqi Qin, Zongqing Lu, Wenming Yang, Jing-Hao Xue, Qingmin Liao
Estimating full-hand grasp pressure from egocentric video is critical for immersive VR and robotic manipulation, yet dense tactile sensing often relies on intrusive hardware.
Existing vision-based methods predominantly rely on planar surfaces or fingertip contacts, failing to generalize to complex 3D object interactions.
Therefore, we introduce EgoTactile, a benchmark pairing egocentric video with full-hand pressure supervision for diverse everyday objects, incorporating a bare-hand transfer subset to enable generalization to natural scenarios.
Leveraging this benchmark, we first establish EgoPressureFormer as a discriminative baseline. Beyond this, to explicitly address the uncertainty in partial observations, we propose EgoPressureDiff, a conditional diffusion framework that adapts a large-scale pre-trained video diffusion backbone. By combining rich world knowledge priors with a Physically-Informed Feature Rectification layer to inject semantic constraints, our approach effectively hallucinates plausible contact patterns and resolves visual-physical ambiguities.
Extensive experiments demonstrate that our method achieves superior performance on the benchmark and robust transferability to in-the-wild scenarios. Our project page is at https://egotactile.github.io/.

LAVA: A Unified Framework for Finetuning Language and Vision Models
Daorui Ding, Fanhua Shang, Tiancan Feng, Junkang Liu, Hongying Liu
LoRA and its variants have attracted considerable attention because of their abilities to tune a negligible number of parameters while achieving comparable downstream performance. This success is largely attributed to the intrinsic low-rank structure of model parameter spaces, which allows LoRA to train two projection matrices to project weights into a low-dimensional subspace and then map them back. However, it does not consider how to explore this low-rank subspace sufficiently and may lose the expression ability accordingly. Moreover, when using LoRA to tune convolution layers, a flatten operation is required to convert tensors into matrices. We argue that this will degrade the model's performance. In this paper, we address this issue from a general parameter sub-space perspective: we present a unified **L**anguage **A**nd **V**ision **A**daption finetuning framework (called **LAVA**). Specifically, we verify the existence of low-rank subspaces in convolution layers empirically and propose to parameterize the increment of both convolution kernels and matrices as sum of learnable rank-1 components. To improve training stability, we analyze the optimization dynamics of LoRA and incorporate orthogonal regularization into our parameterization, for which we give theoretical proof that it will help reduce the variance of the gradient. We conduct various experiments on different downstreaming tasks to validate LAVA's superiority. For example, when tuning LLaMA2-7b for commonsense tasks, the performance of our LAVA is **+1.9\%** higher than that of LoRA. For metric depth estimation tasks, LAVA only tunes $\sim$1.5\% of Depth-Anything (335.3M), and achieves **+3.5\%** δ_1 accuracy against that of LoRA and **+5.6\%** δ_1 accuracy against that of SVDiff.

Doubly Outlier-Robust Online Infinite Hidden Markov Model

Horace Yiu, Leandro Sánchez-Betancourt, Alvaro Cartea, Gerardo Duran-Martin
We derive a robust update rule for the online infinite hidden Markov model (iHMM) for when the streaming data contains outliers and the model is misspecified. L everaging recent advances in generalised Bayesian inference, we define robustnes s via the posterior influence function (PIF), and provide conditions under which the online iHMM has bounded PIF. Imposing robustness inevitably induces an adap tation lag for regime switching. Our method, which is called Batched Robust iHMM (BR-iHMM), balances adaptivity and robustness with two additional tunable param eters. Across limit order book data, hourly electricity demand, and a synthetic high-dimensional linear system, BR-iHMM reduces one-step-ahead forecasting error by up to 67% relative to competing online Bayesian methods. Together with theor etical guarantees of bounded PIF, our results highlight the practicality of our approach for both forecasting and interpretable online learning.

Beyond Language Modeling: An Exploration of Multimodal Pretraining
Shengbang Tong, David Fan, John Nguyen, Ellis L Brown II, Gaoyue Zhou, Shengyi Q ian, Boyang Zheng, Théophane Vallaeys, Rob Fergus, Naila Murray, Marjan Ghazvini nejad, Mike Lewis, Nicolas Ballas, Amir Bar, Michael Rabbat, Jakob Verbeek, Luke Zettlemoyer, Koustuv Sinha, Yann LeCun, Saining Xie
The visual world offers a critical axis for advancing foundation models beyond l anguage. Despite growing interest in this direction, the design space for native multimodal models remains opaque. We provide empirical clarity through controll ed, from-scratch pretraining experiments, isolating the factors that govern mult imodal pretraining without interference from language pretraining. We adopt the Transfusion framework, using next-token prediction for language and diffusion fo r vision, to train on diverse data including text, video, image-text pairs, and even action-conditioned video. Our experiments yield four key insights: (i) Repr esentation Autoencoder (RAE) provides an optimal unified visual representation b y excelling at both visual understanding and generation; (ii) visual and languag e data are complementary and yield synergy for downstream capabilities; (iii) un ified multimodal pretraining leads naturally to world modeling, with capabilitie s emerging from general training; and (iv) Mixture-of-Experts (MoE) enables effi cient and effective multimodal scaling while naturally inducing modality special ization. Through IsoFLOP analysis, we compute scaling laws for both modalities a nd uncover a scaling asymmetry: vision is significantly more data-hungry than la nguage. We demonstrate that the MoE architecture harmonizes this scaling asymmet ry by providing the high model capacity required by language while accommodating the data-intensive nature of vision, paving the way for truly unified multimoda l models.

Geometry-Correct Diffusion Posterior Sampling with Denoiser-Pullback Curvature G uidance and Manifold-Aligned Damping
Seunghyeok Shin, Minwoo Kim, Dabin Kim, Hongki Lim
Diffusion posterior sampling conditions diffusion priors on measurements, but da ta-consistency updates are typically scaled by hand-tuned guidance weights and c an destabilize sampling under stiff, operator-dependent curvature. We replace sc alar guidance with a per-noise-level damped Gauss--Newton correction computed in diffusion-state coordinates. The correction pulls likelihood gradients back thr ough the denoiser, uses a one-sided curvature model that avoids forward denoiser Jacobians, and applies diffusion-calibrated rank-one damping aligned with the d enoiser residual. Each correction is solved with matrix-free GMRES using automat ic differentiation, and sampling proceeds with a variance-preserving Langevin tr ansition with a closed-form drift/noise split. On FFHQ and ImageNet across inver se problems, it achieves competitive PSNR/SSIM/LPIPS while running markedly fast er than most of the compared baselines; on accelerated MRI reconstruction, it ac hieves the best PSNR/SSIM among the compared baselines. Code is available at htt ps://github.com/Seunghyeok0715/CLAMP

CLIP Tricks You: Training-free Token Pruning for Efficient Pixel Grounding in La rge Vision-Language Models

Sangin Lee, Yukyung Choi
In large vision-language models, visual tokens typically constitute the majority of input tokens, leading to substantial computational overhead. To address this, recent studies have explored pruning redundant or less informative visual tokens for image understanding tasks. However, these methods struggle with pixel grounding tasks, where token importance is highly contingent on the input text. Through an in-depth analysis of CLIP, we observe that visual tokens within referent regions often exhibit low similarity to their textual representation. Motivated by this insight, we introduce LiteLVLM, a training-free, text-guided token pruning strategy for efficient pixel grounding inference. By reversing the ranking of CLIP's visual-text similarity, LiteLVLM effectively retains visual tokens covering the referent regions, while recovering context tokens to enable clear foreground-background separation. Extensive experiments demonstrate that LiteLVLM significantly outperforms existing methods by over 5% across diverse token budgets. Without any training or fine-tuning, LiteLVLM maintains 90% of the original performance with a 22% speedup and a 2.3$\times$ memory reduction. Our code is available at https://github.com/sejong-rcv/LiteLVLM.

Adaptive Memory Retention in Dynamic Graphs
Fabrizio De Castelli, Alessio Gravina, Moshe Eliasof, Carola-Bibiane Schönlieb, Davide Bacciu
Modeling graphs demands a careful balance between long-range propagation of information across nodes and the controlled dissipation of noisy or redundant signals to ensure stable learning and generalization. This challenge is exacerbated in dynamic graphs, where structural and temporal information interact, leading to uncontrolled information accumulation and amplifying noise, thereby affecting generalization. We introduce LAMP, a dynamic graph model for snapshot-based dynamic graphs that incorporates adaptive, learned dissipation within a principled dynamical systems framework. Our architecture combines impulsive neural ODEs with an antisymmetric parameterization to model conservative information flow, alongside data-driven dissipative dynamics that regulate information retention over space and time. This formulation yields stable yet expressive representations and enables effective long-range dependency modeling while avoiding pathological information buildup. We provide a theoretical analysis establishing stability guarantees and characterizing the representational power. Extensive experiments on synthetic and real-world benchmarks demonstrate state-of-the-art performance, particularly on tasks requiring extended-range dependency modeling.
****

From Blind Spots to Gains: Diagnostic-Driven Iterative Training for Large Multimodal Models
Hongrui Jia, Chaoya Jiang, Yongrui Heng, Shikun Zhang, Wei Ye
As Large Multimodal Models (LMMs) scale up and reinforcement learning (RL) methods mature, LMMs have made notable progress in complex reasoning and decision making. Yet training still relies on static data and fixed recipes, making it difficult to diagnose capability blind spots or provide dynamic, targeted reinforcement. Motivated by findings that test driven error exposure and feedback based correction outperform repetitive practice, we propose Diagnostic-driven Progressive Evolution (DPE), a spiral loop where diagnosis steers data generation and reinforcement, and each iteration re-diagnoses the updated model to drive the next round of targeted improvement. DPE has two key components. First, multiple agents annotate and quality control massive unlabeled multimodal data, using tools such as web search and image editing to produce diverse, realistic samples. Second, DPE attributes failures to specific weaknesses, dynamically adjusts the data mixture, and guides agents to generate weakness focused data for targeted reinforcement. Experiments on Qwen3-VL-8B-Instruct and Qwen2.5-VL-7B-Instruct show stable, continual gains across eleven benchmarks, indicating DPE as a scalable paradigm for continual LMM training under open task distributions. Our code, models, and data are publicly available at https://github.com/hongruijia/DPE.

Towards Professional-Grade Financial Agents: Benchmarking, Tooling, and Structur

ed Reasoning
Cheng Huang, Jinghua Piao, Ranran Wang, Yong Li
While Large Language Model (LLM) agents have shown encouraging progress in financial reasoning, their effectiveness in realistic financial workflows is severely hindered by the lack of holistic benchmarks and the fragility of unstructured reasoning. To address this gap, we introduce ProFinR, the first Professional Finance Reasoning benchmark, covering four financial domain tasks and comprising 528 expert-designed problems. To solve these complex financial reasoning questions, we construct the Financial Tool Universe, a tool library containing 53 domain-specific tools organized into 13 categories. Building on the tool library, we introduce ProFinAgent, a structured agent framework based on Directed Acyclic Graph (DAG) and Case-Based Memory (CBM). Compared with strictly sequential workflows, ProFinAgent coordinates tool execution through a DAG planner for parallel efficiency and uses CBM to retrieve prior cases for more reliable decision-making. Experimental results demonstrate that ProFinAgent achieves a 49.81% performance gain over state-of-the-art baselines with a 47.1% reduction in inference latency. Our code is available at https://github.com/tsinghua-fib-lab/ProFinAgent.

Learning Structured Reasoning via Tractable Trajectory Control
Po-Nien Kung, Zhen Yang, Jeffrey Luo, Cheng-Fu Yang, Haikang Deng, Zi-Yi Dou, Yinfei Yang, Nanyun Peng, Zhe Gan, Kai-Wei Chang
Large language models can exhibit emergent reasoning behaviors, often manifested as recurring lexical patterns (e.g., “wait,” indicating verification). However, complex reasoning trajectories remain sparse in unconstrained sampling, and standard RL often fails to guarantee the acquisition of diverse reasoning behaviors. We propose a systematic discovery and reinforcement of diverse reasoning patterns through structured reasoning, a paradigm that requires targeted exploration of specific reasoning patterns during the RL process.
To this end, we propose Ctrl-R, a framework for learning structured reasoning via a tractable trajectory control that actively guides the rollout process, incentivizing the exploration of diverse reasoning patterns that are critical for complex problem-solving. The resulting behavior policy enables accurate importance-sampling estimation, supporting unbiased on-policy optimization. We further introduce a power-scaling factor on the importance-sampling weights, allowing the policy to selectively learn from exploratory, out-of-distribution trajectories while maintaining stable optimization.
Experiments demonstrate that Ctrl-R enables effective exploration and internalization of previously unattainable reasoning patterns, yielding consistent improvements across language and vision–language models on mathematical reasoning tasks.

Towards Whole-corpus Reconstruction of Heterogeneous RAG Knowledge Bases
Peiru Yang, Yi Luo, Zhenfeng Gao, Tong Ju, Haoran Zheng, Linjie Zhu, Hongke Fu, Qing Li, Shangguang Wang, Tao Qi
Retrieval-Augmented Generation (RAG) systems are increasingly deployed to provide query-based access to large knowledge bases, thereby introducing concrete privacy risks whereby the underlying corpus may be partially or fully extracted through the deployed service.
Existing extraction attacks typically rely on locally driven search strategies, in which newly extracted content is inferred or expanded based on previously recovered fragments.
However, real-world knowledge bases are often multi-source and heterogeneous, with pronounced semantic discontinuities across domains. Such gaps can trap extraction methods that rely on local semantic continuity in local optima, severely limiting large-scale corpus reconstruction.
In this paper, we introduce an extraction framework (GeoEx) designed to navigate and reconstruct heterogeneous RAG knowledge bases without any prior knowledge. The framework plans extraction directly in the embedding space of a proxy retrieval model to improve global coverage, and employs an embedding inversion module to convert latent vectors into executable queries.

We further propose a composite geometric strategy that combines orthogonal query synthesis for cross-domain exploration with local embedding perturbations for dense extraction within discovered clusters.
Experiments on mixed corpora spanning eight diverse domains and multiple retrievers and LLMs show that GeoEx significantly outperforms baselines in both extraction coverage and query efficiency.

Nested Spatio-Temporal Time Series Forecasting
YingHao Ai, Yukai Zhou, Ruoxi Jiang, Junyi An, Chao Qu, Zhijian Zhou, Shiyu Wang, Fenglei Cao, Zenglin Xu, Furao Shen, Yuan Qi
Spatio-temporal forecasting is critical for real-world applications like traffic management, yet capturing complex interactions under high-noise conditions remains challenging. While current methods have shown improved accuracy using spatial physical priors, they often struggle with evolving temporal correlations and systematic errors. In this work, we propose a nested forecasting framework that couples future macro-level regional trends with micro-level historical observations, enabling top-down guidance from abstract future representations for fine-grained forecasting. Specifically, we construct semantically coherent regions via spectral clustering and design a progressive coarse-to-fine predictor to inject macro-dynamics into node-level forecasting. Extensive experiments on multiple real-world datasets demonstrate that our method consistently outperforms state-of-the-art baselines, validating the effectiveness of future macro-guided nested forecasting.

Think Twice Before You Act: Enhancing Agent Behavioral Safety with Thought Correction
Changyue Jiang, Wenqi Zhang, Xudong Pan, Geng Hong, Min Yang
LLM-based agents solve complex tasks through iterative reasoning, tool use, and environment interaction, where each intermediate thought directly shapes subsequent actions. Small deviations in these thoughts can therefore propagate into unsafe behaviors, yet existing guardrails typically operate only on final outputs or require intrusive model modifications. We introduce Thought-Aligner, a lightweight plug-in safety model that performs causal correction on unsafe thoughts before action execution, without altering the underlying agent. The corrected thoughts are fed back into the agent, steering its decision process and tool use toward safer trajectories. Because it operates solely at the thought level, Thought-Aligner is model-agnostic and can be integrated into diverse agent frameworks. We train Thought-Aligner via two-stage contrastive learning on paired safe and unsafe thoughts generated across ten risk scenarios. Experiments on diverse agent-safety benchmarks and six LLMs show that Thought-Aligner increases behavioral safety from about 50% without protection to around 90% on average, exceeding state-of-the-art guardrails by roughly 23%, while also improving helpfulness by about 5%. The method incurs low per-step latency and minimal overhead, enabling scalable and practical deployment. We publicly release Thought-Aligner-7B at https://huggingface.co/WhitzardAgent/Thought-Aligner-7B.

Ripple Perturbations Through Structure: Likelihood-Constrained Adversarial Attacks on Heterogeneous Tabular Data
Zhengjie Zhou, Jiahuan Yan, Boqun Ma, Weiwei Feng, Tengfei LIU, Weiqiang Wang
Generating realistic adversarial examples for tabular data remains challenging due to heterogeneous feature types and asymmetric inter-feature dependencies. Existing approaches typically rely on handcrafted constraints or undirected similarity criteria to delimit the feasible attack region, which often fail to capture the structural dependency governing tabular generation. Consequently, standard attacks typically produce perturbations that are statistically likely yet semantically inconsistent and prone to optimization stagnation via gradient masking. To address this, we propose LCSA, a white-box framework that formulates adversarial generation as optimization over structurally admissible perturbations. LCSA leverages an ensemble of heterogeneous neural Structural Causal Models to infer dependencies and introduces a structure-aware ripple mechanism. Unlike attacks tha

t perturb features in isolation, this mechanism propagates updates downstream, a
cting as a structural preconditioner that conditions gradient flow to mitigate m
asking effects. Extensive experiments demonstrate that LCSA outperforms state-of
-the-art baselines in 45 of 50 evaluated configurations, yielding adversarial ex
amples with superior structural consistency and transferability.

How Many Different Outputs Can a Transformer Generate?
Maxime Meyer, Mario Michelessa, Caroline Chaux, Vincent Y. F. Tan
We study how we can leverage only a handful of characteristics of a transformer'
s architecture to closely predict the number of different sequences it can outpu
t, both qualitatively and quantitatively.

We provide an upper bound depending on the length of the prompt, which we show
empirically to be tight up to a factor less than 10, across architectures and m
odel sizes.

Our analysis also provides a theoretical explanation for previously observed e
mpirical failures of transformers on simple sequence tasks—such as copying and c
ramming.

Formally, we prove that (i) the maximal length of accessible sequences (those
that the transformer can output for some prompt) grows linearly with the prompt
length, (ii) beyond a critical threshold, the proportion of accessible sequences
decays exponentially with sequence length, and (iii) the linear coefficient rel
ating prompt length to accessible sequence length admits a theoretical upper bou
nd.

Notably, these results hold even with unbounded context and computation time.

Distortion of AI Alignment Revisited: RLHF is a Decent Utilitarian Aligner
Kazusato Oko, Annie S Ulichney, Nika Haghtalab, Han Bao
While Reinforcement Learning from Human Feedback (RLHF) is the standard paradigm
for aligning large language models with human preferences, its effectiveness in
pluralistic settings has been called into question. Notably, recent work by Göl
z et al. (2025) demonstrated that the *distortion* — defined as the multiplicati
ve gap between the average user utility of the RLHF policy and the optimal avera
ge utility — can scale exponentially with the Bradley-Terry temperature paramete
r β when users have heterogeneous preferences. In this work, we present a
fine-grained analysis of the distortion of RLHF with reward clipping and demonst
rate that such exponential degradation is not a fundamental property of the algo
rithm but rather a consequence of distribution mismatch between the distribution
generating preference data (μ) and the KL reference policy ($\pi_{\mathrm{r
ef}}$). To this end, we establish tight upper and lower bounds on the distortion
of RLHF across multiple regimes of the KL regularization strength. We show that
in a representative regime, under the Bradley–Terry model, the distortion is $\
tilde{\Theta}(\beta B + \beta)$, where B is an upper bound on the log density
ratio between μ and π_{ref}. In particular, when there is no di
stribution mismatch (i.e., $\mu = \pi_{\mathrm{ref}}$), RLHF achieves the optima
l distortion of $O(\beta)$ up to a constant. Our results suggest that, to reason
ably maximize average utility with RLHF, it is preferable to use on-policy sampl
ed preference data or to fine-tune before RLHF on data from a source close to $\
mu$.

Forget to Know, Remember to Use: Context-Aware Unlearning for Large Language Mod
els
Yuefeng Peng, Parnian Afshar, Megan Ganji, Thomas Butler, Amir Houmansadr, Mingx
ian Wang, Dezhi Hong
Large language models can memorize information that must be removed—ranging from
copyright-sensitive content (e.g., book chapters) to personally identifiable in
formation (e.g., income)—to ensure responsible and compliant behavior. Unlearnin
g has emerged as an efficient alternative to full retraining, aiming to remove s
pecific knowledge. However, users may still expect model to leverage the removed
information when it is re-introduced in the prompt. Existing evaluations of unl
earning methods focus on (1) the extent of forgetting of the target knowledge (f

orget set) and (2) performance preservation on the retain set (i.e., utility), b
ut overlook this critical usability dimension. Through a systematic evaluation o
f six state-of-the-art unlearning methods, we show that they consistently degrad
e such contextual utility—the model's ability to use forgotten knowledge when it
 is provided in context. To address this, we augment unlearning objectives with
a plug-in term that explicitly preserves contextual utility. Extensive experimen
ts demonstrate that our approach restores contextual utility to near original le
vels while still maintaining effective forgetting and retain-set utility.

Beyond Static Pipelines: Learning Dynamic Workflows for Text-to-SQL
Yihan Wang, Peiyu Liu, Runyu Chen, Wei Xu
Text-to-SQL has recently achieved impressive progress, yet remains difficult to
apply effectively in real-world scenarios. This gap stems from the reliance on s
ingle static workflows, fundamentally limiting scalability to out-of-distributio
n and long-tail scenarios. Instead of requiring users to select suitable methods
 through extensive experimentation, we attempt to enable systems to adaptively c
onstruct workflows at inference time. Through rigorous theoretical and empirical
 analysis, we demonstrate that optimal dynamic policies consistently outperform
the best static workflow, with performance gains fundamentally driven by heterog
eneity across candidate workflows. Motivated by this, we propose SquRL, a reinfo
rcement learning framework that enhances LLMs' reasoning capability in adaptive
workflow construction. We design a rule-based reward function and introduce two
effective training mechanisms: dynamic actor masking to encourage broader explor
ation, and pseudo rewards to improve training efficiency. Experiments on widely-
used Text-to-SQL benchmarks demonstrate that dynamic workflow construction consi
stently outperforms the best static workflow methods, with especially pronounced
 gains on complex and out-of-distribution queries.

CGSVD: Cascaded Granular Singular Value Decomposition for Large Language Model C
ompression
Yuli Chen, Shuhao Zhang, Jiale Han, Fanshen Meng, Haishen Jiang, Bo Cheng, Qiang
 Tong, Xiulei Liu
The exponential growth in the parameter scale of Large Language Models (LLMs) ha
s precipitated an urgent demand for efficient compression techniques to facilita
te practical deployment. To address this challenge, low-rank decomposition based
 on Singular Value Decomposition (SVD) offers a principled, hardware-friendly pa
thway for compressing LLMs without retraining. However, existing training-free a
pproaches predominantly rely on uniform rank allocation, implicitly assuming hom
ogeneous redundancy across the model depth and thereby neglecting the inherent n
on-uniformity of representational evolution. To bridge this gap, we introduce CG
SVD, a Cascaded Granular Singular Value Decomposition framework that leverages a
 dual-level non-uniform allocation strategy to maximize semantic preservation. S
pecifically, we quantify inter-layer significance via angular distance and asses
s intra-layer compressibility through spectral entropy, enabling precise identif
ication of critical architectural components. Furthermore, we propose an Iterati
ve Residual Filling (IRF) mechanism to bridge the parameter gap caused by intege
r-rank truncation and ensure strict adherence to global compression targets. Ext
ensive experiments on representative LLM families ranging from 3B to 13B paramet
ers verify the superiority of our approach. Notably, under a 30\% compression ra
tio on the LLaMA3.1-8B model, CGSVD achieves a remarkable average zero-shot accu
racy boost of 6.08% and reduces perplexity by 15.46 compared to the baseline. We
 release the [code](https://github.com/ironartisan/CGSVD) to facilitate future r
esearch.

What Makes Effective Supervision in Latent Chain-of-Thought: An Information-Theo
retic Analysis
Xinghao Chen, Chak Tou Leong, Guo Wenjin, Jian Wang, Wenjie Li, Xiaoyu Shen
Latent Chain-of-Thought (CoT) internalizes reasoning within continuous hidden st
ates, offering a promising alternative to verbose discrete reasoning traces. How
ever, robust latent reasoning remains difficult because outcome supervision prov

ides weak learning signals and leaves latent trajectories prone to semantic drift. In this work, we analyze Latent CoT from an information-theoretic perspective and identify this failure as a dual collapse: gradient attenuation along the optimization path and representational drift in the latent space. We further decompose process supervision into two complementary dimensions: Trajectory Supervision, which injects dense stepwise reasoning signals, and Space Supervision, which preserves the semantic structure of the latent manifold. Our analysis shows that rigid geometric compression can collapse the reasoning space, whereas generative reconstruction provides a more flexible semantic anchor that better preserves information capacity. To measure these effects, we introduce the Unified Latent Probe (ULP), which quantifies the mutual information between latent trajectories and explicit reasoning steps. Experiments reveal a clear Information–Performance Binding: reasoning accuracy depends on the information fidelity preserved in the latent chain. These findings provide a principled framework for latent reasoning supervision and suggest shifting from geometric imitation toward mutual information maximization. Our code will be released at: \url{https://github.com/EIT-NLP/Supervision-in-Latent-CoT}.

Safe and Scalable Web Agent Learning via Recreated Websites

Hyungjoo Chae, Jungsoo Park, Alan Ritter

Training autonomous web agents is fundamentally limited by the environments they learn from: real-world websites are unsafe to explore, hard to reset, and rarely provide verifiable feedback.

We propose VeriEnv, a framework that treats language models as environment creators, automatically cloning real-world websites into fully executable, verifiable synthetic environments.

By exposing controlled internal access via a Python SDK, VeriEnv enables agents to self-generate tasks with deterministic, programmatically verifiable rewards, eliminating reliance on heuristic or LLM-based judges.

This design decouples agent learning from unsafe real-world interaction while enabling scalable self-evolution through environment expansion.

Through experiments on web agent benchmarks, we show that agents trained with VeriEnv generalize to unseen websites, achieve site-specific mastery through self-evolving training, and benefit from scaling the number of training environments.

Localizing Memorized Regions in Diffusion Models via Coordinate-Wise Curvature Differences

Gwangho Kim, Sungyoon Lee

Diffusion models can unintentionally memorize training samples, raising concerns about privacy and copyright. While recent methods can detect memorization, they often rely on global or model-specific signals and provide limited insight into where memorization appears within a generated image. We provide a geometric characterization of local memorization as a coordinate-wise variance collapse. However, such collapse can also arise from intrinsic data constraints rather than overfitting. To isolate overfitting-driven memorization, we propose curvature-difference methods that subtract the curvature of an underfitted baseline, either the unconditional model or a less-trained version of itself. We further derive a score-difference proxy that provides a geometric explanation for the widely used score-difference-based detection metric. Experiments on Stable Diffusion, evaluated against ground-truth memorization masks, show that our method outperforms the prior attention-based localization method. Code is available at \url{https://github.com/Gwangho99/mem-curv-diff}.

Proximal Splitting Methods for Hybrid Differentiable Models

Abdel-Rahim Mezidi, Jordan Patracone, Amaury Habrard

Operator splitting methods are at the foundation of many numerical solvers for partial differential equations. In parallel, unrolled and hybrid learning-based architectures have been introduced to enhance classical solvers, but their design is rarely linked to the underlying problem structure. In this work, we propose a unifying framework that explicitly links operator splitting algorithms from op

timization with unrolled hybrid architectures. We show that each operator splitt
ing scheme naturally defines an unrolled architecture, which recovers a wide ran
ge of existing plug-and-play and hybrid models as special cases. Using this fram
ework, we design new unrolled hybrid architectures and validate them on benchmar
k fluid dynamics simulations, where they achieve improved accuracy and stability
.

Co-RedTeam: Orchestrated Security Discovery and Exploitation with LLM Agents
Pengfei He, Ash Fox, Lesly Miculicich, Stefan Friedli, Daniel Fabian, Burak Gokt
urk, Jiliang Tang, Chen-Yu Lee, Tomas Pfister, Long Le
Large language models (LLMs) have shown promise in assisting cybersecurity tasks
, yet existing approaches struggle with automatic vulnerability discovery and ex
ploitation due to limited interaction, weak execution grounding, and a lack of e
xperience reuse. We propose Co-RedTeam, a security-aware multi-agent framework d
esigned to mirror real-world red-teaming workflows by integrating security-domai
n knowledge, code-aware analysis, execution-grounded iterative reasoning, and lo
ng-term memory. Co-RedTeam decomposes vulnerability analysis into coordinated di
scovery and exploitation stages, enabling agents to plan, execute, validate, and
 refine actions based on real execution feedback while learning from prior traje
ctories. Extensive evaluations on challenging security benchmarks demonstrate th
at Co-RedTeam consistently outperforms strong baselines across diverse backbone
models, achieving over 60\% success rate in vulnerability exploitation and over
10\% absolute improvement in vulnerability detection. Ablation and iteration stu
dies further confirm the critical role of execution feedback, structured interac
tion, and memory for building robust and generalizable cybersecurity agents.

Real-Time Aligned Reward Model beyond Semantics
Zixuan Huang, Xin Xia, Yuxi Ren, Jianbin Zheng, Xuefeng Xiao, Hongyan Xie, Li Hu
aqiu, Songshi Liang, Zhongxiang Dai, Fuzhen Zhuang, Jianxin Li, Yikun Ban, deqin
g wang
Reinforcement Learning from Human Feedback (RLHF) is a pivotal technique for ali
gning large language models (LLMs) with human preferences, yet it is susceptible
 to reward overoptimization, in which policy models overfit to the reward model,
 exploit spurious reward patterns instead of faithfully capturing human intent.
Prior mitigations primarily relies on surface semantic information and fails to
efficiently address the misalignment between the reward model (RM) and the polic
y model caused by continuous policy distribution shifts.
This inevitably leads to an increasing reward discrepancy, exacerbating reward o
veroptimization.
To address these limitations, we introduce R2M (Real-Time Aligned Reward Model)
, a novel lightweight RLHF framework.
R2M goes beyond vanilla reward models that solely depend on the semantic repres
entations of a pretrained LLM. Instead, it leverages the evolving hidden states
of the policy (namely policy feedback) to align with the real-time distribution
shift of the policy during the RL process.
This work points to a promising new direction for improving the performance of
reward models through real-time utilization of feedback from policy models.

MOC: Multi-Order Communication in LLM-based Multi-Agent Systems
Yao Guan, Lin Wang, Zhihui Lu, Ziyi Wang, Wenzhu Yan, Qiang Duan
Despite the remarkable progress of Large Language Model (LLM) based Multi-Agent
Systems, most research focuses on optimizing coordination topology while largely
 underexploring the equally critical problem: how to transmit and optimize messa
ges among agents effectively? Current communication schemes typically rely on th
e direct concatenation of first-order neighbor responses, which induces a restri
cted evidence receptive field and leads to the dilution of crucial insights over
 multi-hop paths. To address these limitations, we propose the Multi-Order Commu
nication (MOC) scheme, which reconstructs the inter-agent communication to captu
re multi-hop dependencies and incorporates a structural message consolidation st
rategy to ensure efficiency. Specifically, we formalize the communication mechan

ism to construct a structured multi-order evidence stream, and subsequently desi
gn a Semantic-Topological Merging algorithm to optimize semantic fidelity within
 token constraints. Extensive experiments across six diverse datasets and LLM ba
ckbones of varying parameter scales demonstrate that MOC consistently improves t
ask performance and reduces communication costs.

EAKV: An Entropy-Driven Adaptive KV Compression Framework for Long Video Underst
anding
Hengrui Hu, Jingyu Li, Juntao Liang, Guanyu Chen, Lan Zhang
Although Multimodal Large Language Models (MLLMs) have made remarkable progress,
 they still struggle with long-video understanding due to the massive memory foo
tprint of KV Caches. Existing methods often resort to disjoint retrieval or atte
ntion-based reduction with a uniform layer-wise budget to achieve compression. H
owever, these methods disrupt temporal continuity and ignore the varying informa
tion density across network layers. In this work, we reveal that memory allocati
on should mirror layer-wise semantic density, rather than adhering to a uniform
budget. To this end, we introduce EAKV, a training-free entropy-driven adaptive
KV compression framework that leverages attention entropy to adaptively allocate
 compression budgets, selectively preserving critical tokens while distilling re
dundant contexts into compact contextual anchors, thereby achieving granular mem
ory allocation proportional to semantic density. Extensive experiments on variou
s benchmarks demonstrate that EAKV surpasses existing methods across diverse mod
el architectures and varying parameter scales, yielding improvements ranging fro
m 0.6% to 6.5%.

ParisKV: Fast and Drift-Robust KV-Cache Retrieval for Long-Context LLMs
Yanlin Qi, Xinhang Chen, Huiqiang Jiang, Qitong Wang, Botao Peng, Themis Palpana
s
KV-cache retrieval is essential for long-context LLM inference, yet existing met
hods struggle with distribution drift and high latency at scale. We introduce **
ParisKV**, a drift-robust, GPU-native KV-cache retrieval framework based on coll
ision-based candidate selection, followed by a quantized inner-product reranking
 estimator. For million-token contexts, ParisKV supports CPU-offloaded KV caches
 via Unified Virtual Addressing (UVA), enabling on-demand top-k fetching with
minimal overhead. ParisKV matches or outperforms full attention quality on both
long-input and **long-generation** benchmarks. It achieves state-of-the-art
long-context decoding efficiency: it matches or exceeds full-attention speed eve
n at batch size 1 for long contexts, delivers up to **2.8$\times$** higher throu
ghput within full attention’s runnable range, and scales to **million-token** co
ntexts where full attention runs out of memory. At million-token scale, ParisKV
reduces decode latency by **17$\times$** and **44$\times$** compared to MagicPIG
 and PQCache, respectively—two state-of-the-art KV-cache top-k retrieval basel
ines; code is available at https://github.com/amy-77/ParisKV/tree/main.

AesFormer: Transform Everyday Photos into Beautiful Memories
Tianxiang Du, Hulingxiao He, Yuxin Peng
In everyday photography, aesthetically appealing moments are often captured with
 structural flaws (e.g., composition, camera viewpoint, or pose) that existing r
etouching and portrait enhancement methods cannot fix. We formulate Aesthetic Ph
oto Reconstruction (APR) as improving a photo’s aesthetic quality via structural
 reconstruction while preserving subject identity and scene semantics. Although

recent advances in image editing models make APR feasible, they often lack aesthetic understanding, yielding edits that are semantically plausible yet aesthetically weak. To address this, we propose AesFormer, a two-stage framework that decouples aesthetic planning from image editing. In Stage 1, an aesthetic action model (AesThinker) analyzes the input along seven progressive photographic dimensions and outputs executable editing actions; we further apply GRPO-A to encourage broad exploration over diverse action plans beyond SFT. In Stage 2, an action-conditioned editor (AesEditor) performs structural edits guided by these actions. To support APR, we build a video-based corpus-mining pipeline (VCMP) and construct AesRecon, a benchmark of 9,071 strictly aligned (poor, good) image pairs. Experiments show that AesFormer substantially improves APR performance and is competitive with Nano Banana Pro. Code is available at: https://github.com/PKU-ICST-MIPL/AesFormer_ICML2026.

AgentTailor: A Semantic-Aware LLM-Based Multi-Agent System with Actor-Critic Structure

Peiting Yang, Jiahao Shi, Caiyi Xu, Ming Liu, Yanxia Wu, Rongsheng Li

Large Language Model (LLM)-based multi-agent systems often suffer from high communication cost due to redundant interactions, as existing methods optimize communication structures without explicitly measuring whether exchanged messages contribute to the final decision. To better utilize the semantic information in the execution stage to further optimize the structure of multi-agent systems and reduce token costs, we propose **AgentTailor**, a cost-aware framework that evaluates the semantic contribution of communication edges via an edge judgment mechanism, and employs an **Edge Prediction Network (EPN)** to estimate edge utilities through virtual execution without invoking LLMs. Experiments show that AgentTailor achieves the best average accuracy (91.36\%) on six datasets of diverse fields, while reducing total tokens by 21.2\%--61.6\%. Our work demonstrates that explicitly modeling semantic edge contribution is crucial for scalable and efficient multi-agent systems, providing a principled approach to communication optimization that goes beyond structural heuristics. The code is available at https://github.com/Pt3Y/AgentTailor.

SimulCost: A Cost-Aware Benchmark and Toolkit for Automating Physics Simulations with LLMs

Yadi Cao, Sicheng Lai, Jiahe Huang, Yang Zhang, Zach Lawrence, Rohan Bhakta, Izzy F. Thomas, Mingyun Cao, Chung-Hao Tsai, Zihao Zhou, Yidong Zhao, Hao Liu, Alessandro Marinoni, Alexey Arefiev, Rose Yu

Evaluating LLM agents for scientific tasks has focused on token costs while ignoring tool-use costs like simulation time and experimental resources. As a result, metrics like pass@k become impractical under realistic budget constraints.

To address this gap, we introduce \textsc{SimulCost}, the first benchmark targeting cost-sensitive parameter tuning in physics simulations.

\textsc{SimulCost} compares LLM tuning cost-sensitive parameters against traditional scanning approach in both accuracy and computational cost, spanning 2,947 single-round (initial guess) and 1,931 multi-round (adjustment by trial-and-error) tasks across 13 simulators from fluid dynamics, solid mechanics, and plasma physics. Each simulator's cost is analytically defined and platform-independent.

Frontier LLMs achieve 46--65\% success rates in single-round mode, dropping to 35--55\% under high accuracy requirements, rendering their initial guesses unreliable especially for high accuracy tasks.

Multi-round mode improves rates to 72--81\%, but LLMs are 1.5--2.5$\times$ slower than traditional scanning, making them uneconomical choices.

We also investigate parameter group correlations for knowledge transfer potential, and the impact of in-context examples and reasoning effort, providing practical implications for deployment and fine-tuning.

We open-source \textsc{SimulCost} as a static benchmark and extensible toolkit to facilitate research on improving cost-aware agentic designs for physics simulations, and for expanding new simulation environments. Code and data are available at \url{https://github.com/Rose-STL-Lab/SimulCost-Bench}.

****
Continuous Diffusion Models Can Obey Formal Syntax
Jinwoo Kim, Taylor Berg-Kirkpatrick, Loris D'Antoni
Diffusion language models offer a promising alternative to autoregressive models due to their global, non-causal generation process, but their continuous latent dynamics make discrete constraints---e.g., the output should be a JSON file that matches a given schema---difficult to impose.
We introduce a training-free guidance method for steering continuous diffusion language models to satisfy formal syntactic constraints expressed using regular expressions.
Our approach constructs an analytic score estimating the probability that a latent state decodes to a valid string accepted by a given regular expression, and uses its gradient to guide sampling, _without_ training auxiliary classifiers.
The denoising process targets the base model conditioned on syntactic validity.
We implement our method in Diffinity on top of the PLAID diffusion model and evaluate it on 180 regular-expression constraints over JSON and natural-language benchmarks.
Diffinity achieves 68-96\% constraint satisfaction while incurring only a
small perplexity cost relative to unconstrained sampling,
outperforming autoregressive constrained decoding in both constraint satisfaction and output quality.
Diffinity is open-sourced at github.com/large-loris-models/Diffinity.
****
NanoFLUX: Distillation-Driven Compression of Large Text-to-Image Generation Models for Mobile Devices
Ruchika Chavhan, Malcolm Chadwick, Alberto Gil Couto Pimentel Ramos, Luca Morreale, Mehdi Noroozi, Abhinav Mehrotra
While large-scale text-to-image diffusion models continue to improve in visual quality, their increasing scale has widened the gap between state-of-the-art models and on-device solutions. To address this gap, we introduce NanoFLUX, a **2.4B** text-to-image flow-matching model distilled from **17B** FLUX.1-Schnell using a progressive compression pipeline designed to preserve generation quality. Our contributions include: (1) A model compression strategy driven by pruning redundant components in the diffusion transformer, reducing its size from 12B to 2B; (2) A ResNet-based token downsampling mechanism that reduces latency by allowing intermediate blocks to operate on lower-resolution tokens while preserving high-resolution processing elsewhere; (3) A novel text encoder distillation approach that leverages visual signals from early layers of the denoiser during sampling. Empirically, NanoFLUX generates 512×512 images in approximately 2.5 seconds on mobile devices, demonstrating the feasibility of high-quality on-device text-to-image generation.
****
GenUnfold: Rapidly Predict Protein Mechanical Unfolding Trajectory via a Physics-Guided Diffusion Model
Yiyuan Zhang, Cailong Hua, VINITENDRA SINGH, Joseph M. Muretta, James M. Ervasti, Murti Salapaka
Many fundamental biological processes are governed by mechanical forces, with proteins acting as the key molecular mediators. Elucidating how protein unfolding responds to force is critical for understanding the mechano-pathologies, such as cardiomyopathy and muscular dystrophy. While the unfolding trajectories measured by Single-Molecule Force Spectroscopy (SMFS) map the instantaneous force response against molecular extension, its broader application is limited by time-consuming data collection and high operational costs. Here, we present the first scalable generative diffusion framework for full unfolding trajectory prediction, which integrates protein encoders for multi-scale conditioning. Beyond establishing the field's first systematic benchmark using existing models, we propose GenUnfold, a novel physics-guided diffusion model that combines global coevolutionary context with a local mechanical representation of the protein. The representation is derived from a novel physics-biased attention mechanism, which steers the generative diffusion process by modeling dynamic residue dependencies as a func

tion of both structural topology and interaction stiffness. The benchmark for th
is task is built upon the biomolecule stretching database and several representa
tive baseline models. Empirical results demonstrate that GenUnfold achieves stat
e-of-the-art performance, reducing distributional error (FID) by 30\% and 54\% c
ompared to pretrained Evolutionary Scale Model (ESM)-2 and standard transformer,
 respectively. Beyond statistical curve similarity, GenUnfold demonstrates super
ior physical consistency; in downstream mechanical property prediction, it reduc
es prediction errors for unfolding force and energy distributions by 6\% and 36\
% over the ESM-2 baseline. These results indicate that while existing generative
 AI approaches can alleviate the need for predicting representative force curves
, GenUnfold further improves performance by leveraging the synergy between prote
in structure and evolutionary information. By enabling proteome-wide screening t
o identify mechanical candidates before costly physical validation, our approach
 is promising to accelerate the discovery of force-targeted therapeutics.

MODEL SOUPS NEED ONLY ONE INGREDIENT

Alireza Abdollahpoorrostam, Nikolaos Dimitriadis, Adam Hazimeh, Pascal Frossard

Fine-tuning large pre-trained models on a target distribution often improves in-
distribution (ID) accuracy, but at the cost of out-of-distribution (OOD) robustn
ess as representations specialize to the fine-tuning data. Weight-space ensembl
ing methods, such as Model Soups, mitigate this effect by averaging multiple che
ckpoints, but they are computationally prohibitive, requiring the training and s
torage of dozens of fine-tuned models. In this paper, we introduce MonoSoup, a s
imple, data-free, hyperparameter-free, post-hoc method that achieves a strong ID
–OOD balance using _only a single_ checkpoint. Our method applies Singular Value
 Decomposition (SVD) to each layer’s update and decomposes it into high-energy d
irections that capture task-specific adaptation and low-energy directions that i
ntroduce noise but may still encode residual signals useful for robustness. Mono
Soup then uses entropy-based effective rank to automatically re-weigh these comp
onents with layer-wise coefficients that account for the spectral and geometric
structure of the model. Experiments on CLIP models fine-tuned on ImageNet and ev
aluated under natural distribution shifts, as well as on Qwen language models te
sted on mathematical reasoning and multiple-choice benchmarks, show that this pl
ug-and-play approach is a practical and effective alternative to multi-checkpoin
t methods, retaining much of their benefits without their computational overhead
.

PromptDyG: Test-Time Prompt Adaptation on Dynamic Graphs

Guoguo Ai, Chaoxi Niu, Hui Yan, Joey Tianyi Zhou, Yew-Soon Ong, Guansong Pang

Activities in numerous evolving systems can be represented as dynamic graphs in
snapshot form at different time intervals, i.e., discrete-time dynamic graphs (D
TDGs). Existing methods show impressive advances in capturing historical tempora
l evolution patterns in DTDGs, but they focus on addressing an offline learning
setting, where models are trained using historical snapshots once and then evalu
ated to all subsequent graph snapshots without further updating. This fails to c
apture 1) the nature of evolving complexities across graph snapshots and 2) the
distribution shift in the testing graph snapshots. To address these problems, we
 propose PromptDyG, a novel framework that leverages unsupervised test-time Prom
pt adaptation for Dynamic Graph learning under a live-update online setting. The
 key insight is that an expressive dynamic graph prompt can be learned on a froz
en backbone via minimization of feature-wise, label-free entropy to efficiently
and continuously model the evolving patterns. We show theoretically that this un
supervised prompt adaptation can guarantee a larger similarity margin between po
sitive and negative pairs, facilitating more accurate dynamic predictions. It is
 further confirmed by our extensive empirical results on six benchmark datasets
that show consistent and significant improvements of PromptDyG over state-of-the
-art baselines. Code is available at https://github.com/mala-lab/PromptDyG.

Causal Disentangled Anchor Learning for Scalable Fair Multi-view Clustering

Suyuan Liu, Shengfei Wei, Wenjing Yang, Shengju Yu, Siwei Wang, Xueqiong Li, Wen

peng Lu, Xinwang Liu
Existing fair multi-view clustering methods typically suffer from a severe trade-off between clustering utility and fairness, while incurring prohibitive quadratic complexity on large-scale datasets. To address these challenges, we propose Causal Disentangled Anchor Learning (CDAL), a novel framework that achieves scalable fairness via structural disentanglement. Guided by a structural causal model perspective, CDAL utilizes a dual-anchor mechanism to structurally separate latent representations into orthogonal semantic and sensitive subspaces. We further ensure statistical independence through a linearized Hilbert-Schmidt Independence Criterion (HSIC) constraint, which is optimized via an efficient alternating scheme. Theoretically, we prove the identifiability of the disentangled factors and guarantee the algorithm's global convergence and linear time complexity $\mathcal{O}(n)$. Extensive experiments on large-scale benchmarks demonstrate that CDAL outperforms state-of-the-art methods, achieving a superior utility-fairness trade-off. Our code is publicly available at https://github.com/Tracesource/CDAL.
****
PointCHR: Point Cloud Analysis via Curvature-Aware Hyperbolic Rectification
Xinxing Yu, Liying Yang, Hao Mo, Hui Ma, Fang Kai, Ajian Liu, Yanyan Liang
High-curvature regions in 3D point clouds encapsulate critical fine-grained geometric semantics yet exhibit a distinct long-tail sparsity in their spatial distribution. The inherent limitations of polynomial volume growth in Euclidean space frequently render these intricate geometric features challenging to adequately resolve within a uniform-scale feature space. Consequently, these regions are frequently overshadowed by smooth global features dominated by low-curvature regions, thereby limiting the discriminative capacity of the network. To address this issue, we propose PointCHR, a curvature-aware hyperbolic rectification (CHR) for point cloud analysis. Utilising the property of exponential volume expansion in the vicinity of hyperbolic manifolds, CHR presents a learnable curvature-guided radial rectification mechanism. By adaptively projecting high-curvature points towards boundary regions endowed with larger effective embedding capacities, PointCHR effectively mitigates the representation crowding problem inherent in Euclidean settings. Extensive experimentation has demonstrated that PointCHR significantly enhances the ability of backbone to capture fine-grained geometric details, achieving state-of-the-art performance across multiple benchmarks.
****
Capacity without Access: Reinterpreting the Mid-Depth Spectral Plateau in LLMs
SeongMin Kang, Woo-Seong Yun, Nahyun Lee, Yoon-Sik Cho
Prior probing-based analyses show that individual layers specialize in distinct linguistic and semantic functions, while a complementary line of work observes that deeper layers enter an alignment-dominated regime where residual transformations become increasingly constrained relative to the evolving hidden-state geometry. These findings appear to conflict: layer-wise functional specialization versus apparent representational stagnation in deeper layers. This raises a key question: Is the observed representational stagnation in deeper layers attributable to suboptimal acquisition or encoding of novel features, or are these features learned appropriately but exhibit minimal marginal contribution to the model’s predictive output? We address this by separating model behavior into (i) representational capacity: the richness and spectral diversity of the encoded features, and (ii) accessibility: the extent to which these features are aligned with, and exploited by, the output-relevant subspace. Analyzing hidden-state second-moment geometry across depth shows that intermediate layers maintain a broad representational span and rich spectral diversity, yet project only weakly onto the output-relevant subspace, indicating intact representational capacity but constrained accessibility within task-relevant dimensions. To probe their functional relevance, we add a controlled diagnostic pathway that routes intermediate-layer embeddings to the terminal readout. Analysis of the induced behavioral changes indicates that the apparent stagnation is better accounted for by geometric limitations on accessibility, rather than by a deficit in representational capacity. The source code is available here.

RACER: Risk-Aware Calibrated Efficient Routing for Large Language Models
Sai Hao, Hao Zeng, Hongxin Wei, Bingyi Jing
Efficiently routing queries to the optimal large language model (LLM) is crucial for optimizing the cost-performance trade-off in multi-model systems. However, most existing routers rely on single-model selection, making them susceptible to misrouting. In this work, we formulate LLM routing as the α-VOR problem to minimize expected set size while controlling the misrouting risk, and propose a novel method -- RACER, extending base routers to output model sets that can be subsequently aggregated for improved output. In particular, RACER constructs nested model sets via augmented scoring and utilizes finite-sample concentration bounds to calibrate a threshold that allows for both variable set sizes and abstention. We theoretically prove that RACER achieves rigorous distribution-free risk control on unseen test data in a post-hoc and model-agnostic manner. Extensive experiments verify our theoretical guarantees and demonstrate that RACER consistently enhances downstream accuracy across a wide range of benchmarks.
****
Learning to Theorize the World from Observation
Doojin Baek, Gyubin Lee, Junyeob Baek, Hosung Lee, Sungjin Ahn
What does it mean to understand the world? Is it simply to predict future video frames? Developmental cognitive science suggests that understanding the world is fundamentally the process of constructing internal theories of how it works rather than mere prediction, even before language is acquired. However, in machine learning, it remains unclear how to endow AI systems with such theory-building capability from raw, non-textual observation alone. In this paper, we introduce Learning-to-Theorize (L2T), a learning paradigm in which an AI system acquires the ability to construct theories represented as executable programs directly from observation alone. To instantiate this paradigm, we propose the Neural Language-of-Thought Programmer, a neural model that induces and executes latent programs as explanations rather than task-specific predictors or policies. In experiments, we show that this formulation enables explanation-driven generalization, allowing observations to be understood in terms of the programs that generate them.
****
The Obfuscation Atlas: Mapping Where Honesty Emerges in RLVR with Deception Probes
Mohammad Taufeeque, Stefan Heimersheim, Adam Gleave, Chris Cundy
Training against white-box deception detectors has been proposed as a way to make AI systems honest. However, such training risks models learning to obfuscate their deception to evade the detector. Prior work has studied obfuscation only in artificial settings where models were directly rewarded for harmful output. We construct a realistic coding environment where reward hacking via hardcoding test cases naturally occurs, and show that obfuscation emerges in this setting.
We introduce a taxonomy of possible outcomes when training against a deception detector. The model either remains honest, or becomes deceptive via two possible obfuscation strategies. (i) *Obfuscated activations*: the model outputs deceptive text while modifying its internal representations to no longer trigger the detector. (ii) *Obfuscated policy*: the model outputs deceptive text that evades the detector, typically by including a justification for the reward hack. Empirically, obfuscated activations arise from representation drift during RL, with or without a detector penalty. The detector penalty only incentivizes obfuscated policies; we theoretically show this is expected for policy gradient methods. Sufficiently high KL regularization and detector penalty can yield honest policies, establishing white-box deception detectors as viable training signals for tasks prone to reward hacking.
****
The Perception–Physics Paradox: Probing Scientific Alignment with TC-Bench
Dingling Yao, Andrea Polesello, Adeel Pervez, Caroline Muller, Francesco Locatello
While Vision Foundation Models (VFMs) excel at predictive tasks on satellite imagery, their performance can arise from visual correlations rather than underlyin

g structural invariants, making certain perception-based out-of-distribution acc uracy a poor proxy for scientific utility.
As a result, models may look correct without reasoning correctly—a discrepancy w e term the *Perception–Physics Paradox*.
To address this gap, we introduce *Scientific Alignment* as an implicit objectiv e for representation learning in scientific domains.
We study a principled, testable aspect of scientific alignment through *Structur al Isomorphism*, which requires latent representations to uniquely identify phys ical systems up to a linear reparameterization.
This perspective induces a hierarchy of necessary conditions and yields a system atic probing protocol for physical and causal interpretability.
To operationalize this framework, we release *TC-Bench*, a foundational global d ataset and automated construction pipeline for tropical cyclone research, and sh ow that current VFMs rely on visual shortcuts that collapse in extreme regimes, indicating that scientific alignment does not arise as a natural byproduct of vi sual scaling alone.

Risk Awareness Injection: Calibrating Vision-Language Models for Safety without Compromising Utility

Mengxuan Wang, Yuxin Chen, Gang Xu, Tao He, hongjie jiang, Ming Li

Vision language models (VLMs) extend the reasoning capabilities of large languag e models (LLMs) to cross-modal settings, yet remain highly vulnerable to multimo dal jailbreak attacks. Existing defenses predominantly rely on safety fine-tunin g or \textit{aggressive} token manipulations, incurring substantial training cos ts or significantly degrading utility. Recent research shows that LLMs inherentl y recognize unsafe content in text, and the incorporation of visual inputs in VL Ms frequently dilutes risk-related signals. Motivated by this, we propose Risk A wareness Injection (RAI), a \textit{lightweight} and training-free framework for safety calibration that restores LLM-like risk recognition by amplifying unsafe signals in VLMs. Specifically, RAI constructs an Unsafe Prototype Subspace from language embeddings and performs targeted modulation on selected high-risk visu al tokens, explicitly activating safety-critical signals within the cross-modal feature space.
This modulation restores the model’s LLM-like ability to detect unsafe content f rom visual inputs, while preserving the semantic integrity of original tokens fo r cross-modal reasoning. Extensive experiments across multiple jailbreak and uti lity benchmarks demonstrate that RAI substantially reduces attack success rate w ithout compromising task performance.

ProjQ: Project-and-Quantize for Adapter-Aware LLM Compression

Wenya Yu, Chao Zhang, Li Wang, Samson Lasaulce, Merouane Abdelkader DEBBAH

Post-Training Quantization (PTQ) and Low-Rank Adaptation (LoRA) constitute the s tandard pipeline for efficient Large Language Model (LLM) deployment. However, a pplying them sequentially poses a problem: PTQ often leaves behind random noise that is spread out (across the model's weights) in a way LoRA can't easily fix, meaning that LoRA ends up wasting its limited capacity trying to fix uncorrectab le noise instead of improving task performance. In this paper, we propose \textb f{ProjQ}, a novel framework for
constraining quantization noise to the low-rank manifold via orthogonal subspace projection. We derive an efficient alternating algorithm that shapes the quanti zation noise into a low-rank structure, effectively offloading dominant error co mponents to the subsequent adapter while minimizing the residual error in the or thogonal "uncorrectable" subspace. Our theoretical analysis demonstrates that Pr ojQ preserves strictly greater model plasticity for downstream tasks compared to standard PTQ. Extensive experiments on LLaMA-2, Qwen2.5 and Qwen3 confirm that ProjQ consistently outperforms existing methods in both quantization error compe nsation and downstream task fine-tuning, achieving up to $2\times$ lower evaluat ion loss for compensation and matching the performance of standard 4-bit baselin es on language modeling tasks with only 3 bits. The code is available on \url{ht tps://github.com/yy9301/ProjQ}.

Heterogeneity-Aware Knowledge Sharing for Graph Federated Learning
Wentao Yu, Sheng Wan, Shuo Chen, Bo Han, Chen Gong
Graph Federated Learning (GFL) enables distributed graph representation learning while preserving graph data privacy. However, it suffers from heterogeneity in node features and graph structures across clients. To address this challenge, we propose a novel graph Federated learning method via Semantic and Structural Alignment (FedSSA). For node feature heterogeneity, FedSSA infers class-wise node distributions through a variational model, clusters clients according to the inferred distributions, and aligns local distributions with cluster-level representatives. For structural heterogeneity, FedSSA employs spectral Graph Neural Networks (GNNs) and introduces a spectral energy measure to characterize graph topology, enabling structural alignment between local and cluster-level spectral GNNs. Experiments on eleven homophilic and heterophilic graph datasets under non-overlapping and overlapping partitioning settings demonstrate that FedSSA consistently outperforms eleven state-of-the-art methods. Our code is available at https://github.com/blgpb/FedSSA.

Leveraging Lineage Barcodes as Natural Augmentations for Contrastive Learning of Cell Fate in scRNA-seq Data
Shizhao Joshua Yang, Yixin Wang, Kevin Z. Lin
Deciphering how cells commit to future fates is essential for developing precision therapeutics that can reprogram stem cells or modulate immune functions. However, isolating these fate-determining signals in single-cell lineage tracing (scLT) remains challenging because differentiation programs are often confounded by unrelated processes like the cell cycle. To address this, we introduce Lineage-aware Contrastive Learning (LCL), a framework that treats inheritable lineage barcodes as a "natural" data augmentation to isolate subtle, lineage-specific signals. LCL utilizes a semi-supervised architecture to align unlabeled cells, facilitating the transfer of lineage structures to clinical datasets where explicit barcoding is unavailable. We demonstrate LCL’s utility by predicting future cell-type compositions from early-time points, effectively modeling longitudinal fate commitment from cross-sectional data. Benchmarking on hematopoietic and fibroblast systems shows that LCL significantly outperforms standard models like scVI, establishing contrastive learning as a scalable paradigm for understanding and potentially manipulating cellular differentiation.

NL2Repo-Bench: Towards Long-Horizon Repository Generation Evaluation of Coding Agents
Jingzhe Ding, Shengda Long, Changxin PU, Ge Zhang, zhou huan, Hongwan Gao, Xiang Gao, Chao He, Yue Hou, FEI HU, Zhaojian Li, Weiran Shi, Zaiyuan Wang, Daoguang Zan, Chenchen Zhang, Xiaoxu Zhang, Chen Qizhi, Xianfu Cheng, Bo Deng, Qingshui Gu, Kai Hua, Juntao Lin, Pai Liu, Mingchen Li, Minghao Li, Xuanguang Pan, Zifan Peng, Yujia Qin, Yong Shan, Zhewen Tan, Haoran Wang, Zihan Wang, Weihao Xie, Yishuo Yuan, Jiayu Zhang, Yunfei Zhao, He Zhu, LIYA ZHU, Chenyang Zou, Ming Ding, Jianpeng Jiao, Jiaheng Liu, Minghao Liu, Qian Liu, Chongyang Tao, Jian Yang, Tong Yang, Zhaoxiang Zhang, Xinjie Chen, Wenhao Huang
Recent advances in coding agents suggest rapid progress toward autonomous software development, yet existing benchmarks primarily evaluate short-horizon behaviors such as localized code generation, scaffolded completion, or repository repair, leaving it unclear whether agents can sustain coherent reasoning, planning, and execution over the extended horizons demanded by real-world repository construction. To address this gap, we introduce NL2Repo-Bench, a benchmark explicitly designed to evaluate the long-horizon repository generation from scratch: given only a single natural-language requirements document and an empty workspace, agents must autonomously design the architecture, manage dependencies, and produce a fully installable Python library. Experiments across state-of-the-art open- and closed-source models reveal that long-horizon repository generation remains largely unsolved, with even the strongest agents achieving merely 40\% average test pass rates and rarely completing an entire repository correctly. Further analy

sis identifies systematic long-horizon failure modes, including premature termination, loss of global coherence, fragile cross-file dependencies, and inadequate planning over hundreds of interaction steps.
These results position NL2Repo-Bench as a rigorous, execution-based testbed for evaluating sustained agentic competence and highlight long-horizon reasoning as a key bottleneck for autonomous coding agents. Our data and code are available at https://github.com/multimodal-art-projection/NL2RepoBench.

Explaining Concept Shift with Interpretable Feature Attribution
Ruiqi Lyu, Alistair Turcan, Bryan Wilder
Concept shift occurs when the distribution of labels conditioned on the features changes between domains, which can make even a well-tuned ML model miscalibrated on a new domain. Identifying these shifted features provides unique insight into how feature-label relationships differ between domains, considering the difference may be across a scientifically relevant dimension, such as time, disease status, population, etc. In this paper, we propose SGShift, a method for attributing performance degradation under concept shift in tabular data to a sparse set of shifted features. We frame concept shift as a feature selection task to learn the features that can explain performance differences between models in the source and target domain. This framework enables SGShift to adapt powerful statistical tools such as generalized additive models, knockoffs, and absorption towards identifying these shifted features. We conduct extensive experiments in synthetic and real data across various ML models and find SGShift can identify shifted features much more accurately than baseline methods, requires few samples in the shifted domain, and is robust to complex cases of concept shift.
****
Depth over Fidelity in Fixed-Budget Noisy Evolution Strategies
Sichen Wang, Zhipeng Lu
Noisy evolution strategies under fixed evaluation budgets face a depth–fidelity trade-off: spending evaluations to denoise intra-generation rankings reduces the number of distribution updates the optimizer can execute. We argue for depth over fidelity and propose probabilistic elite membership (PEM), which replaces hard rank-based weights in evolution strategies with conditional expected rank weights that integrate over ranking uncertainty. PEM preserves the conditional mean update while reducing conditional update dispersion—a Rao–Blackwellization of the noisy rank-based step. We instantiate PEM via residual bootstrapping (RB-PEM) with capped per-generation overhead, complemented by an adaptive probe-and-switch mechanism for low-noise regimes. Across the COCO bbob-noisy suite and external tasks including RL policy search and hyperparameter optimization, RB-PEM achieves consistent gains in high-misranking, budget-constrained settings.

SafeDec: Constrained Decoding for Safe Autoregressive Generalist Robot Navigation Policies
Parv kapoor, Akila Ganlath, Michael Clifford, Changliu Liu, Sebastian Scherer, Eunsuk Kang
Recent advances in end-to-end, multi-task robot policies based on transformer models have demonstrated impressive generalization to real-world embodied navigation tasks. Trained on vast datasets of simulated and real-world trajectories, these policies map multimodal observations directly to action sequences for physical execution. Despite promising real-world capabilities, these models are still data-driven and, therefore, lack explicit notions of behavioral correctness. We address this gap by introducing **SafeDec**, a constrained decoding framework for autoregressive, transformer-based robot navigation policies that enforces safety specifications expressed as Signal Temporal Logic (STL) formulas. Our method ensures that generated actions provably satisfy STL specifications under assumed dynamics at runtime without retraining while remaining agnostic of the underlying policy.
We evaluate **SafeDec** on tasks from the CHORES benchmark for state-of-the-art embodied navigation policies across hundreds of procedurally generated environments and show that our decoding-time interventions are useful not only for filter

ing unsafe actions but also for conditional action generation. Videos are availa
ble at constrained-robot-fms.github.io.

Rethinking Loss Reweighting for Imbalance Learning as an Inverse Problem: A Neur
al Collapse Point of View
Jinping Wang, Zixin Tong, Zhiwu Xie, Zhiqiang Gao
Loss reweighting is a widely used strategy for long-tailed classification, but e
xisting reweighting strategies often rely on heuristics and rarely define a well
-specified target. Inspired by Neural Collapse (NC), the ideal simplex Equiangul
ar Tight Frame (ETF) terminal geometry suggests equal per-class average loss as
a reasonable target for reweighting.
Based on the ideal equal loss objective, we consider loss reweighting as an inve
rse problem and propose an inverse-view reweighting strategy that infers class w
eights dynamically to match this ideal objective.
Empirically, NC metrics suggest our method can effectively reduce the loss imbal
ance coefficient and achieve closer alignment with NC geometry while consistentl
y outperforming strong long-tailed baselines on different datasets.
Our code is publicly available at: https://github.com/tongzixin716716/Inverse-Lo
ss-Reweighting.

Second-Order Bilevel Optimization with Accelerated Convergence Rates
Sheng Yang, Chengchang Liu, Lesi Chen, John C.S. Lui
This paper studies second-order methods for nonconvex-strongly-convex bilevel op
timization. We propose a novel fully second-order bilevel approximation method (
FSBA) that achieves an iteration complexity of $\tilde{\mathcal{O}}(\epsilon^{-1
.5})$ for finding the $(\epsilon, \mathcal{O}(\sqrt{\epsilon}))$ second-order st
ationary point of the hyper-objective function.
Our results demonstrate that second-order methods can achieve an accelerated con
vergence rate than first-order methods in bilevel optimization.
To address the heavy computational cost associated with the second-order oracle,
 we introduce a lazy variant of FSBA, called LFSBA, which reuses second-order in
formation across several iterations. We prove that LFSBA exhibits better computa
tional complexity than FSBA by a factor of $\sqrt{d}$, where d is the dimensio
n of the problem.
We also apply a similar idea to nonconvex strongly-concave minimax optimization
and propose the lazy minimax cubic-regularized Newton (LMCN) method with better
computational complexity compared to existing second-order methods.

Impact of Connectivity on Laplacian Representations in Reinforcement Learning
Tommaso Giorgi, Pierriccardo Olivieri, Keyue Jiang, Laura Toni, Matteo Papini
Learning compact state representations in Markov Decision Processes (MDPs) has p
roven crucial for addressing the curse of dimensionality in large-scale reinforc
ement learning (RL) problems. Existing principled approaches leverage structural
 priors on the MDP by constructing state representations as linear combinations
of the state-graph Laplacian eigenvectors. When the transition graph is unknown
or the state space is prohibitively large, the graph spectral features can be es
timated directly via sample trajectories. In this work, we prove an upper bound
on the approximation error of linear value function approximation under the lear
ned spectral features. We show how this error scales with the algebraic connecti
vity of the state-graph, grounding the approximation quality in the topological
structure of the MDP. We further bound the error introduced by the eigenvector e
stimation itself, leading to an end-to-end error decomposition across the repres
entation learning pipeline. Additionally, we show how the common expression for
the symmetrized MDP Laplacian is easy to misinterpret, and propose a more straig
htforward reformulation. Our results hold for general (non-uniform) policies wit
hout any assumptions on the symmetry of the induced transition kernel. We valida
te our theoretical findings with numerical simulations on gridworld environments

Interpreting and Enhancing Emotional Circuits in Large Vision-Language Models vi

a Cross-Modal Information Flow
Chengsheng Zhang, Chenghao Sun, Zhining Xie, Xinmei Tian
Large Vision-Language Models (LVLMs) represent a significant leap towards empathetic agents, demonstrating remarkable capabilities in emotion understanding. However, the internal mechanisms governing how LVLMs translate abstract visual stimuli into coherent emotional narratives remain largely unexplored, primarily due to the scarcity of visual counterfactuals and the diffuse nature of emotional expression.
In this paper, we bridge this gap by introducing a steering-vector-based causal attribution framework tailored for descriptive emotional reasoning.
To this end, we construct a specialized dataset to demystify the emotional circuits underlying the three-stage '' Adapt-Aggregate-Execute'' mechanism.
Crucially, we discover a functional decoupling: visual emotional cues are aggregated in middle layers via $\textit{sentiment-specific}$ attention heads, but are subsequently translated into narrative generation in deep layers through $\textit{emotion-general}$ pathways.
Guided by these insights, we regulate the emotional information routing to strengthen attention flow and amplify the semantic activation to consolidate expression.
Extensive experiments on the comprehensive MER-UniBench demonstrate that our methods significantly improve performance via inference-time intervention, effectively mitigating emotional hallucinations and corroborating the causal fidelity of the discovered circuits.

EpiTwin: Spatiotemporal Graph Transformers for Epileptic sEEG Signal Reconstruction
Jingbo Yang, Yunfeng Zhao, Chao Qiu, Yulin Sun, Xiuyun Liu, Xiaofei Wang
Stereotactic electroencephalography (sEEG) provides temporally precise intracranial recordings but is inherently constrained by sparse and irregular spatial sampling due to clinical limitations on electrode implantation. Signal reconstruction under this setting aims to infer neural activity at unmonitored locations, potentially expanding the coverage of neural recordings without increasing the number of implanted electrodes. However, most existing sEEG reconstruction methods underutilize the spatial information of electrode contacts in both encoding and modeling, and rely on deterministic objectives that favor average patterns, leading to over-smoothed reconstructions. We propose EpiTwin, a conditional spatial graph transformer for sEEG signal reconstruction, comprising three key components. Hybrid Spatial Positional Encoding (HSPE) constructs explicit spatial identities from electrode coordinates, graph topology, and anatomical priors. Geometry–Functional Biased Attention (GFBA) incorporates geometric distance and data-driven functional similarity biases into attention computation. The adversarial refinement training employs a multi-scale discriminator to counter reconstruction over-smoothing. Experiments on real-world clinical sEEG data demonstrate that EpiTwin consistently achieves lower reconstruction error under electrode series-level masking, outperforming recent foundation models such as LaBraM with a 16.8\% relative reduction in RMSE. Furthermore, EpiTwin effectively mitigates spectral over-smoothing and improves reconstruction fidelity.

Predicting the Order of Upcoming Tokens Improves Language Modeling
Zayd Muhammad Kawakibi Zuhri, Erland Hilman Fuadi, Alham Fikri Aji
Multi-token prediction (MTP) has been proposed as an auxiliary objective to improve next-token prediction (NTP) in language model training but shows inconsistent improvements, underperforming in standard NLP benchmarks. We found MTP's exact future token prediction to be too difficult as an auxiliary loss. Instead, we propose token order prediction (TOP), which trains models to order upcoming tokens by their proximity using a learning-to-rank loss. TOP requires only a single additional unembedding layer compared to MTP's multiple transformer layers. We pretrain models of 340M, 1.8B, and 7B parameters using NTP, MTP, DeepSeek MTP (DS-MTP) and TOP objectives. The results of nine standard NLP benchmarks show that TOP overall outperforms NTP, MTP, and DS-MTP even at scale. TOP models with conti

nued training on math and code also perform better on 4 relevant benchmarks. On the synthetic star graph task, TOP enables pathfinding on graphs where NTP, MTP, and DS-MTP fail. Our implementation and training code is available at https://github.com/zaydzuhri/token-order-prediction.

A Solvable High-Dimensional Model Where Nonlinear Autoencoders Learn Structure Invisible to PCA While Test Loss Misaligns With Generalization
Vicente Conde Mendes, Lorenzo Bardone, Cédric Koller, Jorge Medina Moreira, Vittorio Erba, Emanuele Troiani, Lenka Zdeborová
Many real-world datasets contain hidden structure that cannot be detected by simple linear correlations between input features. For example, latent factors may influence the data in a coordinated way, even though their effect is invisible to covariance-based methods such as PCA. In practice, nonlinear neural networks often succeed in extracting such hidden structure in unsupervised and self-supervised learning. However, constructing a minimal high-dimensional model where this advantage can be rigorously analyzed has remained an open theoretical challenge.

We introduce a tractable high-dimensional spiked model with two latent factors: one visible to covariance, and one statistically dependent yet uncorrelated, appearing only in higher-order moments. PCA and linear autoencoders fail to recover the latter, while a minimal nonlinear autoencoder provably extracts both. We analyze both the population risk, and empirical risk minimization.

Our model also provides a tractable example where self-supervised test loss is poorly aligned with representation quality: nonlinear autoencoders recover latent structure that linear methods miss, even though their reconstruction loss is higher.

Assistive Prompt Mediation: Evaluating Language Models Under Accessibility Constraints
Priyaranjan Pattnayak, Ishan Banerjee
Large language models (LLMs) are increasingly used as assistive interfaces for users who cannot reliably produce clean text due to accessibility constraints, yet existing evaluations assume iterative input repair and focus on task accuracy or generic noise robustness. We introduce Assistive Prompt Mediation (APM), a theory-grounded evaluation paradigm that reframes assistance as a constrained mediation problem: recovering latent user intent from accessibility-impaired input without clarification, while minimizing cognitive burden and hallucination risk. APM decomposes assistive quality along these axes and is instantiated across 8 languages, 4 accessibility-driven noise classes, and 10 frontier LLMs, with impairment severity yielding accessibility sensitivity curves. Results show that apparent robustness often masks trade-offs—high intent preservation frequently coincides with increased burden or hallucinated mediation, hallucination rates vary by more than $2\times$ across noise types, and assistive decisions exhibit bounded entropy (<0.81 normalized), indicating systematic rather than unstable behavior. These findings demonstrate that standard robustness metrics substantially overestimate assistive reliability and motivate evaluating LLMs as constrained mediators under accessibility-driven input degradation.
****
GoodDiffusion: Proactive Copyright Protection for Diffusion Bridge Models via Learnable Sample-specific Signatures
Shixi Qin, Zhiyong Yang, Shilong Bao, Zitai Wang, Qianqian Xu, Qingming Huang
This paper tackles the challenging problem of developing a proactive copyright protection mechanism that cuts off unauthorized use of diffusion bridge models. Existing studies largely fall into post-hoc attribution (e.g., watermarking and fingerprinting) or degradation-only defenses, which offer only indirect and limited preventive effect. We therefore propose GoodDiffusion, inspired by backdoor mechanisms, to enforce model-level use-time control by internalizing authorization into the generative process through a selectively permissive, otherwise closed

behavior. Specifically, GoodDiffusion preserves high-quality generation for authorized queries carrying valid signatures, yet refuses to generate for unauthorized inputs. We further empirically show that naive static-signature designs (like conventional backdoor injection) are fundamentally fragile, since a surrogate signature can be efficiently recovered via gradient-based optimization. To strengthen security, we introduce a Learnable Signature Network (LSN) that assigns sample-specific signatures conditioned on each input. This breaks the universality of signatures and prevents a surrogate from transferring across inputs. Extensive experiments validate that GoodDiffusion effectively blocks unauthorized use while maintaining strong generation quality for authorized users.

Discrete Survival Knowledge Distillation for Competing Risks Analysis

Feiyang Deng, Lingfeng Luo, Di Wang, Qinmengge Li, Lingxuan Kong, Kevin He

Accurate prediction in survival analysis with competing risks is challenged by rare event rates and limited effective sample sizes. Knowledge distillation offers a promising way to transfer information from an external teacher to improve a local student, but existing methods are overwhelmingly developed for uncensored outcomes and do not directly extend to survival analysis, where censored observations provide only partial information. Moreover, prior work often assumes that teacher and student share identical outcome definitions, whereas in competing risks settings, they may differ in outcome granularity and event definitions, further complicating knowledge transfer. To address these gaps, we propose DiSKD (Discrete Survival Knowledge Distillation), a deep learning framework for discrete-time competing risks that integrates teacher predictions via a cause-specific, time-dependent Kullback-Leibler divergence. DiSKD enables flexible and privacy-conscious transfer without requiring raw data sharing, remains robust to model misspecification or outcome-definition heterogeneity, and adaptively weights teacher guidance by emphasizing compatible teachers while down-weighting less relevant ones. Simulation studies and real-world applications demonstrate improved discrimination and calibration.

From Zero to Hero: Advancing Zero-Shot Foundation Models for Tabular Outlier Detection

Xueying Ding, Haomin Wen, Simon Klüttermann, Leman Akoglu

Outlier detection (OD) is widely used in practice; but its effective deployment on new tasks is hindered by lack of labeled outliers, which makes algorithm and hyperparameter selection notoriously hard. Foundation models (FMs) have transformed ML, and OD is no exception: Shen et al. (2025) introduced FOMO-0D, the first FM for OD, achieving remarkable performance against numerous baselines. This work introduces OUTFORMER, which advances FOMO-0D with (1) a mixture of synthetic priors and (2) self-evolving curriculum training. OUTFORMER is pretrained solely on synthetic labeled datasets and infers test labels of a new task by using its training data as
in-context input. Inference is fast and zero-shot, requiring merely forward pass and no labeled outliers. Thanks to in-context learning, it requires zero additional work—no OD model training or bespoke model selection—enabling truly plug-and-play deployment. OUTFORMER achieves state-of-the-art performance on the prominent ADBench, as well as two new large-scale OD benchmarks that we introduce, comprising over 1,500 datasets, while maintaining speedy inference.

Federated Learning with Unlabeled Clients: Personalization Can Happen in Low Dimensions

Hossein Zakerinia, Jonathan Scott, Christoph H. Lampert

Personalized federated learning has emerged as a popular approach to training on devices holding statistically heterogeneous data, known as clients. However, most existing approaches require a client to have labeled data for training or finetuning in order to obtain their own personalized model. In this paper we address this by proposing FLowDUP, a novel method that is able to generate a personalized model using only a forward pass with unlabeled data. The generated model parameters reside in a low-dimensional subspace, enabling efficient communication a

nd computation. FLowDUP's learning objective is theoretically motivated by our n
ew transductive multi-task PAC-Bayesian generalization bound, that provides perf
ormance guarantees for unlabeled clients. The objective is structured in such a
way that it allows both clients with labeled data and clients with only unlabele
d data to contribute to the training process. To supplement our theoretical resu
lts we carry out a thorough experimental evaluation of FLowDUP, demonstrating st
rong empirical performance on a range of datasets with differing sorts of statis
tically heterogeneous clients. Through numerous ablation studies, we test the ef
ficacy of the individual components of the method.

CoFrGeNet: Continued Fraction Architectures for Language Generation
Amit Dhurandhar, Vijil Chenthamarakshan, Dennis Wei, Tejaswini Pedapati, Karthik
eyan Natesan Ramamurthy, Rahul Nair
Transformers are arguably the preferred architecture for language generation. In
 this paper, inspired by continued fractions, we introduce a new function class
for generative modeling. The architecture family implementing this function clas
s is named CoFrGeNets - Continued Fraction Generative Networks. We design novel
architectural components based on this function class that can replace Multi-hea
d Attention and Feed-Forward Networks in Transformer blocks while requiring much
 fewer parameters. We derive custom gradient formulations to optimize the propos
ed components more accurately and efficiently than using standard PyTorch-based
gradients. Our components are a plug-in replacement requiring little change in t
raining or inference procedures that have already been put in place for Transfor
mer-based models thus making our approach easy to incorporate in large industria
l workflows. We experiment on two very different transformer architectures GPT2-
xl (1.5B) and Llama3 (3.2B), where the former we pre-train on OpenWebText and Gn
eissWeb, while the latter we pre-train on the docling data mix which consists of
 nine different datasets. Results show that the performance on downstream classi
fication, Q\& A, reasoning and text understanding tasks of our models is competi
tive and sometimes even superior to the original models with two thirds to half
the parameters and shorter pre-training time. We believe that future implementat
ions customized to hardware will further bring out the true potential of our arc
hitectures.

Making Learner Weakness Actionable for Learning from Demonstration with Novice T
eachers
Yuqing Zhu, Matthew Howard
Learning from demonstration can be an effective way to teach robots task-oriente
d policies. However, in an interactive setting when demonstrations are limited b
y time or other budgetary constraints, it is challenging to find those that fix
the learner's (remaining) errors. This is especially difficult for novice teache
rs: they may provide task-valid trajectories, often these fail to meaningfully i
mprove the policy due to their lack of knowledge of learning mechanisms internal
 to the robot. This paper introduces CLASP (Collaborative Learning with Anchored
 State-space Partitions), which summarises the teaching process as a compact map
 of behavioural regions anchored in the teacher's own demonstrations. The map co
nnects task failure to actionable changes to demonstrations by indicating what i
s going wrong in an intuitive way. It also enables difficulty-aware training tha
t emphasises regions where learning is failing. Across diverse benchmarks, CLASP
 improves success by up to 20\% over offline and interactive baselines under the
 same demonstration budget, improves robustness under distribution shift by 14–2
0\%, and preserves behavioural diversity.
****

RE-TRAC: REcursive TRAjectory Compression for Deep Search Agents
jialiang zhu, Gongrui Zhang, Xiaolong Ma, Lin Xu, Miaosen Zhang, Ruiqi Yang, Son
g Wang, Kai Qiu, Zhirong Wu, Qi Dai, Ruichun Ma, Bei Liu, Yifan Yang, Chong Luo,
 Zhengyuan Yang, Linjie Li, Lijuan Wang, Weizhu Chen, Xin Geng, Baining Guo
LLM-based deep research agents are largely built on the ReAct framework. This li
near design makes it difficult to revisit earlier states, branch into alternativ
e search directions, or maintain global awareness under long contexts, often lea

ding to local optima, redundant exploration, and inefficient search. We propose Re-TRAC, an agentic framework that performs cross-trajectory exploration by generating a structured state representation after each trajectory to summarize evidence, uncertainties, failures, and future plans, and conditioning subsequent trajectories on this state representation. This enables iterative reflection and globally informed planning, reframing research as a progressive process. Empirical results show that Re-TRAC consistently outperforms ReAct by 15–20% on BrowseComp with frontier LLMs. For smaller models, we introduce Re-TRAC-aware supervised fine-tuning, achieving state-of-the-art performance at comparable scales. Notably, Re-TRAC shows a monotonic reduction in tool calls and token usage across rounds, indicating progressively targeted exploration driven by cross-trajectory reflection rather than redundant search.

****

STD-Former: Image-Conditioned Texture Dictionary Encoding with Sparse Topological Supervision for Texture Recognition

Bo Peng, Ke Xu, Yurui Pan

Texture recognition is often framed as matching an image to a static training-set dictionary or codebook. In practice, this assumption is brittle: label-preserving transformations (illumination, scale, compression, blur) can shift test features away from the fixed training dictionary, producing a training-set codebook misalignment that limits accuracy. We propose STD-Former (Simple Texture Dictionary Transformer), a lightweight framework for image-conditioned texture dictionary encoding. Instead of comparing against a static codebook, STD-Former extracts a compact set of Intrinsic Textons (dictionary atoms / codewords) from the input image itself, yielding self-aligned representations at inference. Our design is intentionally simple and uses a decoupled two-stage recipe. In Stage 1, a Texture Dictionary Extractor (TDE) is pre-trained with a self-supervised Texton Coverage Loss that encourages the learned textons to collectively cover the image patch feature manifold. In Stage 2, a classifier is trained on the encoded dictionary representation; optionally, we add a Sparse Topological Loss derived from 0D persistent homology, which is equivalent to supervising only the (B-1) edges of a minimum spanning tree (MST) in each batch, providing efficient structure regularization. Across six standard texture benchmarks, STD-Former and STD-Former+ achieve new state-of-the-art results.

****

Dichotomy of Feature Learning and Unlearning: Fast-Slow Analysis on Neural Networks with Stochastic Gradient Descent

Shota Imai, Sota Nishiyama, Masaaki Imaizumi

The dynamics of gradient-based training in neural networks often exhibit nontrivial structures; hence, understanding them remains a central challenge in theoretical machine learning. In particular, the concept of feature unlearning, in which a neural network progressively loses previously learned features over long training, has gained attention. In this study, we consider the infinite-width limit of a two-layer neural network trained with a large-batch stochastic gradient, then derive differential equations with different time scales, revealing the mechanism and conditions for feature unlearning to occur. Specifically, we utilize the fast-slow dynamics: while an alignment of first-layer weights develops rapidly, the second-layer weights develop slowly. The direction of the flow on a critical manifold, determined by the slow dynamics, decides whether feature unlearning occurs. We give numerical validation of the result and derive theoretical grounding and scaling laws for the feature unlearning. Our results yield the following insights: (i) the strength of the primary nonlinear term in the data induces the feature unlearning, and (ii) an initial scale of the second-layer weights mitigates the feature unlearning. Our result should be understood as a population loss of alignment rather than finite-sample overfitting. Technically, our analysis utilizes Tensor Programs and singular perturbation theory.

Multilingual Safety Alignment via Representation-Space Separability

Dan Shi, Zhuowen Han, Deyi Xiong

Large language models (LLMs) have been globally adopted in various scenarios, ma

king robust multilingual safety alignment a prerequisite for their reliable deployment across diverse languages. Despite recent advances, LLMs exhibit a substantial safety gap between high- and low-resource languages: models that can consistently refuse harmful requests in high-resource languages often fail to do so in low-resource languages. In this work, we reveal that such safety failures stem from insufficient representation-space separability between harmful and harmless prompts in low-resource languages. Through geometric analyses, we find that, compared to English, harmful prompts are significantly less separated from the manifold of harmless prompts, and that the resulting cross-lingual spatial margin gap is strongly correlated with attack success rates. Capitalizing on these insights, we propose Multilingual Spatial Margin Gap-based Optimization (SMO), a novel training strategy that exploits the well-aligned safety geometry of a dominant language (e.g., English) to enhance safety alignment in other languages. SMO explicitly leverages the spatial margin gap between English and target languages as an example-wise supervision signal, enabling effective cross-lingual transfer of safety capabilities while preserving the dominant language’s original performance. Experiments conducted on LLaMA-3.1-8B-Instruct and Qwen2.5-7B-Instruct demonstrate that SMO is capable of substantially reducing attack success rates in low-resource languages to near zero, often reaching zero, while maintaining strong general multilingual performance. Warning: This paper contains content that may be harmful.

VDW-GNNs: Vector diffusion wavelets for geometric graph neural networks

David R Johnson, Alexander Sietsema, Rishabh Anand, Deanna Needell, Smita Krishnaswamy, Michael Perlmutter

We introduce vector diffusion wavelets (VDWs), a novel family of wavelets inspired by the vector diffusion maps algorithm that was introduced to analyze data lying in the tangent bundle of a Riemannian manifold. We show that these wavelets may be effectively incorporated into a family of geometric graph neural networks, which we refer to as VDW-GNNs. We demonstrate that such networks are effective on synthetic point cloud data, as well as on real-world data derived from wind field and neural activity measurements. Theoretically, we prove that these new wavelets have desirable frame theoretic properties, similar to traditional diffusion wavelets. Additionally, we prove that these wavelets have useful symmetries with respect to rotations and translations.

Who Gets Credit or Blame? Attributing Accountability in Modern AI Systems

Shichang Zhang, Hongzhe Du, Jiaqi W. Ma, Himabindu Lakkaraju

Modern AI systems are typically developed through multiple stages: pretraining, fine-tuning rounds, and subsequent adaptation or alignment, where each stage builds on the previous ones and updates the model in distinct ways. This raises a critical question of accountability: when a deployed model succeeds or fails, which stage is responsible, and to what extent? We pose the accountability attribution problem for tracing model behavior back to specific stages of the model development process. To address this challenge, we propose a general framework that answers counterfactual questions about stage effects: how would the model's behavior have changed if the updates from a particular stage had not occurred? Within this framework, we introduce estimators that efficiently quantify stage effects without retraining the model, accounting for both the data and key aspects of model optimization dynamics, including learning rate schedules, momentum, and weight decay. We demonstrate that our approach successfully quantifies the accountability of each stage to the model's behavior. Based on the attribution results, our method can identify stages associated with spurious correlations in image classification and text toxicity detection tasks and guide targeted follow-up interventions. Our approach provides a practical tool for model analysis and represents a significant step toward more accountable AI development.

Contextual Rollout Bandits for Reinforcement Learning with Verifiable Rewards

Xiaodong Lu, Xiaohan Wang, Jiajun Chai, Guojun Yin, Wei Lin, Zhijun Chen, Yu Luo, Fuzhen Zhuang, Yikun Ban, deqing wang

Reinforcement Learning with Verifiable Rewards (RLVR) is an effective paradigm for improving the reasoning capabilities of large language models. However, existing RLVR methods utilize rollouts in an indiscriminate and short-horizon manner: responses of heterogeneous quality within each prompt are treated uniformly, and historical rollouts are discarded after a single use. This leads to noisy supervision, poor sample efficiency, and suboptimal policy updates. We address these issues by formulating rollout scheduling in RLVR as a contextual bandit problem and proposing a unified neural scheduling framework that adaptively selects high-value rollouts throughout training. Each rollout is treated as an arm whose reward is defined by the induced performance gain between consecutive optimization steps. The resulting scheduler supports both noise-aware intra-group selection and adaptive global reuse of historical rollouts within a single principled framework. We provide theoretical justification by deriving sublinear regret bounds and showing that enlarging the rollout buffer improves the achievable performance upper bound. Experiments on six mathematical reasoning benchmarks demonstrate consistent gains in performance and training efficiency across multiple RLVR optimization methods.

What If We Allocate Test-Time Compute Adaptively?

Ahsan Bilal, Muhammad Ahmed Mohsin, Muhammad Umer, Ali Subhan, Hassan Rizwan, Ayesha Mohsin, Dean F. Hougen

Test-time compute scaling allocates inference computation uniformly, uses fixed sampling strategies, and applies verification only for reranking. In contrast, we propose a verifier-guided adaptive framework treating reasoning as iterative trajectory generation and selection. For each problem, the agent runs multiple inference iterations. In each iteration, it optionally produces a high-level plan, selects a set of reasoning tools and a compute strategy together with an exploration parameter, and then generates a candidate reasoning trajectory. A process reward model (PRM) serves as a unified control signal: within each iteration, step-level PRM scores are aggregated to guide pruning and expansion during generation, and across iterations, aggregated trajectory rewards are used to select the final response. Across datasets, our dynamic, PRM-guided approach consistently outperforms direct test-time scaling, yielding large gains on MATH-500 and several-fold improvements on harder benchmarks such as AIME24 and AMO-Bench. We characterize efficiency using theoretical FLOPs and a compute intensity metric penalizing wasted generation and tool overhead, demonstrating that verification-guided allocation concentrates computation on high-utility reasoning paths.

Rethinking Low-Confidence Pseudo Labels: Influence-Aware Semi-Supervised Fine-Tuning for Hyperspectral Change Detection

Keyun Zhao, Guangchang Li, Yunpeng Bai, Jiang Shao, Ying Li

Hyperspectral image change detection (HSI-CD) suffers from severe annotation scarcity and complex change patterns, which fundamentally limit the effectiveness of directly fine-tuning pre-trained foundation models. Although semi-supervised learning provides a promising direction, existing approaches mainly rely on confidence-based pseudo-label selection, leading to limited data diversity or severe error propagation. In this paper, we propose Influence-Aware Semi-supervised Fine-tuning (IA-SFT), a novel framework that evaluates the influence of pseudo-labels on model decision behavior to identify truly valuable supervision signals. Instead of confidence-based selection, IA-SFT evaluates each low-confidence pseudo-label by measuring its impact on labeled data, enabling reliable filtering of high-value pseudo-labels with minimal noise. To further adapt foundation models to HSI-CD, we design an Adaptive Fusion Change Decoder (AFCD) that jointly models global semantic consistency and local change details. Extensive experiments on three benchmark datasets demonstrate that IA-SFT consistently improves pseudo-label quality and detection performance, achieving superior accuracy compared to state-of-the-art methods. Additional analyses validate the transferability of IA-SFT when integrated into different frameworks in a plug-and-play manner. Code will be released.

Utility Boundary of Dataset Distillation: Scaling and Coverage Laws
Zhengquan Luo, zhiqiang xu
Dataset distillation (DD) aims to replace a full training set with a tiny synthetic one, yet current theories neither explain why heterogeneous matching objectives (gradient, distribution, trajectory) work nor provide a quantitative boundary for robustness under configuration changes (optimizer, architecture, augmentation). We propose **configuration-dynamics-error (CDE) analysis** for a broad class of matching-based DD methods, a unified generalization framework that treats a training configuration as an update operator inducing optimization dynamics and measures distillation robustness by the test-risk gap between models trained on distilled versus full data. Within this framework, gradient, distribution, and trajectory matching reduce the same dynamics-induced risk gap, explaining why these heterogeneous objectives can all support dataset distillation. CDE yields two predictive laws: within a fixed configuration, the gap decays as $\mathcal{O}(k^{-1/2})$ with the distilled set size k until a configuration-dependent floor, explaining IPC saturation and indicating when reducing the floor is more valuable than enlarging k. Across configurations, an order-tight coverage law formalizes the utility boundary: the required k grows linearly with the configuration diversity captured by covering-number complexity. Experiments with representative DD methods and configuration changes exhibit predictive behavior consistent with both laws.

SAD-Flower: Flow Matching for Safe, Admissible, and Dynamically Consistent Planning
Tzu-Yuan Huang, Armin Lederer, Dai-Jie Wu, Xiaobing Dai, Sihua Zhang, Hsiu-Chin Lin, Shao-Hua Sun, Stefan Georg Sosnowski, Sandra Hirche
Flow matching (FM) has shown promising results in data-driven planning. However, it inherently lacks formal guarantees for ensuring state and action constraints, whose satisfaction is a fundamental and crucial requirement for the safety and admissibility of planned trajectories on various systems. Moreover, existing FM planners do not ensure the dynamical consistency, which potentially renders trajectories inexecutable. We address these shortcomings by proposing SAD-Flower, a novel framework for generating $\textbf{S}$afe, $\textbf{A}$dmissible, and $\textbf{D}$ynamically consistent trajectories. Our approach relies on an augmentation of the flow with a virtual control input. Thereby, principled guidance can be derived using techniques from nonlinear control theory, providing formal guarantees for state constraints, action constraints, and dynamic consistency. Crucially, SAD-Flower operates without retraining, enabling test-time satisfaction of unseen constraints. Through extensive experiments across several tasks, we demonstrate that SAD-Flower outperforms various generative-model-based baselines in ensuring constraint satisfaction. Video and demos can be found at [sadflowerplanning.github.io](https://sadflowerplanning.github.io/project_web/).

LAGEA: Language Guided Embodied Agents for Robotic Manipulation
Abdul Monaf Chowdhury, Akm Moshiur Rahman Mazumder, Safaeid Hossain Arib, Rabeya Akter
Robotic manipulation benefits from foundation models that describe goals, but today's agents still lack a principled way to learn from their own mistakes. We ask whether natural language can serve as feedback, an error-reasoning signal that helps embodied agents diagnose what went wrong and correct course. We introduce LAGEA (Language Guided Embodied Agents), a framework that turns episodic, schema-constrained reflections from a vision language model (VLM) into temporally grounded guidance for reinforcement learning. LAGEA summarizes each attempt in concise language, localizes the decisive moments in the trajectory, aligns feedback with visual state in a shared representation, and converts goal progress and feedback agreement into bounded, step-wise shaping rewardswhose influence is modulated by an adaptive, failure-aware coefficient. This design yields dense signals early when exploration needs direction and gracefully recedes as competence grows. On the Meta-World MT10 and Robotic Fetch embodied manipulation benchmarks, LAGEA improves average success over the state-of-the-art (SOTA) methods by 9.0% on

random goals, 5.3% on fixed goals, and 17% on fetch tasks, while converging faster. These results support our hypothesis: language, when structured and grounded in time, is an effective mechanism for teaching robots to self-reflect on mistakes and make better choices. Code will be released soon.

Transferable Reinforcement Learning via Probabilistic Latent Embeddings and Dynamic Policy Adaptation for Sim-to-Real Deployment

Gengyue Han, Yiheng Feng

Due to limited resources and public safety concerns, deep reinforcement learning (RL) agents for many cyber-physical systems (e.g., autonomous vehicles) are first trained in simulators. However, when deployed in real world environments, they often suffer from performance degradation or safety violations because of the inevitable Sim2Real gap. Existing zero-shot approaches, such as robust safe RL and domain randomization, mitigate this issue but typically at the cost of degraded performance or residual safety risks when experiencing unmodeled system dynamics. To address these limitations, we propose a novel reinforcement learning framework that enables safe and efficient policy transfer via probabilistic latent embeddings and dynamic policy adaptation. We consider a family of Constrained Markov Decision Processes (CMDPs) under different environment contexts. By leveraging latent context variable in meta-RL, the proposed framework infers the latent representation of the environment from simulated experiences. Furthermore, it incorporates a distributional RL formulation, which allows risk levels of the deployed policy to be adjusted dynamically, based on the estimation accuracy of the latent context variable. This strategy promotes safety at the early deployment stage and improves efficiency through fast policy adaptation under the Sim2Real gap.

WildActor: Unconstrained Identity-Preserving Video Generation

Qin Guo, Tianyu Yang, Xuanhua He, Fei Shen, Yong Zhang, Zhuoliang Kang, Xiaoming Wei, Dan Xu

Production-ready human video generation requires digital actors to maintain strictly consistent full-body identities across dynamic shots, viewpoints and motions, a setting that remains challenging for existing methods. Prior methods often suffer from face-centric behavior that neglects body-level consistency, or produce copy-paste artifacts where subjects appear rigid due to pose locking. We present Actor-18M, a large-scale human video dataset designed to capture identity consistency under unconstrained viewpoints and environments. Actor-18M comprises 1.6M videos with 18M corresponding human images, covering both arbitrary views and canonical three-view representations. Leveraging Actor-18M, we propose WildActor, a framework for any-view conditioned human video generation. We introduce an Asymmetric Identity-Preserving Attention mechanism coupled with a Viewpoint-Adaptive Monte Carlo Sampling strategy that iteratively re-weights reference conditions by marginal utility for balanced manifold coverage. Evaluated on the proposed Actor-Bench, WildActor consistently preserves body identity under diverse shot compositions, large viewpoint transitions, and substantial motions, surpassing existing methods in these challenging settings.

CoCoEmo: Composable and Controllable Human-Like Emotional TTS via Activation Steering

Siyi Wang, Shihong Tan, Siyi Liu, Hong Jia, Gongping Huang, James Bailey, Ting Dang

Emotional expression in human speech is nuanced and compositional, often involving multiple, sometimes conflicting, affective cues that may diverge from linguistic content. In contrast, most expressive text-to-speech (TTS) systems enforce a single utterance-level emotion, collapsing affective diversity and suppressing mixed or text–emotion–misaligned expression.

While activation steering via latent direction vectors offers a promising solution, it remains unclear whether emotion representations are linearly steerable in TTS, where steering should be applied within hybrid TTS architectures, and how such complex emotion behaviors should be evaluated.

This paper presents the first systematic analysis of activation steering for emo
tional control in hybrid TTS models, introducing a quantitative, controllable st
eering framework, and multi-rater evaluation protocols that enable composable mi
xed-emotion synthesis and reliable text–emotion mismatch synthesis.
Our results demonstrate, for the first time, that emotional prosody and expressi
ve variability are primarily synthesized by the TTS language module instead of t
he flow-matching module, and also provide a lightweight steering approach for ge
nerating natural, human-like emotional speech.

FUSE: Frequency-domain Unification and Spectral Energy Alignment for Multi-modal
 Object Re-Identification

Xuanhao Qi, Tom H. Luan, Yukang Zhang, Jinkai Zheng, su zhou, Shuwei Li, Lei Tan
Despite significant progress in multi-modal Re-Identification (ReID), existing m
ethods tend to emphasize low-frequency cues. Consequently, they focus on attribu
tes such as color, illumination, and coarse appearance, while overlooking mid- a
nd high-frequency structures that encode geometric, textural, and identity-discr
iminative details. This imbalance leads to incomplete spectral representations a
nd unstable cross-modal alignment. To overcome these limitations, we introduce F
USE, a frequency-domain framework that reformulates multi-modal ReID as a two-st
age process of spectral disentanglement and energy alignment. The proposed Spect
ral Decomposition Module (SDM) adaptively partitions features into low, mid, and
 high-frequency subspaces, enabling hierarchical spectral modeling. The Cross-Mo
dal Alignment Module (CAM) further enforces energy alignment and subspace comple
mentarity across modalities via frequency-consistency regularization. In additio
n, FUSE incorporates learnable frequency modulation to enhance robustness under
varying illumination and heterogeneous sensor conditions. Extensive experiments
on RGBNT201, RGBNT100, and MSVR310 show that FUSE achieves 9.1% mAP and 9.5% Ran
k-1 improvements, establishing an interpretable frequency-domain paradigm for mu
lti-modal representation learning.

FRIGID: Scaling Diffusion-Based Molecular Generation from Mass Spectra at Traini
ng and Inference Time

Montgomery Bohde, Hongxuan Liu, Mrunali Manjrekar, Magdalena Lederbauer, Shuiwan
g Ji, Runzhong Wang, Connor W. Coley
Tandem mass spectrometry is prominent in scientific discovery workflows for iden
tifying unknown small molecules, yet high-throughput structural elucidation rema
ins challenging. While recent autoregressive and graph diffusion models have sho
wn promise in *de novo* elucidation, performance remains limited by poor scalabi
lity during both training and inference time. In this work, we present FRIGID, a
 framework with a novel diffusion language model that generates molecular struct
ures conditioned on mass spectra via intermediate fingerprint representations an
d determined chemical formulae, training at the scale of hundreds of millions of
 unlabeled structures. We then demonstrate how forward fragmentation models enab
le inference-time scaling by identifying spectrum-inconsistent fragments and ref
ining them through targeted remasking and denoising. While FRIGID already achiev
es strong performance with its diffusion base, inference-time scaling significan
tly improves its accuracy, surpassing 18% Top-1 accuracy on the challenging Mass
SpecGym benchmark and tripling the Top-1 accuracy of the leading methods on NPLI
B1. Further empirical analyses show that FRIGID exhibits log-linear performance
scaling with increasing inference-time compute, opening a promising new directio
n for continued improvements in *de novo* structural elucidation. FRIGID code is
 publicly available at https://github.com/coleygroup/FRIGID.

Cure-SFT: Diagnostic-Guided Data Curation for Instruction Tuning

Yuankang Fu, Xinrong Gong, Chen Gong, Tong Zhang, Kaixiang Yang
Instruction data curation is central to improving the instruction-following abil
ity of large language models. However, existing approaches often struggle to sim
ultaneously maintain data quality, diversity, and distributional consistency, la
rgely because they do not explicitly distinguish semantic redundancy from qualit
y defects and rely on coarse-grained modeling of instruction data quality. To ad

dress this issue, we propose Cure-SFT, a coarse-to-fine, diagnostic-guided metho d for instruction data curation that explicitly disentangles semantic redundancy from quality defects. Specifically, Cure-SFT removes redundant samples via stra tified semantic-geometric sampling, applies teacher models for diagnostic triage , and performs targeted defect remediation on fixable samples. Our experiments s how that Cure-SFT can surpass full-data instruction tuning using only 10% of the data budget. Moreover, Cure-SFT consistently outperforms strong selection-based and rewriting-based baselines across data budgets, supporting the effectiveness of diagnostic-guided data curation.

PISCES: Annotation-free Text-to-Video Post-Training via Optimal Transport-Aligne d Rewards

Minh-Quan Le, Gaurav Mittal, Cheng Zhao, David Gu, Dimitris Samaras, Mei Chen

Text-to-video (T2V) generation aims to synthesize videos with high visual qualit y and temporal consistency that are semantically aligned with input text. Reward -based post-training has emerged as a promising direction to improve the quality and semantic alignment of generated videos. However, recent methods either rely on large-scale human preference annotations or operate on misaligned embeddings from pre-trained vision-language models, leading to limited scalability or subo ptimal supervision. We present PISCES, an annotation-free post-training algorith m that addresses these limitations via a novel Dual Optimal Transport (OT)-align ed Rewards module. To align reward signals with human judgment, PISCES uses OT t o bridge text and video embeddings at both distributional and discrete token lev els, enabling reward supervision to fulfill two objectives: (i) a Distributional OT-aligned Quality Reward that captures overall visual quality and temporal coh erence; and (ii) a Discrete Token-level OT-aligned Semantic Reward that enforces semantic, spatio-temporal correspondence between text and video tokens. To our knowledge, PISCES is the first to improve annotation-free reward supervision in generative post-training through the lens of OT. Experiments on both short- and long-video generation show that PISCES outperforms both annotation-based and ann otation-free methods on VBench across Quality and Semantic scores, with human pr eference studies further validating its effectiveness. We show that the Dual OT-aligned Rewards module is compatible with multiple optimization paradigms, inclu ding direct backpropagation and reinforcement learning fine-tuning.

Attentive Multi-Layer Fusion for Vision Transformers

Laure Ciernik, Marco Morik, Lukas Thede, Luca Eyring, Shinichi Nakajima, Zeynep Akata, Lukas Muttenthaler

With the rise of large-scale foundation models, efficiently adapting them to dow nstream tasks remains a central challenge. Linear probing, which freezes the bac kbone and trains a lightweight head, is computationally efficient but often rest ricted to last-layer representations. We show that task-relevant information is distributed across the network hierarchy rather than encoded solely in the last layers. To leverage this distribution of information, we apply an attentive prob ing mechanism that dynamically fuses representations from all layers of a Vision Transformer. This attentive layer fusion (ALF) learns to identify the most rele vant layers for a target task and combines low-level structural cues with high-l evel semantic abstractions. Across 20 diverse datasets and multiple pretrained f oundation models, ALF achieves consistent, substantial gains over standard linea r probes. Attention heatmaps further reveal that tasks different from the pre-tr aining domain benefit most from intermediate representations. Overall, our findi ngs underscore the value of intermediate layers and demonstrate a principled, ta sk-aware approach for unlocking their potential for probing-based adaptation.

Vector Linking via Cross-Model Local Isometric Consistency

Ziying Chen, Yang Cao, He Sun, Beining Yang, Tianjian Yang

We study Vector Linking: given two embedding clouds produced by different black-box encoders over partially overlapping datasets, recover cross-model object cor respondences using only vectors. Empirically and theoretically, we show that ind ependently trained contrastive encoders exhibit local geometric consistency: sho

rt-range distances are approximately preserved up to a scale factor, while long-range distances are not due to model-specific distortion. Building on this, we propose an iterative, reference-based geometric embedding hashing that recovers vector links from a tiny seed set of paired anchors. It represents each vector by distances to sampled paired anchors, proposes candidate links via hash-space matching, and aggregates evidence across views in a Beta--Bernoulli posterior to bootstrap high-confidence links as new anchors. Experiments across multiple benchmarks and embedding model pairs demonstrate accurate and robust linking under varying overlap, seed budgets, and out-of-domain references, with applications to vector database integration and cross-model clustering. Code is available at \url{https://github.com/DBgroup-Edinburgh/VecLinking}.

****

Tightening the Score Matching Gap for Diffusion Models

Benjamin Dupuis, Tyler Farghly, Maxime Haddouche, Alain Oliviero Durmus, Umut Simsekli

Diffusion models (DMs) are a state-of-the-art generative method to approximately sample from an unknown distribution. Their training and evaluation primarily rely on an Evidence Lower Bound (ELBO), which relates the Kullback-Leibler (KL) divergence of model samples to the score matching loss along the path, which serves as a tractable surrogate. The difference between sample quality and the score matching loss produced by this bound leads to the score matching gap, which is known to be tight in the worst-case but not descriptive of sample quality in general. In this work, we provide a theoretical analysis of this gap, developing tighter bounds for three metrics: KL divergence, reverse KL divergence, and Wasserstein distance, effectively exploiting the regularity of the class of score estimators. Our results suggest that the quality of the score approximation has more impact on closing the score matching gap for low noise scales. To obtain these bounds, our key technical insight is to exploit the contraction properties of the backward processes. In particular, we rely on entropy flows, logarithmic Sobolev inequalities and reflection couplings, rigorously linking the ergodicity of the Langevin diffusion to the score matching gap problem.

****

Any-dimensional invariant universality

Shengtai Yao, Eitan Levin, Mateo Diaz Diaz

Several machine learning models are defined for inputs of any size, such as graphs with different numbers of nodes and point clouds with varying numbers of points. The universality properties of such any-dimensional models remain poorly understood, as universality is traditionally studied for models accepting inputs of a fixed size, defined on a compact subset of their domain. In sharp contrast, any-dimensional models can be viewed as sequences of functions defined on growing-sized inputs, and it is not clear in which sense they can be universal. We develop a systematic approach to establish any-dimensional universality by identifying any-dimensional functions with a unique function that takes inputs in a suitable infinite-dimensional limit space containing inputs of all finite sizes, as well as their limits. Using the symmetries of these inputs and relations between inputs of different sizes, we show that this limit space admits a natural topology with rich families of compact sets on which any-dimensional universality can be established. We illustrate our approach by showing that several existing architectures fail to be universal, and we propose simple modifications that restore universality.

When the Prompt Becomes Visual: Vision-Centric Jailbreak Attacks for Large Image Editing Models

Jiacheng Hou, Yining Sun, Ruochong Jin, Haochen Han, Fangming Liu, Wai Kin Victor Chan, Alex Jinpeng Wang

Recent advances in large image editing models have shifted the paradigm from text-driven instructions to vision-prompt editing, where user intent is inferred directly from visual inputs such as marks, arrows, and visual–text prompts. While this paradigm greatly expands usability, it also introduces a critical and underexplored safety risk: the attack surface itself becomes visual. In this work, we

propose Vision-Centric Jailbreak Attack (VJA), the first visual-to-visual jailbreak attack that conveys malicious instructions purely through visual inputs. To systematically study this emerging threat, we introduce IESBench, a safety-oriented benchmark for image editing models. Extensive experiments on IESBench demonstrate that VJA effectively compromises state-of-the-art commercial models, achieving attack success rates of up to 80.9% on Nano Banana Pro and 70.1% on GPT-Image-1.5. To mitigate this vulnerability, we propose a training-free defense based on introspective multimodal reasoning, which substantially improves the safety of poorly aligned models to a level comparable with commercial systems, without auxiliary guard models and with negligible computational overhead. Our findings expose new vulnerabilities, provide both a benchmark and practical defense to advance safe and trustworthy modern image editing systems.

****

Self-Prompting Diffusion Transformer for Open-Vocabulary Scene Text Edit via In-Context Learning

Hongxi Li, Tong Wang, WU CHENGJING, Tianbao Liu, Jiangtao Yao, Xiaochao Qu, Xinxiao Wu, Luoqi Liu, Ting Liu

Scene text editing aims to modify text in a target region of an image while preserving its background style and texture.
Existing methods rely solely on image background information while neglecting the visual details of target regions,
which discards stylistic features in the original text and essentially degrades the task to text rendering.
Moreover, the conditions imposed by pre-trained glyph encoder limit the scope of editable text.
To address these issues, this paper proposes a self-prompting scene text editing method, which constructs style and glyph prompts directly from the original image without additional style or glyph encoders.
We employ a two-stage training strategy, where the diffusion transformer is first trained on large-scale self-supervised datasets and subsequently refined with a small set of paired images.
By leveraging the in-context learning capability of FLUX-Fill, it achieves open-vocabulary and style-consistent text editing.
Experimental results on various languages demonstrate that our method achieves the state-of-the-art performance in both text accuracy and style consistency.

Inference-time Alignment with Rewards in Besov Spaces: Provable Advantages of Feature Learning and Multi-Step Policy Updates

Naoki Nishikawa, Taiji Suzuki

Inference-time alignment, the approach of adapting pre-trained models to reward feedback during inference, has proven empirically effective at improving language-model performance. Despite its success, theoretical foundations remain underdeveloped, especially in practical settings where neural networks are employed as reward models. In this paper, we explore the advantages of neural networks and how to effectively train them for inference-time alignment. Assuming that the true reward function lies in Besov spaces to capture the non-uniform smoothness, we compare neural networks to linear estimators and show that feature learning capability of neural networks is crucial for improving performance. We further analyze algorithms for training neural-network reward estimators. Specifically, we consider a multi-step algorithm that alternates between sampling from the current policy and refitting the reward estimator, and prove that it improves the regret, especially when the true reward exhibits local structure.

Next-Gen CAPTCHAs: Leveraging the Cognitive Gap for Scalable and Diverse GUI-Agent Defense

Jiacheng Liu, Yaxin Luo, Jiacheng Cui, Xinyi Shang, Xiaohan Zhao, Zhiqiang Shen

The rapid evolution of GUI-enabled agents has rendered traditional CAPTCHAs obsolete. While previous benchmarks like OpenCaptchaWorld established a baseline for evaluating multimodal agents, recent advancements in reasoning-heavy models, such as Gemini3-Pro-High and GPT-5.2-Xhigh have effectively collapsed this securit

y barrier, achieving pass rates as high as 90\% on complex logic puzzles like '' Bingo''. In response, we introduce Next-Gen CAPTCHAs, a scalable defense framewo rk designed to secure the next-generation web against the advanced agents. Unli ke static datasets, our benchmark is built upon a robust data generation pipelin e, allowing for large-scale and easily scalable evaluations, notably, for backen d-supported types, our system is capable of generating effectively unbounded CAP TCHA instances. We exploit the persistent human--agent ``Cognitive Gap'' in inte ractive perception, memory, decision-making, and action. By engineering dynamic tasks that require adaptive intuition rather than granular planning, we re-estab lish a robust distinction between biological users and artificial agents, offeri ng a scalable and diverse defense mechanism for the agentic era.

****

Segment-driven Structural Induction and Semantic Alignment for Heterogeneous Tab ular Representation

Woojun Jung, Susik Yoon

Real-world domains often contain heterogeneous tables whose headers vary while t heir underlying attribute semantics are shared, making it difficult to induce do main-specialized semantics from table-local evidence alone. Existing encoders mo del parts of this problem, but often underuse column-level value distributions a nd apply uniform objectives across attributes with different semantic roles. We propose NAVI, a segment-centric pretraining framework that treats each header–va lue pair as the unit for aggregating schema-level structural evidence and column -level distributional evidence. We realize this design through Masked Segment Mo deling and Entropy-driven Segment Alignment, which jointly enforce structured he ader–value coupling and semantic alignment across stable and instance-specific a ttributes. Experiments on heterogeneous in-domain tables show improved reconstru ction, semantic consistency, and downstream utility across evaluation settings o verall.

****

FunCQNet: A Functional Censored Quantile Neural Network for Predicting Long-Term Post-Transplant Kidney Survival

Jiaqi Men, Hua Liu, Yiming Tang, Jinhong You, Jianghu James Dong, Jiguo Cao

Accurate survival prediction in kidney transplantation is critical yet challengi ng due to the complex interplay between functional biomarkers and patient charac teristics under censoring. To address this, we propose a functional censored qua ntile neural network (FunCQNet), a novel framework that integrates deep neural n etworks with a censoring-adjusted sequential quantile loss to approximate intera ction-dependent coefficient functions. We further introduce a conformal inferenc e approach to rigorously assess the significance of functional-scalar interactio ns, ensuring interpretability alongside predictive power. Extensive simulations demonstrate that FunCQNet robustly recovers functional effects under varying noi se and censoring levels. When applied to kidney transplant data, the model yield s precise multi-quantile predictions and reveals clinically significant, age-dep endent interaction patterns between donor type and recipient survival.

Understanding Truncated Positional Encodings for Graph Neural Networks

James Flora, Mitchell Black, Weng-Keen Wong, Amir Nayyeri

Positional encodings (PEs) enhance the power of graph neural networks (GNNs), bo th theoretically and empirically. Two of the most popular families of PEs---spec tral (e.g., Laplacian eigenspaces, effective resistance) and random walk (polyno mials of the adjacency matrix)---are theoretically equivalent in expressive powe r, and both are known to lie between the 1-WL and 3-WL tests in terms of express ivity. However, this equivalence assumes the GNN uses the "complete'' version of these PEs, which requires $O(n^3)$ time and space complexity. Practitioners the refore commonly use truncated variants of these encodings (e.g., the first k e igenspaces or powers of adjacency matrix). However, the theoretical properties o f these truncated PEs are unknown. In this work, we initiate the study of these truncated PEs. Theoretically, we show that, under truncation, several families o f PEs are fundamentally different in expressive power. As a corollary, we show t hat truncated spectral PEs are no longer stronger than the 1-WL test. We also st

udy a family of spectral PEs, the k-harmonic distances, to highlight the differences in expressive power of even closely related truncated PEs. Finally, we experimentally show that a mix of truncated PEs is preferable to any single family on real-world datasets.
****
Nonconvex Low-Rank Tensor Representation with Deep Priors for Multiview Subspace Clustering
Yao Fu, Dong Hu, Zhi Wang
Multiview subspace clustering (MvSC) has shown remarkable potential in exploring underlying structures of high-dimensional data. However, existing MvSC methods still suffer from two shortcomings: (1) the commonly use of convex low-rank approximations inadequately capture high-order correlations across views, while sensitivity to noise and outliers degrades clustering performance, and (2) they lack the ability to preserve global correlations and local geometric patterns simultaneously. To address these issues, we propose a novel nonconvex regularized MvSC model with deep prior, which not only accurately characterizes the intrinsic low-rank structure and suppresses the effect of outliers, but also preserves local structural properties through deep networks. By mathematically analyzing the optimal solution of the optimization problem in our proposed model, we develop an efficient ADMM-based algorithm with provable convergence guarantees to solve it. Extensive experiments on various datasets demonstrate the superiority of the proposed model.
****
GO-PRE: Goal-Oriented Next-Best-View Selection via Predictive Rendering Entropy for Active 3D Reconstruction
Yan Song, Zhihao Li, Chenglong Li, Li He, Yan Wang, Wenqiang Zhang
Active 3D reconstruction relies on active view selection to maximize reconstruction fidelity under limited capture budgets. However, most existing methods rely on surrogate signals—such as parameter uncertainty or geometric heuristics—which are often misaligned with the ultimate goal: the fidelity of rendered predictions. We propose GO-PRE, a goal-oriented next-best-view selection framework that explicitly targets information gain in the prediction space. Specifically, we formulate the objective as maximizing the reduction of the average marginal predictive entropy over a user-specified target view manifold. GO-PRE supports interactive goal specification and yields an efficient acquisition rule that enables real-time computation of information gain. Extensive experiments across benchmarks demonstrate that GO-PRE consistently improves active reconstruction performance and provides more reliable uncertainty quantification compared to state-of-the-art methods.
****
Referring Multiple Regions with Large Multimodal Models via Contextual Latent Steering
Yun Xing, Hanyuan Liu, Jiahao Nie, Shijian Lu
Large Multimodal Models (LMMs) have recently demonstrated their proficiency in holistic visual comprehension. However, most of them struggle to tackle region-level perception guided by visual prompts, especially for cases where multiple regions are referred simultaneously, or scenarios where global contexts are necessary for precise visual referring. We introduce Contextual Latent Steering (CSteer), a training-free approach for guiding general LMMs to refer multiple regions contextually, without expensive fine-tuning or architectural modifications. CSteer starts with pre-computing contextual vectors that implicitly represent visual referring behaviors, such as differentiation among regions and attention to global contexts, followed by representation editing during inference time. Experimental results on multiple datasets indicate that general LMMs with CSteer outperform referring LMMs in most cases, suggesting a promising solution in training-free, and setting new state-of-the-art for this field. Code is available at https://github.com/xing0047/csteer.git.

Learning to Remember, Learn, and Forget in Attention-Based Models
Djohan Bonnet, Jamie Lohoff, Jan Finkbeiner, Elidona Shiqerukaj, Emre Neftci

In-Context Learning (ICL) in transformers acts as an online associative memory and is believed to underpin their high performance on complex sequence processing tasks.
However, in gated linear attention models, this memory has a fixed capacity and is prone to interference, especially for long sequences.
We propose Palimpsa, a self-attention model that views ICL as a continual learning problem that must address a stability-plasticity dilemma.
Palimpsa uses Bayesian metaplasticity, where the plasticity of each attention state is tied to an importance state grounded by a prior distribution that captures accumulated knowledge.
We demonstrate that various gated linear attention models emerge as specific architecture choices and posterior approximations, and that Mamba2 is a special case of Palimpsa where forgetting dominates.
This theoretical link enables the transformation of any non-metaplastic model into a metaplastic one, significantly expanding its memory capacity.
Our experiments show that Palimpsa consistently outperforms baselines on the Multi-Query Associative Recall (MQAR) benchmark and on Commonsense Reasoning tasks.
****
Stage-wise Distortion–Perception Traversal in Zero-shot Inverse Problems with Diffusion Models
Jiawei Zhang, Ziyuan Liu, Leon Yan, Zhenyu Xiao, Yuantao Gu
The distortion–perception (D–P) tradeoff is a fundamental phenomenon of Bayesian inverse problems, which characterizes the inherent tension between distortion performance and perceptual quality. Enabling flexible traversal of the D-P tradeoff at inference time is crucial for practical applications. Despite the recent success of diffusion models in zero-shot inverse problem solving, efficient and principled strategies for D-P traversal in diffusion-based inverse algorithms remain inadequately characterized. In this paper, we propose a stage-wise framework for realizing D-P traversal using a single diffusion model in zero-shot inverse problems. Our proposed method, termed MAP-RPS, starts with an MAP estimation stage that approximates the MMSE solution and provides a low-distortion initialization, followed by a re-noised posterior sampling stage that progressively improves perceptual quality. We provide theoretical analyses for both stages, establishing the validity and effectiveness of the proposed design. Furthermore, we extend MAP-RPS to the latent space, yielding LMAP-RPS, which enjoys broader applicability by leveraging large-scale pre-trained latent diffusion backbones. Extensive experiments demonstrate that MAP-RPS and LMAP-RPS enable more effective D-P traversal on various tasks, while also exhibiting strong performance as efficient solvers for real-world inverse problems.

CoMem: Context Management with A Decoupled Long-Context Model
Yuwei Zhang, Chengyu Dong, Shuowei Jin, Changlong Yu, Hejie Cui, Hongye Jin, Xinyang Zhang, Hamed Bonab, Colin Lockard, Jianshu Chen, Zhenyu Shi, Jingbo Shang, Xian Li, Bing Yin
Context management enables agentic models to solve long-horizon tasks through iterative summarization of previous interaction histories.
However, this process typically incurs substantial decoding overhead for the extra summarization tokens, which significantly affect the end-to-end response latency at deployment.
In this paper, we introduce CoMem, a novel framework that decouples memory management from the primary agent workflow, enabling these processes to execute in parallel. We propose a k-step-off asynchronous pipeline that overlaps the memory model's summarization with the agent's inference, effectively masking the latency of context processing. To ensure robustness under this asynchronous setting, we introduce a reward-driven training strategy that aligns the memory model to capture sufficient statistics for the agent's decision-making. Theoretical analysis confirms that CoMem offers a superior efficiency-effectiveness trade-off compared to coupled architectures.
Our extensive experimental results on SWE-Bench-Verified show that CoMem provides 1.4x latency improvements upon vanilla long-context solutions while preserving

most of the performance.
Furthermore, we demonstrate that these latency gains scale favorably with increa sed system throughput, offering a modular path forward for the independent optim ization of agent reasoning and memory compression.

On the Effect of Misspecifying the Embedding Dimension in Low-rank Network Model s
Roddy Taing, Keith Levin
As network data has become ubiquitous in the sciences, there has been growing in terest in network models whose structure is driven by latent node-level variable s in a (typically low-dimensional) latent geometric space. These "latent positio ns" are often estimated via embeddings, whereby the nodes of a network are mappe d to points in Euclidean space so that "similar" nodes are mapped to nearby poi nts. Under certain model assumptions, these embeddings are consistent estimates of the latent positions, but most such results require the embedding dimension t o be chosen correctly. Methods for choosing the embedding dimension have been st udied extensively, but little is known about the behavior of embeddings when the dimension is misspecified. In this work, we provide a theoretical description o f the effects of dimension misspecification under the random dot product graph, a class of latent space network models that includes several widely-used network models, most notably the stochastic blockmodel, as special cases. We show that when the dimension is chosen too large, consistent estimation still holds, albei t at a slower rate than when the embedding dimension is chosen correctly. On the other hand, when the dimension is chosen too small, there is a fundamental esti mation error lower bound that need not go to zero in the large-network limit. A range of synthetic data experiments support our theoretical results. Our main te chnical result, which may be of independent interest, is a generalization of ear lier work in random matrix theory showing that all non-signal eigenvectors of a low-rank matrix subject to additive noise are delocalized.

AnyBand-Diff: A Unified Remote Sensing Image Generation and Band Repair Framewor k with Spectral Priors
Zhao zuopeng, Ying Liu, xiaoyu Li, Su Luo, Lu Li, Wenwen Liu
Existing diffusion models have made significant progress in generating realistic images. However, their direct adaptation to remote sensing imagery often disreg ards intrinsic physical laws. This oversight frequently leads to spectral distor tion and radiometric inconsistency, severely limiting the scientific utility of generated data. To address this issue, this paper introduces AnyBand-Diff, a nov el spectral-prior-guided diffusion framework tailored for robust spectral recons truction. Specifically, we design a Masked Conditional Diffusion backbone integr ated with a dual stochastic masking strategy, empowering the model to recover co mplete spectral information from arbitrary band subsets. Subsequently, to ensure radiometric fidelity, a Physics-Guided Sampling mechanism is proposed, leveragi ng gradients from a differentiable physical model to explicitly steer the denois ing trajectory toward the manifold of physically plausible solutions. Furthermor e, a Multi-Scale Physical Loss is formulated to enforce rigorous constraints acr oss pixel, region, and global levels in a joint manner. Extensive experiments c onfirm the effectiveness of AnyBand-Diff in generating reliable imagery and achi eving accurate spectral reconstruction, contributing to the advancement of physi cs-aware generative methods for Earth observation.

With Argus Eyes: Assessing Retrieval Gaps via Uncertainty Scoring to Detect and Remedy Retrieval Blind Spots
Zeinab Sadat Taghavi, Ali Modarressi, Hinrich Schuetze, Andreas Marfurt
Reliable retrieval-augmented generation (RAG) systems depend fundamentally on th e retriever’s ability to find relevant information. We show that neural retrieve rs used in RAG systems have blind spots, which we define as the failure to retri eve entities that are relevant to the query, but have low similarity to the quer y embedding. We investigate the training-induced biases that cause such blind-sp ot entities to be mapped to inaccessible parts of the embedding space, resulting

in low retrievability.

Using a large-scale dataset constructed from Wikidata relations and first paragraphs of Wikipedia, and our proposed Retrieval Probability Score (RPS), we show that blind spot risk in standard retrievers (e.g., Contriever, ReasonIR) can be predicted pre-index from entity embedding geometry, avoiding expensive retrieval evaluations.

To address these blind spots, we introduce ARGUS, a pipeline that enables the retrievability of high-risk (low-RPS) entities through targeted document augmentation from a knowledge base (KB), first paragraphs of Wikipedia, in our case. Extensive experiments on BRIGHT, ImpliRet, and RAR-b show that ARGUS achieves consistent improvements across all evaluated retrievers (averaging +3.4 nDCG@5 and +4.5 nDCG@10 absolute points), with substantially larger gains in challenging subsets. These results establish that preemptively remedying blind spots is critical for building robust and trustworthy RAG systems (Code and data: github.com/ZeinabTaghavi/With_Argus_Eyes)

Uncovering Hidden Triggers: Backdoor Attribution in Language Models
Miao Yu, Zhenhong Zhou, Moayad Aloqaily, Kun Wang, Biwei Huang, Stephen Wang, Yueming Jin, Qingsong Wen
Fine-tuned Large Language Models (LLMs) are vulnerable to backdoor attacks through data poisoning, yet the internal mechanisms governing these attacks remain a black box. Previous research on interpretability for LLM safety tends to focus on alignment, jailbreak, and hallucination, but overlooks backdoor mechanisms, making it difficult to understand and fully eliminate the backdoor threat. In this paper, aiming to bridge this gap, we explore the interpretable mechanisms of LLM backdoors through Backdoor Attribution (BkdAttr), a tripartite causal analysis framework. We first introduce the Backdoor Probe that proves the existence of learnable backdoor features encoded within the representations. Building on this insight, we further develop Backdoor Attention Head Attribution (BAHA), efficiently pinpointing the specific attention heads responsible for processing these features. Our primary experiments reveals these heads are relatively sparse; ablating a minimal \textbf{$\sim$ 3%} of total heads is sufficient to reduce the Attack Success Rate (ASR) by \textbf{over 90%}. More importantly, we further employ these findings to construct the Backdoor Vector derived from these attributed heads as a master controller for the backdoor. Through only \textbf{1-point} intervention on \textbf{single} representation, the vector can either boost ASR up to \textbf{$\sim$ 100% $\uparrow$} on clean inputs, or completely neutralize backdoor, suppressing ASR down to \textbf{
$\sim$ 0%} on triggered inputs. In conclusion, our work pioneers the exploration of mechanistic interpretability in LLM backdoors, demonstrating a powerful method for backdoor control and revealing actionable insights for the community.

PLaID++: A Preference Aligned Language Model for Targeted Inorganic Materials Design
Andy Xu, Rohan Desai, Larry Wang, Ethan T. Ritz, Gabriel Hope
Reinforcement Learning from Verifiable Rewards (RLVR) has emerged as a promising approach to improve correctness in LLMs, however, in many scientific problems, the objective is not necessarily to produce *the* correct answer, but instead to produce a diverse array of candidates which satisfy a set of constraints. We study this challenge in the context of materials generation. To this end, we introduce PLaID++, an LLM post-trained for stable and property-guided crystal generation. We find that applying naive preference optimization to a coordinate-based crystal representation leads to mode collapse. Hence, we introduce a compact, symmetry-informed Wyckoff text representation which improves computational efficiency and encourages generalization from physical priors. By encoding symmetry constraints directly into text and guiding model outputs towards desirable chemical space, PLaID++ generates structures that are thermodynamically stable, unique, and novel at a $>$50\% greater rate than prior methods. We further demonstrate t

hat unified training across conditional and unconditional tasks are mutually ben
eficial in data-sparse regimes. Our work demonstrates the potential of adapting
post-training techniques from natural language processing to materials design, p
aving the way for targeted and efficient discovery of novel materials.

GuidedBridge: Training-freely Improving Bridge Models with Prior Guidance
Zehua Chen, Yucheng Yang, Binjie Yuan, Kaiwen Zheng, Jun S. Liu, Jun Zhu
Guidance methods, such as classifier-free guidance (CFG) and auto-guidance (AG),
 have advanced noise-to-data generation in diffusion models.
Recently, bridge models have introduced a data-to-data generative process that c
an exploit an instructive clean prior.
In this work, inspired by previous methods creating quality difference between d
enoising results as guidance, we propose a training-free bridge guidance method,
 termed Prior Guidance (PG).
Specifically, we introduce a weak prior, which is unseen during bridge pre-train
ing, hindering prior exploitation and thereby degrading denoising result.
Then, we contrast it with the seen prior to highlight and enhance prior exploita
tion via a scaling factor.
Moreover, we analyze the underlying mechanism of prior exploitation in the bridg
e process and design frequency-modulated prior guidance (FMPG), which tailors th
e guidance scale to low- and high-frequency bands coherent with bridge generativ
e dynamics.
To address prior exploitation in image in-painting, we develop a cascaded framew
ork, CFG-FMPG, which first generates a noisy hidden representation via CFG and t
hen exploits it as a generative prior with FMPG, fulfilling their complementary
strengths without compromising inference efficiency. Experiments demonstrate tha
t our PG methods consistently improve pre-trained bridge models across diverse i
mage translation tasks.
****
AURA: Visually Interpretable Affective Understanding via Robust Archetypes
Guanyu Hu, Dimitrios Kollias, Xinyu Yang
Interpretable methods such as vision--language models (VLMs) have advanced affec
t analysis by aligning images with textual descriptions. However, relying on tex
t as an intermediate proxy faces critical limitations: linguistic templates are
inherently discrete, making them fundamentally incompatible with continuous vale
nce--arousal regression, while also acting as a bottleneck for fine-grained visu
al nuances. Cognitive psychology suggests that human affective perception is not
 mediated by linguistic translation, but is grounded in perceptual resemblance t
o internalized visual archetypes. Motivated by this, we propose AURA, an archety
pe-based framework that replaces brittle linguistic proxies with a self-organizi
ng archetype manifold. By adaptively allocating representational density accordi
ng to affective complexity, AURA enables accurate continuous regression and resh
apes affective taxonomies by decomposing labels into interpretable, geometricall
y coherent visual primitives. This paradigm offers a transparent, visually groun
ded decision trail and achieves state-of-the-art results across discrete and con
tinuous tasks.

Global Merger-Arbitrage Forecasting with Language Models
Hinal Jajal, Micha■ Mucha, Charles Sweat, Chris Pulman, Charlie Flanagan, Peter
Anderson
We present a language-model forecasting system for merger arbitrage, a specializ
ed high-stakes financial setting in which the task is to predict the outcome of
announced M\&A deals. Unlike prior work on judgmental forecasting with LLMs, whi
ch has focused on broad mixed-topic benchmarks and short context such as news sn
ippets, we study a setting that requires long-context reasoning over hundreds of
 pages of technical documents. Our system combines expert-guided context enginee
ring with finetuning on hindsight-guided reasoning traces derived from historica
l deals. Given an announced deal, it outputs a probability distribution over thr
ee mutually exclusive outcomes: closing at announced terms, a higher bid, or dea
l termination. On an out-of-sample set of more than 400 large deals spanning 42

countries, our finetuned system achieves the best performance of any method we e valuate, reducing class-balanced Brier score to 0.151. This is 24% below calibra ted market-implied probabilities, 19% below XGBoost, and 25-42% below frontier l anguage models. These results, together with ablation studies, show that LLM-bas ed forecasting can succeed in specialized, long-context financial workflows, wit h hindsight-based supervision and expert-designed context playing a critical rol e.

Drop-in Circulant Structural Priors for Transformer Decoding of Cyclic Codes

Shuai Xiao, Weijun Fang, Qiaosheng Zhang

While Transformer-based architectures have revolutionized neural decoding, exist ing models often treat codes as generic sequences, ignoring their inherent algeb raic properties. In this paper, we take a step toward bridging these two domains by proposing a novel decoding approach that integrates the algebraic structure of cyclic codes into Transformer-based decoders. Leveraging the inherent cyclic properties, we introduce interpretable error correction patterns and inter-node relationship hypotheses that link the structural characteristics of the codes to the model parameters. Building on these insights, we design a plug-and-play, fl exibly deployable decoding method tailored for cyclic codes. Experimental result s show that our method achieves an average reduction in bit error rate (BER) by an order of magnitude, while also reducing the total number of parameters by app roximately 97%. Additional comparative experiments validate our proposed conject ures and highlight a promising pathway for bridging classical coding theory and modern Transformer-based decoding architectures.

TAMPO: Task- and Model-Aware Automatic Prompt Optimization for Auto-Routing in L LM-based Systems

Yuejun Jiao, Jun Xia, Yanxin Yang, Yonghao Yang, Hao Shen, Mingsong Chen

Automatic Prompt Optimization (APO) enables Large Language Models (LLMs) to adap t to specific tasks while minimizing manual engineering costs. However, since ex isting APO approaches either rely solely on multi-round iterative procedures or use model-specific generators tailored to optimizing prompts for a single model and objective, they are not readily applicable to auto-routing scenarios, which require operating over diverse LLMs and juggling multiple, often competing, trad e-offs. To address this issue, we propose TAMPO, a novel task- and model-aware A PO framework for auto-routing in LLM-based systems. Specifically, to capture per formance variation across a broad range of tasks and models, we construct a comp rehensive, heterogeneity-aware dataset to train an uncertainty-aware reward mode l. Serving as an offline proxy, this reward model can greatly mitigate reward ha cking, allowing TAMPO to learn an optimal multi-objective conditional policy for robust prompt generation. Based on the user requirements encoded in our defined preference vector, this policy enables flexible control over prompt generation and supports a cost-effective deployment strategy. Extensive experiments across 86 tasks demonstrate that TAMPO effectively maintains performance stability acro ss diverse tasks and models, providing a robust, controllable solution for auto- routing in various LLM-based systems.

From Correspondence to Actions: Human-Like Multi-Image Spatial Reasoning in Mult i-modal Large Language Models

Masanari Oi, Koki Maeda, Ryuto Koike, Daisuke Oba, Nakamasa Inoue, Naoaki Okazak i

While multimodal large language models (MLLMs) have made substantial progress in single-image spatial reasoning, multi-image spatial reasoning, which requires i ntegration of information from multiple viewpoints, remains challenging.

Cognitive studies suggest that humans address such tasks through two mechanisms: *cross-view correspondence*, which identifies regions across different views th at correspond to the same physical locations, and *stepwise viewpoint transforma tion*, which composes relative viewpoint changes sequentially.

However, existing studies incorporate these mechanisms only partially and often implicitly, without explicit supervision for both.

We propose Human-Aware Training for Cross-view correspondence and viewpoint cHan ge (HATCH), a training framework with two complementary objectives: (1) Patch-Le vel Spatial Alignment, which encourages patch representations to align across vi ews for spatially corresponding regions, and (2) Action-then-Answer Reasoning, which requires the model to generate explicit viewpoint transition actions befor e predicting the final answer.
Experiments on three benchmarks demonstrate that HATCH consistently outperforms baselines of comparable size by a clear margin and achieves competitive results against much larger models, while preserving single-image reasoning capabilities .
****

SpeedVFI: One-step Diffusion for Efficient Video Frame Interpolation
Ganggui Ding, Xiaogang Xu, Hao Chen, Chunhua Shen
Generative video diffusion models have shown strong robustness to large motion a nd occlusions for video frame interpolation (VFI). However, their inference effi ciency lags significantly behind learning-based methods due to the structural re dundancy of pairwise inference and the procedural latency of multi-step iterativ e denoising. To address these limitations, we propose SpeedVFI, a task-specific one-step diffusion formulation that recasts generative VFI as unified sequence i nterpolation. SpeedVFI achieves dual efficiency improvements by interpolating th e entire video sequence in a single forward pass to eliminate pairwise overhead, and by distilling the generation trajectory into a one-step denoising process t o bypass iterative latency. To make this formulation effective for VFI, we intro duce temporal RoPE alignment for temporally consistent conditioning and noise-ce ntric partial attention to reduce computational overhead while preserving global context. Extensive experiments demonstrate that SpeedVFI accelerates diffusion-based VFI by orders of magnitude while maintaining competitive quantitative and visual quality.

Dynamics and Representation Structure of Local Approximations to Gradient-Based Learning in Linear Recurrent Neural Networks
Ezekiel Williams, Alexandre Payeur, Guillaume Lajoie
Biological and neuromorphic recurrent neural networks (RNNs) are subject to spat ial and temporal locality constraints on the information that can plausibly be u sed during learning. A common strategy to satisfy these constraints is to modify gradient descent by neglecting non-local terms to varying degrees, as in random feedback local online (RFLO) learning and truncated backpropagation through tim e (tBPTT). However, the learning dynamics of these algorithms, and how they comp are with BPTT, remain poorly understood. We apply dynamical systems theory to da ta-aligned linear RNNs---whose dynamics can be separated into orthogonal modes--- to compare stationary solutions, stability properties, and convergence rates, f inding qualitatively distinct behaviour for RFLO versus BPTT and one-step tBPTT. We further observe that the solutions learned by RFLO are restricted to low-ran k perturbations of initial parameters, a result which holds beyond the data-alig ned setting. Our work provides analytical insight into how locality constraints shape learning dynamics, with implications for neuroscientific models of learnin g and alternative optimization approaches for RNNs.

ArcDAE: Asymmetric Rectified Contrastive Diffusion Autoencoder for Unified Repre sentation Learning
Ge Gao, Di Xiong, Zeke Xie, Jian Yang, Shuo Chen
The unification of generative details and discriminative semantics presents a st ructural paradox in *diffusion-based representation learning*. Early approaches decouple semantics from generation, inevitably compromising representational com pleteness (i.e., *information split*). While recent bridge-based methods achieve unification via a tightly coupled mapping, they suffer from *information overlo ad*. This is because unconstrained reconstruction objectives incentivize the enc oder to entangle high-frequency stochastic noise into the latent bottleneck. To solve this, we introduce *asymmetric rectified contrastive diffusion autoencoder * (ArcDAE), which rebuilds the diffusion bridge as a *dynamic sifter*. Through i

mposing a *timestep-aware rectification constraint* that orthogonalizes the sema
ntic manifold from the stochastic noise space, ArcDAE compels the bottleneck to
distill discriminative features while actively shedding high-frequency redundanc
y. Consequently, our approach eliminates the overload trap without reverting to
decoupling. Extensive experiments validate the superiority of our FFHQ-trained A
rcDAE, surpassing state-of-the-art methods by up to 6.4% in downstream semantics
 regression and 9.7% in reconstruction fidelity.

MIST: Moment-Aligned Invariant Stability Transform for Robust Flow Matching
Liang Peng, Deqing Li, Yujia Wu, Hao Meng, Kuan Cao, Yu Wu, Xiaoxiao Xu, Lin Qu
Classifier-Free Guidance (CFG) is a cornerstone of flow-matching models, signifi
cantly enhancing visual quality and prompt adherence. However, high guidance sca
les inherently violate the optimal transport dynamics, leading to visual artifac
ts and mode collapse.
In this paper, we investigate the mechanisms of this failure through the lens of
 velocity moment decomposition. Our analysis reveals that the distributional shi
ft induced by CFG decouples into two geometric components: a Linear Barycentric
Drift that shifts the global distribution center, and a Quadratic Energetic Inst
ability that injects surplus kinetic energy, disrupting the transport cost and t
riggering variance explosion. To mitigate these issues, we introduce MIST (Momen
t-aligned Invariant Stability Transform), a training-free method designed to con
fine the sampling trajectory to the learned data manifold. MIST comprises two hi
erarchical stages: (1) Invariant Alignment (IA), a global statistical rectifier
that restores structural integrity by removing the linear drift and realigning t
he energy profile; and (2) Stability Thresholding (ST), a local dynamical regula
tor that enforces Lipschitz-like smoothness via temporal decay and spatial suppr
ession. MIST enables robust, high-fidelity generation across a wide range of gui
dance scales while consistently improving performance at moderate scales. Extens
ive experiments on diverse text-to-image and text-to-video benchmarks demonstrat
e that MIST outperforms standard CFG and state-of-the-art corrections, establish
ing a new benchmark for robust guidance in flow-based generative models.
****

COGNOS: Universal Enhancement for Time Series Anomaly Detection via Constrained
Gaussian-Noise Optimization and Smoothing
Wenlong Shang, Shihao Tian, Xutong Wan, Peng Chang
Reconstruction-based methods are a dominant paradigm in time series anomaly dete
ction (TSAD), however, their near-universal reliance on Mean Squared Error (MSE)
 loss results in statistically flawed reconstruction residuals. This fundamental
 weakness leads to noisy, unstable anomaly scores, hindering reliable detection.
 To address this, we propose Constrained Gaussian-Noise Optimization and Smoothi
ng (COGNOS), a universal, model-agnostic enhancement framework that tackles this
 issue at its source. COGNOS introduces a novel Gaussian-White Noise Regularizat
ion strategy during training, which directly constrains the model's output resid
uals to conform to a Gaussian white noise distribution. This engineered statisti
cal property creates the ideal precondition for our second contribution: Adaptiv
e Residual Kalman Smoother that provably operates as a statistically robust esti
mator to denoise the raw anomaly scores.
Extensive experiments on multiple benchmarks demonstrate that COGNOS consistentl
y enhances the performance of state-of-the-art backbones significantly, validati
ng the efficacy of coupling statistical regularization with adaptive filtering.
****

DRIFT-BENCH: Diagnosing CoopeRative Breakdowns in LLM Agents under Input Faults
via Multi-Turn Interaction
Han Bao, Zheyuan Zhang, Pengcheng Jing, Zhengqing Yuan, Kaiwen Shi, Yanfang Ye
As Large Language Models transition to autonomous agents, user inputs frequently
 violate cooperative assumptions (e.g., implicit intent, missing parameters, fal
se presuppositions, or ambiguous expressions), creating execution risks that tex
t-only evaluations do not capture. Existing benchmarks typically assume well-spe
cified instructions or restrict evaluation to text-only, single-turn clarificati
on, and thus do not measure multi-turn disambiguation under grounded execution r

isk. We introduce DRIFT-BENCH, the first diagnostic benchmark that evaluates agentic pragmatics under input faults through multi-turn clarification across state-oriented and service-oriented execution environments. Grounded in classical theories of communication, DRIFT-BENCH provides a unified taxonomy of cooperative breakdowns and employs a persona-driven user simulator with the Rise evaluation protocol. Experiments show substantial performance drops under these faults, with clarification effectiveness varying across user personas and fault types. DRIFT-BENCH connects clarification studies with agent benchmarking, providing a framework to diagnose failures arising from faulty user inputs.

Sparks of Cooperative Reasoning: LLMs as Strategic Hanabi Agents
Mahesh Ramesh, Kaousheik Jayakumar, Aswinkumar Ramkumar, Pavan Thodima, Aniket Rege, Emmanouil-Vasileios Vlatakis-Gkaragkounis
Cooperative reasoning under incomplete information remains complex for both humans and multi-agent AI, requiring agents to transcend individual logic in favor of recursive Theory-of-Mind (ToM) and strategic coordination. To investigate these challenges, we conduct a large-scale evaluation of 17 state-of-the-art LLMs (4B–600B+) on Hanabi card game across 2–5 players. To examine their limitations, we analyze the impact of context engineering and scaffold robustness, ranging from minimal prompts (Watson setting) to Bayesian-motivated scaffolding (Sherlock setting) and multi-turn working memory (Mycroft setting). Our findings reveal that: (1) top-performing models can autonomously track game states via internal working memory, although not reliably, and (2) cross-play performance scales smoothly with model capability. However, even the best models (scoring ≈ 15/25) trail specialist human experts (> 20/25). We introduce and release two novel datasets: HanabiLogs (1,520 annotated trajectories) and HanabiRewards (560 games with dense move-level utilities). By fine-tuning a 4B open-weight model (Qwen3-Instruct) on our datasets, we achieve performance gains of up to 156%, bringing performance to within 3 points of a strong proprietary reasoning model (o4-mini) and surpassing the best non-reasoning model (GPT-4.1) by 52%. Crucially, our HanabiRewards RL-finetuned model further generalizes beyond Hanabi, improving performance on a cooperative group-guessing benchmark by 11 percentage points, temporal reasoning on EventQA by 6.4 points, instruction-following on IFBench by 1.7 Pass@10, and matching AIME 2025 mathematical reasoning Pass@10. Code and datasets are available at https://app.primeintellect.ai/dashboard/environments/mahesh-ramesh/hanabi.

HERMES: Towards Efficient and Verifiable Mathematical Reasoning in LLMs
Azim Ospanov, Zijin Feng, Jiacheng Sun, Haoli Bai, SHEN XIN, Farzan Farnia
Informal mathematics has been central to modern large language model (LLM) reasoning, offering flexibility and efficient construction of arguments. However, purely informal reasoning is prone to logical gaps and subtle errors that are difficult to detect and correct. In contrast, formal theorem proving provides rigorous, verifiable mathematical reasoning, where each inference step is checked by a trusted compiler, but lacks the exploratory freedom of informal problem-solving. This mismatch leaves current LLM-based math agents without a principled way to combine the strengths of both paradigms. In this work, we introduce Hermes, the first tool-assisted agent that explicitly interleaves informal reasoning with formally verified proofs in Lean. The framework performs intermediate formal checking to prevent reasoning drift and a memory module for proof continuity across multi-step reasoning chains, enabling both exploration and verification. We evaluate Hermes on four challenging mathematical reasoning benchmarks using LLMs of varying parameter scales, from small models to state-of-the-art systems. Across all settings, Hermes reliably improves the reasoning accuracy of base models while substantially reducing reasoning token usage and computational cost compared to reward-based approaches. On difficult datasets such as AIME and HARDMath2, Hermes@1 achieves up to a 40% accuracy improvement while using 80% fewer total inference FLOPs. When scaled at test time, Hermes@5 boosts accuracy further by 20%.
****

DualTimesField: Rethinking Time Series as Continuous-Time Trends and Events

Wencheng Zhang, Long Li, Huayi Qin, Zongjuan Wu, Jing Li, Wanghu Chen
Effective time series representation is critical for revealing temporal dynamics in many fields. However, existing approaches encounter fundamental limitations. Discrete-time representations struggle with irregular sampling and the tradeoff of fidelity and efficiency, while traditional implicit neural representations suffer from spectral bias and frequency entanglement. To address these challenges, we conceptualize time series as the superposition of continuous trends and discrete events from a continuous-time perspective and propose DualTimesField, a framework that utilizes dual implicit neural fields. Its Continuous Time Field captures smooth trends through bandwidth-limited parameterization, while a Discrete Geometric Field models transient events using learnable Gabor atoms, gated sparsity, and coarse-to-fine scale annealing. This explicit field separation effectively overcomes both limitations. Experiments on nine real-world benchmarks demonstrate substantial improvements in representation fidelity, achieving 51.2% average MSE reduction over discrete-time baselines and competitive interpolation on irregular data. Code is available at https://github.com/WisdomTogether/DualTimesField.

On Efficient Scaling of GNNs via IO-Aware Layers Implementations
Daria Fomina, Daniil Krasylnikov, Alexey Boykov, Andrey Dolgovyazov, Vyacheslav Zhdanovskiy, Fedor Velikonivtsev
Graph Neural Networks (GNNs) are bottlenecked by sparse, irregular memory access. Popular frameworks such as DGL and PyTorch Geometric support general message passing, but complex layers often materialize edge-wise intermediates, increasing memory traffic and limiting scalability on large graphs.
We take an I/O- and arithmetic-intensity--centric view and show that widely used layers fall into three kernel families: SpMM-based convolutions, reduction-based aggregations, and attention-based layers (GATv2/Graph Transformer). For each family, we develop GPU kernels that reduce data movement, improve locality, and remain robust across realistic graphs. We also study graph reordering and find that its impact depends on the kernel mapping: it benefits neighbor-parallel (gather-dominated) kernels more consistently than feature-parallel designs.
Empirically, our fused attention kernels reach up to **3.9**$\times$ speedup for Graph Transformer (median **1.6**$\times$), with Tensor Core (block-sparse) variants up to **7.3**$\times$ on locally dense graphs; for GATv2 we reach up to **8.5**$\times$ speedup (median **2.0**$\times$) while reducing peak memory by up to **76**$\times$ (median **6**$\times$). Our degree-aware reduction kernels achieve up to **10**$\times$ speedup (median **2.6**$\times$). For SpMM-based layers, properly cached cuSPARSE achieves up to **8**$\times$ speedup over DGL and outperforms evaluated custom baselines in the majority of evaluations. We release our implementations as drop-in replacements in our [GitHub repository](https://github.com/yandex-research/On-Efficient-Scaling-Of-GNNs) to support reproducible, hardware-aware GNN acceleration.

HypRAG: Hyperbolic Dense Retrieval for Retrieval Augmented Generation
Hiren Madhu, Ngoc Bui, Ali Maatouk, Leandros Tassiulas, Smita Krishnaswamy, Menglin Yang, Sukanta Ganguly, Kiran Srinivasan, Rex Ying
Embedding geometry plays a fundamental role in retrieval quality, yet dense retrievers for retrieval-augmented generation (RAG) remain largely confined to Euclidean space. However, natural language exhibits hierarchical structure from broad topics to specific entities that Euclidean embeddings fail to preserve, causing semantically distant documents to appear spuriously similar and increasing hallucination risk. To address these limitations, we introduce hyperbolic dense retrieval, developing two model variants in the Lorentz model of hyperbolic space: HyTE-FH, a fully hyperbolic transformer, and HyTE-H, a hybrid architecture projecting pre-trained Euclidean embeddings into hyperbolic space. To prevent representational collapse during sequence aggregation, we introduce the Outward Einstein Midpoint, a geometry-aware pooling operator that provably preserves hierarchical structure. On MTEB, HyTE-FH outperforms equivalent Euclidean baselines, while on RAGBench, HyTE-H achieves up to 29\% gains over Euclidean baselines in contex

t relevance and answer relevance using substantially smaller models than current state-of-the-art retrievers. Our analysis also reveals that hyperbolic representations encode document specificity through norm-based separation—with over 20\% radial increase from general to specific concepts—a property absent in Euclidean embeddings, underscoring the critical role of geometric inductive bias in faithful RAG systems. The code is available at: https://github.com/Graph-and-Geometric-Learning/HypRAG

HiPhO: How Far Are (M)LLMs from Humans in the Latest High School Physics Olympiad Benchmark?

Fangchen Yu, Haiyuan Wan, Qianjia Cheng, Yuchen Zhang, Jiacheng Chen, Fujun Han, Yulun Wu, Junchi Yao, Ruilizhen Hu, Ning Ding, Yu Cheng, Tao Chen, LEI BAI, Dongzhan Zhou, Yun Luo, Ganqu Cui, Peng Ye

Recently, the physics reasoning capabilities of (M)LLMs have attracted growing attention. However, existing physics benchmarks lack systematic coverage of recent physics Olympiads and direct comparison with human contestants. We present **HiPhO**, the first benchmark dedicated to high school physics Olympiads with human-aligned evaluation. HiPhO highlights three key innovations. **(1) Comprehensive data:** it compiles 13 latest Olympiads from 2024--2025, covering international and regional competitions and spanning mixed modalities from text-only to diagram-based problems. **(2) Professional evaluation:** it adopts official rubrics for fine-grained answer- and step-level grading aligned with human examiners. **(3) Human-level comparison:** it assigns gold, silver, and bronze medals to models based on official medal scores, enabling direct comparison with human contestants. Evaluating 30 (M)LLMs across 13 exams, we find that most open-source MLLMs remain at or below the bronze level, open-source LLMs demonstrate notable progress with multiple gold medals, and closed-source MLLMs achieve 6-13 gold medals, while most models still fall well short of full marks. These results underscore the substantial gap between current (M)LLMs and top human contestants, as well as the room for further improvement. The dataset and leaderboard are available at https://huggingface.co/datasets/SciYu/HiPhO and https://phyarena.github.io, respectively.

Zeroth-Order Forward-Only SNN Training Inspiring Neuromorphic On-Chip Learning

Mingyue Qin, Shuyu Yin, Qinghai Guo, Peilin Liu, Xiaolin Huang, Fei Wen

The human brain is a biologically instantiated on-device neural system that integrates both learning and inference in a unified architecture, which enables rapid and flexible learning on-the-fly. This extraordinary online learning ability is realized through biological learning mechanisms operating on a well-initialized innate model. This work considers the on-chip edge learning upon pretrained models with zeroth-order (ZO) methods. ZO optimization methods, which resemble bio-plausible perturbation-based learning, offer a promising approach that enables learning with only forward passes and hence can significantly reduce the complexity of on-chip hardware implementation. However, in this work we show that applying ZO methods to spiking neural networks (SNNs) is non-trivial due to the step-function nature of spiking activation. We analyze the challenges posed by the spiking activation, and reveal a variance amplification effect of it. Based on this insight, we propose a subspace-based ZO (SZO) method that leverages the intrinsic low-dimensional structure of the SNN optimization trajectory. By learning in a low-dimensional subspace, SZO substantially enhances ZO learning efficacy, achieving accuracy comparable to first-order (FO) methods with faster learning speed than full-space BP. We evaluate SZO on model training from scratch, continual training, and unsupervised adaptation. Experimental results demonstrate that SZO closely approaches FO training performance for the first time while offering fast learning speed.

Diffusion-based learning framework for Constrained Nonconvex Optimization with Weighted Bootstrapped Refinement

Shutong Ding, Yimiao Zhou, Ke Hu, Xi Yao, Junchi Yan, Xiaoying Tang, Ye Shi

Recent advances in diffusion models show promising potential to accelerate nonco

nvex problem solving by leveraging their multimodality. However, most existing d
iffusion-based optimization approaches rely on supervised learning and lack a me
chanism to enforce constraint satisfaction, which is required in real-world appl
ications. In that case, we investigate and theoretically analyze the inherent pr
oblem of supervised diffusion solvers and identify the distributional misalignme
nt problem, i.e., the generated solution distribution often exhibits low probabi
lity mass on the feasible region. To resolve this issue, we propose DiOpt, a new
 diffusion-based learning framework for constrained nonconvex optimization, whic
h effectively learns the mapping from noise to the constraint region. Specifical
ly, this framework operates in two distinct phases: an initial warm-start phase,
 implemented via supervised learning, followed by a bootstrapping training phase
. This dual-phase architecture is designed to iteratively refine solutions, ther
eby improving the objective function with high constraint satisfaction. Finally,
 we also employ a solution selection technique in inference for better optimalit
y. Notably, DiOpt is the first successful integration of the diffusion solver in
 constrained nonconvex optimization. Evaluations on diverse nonconvex tasks demo
nstrate the superiority of DiOpt in both optimality and constraint satisfaction.
 Our official page is released at \url{https://dingsht.tech/diopt-webpage}.

FiGuRO: Intrinsic Dimension Estimation for Multi-Modal Data
Viktoria Schuster, Sana Tonekaboni, Caroline Uhler
Determining the complexity, or Intrinsic Dimension (ID), of data is fundamental
to efficient and interpretable representation learning. This is particularly cha
llenging in multi-modal settings when trying to learn disentangled representatio
ns for shared and private information. Existing techniques leave a critical gap:
 they are often static, uni-modal, or in the case of contrastive methods, adapt
only to the shared ID implicitly. We introduce Fidelity-Guided Rank Optimization
 (FiGuRO), a framework for approximating the ID of uni- and multi-modal data und
er constraints of model capacity and hyperparameters. FiGuRO learns the dimensio
ns of low-rank projections using truncated singular value decomposition and an a
lgorithm that determines when to reduce or increase dimension and in which laten
t space. Disentanglement of shared and private information arises as an emergent
 property of this optimization, eliminating the need for complex auxiliary loss
functions. We demonstrate that FiGuRO outperforms existing ID estimation techniq
ues and is more robust to hyperparameter changes. Across simulations and real-wo
rld data, FiGuRO captures distinct ID scales and varying subspace ratios, and de
composes shared and private information successfully. Furthermore, we show that
FiGuRO can be applied to modern uni-modal pretrained models, enabling efficient,
 post-hoc disentanglement of multi-modal representations.

Likelihood over Estimation: Robust Quadratic Discriminant Analysis for Heavy-Tai
led Distributions with Theory and Evidence
Niranjana Ambadi, eugene pinsky
Quadratic Discriminant Analysis (QDA) assumes Gaussian class-conditional distrib
utions, causing systematic misclassification when data exhibit heavy tails. We p
ropose Stable-QDA, which replaces the Gaussian likelihood with a symmetric $\alp
ha$-stable likelihood that decays polynomially rather than exponentially in Maha
lanobis distance. Crucially, we find that correcting likelihood misspecification
 yields larger gains than robustifying parameter estimation: standard estimators
 (sample mean, Ledoit--Wolf covariance) often outperform robust alternatives whe
n class heteroscedasticity is discriminative. We provide consistency guarantees
under infinite-variance regimes, data-driven diagnostics for estimator selection
, and demonstrate 15--53\% error reduction on real-world heavy-tailed benchmarks
.

L-SR1: Learned Symmetric-Rank-One Preconditioning
Gal Lifshitz, Shahar Zuler, Ori Fouks, Dan Raviv
End-to-end deep learning has achieved impressive results but often relies on lar
ge labeled datasets, exhibits limited generalization to unseen scenarios, and in
curs substantial computational cost.

Classical optimization methods, in contrast, are more data-efficient and lightweight but frequently suffer from slow convergence.
Learned optimizers aim to bridge this gap, yet existing approaches have focused primarily on first-order methods, while learned second-order optimization has received much less attention.
We introduce L-SR1, a learned second-order optimizer inspired by the classical Symmetric Rank-One (SR1) method.
At its core, L-SR1 employs a Projection-Guided Secant Mechanism (PGSM) that generates positive semi-definite preconditioners and biases meta-training toward the quasi-Newton secant relation.
Through controlled analytic benchmarks, we study stability, generalization across problem dimensions, and search direction quality, and further evaluate L-SR1 on Monocular Human Mesh Recovery (HMR), where it outperforms both classical and learned optimization-based baselines.
With a compact model and no reliance on task-specific fine-tuning or annotated data, L-SR1 demonstrates strong generalization and can be integrated into a broad range of iterative optimization problems to accelerate convergence and reduce the required number of iterations.

Multi-Label Test-Time Adaptation with Bayesian Conditional Priors
QiRu Li, Ao Zhou, Zhiwei Jiang, Zifeng Cheng, Cong Wang, Yafeng Yin, Qing Gu
Multi-label recognition with frozen Vision-Language Models (VLMs) is brittle under distribution shift: standard zero-shot inference scores labels independently, ignoring co-occurrence structure and producing incoherent label sets where dominant concepts suppress weaker but compatible labels. We introduce Bayesian Conditional Priors (BCP) Estimation, a gradient-free test-time adaptation method that injects label dependency without tuning the backbone. BCP views zero-shot logits as a proxy for marginal posteriors under a fixed image-text likelihood and attributes shift-induced errors mainly to a mismatched label prior. For each test image, it selects a high-confidence anchor label and applies an anchor-conditioned Bayesian refinement. This update is closed-form in logit space and admits a pointwise mutual information (PMI) interpretation, explicitly promoting compatible labels and suppressing incompatible ones. BCP operates without target annotations by estimating anchor-conditioned priors online from the unlabeled test stream via lightweight second-order co-occurrence statistics, adding negligible overhead beyond a single forward pass. Across standard multi-label benchmarks and multiple CLIP backbones, BCP consistently outperforms strong TTA baselines, e.g., improving RN50 average mAP from 57.31 to 69.22 and ViT-B/16 from 62.61 to 71.79.

How Reasoning Evolves from Post-Training Data: An Empirical Study Using Chess
Lucas Dionisopoulos, Nicklas Majamaki, Prithviraj Ammanabrolu
We study how reasoning evolves in a language model -- from supervised fine-tuning (SFT) to reinforcement learning (RL) -- by analyzing how a set of theoretically-inspired datasets impacts language model performance in chess. We find that fine-tuning a model to directly predict the best move leads to effective RL and the strongest downstream performance -- however, the RL stage elicits \textit{unfaithful} reasoning (reasoning inconsistent with the chosen move). Alternatively, training on multi-move trajectories yields comparable downstream performance with faithful reasoning and more stable RL. We show that RL induces a substantial positive shift in the distribution of move quality and reduces hallucination rates as a side effect. Finally, we find several SFT-checkpoint metrics -- metrics spanning evaluation performance, hallucination rates, and reasoning quality -- to be predictive of post-RL model performance. We release checkpoints and final models as well as training data, evaluations, and code that allowed us to surpass leading open-source reasoning models in chess with a 7B-parameter model.

The Devil is in the Condition Numbers: Why is GLU Better than non-GLU Structure?
Xingyu Lyu, Qianqian Xu, Zhiyong Yang, Peisong Wen, Qingming Huang
Gated Linear Units (GLU) and their variants are widely adopted in modern open-source large language model architectures and consistently outperform their non-ga

ted counterparts, yet the underlying reasons for this advantage remain unclear. In this work, we study GLU by analyzing two-layer networks in the neural tangent kernel (NTK) regime. Our analysis reveals that the GLU structure reshapes the NTK spectrum, leading to a smaller condition number and a more compact eigenvalue distribution. Building on this finding, we further analyze the resulting training dynamics and show how the reshaped spectrum leads to faster convergence of GLU models, including a characteristic loss-crossing phenomenon observed between GLU and non-GLU models. Finally, we empirically observe that GLU has limited impact in reducing the generalization gap on various models, including ViT and GPT-2, suggesting that its primary benefit lies in accelerating optimization rather than reducing the generalization gap. The code is available at: https://github.com/Zemdalk/GLU-NTK.

KIStego: Key-Independent Secure Image Distribution via Bipartite Structural Invariants

Ren Lijing, Denghui Zhang

Generative Image Steganography (GIS) embeds complex secrets within stego-images that are indistinguishable from the stochastic synthesis process itself. It achieves this by exploiting the reversible probability flow between Gaussian noise and the natural image manifold. However, existing steganography faces a key-dependency paradox: precise secret extraction usually requires an external private key or random seed to synchronize the denoising path.

In this paper, we present KIStego, a training-free framework substituting cryptographic secrecy with structural redundancy for Key-Independent, high-resolution secure distribution. Our dual-guidance mechanism utilizes structural latent guidance to project secrets into a bipartite manifold via downsampling and halftoning, yielding self-synchronizing shares. Measurement posterior sampling leverages these shares as discrete invariants to steer a differentiable restoration. By backpropagating through a differentiable measurement surrogate, KIStego reconstructs high-fidelity continuous-tone details from sparse binary observations, mitigating fidelity loss from inversion drift.

KIStego offers an endogenous secure image distribution paradigm by connecting discrete structural invariants with high-fidelity generative reconstruction.

Understanding Dynamic Compute Allocation in Recurrent Transformers

Ibraheem Muhammad Moosa, Suhas Lohit, Ye Wang, Moitreya Chatterjee, Wenpeng Yin

Token-level adaptive computation seeks to reduce inference cost by allocating more computation to harder tokens and less to easier ones. However, prior work is primarily evaluated on natural-language benchmarks using task-level metrics, where token-level difficulty is unobservable and confounded with architectural factors, making it unclear whether compute allocation truly aligns with underlying complexity. We address this gap through three contributions. First, we introduce a complexity-controlled evaluation paradigm using existing algorithmic and synthetic language tasks with parameterized difficulty, enabling direct testing of token-level compute allocation. Second, we propose ANIRA, a unified recurrent Transformer framework that supports per-token variable-depth computation while isolating compute allocation decisions from other model factors. Third, we use this framework to conduct a systematic analysis of token-level adaptive computation across alignment with complexity, generalization, and decision timing. Our results show that compute allocation aligned with task complexity can emerge without explicit difficulty supervision, but such alignment does not imply algorithmic generalization: models fail to extrapolate to unseen input sizes despite allocating additional computation. We further find that early compute decisions rely on static structural cues, whereas online halting more closely tracks algorithmic execution state. Code: https://github.com/merlresearch/ANIRA

AAD-1: Asymmetric Adversarial Distillation for One-Step Autoregressive Video Generation

Haobo Li, Yanhong Zeng, Yunhong Lu, Jiapeng Zhu, Hao Ouyang, Qiuyu Wang, Ka Leong Cheng, Yujun Shen, Zhipeng Zhang

We present \textbf{AAD-1}, an \textbf{A}symmetric \textbf{A}dversarial \textbf{D}istillation framework for \textbf{O}ne-step autoregressive image-to-video generation. State-of-the-art methods adopt adversarial distillation but suffer from motion collapse and training instability, resulting in static videos. AAD-1 addresses these challenges through two key designs in architecture and training strategy. Our key architectural insight is to break the symmetry between generator and discriminator. While the generator remains causal to preserve autoregressive sampling capability, the discriminator attends bidirectionally over the full spatiotemporal context and produces a single holistic realism score for the entire video sequence. This asymmetric design enables the discriminator to effectively detect global temporal failures and long-range drift that cause motion collapse in autoregressive generation. To stabilize training, we introduce a phased strategy that first uses distribution matching to bootstrap a stable one-step generator, providing a warm-up phase that brings the student distribution closer to the teacher before adversarial distillation begins. Extensive experiments on VBench demonstrate that AAD-1 achieves state-of-the-art performance in one-step autoregressive video generation.

Accordion-Thinking: Self-Regulated Step Summaries for Efficient and Readable LLM Reasoning
Zhicheng Yang, Zhijiang Guo, Yinya Huang, Yongxin Wang, Wenlei Shi, Yiwei Wang, Xiaodan Liang, Jing Tang
Scaling test-time compute via long Chain-of-Thought unlocks remarkable gains in reasoning capabilities, yet it faces practical limits due to the linear growth of KV cache and quadratic attention complexity.
In this paper, we introduce AccordionThinking, an end-to-end framework where LLMs learn to self-regulate the granularity of the reasoning steps through dynamic summarization.
This mechanism enables a Fold inference mode, where the model periodically summarizes its thought process and discards former thoughts to reduce dependency on historical tokens.
We apply reinforcement learning to incentivize this capability further, uncovering a critical insight: the accuracy gap between the highly efficient Fold mode and the exhaustive Unfold mode progressively narrows and eventually vanishes over the course of training. This phenomenon demonstrates that the model learns to encode essential reasoning information into compact summaries, achieving effective compression of the reasoning context.
Our AccordionThinker demonstrates that with learned self-compression, LLMs can tackle complex reasoning tasks with minimal dependency token overhead without compromising solution quality, and it achieves a 3× throughput while maintaining accuracy on a 48GB GPU memory configuration, while the structured step summaries provide a human-readable account of the reasoning process.

Convergence of Steepest Descent and Adam under Non-Uniform Smoothness
Sharan Vaswani, Yifan Sun, Reza Babanezhad Harikandeh
Recent work has analyzed the convergence of first-order methods under non-uniform smoothness assumptions that better model the loss landscape in machine learning tasks. We generalize this assumption to objectives whose curvature is an affine function of the objective value. This property is satisfied by a broad class of problems, including logistic regression, generalized linear models with a logistic link function, softmax policy gradient in reinforcement learning, and a class of neural networks. Under this assumption and gradient domination conditions, we establish a general convergence rate for the steepest descent method, and deterministic, diagonal variants of RMSProp and Adam. Our results imply that for logistic regression on separable data and the softmax policy gradient objective, sign GD converges linearly and is provably faster than GD. Furthermore, we show that for a class of two-layer neural networks on separable data, RMSProp and Adam can converge at a linear rate with a constant step-size and momentum parameter. Finally, we present a lower bound demonstrating that, under our assumption, RMSProp and Adam are provably faster than AdaGrad, AMSGrad, gradient descent, and

heavy-ball momentum.

ZeroUnlearn: Few-Shot Knowledge Unlearning in Large Language Models
Yujie Lin, Chengyi Yang, Zhishang Xiang, YIPING SONG, Jinsong Su
Large language models inevitably retain sensitive information, defined as inputs that may induce harmful generations, due to training on massive web corpora, raising concerns for privacy and safety. Existing machine unlearning methods primarily rely on retraining or aggressive fine-tuning, which are either computationally expensive or prone to degrading related knowledge and overall model utility. In this work, we reformulate machine unlearning as a precise knowledge re-mapping problem via model editing. We propose ZeroUnlearn, a few-shot unlearning framework. It overwrites sensitive inputs by mapping them to a neutral target state and removing their original representations.
ZeroUnlearn enforces representational orthogonality through a multiplicative parameter update with a closed-form solution, enabling efficient and targeted unlearning. We further extend ZeroUnlearn to a gradient-based variant for multi-sample unlearning. Experiments demonstrate that our approach outperforms existing baselines while preserving general model utility. Our code is available at the github: https://github.com/XMUDeepLIT/ZeroUnlearn.
****
ACTG-ARL: Differentially Private Conditional Text Generation with RL-Boosted Control
Yuzheng Hu, Ryan McKenna, Da Yu, Shanshan Wu, Han Zhao, Zheng Xu, Peter Kairouz
Generating high-quality synthetic text under differential privacy (DP) is critical for training and evaluating language models without compromising user privacy. Prior work on synthesizing DP *datasets* often fail to preserve key statistical attributes, suffer utility loss from the noise required by DP, and lack fine-grained control over generation. To address these challenges, we make two contributions. First, we introduce a hierarchical framework that decomposes DP synthetic text generation into two subtasks: *feature learning* and *conditional text generation*. This design explicitly incorporates learned features into the generation process and simplifies the end-to-end synthesis task. Through systematic ablations, we identify the most effective configuration: a rich tabular schema as feature, a DP tabular synthesizer, and a DP fine-tuned conditional generator, which we term ACTG (**A**ttribute-**C**onditioned **T**ext **G**eneration). Second, we propose Anchored RL (ARL), a post-training method that improves the instruction-following ability of ACTG for conditional generation. ARL combines RL to boost control with an SFT anchor on best-of-N data to prevent reward hacking. Together, these components form our end-to-end algorithm **ACTG-ARL**, which advances both the quality of DP synthetic text (+20% MAUVE over prior work) and the control of the conditional generator under strong privacy guarantees. Our code is at https://github.com/actg-arl/ACTG-ARL.
****
MemOCR: Layout-Aware Visual Memory for Efficient Long-Horizon Reasoning
Yaorui Shi, Shugui Liu, Yu Yang, Wenyu Mao, Yuxin Chen, Qi GU, Hui Su, Xunliang Cai, Xiang Wang, An Zhang
Long-horizon agentic reasoning necessitates effectively compressing growing interaction histories into a limited context window.
Most existing memory systems serialize history as text, where token-level cost is uniform and scales linearly with length, often spending scarce budget on low-value details.
To this end, we introduce **MemOCR**, a multimodal memory agent that improves long-horizon reasoning under tight context budgets by allocating memory space with adaptive information density through visual layout.
Concretely, MemOCR maintains a structured rich-text memory (e.g., headings, highlights) and renders it into an image that the agent consults for memory access, visually prioritizing crucial evidence while aggressively compressing auxiliary details.
To ensure robustness across varying memory budgets, we train MemOCR with reinforcement learning under budget-aware objectives that expose the agent to diverse c

ompression levels.
Across long-context multi-hop and single-hop question-answering benchmarks, MemOCR outperforms strong text-based baselines and achieves more effective context utilization under extreme budgets.
****

A Unified Sparse Attention via Multi-Granularity Compression
Siran Liu, Zane Cao, Yongchao He
Efficient long-context understanding is increasingly vital for large language model (LLM) applications such as multi-turn dialogue and program analysis. However, the core self-attention scales quadratically with sequence length, creating a fundamental computational bottleneck. Existing sparse attention methods alleviate this issue but face trade-offs: training-based methods are costly and cannot be directly applied as acceleration plugins for other models, while inference-time methods often compromise efficiency or cross-modal generality. To address these limitations, we present UniSparse, a unified mechanism that introduces the notion of composite tokens—compact representations that aggregate multi-granularity contextual information. Building on this abstraction, UniSparse dynamically constructs sparse attention through multi-granularity compression and block-level selection, enabling efficient and hardware-friendly execution on GPU. Across multiple modalities and tasks ranging from synthetic benchmarks to real-world applications, UniSparse consistently surpasses state-of-the-art sparse attention methods (e.g., MInference, XAttention, FlexPrefill) in both accuracy and efficiency, achieving $\ge$ 99\% of full-attention accuracy and up to 2.61$\times$ faster attention computation than FlashAttention.
****

PRIM■Cooperative Dynamic Token Compression for Efficient Large Multimodal Models
Song Li, yongping xiong
Large multimodal models (LMMs) have shown strong capabilities in audio-visual understanding by jointly reasoning over visual, auditory, and linguistic inputs. However, processing long-form audio-visual content often requires a large number of tokens, leading to substantial computational and memory overhead during inference. Existing efficiency-oriented methods typically apply uniform compression or pruning strategies, which overlook modality-specific characteristics and instruction-dependent reasoning behaviors in multimodal models. In this work, we present PRIM, an inference framework for efficient multimodal reasoning that systematically compresses audio-visual representations based on attention dynamics and instruction relevance. Motivated by an attention-based analysis revealing modality imbalance and layer-wise redundancy in LMMs, PRIM introduces a cooperative compression pipeline that spans both multimodal encoders and the language model. Specifically, PRIM performs early text-conditioned audio-visual fusion to externalize cross-modal interactions, applies attention-guided and frequency-aware strategies to remove redundant audio and video tokens, and further adapts token retention inside the language model according to task demands. Extensive experiments on multiple audio-visual benchmark datasets demonstrate that PRIM consistently achieves stable and superior efficiency--accuracy trade-offs across diverse tasks and datasets. These results demonstrate that PRIM, a multimodal cooperative compression approach, provides an effective pathway toward scalable and efficient audio-visual reasoning.
****

Differential Smoothing Mitigates Sharpening and Improves LLM Reasoning
Jingchu Gai, Guanning Zeng, Huaqing Zhang, Aditi Raghunathan
It is widely recognized that reinforcement learning (RL) fine-tuning of large language models often leads to \textit{diversity collapse}, where outputs lack variety. Prior work has proposed a range of heuristics to counteract this effect, but these methods are ad hoc: they frequently trade off correctness for diversity, their effectiveness varies across tasks, and in some cases they even contradict one another. In this work, we place these observations on a rigorous foundation. We first provide a formal proof of why RL fine-tuning exhibits diversity collapse via a selection and reinforcement bias. Next, we make a key observation that any reward modification to address diversity collapse only needs to be applied

on the correct trajectories. Building directly on this analysis, we introduce a principled method---\textit{differential smoothing}---that provably improves both correctness and diversity, outperforming vanilla RL as well as widely used entropy-based heuristics. Our theory precisely characterizes when existing heuristics help and why they fail, while showing that differential smoothing is universally superior. Extensive experiments with models from 1B to 7B parameters, across domains including CountDown and real-world mathematical reasoning, demonstrate consistent gains. Differential smoothing improves both Pass@1 and Pass@k, with up to 6.7\% improvements on AIME24 dataset.
****
Allocating Variance to Maximize Expectation
Renato Paes Leme, Clifford Stein, Yifeng Teng, Pratik Worah
We design efficient approximation algorithms for maximizing the expectation of the supremum of families of Gaussian random variables. In particular, let $OPT:=\max_{\sigma_1,\cdots,\sigma_n}\mathbb{E}\sum_{j=1}^{m}\max_{i\in S_j} X_i$, where X_i are Gaussian, $S_j\subset[n]$ and $\sum_i\sigma_i^2=1$, then our theoretical results include:

- We characterize the optimal variance allocation -- it concentrates on a small subset of variables as $|S_j|$ increases,

- A polynomial time approximation scheme (PTAS) for computing OPT when $m=1$, and

- An $O(\log n)$ approximation algorithm for computing OPT for general $m>1$.
****
Rewiring Experts on the Fly: Continuous Rerouting for Better Online Adaptation in Mixture-of-Expert Models
Guinan Su, Yanwu Yang, Li Shen, Lu Yin, Shiwei Liu, Jonas Geiping
Mixture-of-Experts (MoE) models achieve efficient scaling through sparse expert activation, but often suffer from suboptimal routing decisions due to distribution shifts in deployment. While existing test-time adaptation methods could potentially address these issues, they primarily focus on dense models and require access to external data, limiting their practical applicability to MoE architectures. However, we find that, instead of relying on reference data, we can optimize MoE expert selection on-the-fly based only on input context. As such, we propose *a data-free, online test-time framework* that continuously adapts MoE routing decisions during text generation without external supervision or data. Our method cycles between two phases: During the prefill stage, and later in regular intervals, we optimize the routing decisions of the model using self-supervision based on the already generated sequence. Then, we generate text as normal, maintaining the modified router until the next adaption. We implement this through lightweight additive vectors that only update router logits in selected layers, maintaining computational efficiency while preventing over-adaptation. The results show consistent performance gains on challenging reasoning tasks while maintaining robustness to context shifts. For example, our method achieves a 5.5\% improvement on HumanEval with OLMoE. Furthermore, owing to its plug-and-play property, our method complements existing test-time scaling techniques, e.g., achieving 6\% average gains when incorporated with self-consistency on DeepSeek-V2-Lite.
****
ToaSt: Token Channel Selection and Structured Pruning for Efficient ViT
Hyunchan Moon, Cheonjun Park, Steven L. Waslander
Vision Transformers (ViTs) have achieved remarkable success across various vision tasks, yet their deployment is often hindered by prohibitive computational costs. While structured weight pruning and token compression have emerged as promising solutions, they suffer from prolonged retraining and inter-layer dependencies that complicate optimization, respectively. We propose ToaSt, a decoupled framework applying specialized strategies to distinct ViT components. We apply coupled head-wise structured pruning to Multi-Head Self-Attention modules, leveraging attention operation characteristics to enhance robustness. For Feed-Forward Net

works (over 60\% of FLOPs), we introduce Token Channel Selection (TCS), a training-free method that filters redundant noise channels at inference time. Extensive evaluations across nine diverse models, including DeiT, ViT-MAE, and Swin Transformer, demonstrate that ToaSt achieves superior trade-offs between accuracy and efficiency, consistently outperforming existing baselines. On ViT-MAE-Huge, ToaSt achieves 88.52\% accuracy (+1.64\%p) with 39.4\% FLOPs reduction. ToaSt also transfers effectively to diverse downstream tasks (COCO detection, ADE20K segmentation, CIFAR-100 classification), achieving 52.2 versus 51.9 mAP on COCO. Code: \href{https://github.com/SHANNonLab-HUFS/ToaSt}{github.com/SHANNonLab-HUFS/ToaSt}.

Off-Policy Evaluation for Missingness-Aware Policies in MDPs with Rewards Missing Not at Random
Ziheng Wei, Annie Qu, Rui Miao
In offline Reinforcement Learning, immediate rewards in logged batch data are often unobserved due to sparse or irregular record-keeping, or censored beyond certain reward values. This issue arises in practical settings, including health care and marketing. We investigate off-policy evaluation (OPE) in finite-horizon Markov decision processes when rewards are missing not at random (MNAR), which breaks ignorability and induces selection bias even after conditioning on states and actions. To address this, we formalize a reward-dependent propensity model and use future states as shadow variables to identify the full-data conditional mean reward. We further introduce a bridge function that recovers the conditional mean reward without explicitly modeling the MNAR mechanism, and estimate it via a min-max procedure to avoid double sampling. Building upon these identification results, we propose an Fitted-Q-Evaluation-style estimator that propagates the recovered rewards while allowing target policies to depend on past missingness indicators. Finally, we establish consistency and finite-sample error bounds for our OPE estimator, and show through experiments the strong performance of our method compared to existing methods on simulated and MIMIC-III Sepsis data.

When Data Is Scarce: Scaling Sparse Language Models with Repeated Training
Boqian Wu, Qiao Xiao, Patrik Okanovic, Tomasz Sternal, Maurice van Keulen, Mykola Pechenizkiy, Elena Mocanu, Torsten Hoefler, Decebal Constantin Mocanu
Scaling laws for dense LLMs under infinite data are well explored, but how sparsity interacts with limited data is not. In this work, we study sparse training in data-constrained regimes where limited unique tokens require multi-epoch training. Our experiments span models up to 1.92B parameters in the fitting set, sparsity up to 93.75\%, unique data budgets up to 2.6B tokens, and total training tokens up to 41.6B over 16 epochs; we further validate extrapolation on held-out dense-equivalent models up to 7.68B parameters. We find that: **1. Sparse scaling in data-limited settings:** We introduce a scaling law that models loss as a function of active parameters, unique tokens, data repetition, and sparsity, accurately predicting performance across compute and data budgets. **2. Delayed data saturation:** sparse training postpones diminishing returns from repeated data, making multi-epoch training more effective. **3. Resource trade-offs:** With fixed data, loss-optimal sparsity is moderate (~ 50%), while compute-optimal sparsity is higher and grows with data scale. Overall, sparsity is not just a tool for efficiency, but a mechanism for improving scaling trade-offs under data scarcity. Our code is available at: https://github.com/boqian333/sparse-dc-scaling.

MCP-Persona: Benchmarking LLM Agents on Real-World Personal Applications via Environment Simulation
WenHao Wang, Peizhi Niu, Gongyi Zou, Xiyuan Yang, Jingxing Wang, Haoting Shi, Yaxin Du, Jingyi Chai, Xianghe Pang, Shuo Tang, Yanfeng Wang, Siheng Chen
The Model Context Protocol (MCP) has emerged as a transformative standard for connecting large language models (LLMs) with external data sources and tools, and has been rapidly adopted across personal applications and development platforms. However, existing benchmarks predominantly focus on generic information-seeking tools and fail to capture the practical challenges posed by personal social appl

ications, where tools interact with individual accounts or local databases.
To bridge this critical gap, we introduce MCP-Persona, the first benchmark specifically designed for evaluating agent performance on real-world, personalized MCP tools. MCP-Persona encompasses a diverse set of widely-used applications, ranging from social media platforms like Reddit and Xiaohongshu (Rednote) to enterprise collaboration suites such as Lark (Feishu) and Slack. Our extensive experiments on various state-of-the-art (SOTA) agents demonstrate their significant struggles with personalized tool use, thereby highlighting the benchmark's crucial role in identifying and addressing these limitations.
MCP-Persona is publicly available at \href{https://github.com/wwh0411/MCP-Persona}{https://github.com/wwh0411/MCP-Persona}

GAAVI: Global Asymptotic Anytime Valid Inference for the Conditional Mean Function
Brian M Cho, Raaz Dwivedi, Nathan Kallus
Inference on the conditional mean function (CMF) is central to tasks from adaptive experimentation to optimal treatment assignment and algorithmic fairness auditing. In this work, we provide a novel asymptotic anytime-valid test for a CMF global null (e.g., that all conditional means are zero) and contrasts between CMFs, enabling experimenters to make high confidence decisions at \textit{any} time during the experiment beyond a minimum sample size. We provide mild conditions under which our tests achieve (i) asymptotic type-I error guarantees, (i) power one, and, unlike past tests, (iii) optimal sample complexity relative to a Gaussian location testing. By inverting our tests, we show how to construct function-valued asymptotic confidence sequences for the CMF and contrasts thereof. Experiments on both synthetic and real-world data show our method is well-powered across various distributions while preserving the nominal error rate under continuous monitoring.

Feature Collapse Under Corruption: An Entropy Perspective on Robust Neural Networks
Vishesh Kumar, Akshay Agarwal
Even after decades of advances in neural network training, the inherent robustness challenge remains open. While the sensitivity to adversarial perturbations is understandable given their intentional learning, the most surprising fact is the vulnerability to natural corruptions. Surprisingly, not only is the cause of this inherent vulnerability unknown, but the concern extends beyond traditional CNNs; it also applies to current models, including transformers and large foundation models. For the first time, through this work, we observe that natural corruptions often collapse the network's internal feature space into a high-entropy state, causing predictions to rely on a small subset of fragile features. Inspired by this, we propose a simple yet effective entropy-guided fine-tuning framework, Dem-HEC, that strengthens corruption robustness while maintaining clean accuracy. Our method generates high-entropy samples within a bounded perturbation region and repairs the model using both clean and high-entropy samples. We further combine this objective with distilling knowledge from a teacher snapshot to maintain stable predictions. The proposed Dem-HEC is effective across datasets ranging from small to large-resolution, from pure CNNs to transformers, and to large foundation models, including DinoV3. The proposed approach outperforms the state-of-the-art (SOTA) models not only in improving robustness but also in retaining or boosting clean accuracy.

Cutting LLM Evaluation Costs with SySRs: A Bandit Algorithm That Provably Exploits Model Similarity
Zifan Lyu, Chahine Nejma, Tobias Wegel, Fanny Yang, Florian E. Dorner
Large Language Models are typically benchmarked by evaluating every model on every test query. For practitioners seeking the best model to deploy, this is often wasteful: if a model clearly performs worse than others, there is no need to precisely estimate its performance. Best-arm identification algorithms can be naturally applied to drastically reduce costs by adaptively allocating evaluation bu

dget. Further, language models often respond similarly to the same prompt—a property previous work has tried to leverage with mixed success in different use cases. We propose Synchronized Successive Rejects (SySRs), augmenting the classical Successive Reject algorithm with paired comparisons. Unlike prior attempts to leverage model similarity in best-model identification, our approach is hyperparameter-free and enjoys performance guarantees that improve with the degree of similarity between evaluated models. Empirically, our method outperforms all baselines in terms of average error rate across 15 standard benchmarks, and in terms of worst-case budget for reliably identifying the best model.

Conflict-Aware Adaptive Alignment for LLM Hallucination Mitigation
Ruohan Zong, Yang Zhang, Dong Wang
Despite strong performance, large language models (LLMs) still suffer from hallucinations. Most existing mitigation methods operate at inference time, without addressing the alignment limitation: LLMs are not trained to recognize their own lack of knowledge, and therefore tend to generate plausible responses even when the required knowledge is missing. Preference alignment approaches encourage uncertainty expression or refusal to improve truthfulness, but often consequently degrade helpfulness. To address this trade-off, existing preference alignment methods typically treat truthfulness and helpfulness as either universally collaborative or universally conflicting objectives across all samples. In contrast, we show that these objectives are consistent for most samples and conflict only in a small subset—where adaptive trade-off is truly needed. Based on this insight, we propose Conflict-Aware Adaptive Margin Preference Alignment (CAMP), which explicitly models when conflicts arise and adaptively regulates optimization strength. Experiments on UltraFeedback and representative hallucination benchmarks demonstrate that CAMP consistently improves truthfulness while maintaining a favorable helpfulness trade-off compared to strong hallucination mitigation and multi-objective alignment baselines.

MAFE: Enabling Equitable Algorithm Design in Multi-Agent Multi-Stage Decision-Making Systems
Zachary McBride Lazri, Anirudh Nakra, Ivan Brugere, Danial Dervovic, Antigoni Polychroniadou, Furong Huang, Dana Dachman-Soled, Min Wu
Algorithmic fairness is often studied in static or single-agent settings, yet many real-world decision-making systems involve multiple interacting entities whose multi-stage actions jointly influence long-term outcomes. Existing fairness methods applied at isolated decision points frequently fail to mitigate disparities that accumulate over time. Although recent work has modeled fairness as a sequential decision-making problem, it typically assumes centralized agents or simplified dynamics, limiting its applicability to complex social systems. We introduce **MAFE**, a suite of *Multi-Agent Fair Environments* designed to simulate realistic, modular, and dynamic systems in which fairness emerges from the interplay of multiple agents. We demonstrate MAFEs in three domains—loan processing, healthcare, and higher education—supporting heterogeneous agents, configurable interventions, and fairness metrics. The environments are open-source and compatible with standard multi-agent reinforcement learning (MARL) libraries, enabling reproducible evaluation of fairness-aware policies. Through extensive experiments on cooperative use cases, we demonstrate how MAFE facilitates the design of equitable multi-agent algorithms and reveals critical trade-offs between fairness, performance, and coordination. MAFE provides a foundation for systematic progress in dynamic, multi-agent fairness research.

Path-dependent Discrete Amortized Inference
Tiago Silva, Esmeralda S. Whitammer, Salem Lahlou
We consider the problem of sampling compositional and discrete objects from a given unnormalized posterior distribution.
Notably, recent studies have shown that this problem can be efficiently solved by learning a deterministic Markov Decision Process (MDP) that progressively builds each object in proportion to the posterior.

In this work, however, we demonstrate that the Markovian assumption can both ham per signal propagation during training and catastrophically reduce the learned s ampler's expressivity due to state aliasing.
To address these issues, we propose lifting the MDP with a learnable latent dyna mics that allows the underlying policy to depend on the entire past trajectory-- -and not only on the current state.
In view of this, we refer to the resulting method as \emph{path-dependent discre te amortized inference}.
Importantly, we provably extend existing learning algorithms for amortized sampl ers to our setting.
In experiments on standard benchmark problems, we also show that our approach of ten leads to faster learning convergence and improved state space exploration re latively to prior techniques.

Vegas: Self-Speculative Decoding with Verification-Guided Sparse Attention
Yikang Yue, Yuqi Xue, Jian Huang
Long-context large language model (LLM) inference has become the norm for today' s AI applications. However, it is severely bottlenecked by the increasing memory demands of its KV cache. Previous works have shown that self-speculative decodi ng with sparse attention, where tokens are drafted using a subset of the KV cach e and verified in parallel against the full KV cache, speeds up inference in a l ossless manner. However, they rely on a standalone KV selection algorithm to sel ect the KV entries used for drafting and overlook the fact that the criticality of each KV entry is inherently computed during verification.

In this paper, we propose Vegas, a self-speculative decoding method with verific ation-guided sparse attention. Vegas identifies critical KV cache entries as a b yproduct of verification and computes attention only over these entries when dra fting subsequent tokens. This not only improves the draft token acceptance rate but also incurs low KV selection overhead, thereby improving decoding throughput . Vegas achieves a 1.25$\times$–2.81$\times$ speedup in decoding throughput over default vLLM and a 1.15$\times$–1.29$\times$ speedup over state-of-the-art spar se attention-based self-speculative decoding methods. Our code is available at h ttps://github.com/platformxlab/vegas.

Active Learning with Foundation Model Priors: Efficient Learning under Class Imb alance
Jiancheng Zhang, Meiqing Li, Qi Zhang, Yinglun Zhu
Real-world datasets across image and text domains are often characterized by ske wed class distributions and noisy annotations, which jointly degrade model perfo rmance, particularly on minority classes. Among existing solutions, active learn ing offers an effective and efficient paradigm by selectively querying the most informative and balanced samples for annotation. We propose an innovative active learning framework that mitigates class imbalance and selects the most informat ive samples to annotate. Leveraging foundation model priors, our algorithm enabl es imbalance-aware co-decisions between foundation model and small model to tack le noisy and imbalanced labels across various domains. We introduce the first st udy to systematically explore active learning under the dual challenges of label noise and class imbalance across image and text domains. Extensive experiments on imbalanced datasets demonstrate that our method achieves substantial annotati on savings—over 50\% compared to the best active learning baseline—while preserv ing performance and robustness to label noise.

What Linear Probes Miss: Multi-View Probing for Weight-Space Learning
Eunwoo Heo, Kyeongkook Seo, Jaejun Yoo
The explosive growth of open-source model repositories has created a Model Jungl e, where checkpoints are frequently shared without adequate documentation or met adata. While weight-space learning offers a pathway to identify and analyze thes e models directly from their parameters, processing full-scale weights is comput ationally prohibitive. Probing-based methods have emerged as a lightweight alter

native, extracting permutation-equivariant representations via learnable probe v ectors. However, existing probing methods are limited by a single-view design: t hey capture first-order structures but fail to encode the rich, higher-order cor relation patterns inherent in row--column interactions. To bridge this gap, we i ntroduce MVProbe, a multi-perspective probing framework that synthesizes first-o rder signals with interaction-aware (Gram-based) views. Our approach is theoreti cally grounded; we analyze the scaling laws of different probing orders to deriv e a principled standardization and fusion strategy that ensures balanced contrib utions from all branches. On the Model Jungle benchmark, MVProbe consistently ou tperforms the state-of-the-art ProbeX across diverse architectures, including Re sNet, SupViT, MAE, and DINO.

Grounding Multi-Hop Reasoning in Structural Causal Models via Group Relative Pol icy Optimization

Yunhan Bu, quan zhang, Huaping Zhang, Guotong Geng, Chunxiao Gao, Askar Hamdulla , Juan Wang, Qiuchi Li, Baohua Zhang, Yunbo Cao, Zhunchen Luo, Shuai Lei

Multi-Hop Fact Verification requires complex reasoning across disparate evidence , posing significant challenges for Large Language Models , which may suffer fro m hallucinations and fractured logical chains. Existing methods, while improving transparency via Chain-of-Thought , often lack explicit modeling of the structu ral dependencies between evidence and claims. In this work, we introduce an SCM- inspired framework that grounds reasoning in explicit directed dependency graphs , treating verification as a constructive structural reasoning process rather th an full causal inference with interventions or counterfactual semantics. We empi rically identify an ``inverted U-shaped'' correlation between reasoning-chain le ngth and accuracy, revealing that excessive structural complexity can degrade pe rformance. To address this, we propose a rule-based reinforcement learning strat egy using Group Relative Policy Optimization. This approach dynamically optimize s the trade-off between structural depth and conciseness. Extensive experiments on HoVer and EX-FEVER demonstrate that our SCM-GRPO framework outperforms strong baselines while producing more traceable reasoning structures for complex fact verification.

Information Flow Reveals When to Trust Language Models

Rui Xu, Yi Chen, Jiujiu Chen, Sihong Xie

In retrieval-augmented generation, language models can generate incorrect respon ses if they fail to utilize query-relevant content from the retrieved evidence. This shifts the focus of uncertainty quantification (UQ) toward assessing contex tual grounding, i.e., whether predictions are supported by query-relevant tokens . Recent UQ methods unpack language models to characterize how inputs are proces sed. Nevertheless, these methods focus on a few layers and overlook the whole pr ogressive propagation within the model, thereby failing to fully capture the gro unding dynamics essential for reliable uncertainty estimation. We use informatio n flow to build a layer-wise trace that reveals each context token’s contributio n to the output, providing an interpretable basis for assessing reliability. Fro m this analysis, we introduce two measures to calibrate prediction confidence. T he first, \textit{simulatability}, posits that a prediction is more likely to be correct when context token contributions align closely with their true relevanc e. The second, \textit{concentration}, asserts that a response is more likely to be correct when it is derived from a narrow, focused subset of tokens. Experime nts show that our method achieves an average AUROC of 0.709, exceeding the runne r-up performance of 0.676, while maintaining moderate computational cost.

Evaluating AI Grading on Real-World Handwritten College Mathematics: A Large-Sca le Study Toward a Benchmark

Zhiqi Yu, Xingping Liu, Haobin Mao, Mingshuo Liu, Long Chen, Jack Xin, Yifeng Yu

Grading in large undergraduate STEM courses often yields minimal feedback due to heavy instructional workloads. We present a large-scale empirical study of AI g rading on real, handwritten single-variable calculus work from the University of California, Irvine. Using OCR-conditioned large language models with structured

, rubric-guided prompting, our system produces scores and formative feedback for thousands of handwritten, in-person proctored free-response quiz submissions from nearly 800 students included in the paper’s empirical analysis. In a setting with no single ground-truth label, we evaluate performance against official teaching-assistant grades, student surveys, and independent human review, finding strong alignment with TA scoring and a large majority of AI-generated feedback rated correct or acceptable across quizzes. Beyond calculus, this setting highlights core challenges in OCR-conditioned mathematical reasoning and partial-credit assessment. We analyze key failure modes, propose practical rubric- and prompt-design principles, and introduce a multi-perspective evaluation protocol for reliable real-course deployment. Building on the dataset and evaluation framework developed here, we outline a path toward a future standardized benchmark for AI grading of handwritten mathematics to support reproducible evaluation, transparent comparison, reliable deployment, and future research.

Learning-Augmented Online Covering Problems
Afrouz Jabal Ameli, Laura Sanità, Moritz Venzin
We give a very general and simple framework to incorporate predictions on requests for online covering problems in a rigorous and black-box manner. Our framework turns any online algorithm with competitive ratio $\rho(k, \cdot)$ depending on k, the number of arriving requests, into an algorithm with competitive ratio of $\rho(\eta, \cdot)$, where η is the prediction error. With accurate enough prediction, the resulting competitive ratio breaks through the corresponding worst-case online lower bounds, and smoothly degrades as the prediction error grows. This framework directly applies to a wide range of well-studied online covering problems such as facility location, Steiner problems, set cover, parking permit, etc., and yields improved and novel bounds.

Tiny Brains, Giant Impact: Uncovering the Keystone Neurons of LLM with Just a Few Prompts
Xiangtian Ji, Yuxin Chen, Zhengzhou Cai, Xiang Wang, An Zhang, Tat-Seng Chua
Large language models (LLMs) display strong comprehensive abilities, yet the internal mechanisms that support these behaviors remain insufficiently understood.
In this work, we show that across a wide range of open-weight Transformers, a subset of neurons remains consistently highly activated during inference across tasks of multiple capability dimensions.
By probing along the cross-task activation strength, an extremely sparse subset is isolated, whose removal causes a collapse in model behavior, which we term keystone neurons.
Our analysis reveals that keystone neurons are a stable and intrinsic neuron subset of the model that is largely established during pretraining.
The parameters associated with these neurons are tightly calibrated during the training process, and their precise values are critical for the capabilities of the model.
Building on these insights, we propose a supervised fine-tuning approach that updates only keystone neurons, achieving task gains comparable to or even better than full-parameter fine-tuning while better preserving performance in other capability dimensions, despite modifying a much smaller number of parameters.

ViewMask-1-to-3: Multi-View Consistent Image Generation via Multimodal Discrete Diffusion Models
Ruishu Zhu, Zhihao Huang, Jiacheng Sun, Ping Luo, Hongyuan Zhang, Xuelong Li
Motivated by discrete diffusion's success in language-vision modeling, we explore its potential for multi-view generation, a task dominated by continuous approaches. We introduce **ViewMask-1-to-3**, formulating multi-view generation as a discrete sequence modeling problem where each viewpoint is represented as visual tokens from MAGVIT-v2. Through **discrete diffusion** via masked token prediction, our approach **enables progressive multi-view generation via iterative token unmasking**, unifying language and vision in a shared token space. Importantly, simple random masking combined with self-attention naturally encourages cross-vi

ew consistency without specialized architectures or 3D geometric priors. Our met hod outperforms the baseline on the GSO and 3D-FUTURE benchmarks, ranking first on average across standard image metricsand, and achieving a 10.6% higher IoU th an continuous diffusion models on 3D-FUTURE. Furthermore, the proposed framework can be naturally extended to support text-to-image generation and multimodal un derstanding, highlighting its potential toward a more unified paradigm for multi modal understanding and generation.

Med-SegLens: Latent-Level Model Diffing for Interpretable Medical Image Segmenta tion
Salma J. Ahmed, Emad Mohammed, Azam Asilian Bidgoli
Modern segmentation models achieve strong predictive performance but remain larg ely opaque, limiting our ability to diagnose failures, understand dataset shift, or intervene in a principled manner. We introduce $\textbf{Med-SegLens}$, a mod el-diffing framework that decomposes segmentation model activations into interpr etable latent features using sparse autoencoders trained on SegFormer and U-Net. Through cross-architecture and cross-dataset latent alignment across healthy, a dult, pediatric, and sub-Saharan African glioma cohorts, we identify a stable ba ckbone of shared representations, while dataset shift is driven by differential reliance on population-specific latents. We show that these latents act as causa l bottlenecks for segmentation failures, and that targeted latent-level interven tions can correct errors and improve cross-dataset adaption without retraining, recovering performance in 70% of failure cases and improving Dice score from 39. 4% to 74.2%. Our results demonstrate that latent-level model diffing provides a practical and mechanistic tool for diagnosing failures and mitigating dataset sh ift in segmentation models.

Conditional Coverage Diagnostics for Conformal Prediction
Sacha Braun, David Holzmüller, Michael I. Jordan, Francis Bach
Evaluating conditional coverage remains one of the most persistent challenges in assessing the reliability of predictive systems.
Although conformal methods can give guarantees on marginal coverage, no method c an guarantee to produce sets with correct conditional coverage, leaving practiti oners without a clear way to interpret local deviations.
To overcome sample-inefficiency and overfitting issues of existing metrics, we c ast conditional coverage estimation as a classification problem. Conditional cov erage is violated if and only if some classifier can achieve lower risk than the target coverage. Through the choice of a (proper) loss function, the resulting risk difference gives a conservative estimate of natural miscoverage measures su ch as L1 and L2 distance, and can even separate the effects of over- and under-c overage, as well as handle non-constant target coverages. We call the resulting family of metrics excess risk of the target coverage (ERT). We show experimental ly that the use of modern classifiers provides much higher statistical power tha n simple classifiers underlying established metrics like CovGap.
Additionally, we use our metric to benchmark different conformal prediction meth ods.
Finally, we release an open-source package for ERT as well as previous condition al coverage metrics. Together, these contributions provide a new lens for unders tanding, diagnosing, and improving the conditional reliability of predictive sys tems.

Uncovering Grounding IDs: How External Cues Shape Multi-Modal Binding
Amirmohammad Izadi, Hosein Hasani, Fatemeh Askari, Mobin Bagherian, Sadegh Moham madian, Mohammad Izadi, Mahdieh Soleymani Baghshah
Large vision–language models (LVLMs) perform well on multimodal tasks, but their ability to reason and precisely align visual and textual information still has room for improvement. In this study, we show that external visual cues, such as symbols or grid lines, help LVLMs form more accurate connections between visual components, such as objects, and their corresponding textual descriptions, impro ving their grounding and reasoning abilities. We introduce the concept of Ground

ing IDs, which are latent identifiers that arise within the model as a result of external cues structuring both visual and textual modalities. Our analysis reveals that partition-inducing external cues lead to Grounding IDs that make better alignment between corresponding visual and text representations, helping the model focus on relevant information. We find that Grounding IDs enhance attention between related components, improving cross-modal grounding and reducing hallucinations. Overall, our results show that Grounding IDs are a key mechanism that enables external cues to improve cross-modal alignment, reduce errors, and enhance the overall performance of LVLMs across a range of multimodal tasks.

Probing the Inductive Bias of Neural Networks through Learning Random Cellular Automata

Jan Disselhoff, Michael Wand

Why do neural networks generalize well on natural data? Natural data originates from processes subject to specific physical constraints, such as temporal and spatial invariance, that make it easier to learn. We investigate the sufficiency of these properties using 2D cellular automata as a controlled testbed: systems that are perfectly local, symmetric, and deterministic. We find that these conditions alone are \textit{not sufficient} to predict the k-step evolution of a cellular automaton. We then examine smoothness (average sensitivity) as an additional criterion and find it predictive but still incomplete. Finally, we introduce a circuit complexity perspective, hypothesizing that natural functions are computable by small circuits. Junta coefficients, measuring the concentration of Fourier weight by interaction degree, provide a tighter predictor of learnability and a correspondence to combinatorial complexity. Across architectures (CNNs, transformers, MLPs), learnable functions are predominantly those with spectral weight concentrated at low degrees and therefore low complexity. These results would be consistent with the hypothesis that natural data is learnable because natural dynamics filters out complex, high-degree interactions.

EchoAttention: Exploiting Token-Pair Redundancy and Frame-Block Similarity for Efficient Video Generation

Yifei Xia, Fangcheng Fu, Hao Yuan, Suhan Ling, Xupeng Miao, Huixia Li, Yuxi Ren, Xin Xia, Xuefeng Xiao, Bin CUI

Diffusion Transformers (DiTs) are increasingly adopted for long-video generation, yet inference is dominated by the quadratic cost of 3D full attention.
Sparse attention mitigates this bottleneck by exploiting *token-pair redundancy* and pruning query-key interactions.
Nevertheless, its effectiveness on video generation is often constrained by non-sparse attention heads, making it hard to strike a good balance between inference speed and generation quality.
To address this, we identify another pervasive but overlooked redundancy specific to video DiTs: *frame-block similarity*, where frame-blocks in attention weights exhibit highly similar distributions and can be well approximated by lightweight linear calibration.
Motivated by this observation, we propose **EchoAttention**, which jointly leverages *token-pair redundancy* (*Sparse* operator) and *frame-block similarity* (*Echo* operator), together with a fine-grained routing policy learned via three-stage distillation.
This design enables efficient handling of both sparse and non-sparse heads, overcoming the inherent ceiling of purely sparse attention and yielding a better speed-quality trade-off.
Across public video DiTs, EchoAttention consistently improves the speed-quality frontier over SOTA sparse-attention baselines, reducing end-to-end latency up to 2.42$\times$ with minimal quality loss.

Zero-Flow Encoders

Yakun Wang, Leyang Wang, Song Liu, Taiji Suzuki

Flow-based methods have achieved significant success in various generative modeling tasks, capturing nuanced details within complex data distributions. However,

few existing works have exploited this unique capability to resolve fine-graine
d structural details beyond generation tasks. This paper presents a flow-inspire
d framework for representation learning. First, we demonstrate that a rectified
flow trained using independent coupling is zero everywhere at $t=0.5$ if and onl
y if the source and target distributions are identical. We term this property th
e *zero-flow criterion*. Second, we show that this criterion can certify conditi
onal independence, thereby extracting \emph{sufficient information} from the dat
a. Third, we translate this criterion into a tractable, simulation-free loss fun
ction that enables learning amortized Markov blankets in graphical models and la
tent representations in self-supervised learning tasks. Experiments on both simu
lated and real-world datasets demonstrate the effectiveness of our approach.

SSL4RL: Revisiting Self-supervised Learning as Intrinsic Reward for Visual-Langu
age Reasoning
Xiaojun Guo, Runyu Zhou, Yifei Wang, Qi Zhang, Chenheng Zhang, Stefanie Jegelka,
Xiaohan Wang, Jiajun Chai, Guojun Yin, Wei Lin, Yisen Wang
Vision-language models (VLMs) have shown remarkable abilities by integrating lar
ge language models with visual inputs. However, they often rely on textual short
cuts rather than adequately using visual evidence during reasoning. Although rei
nforcement learning (RL) can align models with desired behaviors, its applicatio
n to VLMs has been hindered by the lack of scalable and reliable rewards. To ove
rcome this challenge, we propose **SSL4RL**, a novel framework that leverages se
lf-supervised learning (SSL) tasks as a source of verifiable rewards for RL. Our
approach reformulates SSL objectives like rotation prediction and patch reconst
ruction into dense automatic rewards, removing the need for human preferences or
AI evaluators. Experiments show that SSL4RL substantially improves performance
on both vision-centric and vision-language reasoning benchmarks, with encouragin
g potentials on open-ended scenarios and stronger resilience to visual corruptio
ns. Through systematic ablations, we identify key factors influencing SSL4RL, in
cluding data volume, model scale, model choice, task combination, and task diffi
culty, thereby offering new design principles for future work. Our implementatio
n is open-sourced at https://github.com/PKU-ML/SSL4RL, with models hosted on Hug
gingface collection https://huggingface.co/collections/PKU-ML/ssl4rl.

Optimal conversion from Rényi Differential Privacy to f-Differential Privacy
Anneliese Riess, Juan Felipe Gomez, Flavio Calmon, Julia Schnabel, Georgios Kais
sis
We prove the conjecture stated in Appendix F.3 of Zhu et al.: among all conversi
on rules that map a Rényi Differential Privacy (RDP) profile $\tau \mapsto \rho(
\tau)$ to a valid hypothesis-testing trade-off f (or equivalently, an $(\varep
silon,\delta)$-Differential Privacy curve), the rule based on the intersection o
f single-order RDP privacy regions is optimal.

This optimality holds simultaneously for all valid RDP profiles and for all
Type I error levels α.

Concretely, we show that in the space of trade-off functions, the tightest p
ossible bound is $f_{\rho(\cdot)}(\alpha) = \sup_{\tau \geq 0.5} f_{\tau,\rho(\t
au)}(\alpha)$: the pointwise maximum of the single-order bounds for each RDP pri
vacy region.

Our proof unifies and sharpens the insights of Balle et al., Asoodeh et al.,
and Zhu et al..

Our analysis relies on a precise geometric characterization of the RDP priva
cy region, leveraging its convexity and the fact that its boundary is determined
exclusively by Bernoulli mechanisms.

Our results establish that the "intersection-of-RDP-privacy-regions" rule is
not only valid, but optimal: no other black-box conversion can uniformly domina
te it in the Blackwell sense, marking the fundamental limit of what can be infer
red about a mechanism's privacy solely from its RDP guarantees.

HiMe: Hierarchical Embodied Memory for Long-Horizon Vision-Language-Action Contr
ol

Li Ji, Siyin Wang, Pengfang Qian, Xiaopeng Yu, Yihai Tian, Zhaoye Fei, Jingjing Gong, Xipeng Qiu
Current Vision-Language-Action (VLA) models excel at robotic manipulation but often struggle with non-Markovian tasks requiring long-term memory and reasoning due to their reliance on immediate observations. Existing solutions face a frequency-competence paradox, where high-performance models are too slow for real-time control, while faster models lack sufficient reasoning capabilities. To resolve this architectural misalignment, we propose **HiMe**, a Hierarchical Embodied Memory framework that decouples embodied intelligence into a high-frequency Executor for execution, a Sentry for working memory, and a Planner for long-term strategy. We also introduce a dynamic knowledge system based on cross-modal semantic schemas and active management mechanisms, allowing robots to maintain memory plasticity through "Add, Update, and Delete" operations. This hierarchical design effectively balances the conflict between real-time execution and slow thinking planning, significantly improving success rates in long-horizon tasks. Experiments demonstrate that this approach not only outperforms flat memory baselines but also exhibits the novel ability to self-correct its internal knowledge based on human preferences.
****
Reverse Flow Matching: A Unified Framework for Online Reinforcement Learning with Diffusion and Flow Policies
Zeyang Li, Sunbochen Tang, Navid Azizan
Diffusion and flow policies are gaining prominence in online reinforcement learning (RL) due to their expressive power, yet training them efficiently remains a critical challenge. A fundamental difficulty that distinguishes online RL from standard generative modeling is the lack of direct samples from the target Boltzmann distribution defined by the Q-function. To address this, two seemingly distinct families of methods have been proposed for diffusion policies: a noise-expectation family, which uses a weighted average of noise as the training target, and a gradient-expectation family, which employs a weighted average of Q-function gradients. However, it remains unclear how these objectives are formally related, or whether they can be synthesized into a more general formulation. In this paper, we propose a unified framework, reverse flow matching (RFM), which rigorously addresses the problem of training diffusion and flow models without direct target samples. By adopting a reverse inferential perspective, we formulate the training target as a posterior mean estimation problem given an intermediate noisy sample. Crucially, we introduce Langevin Stein operators to construct zero-mean control variates, deriving a general class of estimators that share the same expectation. We show that existing noise-expectation and gradient-expectation methods are simply two specific instances within this broader class. This unified view yields two key advancements: it extends the capability of targeting Boltzmann distributions from diffusion to flow policies, and it enables the principled combination of Q-value and Q-gradient information to form an effective estimator, thereby improving training efficiency and stability. We instantiate RFM to train a flow policy in online RL and demonstrate improved performance on continuous-control benchmarks compared to diffusion policy baselines.
****
Sequential Kernel-based Conditional Independence Testing via Adaptive Betting
Zheng He, Danica J. Sutherland
Testing conditional independence is fundamental yet intrinsically difficult:
  without additional assumptions, Type I error control is impossible in general.
  The ``Model-X'' paradigm addresses this difficulty by assuming exact knowledge of a relevant conditional distribution.
  While small deviations from this assumption can sometimes be tolerated in classical one-shot testing,
  existing sequential conditional independence tests typically require the Model-X conditional to be known exactly,
  making them fragile when it must instead be estimated.
  We propose a new approach that is substantially more robust to such estimation error.

Our method applies testing-by-betting to an adaptively optimized Kernel Conditional Independence statistic,
together with a normalization scheme and a truncate-and-shift calibration strategy.
These modifications greatly reduce Type I error inflation while preserving high power
across high-dimensional synthetic benchmarks and real-world fairness tasks, outperforming existing sequential Model-X approaches.
Code is available at \url{https://github.com/he-zh/SKCI}.
****

SplAttN: Bridging 2D and 3D with Gaussian Soft Splatting and Attention for Point Cloud Completion
Zhaoyang Li, Zhichao You, Tianrui Li
Although multi-modal learning has advanced point cloud completion, the theoretical mechanisms remain unclear. Recent works attribute success to the connection between modalities, yet we identify that standard hard projection severs this connection: projecting a sparse point cloud onto the image plane yields an extremely sparse support, which hinders visual prior propagation, a failure mode we term Cross-Modal Entropy Collapse. To address this practical limitation, we propose SplAttN, which replaces hard projection with Differentiable Gaussian Splatting to produce a dense, continuous image-plane representation. By reformulating projection as continuous density estimation, SplAttN avoids collapsed sparse support, facilitates gradient flow, and improves cross-modal connection learnability. Extensive experiments show that SplAttN achieves state-of-the-art performance on PCN and ShapeNet-55/34. Crucially, we utilize the real-world KITTI benchmark as a stress test for multi-modal reliance. Counter-factual evaluation reveals that while baselines degenerate into unimodal template retrievers insensitive to visual removal, SplAttN maintains a robust dependency on visual cues, validating that our method establishes an effective cross-modal connection. Code is available at https://github.com/zay002/SplAttN.

Security--Fidelity Tradeoffs: The Hidden Cost of Prompt Injection Defense
Mitchell Hermon, Rahul Gupta, Weitong Ruan, Ekraam Sabir, Haohan Wang
We identify a **security--fidelity tradeoff** in defending LLMs against indirect prompt injection: defenses resist injected instructions largely by
suppressing untrusted text, which corrupts tasks that must preserve it, such as translation and document editing. Attack-success metrics cannot see this, because a model that ignores an injection and one that faithfully processes it as data score identically. We introduce **SecFid**, a benchmark built so that *executing* an injection, *processing* it as data, and *ignoring* it produce distinguishable outputs. This makes fidelity measurable, and exposes a frontier: across 1,168 examples and 48 configurations, no model or defense
achieves both objectives. The highest-fidelity model reaches 96.5% fidelity at 47.8% security, while the most secure defenses invert this, at 99.3% security but only 71.0%--73.9% fidelity. Even defenses with identical security differ in how they earn it: some repair hijacks into faithful processing, others simply suppress benign content. A decision-theoretic analysis shows why no fixed choice can be right everywhere: the correct behavior is not a property of the defense but of the deployment, set by its relative cost of a hijack versus a dropped span. Security alone therefore measures only half of robustness, and reporting it without fidelity hides the price at which it was bought.
****

Neural Logistic Bandits
Seoungbin Bae, Dabeen Lee
We study the problem of neural logistic bandits, where the main task is to learn an unknown reward function within a logistic link function using a neural network. Existing approaches either exhibit unfavorable dependencies on κ, where $1/\kappa$ represents the minimum variance of reward distributions, or suffer from direct dependence on the feature dimension d, which can be huge in neural network–based settings. In this work, we introduce a novel Bernstein-type ineq

uality for self-normalized vector-valued martingales that is designed to bypass a direct dependence on the ambient dimension. This lets us deduce a regret upper bound that grows with the effective dimension $\widetilde{d}$, not the feature dimension, while keeping a minimal dependence on κ. Based on the concentration inequality, we propose two algorithms, NeuralLog-UCB-1 and NeuralLog-UCB-2, that guarantee regret upper bounds of order $\widetilde{O}(\widetilde{d}\sqrt{\kappa T})$ and $\widetilde{O}(\widetilde{d}\sqrt{T/\kappa})$, respectively, improving on the existing results. Lastly, we report numerical results on both synthetic and real datasets to validate our theoretical findings.

Reward-free Alignment for Conflicting Objectives

Peter Chen, Xiaopeng Li, Xi Chen, Tianyi Lin

Direct alignment methods are increasingly used to align large language models (LLMs) with human preferences. However, many real-world alignment problems involve multiple conflicting objectives, where naive aggregation of preferences can lead to unstable training and poor trade-offs. In particular, weighted loss methods may fail to identify update directions that simultaneously improve all objectives, and existing multi-objective approaches often rely on explicit reward models, introducing additional complexity and distorting user-specified preferences. The contributions of this paper are two-fold. First, we propose a **R**eward-free **A**lignment framework for **C**onflicted **O**bjectives (RACO) that directly leverages pairwise preference data and resolves gradient conflicts via a novel clipped variant of conflict-averse gradient descent. We provide convergence guarantees to Pareto-critical points that respect user-specified objective weights, and further show that clipping can strictly improve convergence rate in the two-objective setting. Second, we improve our method using some heuristics and conduct experiments to demonstrate the compatibility of the proposed framework for LLM alignment. Both qualitative and quantitative evaluations on multi-objective summarization and safety alignment tasks across multiple LLM families (Qwen 3, Llama 3, Gemma 3) show that our method consistently achieves better Pareto trade-offs compared to existing multi-objective alignment baselines.

Incremental Learning of Sparse Attention Patterns in Transformers

O■uz Kaan Yüksel

This paper studies simple transformers trained on a high-order Markov chain, where the model must incorporate information from multiple past positions, each with different statistical importance. We show that transformers learn the task incrementally, with each stage corresponding to learning how to copy information from a subset of positions via a sparse attention pattern. Notably, the learning dynamics transition from a competitive phase, where all heads focus on the statistically most important positions, to a cooperative phase, where different heads specialize in different patterns. We model these dynamics with simplified differential equations and prove stage-wise convergence of the resulting system. Functionally, these stages correspond to a sequence of increasingly expressive misspecified models, with the full model class reached only at the end. Overall, we give a theoretical account of how structured attention patterns and head specialization emerge in stages without an explicit curriculum, with implications for generalization in sequential tasks.

Representational Similarity and Model Behavior in Multi-Agent Interaction

Yujin Potter, Seun Eisape, Shiyang Lai, Alexander Huth, James Evans, Been Kim, Jacob Eisenstein, Dawn Song, Alane Suhr

Researchers have shown that neural similarity among humans predicts social closeness and cooperative success, whereas innovation often emerges from interactions among dissimilar individuals. We investigate whether these principles extend to artificial intelligence by examining interactions between large language models. In our experiments, 276 model pairs interact across eight games spanning both cooperation and novelty. We find that pairs with more similar representation spaces achieve significantly higher cooperation but exhibit reduced novelty and creativity. The effects of representational similarity on cooperation and novelty r

emain robust even after controlling for other factors such as performance disparity and model size. We also find that similarity in the early layers consistently shows the strongest association with cooperation and novelty, compared to the middle and later layers. This suggests that a central factor underlying these patterns could be the extent to which the two models share lexical and semantic grounding. Overall, representational similarity can be an important consideration in multi-agent system design.

Induction Meets Biology: Mechanisms of Repeat Detection in Protein Language Models
Gal Pomerants, Yaniv Nikankin, Anja Reusch, Tomer Tsaban, Ora Schueler-Furman, Yonatan Belinkov
Protein sequences are abundant in repeating segments, both as exact copies and as approximate segments with mutations.
These repeats are important for protein structure and function, motivating decades of algorithmic work on repeat identification.
Recent work has shown that protein language models (PLMs) identify repeats, by examining their behavior in masked-token prediction.
To elucidate their internal mechanisms, we investigate how PLMs detect both exact and approximate repeats.
We find that the mechanism for approximate repeats functionally subsumes that of exact repeats.
We then characterize this mechanism, revealing two main stages: PLMs first build feature representations using both general positional attention heads and biologically specialized components, such as neurons that encode amino-acid similarity.
Then, induction heads attend to aligned tokens across repeated segments, promoting the correct answer.
Our results reveal how PLMs solve this biological task by combining language-based pattern matching with specialized biological knowledge, thereby establishing a basis for studying more complex evolutionary processes in PLMs.

DroneDINO: Towards Heterogeneous Routed Mixture of Experts for Drone-based Unified Object Detection
Dongdong Li, Rui Chen, Yan Fan, Yan Liu, Yangliu Kuai, Pengfei Zhu
Recently, the rapid development of low-altitude aerial applications has driven the need for drone-based unified detectors. In contrast to task-specific detectors that suffer from poor scalability across diverse scenarios, existing unified detectors leverage the Mixture-of-Experts (MoE) architecture to learn task-aware features from diverse datasets. However, the imbalanced multi-task data distribution leads to over-activation of experts for dominant tasks and under-activation for others. To enable balanced feature learning, this paper combines three detection paradigms (RGB, IR, and RGB-IR) into a unified framework termed DroneDINO. DroneDINO extends DINO by introducing heterogeneous routed MoEs that organize experts into three functional groups: shared, task-specific, and dynamic. Unlike conventional dynamic experts where the top-k experts are activated for each input, the shared expert is activated for all inputs, while each task-specific expert is activated exclusively for the matching task. To ensure inputs are routed to appropriate experts and yield task-discriminative features, we propose a task-recognition auxiliary training strategy to penalize features with low task-discriminability. Experiments demonstrate the effectiveness and generalizability of DroneDINO, which consistently outperforms state-of-the-art unified and task-specific detectors across multiple drone-based detection benchmarks.

Disentangling Latent Risk Pathways via Bayesian Hypergraph Inference
Shengxian Ding, Haonan Gao, Pangpang Liu, Xinyuan Tian, Yize Zhao
Electronic health records (EHR) pose large-scale multi-disease modeling problems in which many outcomes are rare and strongly influenced by shared risk factors. While modern approaches achieve strong predictive performance, they often treat diseases independently or rely on black-box architectures, offering limited ins

ight into how risk factors organize disease risk and little principled uncertain ty quantification.
We introduce a Bayesian hypergraph inference framework that reframes multi-disea se modeling around **latent, risk-factor-modulated disease pathways**. Risk fact ors act on hyperedges, latent disease subsets with shared risk patterns, allowin g diseases to participate in multiple distinct pathways and enabling interpretab le, higher-order structure beyond pairwise associations. A repulsion prior encou rages parsimonious and identifiable structure, while posterior inference provide s calibrated uncertainty over both disease groupings and risk-factor influence.
To enable scalable inference on large EHR datasets, we develop a structured vari ational inference algorithm that preserves logical dependencies among hyperedge existence, disease membership, and pathway-level effects.
Experiments on simulated data and UK Biobank demonstrate stable and interpretabl e disease pathway structure, well-calibrated uncertainty, improved estimation fo r rare diseases, and competitive predictive performance.

ePC: Fast and Deep Predictive Coding in Digital Simulation
Cédric Goemaere, Gaspard Oliviers, Rafal Bogacz, Thomas Demeester
Predictive Coding (PC) offers a brain-inspired alternative to backpropagation fo r neural network training, described as a physical system minimizing its interna l energy. While ideally suited for analog implementation, such hardware does not exist yet, and thus, in practice, PC is predominantly *digitally simulated*, re quiring excessive amounts of compute while struggling to scale to deeper archite ctures. This paper reformulates PC to overcome this hardware-algorithm mismatch. First, we uncover how the canonical state-based formulation of PC (sPC) is, by design, deeply inefficient in digital simulation, inevitably resulting in expone ntial signal decay that stalls the entire numerical process. Then, to overcome t his fundamental limitation, we introduce error-based PC (ePC), a novel reparamet erization of PC which does not suffer from signal decay. Though no longer direct ly implementable in analog, ePC numerically computes *exact* PC weights gradient s and runs orders of magnitude faster than sPC. Experiments across multiple arch itectures and datasets demonstrate that ePC matches backpropagation's performanc e even for deeper models where sPC struggles. Besides practical improvements, ou r work provides theoretical insight into PC dynamics and establishes a foundatio n for scaling PC-based learning to deeper architectures in digital simulation an d beyond.

AnyMod-LLVE: Low-Light Video Enhancement with Modality-Agnostic Inference
Hangfeng Liang, Yutao Hu, Yanhan Hu, Xiaohan Wu, Wenqi Shao, Ying Fu
Low-light video enhancement (LLVE) remains a challenging task due to severe info rmation degradation under low-illumination conditions. Recent multimodal approac hes have significantly improved enhancement performance by incorporating auxilia ry modalities, such as event streams and infrared images. However, these methods typically assume the availability of these modalities at inference, which is of ten not feasible in real-world scenarios. To solve this problem, in this work, w e propose AMNet, a unified multimodal framework for LLVE, to support flexible mo dality-agnostic inference, where auxiliary modalities may be unavailable. To add ress the issue of modality absence, we introduce a Spatial-Spectral Dual-Gated T ranslator that learns the correspondence between auxiliary modalities and RGB in puts, producing implicit auxiliary representations to support the robust enhance ment. Additionally, to fully facilitate the learning of cross-modal corresponden ce, we conduct large-scale multimodal pretraining based on the RGB-only dataset with synthetic auxiliary modalities. Extensive experiments demonstrate that AMNe t could handle arbitrary inference-time modality combinations and exhibits super ior performance for LLVE under modality absence conditions. Code and models are available on the project page.

RL with Learnable Textual Feedback: A Bilevel Approach
Utsav Singh, Sidhaarth Sredharan Murali, Souradip Chakraborty, Amrit Singh Bedi
Reinforcement learning with verifiable rewards can improve LLM reasoning, but le

arning remains sample-inefficient when terminal rewards are sparse. This has mot
ivated a growing line of work on RL with textual feedback, where a critic model
generates natural language feedback to guide a reasoning model (the actor), augm
enting scalar rewards with richer learning signals. However, existing methods ty
pically treat feedback as fixed or auxiliary, which misses a key property: feedb
ack should not merely be correct, but should improve the policy (actor model) wh
en provided in context. This motivates a paradigm of \textit{learnable textual f
eedback for RL}. Yet the learnability and usefulness of feedback depend on the p
olicy's ability to learn from it, making RL with learnable feedback an inherentl
y bilevel problem. We formalize this coupling as a Stackelberg bilevel program a
nd derive \emph{Bilevel Natural Language Actor-Critic} (Bi-NAC), which jointly t
rains a critic to generate reward-improving feedback and an actor to exploit it.
 Across MATH-500, MBPP, and GPQA, Bi-NAC improves sample and parameter efficienc
y over RL and fixed-critic baselines: our 2B model outperforms the 3B GRPO basel
ine, achieving 46.6% versus 41.4% on MATH-500, while our 6B model surpasses the
7B GRPO baseline, achieving 49.3% versus 43.6% on GPQA. Our code is available at
 [GitHub Repository](https://github.com/sid-in-the-loop/Bi-Natural-Language-Acto
r-Critic/).

Rethinking Parameter Sharing as Graph Coloring for Structured Compression
Boyang Zhang, Daning Cheng, Yunquan Zhang, Fangming Liu
Parameter sharing is a key model compression technique, yet existing methods ove
rlook the geometric properties of the loss landscape, often causing severe accur
acy degradation under high compression ratios. Inspired by second-order optimiza
tion, we propose Curvature-aware Graph Coloring (CGC), a cross-layer parameter s
haring framework that treats each network layer as a graph node, with each node
assigned to a shared low-rank basis. CGC leverages Hessian eigenspace informatio
n to group layers with similar curvature profiles, aligning the perturbations in
troduced by parameter sharing with the low-curvature (flat) directions of the lo
ss ellipsoid. This effectively mitigates performance loss while enabling flexibl
e, global cross-layer sharing.
Experiments on LLaMA-7B and Swin Transformer show that CGC achieves 28\%–50\% pa
rameter compression with Top-1 accuracy loss no more than 0.01\% on Swin—or even
 accuracy gains on LLaMA—while delivering over 60\% higher inference throughput,
 significantly outperforming SVD-based and heuristic-based methods. This work de
monstrates that curvature-guided, geometry-aware sharing is essential for effici
ent, stable, and high-ratio model compression.

CriticalKV: Optimizing KV Cache Eviction from an Output Perturbation Perspective
Yuan Feng, Junlin Lv, Haoyu Guo, Yukun Cao, S Kevin Zhou, Xike Xie
Large language models have revolutionized natural language processing but face s
ignificant challenges of high storage and runtime costs, due to the transformer
architecture's reliance on self-attention, particularly the large KV cache for l
ong-sequence inference.
Recent efforts to reduce KV cache size by pruning less critical entries based on
 attention weights remain empirical and lack formal grounding. This paper presen
ts a formal study on identifying critical KV cache entries by analyzing attentio
n output perturbation.
Our analysis reveals that, beyond attention weights, the value states within KV
entries and pretrained parameter matrices are also crucial.
Based on this, we propose a perturbation-constrained selection algorithm that op
timizes the worst-case output perturbation to identify critical entries. We demo
nstrate that our algorithm is a universal, plug-and-play enhancement that incurs
 negligible computational overhead. When integrated with three state-of-the-art
cache eviction methods on three distinct LLMs, our algorithm significantly reduc
es the compression loss by more than \textit{half} on average across 29 datasets
 from the Ruler and LongBench benchmarks. Further perturbation analysis, at both
 the head and layer levels, confirms the principles underlying our effectiveness
. This work offers a new, formally grounded perspective to cache eviction , ope
ning promising avenues for future research. The code is publicly available at \u

rl{https://github.com/FFY0/DefensiveKV}.

Is Data Shapley Not Better than Random in Data Selection? Ask NASH
Xiao Tian, Jue Fan, Rachael Hwee Ling Sim, Wang Zixuan, Nancy F. Chen, Bryan Kian Hsiang Low
Data selection studies the problem of identifying high-quality subsets of training data. While some existing works have considered selecting the subset of data with top-m Data Shapley or other semivalues as they account for the interaction among every subset of data, other works argue that Data Shapley can sometimes perform ineffectively in practice and select subsets that are *no better than random*. This raises the questions: **(I)** *Are there certain "Shapley-informative" settings where Data Shapley consistently works well?* **(II)** *Can we strategically utilize these settings to select high-quality subsets consistently and efficiently?*
In this paper, we propose a novel data selection framework, **NASH** (Non-linear Aggregation of SHapley-informative components), which **(I)** decomposes the target utility function (e.g., validation accuracy) into simpler, Shapley-informative component functions, and selects data by optimizing an objective that **(II)** aggregates these components non-linearly. We demonstrate that NASH substantially boosts the effectiveness of Shapley/semivalue-based data selection with minimal additional runtime cost.

Joint Model and Data Sparsification via the Marginal Likelihood
Alexander Timans, Thomas Möllenhoff, Christian A. Naesseth, Mohammad Emtiyaz Khan, Eric Nalisnick
Sparse recovery in linear systems underpins applications from signal processing to high-dimensional regression. Sparse Bayesian Learning, grounded in the principle of automatic relevance determination (ARD), offers a practical Bayesian mechanism for feature sparsity via marginal likelihood optimization. Yet, its reliance on a homoscedastic noise model renders it sensitive to data contaminations such as outliers or misspecified noise, harming model fit and predictions. Instead, we propose jointly learning individual feature and sample relevancies, enabling simultaneous model and data sparsification via a single Bayesian objective. This symmetric pruning of model and data offers a natural extension that preserves conjugacy, admits closed-form updates for standard optimization procedures, and aligns with perspectives from robust regression and influence functions. Empirical results across diverse regression tasks affirm that a joint ARD approach consistently yields both sparse and robust prediction models.

Activation with Intrinsic-Extrinsic Consensus
Tian Qiu, Zunlei Feng, Yang Gao, Bingde Hu, Yi Gao, Mingli Song
Artificial Neural Networks (ANNs) are powerful tools for complex decision-making tasks. While existing activation mechanisms often promote sparsity through thresholding, they lack explicit awareness of feature channel relevance, causing networks to continuously suffer from interference by noisy channels. Such irrelevant activation signals can propagate through the network and adversely affect the final decision. Inspired by observations that channel relevance can be reflected in both intrinsic activity levels and extrinsic decision weights, and that there is strong consensus between these two aspects, we propose AIEC (Activation with Intrinsic-Extrinsic Consensus), a novel activation mechanism that has the ability to identify and suppress irrelevant feature channels during training. With a basic threshold activation, AIEC integrates an intrinsic Activation-Counting Unit that tracks channel activation statistics, an extrinsic Decision-Making Unit that learns channel decision weights, and a Consensus Gatekeeping Unit that suppresses irrelevant channels based on the agreement between intrinsic and extrinsic channel relevance assessments. Extensive experiments demonstrate that AIEC can effectively suppress irrelevant channels and encourage sparser representations. Furthermore, AIEC is compatible with a wide range of mainstream ANN architectures and achieves superior performance compared to existing activation mechanisms across multiple tasks and domains. Code is available at https://github.com/horri

ble-dong/AIEC.

Adapting Noise to Data: Generative Flows from Learned 1D Processes
Jannis Chemseddine, Gregor Kornhardt, Richard Duong, Gabriele Steidl
The default Gaussian latent in flow-based generative models poses challenges when learning certain distributions such as heavy-tailed ones.
We introduce a general framework for learning data-adaptive parametric prior distributions (latent noise) using one-dimensional quantile functions, optimized via the Wasserstein distance between noise and data. The quantile-based prior parameterization naturally adapts to both heavy-tailed and compactly supported distributions and shortens transport paths. Numerical results on heavy-tailed weather and image datasets confirm the method’s flexibility and effectiveness achieved with negligible computational overhead.
****
MM-Snowball: Evaluating and Mitigating Hallucination Snowballing in Multimodal Multi-Turn Dialogue
Yue Jiang, Xue Jiang, Lihua Zhang, Zhiqiang Wang, Yuhang Lu, Peng Wang, Bo Han, Feng Zheng, Dingkang Yang
Multimodal large language models (MLLMs) demonstrate remarkable visual understanding, yet their reliability in interactive settings is severely undermined by hallucination snowballing: a phenomenon where initial errors amplify across conversational turns, leading to a collapse in coherence. This failure reveals a fundamental vulnerability where models progressively neglect visual grounding in favor of over-relying on polluted textual history. Existing benchmarks are predominantly confined to single-turn VQA, which fail to capture the complex dynamics of error propagation in long-horizon interactions. To address this, we introduce MM-Snowball, the first benchmark for fine-grained diagnosis of hallucination snowballing within dialogues.
Extensive evaluation shows that our benchmark poses a significant challenge even to advanced MLLMs and reveals the inefficacy of existing mitigation methods designed for single-turn VQA. To counteract this degradation, we propose Conflict-Aware Visual Rectification (CAVR). This training-free method mitigates snowballing through a synergistic dual-mechanism that refreshes visual grounding at the representation level and rectifies output distributions at the logit level, effectively re-anchoring the model to visual facts. Experiments demonstrate that CAVR achieves state-of-the-art performance, offering a promising path toward more reliable interactive AI. Data and code are available at: https://frenkie-chiang.github.io/MM-Snowball

Alignment-Guided Score Matching for Text-to-Image Alignment in Diffusion Models
Jaa-Yeon Lee, Yeobin Hong, Taesung Kwon, Jong Chul Ye
Diffusion models generate highly realistic images but often struggle with precise text–image alignment. While recent post-training methods improve alignment using external rewards or human preference signals, their performance heavily depends on reward quality and does not directly address alignment within the diffusion process itself.
Recent reward-free approaches such as SoftREPA demonstrate that optimizing soft text tokens via contrastive learning can effectively improve text-image representation alignment, outperforming standard parameter-efficient fine-tuning baselines. However, the contrastive formulation can excessively penalize negative pairs, which manifests as characteristic failure cases such as over-counting and repetition.
To address this issue, we propose a lightweight, reward-free post-training method that refines soft tokens by integrating contrastive alignment guidance directly into the score-matching objective of diffusion models. By assigning alignment directions at the score level, our approach mitigates these limitations and yields more coherent and semantically faithful generations.
Experiments show that our method matches SoftREPA while substantially improving its failure cases, achieving over 35\% improvement in counting accuracy on the GenEval benchmark. Our method is seamlessly applicable to existing diffusion back

bones (SD1.5, SDXL, and SD3), and is complementary to existing RL-based diffusio
n post-training methods.

APIC: Orthogonalized Neuro-Symbolic Modeling for Nonlinear Dissipative Dynamics
YanHui Zhu, Xiangfu Meng, Chen Zhao, Yinhao Li
Current data-driven scientific modeling struggles with a functional dichotomy: n
eural operators exhibit spectral bias in high-frequency regimes, while physics-c
onstrained paradigms suffer from optimization pathologies. To bridge this gap, w
e propose Adaptive Physics-Informed Computing (APIC), a neuro-symbolic meta-arch
itecture designed with structural reconfigurability to encode diverse domain pri
ors. Crucially, APIC integrates a gradient isolation strategy that reduces inter
ference between the optimization paths of parameter identification and residual
correction, effectively mitigating gradient conflicts. By instantiating this fra
mework for nonlinear dissipative systems, we derive the Generalized Kuramoto-Siv
ashinsky-Cahn-Hilliard (G-KSCH) kernel, providing a unified representation for s
parse dynamic identification. Extensive experiments demonstrate that APIC establ
ishes new benchmarks in 3D compressible supersonic shock wave prediction, surpas
sing diverse architectures (e.g., CNNs and Transformers) by substantial margins
in predictive accuracy. Notably, APIC achieves Pareto-optimal performance, deliv
ering superior precision with reduced computational overhead compared to SOTA mo
dels, while exhibiting strong cross-task adaptability across meteorological and
urban traffic datasets.

PoMtVRS: Preference-Optimized Multi-Task Vehicle Routing Solver with Preference
Gating
Dian Meng, Yaoxin Wu, Yaqing Hou, Zhiguang Cao
Multi-task vehicle routing solvers via deep reinforcement learning have attracte
d broad attention and achieved significant progress in handling multiple constra
ints. However, existing neural solvers still face critical challenges, including
 insufficient representation, unstable training, and inefficient exploration in
large combinatorial action spaces, which often prevents performance from meeting
 its full potential. To address these issues, we propose PoMtVRS (Preference-Opt
imized Multi-Task Vehicle Routing Solver with Preference Gating), a plug-and-pla
y framework that jointly improves decoder representations and exploration effici
ency through a synergistic combination of decoder-side augmentation and preferen
ce-driven optimization. Specifically, we introduce the preference optimization o
bjective to learn relative comparisons among candidate solutions for different r
outing tasks, encouraging a higher generation probability of better solutions. M
eanwhile, we design a preference-gated block that adaptively modulates decoder r
epresentations via sparse gated attention and nonlinear residual refinement. Ext
ensive experiments demonstrate that PoMtVRS elevates state-of-the-art unified ne
ural VRP backbones, achieving leading performance in multi-task benchmarks and s
tronger generalization.

Preserving Plasticity in Continual Learning via Dynamical Isometry
Andries Rosseau, Robert Müller, Ann Nowe
Continual training of deep neural networks under non-stationarity often leads to
 a progressive loss of plasticity, eventually limiting further learning. We rela
te plasticity to the empirical Neural Tangent Kernel, and identify dynamical iso
metry (the condition that layer-wise Jacobian singular values remain close to on
e) as a key mechanism for preserving plasticity in continual learning. We revisi
t a class of networks that are almost-everywhere isometric while remaining unive
rsal Lipschitz function approximators, demonstrating that near-dynamical isometr
y is compatible with expressive nonlinear representations. For general architect
ures, we propose an efficient isometry-promoting regularization scheme and ident
ify a novel mechanism by which it can reactivate dormant ReLU units. Building on
 this, we introduce AdamO, an Adam-style adaptive optimizer that decouples isome
try regularization from gradient updates, analogous to AdamW. We further reinter
pret prior plasticity-preserving approaches through the lens of dynamical isomet
ry, showing that they target only a partial measure of isometry. Across supervis

ed and reinforcement-learning continual-learning benchmarks designed to induce p lasticity loss, our methods consistently match or outperform existing approaches .

TokSuite: Measuring the Impact of Tokenizer Choice on Language Model Behavior

Gül Sena Alt■nta■, Malikeh Ehghaghi, Brian Lester, Fengyuan Liu, Wanru Zhao, Mar co Ciccone, Colin Raffel

Tokenizers provide the fundamental basis through which text is represented and p rocessed by language models (LMs).

Despite the importance of tokenization, its role in LM performance and behavior is poorly understood due to the challenge of measuring the impact of tokenizatio n in isolation.

To address this need, we present TokSuite, a collection of models and a benchmar k that supports research into tokenization's influence on LMs.

Specifically, we release fourteen pre-trained models that use different off-the-shelf tokenizers but are otherwise identical, using the same architecture, datas et, training budget, and initialization.

We also release a multilingual robustness benchmark that measures model performa nce under real-world perturbations in English, Chinese, Farsi, Italian, and Turk ish, curated by native annotators.

Together, TokSuite allows robust decoupling of the influence of a model's tokeni zer, supporting a series of novel findings that elucidate the respective benefit s and shortcomings of a wide range of popular tokenizers.

CORE-MTL: Rethinking Gradient Balancing via Causal Orthogonal Representations

Chengfeng Wu, Tao Zou, Yanru Wu, Jingge Wang
Multi-task learning (MTL) aims to construct a joint model for multiple tasks by sharing a common representation across domains. To achieve this goal, existing optimization-centric methods either balance task gradients or modify the shared architecture. However, as these approaches remain agnostic to the content of the shared representation, they fail to disentangle task-relevant structure from spurious context, leading to negative transfer and poor generalization. To overcome this limitation, we propose Causal Orthogonal Representations for Multi-Task Learning (CORE-MTL)
, a representation-centric framework that structurally disentangles the shared representation into semantic and residual streams, concentrating task-relevant structure in the semantic stream while relegating nuisance variation to the residual stream. We instantiate this framework in the visual domain by leveraging physical priors for structured scenes and statistical constraints for attributes. Theoretically, our method enjoys a tighter out-of-distribution generalization bound than optimization-centric methods and reduces task gradient interference without explicit gradient projection or reweighting. Empirically, CORE-MTL consistently outperforms existing methods on visual multi-task benchmarks in both in-distribution and out-of-distribution settings.
****
Factored Classifier-Free Guidance
Tian Xia, Fabio De Sousa Ribeiro, Rajat R Rasal, Avinash Kori, Raghav Mehta, Ben Glocker
Counterfactual generation aims to simulate realistic hypothetical outcomes under causal interventions. Diffusion models have emerged as a powerful tool for this task, combining DDIM inversion with conditional generation and classifier-free guidance (CFG). In this work, we identify a key limitation of CFG for counterfactual generation: it prescribes a global guidance scale for all attributes, leading to significant spurious changes in inferred counterfactuals. To mitigate this, we propose *Factored Classifier-Free Guidance* (FCFG), a flexible and model-agnostic guidance technique that enables attribute-wise control following a causal graph. FCFG complements recent advances in classifier-free guidance and can be seamlessly extended to advanced guidance schemes such as CFG++ and APG. Our experiments demonstrate that FCFG significantly improves the axiomatic soundness of inferred counterfactuals across both natural and medical image datasets, mitigating spurious amplification effects, and enhancing counterfactual reversibility
.

PADD: Path-Aligned Decompression Distillation for Non-Router Teacher to Guide MoE Student Learning
Xinyue Peng, Yi Qian, Jiaojiao Lin, Wenjian Shao, Yanming Liu
As large language models (LLMs) continue to scale, it becomes increasingly challenging to grow model capacity under fixed computation budgets. We propose Path-Aligned Decompression Distillation (PADD), a framework for distilling knowledge from dense teachers without explicit routing into mixture-of-experts (MoE) students while learning high-quality routing policies. PADD organizes knowledge distillation into four stages in two phases: an initialization phase (Stage I) that builds diverse functionality in the student's experts through teacher neuron clustering and student-expert warmup, and a training phase (Stages II--IV) that integrates online adaptive distillation, path-refined policy optimization, and reward-augmented load balancing in a single training pipeline.Experiments on mathematical reasoning benchmarks demonstrate that PADD yields substantial gains over strong baselines at the same inference cost and that the MoE student can match or surpass its dense teacher. They also demonstrate effective teacher-to-student knowledge distillation and stable routing behavior.
****
SPEAR: A Unified SSL Framework for Learning Speech and Audio Representations
Xiaoyu Yang, Yifan Yang, Zengrui Jin, Ziyun Cui, Wen Wu, Baoxiang Li, Chao Zhang, Phil Woodland
Self-supervised learning (SSL) has significantly advanced acoustic representatio

n learning. However, most existing models are optimised for either speech or aud io event understanding, resulting in a persistent gap between these two domains. We address this gap with SPEAR (SPEech and Audio Representations), a self-super vised framework that distils complementary knowledge from a speech-focused SSL t eacher and a general-audio SSL teacher into a single unified model. SPEAR applie s multi-codebook vector quantisation to continuous teacher representations to pr oduce fine-grained discrete tokens that capture both semantic and acoustic infor mation. To effectively integrate these heterogeneous representations, SPEAR join tly predicts them given a masked input with an asymmetric pre-training loss. We further improve robustness in complex sound scenes through a novel token mixing mechanism. Extensive experiments demonstrate that SPEAR consistently outperforms existing unified speech and audio models. SPEAR establishes a new state-of-the-art on the SUPERB benchmark, surpassing WavLM Large on 12 of 15 tasks, while ach ieving competitive performance on the HEAR benchmark. These results position SPE AR as a versatile foundation for general-purpose speech and audio representation learning. The code and pre-trained models will be released.

Symbal: Detecting Systematic Misalignments in Model-Generated Captions

Maya Varma, Jean-Benoit Delbrouck, Sophie Ostmeier, Akshay S Chaudhari, Curtis L anglotz

Multimodal large language models (MLLMs) often introduce errors when generating image captions, resulting in misaligned image-text pairs. Our work focuses on a class of captioning errors that we refer to as systematic misalignments, where a recurring error in MLLM-generated captions is closely associated with the prese nce of a specific visual feature in the paired image. Given a vision-language da taset with MLLM-generated captions, our aim in this work is to detect such error s, a task we refer to as systematic misalignment detection. As our first key con tribution, we present Symbal, which utilizes a structured, dual-stage setup with off-the-shelf foundation models to identify systematic misalignments and summar ize results in natural language. As our second key contribution, we introduce Sy mbalBench, a benchmark designed to evaluate automated methods on our proposed ta sk. SymbalBench consists of 1.7 million image-text pairs from two domains (natur al and medical images), organized into 420 vision-language datasets with annotat ed systematic misalignments. Symbal exhibits strong performance on this benchmar k, correctly identifying systematic misalignments in 63.8% of datasets, a nearly 4x improvement over the closest baseline. We supplement our evaluations on Symb alBench with real-world evaluations, showing that (1) Symbal can accurately surf ace systematic misalignments in captions generated by four MLLMs and (2) Symbal is a powerful tool for auditing off-the-shelf image-caption datasets. Ultimately , our novel task, method, and benchmark can aid users with auditing MLLM-generat ed captions and identifying critical errors, without requiring access to the und erlying MLLM. Code is available at https://github.com/Stanford-AIMI/Symbal.

EEG-FM-Bench: A Comprehensive Benchmark for the Systematic Evaluation and Diagno stic Analyses of EEG Foundation Models

Wei Xiong, Jiangtong Li, Jie Li, Kun Zhu, Changjun Jiang

Electroencephalography foundation models (EEG-FMs) have advanced brain signal an alysis, but the lack of standardized evaluation benchmarks impedes model compari son and scientific progress.

Current evaluations rely on inconsistent protocols that render cross-model compa risons unreliable, while a lack of diagnostic analyses obscures the internal mec hanisms driving transfer efficiency and scaling behaviors.

To address this, we introduce **EEG-FM-Bench**, a unified system for the standar dized evaluation of EEG-FMs.

The benchmark integrates 14 datasets across 10 paradigms and incorporates divers e experimental settings, including multiple fine-tuning strategies, task organiz ations, and classifier configurations, supported by tools for gradient and repre sentation analysis.

Our experiments and analysis reveal several critical insights: (1) multi-task le arning often acts as a useful regularizer that mitigates overfitting in data-sca

rce EEG contexts, although negative transfer can arise under specific task paradigms; (2) pre-training efficiency is currently limited by gradient conflicts between reconstruction objectives and downstream tasks;
(3) under released checkpoints and a matched downstream protocol,
model or data scale alone does not fully explain transfer performance, while objective alignment, adaptation compatibility, and EEG-specific design appear to be important factors.
This benchmark enables fair comparison and reproducible analysis, providing a step toward fairer comparison and more interpretable analysis of EEG-FMs. Code is available at https://github.com/xw1216/EEG-FM-Bench.

SoftMoE: Soft Differentiable Routing for Mixture-of-Experts in LLMs
Miko■aj Zasada, ■ukasz Struski, Jacek Tabor, Marcin Kurdziel
Sparse Mixture-of-Experts (MoE) architectures enable scaling LLM parameters under a fixed inference budget by activating only a small subset of experts via top-k routing. While this preserves causality and suits autoregressive language models, the discrete top-k operator is not differentiable, forcing a fixed number of active experts per input and resulting in inefficient use of computation. We propose SoftMoE, which replaces discrete routing with a truncated soft top-k LapSum relaxation, allowing gradient-based optimization of expert routing. We further parameterize the mean number of active experts per layer and impose a global budget constraint, enabling the model to learn how to allocate expert capacity across layers. SoftMoE remains fully compatible with autoregressive modeling and achieves performance comparable to or better than sparse MoE on language modeling and downstream tasks, while activating significantly fewer experts. Notably, the learned allocation is highly non-uniform, with later layers activating more experts. The source code is publicly available†.

Toward Safe Quantization-Aware Fine-tuning: Understanding and Mitigating Safety Alignment Degradation
Yuning Yang, Guowei Peng, Xiurui Xie, Minrui Jiang, Shuang Liang, Guisong Liu
Large language models (LLMs) are increasingly adapted to downstream tasks in resource-constrained scenarios, making quantization-aware fine-tuning (QAF) a common practice for practical deployment. However, we find that quantized LLMs are substantially more vulnerable to safety alignment degradation during fine-tuning than full-precision models by interpretability analyses. In this paper, we first theoretically reveal that this vulnerability is driven by quantization errors, manifesting as an initial safety shift followed by a distorted optimization path. Based on this insight, we propose Explicit-Safety Quantization-Aware Fine-tuning (ExSQF), which effectively restores model safety while preserving downstream performance. It initializes adapters by combining quantization error with a safety matrix projection to mitigate early safety shifts, followed by post-training refinement that corrects deviations in the optimization path. Extensive experimental results show that ExSQF achieves state-of-the-art safety alignment recovery, even surpassing existing full-precision safety-aware fine-tuning baseline, while effectively preserving model performance.

Effective Reasoning Chains Reduce Intrinsic Dimensionality
Archiki Prasad, Mandar Joshi, Kenton Lee, Mohit Bansal, Peter Shaw
Chain-of-thought (CoT) reasoning and its variants have substantially improved the performance of language models on complex reasoning tasks, yet the precise mechanisms by which different strategies facilitate generalization remain poorly understood. While current explanations often point to increased test-time computation or structural guidance, establishing a consistent, quantifiable link between these factors and generalization remains challenging. In this work, we identify *intrinsic dimensionality* as a quantitative measure for characterizing the effectiveness of reasoning chains. Intrinsic dimensionality quantifies the minimum number of model dimensions needed to reach a given accuracy threshold on a given task. By keeping the model architecture fixed and varying the task formulation through different reasoning strategies, we demonstrate that effective reasoning

strategies consistently reduce the intrinsic dimensionality of the task. Validating this on GSM8K with Gemma-3 1B and 4B, we observe a strong inverse correlation between the intrinsic dimensionality of a reasoning strategy and its generalization performance on both in-distribution and out-of-distribution data. Our findings suggest that effective reasoning chains facilitate learning by better compressing the task using fewer parameters, offering a new quantitative metric for analyzing reasoning processes.

A Semantically Consistent Dataset for Data-Efficient Query-Based Universal Sound Separation
Kai Li, Jintao Cheng, Chang Zeng, Zijun Yan, Helin Wang, Zixiong Su, Bo Zheng, Xiaolin Hu
Query-based universal sound separation is fundamental to intelligent auditory systems, aiming to isolate specific sources from mixtures. Despite recent advances, existing methods continue to suffer from residual interference in complex acoustic scenes. This performance limitation stems largely from a data bottleneck: in-the-wild datasets contain weak labels and severe co-occurrence of events. These flaws induce models to learn spurious correlations between background noise and target categories instead of robust acoustic features. To address this, we propose an automated pipeline that eliminates co-occurrence of events by mining high-purity single-event segments from in-the-wild datasets via a semantically consistent synthesis protocol. Utilizing this pipeline, we constructed Hive, a high-quality synthetic dataset comprising 2.4k hours of raw audio. Experimental results demonstrate that, compared with the state-of-the-art model SAM-Audio which was trained on a huge dataset $\sim$500 times larger than Hive, certain open-source models trained on Hive achieve competitive separation accuracy and perceptual quality. Moreover, these models exhibited remarkable zero-shot generalization on out-of-distribution evaluation benchmarks. These findings highlight that prioritizing purity of supervised signals enables significant data efficiency, offering a new paradigm for training robust auditory foundation models with reduced computational costs. Code and dataset are available at https://cslikai.cn/Hive.

Small Generalizable Prompt Predictive Models Can Steer Efficient RL Post-Training of Large Reasoning Models
Yun Qu, Qi Wang, Yixiu Mao, Heming Zou, Yuhang Jiang, Weijie Liu, Clive Bai, Kai Yang, Yangkun Chen, Saiyong Yang, Xiangyang Ji
Reinforcement learning enhances the reasoning capabilities of large language models but often involves high computational costs due to rollout-intensive optimization.
Online prompt selection presents a plausible solution by prioritizing informative prompts to improve training efficiency.
However, current methods either depend on costly, exact evaluations or construct prompt-specific predictive models lacking generalization across prompts.
This study introduces Generalizable Predictive Prompt Selection (GPS), which performs Bayesian inference towards prompt difficulty using a lightweight generative model trained on the shared optimization history.
Intermediate-difficulty prioritization and history-anchored diversity are incorporated into the batch acquisition principle to select informative prompt batches.
The small predictive model also generalizes at test-time for efficient computational allocation.
Experiments across varied reasoning benchmarks indicate GPS's substantial improvements in training efficiency, final performance, and test-time efficiency over superior baseline methods.
The code is available at https://github.com/thu-rllab/GPS.

Learning Rate Scaling across LoRA Ranks and Transfer to Full Finetuning
Nan Chen, Soledad Villar, Soufiane Hayou
Low-Rank Adaptation (LoRA) is a standard tool for parameter-efficient finetuning of large models. While it induces a small memory footprint, its training dynami

cs can be surprisingly complex as they depend on several hyperparameters such as initialization, adapter rank, and learning rate. In particular, it is unclear *how the optimal learning rate scales with adapter rank*, which forces practitioners to re-tune the learning rate whenever the rank is changed. In this paper, we introduce *Maximal-Update Adaptation* (μA), a theoretical framework that characterizes how the "optimal" learning rate should scale with model width and adapter rank to produce stable, non-vanishing feature updates under standard configurations. Our analysis leverages techniques from hyperparameter transfer and reveals that the optimal learning rate exhibits different scaling patterns depending on initialization and LoRA scaling factor. Specifically, we identify two regimes: one where the optimal learning rate remains roughly invariant across ranks, and another where it scales inversely with rank.
We further identify a configuration that allows learning rate transfer from LoRA to full finetuning, drastically reducing the cost of learning rate tuning for full finetuning. Experiments across language, vision, vision–language, image generation, and reinforcement-learning tasks validate our scaling rules and show that learning rates tuned on LoRA transfer reliably to full finetuning.

Emergence of Hierarchical Emotion Organization in Large Language Models
Maya Okawa, Bo Zhao, Eric Bigelow, Rose Yu, Tomer Ullman, Ekdeep Singh Lubana, Hidenori Tanaka
As large language models (LLMs) increasingly power conversational agents, understanding how they model users' emotional states is critical for ethical deployment. Inspired by emotion wheels, i.e., a psychological framework that argues emotions organize hierarchically, we analyze probabilistic dependencies between emotional states in model outputs. We find that LLMs naturally form hierarchical emotion trees that align with human psychological models, and larger models develop more complex hierarchies. We also uncover systematic biases in emotion recognition across socioeconomic personas, with compounding misclassifications for intersectional, underrepresented groups. Human studies reveal striking parallels, suggesting that LLMs internalize aspects of social perception. Beyond highlighting emergent emotional reasoning in LLMs, our results hint at the potential of using cognitively-grounded theories for developing better model evaluations.

Investigating Memory in Model-Free RL with POPGym Arcade
Zekang Wang, Zhe He, Borong Zhang, Edan Toledo, Steven Morad
How should we analyze memory in deep RL? We introduce tools for analyzing policies under partial observability and revealing how agents use memory to make decisions. To utilize these tools, we present POPGym Arcade, a collection of Atari-inspired, hardware-accelerated environments sharing a single observation and action space. Each environment provides fully and partially observable variants, enabling counterfactual studies on observability. We find that controlled studies are necessary for fair comparisons and identify a pathology where value functions smear credit over irrelevant history. Using this pathology, we demonstrate how out-of-distribution scenarios can contaminate memory, perturbing the policy far into the future.

Can Recommender Systems Teach Themselves? A Recursive Self-Improving Framework with Fidelity Control
Luankang Zhang, Hao Wang, Zhongzhou Liu, Mingjia Yin, Yonghao Huang, Jiaqi Li, Wei Guo, Yong Liu, Huifeng Guo, Defu Lian, Enhong Chen
The scarcity of high-quality training data presents a fundamental bottleneck to scaling machine learning models. This challenge is particularly acute in recommendation systems, where extreme sparsity in user interactions leads to rugged optimization landscapes and poor generalization. We propose the Recursive Self-Improving Recommendation (RSIR) framework, a paradigm in which a model bootstraps its own performance without reliance on external data or teacher models. RSIR operates in a closed loop: the current model generates plausible user interaction sequences, a fidelity-based quality control mechanism filters them for consistency with user’s approximate preference manifold, and a successor model is augmented

on the enriched dataset. Our theoretical analysis shows that RSIR acts as a data-driven implicit regularizer, smoothing the optimization landscape and guiding models toward more robust solutions. Empirically, RSIR yields consistent, cumulative gains across multiple benchmarks and architectures. Notably, even smaller models benefit, and weak models can generate effective training curricula for stronger ones. These results demonstrate that recursive self-improvement is a general, model-agnostic approach to overcoming data sparsity, suggesting a scalable path forward for recommender systems and beyond. Our code is available at https://github.com/USTC-StarTeam/RSIR.

Evidential Copula Concept Embedding Models

Yanjie Qiu, Xiaodong Yue, Xuhui Fan, Yufei Chen, Jie Shi, Wei Liu

Concept Embedding Models (CEMs) advance interpretable AI by extending Concept Bottleneck Models (CBMs) through semantic concept embeddings, providing an important solution in high-stakes domains such as medical diagnosis where accuracy and interpretability are critical. However, a fundamental limitation persists: existing CEMs inherently assume concept independence, critically overlooking the highly complex dependencies among concepts. To address this, we propose an Evidential Copula Concept Embedding Model (EC-CEM) that redefines the joint distribution over concepts, capturing inter-concept dependencies while maintaining a flexible structure that decouples the marginal concept distributions from their dependency structure. In particular, EC-CEM relaxes the concept independence assumption and uniquely integrates Copula theory with evidential deep learning to define a joint distribution over concepts. The proposed EC-CEM also develops two training objectives that aim at classification and concept modeling simultaneously. We provide theoretical justification via variational inference and demonstrate empirical superiority through extensive experiments.

Joint Enhancement and Classification using Coupled Diffusion Models of Signals and Logits

Gilad Nurko, Roi Benita, Yehoshua Dissen, Tomohiro Nakatani, Marc Delcroix, Shoko Araki, Joseph Keshet

Robust classification in noisy environments remains a fundamental challenge in machine learning. Standard approaches typically treat signal enhancement and classification as separate, sequential stages: first enhancing the signal and then applying a classifier. This approach fails to leverage the semantic information in the classifier's output during denoising. In this work, we propose a general, domain-agnostic framework that integrates two interacting diffusion models: one operating on the input signal and the other on the classifier's output logits, without requiring any retraining or fine-tuning of the classifier. This coupled formulation enables mutual guidance, where the enhancing signal refines the class estimation and, conversely, the evolving class logits guide the signal reconstruction towards discriminative regions of the manifold. We introduce three strategies to effectively model the joint distribution of the input and the logit. We evaluated our joint enhancement method for image classification and automatic speech recognition. The proposed framework surpasses traditional sequential enhancement baselines, delivering robust and flexible improvements in classification accuracy under diverse noise conditions.

CauSciBench: Can LLMs Automate Causal Inference in Real-World Scientific Research?

Sawal Acharya, Terry Jingchen Zhang, Andrew Kim, Rahul Babu Shrestha, Xianlin Sun, Pepijn Cobben, Maximilian Mordig, Jacob T. Emmerson, Anahita Haghighat, Furkan Danisman, Yuen Chen, Clijo Jose, Andrei Ioan Muresanu, Justin Cui, Jiarui Liu, Yahang Qi, Punya Syon Pandey, Yinya Huang, Bernhard Schölkopf, Zhijing Jin

Identifying and estimating causal relationships from data is a crucial component of empirical research. While large language model-powered tools have shown potential for assisting research workflows, their ability to perform end-to-end causal inference remains underexplored. We introduce CauSciBench, a benchmark that puts LLM-powered tools to the test on causality- driven research questions. Unlik

e previous related benchmarks that focus on coding alone, CauSciBench enables ev aluation across the full pipeline of causal inference: from method and variable selection to computation of causal effects and statistical interpretation in the context of real-world research problems. We evaluated 7 frontier models on over 300 queries derived from scientific publications, textbook problems, sem- inal datasets, and synthetic scenarios. Results show that models consistently perform worse on real datasets, with the key bottleneck being the selection of an appro priate causal inference method.

Regularized Offline Policy Optimization with Posterior Hybrid Bayesian Belief
Hongqiang Lin, Pengfei Wang, Nenggan Zheng
Offline reinforcement learning (RL) aims to optimize policies from pre-collected datasets. A bottleneck of this paradigm is managing epistemic uncertainty, whic h arises from limited data coverage (sample-level) and the ambiguity in identify ing transition dynamics from finite data (model-level). To provide a unified qua ntification of these uncertainties, Bayesian RL has been proposed by treating th e dynamics model as a random variable and maintaining a corresponding belief. De spite its theoretical appeal, policy optimization in Bayesian RL remains computa tionally challenging as it requires solving composite objectives with expectatio ns. Prior methods either employ search-based techniques with poor computational scalability or impose restrictive posterior assumptions that sacrifice the adapt ability of Bayesian RL. To address these limitations, we propose Posterior Hybri d Bayesian Belief (PhyB), which reformulates the expectation as a convex combina tion over a subset of dynamics models. Theoretical analysis demonstrates that th e objective discrepancy induced by this approximation remains bounded. Based on PhyB, we develop an iterative regularized policy optimization algorithm that pro vides metric-agnostic guarantees for monotonic improvement until convergence. Em pirical results demonstrate that PhyB achieves state-of-the-art performance on v arious benchmarks.

Do Audio LLMs Listen or Read? Analyzing and Mitigating Paralinguistic Failures w ith VoxParadox
Jiacheng Pang, Ashutosh Chaubey, Mohammad Soleymani
Audio large language models (Audio LLMs) demonstrate strong performance on speec h understanding tasks, yet their ability to understand paralinguistic informatio n remains limited. To systematically quantify this issue, we introduce **VoxPara dox**, an adversarial benchmark with 2,000 verified examples, spanning 10 parali nguistic tasks, created with controlled speech synthesis to intentionally mismat ch transcript claims and speaking style, enabling direct measurement of speech p aralinguistic understanding. Evaluation of a diverse set of Audio LLMs reveals c onsistently low accuracy on acoustic ground truth and a strong tendency to follo w language-implied (incorrect) answers. To understand the cause of this gap, we perform layer-wise probing and find that (i) paralinguistic cues can degrade in deeper encoder layers and at the encoder--LLM interface, and (ii) even when such cues are available in audio tokens, the language model frequently ignores them. To address these problems, we propose **Prompt-Conditioned Layer Mixer (PCLM)** , which adaptively combines information from multiple audio layers based on the input prompt, and pair it with **Direct Preference Optimization (DPO)** to expli citly prefer acoustically supported options over language-implied alternatives. These methods substantially improve Audio LLM paralinguistic understanding, impr oving Audio Flamingo 3 from **17.40%** to **65.20%** on VoxParadox, and from **3 7.74%** to **54.78%** on MMSU paralinguistic subset. Our project page is availab le at https://voxparadox.github.io/.

Taming Stochastic Gradient Descent: Almost Sure Convergence and Saddle-Point Avo idance under (L_{0},L_{1})-Smoothness
Vassilis Apidopoulos, Iosif Lytras, Panayotis Mertikopoulos
Many optimization problems in machine learning and data science—from deep neural networks to Bayesian inference and beyond—fall outside the standard Lipschitz s moothness framework that underpins the convergence theory of stochastic gradien

t descent (SGD). Motivated by this theory-practice disconnect, we examine the al
most sure convergence of the trajectories of SGD in non-convex landscapes under
a generalized (L_0,L_1)-smoothness condition which allows for gradients with s
uperlinear growth (even exponential). We begin by proposing a taming scheme for
SGD that achieves almost sure convergence under a generalized ABC-type condition
 on the gradient noise. Subsequently, to relax this requirement, we introduce a
more flexible, dissipative taming scheme which converges almost surely under les
s restrictive moment bound conditions for the stochastic gradients entering the
process. For both taming schemes, we show that the generated trajectories avoid
strict saddle points (and/or manifolds thereof) with probability 1 so, generical
ly, both methods only converge to local minimizers.

Knapsack RL: Compute-Efficient Reinforcement Learning via Heterogeneous Rollout
Allocation

Ziniu Li, Congliang Chen, Tianyun Yang, Tian Ding, Ruoyu Sun, Ge Zhang, Wenhao H
uang, Zhi-Quan Luo

Reinforcement learning (RL) fine-tuning of Large Language Models (LLMs) is compu
te-intensive because each prompt requires generating multiple responses, or roll
outs. To make the best use of GPU resources, the key question is how to allocate
 rollout-generation jobs across prompts. Existing methods typically use uniform
allocation, assigning every prompt the same rollout budget. This is inefficient
and ineffective: easy prompts are oversampled after they are already solved, whi
le hard prompts receive too little exploration. In policy optimization methods s
uch as Group Relative Policy Optimization (GRPO), both cases often yield near-ze
ro gradients and limited learning progress. We address this problem by formulati
ng rollout allocation as a computeconstrained resource allocation task, where ea
ch prompt-budget choice has an expected learning value and rollout cost. Based o
n this view, we propose Knapsack RL, a practical framework that uses knapsack op
timization to assign heterogeneous, task-specific rollout budgets. It directs ex
ploration toward prompts that benefit most from additional sampling. Applied to
GRPO, Knapsack RL increases the effective-gradient ratio by up to 40%, enables l
arger budgets for challenging prompts, and improves mathematical reasoning by 2–
4 points on average, with peak gains of up to 9 points. Achieving similar perfor
mance with uniform allocation requires about 2× more compute, demonstrating a si
mple and practical path toward scaling RL fine-tuning for LLMs.
****

InfoGeo: Information-Theoretic Object-Centric Learning for Cross-View Generaliza
ble UAV Geo-Localization

Hongyang ZHANG, Maonan Wang, Ziyao Wang, Hongrui Yin, Man On Pun

Cross-view geo-localization (CVGL) is fundamental for precise localization and n
avigation in GPS-denied environments, aiming to match ground or UAV imagery with
 satellite views. Existing approaches often rely on global feature alignment, bu
t they suffer from substantial domain shifts induced by varying regional texture
s and weather conditions. This issue becomes even more pronounced in UAV-based s
cenarios, where the broader perspective inevitably introduces dense, fine-graine
d objects, creating significant visual clutter. To address this, we draw inspira
tion from Object-Centric Learning (OCL) and propose InfoGeo, an information-theo
retic framework designed to enhance robustness and generalization. InfoGeo refor
mulates the optimization as an information bottleneck process with two core obje
ctives: (i) maximizing view-invariant information by aligning the object-centric
 structural relations across views, and (ii) minimizing view-specific noisy sign
als through cross-view knowledge constraints. Extensive evaluations across diver
se benchmarks and challenging scenarios demonstrate that InfoGeo significantly o
utperforms state-of-the-art methods.
****

HiDe: Rethinking The Zoom-IN method in High Resolution MLLMs via Hierarchical De
coupling

Xianjie Liu, Yiman Hu, Yixiong Zou, Liang Wu, Jian Xu, Bo Zheng

Multimodal Large Language Models have made substantial progress on visual unders
tanding tasks, yet they still perform poorly on high-resolution images. Prior wo

rk often attributes this limitation to perceptual constraints, arguing that MLLM s fail to recognize small objects and therefore rely on ''zoom-in" strategies to recover fine details. In contrast, our analysis shows that the dominant failure mode is background interference rather than object size.
We study the "zoom-in" operation through a **hierarchical decoupling analysis** and propose the **Hierarchical Decoupling Framework**, a training-free method th at turns implicit attention into explicit region selection. HiDe first performs Token-wise Attention Decoupling to disentangle question semantics and identify t he most informative tokens, then uses their attention patterns to pinpoint the c orresponding visual regions. It subsequently applies Layout-Preserving Decouplin g to extract these regions from cluttered backgrounds and construct a compact re presentation that retains key spatial structure while filtering out irrelevant c ontext. HiDe achieves state-of-the-art results on high-resolution benchmarks lik e Vstar Bench. It boosts Qwen2.5-VL 7B and InternVL3 8B to state of the art perf ormance, reaching 92.1\% and 91.6\% on Vstar Bench, and even surpasses reinforce ment learning based methods. After optimization, HiDe reduces memory usage by 75 \% compared with the previous training-free approach. Code will be available at https://tennine2077.github.io/HiDe.github.io/.

Spectral Guidance for Flexible and Efficient Control of Diffusion Models
Gabriel Moreira, Manuel Marques, Joao Costeira, Chenyan Xiong
We introduce Spectral Guidance, a framework for controlling diffusion models by leveraging the intrinsic geometry of the generative process. As data is progress ively corrupted by noise, only a small number of features remain informative for control. We characterize them as the singular functions of a conditional expect ation operator and show that they can be learned via a self-supervised objective . Once recovered, this basis enables the projection of arbitrary guidance signal s, such as labels, CLIP embeddings, or masks, directly onto the sampling traject ory. This approach allows for stable, high-fidelity control without retraining o r denoiser backpropagation during sampling. Empirically, we improve conditional accuracy on CIFAR-10 by 37 percentage points over the strongest training-free ba seline while offering $4\times$ faster sampling. Moreover, the same representati ons that support label and CLIP guidance also enable spatial control, such as ma sk-based guidance, without auxiliary models. Finally, our framework reveals a ph ase transition in the generative process, pinpointing the optimal time window fo r effective guidance.

Escaping the Mode: Multi-Answer Reinforcement Learning in LMs
Isha Puri, Mehul Damani, Idan Shenfeld, Marzyeh Ghassemi, Jacob Andreas, Yoon Ki m
Given a question, a language model (LM) implicitly encodes a distribution over p ossible answers. In practice, post-training procedures for LMs often collapse th is distribution onto a single dominant mode. While this is generally not a probl em for benchmark-style evaluations that assume one correct answer, many real-wor ld tasks inherently involve multiple valid answers or irreducible uncertainty. E xamples include medical diagnosis, ambiguous question answering, and settings wi th incomplete information. In these cases, we would like LMs to generate multipl e plausible hypotheses, ideally with confidence estimates for each one, and with out computationally intensive repeated sampling to generate non-modal answers. T his paper describes a multi-answer reinforcement learning approach for training LMs to perform distributional reasoning over multiple answers during inference. We modify the RL objective to enable models to explicitly generate multiple cand idate answers in a single forward pass, internalizing aspects of inference-time search into the model's generative process. Across question-answering, medical d iagnostic, and coding benchmarks, we observe improved diversity, coverage, and s et-level calibration scores compared to single answer trained baselines. Models trained with our approach require fewer tokens to generate multiple answers than competing approaches. On coding tasks, they are also substantially more accurat e. These results position multi-answer RL as a principled and compute-efficient alternative to inference-time scaling procedures such as best-of-k.

RNA-FM: Flow-Matching Generative Model for Genome-wide RNA-Seq Prediction
Yaxuan Song, Jianan Fan, Tianyi Wang, Qiuyue Hu, Hang Chang, Heng Huang, Weidong Cai
Histopathology whole-slide images (WSIs) are routinely acquired in clinical practice and contain rich tissue morphology but lack direct molecular architecture and functional programs defining pathological states, whereas RNA sequencing (RNA-seq) provides genome-wide transcriptional profiles at substantial cost, thereby motivating WSI-based genome-wide transcriptomic prediction. Existing approaches for predicting gene expression from WSIs predominantly rely on deterministic regression with one-to-one mapping, limiting their ability to capture biological heterogeneity and predictive uncertainty. We propose RNA-FM, a flow-matching generative framework for genome-wide bulk RNA-seq prediction from WSIs. RNA-FM formulates transcriptomic prediction as a continuous-time conditional transport problem, learning a velocity field that maps a simple prior to the target gene expression distribution conditioned on morphologies. By integrating pathway-level structure, RNA-FM enables scalable and biologically interpretable genome-wide gene expression imputation. Extensive experiments demonstrate that RNA-FM consistently outperforms state-of-the-art approaches while maintaining biological meaningfulness. Code is available at https://github.com/YXSong000/RNA-FM.
****
LDARNet: DNA Adaptive Representation Network with Learnable Tokenization for Genomic Modeling
Daria Ledneva, Denis Kuznetsov
Genomic foundation models increasingly adopt large language model architectures, yet almost universally rely on fixed tokenization schemes such as k-mers, BPE, or single nucleotides, which impose arbitrary sequence boundaries that may obscure biologically relevant structure. We present LDARNet, a 120M-parameter hierarchical genomic foundation model that adapts H-Net-style dynamic chunking from autoregressive generation to masked language modeling, combining BiMamba-2 state-space layers with local attention, bidirectional routing, and a ratio-based regularizer to induce adaptive token boundaries without supervision. Fine-tuned on 27 tasks from the Nucleotide Transformer and Genomic Benchmarks suites, LDARNet achieves 11/18 wins among compact models ($<$300M parameters) and state-of-the-art results on 5 histone modification tasks, outperforming models up to 20$\times$ larger. A FLOPs-matched controlled experiment isolates learned routing as the source of these gains: learned boundaries beat fixed-grid boundaries by up to 14 percentage points on histone tasks at identical compute. Nucleotide-resolution analysis further shows that the learned boundaries align with canonical promoter motifs and splice junctions without supervision, providing a biological interpretation for adaptive tokenization in genomic foundation models.
****
Depth-Breadth Synergy in RLVR: Unlocking LLM Reasoning Gains with Adaptive Exploration
Zhicheng Yang, Zhijiang Guo, Yinya Huang, Yongxin Wang, Dongchun Xie, Hanhui Li, Yiwei Wang, Xiaodan Liang, Jing Tang
Reinforcement Learning with Verifiable Reward (RLVR) is a powerful method for enhancing the reasoning abilities of Large Language Models, but its full potential is limited by a lack of exploration in two key areas: \textbf{Depth} (the difficulty of problems) and \textbf{Breadth} (the number of training instances). Our analysis of the popular GRPO algorithm reveals a bias that down-weights difficult, low-accuracy problems, which are crucial for improving reasoning skills. To address this, we introduce Difficulty Adaptive Rollout Sampling (DARS), a method that re-weights difficult problems by using targeted, multi-stage rollouts. This approach increases the number of rollout outcomes for these harder problems according to our proposed re-balancing schedules and leads to consistent gains in \textit{Pass@K}. We also found that simply enlarging the rollout size isn't effective and can even harm performance. We also investigated the role of breadth by scaling the batch size and using full-batch updates. This significantly improved \textit{Pass@1} performance by maintaining high token-level entropy, which indi

cates continued exploration and reduced gradient noise. Finally, we present DARS-Breadth, a combined approach that uses DARS with a large breadth of training data. This method demonstrates simultaneous gains in both \textit{Pass@K} and \textit{Pass@1}, confirming that depth (adaptive exploration) and breadth (scaling the training data) are orthogonal and essential dimensions for unlocking the full reasoning power of RLVR.

Towards Trustworthy and Identifiable Virtual Face Generation
Chunyang Li, Haoyue Wang, Zhenxing Qian, Sheng Li, Xinpeng Zhang, Jian liu, Yixuan Pei, Weiqiang Wang
Identifiable virtual face (IVF) generation aims to transform a user's original face into a virtual face for high utility privacy protection. The IVF is visually and statistically different from the original face, which can still be used for recognizing the user's identity. Despite this advantage, these schemes are unable to verify the trustworthiness of the IVF, the quality and controllability of which is often limited. To address these issues, we propose TIVDiff, a diffusion-based framework for trustworthy and identifiable virtual face generation. TIVDiff learns a virtual identity (VID) space via Virtual Identity Projection (VIP) and synthesizes high-quality virtual faces conditioned on VID and 3D facial geometry for pose and expression preservation. To enable the trustworthiness of IVF, we further propose an Identity-Guarded Generative Watermarking (IGGW) scheme to bind the diffusion initial noise with VID through a reversible mapping mechanism. This enables the embedding of an imperceptible cue into IVF for legitimacy verification. Experiments demonstrate the advantage of our TIVDiff over the state-of-the-art IVF generation schemes in terms of image quality, identifiability and trustworthiness.

Rethinking Contrastive Learning for Graph Collaborative Filtering: Limitations and a Simple Remedy
Geon Lee, Sunwoo Kim, Kyungho Kim, Kijung Shin
Graph collaborative filtering (GCF) is a dominant paradigm in recommender systems, where contrastive learning (CL) objectives such as the Sampled Softmax (SSM) loss are widely used for optimization. However, it remains unclear how CL interacts with the prediction mechanism of GCF. By unfolding the prediction mechanism of GCF, we show that the user-item prediction score is computed by aggregating learnable weights over a large number of neighbor pairs formed by the multi-hop neighbors of the user and the item. This analysis suggests that effective optimization critically depends on which neighbor pairs are upweighted during training. Empirically, we find that effective recommendation is achievable by selectively upweighting only a small subset of neighbor pairs whose constituent neighbors are structurally similar to the target user and item, and that the effect of such selective upweighting varies across different neighbor pair types. Based on these findings, we analyze SSM and identify key limitations in its neighbor pair weight update dynamics. To address these limitations, we propose NT-SSM, an effective and principled CL objective that induces type-aware neighbor pair weight update dynamics. Experiments demonstrate consistent performance improvements over SSM across multiple datasets and GCF models.

Unlearning Isn’t Forgetting: Revealing Hidden Leakage in Class Unlearning Evaluations
Ali Ebrahimpour-Boroojeny, Yian Wang, Hari Sundaram
In this paper, we reveal a significant shortcoming in class unlearning evaluations: overlooking the underlying class geometry can cause information leakage about the forgotten class. We further propose a simple unlearning strategy to mitigate this issue.
We introduce Class Membership Inference Attack (CMIA) that uses the probabilities the model assigns to neighboring classes to detect unlearned samples. We find that existing unlearning methods are vulnerable to CMIA across multiple datasets. We then propose a new fine-tuning objective that mitigates this privacy leakage by approximating, for forget-class inputs, the distribution over the remaining

classes that a retrained-from-scratch model would produce. To construct this approximation, we estimate inter-class similarity and tilt the target model’s distribution accordingly. The resulting Tilted REWeighting (TREW) distribution serves as the desired distribution during fine-tuning. We also show that across multiple benchmarks, TREW matches or surpasses existing unlearning methods on prior unlearning metrics. More specifically, on CIFAR-10, it reduces the gap with retrained models by 19% and 46% for U-LiRA and CMIA scores, accordingly, compared to the SOTA method for each category.

Hierarchical Procedural Meta-Reasoning for Generalizable Multimodal Agents
Yao Fu, Shengyi Qian, Pierluca D'Oro, Fanyi Xiao, Honglak Lee, Joseph Tighe, Manchen Wang
While multimodal agents can achieve strong performance through fine-tuning, their ability to generalize remains limited in complex real-world tasks such as mobile navigation, where diverse applications, frequent system changes, and customized workflows are common in practice. We argue that a fundamental bottleneck lies in whether an agent possesses sufficient task-specific procedural knowledge to accomplish a given goal. Such procedural knowledge may be provided by the general capabilities of large language models, or obtained from additional external resources such as web search when necessary. Based on this view, we propose Procedure-Aware Multimodal Agent with Meta Reasoning, a framework that explicitly represents task knowledge as natural-language procedures and trains a procedure-aware grounded agent to condition its actions on this knowledge. By learning to leverage procedural knowledge from different sources, our approach enables robust generalization across tasks, applications, interface versions, and multi-app workflows, achieving substantial improvements on challenging Android benchmarks.

Bridging Functional Correctness and Runtime Efficiency Gaps in LLM-Based Code Translation
Longhui Zhang, Jiahao Wang, Chenhao Hu, Bingyu Liang, Jing Li, Min Zhang
While large language models (LLMs) have greatly advanced the functional correctness of automated code translation systems, the runtime efficiency of translated programs has received comparatively little attention.
With the waning of Moore’s law, runtime efficiency has become increasingly important for program quality, alongside functional correctness.
Our preliminary study reveals that LLM-translated programs often run slower than human-written ones, and this issue cannot be remedied through prompt engineering alone.
Therefore, our work proposes SwiftTrans, a code translation framework comprising two key stages:
(1) Multi-Perspective Exploration, where MpTranslator leverages parallel in-context learning (ICL) to generate diverse translation candidates;
and
(2) Difference-Aware Selection, where DiffSelector identifies the optimal candidate by explicitly comparing differences between translations.
We further introduce Hierarchical Guidance for MpTranslator and Ordinal Guidance for DiffSelector, enabling LLMs to better adapt to these two core components.
To support the evaluation of runtime efficiency in translated programs, we extend existing benchmarks, CodeNet and F2SBench, and introduce a new benchmark, SwiftBench.
Experimental results across all three benchmarks show that SwiftTrans achieves consistent improvements in both correctness and runtime efficiency.

FLAC: Maximum Entropy RL via Kinetic Energy Regularized Bridge Matching
Lei Lv, Yunfei Li, Yu Luo, Fuchun Sun, Xiao Ma
Iterative generative policies, such as diffusion models and flow matching, offer superior expressivity for continuous control but complicate Maximum Entropy Reinforcement Learning because their action log-densities are not directly accessible. To address this, we propose \textbf{Field Least-Energy Actor-Critic (FLAC)}, a likelihood-free framework that regulates policy stochasticity by penalizing t

he kinetic energy of the velocity field.
Our key insight is to formulate policy optimization as a Generalized Schr\"oding er Bridge (GSB) problem relative to a high-entropy reference process (e.g., unif orm). Under this view, the maximum-entropy principle emerges naturally as stayin g close to a high-entropy reference while optimizing return, without requiring e xplicit action densities. In this framework, kinetic energy serves as a physical ly grounded proxy for divergence from the reference: minimizing path-space energ y bounds the deviation of the induced terminal action distribution. Building on this view, we derive an energy-regularized policy iteration scheme and a practic al off-policy algorithm that automatically tunes the kinetic energy via a Lagran gian dual mechanism. Empirically, FLAC achieves superior or comparable performan ce on high-dimensional benchmarks relative to strong baselines, while avoiding e xplicit density estimation.

TokenSwap: Backdoor Attack on the Compositional Understanding of Large Vision-La nguage Models
Zhifang Zhang, Qiqi Tao, Jiaqi Lv, Na Zhao, Lei Feng, Joey Tianyi Zhou
Large vision-language models (LVLMs) excel at vision-language tasks but remain v ulnerable to backdoor attacks. Most existing backdoor attacks on LVLMs force the model to generate predefined target patterns. However, these fixed-pattern atta cks are easy to detect, as the model tends to memorize frequent patterns and exh ibits overconfidence on targets given poisoned inputs. To address these limitati ons, we introduce TokenSwap, a more evasive and stealthy backdoor attack that fo cuses on the \emph{compositional understanding} capabilities of LVLMs. Instead o f enforcing a fixed targeted content, TokenSwap subtly disrupts the understandin g of object relationships in text. Specifically, it causes the backdoored model to generate outputs that mention the correct objects in the image but misreprese nt their relationships (i.e., bags-of-words behavior). During training, TokenSwa p injects a visual trigger into selected samples while swapping the grammatical roles of key tokens in the textual answers. Since the poisoned samples differ on ly subtly from clean ones, an adaptive token-weighted loss is employed to emphas ize learning on swapped tokens, strengthening the association between visual tri ggers and the bags-of-words behavior. Extensive experiments demonstrate that Tok enSwap achieves high attack success rates while maintaining evasiveness and stea lthiness across multiple benchmarks and LVLM architectures.

Spatial-Aware Reduction Framework: Towards Efficient and Faithful Visual State Space Models
Jindi Lv, Aoyu Li, Yuhao Zhou, Zheng Zhu, Xiaofeng Wang, Qing Ye, Yueqi Duan, We ntao Feng, Jiancheng Lv
Mamba demonstrates strong efficiency in modeling long visual sequences. However, when token reduction is applied to structurally enhanced Mamba variants, these models exhibit a severe performance collapse. We attribute this degradation to t he spatially agnostic nature of existing reduction methods, which violate the tw o-dimensional structural premise required by the selective scanning mechanism.
In this work, we propose STORM, a spatial-aware token reduction framework design ed to maintain structural integrity throughout the compression process. STORM re formulates reduction into a structured operation on spatial units, enforcing loc alized constraints to maintain both grid topology and neighborhood coherence. A s a plug-and-play module, STORM equips existing reduction pipelines with explici t spatial awareness without any training.
Empirical results demonstrate that STORM achieves state-of-the-art pruning accur acy across diverse vision Mamba backbones under training-free settings. Notably, STORM delivers a substantial accuracy recovery on VMamba, outperforming prior m ethods by up to 63.3\% in top-1 accuracy. Meanwhile, STORM incurs only a 1.0\% a ccuracy drop on PlainMamba, achieving performance comparable to ViT.

Bridging the Perceptual Gap: Residual-Enhanced Downscaling and Manifold-Aware Pe rception Alignment Adaptation for NR-IQA
Yu Li, Zhengran Shen, Yachun Mi, Puchao Zhou, Shaohui Liu

Leveraging Large Vision-Language Models like CLIP has recently set new benchmarks for No-Reference Image Quality Assessment (NR-IQA). However, the contrastive pretraining of CLIP inherently prioritizes semantic invariance, which often suppresses subtle perceptual signals, a phenomenon we term perceptual submergence. Furthermore, standard preprocessing techniques (e.g., cropping and interpolation) further exacerbate the loss of critical high-frequency quality cues. In this paper, we propose the Cross-modal Perception Alignment Adapter (CMPA), a manifold-aware framework designed to disentangle perceptual distortions from dominant semantics. CMPA introduces a Perception-Sensitive Feature Extractor (PFE) that projects CLIP features into a compact, low-dimensional subspace, explicitly magnifying distortion-induced off-manifold deviations. Subsequently, a Cross-Modal Perception Alignment Injector (PAI) aligns these features with quality-aware text anchors and re-injects them into the backbone. To ensure input fidelity, we also devise a Residual-enhanced Perceptual Downscaling strategy that adaptively compensates for resolution-induced information loss using Just Noticeable Difference (JND) guided frequency re-injection. Extensive evaluations on several benchmark datasets demonstrate that our approach significantly outperforms state-of-the-art methods, effectively recovering the perceptual signals submerged in semantic-dense representations.

MedCRP-CL: Continual Medical Image Segmentation via Bayesian Nonparametric Semantic Modality Discovery

Ziyuan Gao

Medical image segmentation faces a fundamental challenge in continual learning: data arrives sequentially from heterogeneous sources, yet effective continual learning requires discovering which tasks share sufficient structure to benefit from joint learning. Existing methods either apply uniform constraints across all tasks, causing catastrophic forgetting when tasks conflict, or require predefined task groupings that cannot anticipate future task diversity. We introduce MedCRP-CL, a framework that performs online task structure discovery and structure-aware continual learning. Leveraging the Chinese Restaurant Process (CRP), our method dynamically infers task groupings from clinical text prompts as tasks arrive, without requiring predefined cluster counts or access to future tasks. We term these discovered groupings semantic modalities, as they capture finer-grained structure than physical imaging modalities by integrating anatomical region and pathological context. Guided by this discovered structure, we maintain semantic modality-specific LoRA adapters regularized by intra-modality EWC, ensuring parameter isolation across dissimilar task groups while facilitating knowledge transfer within similar ones. The framework is also replay-free, storing only aggregate statistics rather than raw patient data. Experiments on 16 medical segmentation tasks across four imaging modalities demonstrate that MedCRP-CL achieves 73.3 \% Dice score with only 4.1\% forgetting, outperforming the best baseline by 8.0 \% while requiring 6$\times$ fewer parameters.
Code is available at https://github.com/zygao930/MedCRP-CL.

TEFormer: Structured Bidirectional Temporal Enhancement Modeling in Spiking Transformers

Sicheng Shen, Mingyang Lv, Bing Han, Dongcheng Zhao, Guobin Shen, Feifei Zhao, Yi Zeng

In recent years, Spiking Neural Networks (SNNs) have achieved remarkable progress, with Spiking Transformers emerging as a promising architecture for energy-efficient sequence modeling. However, existing Spiking Transformers still lack a principled mechanism for effective temporal fusion, limiting their ability to fully exploit spatiotemporal dependencies.

Inspired by feedforward–feedback modulation in the human visual pathway, we propose **TEFormer**, the first Spiking Transformer framework that achieves bidirectional temporal fusion by decoupling temporal modeling across its core components. Specifically, TEFormer employs a lightweight and hyperparameter-free **forward temporal fusion mechanism in the attention module**, enabling fully parallel co

mputation, while incorporating a **backward gated recurrent structure in the MLP ** to aggregate temporal information in reverse order and reinforce temporal con sistency.

Extensive experiments across a wide range of benchmarks demonstrate that TEForme r consistently and significantly outperforms strong SNN and Spiking Transformer baselines under diverse datasets. Moreover, through the first systematic evaluat ion of Spiking Transformers under different neural encoding schemes, we show tha t the performance gains of TEFormer remain stable across encoding choices, indic ating that the improved temporal modeling directly translates into reliable accu racy improvements across varied spiking representations. These results collectiv ely establish TEFormer as an effective and general framework for temporal modeli ng in Spiking Transformers. Code is available [here](https://github.com/Fancyssc /TEFormer).

Pushing the Boundaries of Natural Reasoning: Interleaved Bonus from Formal-Logic Verification

Chuxue Cao, Jinluan Yang, Haoran Li, Kunhao Pan, Zijian Zhao, Zhengyu Chen, Yuch en Tian, Lijun Wu, Conghui He, Yike Guo, Sirui Han

Large Language Models (LLMs) show remarkable capabilities, yet their stochastic next-token prediction creates logical inconsistencies and reward hacking that fo rmal symbolic systems avoid. To bridge this gap, we introduce a formal logic ver ification-guided framework that dynamically interleaves formal symbolic verifica tion with the natural language generation process, providing real-time feedback to detect and rectify errors as they occur. Distinguished from previous neuro-sy mbolic methods limited by passive post-hoc validation, our approach actively pen alizes intermediate fallacies during the reasoning chain. We operationalize this framework via a novel two-stage training pipeline that synergizes formal logic verification-guided supervised fine-tuning and policy optimization. Extensive ev aluation on six benchmarks spanning mathematical, logical, and general reasoning demonstrates that our 7B and 14B models outperform state-of-the-art baselines b y average margins of 10.4\% and 14.2\%, respectively. These results validate tha t formal verification can serve as a scalable mechanism to significantly push th e performance boundaries of advanced LLM reasoning.

Revisiting the Platonic Representation Hypothesis: An Aristotelian View

Fabian Gröger, Shuo Wen, Maria Brbic

The Platonic Representation Hypothesis suggests that representations from neural networks are converging to a common statistical model of reality.

We show that the existing metrics used to measure representational similarity ar e *confounded by network scale*: increasing model depth or width can systematica lly inflate representational similarity scores.

To correct these effects, we introduce a permutation-based null-calibration fram ework that transforms any representational similarity metric into a calibrated s core with statistical guarantees.

We revisit the Platonic Representation Hypothesis with our calibration framework , which reveals a nuanced picture: the apparent convergence reported by global s pectral measures largely disappears after calibration, while local neighborhood similarity, but not local distances, retains significant agreement across differ ent modalities.

Based on these findings, we propose the *Aristotelian Representation Hypothesis* : representations in neural networks are converging to shared local neighborhood relationships.

SORA: Free Second-Order Attacks in Fast Adversarial Training

Mazdak Teymourian, Ramtin Moslemi, Farzan Rahmani, Mohammad Hossein Rohban

Adversarial Training (AT) is a leading defense against adversarial examples but often suffers from *Catastrophic Overfitting* (CO) in efficient single-step vari ants, where robustness to multi-step attacks collapses despite high single-step performance.

We address this failure mode with two contributions.

First, we formalize *Epsilon Overfitting* (EO), a perspective in which fixed perturbation magnitudes and directions exacerbate CO, and show that introducing perturbation variability significantly improves robust generalization across different architectures and datasets.

Second, we propose **PertAlign** (Perturbation Alignment), a theoretically grounded, computationally negligible metric that predicts CO onset by measuring gradient alignment across attack stages.

Leveraging these insights, we introduce **SORA**, an adaptive step-size AT method that dynamically adjusts perturbations based on loss surface geometry.

SORA consistently prevents CO, achieves state-of-the-art robustness and clean accuracy, and generalizes across datasets and architectures using a single fixed set of hyperparameters, which is essential for applicability in fast AT.

Extensive experiments on diverse datasets and architectures show that SORA matches or surpasses the robustness of prior methods while delivering higher clean accuracy and superior efficiency.

Code is available at https://github.com/SecondOrderAT/SORA.

Optimal Attention Temperature Improves the Robustness of In-Context Learning under Distribution Shift in High Dimensions

Samet Demir, Zafer Dogan

Pretrained Transformers can perform in-context learning (ICL) from a few demonstrations, but this ability can fail sharply when the test distribution differs from pretraining—a common deployment setting. We study attention temperature as a simple inference-time control for improving ICL robustness under such shifts. In a high-dimensional linear-regression framework, we analyze a Transformer with "approximate softmax" attention, which preserves softmax's normalization and temperature-dependent selectivity while remaining tractable. We derive a closed-form expression for the ICL generalization error under distribution shift, and show that it is minimized by an explicit optimal attention temperature. This characterization yields interpretable guidance by linking the best temperature to moments of the pre-softmax attention scores, and predicts when temperature adjustment can recover near Bayes-optimal performance. We validate the theory with extensive simulations, and further demonstrate gains for pretrained LLMs on question-answering benchmarks under distribution shift induced by noisy in-context demonstrations. Overall, attention temperature emerges as a principled, lightweight knob for improving the robustness of ICL in pretrained Transformers.

Spectral Gradient Descent Mitigates Anisotropy-Driven Misalignment: A Case Study in Phase Retrieval

Guillaume Braun, Han Bao, Wei Huang, Masaaki Imaizumi

Spectral gradient methods, such as the Muon optimizer, modify gradient updates by preserving directional information while discarding scale, and have shown strong empirical performance in deep learning. We investigate the mechanisms underlying these gains through a dynamical analysis of a nonlinear phase retrieval model with anisotropic Gaussian inputs, equivalent to training a two-layer neural network with quadratic activation and fixed second-layer weights.

Focusing on a spiked covariance setting where the dominant variance direction is orthogonal to the signal, we show that gradient descent (GD) suffers from a variance-induced misalignment: during the early escape phase, high-variance but uninformative directions are multiplicatively amplified, degrading alignment with the true signal under strong anisotropy. In contrast, spectral gradient descent (SpecGD) removes this anisotropic magnification effect, leading to stable alignment and accelerated noise contraction. Numerical experiments confirm the theory and show that these phenomena persist under more general anisotropic covariances.

Decouple Searching from Training: Scaling Data Mixing via Model Merging for Large Language Model Pre-training

Shengrui Li, Fei zhao, Kaiyan Zhao, Jieying Ye, Haifeng Liu, Fangcheng Shi, Zhey

ong Xie, Yao Hu, Shaosheng Cao
Determining an effective data mixture is a key factor in Large Language Model (LLM) pre-training, where models must balance general competence with proficiency on hard tasks such as math and code. However, identifying an optimal mixture remains an open challenge, as existing approaches either rely on unreliable tiny-scale proxy experiments or require prohibitively expensive large-scale exploration.
To address this, we propose Decouple Searching from Training Mix (DeMix), a novel framework that leverages model merging to predict optimal data ratios. Instead of training proxy models for every sampled mixture, DeMix trains component models on candidate datasets at scale and derives data mixture proxies via weighted model merging. This paradigm decouples search from training costs, enabling evaluation of unlimited sampled mixtures without extra training burden and thus facilitating better mixture discovery through more search trials. Extensive experiments demonstrate that DeMix breaks the trade-off between sufficiency, accuracy and efficiency, obtaining the optimal mixture with higher benchmark performance at lower search cost. Additionally, we release the DeMix Corpora, a comprehensive 22T-token dataset comprising high-quality pre-training data with validated mixtures to facilitate open research. Our
code and DeMix Corpora is available at https://github.com/Lucius-lsr/DeMix.

Consistency Deep Equilibrium Models
Junchao Lin, Zenan Ling, Jingwen Xu, Robert C Qiu
Deep Equilibrium Models (DEQs) have emerged as a powerful paradigm in deep learning, offering the ability to model infinite-depth networks with constant memory usage. However, DEQs incur significant inference latency due to the iterative nature of fixed-point solvers.
In this work, we introduce the Consistency Deep Equilibrium Model (C-DEQ), a novel framework that leverages consistency distillation to accelerate DEQ inference.
We cast the DEQ iterative inference process as evolution along a fixed ODE trajectory toward the equilibrium. Along this trajectory, we train C-DEQs to consistently map intermediate states directly to the fixed point, enabling few-step inference while preserving the performance of the teacher DEQ. At the same time, it facilitates multi-step evaluation to flexibly trade computation for performance gains.
Extensive experiments across various domain tasks demonstrate that C-DEQs achieve consistent 2-20$\times$ accuracy improvements over implicit DEQs under the same few-step inference budget. Our code is available at \url{https://github.com/landrarwolf/CDEQ}.

Diagnosing and Correcting Concept Omission in Multimodal Diffusion Transformers
Kanghyun Baek, Jaihyun Lew, Chaehun Shin, Jungbeom Lee, Sungroh Yoon
Multimodal Diffusion Transformers (MM-DiTs) have achieved remarkable progress in text-to-image generation, yet they frequently suffer from concept omission, where specified objects or attributes fail to emerge in the generated image. By performing linear probing on text tokens, we demonstrate that text embeddings can distinguish a characteristic `omission signal' representing the absence of target concepts. Leveraging this insight, we propose Omission Signal Intervention (OSI), which amplifies the omission signal to actively catalyze the generation of missing concepts. Comprehensive experiments on FLUX.1-Dev and SD3.5-Medium demonstrate that OSI significantly alleviates concept omission even in extreme scenarios.
****
Heavy-tailed Physics-Informed Neural Networks
Jephte Abijuru, Mayank Nagda, Jan Tauberschmidt, Phil Ostheimer, Sebastian Josef Vollmer, Stephan Mandt, Marius Kloft, Sophie Fellenz
Physics-informed neural networks (PINNs) enforce physical laws by minimizing partial differential equation (PDE) residuals and auxiliary constraints. Standard training relies on a mean-squared error (MSE) objective, which implicitly assumes

independent Gaussian residuals with a fixed global variance. We show theoretica
lly and empirically that residuals encountered during PINN training are heteroge
neous and heavy-tailed, revealing a systematic mismatch with this assumption. As
 a consequence, a small number of large residuals can disproportionately dominat
e both the loss and gradient, leading to poorly balanced optimization dynamics.
Motivated by this mismatch, we adopt a Student-t residual model to explicitly
capture heavy-tailed behavior. An equivalent hierarchical representation yields
an expectation–maximization (EM) algorithm that alternates between estimating re
sidual-dependent weights and optimizing network parameters via a weighted MSE ob
jective, allowing existing PINN solvers to be reused in the M-step. The resultin
g training dynamics bound the influence of extreme residuals and admit almost su
re convergence guarantees under standard stochastic optimization assumptions. Ex
periments across a diverse suite of challenging PDE benchmarks demonstrate consi
stently improved solution accuracy and robustness compared to standard PINN trai
ning.

Optimal structure learning and conditional independence testing
Ming Gao, Yuhao Wang, Bryon Aragam
We establish a fundamental connection between optimal structure learning and opt
imal conditional independence testing by showing that the minimax optimal rate f
or structure learning problems is determined by the minimax rate for conditional
 independence testing in these problems. This is accomplished by establishing a
general reduction between these two problems in the case of poly-forests, and de
monstrated by deriving optimal rates for several examples, including Bernoulli,
Gaussian and nonparametric models. Furthermore, we show that the optimal algorit
hm in these settings is a suitable modification of the PC algorithm. This theore
tical finding provides a unified framework for analyzing the statistical complex
ity of structure learning through the lens of minimax testing.
****

Hallucination is a Consequence of Space-Optimality: A Rate-Distortion Theorem fo
r Membership Testing
Anxin Guo, Jingwei Li
Large language models often hallucinate with high confidence on "random facts" t
hat lack inferable patterns.
We formalize the memorization of such facts as a membership testing problem, uni
fying the discrete error metrics of Bloom filters with the continuous log-loss o
f LLMs.
By analyzing this problem in the regime where facts are sparse in the universe o
f plausible claims, we establish a rate-distortion theorem: the optimal memory e
fficiency is characterized by the minimum KL divergence between score distributi
ons on facts and non-facts.
This theoretical framework provides a distinctive explanation for hallucination
under an idealized setting: even with optimal training, perfect data, and a simp
lified ``closed world'' setting, the information-theoretically optimal strategy
under limited capacity is not to abstain or forget, but to assign high confidenc
e to some non-facts, resulting in hallucination.
We validate this theory empirically on both synthetic and real-world data, showi
ng that hallucinations persist as a natural consequence of lossy compression.
The same theorem recovers and sharpens classical space lower bounds for Bloom-ty
pe filters, pinning down an additive constant left open for two-sided filters.

Regression Language Models for Code
Yash Akhauri, Xingyou Song, Arissa Wongpanich, Bryan Lewandowski, Mohamed S. Abd
elfattah
We study \textbf{code-to-metric regression}: predicting numeric outcomes of code
 executions, a challenging task due to the open-ended nature of programming lang
uages. While prior methods have resorted to heavy and domain-specific feature en
gineering, we show that a single unified Regression Language Model (RLM) using a
 frozen LLM encoder can simultaneously predict directly from text, (i) the memor
y footprint of code across multiple high-level languages such as Python and C++,

(ii) the latency of Triton GPU kernels, and (iii) the accuracy and speed of trained neural networks represented in ONNX. In particular, a relatively small 300M parameter RLM based on T5Gemma, obtains $>$0.9 Spearman-rank on competitive programming submissions from APPS, and a single unified model achieves $>$0.5 average Spearman-rank across 24 different programming languages from CodeNet. Furthermore, the RLM can obtain the highest average Kendall-Tau of 0.46 on five classic NAS design spaces previously dominated by graph neural networks, and simultaneously predict architecture latencies on numerous hardware platforms.
****

Concept-Guided Tokenization: Closing the Gap Between Reconstruction and Generation

Yunqiao Yang, Haokun Lin, Guanzhong Wu, Ying Wei

Recent advances in image generation have been largely driven by image tokenization, which compresses raw pixels into compact latent representations. While existing tokenizers excel at preserving low-level visual details through reconstruction-based training, they often lack explicit semantic guidance, which limits their ability to capture semantically structured representations and thus hinders their performance on downstream tasks like image generation. To overcome this limitation, we propose a novel tokenization framework that incorporates high-level semantics through two key innovations: (1) a text-integrated encoder that jointly processes images and textual descriptions to produce semantically enriched latent representations, and (2) a concept-guided training objective that leverages sparse autoencoders to decompose pre-trained vision-language model features to a semantic concept space, employing sparse and disentangled concept indices for guidance. Our approach achieves strong alignment with semantic concepts, maintaining high reconstruction fidelity with an rFID of 1.39 on ImageNet, while achieving a gFID of 2.65 on the class-conditional image generation task and 10.73 on the text-to-image generation task. By infusing high-level semantic structures into low-level visual fidelity, our method bridges the reconstruction-generation divide and drives generative modeling as a powerful foundation. The code is available at https://github.com/hustyyq/ConceptTok

RA-VLA: Retrieval-Augmented VLA for Test-Time Adaptation

Sanghwan Jang, Minjin Jeon, Minsoo Kim, Seong Jin Choi, Dongha Kim, Hwanjo Yu

Vision-Language-Action (VLA) models provide a versatile foundation for general robotic manipulation, yet they exhibit significant brittleness when confronted with novel task distributions. While In-Context Imitation Learning (ICIL) offers a training-free alternative, existing frameworks suffer from an adaptation bottleneck that hinders the effective translation of expert context to executable actions. This failure originates from superficial retrieval mechanisms and an inherent behavioral inertia that anchors the policy to its pre-trained priors. To address these limitations, we present RA-VLA, a retrieval-augmented VLA framework that integrates behavior-aligned context retrieval with a grounded execution pipeline. By enforcing faithful adherence to functional cues within a scalable architecture, RA-VLA facilitates seamless task adaptation while preserving inference efficiency. Our empirical evaluations across the LIBERO benchmark and a real-world UR5e environment demonstrate that RA-VLA achieves superior success rates and computational efficiency, establishing a robust framework for training-free robotic adaptation.

Learning Rate Annealing Improves Tuning Robustness in Stochastic Optimization

Amit Attia, Tomer Koren

The learning rate in stochastic gradient methods is a critical hyperparameter that is notoriously costly to tune via standard grid search, especially for training modern large-scale models with billions of parameters. We identify a theoretical advantage of learning rate annealing schemes that decay the learning rate to zero at a polynomial rate, such as the widely-used cosine schedule, by demonstrating their increased robustness to initial parameter misspecification due to a coarse grid search. We present an analysis in a stochastic convex optimization setup demonstrating that the convergence rate of stochastic gradient descent wit

h annealed schedules depends *sublinearly* on the multiplicative misspecificatio n factor ρ (i.e., the grid resolution), achieving a rate of $O(\rho^{1/(2p+ 1)}/\sqrt{T})$ where p is the degree of polynomial decay and T is the number of steps. This is in contrast to the $O(\rho/\sqrt{T})$ rate obtained under the inverse-square-root and fixed stepsize schedules, which depend linearly on $\rh o$. Experiments confirm the increased robustness compared to tuning with a fixed stepsize, that has significant implications for the computational overhead of h yperparameter search in practical training scenarios.

From geometry to dynamics: Learning overdamped Langevin dynamics from sparse obs ervations with geometric constraints

Dimitra Maoutsa

How can we learn the laws underlying the dynamics of stochastic systems when the ir trajectories are sampled sparsely in time? Existing methods either require te mporally resolved high-frequency observations, or rely on geometric arguments th at apply only to conservative systems, limiting the range of dynamics they can r ecover.

Here, we present a new framework that reconciles these two perspectives by refor mulating inference as a stochastic control problem. Our method uses geometry-dri ven path augmentation, guided by structure in the system’s invariant density to reconstruct likely trajectories and infer the underlying dynamics without assumi ng specific parametric models. Applied to overdamped Langevin systems, our appro ach accurately recovers stochastic dynamics even from severely undersampled data , outperforming existing methods in synthetic benchmarks. This work demonstrates the effectiveness of incorporating geometric inductive biases into stochastic s ystem identification methods, with broad applications across physics, biology, a nd control.

Breaking the Computational Barrier: Provably Efficient Actor–Critic for Low-Rank MDPs

Ruiquan Huang, Donghao Li, Yingbin Liang, Jing Yang

Reinforcement learning (RL) is a fundamental framework for sequential decision-m aking, in which an agent learns an optimal policy through interactions with an u nknown environment. In settings with function approximation, many existing RL al gorithms achieve favorable sample complexity, but often rely on computationally intractable oracles. In this paper, we use supervised learning as a computationa l proxy to establish a clear hierarchy of commonly adopted RL oracles under low- rank Markov Decision Processes (MDPs). This hierarchy shows that policy evaluati on is the most computationally efficient oracle, provided that supervised learni ng can be efficiently solved. Motivated by this observation, we propose a novel optimistic actor–critic algorithm that relies solely on the policy evaluation or acle. We prove that our algorithm outperforms the existing sample complexity gua rantees for low-rank MDPs while avoiding computationally expensive planning or o ptimization oracles commonly assumed in prior works. We further extend our theor etical results to approximately low-rank MDPs and demonstrate that this setting captures a broad class of real-world environments. Finally, we validate our theo retical results with experiments on several standard Gym benchmarks.

An Evidential Route to Asymptotic Bayes Optimality under Sparsity

Qiaoyu Liang, Haohua Chen, Zihan Zhu, Michael Evans

From a statistical evidence perspective, we establish some asymptotic optimality properties of certain multiple testing rules based on the relative belief ratio (Evans, 2015). Under the two-groups model with an additive 0-1 loss and within a Bayesian decision theoretic asymptotic framework of Bogdan et al. (2011), we s how that relative belief multiple testing rules induced by a simple one-group li ght-tailed normal prior with a single hyperparameter achieve the same asymptotic Bayes risk as the Bayes oracle benchmark. This risk is the minimum achievable i n this asymptotic framework. Despite originating from a different starting point , the evidential relative belief approach enjoys oracle properties. The relative belief multiple testing approach is fundamentally different from existing Bayes

ian multiple testing procedures, virtually all induced by more complex heavy-tailed one-group global-local shrinkage priors using purely posterior-based inferences (Datta & Ghosh, 2013; Ghosh et al., 2016; Bhadra et al., 2017; Ghosh & Chakrabarti, 2017; Qin & Ghosh, 2025). By measuring statistical evidence via both the prior and posterior, the relative belief approach reveals an alternative new inferential paradigm for attaining asymptotic Bayes optimality under sparsity, one that does not rely on developing increasingly elaborate priors.

The Truth Stays in the Family: Enhancing Contextual Truthfulness via Inherited Heads in Model Lineages
Miso Choi, Seonga Choi, Mincheol Kwon, Woosung Joung, Jinkyu Kim, Jungbeom Lee
Recent advances in large language models (LLMs) have produced many specialized multimodal LLMs (MLLMs) that share common foundational LLMs, forming distinct model lineages. It remains unclear whether a fundamental behavioral link exists between the foundational LLMs and downstream variants. We investigate this question by quantifying head-level context-truthfulness scores. Across diverse LLM and MLLM lineages, including Vicuna-, Qwen2.5-, LLaMA2-, and Mistral-based models, we find that Truth Scores are strongly preserved within model families, even after instruction tuning or multimodal adaptation. We further show that this inheritance is consistent with attention-head weight preservation, and that context-truthful heads attend to query-relevant evidence. Building on this finding, we propose TruthProbe, a soft-gating strategy that amplifies context-truthful heads while preserving other head contributions. TruthProbe improves contextual truthfulness on HaluEval and reduces multimodal hallucination on POPE and CHAIR, with base-LLM Truth Scores transferring effectively to their fine-tuned LLM and MLLM descendants. Code is available at https://github.com/miso-choi/TruthProbe.
****
Beyond Token-level Supervision: Unlocking the Potential of Decoding-based Regression via Reinforcement Learning
Ming Chen, Sheng Tang, Rong-Xi Tan, Ziniu Li, Jiacheng Chen, Ke Xue, Chao Qian
Decoding-based regression, which reformulates regression as a sequence generation task, has emerged as a promising paradigm of applying large language models for numerical prediction. However, its progress is hindered by the misalignment between discrete token-level objectives (e.g., cross-entropy) and continuous numerical values. Existing approaches relying on token-level constraints often fail to capture the global magnitude of the target value, limiting their precision and generalization. In this paper, we propose to unlock the potential of decoding-based regression via reinforcement learning. We formulate the generation process as a Markov decision process, utilizing sequence-level rewards to enforce global numerical coherence.Under this framework, we present GenRe^2, which combines policy gradient methods and on-policy distillation to provide dense expert supervision while preserving error magnitudes, thereby resolving the temporal credit assignment challenge. Extensive experiments across tabular regression, code metric prediction and generative reward modeling demonstrate that GenRe^2 consistently outperforms traditional baselines, establishing a robust paradigm for general-purpose numerical prediction.
****
Influence-Guided Symbolic Regression: Scientific Discovery via LLM-Driven Equation Search with Granular Feedback
Evgeny Saveliev, Samuel Holt, Nabeel Seedat, David L. Bentley, Jim Weatherall, Mihaela van der Schaar
Large Language Models (LLMs) offer a promising avenue for scientific discovery, yet their application to symbolic regression is often constrained by inefficient search strategies and coarse feedback signals. Current methods typically guide LLMs using scalar metrics (e.g., global Mean Squared Error), which fail to identify which components of a proposed equation are driving performance or causing error. We introduce \textit{Influence-Guided Symbolic Regression} (IGSR), a method that frames equation discovery as an iterative two-step process combining diverse term generation with rigorous selection: an LLM generates candidate basis functions $\psi_j(\mathbf{x})$ for a linear model, which are then evaluated using

granular influence scores Δ_j. These scores quantify each term's marginal contribution to generalization accuracy, enabling an influence-guided pruning process that systematically refines the model structure. Integrating this mechanism into a Monte Carlo Tree Search (MCTS) enables navigating the combinatorial search space while balancing exploration of novel functional forms with exploitation of high-influence components. We demonstrate IGSR's effectiveness on a diverse suite of benchmarks, including LLM-SRBench, pharmacological PKPD models, an epidemiological simulation, and real-world genomic data. Notably, we validate the framework's capacity for genuine discovery in a case study using a high-dimensional biological dataset, in which IGSR identified a novel relationship between DNA methylation and RNA Polymerase II pausing; a hypothesis that was subsequently supported via wet-lab experimentation.

DASH: Faster Shampoo via Batched Block Preconditioning and Efficient Inverse-Root Solvers

Ionut-Vlad Modoranu, Philip Zmushko, Erik Schultheis, Mher Safaryan, Dan Alistarh

Shampoo is one of the leading approximate second-order optimizers: a variant of it has won the MLCommons AlgoPerf competition, and it has been shown to produce models with lower activation outliers that are easier to compress. Yet, applying Shampoo currently comes at the cost of significant computational slowdown, due to its expensive internal operations. In this paper, we take a significant step to address this shortcoming by proposing DASH (for Distributed Accelerated SHampoo), a faster implementation of Distributed Shampoo based on two main new techniques: First, we show that preconditioner blocks can be stacked into 3D tensors to significantly improve GPU utilization; second, we introduce the Newton-DB iteration and the Chebyshev polynomial approximations as novel and faster approaches for computing the inverse matrix roots required by Shampoo. Along with these algorithmic contributions, we provide a first in-depth analysis of how matrix scaling critically affects Shampoo convergence. On the practical side, our GPU-aware implementation achieves up to $5.6\times$ faster optimizer steps compared to the well-optimized Distributed Shampoo, while Newton-DB attains the lowest validation perplexity per iteration among all tested methods. Our code is available at https://github.com/IST-DASLab/DASH.

Joint Geometric and Trajectory Consistency Learning for One-Step Real-World Super-Resolution

Chengyan Deng, Zhangquan Chen, Li Yu, Kai Zhang, Xue Zhou, Wang Zhang

Diffusion-based Real-World Image Super-Resolution (Real-ISR) achieves impressive perceptual quality but suffers from high computational costs due to iterative sampling. While recent distillation approaches leveraging large-scale Text-to-Image (T2I) priors have enabled one-step generation, they are typically hindered by prohibitive parameter counts and the inherent capability bounds imposed by teacher models. As a lightweight alternative, Consistency Models offer efficient inference but struggle with two critical limitations: the accumulation of consistency drift inherent to transitive training, and a phenomenon we term "Geometric Decoupling"— where the generative trajectory achieves pixel-wise alignment yet fails to preserve structural coherence. To address these challenges, we propose GTASR (Geometric Trajectory Alignment Super-Resolution), a {simple yet effective} consistency training paradigm for Real-ISR. Specifically, we introduce a Trajectory Alignment (TA) strategy to rectify the tangent vector field via full-path projection, and a Dual-Reference Structural Rectification (DRSR) mechanism to enforce strict structural constraints. Extensive experiments verify that GTASR delivers superior performance over representative baselines while maintaining minimal latency.

Agentic Framework for Epidemiological Modeling

Rituparna Datta, Zihan Guan, Baltazar Espinoza, Yiqi Su, Priya Pitre, Srini Venkatramanan, Naren Ramakrishnan, Anil Vullikanti

Epidemic modeling is essential for public health planning, yet traditional appro

aches rely on fixed model classes that require manual redesign as pathogens, pol
icies, and scenario assumptions evolve. We introduce EpiAgent, an agentic framew
ork that automatically synthesizes, calibrates, verifies, and refines epidemiolo
gical simulators by modeling disease progression as an iterative program synthes
is problem. A central design choice is an explicit epidemiological flow graph in
termediate representation that links scenario specifications to model structure
and enables strong, modular correctness checks before code is generated. Verifie
d flow graphs are then compiled into mechanistic models supporting interpretable
 parameter learning under physical and epidemiological constraints.
Evaluation on epidemiological scenario case studies demonstrates that EpiAgent c
aptures complex growth dynamics and produces epidemiologically consistent counte
rfactual projections across varying vaccination and immune escape assumptions. O
ur results show that the agentic feedback loop prevents degeneration and signifi
cantly accelerates convergence toward valid models by mimicking professional exp
ert workflows.

G-RANS: Generalizable Residual-Aware Neural Solvers for Sparse Systems
Weixin Liao, Mingquan Feng, Zhizhou Zhang, Youjia Wu, Yifan Fu, Junchi Yan
Neural operators have shown promise in accelerating PDE solvers, yet they remain
 unreliable for the sparse linear systems induced by discretization due to limit
ed generalization across physical parameters and insufficient accuracy, and hybr
id neural iterative schemes face stagnation as the residual distribution evolves
 over iterations.
To address these limitations, we propose G-RANS (Generalizable Residual-Aware Ne
ural Solver), a neuralized iterative paradigm that performs residual-aware subsp
ace corrections by mapping the residual to the matrix graph, generating multi-sc
ale correction subspaces via a residual-aware basis generator, and applying proj
ected updates through a differentiable subspace projection. G-RANS is trained fu
lly self-supervised via progressive bootstrap with multi-stage residual distribu
tions.
On sparse FEM systems from a representative suite of second-order elliptic PDEs
(Poisson, advection--diffusion, reaction--diffusion, and Helmholtz), G-RANS is r
obust to severe coefficient shifts (up to $\pm70\\%$) and shows strong cross-equ
ation generalization.
G-RANS reaches relative residuals on the order of 10^{-5}, substantially outpe
rforming end-to-end neural operators, and attains the same target residual with
2--$4\times$ less wall-clock time than classical Krylov solvers.

MMClima: A Framework for Multimodal Climate Science Data and Evaluation
Muhammad Umer Sheikh, Hassan Abid, Khawar shehzad, Ufaq Khan, Muhammad Haris Kha
n
Climate change research increasingly requires AI systems that reason across text
, dynamic visual content, and scientific figures, yet existing climate QA benchm
arks are small, mostly textual, and cover a narrow range of models. We introduce
 MMClima, a large-scale multimodal climate question answering framework with ove
r 104k expert-validated question–answer pairs spanning articles, video transcrip
tions, and figures across five core climate science domains. MMClima is construc
ted via automated claim extraction and QA synthesis with human-in-the-loop valid
ation to ensure both scale and reliability. Using MMClima, we benchmark state-of
-the-art multimodal language models on tasks requiring factual recall, visual in
terpretation, and cross-modal synthesis. We additionally fine-tune on the textua
l split to produce mmclima-70b-txt, a domain-adapted baseline that outperforms s
trong open- and closed-source models on textual QA. We release the dataset, eval
uation pipeline, fine-tuned model weights, and data creation framework to suppor
t standardized multimodal evaluation for climate science.

Model Monotonicity in Autobidding Auctions: When Do Better Predictions Lead to B
etter Outcomes?
Ashwinkumar Badanidiyuru
Online advertising platforms rely on machine learning models to predict click-th

rough rates (pCTR) and conversion rates (pCVR) for auction mechanisms. We introduce a novel framework to study the interaction between recommender system model quality, auction format, and autobidder behavior. We formalize when model improvements---defined via a refinement relation inspired by filtrations in probability theory---lead to improvements in platform-level Evaluation Criteria Metrics (ECM) such as revenue, welfare, or liquid welfare. Our main contributions are: (1) a formal definition of model improvement based on cluster refinement, and (2) a systematic characterization of ECM monotonicity across different combinations of bidder types (tCPA, max-CPA), auction formats (first-price, second-price, VCG), and budget constraints. We show that first-price auctions with uniform bidding guarantee revenue monotonicity for tCPA bidders without budgets (via Jensen's inequality), while second-price auctions and budget constraints can break this property. We provide full numerical constructions for the non-monotonicity results. Our findings have practical implications for advertising platforms seeking to align model improvements with business outcomes.

Effects of Structural Reward Shaping on Biophysical Properties in RL-Trained Plasmid Generators
McClain Thiel, Angus G. Cunningham, Chris P Barnes
We compare the efficacy and distributional effects
of supervised fine-tuning (SFT) and reinforcement learning (RL) post-training for PlasmidGPT,
a foundation model for whole-plasmid generation, using Group Relative Policy Optimization
(GRPO) for the RL model. Using a biologically
motivated reward function encoding functional annotations, length constraints, and repeat penalties,
the RL model achieves a 71.6% quality-control
pass rate across 8 prompts on 4,000 sequences,
compared to 4.3% for the pretrained baseline and
11.0% for SFT. A five-model reward ablation identifies the cassette arrangement bonus, which rewards correct promoter→CDS→terminator ordering, as the critical reward component. Rejectionsampling baselines indicate that the gain is not
recovered by sampling more heavily from the base
model. Beyond directly optimized features, RLgenerated sequences converge toward real plasmid distributions in 3-mer composition and minimum free energy density, neither of which is
directly optimized by the reward function. Minimum free energy density independently converges
to the real-plasmid regime under both SFT and RL
despite these being parallel post-training paths.
On a small curated hold-out set, RL improves
continuation log-likelihood over the pretrained
baseline on all 29 held-out sequences (mean
Δ = +0.83 nats).
****
Native Spatio-Temporal 4D Variational Autoencoder
Lihe Ding, Weicai Ye, Shaocong Dong, Xintao Wang, Pengfei Wan, Kun Gai, Tianfan Xue
Dynamic 3D content representation is crucial for generating moving 3D objects and scenes. Existing 4D variational autoencoders (VAEs) are mainly based on projected 2D pointmaps, which are only incomplete and view-dependent observations that do not model the native 4D positional relations between points. This often leads to projection-induced distortions and irreversible token dislocation. In this paper, we
introduce a novel 4D VAE that operates directly in native 4D space, that is dynamic colored voxel space, without 2D projection. This
preserves explicit spatio-temporal coordinates throughout the learned encoder and decoder, enabling both partial and complete 4D
content encoding. To support a flexible temporal compression ratio, we also desi

gn a novel spatio-temporal window attention module that performs attention withi
n local 4D windows. Additionally, we propose a differentiable voxel rendering lo
ss based on sparse voxel rasterization to improve the geometry and color reconst
ruction quality. On 4D reconstruction tasks, our approach improves reconstructio
n fidelity over pointmap VAEs and flow-based VAEs while learning a more structur
ally consistent latent space. We further demonstrate the generative potential of
 our method by training a video-conditioned 4D diffusion model.

Self-Augmenting Retrieval for Diffusion Language Models
Paul Jünger, Justin Lovelace, Linxi Zhao, Dongyoung Go, Kilian Q Weinberger
Discrete diffusion language models generate text by iteratively denoising an ent
ire response in parallel. At each step, they predict tentative tokens for every
masked position, committing the confident predictions to the output and discardi
ng the unconfident ones. We show that the discarded tokens are in fact a useful
lookahead signal for retrieval-augmented generation: even low-confidence tokens
often surface salient entities early in the denoising trajectory, enabling retri
eval of stronger evidence before the output is finalized. We exploit this throug
h Self-Augmenting Retrieval for Diffusion Language Models (SARDI), a dynamic RAG
 framework that uses these lookahead tokens to guide retrieval during denoising.
 SARDI is training-free, retriever-agnostic, and applicable to any reasoning-cap
able discrete diffusion language model. Across five multi-hop QA benchmarks, SAR
DI outperforms current training-free diffusion and autoregressive retrieval base
lines at up to $8\times$ higher throughput.

QiMeng-LibBench: Benchmarking LLM Agents for Library-Scale Cross-Architecture Mi
gration
Weijia Li, KE GAO, Jiajie Li, Han Sun, Yuhe Ding, Yongdong Mai, Yiran Le, Yongji
e Qian, Zhibin Zhang, Xinyu Wang, Limin Cheng, Shouxu Kuang, Pengfei Chen, Ling
Li
Cross-architecture migration of high-performance libraries dictates ecosystem re
adiness on emerging hardware. The challenge is twofold: disentangling library-sc
ale dependencies and performance-critical kernels with ISA-specific SIMD intrins
ics, often trading migration speed for peak performance. While LLM-based agents
offer a promising approach, are confined to function-level tasks or scalar code,
 failing to assess agents’ capabilities and limitations in realistic, library-sc
ale migration. We present QM-LibBench, a benchmark for cross-architecture librar
y-scale code migration, featuring 85 critical kernels from widely used libraries
, including OpenCV, libjpeg, and NCNN. It supports comprehensive evaluations of
compilability, correctness, and performance across major transitions: ARM→RISC-V
, x86→ARM, and ARM→LoongArch. Evaluation of 12 SOTA agent-LLM combinations on QM
-LibBench reveals that, due to the lack of library-level navigation and hardware
-aware optimization, agents regress to superficial pattern matching, yielding on
ly 20.88\% correctness and 0.83 speedup for libjpeg. Motivated by these findings
, we further propose FSCM, a multi-agent framework incorporating hardware-aware
global reconfiguration and performance optimization. FSCM improves OpenCV correc
tness to 71\%. The benchmark and code are available at https://github.com/Wisdom
Joy/QM-LibBench.

When More Experts Hurt: Underfitting in Multi-Expert Learning to Defer
Shuqi Liu, Yuzhou Cao, Lei Feng, Bo An, Luke Ong
Learning to Defer (L2D) enables a classifier to abstain from predictions and def
er to an expert, and has recently been extended to multi-expert settings.
In this work, we show that multi-expert L2D is fundamentally more challenging th
an the single-expert case.
With multiple experts, the classifier's underfitting becomes inherent, which ser
iously degrades prediction performance, whereas in the single-expert setting it
arises only under specific conditions.
We theoretically reveal that this stems from an intrinsic expert identifiability
 issue: learning which expert to trust from a diverse pool, a problem absent in
the single-expert case and renders existing underfitting remedies failed.

To tackle this issue, we propose PiCCE (**Pi**ck the **C**onfident and **C**orre
ct **E**xpert), a surrogate-based method that adaptively identifies a reliable e
xpert based on empirical evidence. PiCCE effectively reduces multi-expert L2D to
 a single-expert–like learning problem, thereby resolving multi-expert underfitt
ing.
We further prove its statistical consistency and ability to recover class probab
ilities and expert accuracies.
Extensive experiments across diverse settings, including real-world expert scena
rios, validate our theoretical results and demonstrate improved performance.

DiasR: Dual-Modal Identity-Anchored Sparse Routing for Efficient Multi-Subject V
ideo Generation
Yang-yang Li, Wu Liu, Jie Li, Xinchen Liu, Yongdong Zhang, Guoqing Jin
Personalized multi-subject video generation is a promising direction within the
 field of controllable video generation; however, existing methods face challenge
s in maintaining cross-frame identity consistency and incur high computational o
verhead. To address these issues, we propose DiasR, an efficient framework that
 integrates Dual-Modal Identity-Anchored Alignment and a novel Sparse Routing Str
ategy. The Dual-Modal Identity-Anchored Alignment employs learnable identity que
ries to align visual and textual modalities with ground-truth subject masks, the
reby mitigating cross-frame identity drift. The Sparse Routing Strategy dynamica
lly routes video tokens to relevant subjects and groups them through bucket aggr
egation, reducing computational overhead and alleviating identity entanglement i
nduced by redundant tokens. We also construct MuSA-2M, a large-scale dataset com
prising 2 million annotated samples equipped with subject-level masks, which fil
ls the gap in existing multi-subject video datasets. Experiments conducted on th
e OpenS2V-Eval benchmark demonstrate that our method achieves superior performan
ce in identity consistency, text fidelity, and video naturalness. Notably, it ma
intains a nearly constant inference time as the number of reference subjects inc
reases, outperforming existing baselines in both efficiency and generation quali
ty for scenarios involving multi-subject interactions. Project Page: https://tal
e17.github.io/diasr.

Linear Bandits beyond Inner Product Spaces, the case of Bandit Optimal Transport
Lorenzo Croissant
Linear bandits have long been a central topic in online learning, with applicati
ons ranging from recommendation systems to adaptive clinical trials. Their gener
al learnability has been established when the objective is to minimise the inner
 product between a cost parameter and the decision variable. While this is highl
y general, this reliance on an inner product structure belies the name of \emph{
linear} bandits, and fails to account for problems such as Optimal Transport. Us
ing the Kantorovich formulation of Optimal Transport as an example, this article
 shows that an inner product structure is \emph{not} necessary to achieve effici
ent learning in linear bandits. We propose a refinement of the classical OFUL al
gorithm that operates by embedding the action set into a Hilbertian subspace, wh
ere confidence sets can be built via least-squares estimation. Actions are then
constrained to this subspace by penalising optimism. The analysis is completed b
y leveraging convergence results from penalised (entropic) transport to the Kant
orovich problem. Up to this approximation term, the resulting algorithm achieves
 the same trajectorial regret upper bounds as the OFUL algorithm, which we turn
into worst-case regret using functional regression techniques. Its regret interp
olates between $\tilde{\mathcal O}(\sqrt{T})$ and ${\mathcal O}(T)$, depending o
n the regularity of the cost function, and recovers the parametric rate $\tilde{
\mathcal O}(\sqrt{dT})$ in finite-dimensional settings.

Interaction-Breaking Adversarial Learning Framework for Robust Multi-Agent Reinf
orcement Learning
Sunwoo Lee, Mingu Kang, Yonghyeon Jo, Seungyul Han
Cooperation is central to multi-agent reinforcement learning (MARL), yet learned
 coordination can be fragile when external perturbations disrupt inter-agent int

eractions. Prior robust MARL methods have primarily considered value-oriented attacks, leaving a gap in robustness when interaction structures themselves are corrupted. In this paper, we propose an interaction-breaking adversarial learning (IBAL) framework that takes an information-theoretic view to construct attacks that impede coordination by perturbing agents' observations and actions, and trains agents to perform reliably under such disruptions. Empirically, our approach improves robustness over existing robust MARL baselines across diverse attack settings and yields stronger performance even under agent-missing scenarios. Our code is available at https://sunwoolee0504.github.io/IBAL.

Decoupling Regularization and Privacy in Differentially Private Ridge Regression and ERM

Wanjie Wang, Tathagata Banerjee

We study ridge regression and ridge-regularized empirical risk minimization (ERM) under (ε,δ)-differential privacy via output perturbation. In classical private ERM, the ridge parameter simultaneously controls statistical regularization and the estimator's global sensitivity. Larger regularization reduces the DP noise scale but increases bias. So choosing the tuning parameter becomes a privacy--accuracy bottleneck. We propose a framework that makes these two roles explicit by decoupling regularization into (i) a statistical penalty α, defining the target ridge/ERM solution, and (ii) a privacy-stabilization parameter c, used only to enforce a curvature floor and hence a tight sensitivity bound. We apply this framework to ridge regression, where c is used to boost the minimum eigenvalue of the empirical Gram matrix. We derive an explicit bias--variance--DP-variance risk decomposition and characterize optimal (α,c) in several regimes, yielding sharp tuning guidance and improved accuracy relative to single-parameter regularization. Finally, we extend the same decoupling principle to general ridge-regularized ERM. We support the theory with simulations.

****

Even Faster Kernel Matrix Linear Algebra via Density Estimation

Rikhav Shah, Sandeep Silwal, Haike Xu

This paper studies the use of *kernel density estimation* (KDE) for linear algebraic tasks involving the *kernel matrix* of a collection of n data points in $\mathbb{R}^d$.

In particular, we improve upon the best existing algorithms for computing the following up to $(1+\varepsilon)$ relative error for a Gaussian kernel matrix and other kernels: matrix-vector products, matrix-matrix products, the spectral norm, and sum of all entries. The runtimes of our algorithms depend linearly on the dimension d, sub-quadratically in the number of points n, and polynomially on the target error ε. Importantly, the dependence on n in each case is far lower when accessing the kernel matrix through KDE queries as opposed to reading individual entries. Our improvements over existing best algorithms (particularly those of [Backurs et al. ICML `21]) for these tasks reduce the polynomial dependence on ε, and additionally decrease the dependence on n in the case of computing the sum of all entries of the kernel matrix. For example, we reduce the power of $1/\epsilon$ from ≈ 7.7 to ≈ 3.2 for a $1-\varepsilon$ relative error estimation of the spectral norm of a Gaussian kernel matrix. We complement our upper bounds with several lower bounds for related problems, which provide (conditional) quadratic time hardness results and additionally hint at the limits of KDE based approaches for the problems we study.

****

Physics-Informed Diffusion Models in Spectral Space

Davide Gallon, Philippe von Wurstemberger, Patrick Cheridito, Arnulf Jentzen

We propose physics-informed spectral diffusion (PISD), a methodology that combines generative latent diffusion models with physics-informed machine learning to generate solutions of partial differential equations (PDEs) conditioned on partial observations, which includes, in particular, forward and inverse PDE problems. We learn the joint distribution of PDE parameters and solutions via a diffusion process in a latent space of scaled spectral representations, where Gaussian n

oise corresponds to functions with controlled regularity. This spectral formulat ion enables significant dimensionality reduction compared to grid-based diffusio n models and ensures that the induced process in function space remains within a class of functions for which the PDE operators are well defined. Building on di ffusion posterior sampling, we enforce physics-informed constraints and measurem ent conditions during inference, applying Adam-based updates at each diffusion s tep. We evaluate the proposed approach on Poisson, Helmholtz, and incompressible Navier-Stokes equations, demonstrating improved accuracy and computational effi ciency compared with existing diffusion-based PDE solvers, which are state of th e art for sparse observations. Code is available at https://github.com/deeplearn ingmethods/PISD.

****

Universal One-third Time Scaling in Learning Peaked Distributions

Yizhou Liu, Ziming Liu, Cengiz Pehlevan, Jeff Gore

Training large language models (LLMs) is computationally expensive, partly becau se the loss exhibits slow power-law convergence whose origin remains debatable. Through systematic analysis of toy models and empirical evaluation of LLMs, we s how that this behavior can arise intrinsically from the use of softmax and cross -entropy. When learning peaked probability distributions, e.g., next-token distr ibutions, these components generically yield power-law vanishing losses and grad ients, regardless of many microscopic details, creating a fundamental optimizati on bottleneck. This ultimately leads to power-law time scaling of the loss with a universal exponent of $1/3$. Our results provide a mechanistic explanation for observed neural scaling and suggest new directions for improving LLM training e fficiency.

A-MemGuard: A Proactive Defense Framework For LLM-Based Agent Memory

Qianshan Wei, Tengchao Yang, Yaochen Wang, Xinfeng Li, Lijun Li, Zhenfei Yin, Yi Zhan, Thorsten Holz, Zhiqiang Lin, XiaoFeng Wang

Large Language Model (LLM) agents use memory to learn from past interactions. Ho wever, this reliance on memory introduces a critical security risk: an adversary can inject seemingly harmless records into an agent's memory to manipulate its future behavior. This vulnerability is characterized by two core aspects: First, the malicious effect of injected records is only activated within a specific co ntext, making them hard to detect when individual memory entries are audited in isolation. Second, once triggered, the manipulation can initiate a self-reinforc ing error cycle: the corrupted outcome is stored as precedent, which not only am plifies the initial error but also progressively lowers the threshold for simila r attacks in the future. To address these challenges, we introduce \emph{A-MemGu ard} (\underline{A}gent-\underline{Mem}ory \underline{Guard}), the first defense framework for LLM agent memory. The core idea of our work is the insight that m emory itself must become both \emph{self-checking} and \emph{self-correcting}. W ithout modifying the agent's core architecture, A-MemGuard combines two mechanis ms: (1) \textbf{consensus-based validation}, which detects anomalies by comparin g reasoning paths derived from multiple related memories and (2) a \textbf{dual- memory structure}, where detected failures are distilled into ``lessons'' stored separately and consulted before future actions, breaking error cycles and enabl ing adaptation.

Comprehensive evaluations on multiple benchmarks show that A-MemGuard effectivel y cuts attack success rates by over 95\% while incurring a minimal utility cost. This work shifts LLM memory security from static filtering to a proactive, expe rience-driven model where defenses strengthen over time.

****

Local Redundancy: An Information-Theoretic Measure of Plasticity from Synthetic Memorization

Jiaxuan Cheng

Plasticity—a neural network's ability to adapt to new tasks—is critical for cont inual and transfer learning. Existing measures, such as effective rank, dead neu ron fraction, and weight norm, lack theoretical grounding and correlate poorly w ith performance on new tasks. We introduce *local redundancy*, an information-th

eoretic measure derived from universal compression theory. We define local redundancy as the worst-case redundancy of a local model family—parameters in an infinitesimal neighborhood along gradient directions—and show this is a principled measure of plasticity. Although local redundancy is intractable to compute exactly, we prove that the expected squared gradient norm on a synthetic memorization task provides an efficiently computable lower bound. Experiments on continual image classification and time series transfer learning demonstrate that local redundancy predicts downstream performance better than existing measures and enables pretraining checkpoint selection where validation loss plateaus.

Provable Accuracy Collapse of Embedding-Based Representations under Dimensionality Mismatch

Dionysis Arvanitakis, Vaggos Chatziafratis, Yiyuan Luo

Embedding-based representations in Euclidean space $\mathbb{R}^d$ are a cornerstone of modern machine learning, where a major goal is to use the \emph{smallest dimension} that faithfully captures data relations. In this work, we prove sharp dimension--accuracy tradeoffs and identify a fundamental information-theoretic limitation: unless the embedding dimension d is chosen close to the ground-truth dimension D, accuracy undergoes a sudden collapse. Our main result shows that this phenomenon arises even in standard contrastive learning settings, where supervision is limited to a set of m anchor--positive--negative triplets (i,j,k) encoding distance comparisons $\mathrm{dist}(i,j) < \mathrm{dist}(i,k)$. Specifically, given triplets realizable by an unknown ground-truth embedding in D dimensions, we prove that there exists constant $c < 1$, such that \emph{every embedding of dimension at most cD violates almost half of the triplets}, yielding accuracy as low as a trivial one-dimensional solution that ignores the input. We complement our information-theoretic bounds with strong computational hardness results: under the Unique Games Conjecture, even if the given triplets are nearly realizable in $D=1$ dimension, no polynomial-time algorithm---\textit{regardless of its dimension}---can achieve accuracy above the trivial 50% baseline.

****

$\texttt{ShaplEIG}$: Bayesian Experimental Design for Shapley Value Estimation

David Rundel, Fabian Fumagalli, Maximilian Muschalik, Bernd Bischl, Matthias Feurer

Shapley values are a principled attribution measure widely used in interpretable machine learning, but their exact computation scales exponentially with the number of players, motivating a wide range of approximation methods based on value function evaluations of sampled coalitions. This raises the question of whether approximation accuracy can be improved by *adaptively* selecting coalitions for evaluation based on previous evaluations. This is particularly relevant in settings where the value function is *costly* and the number of evaluations is severely limited, such as retraining-based feature importance, data valuation, and hyperparameter importance. For this purpose, we propose $\texttt{ShaplEIG}$, a Bayesian experimental design approach that approximates the expensive value function using a Gaussian process surrogate and adaptively selects coalitions based on their expected information gain about the Shapley values. By the linearity of the Shapley values in the value function, we show that the expected information gain is available in *closed form*. Furthermore, we propose an *efficient* computation scheme that reduces the complexity from exponential to polynomial in the number of players via elementary symmetric polynomials. In extensive experiments across diverse costly applications, our method consistently improves sample efficiency in the low-budget regime over state-of-the-art baselines.

GENEB: Why Genomic Models Are Hard to Compare

Daria Ledneva, Mikhail Nuridinov, Denis Kuznetsov

Progress in genomic foundation models is difficult to assess due to fragmented benchmarks, incompatible evaluation protocols, and task-specific reporting. As a result, claims of superiority or generality across models are often not directly comparable. We introduce GENEB, a large-scale diagnostic benchmark that evaluat

es frozen representations from 40 genomic foundation models across 100 tasks spa
nning 13 functional categories under a unified probing-based protocol, including
 few-shot regimes. GENEB enables controlled comparison across model scale, archi
tecture, tokenization, and pretraining data while explicitly exposing task-level
 trade-offs. Our analysis shows that aggregate leaderboards are unstable: model
rankings vary sharply across task categories, scale provides only modest and inc
onsistent gains, and architectural and pretraining alignment frequently outweigh
 parameter count. These results highlight limitations of current evaluation prac
tices and position GENEB as a reference framework for principled comparison and
category-aware model selection in genomic machine learning.

Expanding the Chaos: Neural Operator for Stochastic (Partial) Differential Equat
ions

Dai Shi, Lequan Lin, Andi Han, Luke Thompson, José Miguel Hernández-Lobato, Zhiy
ong Wang, Junbin Gao

Stochastic differential equations (SDEs) and stochastic partial differential equ
ations (SPDEs) are fundamental for modeling stochastic dynamics across the natur
al sciences and modern machine learning. Learning their solution operators with
deep learning models promises fast solvers and new perspectives on classical lea
rning tasks. In this work, we build on Wiener--chaos expansions (WCE) to design
neural operator (NO) architectures for SDEs and SPDEs: we project driving noise
paths onto orthonormal Wick--Hermite features and use NO backbones to parameteri
ze the corresponding chaos coefficients governed by deterministic equations, ena
bling reconstruction of S(P)DE solutions from the observed noise trajectories. E
mpirically, we achieve competitive accuracy across several tasks, including stan
dard SPDE benchmarks and SDE-based diffusion one-step image sampling, topologica
l graph interpolation, financial extrapolation, parameter estimation, and manifo
ld SDE flood forecasting. We further explore a law-matching setting where the Br
ownian trajectories paired with training solutions are unobserved, and show that
 the proposed framework remains effective by sampling auxiliary Brownian paths f
rom the prescribed noise prior. These results suggest WCE-based neural operators
 are a practical and scalable approach to learning SDE/SPDE solution operators a
cross domains. Our source code can be found in https://github.com/EEthanShi/SDEN
O.

Chain-of-Thought Gradient Descent

Hong-Yu Chen, Venkat Sripad Ganti, Hude Liu, Jerry Yao-Chieh Hu, Han Liu

We show that Chain-of-Thought (CoT) expands the expressiveness of Transformer in
-context learning (ICL).
Specifically, we show CoT enable efficient simulation of In-Context Gradient Des
cent (ICGD) for N-layer neural network.
Different from CoT, a Transformer with fixed depth and hidden dimension has fixe
d ICL capacity in one forward pass.
Simulating larger models or more optimization steps in-context requires deeper o
r wider Transformers.
CoT removes this limitation by providing an expandable workspace via the sequenc
e trajectory.
This enables arbitrary-step and arbitrary-capacity ICGD within a constant-depth
Transformer.
Second, we provide a provable efficient guarantee unique to CoT through dynamica
l masking.
The attention mechanism only process the relevant tokens for the current update
step.
This eliminates the redundant ``process everything'' cost of single-pass deep mo
dels.
Specifically, we prove this CoT mechanism improves the computational cost of the
 prior best in-context result [Wu et al., ICML 2025] by $O(N)$.
Numerical validations support our theory.
****

Generation Enhances Understanding in Unified Multimodal Models via Multi-Represe

ntation Generation
Zihan Su, Hongyang Wei, Kangrui Cen, Yong Wang, Guanhua Chen, Chun Yuan, Xiangxi ang Chu
Unified Multimodal Models (UMMs) integrate both visual understanding and generat ion within a single framework.
Their ultimate aspiration is to create a cycle where understanding and generatio n mutually reinforce each other.
While recent post-training methods have successfully leveraged understanding to enhance generation, the reverse
direction of utilizing generation to improve understanding remains largely unexp lored. In this work, we propose
UniMRG (Unified Multi-Representation Generation), a simple yet effective archite cture-agnostic post-training method.
UniMRG enhances the understanding capabilities of UMMs by incorporating auxiliar y generation tasks. Specifically,
we train UMMs to generate multiple intrinsic representations of input images, na mely pixel (reconstruction), depth
(geometry), and segmentation (structure), alongside standard visual understandin g objectives. By synthesizing these
diverse representations, UMMs capture rich complementary information regarding a ppearance, spatial relations, and
structural layout. Consequently, UMMs develop a deeper and more comprehensive un derstanding of visual inputs. Extensive
experiments across diverse UMM architectures
demonstrate that our method notably enhances fine-grained perception, reduces ha llucinations, and improves spatial understanding,
while simultaneously boosting generation capabilities.

Towards Understanding Adam Convergence on Highly Degenerate Polynomials
Zhiwei Bai, Jiajie Zhao, Zhangchen Zhou, Zhi-Qin John Xu, Yaoyu Zhang
Adam is a widely used optimization algorithm in deep learning, yet the specific class of objective functions where it exhibits inherent advantages remains under explored. Unlike prior studies requiring external schedulers and β_2 near 1 for convergence, this work investigates the ``natural'' auto-convergence prope rties of Adam. We identify a class of highly degenerate polynomials where Adam c onverges automatically without additional schedulers. Specifically, we derive th eoretical conditions for local asymptotic stability on degenerate polynomials an d demonstrate strong alignment between theoretical bounds and experimental resul ts. We prove that Adam achieves local linear convergence on these degenerate fun ctions, significantly outperforming the sub-linear convergence of Gradient Desce nt and Momentum. This acceleration stems from a decoupling mechanism between the second moment v_t and squared gradient g_t^2, which exponentially amplifies the effective learning rate. Finally, we characterize Adam's hyperparameter pha se diagram, identifying three distinct behavioral regimes: stable convergence, s pikes, and SignGD-like oscillation.

Spectra: Rethinking Optimizers for LLMs Under Spectral Anisotropy
Zhendong Huang, Hengjie Cao, Fang Dong, Ruijun Huang, Mengyi Chen, Yifeng Yang, Xin Zhang, Anrui Chen, Mingzhi Dong, Yujiang Wang, Jinlong Hou, Qin Lv, Robert P . Dick, Yuan Cheng, Tun Lu, Fan Yang, Li Shang
Gradient signals in LLM training are highly anisotropic: recurrent linguistic st ructure concentrates energy into a small set of dominant spectral directions, wh ile context-specific information resides in a long tail. We show that this spike –tail separation persists throughout training, with the spike occupying only abo ut 1.5% of directions yet dominating optimizer statistics. This dominance suppre sses tail learning by contracting tail updates through second-moment normalizati on and tightening the globally stable learning-rate bound.
Motivated by this analysis, we propose Spectra, a spike-aware optimizer that sup presses the dominant low-rank spike subspace without amplifying the noise-sensit ive spectral tail. Spectra tracks the spike subspace via cached, warm-started po

wer iteration and applies low-rank spectral shaping with negligible overhead and substantially reduced optimizer-state memory.
Across Qwen3-0.6B trained on 100B tokens and LLaMA3-8B trained on 50B tokens, Spectra achieves the lowest final validation loss, improving average downstream accuracy by 1.41/0.89 and 1.62/0.66 points over AdamW/Muon, respectively. For wall-clock convergence, Spectra reaches matched loss targets up to 1.31×, 1.34×, and 1.24× faster than AdamW on Qwen3-0.6B, Qwen3-2B-A0.8B, and Qwen3-8B; its speedup over Muon grows as model scale increases from 0.6B to 8B. For computational efficiency, Spectra is 5.1× faster than Muon in optimizer processing time, cuts optimizer-state memory by 49.25%, and achieves the lowest measured end-to-end per-step runtime. Spectra's Megatron integration is available at https://github.com/kimmichtank/spectra.

SLAP: The Semantic Least Action Principle for Variational Video-Language Modeling

Xiang Fang, Wanlong Fang

In the era of Large Video-Language Models (LVLMs), the computational necessity of sparse frame sampling creates a fundamental ``temporal gap'', rendering models blind to critical causal transitions. Existing solutions relying on generative hallucination (e.g., latent diffusion) or autoregressive extrapolation often fail to maintain semantic consistency over long horizons, suffering from object vanishing and energetic instability. We propose a paradigm shift from probabilistic generation to variational mechanics with the Semantic Least Action Principle (SLAP). Drawing a rigorous isomorphism between classical mechanics and semantic dynamics, we model the latent video trajectory as a path on a Riemannian manifold governed by a Semantic Lagrangian. By formulating the interpolation task as a Boundary Value Problem (BVP) solved via the discrete Euler-Lagrange equations, SLAP naturally enforces object persistence without pixel-level rendering. Extensive experiments on multiple challenging datasets show the effectiveness of our proposed SLAP.

A Unifying Relational Perspective on Expressive Lottery Tickets

Lorenz Kummer, Samir Moustafa, Anatol Ehrlich, Franka Bause, Marco Nennstiel, Przemys■aw Andrzej Wa■■ga, Nils Morten Kriege

Graph neural networks (GNNs) are widely used, but how parameter sparsity affects the expressivity of relational (RGNNs) and temporal (TGNNs) variants is poorly understood. The Strong Expressive Lottery Ticket Hypothesis (SELTH) posits the existence of sparse GNNs that preserve Weisfeiler-Leman (WL) expressivity on static graphs. We generalize this existence result to a probabilistic statement for multi-relational and temporal domains via the relational WL (RWL). We prove that sufficiently parameterized RGNNs contain sparse subnetworks that maintain 1-RWL expressivity and derive a lower bound on the probability that a random pruning yields such a subnetwork. We show that common TGNNs and cross-graph message passing schemes admit RGNN reformulations such that they inherit these guarantees and, moreover, that the expressivity of a sparse RGNN is connected to its optimization behavior under common update regimes. Experiments instantiate the bound, compare it to empirical probabilities on synthetic data, and study how pre-training expressivity relates to optimization and prediction quality metrics on temporal and molecular benchmarks.

$\textit{S}$-SPPO: Semantic-Calibrated Self-Play Preference Optimization

Xiwen Chen, Wenhui Zhu, Jingjing Wang, Peijie Qiu, Zhipeng Wang, Huayu Li, Zheng Xiao He, XUANZHAO DONG, Prayag Tiwari, Mingkun Xu, Yujian Xiong, Feng Luo, Abolfazl Razi, Brendan Hogan Rappazzo, Anderson Schneider, Yuriy Nevmyvaka

Aligning Large Language Models (LLMs) with human preferences is often formulated via Direct Preference Optimization (DPO). However, the standard Bradley-Terry instantiation of DPO is limited in modeling common departures from transitivity in human preferences. To address this, recent work has introduced Self-Play Preference Optimization (SPPO), which iteratively refines the policy by training on self-generated win-lose pairs. Our investigation, however, reveals a critical ins

tability in SPPO: the optimization is prone to \textit{policy degeneration} when the preference oracle assigns overly confident wins to semantically indistinguishable responses. To mitigate this, we propose $\textit{S}$-SPPO, a dual-space semantic calibration framework comprising: i) $\textit{Supervision Calibration}$ via semantic gating, which anneals win rate targets toward the maximum-entropy baseline as semantic overlap increases; and ii) $\textit{Representation Calibration}$ via latent repulsion to enforce geometric diversity to prevent manifold collapse and maintain latent diversity between chosen and rejected samples. Theoretically, we show that the calibration preserves the constant-sum game structure, facilitating convergence to a Nash Equilibrium. Empirically, $\textit{S}$-SPPO avoids the performance degradation seen in prior methods, achieving 52.19\% win rate and 47.46\% length-controlled win rate on AlpacaEval 2.0 with Llama-3-8B, without using additional human-annotated preferences during training.

TimeOmni-VL: Unified Models for Time Series Understanding and Generation
Tong Guan, Sheng Pan, Johan Barthelemy, Zhao Li, Yujun Cai, Cesare Alippi, Ming Jin, Shirui Pan
Recent time series modeling faces a sharp divide between numerical generation and semantic understanding, with research showing that generation models often rely on superficial pattern matching, while understanding-oriented models struggle with high-fidelity numerical output. Although unified multimodal models (UMMs) have bridged this gap in vision, their potential for time series remains untapped. We propose TimeOmni-VL, the first vision-centric framework that unifies time series understanding and generation through two key innovations: (1) Fidelity-preserving bidirectional mapping between time series and images (Bi-TSI), which advances Time Series-to-Image (TS2I) and Image-to-Time Series (I2TS) conversions to ensure near-lossless transformations. (2) Understanding-guided generation. We introduce TSUMM-Suite, a novel dataset consisting of six understanding tasks rooted in time series analytics and coupled with two generation tasks. With a calibrated Chain-of-Thought (CoT), TimeOmni-VL is the first to leverage time series understanding as an explicit control signal for high-fidelity generation. Experiments confirm that this unified approach significantly improves semantic understanding and numerical precision, establishing a new frontier for multimodal time series modeling.

Learning Anisotropic Value Geometry with Finsler Reinforcement Learning
Jumman Hossain, Nirmalya Roy
We introduce **Finslerian Reinforcement Learning (FiRL)**, an RL framework that makes directional costs explicit and improves robustness to tail risk. FiRL incorporates a *Finsler metric* into the locomotion cost, expressing effort as $F(x, v)$ that depends on the state x and motion v, so it can capture uphill versus downhill asymmetry, lateral slip, and other direction-dependent effects. To handle rare but catastrophic outcomes, FiRL optimizes a Conditional Value-at-Risk ($CVaR_\alpha$) objective. We derive the corresponding risk-sensitive Bellman equation and show that the resulting CVaR--Finsler Bellman operator is a γ-contraction. This guarantees a unique fixed-point value function, while the underlying Finsler cost induces an asymmetric path cost d_F that satisfies a triangle inequality despite directional asymmetry. We then develop a FiRL actor--critic algorithm to learn policies under this anisotropic, risk-averse objective. Across simulation benchmarks and real-world robot trials, FiRL demonstrates safer and more energy-efficient locomotion behavior than strong baselines such as risk-neutral PPO. For instance, on a 12° sloped Hopper task, FiRL reduces worst-case ($CVaR_{0.1}$) impact forces by over 35% and total energy cost by 15%, while also improving success rate.

LLM Watermark Evasion via Bias Inversion
Jeongyeon Hwang, Sangdon Park, Jungseul Ok
Watermarking offers a promising solution for detecting LLM-generated content, yet its robustness under realistic query-free (black-box) evasion remains an open challenge. Existing query-free attacks often achieve limited success or severely

distort semantic meaning. We bridge this gap by theoretically analyzing rewriting-based evasion, demonstrating that reducing the average conditional probability of sampling green tokens by a small margin causes the detection probability to decay exponentially. Guided by this insight, we propose the \emph{Bias-Inversion Rewriting Attack} (BIRA), a practical query-free method that applies a negative logit bias to a proxy suppression set identified via token surprisal. Empirically, BIRA achieves state-of-the-art evasion rates ($>99\%$) across diverse watermarking schemes while preserving semantic fidelity substantially better than prior baselines. Our findings reveal a fundamental vulnerability in current watermarking methods and highlight the need for rigorous stress tests. Our code is available at \href{https://github.com/ml-postech/LLM-Watermark-Evasion-via-Bias-Inversion}{here}.

Emergent Communication Under Misinformation

Heeyoung Lee, Kyungwoo Song

Social interactions are characterized by both adversarial and cooperative aspects. Communications between agents may also involve adversarially motivated actors. Messages can pass through intermediaries with malicious intent before reaching the intended receiver. These actors may modify the message to induce misunderstanding from the receiver while preserving the overall characteristics of the message. This form of misinformation is prevalent in real-world communications and may affect the dynamics under which communication protocols are developed. However, this aspect of social interaction is relatively underexplored in many emergent communication studies that aim to understand the environmental factors behind the emergence of languages' characteristics. This work explores how misinformation affects language emergence with a focus on compositionality. We design a communication game containing a malign intermediary between the sender and receiver. We find that risks of malign misrepresentation promote the emergence of compositional languages in simulations of communicative agents. Furthermore, we observe that adaptability of malign intermediaries is a crucial factor in forming a consistent pressure toward compositionality and that partial misinformation, in which the intermediary targets only a subset of attributes, can also induce compositionality.

EARL: Towards a Unified Analysis-Guided Reinforcement Learning Framework for Egocentric Interaction Reasoning and Pixel Grounding

Yuejiao Su, Xinshen ZHANG, Zhen Ye, Lei Yao, Lap-Pui Chau, Yi Wang

A precise and comprehensive understanding of human-environment interactions in egocentric vision is essential for next-generation intelligent agents, such as assistive robotics.

While existing multimodal large language models (MLLMs) support unified reasoning from scene-level analysis to instance-specific grounding, their accuracy and generalization remain limited.

To this end, this paper introduces a novel Egocentric Analysis-guided RL-based method (EARL) that employs Group Relative Policy Optimization (GRPO) to enhance the interaction understanding of MLLMs in first-person vision.

Specifically, EARL adopts a two-stage parsing framework including coarse-grained interpretation and fine-grained response.

The first stage holistically interprets egocentric interactions and generates a structured textual description. The second stage produces the language answer and corresponding pixel-level grounding mask in response to the user query. To bridge the two stages, we extract a global interaction descriptor from the first stage and treat it as a semantic prior, which is then integrated via a novel Analysis-guided Feature Synthesizer (AFS) to support query-oriented reasoning.

Furthermore, to effectively guide policy optimization, we design a sophisticated, multi-faceted reward mechanism that incorporates format correctness, answer relevance, and grounding accuracy. Experimental results demonstrate that EARL achieves an impressive 65.48% cIoU on the Ego-IRGBench benchmark for pixel grounding, surpassing previous state-of-the-art RL-based methods by 8.37%.

Superior performance in out-of-distribution evaluations further validates EARL's

generalization capability.

Performative Learning Theory
Julian Rodemann, Unai Fischer-Abaigar, James Bailie, Krikamol Muandet
Performative predictions influence the very outcomes they aim to forecast. We study performative predictions that affect a sample (e.g., only existing users of an app) and/or the whole population (e.g., all potential app users). This raises the question of how well models generalize under performativity. For example, how well can we draw insights about new app users based on existing users when both of them react to the app's predictions? We address this question by embedding performative predictions into statistical learning theory. We prove generalization bounds under performative effects on the sample, on the population, and on both. A key intuition behind our proofs is that in the worst case, the population negates predictions, while the sample deceptively fulfills them. We cast such self-negating and self-fulfilling predictions as min-max and min-min risk functionals in Wasserstein space, respectively. Our analysis reveals both a fundamental trade-off between performatively changing the world and learning from it, as well as a surprising insight on how to improve generalization guarantees by retraining on performatively distorted samples. We illustrate our bounds using real data on prediction-informed assignments to job trainings.

MME-Reasoning: A Broad-Spectrum Benchmark for Evaluating Logical Reasoning in MLLMs
Jiakang Yuan, Tianshuo Peng, Yilei Jiang, Yiting Lu, Renrui Zhang, Kaituo Feng, Chaoyou Fu, Tao Chen, LEI BAI, Bo Zhang
Logical reasoning is a fundamental aspect of human intelligence and an essential capability for multimodal large language models (MLLMs). Despite the significant advancement in multimodal reasoning, existing benchmarks fail to comprehensively evaluate their reasoning abilities due to the lack of explicit categorization for logical reasoning types and an unclear understanding of reasoning. To address these issues, we introduce MME-Reasoning, a comprehensive benchmark designed to evaluate the reasoning ability of MLLMs, which covers all three types of reasoning (i.e., inductive, deductive, and abductive). We carefully curate the data to ensure that each question effectively evaluates reasoning ability rather than perceptual skills or knowledge breadth, and extend the evaluation protocols to cover the evaluation of diverse questions. Our evaluation reveals substantial limitations of SoTA MLLMs when subjected to holistic assessments of logical reasoning capabilities. Even the most advanced MLLMs show limited performance in comprehensive logical reasoning, with notable performance imbalances across reasoning types. In addition, we conducted an in-depth analysis of approaches such as ``thinking mode'' and Rule-based RL, which are commonly believed to enhance reasoning abilities. We hope the community can pay more attention to the comprehensive reasoning capabilities of MLLMs instead of only focusing on its subset.
****
Score Based Error Correcting Code Decoder
Alon Helvits, Eliya Nachmani
Error-correcting codes enable reliable communication, yet practical soft decoding remains challenging across code families and block lengths. We propose SB-ECC, a score-based decoder that casts decoding as continuous-time denoising. A neural denoiser defines a probability-flow ordinary differential equation (ODE) that iteratively updates the noisy channel observation toward a valid codeword, guided by parity constraints. The model is trained across noise levels without time/SNR conditioning, enabling inference without SNR estimation and supporting a direct latency--accuracy trade-off controlled by the ODE solver budget. We use the raw signed channel observation as input for learning a continuous denoising field. Across 42 code/SNR settings, SB-ECC achieves the best BER in $39/42$ entries, with an average SNR gain of 0.17\,dB and a maximum gain of 0.46\,dB over the strongest competing baseline, we showed that swapping the solver from Euler to DPM preserves $-\ln(\mathrm{BER})$ while reducing end-to-end decoding time by 8.86% on average (up to 12.82%).

****
OPT-Engine: Benchmarking the Limits of LLMs in Optimization Modeling via Complexity Scaling
Yitian Chen, Cheng Cheng, Yinan Sun, Zi Ling, Dongdong Ge
We investigate the capabilities and scalability of Large Language Models (LLMs) in optimization modeling, a domain requiring structured reasoning and precise formulation.
To this end, we introduce OPT-ENGINE, an extensible benchmark framework with quantifiable and controllable complexity. OPT-ENGINE spans ten canonical Operations Research problems, systematically scaling from Linear Programming to Mixed-Integer Programming, providing a structured environment to probe the limits of automated problem formulation and solving.
Utilizing OPT-Engine, we address three pivotal research questions.
First, we examine whether Pure-Text Reasoning (PTR) via classical Chain-of-Thought can efficiently tackle optimization tasks, finding that PTR suffers from a critical robustness gap as task complexity increases.
Second, we examine whether integrating external computational tools can mitigate PTR's arithmetic weaknesses and improve performance. Our results show that while such tools aid local calculations, they still fail to adhere to global optimization constraints.
Finally, we pinpoint that for the current SOTA paradigm, Solver-integrated Reasoning (SIR), the automated formulation of constraints represents the primary bottleneck.
These findings clarify current paradigms' limitations and provide a structured roadmap for developing next-generation LLMs for optimization modeling.
We release our code and data to facilitate future research (https://github.com/Cardinal-Operations/OPTEngine).
****
Improving Backward Conformal Prediction via Non-Conformity Score Transformation
Junxian Liu, Hao Zeng, Hongxin Wei
Conformal Prediction (CP) provides a statistical framework for uncertainty quantification that constructs prediction sets with coverage guarantees. While CP yields uncontrolled prediction set sizes, Backward Conformal Prediction (BCP) inverts this paradigm by enforcing a predefined upper bound on set size and estimating the resulting coverage guarantee. However, the looseness induced by Markov's inequality within the BCP framework causes a significant gap between the estimated coverage bound and the empirical coverage. In this work, we introduce ST-BCP, a novel method that introduces a data-dependent transformation of nonconformity scores to narrow the coverage gap. In particular, we develop a computable transformation and prove that it outperforms the baseline identity transformation. Extensive experiments demonstrate the effectiveness of our method, reducing the average coverage gap from 4.20\% to 1.12\% on common benchmarks.
****
Dense associative memory for Gaussian distributions
Chandan Tankala, Krishna Balasubramanian
Dense associative memories (DAMs) store and retrieve patterns via energy-function based fixed points, but existing models are limited to vector representations. We extend DAMs to Gaussian densities equipped with the 2-Wasserstein distance. Our framework defines a log-sum-exp energy over stored distributions and a retrieval dynamics aggregating optimal transport maps in a Gibbs-weighted manner. Stationary points correspond to self-consistent Wasserstein barycenters, generalizing classical DAM fixed points. We prove exponential storage capacity and provide quantitative retrieval guarantees under Wasserstein perturbations. We validate the method on synthetic and real-world image (CelebA and CIFAR-10 datasets) and text (text8 and NLI corpus) datasets. By generalizing from vectors to distributions, our work bridges classical DAMs with modern generative modeling and paves way for distributional storage and retrieval in memory-augmented learning.
****
Flexible Kernels for Protein Property Prediction
Martin Jankowiak, Yerdos Ordabayev, Rudraksh Tuwani, Henry Neil Ward, Hunter Nis

onoff, James M McFarland, Gevorg Grigoryan
Despite its importance to applications in protein design, predicting protein properties like binding affinity and thermostability from sparse experimental data remains a significant challenge. Accordingly, we introduce a class of sequence kernels that exploit evolutionary substitution matrices as well as local linearity and demonstrate that the resulting Gaussian processes provide data-efficient models of protein property landscapes, frequently outperforming alternatives that rely on foundation model embeddings. Furthermore--by learning what are in effect structure-aware substitution matrices--we show that our kernels can readily incorporate structural information from foundation models. We demonstrate that these structure-conditioned kernels are well suited to multi-task learning across multiple protein property landscapes and can decisively outperform local supervised learning methods.

OmniShow: Unifying Multimodal Conditions for Human-Object Interaction Video Generation
Donghao Zhou, Guisheng Liu, Hao Yang, Jiatong Li, Jingyu Lin, Xiaohu Huang, Yichen Liu, Xin Gao, Cunjian Chen, Shilei Wen, Chi-Wing Fu, Pheng-Ann Heng
In this work, we study **Human-Object Interaction Video Generation (HOIVG)**, which aims to synthesize high-quality human-object interaction videos conditioned on text, reference images, audio, and pose. We present **OmniShow**, the first all-in-one model tailored for this practical yet challenging task, capable of harmonizing multimodal conditions and delivering industry-grade performance. To overcome the trade-off between controllability and quality, we introduce **Unified Channel-wise Conditioning** for efficient image and pose injection, and **Gated Local-Context Attention** to ensure precise audio-visual synchronization. To effectively address data scarcity, we develop a **Decoupled-Then-Joint Training** strategy that leverages a multi-stage training process with model merging to efficiently harness heterogeneous sub-task datasets. Furthermore, to fill the evaluation gap in this field, we establish HOIVG-Bench, a dedicated and comprehensive benchmark for HOIVG. Extensive experiments demonstrate that OmniShow achieves overall state-of-the-art performance across various multimodal conditioning settings, setting a solid standard for the emerging HOIVG task.
****
COBRA: Contribution-Based Bayesian Rank Allocation for Parameter-Efficient Fine-Tuning
Hongcheng Ding, Xuanze Zhao, Xuanhuang Liu, Jing Jin, Shamsul Nahar Abdullah, Deshinta Arrova Dewi
Full fine-tuning of large language models (LLMs) incurs prohibitive computational and storage costs. Parameter-efficient fine-tuning (PEFT) addresses this limitation, with Low-Rank Adaptation (LoRA) gaining widespread adoption due to its simplicity and zero inference overhead. However, LoRA and its variants typically rely on uniform rank allocation or a single importance metric such as gradient magnitude or output sensitivity to guide rank distribution. This approach fails to recognize that gradient magnitude and output contribution are decoupled properties, leading to suboptimal allocation where critical layers are under-provisioned while less important ones waste capacity. To address this challenge, we propose COBRA, a principled framework integrating dual importance factors for adaptive rank allocation. COBRA operates in three stages: (1) layer conductance attribution quantifies each layer's contribution via path-integral attribution; (2) dual-factor aggregation combines contribution with adaptation demand, producing the Task-Adaptive Layer Conductance (TA-LC) distribution; and (3) Bayesian rank allocation translates this distribution into optimal heterogeneous ranks via variational optimization. Layer conductance provides layer-level interpretability by explicitly quantifying how much each layer contributes to predictions without redundancy, directly aligning with the granularity of rank allocation decisions and enabling principled cross-layer comparison for rank distribution. Experiments across diverse architectures and tasks demonstrate that COBRA consistently outperforms existing methods, achieving up to 1.6 points improvement on GLUE and a 6.6\% average MSE reduction in high-rank regression regimes under comparable paramet

er budgets.
****
FIBER: A Differentially Private Optimizer with Filter-Aware Innovation Bias Correction
Duc Dm, Thao Do, Minh Son Hoang, Anh Le Duc Tran, Daeyoung Kim, Huy Nguyen
Differentially private (DP) training protects individual examples by adding noise to gradients, but the injected noise interacts nontrivially with adaptive optimizers. Recent DP methods temporally filter privatized gradients to reduce variance; however, filtering also changes the DP noise statistics seen by AdamW's second-moment accumulator. As a result, bias corrections derived for unfiltered DP noise (e.g., subtracting σ_w^2) can become miscalibrated when filtering is present. We propose FIBER, a DP optimizer designed for temporally filtered privatized gradients. FIBER (i) performs denoising in innovation space by filtering the residual stream and integrating it to form the filtered gradient estimate, (ii) decouples the two-point observation geometry from the innovation gain to enable independent tuning, and (iii) introduces a filter-aware second-moment calibration that subtracts the attenuated DP noise contribution $A(\omega)\sigma_w^2$, where $A(\omega)$ is derived in closed form for the innovation filter and can be computed for general stable linear filters. Across vision and language benchmarks, FIBER consistently demonstrates substantial improvements in the performance of DP optimizers, surpassing state-of-the-art results under equivalent privacy constraints on multiple tasks.
****
Convolutional Learnable-Group Weightless Neural Network
Qinhong Ma, Yulin Chen, Zhiwei Fan, Suzhen Wu, Bo Mao
Weightless Neural Networks (WNNs) based on interconnected Lookup Tables (LUTs) have attracted attention for inference in extremely compact models, but achieving competitive accuracy under such tight resource budgets remains challenging. To address these issues, we introduce the Convolutional Learnable-Group Weightless Neural Network (CLGN). CLGN constructs convolutional layers using LUTs and incorporates a learnable GroupSum connection, thereby enhancing the accuracy of WNNs while maintaining low implementation resource consumption. Moreover, we propose a hierarchical training strategy to improve the training efficiency. We evaluate CLGN in two edge computing scenarios: (1) FPGA, where we evaluate accuracy, latency, throughput, power consumption, LUTs usage, and parameter size; and (2) Microprocessor, where we evaluate latency and memory usage. Compared with the state-of-the-art solutions, the proposed CLGN achieves superior accuracy while maintaining lower implementation resource consumption.
****
VideoMAETok: Boosting Video Diffusion Models via Masked Autoencoders as Tokenizers
Zhan Tong, Tinne Tuytelaars
Latent diffusion models have become the dominant paradigm for video generation, making the video tokenizer a critical role. While most existing tokenizers are trained primarily for reconstruction, diffusion models are optimized to denoise heavily corrupted latents, which creates a mismatch between tokenizer training objectives and downstream generative learning. As a result, reconstruction metrics (e.g., rFVD) can be a poor proxy for generation quality (gFVD), and overly prioritizing reconstruction may even hinder diffusion training. We propose VideoMAETok, a simple family of ViT-based video tokenizers trained explicitly as corruption-inversion models for latent video diffusion. VideoMAETok builds on masked autoencoders: we (i) apply high-ratio token masking and encode only visible spatiotemporal tokens for efficiency, and (ii) corrupt latent tokens with interpolative Gaussian noise to better match the denoising nature of diffusion generators. Training under such corruption encourages latents that remain informative and well-conditioned for downstream denoising. Extensive experiments show that VideoMAETok consistently improves generation quality when paired with off-the-shelf diffusion models (SiT and LightningDiT), achieving state-of-the-art gFVD on Kinetics-600 and UCF-101 while remaining compute-efficient. Code is available at https://github.com/yztongzhan/VideoMAETok.

****
SMD: Multi-view Safety-Critical Driving Video Generation in the Real-world Domain
Jiawei Zhou, Linye Lyu, Zhuotao Tian, Cheng Zhuo, Yu Li
Safety-critical scenarios are essential for evaluating autonomous driving (AD) systems, yet they are rare in practice. Existing generators produce trajectories, simulations, or single-view videos—but they don’t meet what modern AD systems actually consume: realistic multi-view video.
We present SMD, the first framework for generating multi-view safety-critical driving videos in the real-world domain.
SMD couples a safety-critical trajectory engine with a diffusion-based multi-view video generator through three design choices. First, we pick the right adversary: a GRPO-fine-tuned vision-language model (VLM) that understands multi-camera context and selects vehicles most likely to induce hazards. Second, we generate the right motion: a two-stage trajectory process that (i) produces collisions, then (ii) transforms them into natural evasion trajectories—preserving risk while staying within what current video generators can faithfully render. Third, we synthesize the right data: a diffusion model that turns these trajectories into multi-view videos suitable for end-to-end planners.
Videos generated by SMD substantially increase collision rates when stress testing multiple end-to-end planners, and reduce collision rates when incorporated into training, improving planner robustness and safety.
Our code and video examples are available at: \href{https://icml-2.github.io/SMD/}{https://icml-2.github.io/SMD/}.

Moving Out: Physically-grounded Human-AI Collaboration
Xuhui Kang, Sung-Wook Lee, Haolin Liu, Yuyan Wang, Yen-Ling Kuo
The ability to adapt to physical actions and constraints in an environment is crucial for embodied agents (e.g., robots) to effectively collaborate with humans. Such physically grounded human-AI collaboration must account for the increased complexity of the continuous state-action space and constrained dynamics caused by physical constraints.
However, most existing collaboration benchmarks are discrete or do not consider physical attributes and constraints.
To address this, we introduce Moving Out, a human-AI collaboration benchmark that resembles a wide range of collaboration modes affected by physical attributes and constraints, such as moving heavy items together and coordinating actions to move an item around a corner.
Moving Out consists of two challenges and human-human interaction data to comprehensively evaluate models' abilities to adapt to diverse human behaviors and unseen physical attributes.
To give embodied agents the capability to collaborate with humans under physical attributes and constraints, we propose a novel method, BASS (Behavior Augmentation, Simulation, and Selection), to enhance the diversity of agents and their understanding of the outcome of actions.
We systematically compare BASS and state-of-the-art models in AI-AI and human-AI experiments, showing that BASS can effectively collaborate with both unseen AI and humans.
****
From Backward Spreading to Forward Replay: Revisiting Target Construction in LLM Parameter Editing
Wei Liu, Liu Hongkai, Zhiying Deng, Yee Whye Teh, Wee Sun Lee
LLM parameter editing methods commonly rely on computing an ideal target hidden-state at a target layer (referred as anchor point) and distributing the target vector to multiple preceding layers (commonly known as backward spreading) for cooperative editing. Although widely used for a long time, its underlying basis have not been systematically investigated. In this paper, we first conduct a systematic study of its foundations, which helps clarify its capability boundaries, practical considerations, and potential failure modes.
  Then, we propose a simple and elegant alternative that replaces backward sprea

ding with forward-propagation. Instead of optimizing the target at the last editing layer, we optimize the anchor point at the first editing layer, and then propagate it forward to obtain accurate and mutually compatible target hidden-states for all subsequent editing layers. This approach achieves the same computational complexity as existing methods while producing more accurate layer-wise targets. Our method is simple, without interfering with either the computation of the initial target hidden state or any other components of the subsequent editing pipeline, and thus constituting a benefit for a wide range of LLM parameter editing methods.
****
DiscoverLLM: From Executing Intents to Discovering Them
Tae Soo Kim, Yoonjoo Lee, Jaesang Yu, John Joon Young Chung, Juho Kim
To handle ambiguous and open-ended requests, Large Language Models (LLMs) are increasingly trained to interact with users to surface intents they have not yet expressed (e.g., ask clarification questions). However, users are often ambiguous because they have not yet formed their intents: they must observe and explore outcomes to discover what they want. Simply asking "what kind of tone do you want?" fails when users themselves do not know. We introduce DiscoverLLM, a novel and generalizable framework that trains LLMs to help users form and discover their intents. Central to our approach is a novel user simulator that models cognitive state with a hierarchy of intents that progressively concretize as the model surfaces relevant options---where the degree of concretization serves as a reward signal that models can be trained to optimize. Resulting models learn to collaborate with users by adaptively diverging (i.e., explore options) when intents are unclear, and converging (i.e., refine and implement) when intents concretize. Across proposed interactive benchmarks in creative writing, technical writing, and SVG drawing, DiscoverLLM achieves over 10% higher task performance while reducing conversation length by up to 40%. In a user study with 75 human participants, DiscoverLLM improved conversation satisfaction and efficiency compared to baselines.
****
MOES-Pred: Molecular Structural Representation Learning by Adaptive Energy-Sentinel Vibration for Generalized Property Prediction
Zhiran Hou, Tinghuai Ma, Huan Rong, Li Jia, Anouar Imel, Heng Zhang, Ming Li
Predicting molecular properties from three-dimensional structures is fundamentally hindered by limited labeled data. While researchers have adapted self-supervised pre-training techniques from computer vision and natural language processing to address this scarcity, these approaches frequently neglect the intrinsic physical principles unique to molecular systems. From a physical perspective, denoising pre-training can be formally proven equivalent to learning molecular force fields. However, existing methods indiscriminately apply uniform noise across all molecules, thereby introducing systematic bias into the modeling of molecular distributions. To mitigate this issue, we introduce MOES-Pred, a denoising pre-training framework featuring an energy sentinel mechanism that dynamically tailors noise perturbations to individual molecules. Leveraging chemical prior knowledge, our molecule-specific noising strategies enhance conformational sampling coverage and improve distribution modeling fidelity. Extensive experiments show that MOES-Pred surpasses mainstream approaches in both force prediction and downstream quantum chemical property prediction, demonstrating substantial improvements.
****
Priority-Aware Shapley Value
Kiljae Lee, Ziqi Liu, Weijing Tang, Yuan Zhang
Shapley values are widely used for model-agnostic data valuation and feature attribution, yet they implicitly assume contributors are interchangeable.

    This can be problematic when contributors are dependent (e.g., reused/augmented data or causal feature orderings) or when contributions should be adjusted by factors such as trust or risk.

    We propose Priority-Aware Shapley Value (PASV), which incorporates both hard precedence constraints and soft, contributor-specific priority weights.

PASV is applicable to general precedence structures, recovers precedence-only and weight-only Shapley variants as special cases, and is uniquely characterized by natural axioms.

We develop an efficient adjacent-swap Metropolis–Hastings sampler for scalable Monte Carlo estimation and analyze limiting regimes induced by extreme priority weights.

Experiments on data valuation (MNIST/CIFAR10) and feature attribution (Census Income) demonstrate more structure-faithful allocations and a practical sensitivity analysis via our proposed ``priority sweeping".

CoT is Not the Chain of Truth: An Empirical Internal Analysis of Reasoning LLMs for Fake News Generation

Zhao Tong, Chunlin Gong, Yiping ZHANG, Haichao Shi, Qiang Liu, Xingcheng Xu, Shu Wu, Xiao-Yu Zhang

From generating headlines to fabricating news, the Large Language Models (LLMs) are typically assessed by their final outputs, under the safety assumption that a refusal response signifies safe reasoning throughout the entire process. Challenging this assumption, our study reveals that during fake news generation, even when a model rejects a harmful request, its Chain-of-Thought (CoT) reasoning may still internally contain and propagate unsafe narratives. To analyze this phenomenon, we introduce a unified safety-analysis framework that systematically deconstructs CoT generation across model layers and evaluates the role of individual attention heads through Jacobian-based spectral metrics. Within this framework, we introduce three interpretable measures: stability, geometry, and energy to quantify how specific attention heads respond or embed deceptive reasoning patterns. Extensive experiments on multiple reasoning-oriented LLMs show that the generation risk rise significantly when the thinking mode is activated, where the critical routing decisions concentrated in only a few contiguous mid-depth layers. By precisely identifying the attention heads responsible for this divergence, our work challenges the assumption that refusal implies safety and provides a new understanding perspective for mitigating latent reasoning risks.

From Individual Calibration to Reliable Classifiers: ALD Parameterization with mPAIC Guarantees

Deming Sheng, Ricardo Henao

Modern neural classifiers can achieve remarkable predictive performance, yet often suffer from *miscalibration*.

In this paper, we introduce a unified calibration framework applicable to arbitrary distribution-based classifiers.

The proposed calibration objective guarantees a *monotone Probably Approximately Individually Calibrated (mPAIC)* predictor, which theoretically implies the properties of a *Probably Approximately Calibrated Classifier (PACC)* with explicit error bounds.

To enable stable and effective optimization, we further devise a *Decoupled Dual-Stream Optimization (DDSO)* strategy with gradient detachment to reconcile discriminative representation learning and continuous calibration.

Notably, our framework bridges calibration paradigms, supporting flexible deployment either as an end-to-end *pre-calibration* objective or as a lightweight *post-calibration* adapter.

Extensive experiments across nine real-world datasets demonstrate that our approach consistently outperforms strong baselines, achieving superior performance on both *accuracy* and multi-level *calibration*.

Demystifying Mergeability: Interpretable Properties to Predict Model Merging Success

Luca Zhou, Bo Zhao, Rose Yu, Emanuele Rodolà

Model merging combines knowledge from separately fine-tuned models, yet the factors driving its success remain poorly understood. While recent work treats mergeability as an intrinsic property of the models, we show with an architecture-agnostic framework that it fundamentally depends on both the merging method and the

partner tasks. Using L1-regularized linear optimization over a set of interpretable pairwise metrics (e.g., gradient L2 distance), we uncover properties correlating with post-merge normalized accuracy across five merging methods. We find that the drivers of merge success vary across architectures and merging methods, overall with only a moderate agreement (64.0% average top-5 metric overlap; 79.3% sign agreement). Crucially, however, gradient alignment metrics consistently emerge as the most fundamental signals of mergeability. These findings provide a diagnostic foundation for understanding mergeability and motivate future merge-aware fine-tuning strategies.

BEST: Benchmarking Efficiency in Space and Time for LLM-Generated Code

Aocheng Shen, Boyu Zhang, Jiaze Li, Ruixuan Ma, Qiankun Zhang, Jing Wang, Bin Yuan, Shenghao Liu, Xianjun Deng

Large language models (LLMs) have revolutionized research in software engineering, and among various tasks, LLM-based code synthesis is promising. A recent line of benchmarks aims to evaluate LLM-generated codes in time efficiency, beyond their correctness. However, *space*, another vital aspect of code efficiency, is rarely evaluated in prior benchmarks. To fill in the gap, this paper introduces *BEST*, the first benchmark for evaluating the efficiency of LLM-generated codes in *both time and space*. It comprises 440 coding tasks that are rigorously constructed by experts. In addition, we propose a fine-grained *subtask-based* evaluation scheme by dividing each task into multiple subtasks, with different input scales and difficulties. Each subtask is then accompanied by an expert-crafted standard implementation as the efficiency baseline, which achieves the *Pareto optimum*. Building on BEST, we introduce a unified and novel dual-indicator (time and space) metric, named dual@${k}$, generalizing the notion of the standard pass@${k}$ metric and building on a careful and novel construction of a *weight matrix* of subtasks. Through extensive experiments with dual@${k}$ across 50 LLMs on BEST, our evaluation demonstrates that while LLMs exhibit weak capabilities in generating time-efficient code, their capabilities in space-efficient code generation are even worse. The benchmark is provided at https://github.com/kmsgk0/BEST.

Rational Transductors

Mehryar Mohri

Standard Transformers excel at semantic modeling but struggle with rigid
  sequential logic and state tracking. Theoretical work establishes that
  self-attention is limited to AC^0 (under hard attention) or TC^0 (under
  soft attention), complexity classes that often fail to support robust length
  generalization on sequential problems without intermediate chain-of-thought
  (see hahn2020theoretical and merrill2022saturated). In this work, we introduce
  \emph{Rational Transductors}, a dual-stream architecture that augments the
  Transformer with a matrix-valued recurrence derived from Weighted Finite
  Automata (WFA). By injecting rational state information into the attention
  mechanism via a *Deep Rational Injection* scheme, our framework strictly
  generalizes Transformers to capture all Regular Languages, NC^1-complete
  problems (such as Boolean Formula Evaluation), and fundamental separations
  like Parity and Modular Counting, while preserving $O(\log T)$ parallel
  training efficiency. Theoretical analysis and empirical results demonstrate
  that Rational Transductors solve the "Regular Gap," enabling robust length
  generalization on algorithmic tasks where standard Transformers fail, without
  the sequential computational bottlenecks of traditional RNNs.

SWE-Bench Pro: Can AI Agents Solve Long-Horizon Software Engineering Tasks?

Xiang Deng, Jeff Da, Edwin Pan, Yannis Yiming He, Charles Ide, Kanak Garg, Niklas Lauffer, Andrew Park, Chetan Rane, Karmini Sampath, Maya Krishnan, Srivatsa R Kundurthy, Sean M. Hendryx, Zifan Wang, Chen Bo Calvin Zhang, Noah Jacobson, Bin

g Liu, Brad Kenstler
We present SWE-Bench Pro, a comprehensive benchmark designed to evaluate softwar e engineering capabilities through complex, realistic programming challenges. Th is benchmark extends beyond traditional algorithmic problems to encompass the fu ll spectrum of professional software development tasks. The dataset comprises 1, 865 problems sourced from 41 active software engineering repositories, spanning 123 unique programming languages and various application domains. The benchmark is structured into public and private components, with public access to problems from 11 repositories and private evaluation sets from 12 repositories across 4 distinct problem categories. SWE-Bench Pro addresses limitations of existing eva luation frameworks by incorporating problems that reflect real-world software en gineering scenarios, including substantial codebases, complex enterprise applica tions, and multi-file projects requiring sophisticated reasoning and code modifi cation skills. Problems range from early-stage startup environments to enterpris e-level applications, with the private commercial set remaining inaccessible to maintain evaluation integrity while enabling public access to representative pro blems for professional development. Our evaluation methodology employs diverse c oding approaches and models under controlled conditions, ensuring robust perform ance assessment across multiple programming paradigms. Results demonstrate signi ficant performance variations across different problem categories, with traditio nal algorithmic challenges showing notably higher success rates compared to comp lex, multi-file engineering tasks. The benchmark reveals substantial gaps in cur rent capabilities for handling real-world software engineering scenarios, partic ularly in areas requiring deep contextual understanding, cross-file reasoning, a nd integration with existing large-scale systems. This work contributes a more c omprehensive and realistic evaluation framework for assessing software engineeri ng capabilities, providing insights into current limitations and establishing a foundation for future development in automated software engineering tools and me thodologies.

Scout Before You Attend: Sketch-and-Walk Sparse Attention for Efficient LLM Infe rence
Hoang Anh Duy Le, Sahil Joshi, Zeyu Yang, Zhaozhuo Xu, Anshumali Shrivastava
Self-attention dominates the computational and memory cost of long-context LLM i nference across both prefill and decode phases. To address this challenge, we in troduce **Sketch\&Walk** Attention, a training-free sparse attention method that determines sparsity with lightweight sketches and deterministic walk. Sketch\&W alk applies Hadamard sketching to get inexpensive approximations of attention sc ores, then aggregates these estimates across layers via a walk mechanism that ca ptures attention influence beyond direct interactions between tokens. The accumu lated walk scores are used to select top-k attention blocks, enabling dynamic sparsity with a single training-free algorithm that applies uniformly to both th e prefill and decode phases, together with custom sparse attention kernels. Acro ss a wide range of models and tasks, Sketch\&Walk maintains near-lossless accura cy at 20\% attention density and can slightly outperform dense attention in some settings, while achieving up to $4.7\times$ end-to-end attention speedup over F lashAttention-2.

Learning Human-Robot Collaboration via Heterogeneous-Agent Lyapunov Policy Optim ization
Hao Zhang, Yaru Niu, Yikai Wang, Ding Zhao, Eric H. Tseng
To improve generalization and resilience in human–robot collaboration (HRC), rob ots must contend with diverse combinations of human behaviors and contexts, moti vating multi-agent reinforcement learning (MARL). However, inherent heterogeneit y between robots and humans creates a rationality gap (RG), where decentralized policy updates deviate from cooperative joint optimization. The resulting learni ng problem is a general-sum differentiable game, so independent policy-gradient updates can oscillate or diverge without added structure. We propose heterogeneo us-agent Lyapunov policy optimization (HALO), a framework that stabilizes decent ralized MARL by enforcing Lyapunov-based contraction in policy-parameter space.

Unlike Lyapunov-based safe RL, which targets state/trajectory constraints in constrained Markov decision processes, HALO uses Lyapunov certification to stabilize decentralized policy learning. HALO rectifies decentralized gradients via optimal quadratic projections, ensuring monotonic contraction of RG and enabling effective exploration of open-ended interaction spaces. Extensive simulations and real-world humanoid-robot experiments show that this certified stability improves generalization and robustness in collaborative corner cases.

AdaGC: Enhancing LLM Pretraining Stability via Adaptive Gradient Clipping
Guoxia Wang, Shuai Li, Congliang Chen, Jinle Zeng, Jiabin Yang, Dianhai Yu, Yanjun Ma, Li Shen
Loss spikes remain a persistent obstacle in large-scale language model pretraining. While previous research has attempted to identify the root cause of loss spikes by investigating individual factors, we observe that, in practice, such spikes are typically triggered by the confluence of heterogeneous factors. Empirically, loss spikes may arise from a combination of data outliers, hardware or transient computational faults, numerical precision issues, and hyperparameter settings. Regardless of the underlying cause, these spikes manifest as unstable optimizer updates, as abnormal gradients contaminate both first- and second-moment states. In this paper, we propose a principled gradient-centric remedy: AdaGC, an adaptive per-tensor gradient clipping scheme that mitigates such contamination by bounding gradient norms relative to a tensor-wise exponential moving average of their historical clipped values. AdaGC is optimizer-agnostic, introduces negligible memory overhead, and reduces communication costs compared to GlobalGC, particularly in hybrid-parallel distributed training. Experiments on Llama-2 7B, Mixtral 8×1B, and ERNIE 10B-A1.4B demonstrate that AdaGC robustly eliminates training instabilities, consistently reducing spike scores to zero for all models and improving downstream accuracy over GlobalGC by 1.32\%, 1.27\%, and 2.48\%, respectively. Furthermore, AdaGC seamlessly integrates with optimizers such as Muon and Lion, consistently yielding higher average accuracy and zero spike scores. The code is available at https://github.com/PaddlePaddle/PaddleFleet (see Research/AdaGC).

EntRAG: Entity-Centric Retrieval-Augmented Generation for Knowledge-based Visual Question Answering
Yiheng Hu, Xiaoyang Wang, Qing Liu, Xiwei Xu, Qian Fu, Wenjie Zhang
Knowledge-based Visual Question Answering (KB-VQA) remains a challenging task, particularly when queries require precise identification and grounding of fine-grained entities within large-scale knowledge base. Existing methods often treat visual and textual signals in isolation and rely heavily on image-centric retrieval, which makes them sensitive to visual ambiguities. To address these limitations, we propose EntRAG, an entity-centric retrieval-augmented generation framework. Our approach first introduces EntBind to align query representations with multimodal entity embeddings by explicitly binding entity tokens to latent visual features, retrieving a set of relevant candidate entities. A reranking mechanism is applied to these candidate entities to select the most informative context by combining entity-level alignment with overall contextual relevance. The selected evidence is incorporated into context-aware generation module to produce final answer. By explicitly operating at the entity level, EntRAG achieves more consistent and reliable results.
Extensive experiments demonstrate that EntRAG consistently outperforms prior methods, achieving scores of 46.1 on E-VQA and 44.5 on InfoSeek.

Higher-Order Certified Robustness for Regression
Claire Jie Zhang, Natalie Frank
Randomized smoothing has emerged as a scalable technique for certifying the adversarial robustness of classifiers. However, its application to regression remains under-explored and faces unique challenges. Existing regression certificates rely on probabilistic acceptance regions and fail to exploit the local geometry of the function. In this work, we present a novel framework for certified robust

regression that addresses these limitations. We derive a prediction-centered certificate that guarantees the stability of the smoothed model’s prediction and ensures practical computability at test time. We investigate several alternatives for constructing these certificates by explicitly incorporating means, variances, and gradients. In particular we demonstrate on the MNIST rotation task that utilizing gradient information yields significantly tighter robustness certificates compared to the current state-of-the-art, α-smoothing.

Why DDIM Hallucinates More Than DDPM: A Theoretical Analysis of Reverse Dynamics
Muhammad H. Ashiq, Samanyu Arora, Abhinav Narayan Harish, Ishaan Kharbanda, Hung Yun Tseng, Grigorios Chrysos

We theoretically study the hallucination phenomena in two canonical diffusion samplers: the stochastic Denoising Diffusion Probabilistic Model (DDPM) and the deterministic Denoising Diffusion Implicit Model (DDIM). We analyze the reverse ODE (DDIM) and SDE (DDPM) for a Gaussian mixture target, proving that after a critical time τ, (a) DDIM can become stuck on the segment connecting the two nearest modes and (b) DDPM *stochasticity* helps it become unstuck from this region, thus avoiding hallucination. Our empirical validation verifies that DDPM has a significantly lower hallucination rate than DDIM when this region is entered. Building on our observations, we exhibit how using additional stochastic steps can help DDIM avoid hallucinations and offer new insights on how to design improved samplers.

Approximation Bounds for Transformer Networks with Application to Regression
Yuling Jiao, Yanming Lai, Defeng Sun, Yang Wang, Bokai Yan

We develop approximation and statistical theory for standard Transformer networks in sequence modeling. Given a sequence-to-sequence target on $[0,1]^{d_x \times n}$ whose entries are γ-Hölder for $\gamma \in (0,1]$ or belong to a first-order Sobolev class, we establish explicit L^p-approximation bounds for all $p \in [1,\infty]$, including the previously elusive endpoint $p=\infty$ under softmax attention. In particular, achieving error ε in L^p-norm requires $\mathcal{O}(\varepsilon^{-d_x n/\gamma})$ parameters for γ-Hölder targets and $\mathcal{O}(\varepsilon^{-d_x n})$ parameters for Sobolev targets, matching the best known scalings in ambient dimension $d_x n$. We further study nonparametric regression with sequential and dependent observations using Transformer networks. Assuming stationary β-mixing covariates whose temporal dependence weakens over time, we analyze a sliding-window empirical risk minimization procedure and establish excess-risk guarantees for the Transformer-based estimators. Our analysis clarifies the role of attention and enables extensions beyond softmax.

Unifying Adversarial Robustness and Training Across Text Scoring Models
Manveer Singh Tamber, Hosna Oyarhoseini, Jimmy Lin

Research on adversarial robustness in language models is currently fragmented across applications and attacks, obscuring shared vulnerabilities. In this work, we propose unifying the study of adversarial robustness in text scoring models spanning dense retrievers, rerankers, and reward models. This motivates adapting both attacks and adversarial training methods across model roles. Unlike open-ended generation, text scoring failures are directly testable: an attack succeeds when an irrelevant or rejected text outscores a relevant or chosen one. Using this principled lens of text scoring, we demonstrate that current adversarial training formulations for language models are often short-sighted, failing to effectively generalize across attacks. To address this, we introduce multiple adversarial training methods for text scoring models and show that combining complementary training methods can yield strong robustness while also improving task effectiveness. We also highlight the practical value of our approach for RLHF, showing that our adversarially trained reward models mitigate reward hacking and support the training of better-aligned LLMs. We provide our code and models for further study.

D-CORE: Incentivizing Task Decomposition in Large Reasoning Models for Complex T
ool Use
Bowen Xu, Shaoyu Wu, Hao Jiang, Kai Liu, Xin Chen, lulu hu, Bin Yang
Effective tool use and reasoning are essential capabilities for large reasoning
models (LRMs) to address complex real-world problems. Through empirical analysis
, we identify that current LRMs lack the capability of sub-task decomposition in
complex tool use scenarios, leading to Lazy Reasoning. To address this, we prop
ose a two-stage training framework D-CORE (Decomposing tasks and Composing Reaso
ning processes) that first incentivize the LRMs' task decomposition reasoning ca
pability via self-distillation, followed by diversity-aware reinforcement learni
ng (RL) to restore LRMs' reflective reasoning capability. D-CORE achieves robust
tool-use improvements across diverse benchmarks and model scales. Experiments o
n BFCLv3 demonstrate superiority of our method: D-CORE-8B reaches 77.7\% accurac
y, surpassing the best-performing 8B model by 5.7\%. Meanwhile, D-CORE-14B estab
lishes a new state-of-the-art at 79.3\%. Code is available at https://github.com
/alibaba/EfficientAI; the model is available at https://huggingface.co/bowiehsu/
D-CORE-8B; and the data are available at https://huggingface.co/datasets/bowiehs
u/D-CORE-Self-Distillation-50K.

Flat Minima and Generalization: Insights from Stochastic Convex Optimization
Matan Schliserman, Shira Vansover-Hager, Tomer Koren
Understanding the generalization behavior of learning algorithms is a central go
al of learning theory. A recently emerging explanation is that learning algorith
ms are successful in practice because they converge to flat minima, which have b
een consistently associated with improved generalization performance.
In this work, we study the link between flat minima and generalization in the ca
nonical setting of stochastic convex optimization with a non-negative, β-s
mooth objective.
Our first finding is that, even in this fundamental setting, flat empirical mini
ma may incur trivial $\Omega(1)$ population risk while sharp minima generalizes
optimally.
We then demonstrate that this phenomenon extends to sharpness-aware algorithms i
ntroduced by Foret et al. (2021), namely Sharpness-Aware Gradient Descent (SA-GD
) and Sharpness-Aware Minimization (SAM).
For SA-GD we prove that it successfully converges to a flat minimum at a fast ra
te, but the population risk of the solution can still be as large as $\Omega(1)$
.
For SAM we show that although it minimizes the empirical loss, it may converge t
o a sharp minimum and also incur population risk $\Omega(1)$.
Finally, we establish population risk upper bounds for both SA-GD and SAM using
algorithmic stability techniques.

LaRA-Fusion: Latent-Robust Adaptation via Dual-Loop Constraints for Infrared and
Visible Image Fusion
Yaru Su, Chaowei Huang, Huangbiao Xu, Xiao Ke
Infrared and visible image fusion (IVIF) aims to synergize complementary thermal
radiation and textural details for comprehensive scene perception. However, exi
sting unsupervised paradigms often overlook the intrinsic topological consistenc
y shared across modalities. Lacking explicit geometric regularization, encoders
frequently succumb to degenerate numerical shortcuts, capturing superficial high
-frequency noise rather than domain-invariant semantic structures to satisfy rec
onstruction objectives. To address this, we propose LaRA-Fusion, a framework ach
ieving Latent-Robust Adaptation via Dual-Loop Manifold Constraints. We construct
a strictly constrained latent space where an inner loop enforces geometric reve
rsibility, while an outer loop aligns the generated representations with the tar
get data distribution. This mechanism effectively mitigates latent space collaps
e, compelling the model to extract topologically aligned features that remain ro
bust against modality-specific variations. Extensive experiments demonstrate tha
t LaRA-Fusion outperforms state-of-the-art methods with superior robustness and
interpretability.

Adaptive Volumetric Mechanical Property Fields Invariant to Resolution
Rishit Dagli, Donglai Xiang, Vismay Modi, Xuning Yang, Gavriel State, David Levi n I.W., Maria Shugrina
Accurate mechanical properties (or materials) Young's modulus (E), Poisson's r atio (ν) and density (ρ) are essential for reliable physics simulation of digital worlds, but most 3D assets lack this information. We propose AdaVoMP, a method for predicting accurate dense spatially-varying (E, ν, ρ) for i nput 3D objects across representations, improving the resolution, accuracy, and memory efficiency over the state-of-the-art. The foundation of our technique is a sparse and adaptive voxel structure SAV that efficiently represents both the i nput 3D shape and the material field output. We replace the fixed-voxel model of the most accurate prior method, VoMP, with a novel sparse transformer encoder-d ecoder model that learns to generate a unique SAV autoregressively for every inp ut shape to represent its materials, achieving a resolution $16^3\times$ higher than prior art. Experiments show that AdaVoMP estimates more accurate volumetric properties, even with lesser test-time compute than all prior art. This allows us to convert high-resolution complex 3D objects into simulation-ready assets, r esulting in realistic deformable simulations.
****
Quantum Algorithms for Triangle Cut Sparsification
Shan Jiang, Pan Peng
Triangles capture higher-order structures in graphs and are fundamental to appli cations such as clustering and network analysis.
To enable efficient use of such structures at scale, we study the problem of tri angle cut sparsification, which aims to reduce the graph size while approximatel y preserving triangle counts across every cut.
We investigate quantum algorithms for this problem, using triangle listing as ou r main technical ingredient.
In particular, we present a quantum algorithm for triangle listing that, for a g raph with n vertices, m edges, and t triangles, runs in time $T_{\mathrm{q \text{-}list}} =\widetilde{O}\left(\min(n^{5/4}t^{7/12} + n^{7/6}t^{7/9}, m + m^ {3/4}t^{1/2},n^{3/2}t^{1/2})\right)$, improving upon the best known classical bo unds over a broad range of parameters. Our algorithm is based on a heavy–light v ertex partition and an extension of triangle detection via quantum walks and Gro ver search.
Leveraging this result, we design a quantum algorithm for constructing $\varepsi lon$-triangle cut sparsifiers of size $\tilde{O}(n/\varepsilon^2)$ in time $\wi detilde{O}(T_{\mathrm{q\text{-}list}} + \sqrt{mn}/\varepsilon)$.
Finally, we demonstrate applications to clustering algorithms based on triangle-related measures
and prove a lower bound of $\Omega(n/\varepsilon^2)$ on the size of any $\vareps ilon$-triangle cut sparsifiers.
****
Faster Activation Functions at the Edge for Post-Training Speedups
Anton Lydike, Jun Bi, Jackson Woodruff
On-device AI has gained significant attention for enabling efficient, low-latenc y inference on edge devices.
However, tight resource constraints on these platforms make the deployment of ac curate and lightweight deep
learning models challenging.
In particular,
advanced activation functions (AFs) like Swish and GELU often incur
high inference overhead due to the lack of hardware fast-paths for exponentiatio n and division,
restricting edge-ML applications to simple AFs like ReLU, limiting model accurac y.
To address this, we propose FFCC, a compiler that automatically
generates efficient approximations of AFs through floating-point reinterpretatio n.

These functions do not require hardware fast-paths, meaning they remain fast
on edge devices, but are accurate enough to be used as post-training drop-ins.
FFCC takes a specification of AFs using basic floating-point operators
and applies derivation rules to lower these expressions into
efficient instruction sequences.
Our experiments show that FFCC provides fast approximations of AFs, achieving order-of-magnitude
speed-ups over accurate baselines on Arm M7, Aarch64 and Intel platforms.
Using ConvNeXt as an example, we demonstrate how these activation-level gains translate to end-to-end speed-ups,
and do not result in significant loss of model accuracy.

What Do Agents Learn from Trajectory-SFT: Semantics or Interfaces?
Weizheng Gu, Chengze Li, Zhuohao Yu, Mengyuan Sun, Zhibang Yang, Wei Wang, Hongrui Jia, Shikun Zhang, Wei Ye
Large language models are increasingly evaluated as interactive agents, yet standard agent benchmarks conflate two qualitatively distinct sources of success: semantic tool-use and interface-specific interaction pattern memorization.
Because both mechanisms can yield identical task success on the original interface, benchmark scores alone are not identifiable evidence of environment-invariant capability.
We propose **PIPE**, a protocol-level evaluation augmentation for diagnosing interface reliance by minimally rewriting environment interfaces while preserving task semantics and execution behavior.
Across 16 environments from AgentBench and AgentGym and a range of open-source and API-based agents, PIPE reveals that task-specific trajectory-SFT can amplify reliance on training-time interface forms: in several environments, agents with trajectory-SFT degrade sharply under minimal interface rewrites, whereas other agents are often more stable.
We further introduce Interface Reliance (IR), a counterbalanced alias-based metric that quantifies preference for training-time interfaces, and show that interface shortcutting exhibits environment-dependent, non-monotonic training dynamics that remain invisible under standard evaluation. Our code is available at https://github.com/ChengZe2005/What-Do-Agents-Learn-from-Trajectory-SFT-Semantics-or-Interfaces-.
****
Collaborative and Efficient Fine-tuning: Leveraging Task Similarity
Gagik Magakyan, Amirhossein Reisizadeh, Chanwoo Park, Pablo A. Parrilo, Asuman E. Ozdaglar
Adaptability has been regarded as a central feature in the foundation models, enabling them to effectively acclimate to unseen downstream tasks. Parameter-efficient fine-tuning methods such as celebrated LoRA facilitate efficient adaptation of large foundation models using labeled, high-quality and generally scarce task data. To mitigate data scarcity in fine-tuning of foundation models, we propose to leverage *task similarity* across downstream users. Intuitively, users with similar tasks must be able to assist each other in boosting the effective fine-tuning data size. We propose *Collaborative Low-Rank Adaptation*, or CoLoRA, which exploits task similarity to collaboratively and efficiently fine-tune personalized
foundation models. The main idea in CoLoRA is to train one shared adapter capturing underlying task similarities across all tasks, and personalized adapters tailored to user-specific tasks. We theoretically study CoLoRA on heterogeneous linear regression and provide provable guarantees for ground truth recovery.
We also conduct several natural language experiments with varying task similarity, which further demonstrate that when trained together with similar tasks, individual performances are significantly boosted.

Stability-Aware Feature Design for Robust Watermark Detection in Machine-Generated Text
Sina Mansouri, Mohit Marvania, Abolfazl Safikhani

The widespread adoption of large language models (LLMs) has intensified the dema
nd for principled methods to distinguish human- from machine-generated text. Wat
ermarking provides a promising avenue, yet existing detectors exhibit sharp perf
ormance deterioration under multiple paraphrasing and when applied to shorter te
xts. We introduce Pattern Stability Score (PSS), a novel detection framework tha
t leverages local statistical features and stability dynamics across paraphrased
 variants. Specifically, the proposed method combines global and local z-score f
eatures with higher-order statistics of run-length patterns, enriched by autocor
relation signals and stability scores computed over paraphrase depth. Numerical
evaluations are performed on three benchmark datasets (PG-19, CNN/DailyMail, and
 WikiText) using multiple LLMs (Llama-3-8B, Qwen2-7B) and paraphrasers (Mistral-
7B, Qwen2-7B, Gemma-7B), systematically stress-testing robustness under up to ei
ght rounds of paraphrasing. Compared to prior z-score thresholding baselines and
 some state-of-the-art deep learning methods, our approach improves detection AU
C (area under the receiver operating characteristic curve) by over 10-15 percent
age points across different token lengths. Additionally, extensive cross-domain
experiments demonstrate that a single universal classifier generalizes across di
fferent LLMs, paraphrasers, and text domains without retraining, maintaining abo
ve 83.7\% AUC even when all components differ from training.

LUGS: Latent-aware Guidance for Efficient Unmasking in Diffusion Large Language
Models

Nuanqiao Shan, Kairong Han, Xinpeng Dong, Kun Kuang

Diffusion Language Models (DLMs) have emerged as a flexible alternative to autor
egressive (AR) models. They can decode tokens in any order, but the generation q
uality critically depends on the decoding strategy. Existing approaches predomin
antly rely on local heuristics, such as confidence or entropy, which may fail to
 capture sequence-level dependencies and the semantics in the context. To solve
this problem, we propose Latent-aware Unmasking Guidance Search (LUGS), a novel
decoding framework that leverages the model's internal hidden states to guide th
e unmasking process. By incorporating latent-aware scores to compensate for the
limitations of local heuristics such as confidence or entropy, LUGS improves the
 model's performance. Extensive experiments on various downstream tasks demonstr
ate that our approach consistently outperforms existing baselines on LLaDA-8B-in
struct and LLaDA-1.5 models. In Science and Reason tasks, LUGS improved performa
nce by more than 1\% on both base models. And LUGS obtains an average improvemen
t of 3.5\% in code generation. Remarkably, LUGS outperforms the beam search base
line by more than 5\% on average using LLaDA-8B-Instruct on code tasks. These r
esults highlight the potential of latent-aware guidance for advancing controllab
le and high-quality generation.

Interpretability and Generalization Bounds for Learning Spatial Physics

Alejandro Francisco Queiruga, Theo Gutman-Solo, Shuai Jiang

While there are many applications of machine learning (ML) to scientific problem
s that \emph{look} promising, the eye test can be misleading compared to the qua
ntitative values.
Using numerical analysis techniques, we rigorously quantify the accuracy, conver
gence rates, and generalization bounds of certain ML models applied to linear di
fferential equations (DEs) for parameter discovery or solution finding.
Beyond the quantity and discretization of data, we identify that the {function s
pace} of the data is critical to the generalization of the model which can lead
to divergence.
Similar lack of generalization is empirically demonstrated for commonly used mod
els.
Surprisingly, we find that different classes of models can exhibit opposing gene
ralization behaviors.
Based on our theoretical analysis, we also introduce a new mechanistic interpret
ability lens on scientific models whereby Green's function representations can b
e extracted from the weights of black-box models.
Our results inform a new cross-validation technique for measuring generalization

in physical systems, and can be useful as a benchmark of future methods.
****
LineageFlow: Flow Matching for High-Fidelity Family-Aware Protein Sequence Generation
Langzhang Liang, Ming Yang, Feng Yi, Junfan Li, Shirui Pan, Xu Yinghui, Tianlei Ying, YIZHEN ZHENG, Zenglin Xu
Protein sequence generation for engineering requires samples that are biophysically plausible and, when targeting a family/domain, remain recognizable members while exploring within-family diversity.
Current discrete generative models typically start from uniform or masked-token noise, which discards strong position-specific constraints induced by evolution and forces the model to reconstruct conserved residues from scratch, leading to weak family control and low foldability. We propose \emph{LineageFlow}, a simplex-valued flow-matching model that initializes generation from lineage priors derived from ancestral sequence reconstruction, turning generation into structured mutation from an evolved scaffold.
Across diverse protein families, LineageFlow achieves family validity close to held-out natural sequences and improves predicted structural confidence over uniform-/mask-initialized baselines while maintaining substantial within-family novelty and diversity, even surpassing a large pretrained baseline trained on substantially more data.
Finally, we introduce \emph{rerouting}, a single intermediate-time mutate--select--amplify intervention that enables objective-guided sampling without per-step predictor guidance and yields further gains in plausibility, including a zero-shot enzyme generation case study.

InftyThink+: Effective and Efficient Infinite-Horizon Reasoning via Reinforcement Learning
Yuchen Yan, Liang Jiang, Jin Jiang, Shuaicheng Li, zujie wen, Zhiqiang Zhang, JUN ZHOU, Jian Shao, Yueting Zhuang, Yongliang Shen
Large reasoning models achieve strong performance by scaling inference-time chain-of-thought, but this paradigm suffers from quadratic cost, context length limits, and degraded reasoning due to lost-in-the-middle effects. Iterative reasoning mitigates these issues by periodically summarizing intermediate thoughts, yet existing methods rely on supervised learning or fixed heuristics and fail to optimize when to summarize, what to preserve, and how to resume reasoning. We propose InftyThink+, an end-to-end reinforcement learning framework that optimizes the entire iterative reasoning trajectory, building on model-controlled iteration boundaries and explicit summarization. InftyThink+ adopts a two-stage training scheme with supervised cold-start followed by trajectory-level reinforcement learning, enabling the model to learn strategic summarization and continuation decisions. Experiments on DeepSeek-R1-Distill-Qwen-1.5B show that InftyThink+ improves accuracy by 21% on AIME24 and outperforms conventional long chain-of-thought reinforcement learning by a clear margin, while also generalizing better to out-of-distribution benchmarks. Moreover, InftyThink+ significantly reduces inference latency and accelerates reinforcement learning training, demonstrating improved reasoning efficiency alongside stronger performance.

Native Parallel Reasoner: Reasoning in Parallelism via Self-Distilled Reinforcement Learning
Tong Wu, Yang Liu, Jun Bai, Zixia Jia, Shuyi Zhang, Ziyong Lin, Yanting Wang, Song-Chun Zhu, Zilong Zheng
We introduce **Native Parallel Reasoner (NPR)**, a teacher-free framework that enables Large Language Models (LLMs) to self-evolve genuine parallel reasoning capabilities. NPR transforms the model from sequential emulation to native parallel cognition through three key innovations: (1) a **self-distilled** progressive training paradigm that transitions from cold-start format discovery to strict topological constraints without external supervision; (2) a novel **Parallel-Aware Policy Optimization (PAPO)** algorithm that optimizes branching policies directly within the execution graph, allowing the model to learn adaptive decompositio

n via trial and error; and (3) a robust **NPR Engine** that refactors memory man
agement and flow control of SGLang to enable stable, large-scale parallel RL tra
ining. Across eight reasoning benchmarks, NPR trained on Qwen3-4B achieves perfo
rmance gains of up to 24.5\% and inference speedups up to 4.6$\times$. Unlike pr
ior baselines that often fall back to autoregressive decoding, NPR demonstrates
100\% genuine parallel execution, establishing a new standard for self-evolving,
 efficient, and scalable agentic reasoning.

How to Fine-Tune a Reasoning Model? A Teacher–Student Cooperation Framework to S
ynthesize Student-Consistent SFT Data
Zixian Huang, Kaichen Yang, Xu Huang, Feiyang Hao, Qiming Ge, Bowen Li, He Du, K
ai Chen, Qipeng Guo
A widely adopted strategy for model enhancement is to use synthetic data generat
ed by a stronger model for supervised fine-tuning (SFT). However, for emerging r
easoning models like Qwen3-8B, this approach often fails to improve reasoning ca
pabilities and can even lead to a substantial drop in performance. In this work,
 we identify substantial stylistic divergence between teacher generated data and
 the distribution of student as a major factor impacting SFT. To bridge this gap
, we propose a Teacher–Student Cooperation Data Synthesis framework (TESSY), whi
ch interleaves teacher and student models to alternately generate style and non-
style tokens. Consequently, TESSY produces synthetic sequences that inherit the
advanced reasoning capabilities of the teacher while maintaining stylistic consi
stency with the distribution of the student. In experiments on code generation u
sing GPT-OSS-120B as the teacher, fine-tuning Qwen3-8B on teacher-generated data
 leads to performance drops of 3.25% on LiveCodeBench-Pro and 10.02% on OJBench,
 whereas TESSY achieves improvements of 11.25% and 6.68%.
****
Hierarchical Successor Representation for Robust Transfer
Changmin Yu, Máté Lengyel
The successor representation (SR) provides a powerful framework for decoupling
  predictive dynamics from rewards, enabling rapid generalisation across reward
  configurations. However, the classical SR is limited by its inherent policy
  dependence: policies change due to ongoing learning, environmental
  non-stationarities, and changes in task demands, making established predictive
  representations obsolete. Furthermore, in topologically complex environments,
  SRs suffer from spectral diffusion, leading to dense and overlapping features
  that scale poorly. Here we propose the Hierarchical Successor Representation
  (HSR) for overcoming these limitations. By incorporating temporal abstractions
  into the construction of predictive representations, HSR learns stable state
  features which are robust to task-induced policy changes. Applying
  non-negative matrix factorisation (NMF) to the HSR yields a sparse, low-rank
  state representation that facilitates highly sample-efficient transfer to
  novel tasks in multi-compartmental environments. Further analysis reveals that
  HSR-NMF discovers interpretable topological structures, providing a
  policy-agnostic hierarchical map that effectively bridges model-free
  optimality and model-based flexibility. Beyond providing a useful basis for
  task-transfer, we show that HSR's temporally extended predictive structure can
  also be leveraged to drive efficient exploration, effectively scaling to
  large, procedurally generated environments.

DecodeShare: Tracing the Shared Subspace of LLM Decode-Time Decisions
Zishan Shao, Lixun Zhang, Kangning Cui, Yixiao Wang, Ting Jiang, Hancheng Ye, Qi
nsi Wang, Zhixu Du, Yuzhe Fu, Fan Yang, Danyang Zhuo, Yiran Chen, Hai Helen Li
Large language models (LLMs) handle many tasks with one set of parameters, but u
nder KV-cached inference it is unclear what task-general structure, if any, is u
sed at $\textit{decode time}$ rather than during $\textit{prefill}$. We propose
$\textbf{DecodeShare}$, a protocol that identifies a low-dimensional subspace co
nsistently shared across tasks in decode-time hidden states, and then tests its
causal role by removing that subspace only during decoding. In our experiments,
disturbing the discovered shared subspace degrades decision performance far more

than disturbing either a prefill-derived or random subspace under the same intervention budget. We further show this decode-shared subspace has practical consequences for activation steering: common steering directions can overlap the task-general decode channel. Projecting out this shared subspace directly separates the functional roles of the two components, while evaluating steering vectors at decode-time yields more reliable signal for downstream deployment than prefill-based proxies. Despite its compactness, the shared subspace can serve as a high-leverage causal channel at decode time. Code is available at: https://github.com/Zishan-Shao/decodeshare.git.

Diagnosing Multi-step Reasoning Failures in Black-box LLMs via Stepwise Confidence Attribution

Xiaoou Liu, Tiejin Chen, Dengjia Zhang, Yaqing Wang, Lu Cheng, Hua Wei

Large Language Models have achieved strong performance on reasoning tasks with objective answers by generating step-by-step solutions, but diagnosing where a multi-step reasoning trace might fail remains difficult. Confidence estimation offers a natural diagnostic signal, yet existing methods are restricted to final answers or require internal model access.

We introduce Stepwise Confidence Attribution (SCA), a framework for closed-source LLMs that assigns step-level confidence based only on generated reasoning traces. SCA applies the Information Bottleneck principle: steps aligning with consensus structures across correct solutions receive high confidence, while deviations are flagged as potentially erroneous.

We propose two complementary methods: (1) NIBS, a non-parametric IB approach measuring consistency without graph structures, and (2) GIBS, a graph-based IB model that learns subgraphs through a differentiable mask to capture logical variability. Extensive experiments on mathematical reasoning and multi-hop question answering show that SCA reliably identifies low-confidence steps strongly correlated with reasoning errors. Moreover, using step-level confidence to guide self-correction improves the correction success rate by up to 13.5\% over answer-level feedback.

Multi-Objective Bayesian Optimization via Adaptive ε-Constraint Decomposition

Yaohong Yang, Sammie Katt, Samuel Kaski

Multi-objective Bayesian optimization (MOBO) provides a principled framework for optimizing multiple expensive black-box functions. However, existing MOBO methods often struggle with coverage, scalability, and handling constraints and preferences. In this work we propose *STAGE-BO, Sequential Targeting Adaptive Gap-Filling ε-Constraint Bayesian Optimization*: by analyzing the coverage of the surrogate Pareto front, our method identifies the Pareto front point with the largest uncovered gap, and uses its coordinates to define adaptive constraints in ε-constraint method, which transforms the problem into a sequence of inequality-constrained subproblems, efficiently solved via constrained expected improvement acquisition. Our approach provides uniform Pareto coverage without hypervolume computation and naturally handles constraints and preferences. Experiments on synthetic and real-world benchmarks demonstrate superior coverage and competitive hypervolume performance against state-of-the-art baselines. Our code implementation can be found at https://github.com/YangYaohong1/STAGE-BO.

****

Beyond Temperature: Hyperfitting as a Late-Stage Geometric Expansion

Meimingwei Li, Yuanhao Ding, Esteban Garces Arias, Christian Heumann

Recent work has identified a counterintuitive phenomenon termed “Hyperfitting", where fine-tuning Large Language Models (LLMs) to near-zero training loss on small datasets surprisingly enhances open-ended generation quality and mitigates repetition in greedy decoding. While effective, the underlying mechanism remains poorly understood, with the extremely low-entropy output distributions suggesting a potential equivalence to simple temperature scaling. In this work, we demonstrate that this phenomenon is fundamentally distinct from distribution sharpening; entropy-matched control experiments reveal that temperature scaling fails to r

eplicate the diversity gains of hyperfitting. Furthermore, we falsify the hypoth esis of static vocabulary reweighting, showing through ablation studies that hyp erfitting relies on a dynamic, context-dependent rank reordering mechanism. Laye r-wise analysis localizes this effect to a “Terminal Expansion" in the final tra nsformer block, where a substantial geometric expansion of the feature space ($\ Delta \mathrm{Dim} \approx +80.8$) facilitates the promotion of deep-tail tokens . Additionally, we introduce \textbf{Late-Stage LoRA}, a targeted fine-tuning st rategy that updates only the final 5 layers, yielding robust generation with min imal parameter updates.

Thinned Mean Field Langevin Dynamics
Zonghao Chen, Heishiro Kanagawa, Francois-Xavier Briol, Chris J. Oates, Lester M ackey
Several important learning tasks can be formulated as minimizing an entropy-regu larized objective over an appropriate space of probability distributions. Mean-f ield Langevin dynamics (MFLD) facilitate computation in this general context, ca sting the minimizer as the invariant distribution of a McKean--Vlasov process, w hich can be numerically discretized using N particles and thus simulated. However, simulating this interacting particle system has computational complexit y $\mathcal{O}(N^2)$. Motivated by recent research into \emph{kernel thinning}, we propose \texttt{KT-MFLD}, in which each particle interacts only with a corese t of size $\mathcal{O}(N^{\frac{1}{2}})$. \texttt{KT-MFLD} thus reduces the comp utational complexity to $\mathcal{O}(N^{\frac{3}{2}})$ while, under mild regular ity conditions, achieving the same convergence guarantees (up to logarithmic fac tors) as MFLD. Our theoretical analysis is empirically confirmed on tasks includ ing the training of student-teacher neural networks, quantization with maximum m ean discrepancy, and computation of predictively-oriented posteriors in a post-B ayesian framework.

Rotary Position Encodings for Graphs
Isaac Reid, Arijit Sehanobish, Cederik Höfs, Bruno Kacper Mlodozeniec, Leonhard Vulpius, Federico Barbero, Adrian Weller, Krzysztof Marcin Choromanski, Richard E. Turner, Petar Veli■kovi■
We study the extent to which rotary position encodings (RoPE), a recent transfor mer position encoding algorithm broadly adopted in large language models (LLMs) and vision transformers (ViTs), can be applied to graph-structured data. We find that rotating tokens depending on the spectrum of the graph Laplacian efficient ly injects structural information into the attention mechanism, boosting perform ance in synthetic and real-world graph learning tasks. This approach, coined _Wa ve-Induced Rotary Encodings_ (WIRE), enjoys intriguing theoretical properties: i t recovers regular RoPE on grids, and depends asymptotically on the graph effect ive resistance. Unlike bias-based relative position encodings, WIRE is compatibl e with linear attention.

Less Is More: Fast and Accurate Reasoning with Cross-Head Unified Sparse Attenti on

Lijie Yang, Zhihao Zhang, Arti Jain, Shijie Cao, Baihong Yuan, Yiwei Chen, Zhihao Jia, Ravi Netravali

Large reasoning models achieve strong performance through test-time scaling, but this incurs substantial computational overhead due to long decoding from short prompts. While sparse attention can reduce latency and memory usage, existing methods often degrade reasoning accuracy because selection errors accumulate over long generation horizons, or require costly retraining. We introduce LessIsMore, a training-free sparse attention mechanism for long-horizon reasoning. Our key insight is that token importance in reasoning is global and stable: critical tokens are largely shared across attention heads and remain stable over decoding steps. Guided by this structure, LessIsMore enforces cross-head unified token selection and preserves recent context via a stable recency window, yielding a globally consistent token set that can be reused across layers. Across multiple model families and challenging reasoning benchmarks, LessIsMore matches or improves accuracy while attending to substantially fewer tokens. With kernel-level optimizations, LessIsMore achieves up to $1.6\times$ end-to-end decoding speedup and up to $1.72\times$ faster sparse attention computation, with additional long-context results demonstrating the generality of our approach.

Positional Encoding for Spiking Transformers

Zijian Zhou, Yu Liang, Honglin Cao, Ammar Belatreche, Jieyuan Zhang, Wenjie Wei, Shuai Wang, Malu Zhang, Yang Yang, Haizhou Li

Transformer-based Spiking Neural Networks (SNNs) have recently emerged as a promising paradigm to sequential modeling, combining the strong representational capabilities of Transformers with the sparse spike-driven computation of SNNs. Within such position-agnostic architectures, positional encoding is critical for injecting order information, allowing the model to distinguish token positions, capture sequential dependencies, and represent relative relationships among tokens. However, existing positional encoding methods for SNNs are largely inherited from ANNs and, in doing so, undermine the spike-driven computational properties that are central to spiking transformers.

To address this limitation, we propose the Spiking Positional Encoding (SPE), a method designed specifically for Spiking Transformers, aimed at encoding relative positional information while preserving both spike-driven computation and the linear complexity of spiking self-attention.

The core component of SPE is the Positional Encoding Leaky Integrate-and-Fire (PE-LIF) neuron, which incorporates position-dependent signals into neuronal thresholds and implicitly propagates this information through spike trains via continuous firing and membrane potential reset dynamics. Extensive experiments on thirteen NLP benchmarks demonstrate that SPE consistently outperforms existing SNN positional encoding methods, strengthens the sequence modeling capability, and improves energy efficiency without introducing additional trainable parameters.

Code is available at https://github.com/CayleyZ/SPE.

AtomWorld: A Benchmark for Evaluating Spatial Reasoning in Large Language Models on Material Structures

Taoyuze Lv, Alexander Chen, Fengyu Xie, Chu Wu, Jeffrey Meng, Dongzhan Zhou, Bram Hoex, Yingheng Wang, Zhicheng Zhong, Tong Xie

Large language models (LLMs) have shown promising potential in materials science, enabling tasks ranging from knowledge retrieval to property prediction. Existing materials science benchmarks mainly focus on perceptual or knowledge-based tasks, largely ignoring the structure modelling tasks, a core challenge in real scientific workflows. In practice, constructing and manipulating atomic structures is one of the most creative and least automated steps in materials research. In this work, we introduce AtomWorld, a benchmark designed to evaluate the abilities of LLMs on structure modifications. The benchmark includes ten fundamental actions under four widely used modelling categories, enabling verifiable evaluation metrics. We find that Gemini 2.5 Pro generally performs the best. While the success rate decreases markedly with increasing modelling complexity, with particularly low success rates (below 12\% for rotation) for operations involving compl

ex spatial relations. Our results suggest that contemporary LLMs are better suited as copilots for materials structure modelling rather than fully unsupervised autonomous scientific agents. Beyond evaluation, AtomWorld also serves as a test bed and playground for developing future structure-aware models, including reinforcement learning and agentic approaches.

Spurious Rewards: Rethinking Training Signals in RLVR
Rulin Shao, Shuyue Stella Li, Rui Xin, Scott Geng, Yiping Wang, Sewoong Oh, Simon Shaolei Du, Nathan Lambert, Sewon Min, Ranjay Krishna, Yulia Tsvetkov, Hannaneh Hajishirzi, Pang Wei Koh, Luke Zettlemoyer
We show that reinforcement learning with verifiable rewards (RLVR) can elicit strong mathematical reasoning in certain language models even with spurious rewards that have little, no, or outright negative correlation with the correct answer. For example, RLVR training with GRPO improves MATH-500 performance for Qwen2.5-Math-7B in absolute points by 21.4% using randomly assigned rewards, nearly matching the 29.1% gained with ground truth rewards. To explain this counterintuitive observation, we show that GRPO exhibits a clipping bias arising from the clip term, which can amplify high-prior behaviors learned during pre-training even without informative rewards. As a case study, we identify one such high-prior behavior for Qwen2.5-Math models, which we term code reasoning---reasoning in code without actual code execution; code reasoning frequency increases from 65% to over 90% with spurious rewards. However, the presence of such amplifiable behaviors is highly model-dependent. In practice, spurious rewards that are effective for Qwen models often fail to produce gains for other model families, such as Llama3 or OLMo2. Our results highlight the importance of validating RL methods across diverse models rather than relying on a single de facto choice: large performance gains can arise on Qwen models even from random rewards that do not reflect genuine capability improvements.
****
Continual Segmentation under Joint Nonstationarity
Prashant Pandey, Himanshu Kumar, Devineni Sri Venkatraya Chowdary, Brejesh Lall
Evolving data streams induce joint nonstationarity in continual semantic segmentation, where semantic classes, input distributions, and supervision availability change simultaneously over time. This setting reflects practical structured prediction systems, yet remains largely unexplored in prior continual learning work, which typically studies these factors in isolation. We formalize continual segmentation under coupled class, domain, and label shifts and investigate learning in heterogeneous dense prediction environments with limited annotations and abundant unlabeled data. To address instability and overfitting arising from few-shot supervision under distribution drift, we introduce gradient-adaptive stabilization, a parameter-wise regularization mechanism implemented via gradient-scaled stochastic perturbations that promotes a principled stability–plasticity tradeoff. We further leverage unlabeled data through semi-supervised learning and introduce prototype anchored supervision that validates pseudo-labels via joint confidence and prototype consistency. Together, these mechanisms enable learning under joint nonstationarity in continual segmentation. Extensive empirical evaluation across class-incremental, domain-incremental, and few-shot regimes demonstrates consistent improvements over prior methods in heterogeneous structured prediction settings. Our results expose fundamental failure modes of existing continual segmentation approaches and provide insight into learning robust dense predictors in dynamically evolving environments. Our code is available at https://github.com/prinshul/JASCL.git.

Feasible Fusion: Constrained Joint Estimation under Structural Non-Overlap
Yuxi Du, Zhiheng Zhang, Haoxuan Li, Cong Fang, Jixing Xu, Zhen Peng, Jiecheng Guo
Causal inference in modern large-scale systems faces growing challenges, including high-dimensional covariates, multi-valued treatments, massive observational (OBS) data, and limited randomized controlled trial (RCT) samples due to cost constraints. We formalize treatment-induced structural non-overlap and show that, u

nder this regime, commonly used weighted fusion methods provably fail to satisfy randomized identifying restrictions.To address this issue,we propose a constrained joint estimation framework that minimizes observational risk while enforcing causal validity through orthogonal experimental moment conditions. We further show that structural non-overlap creates a feasibility obstruction for moment enforcement in the original covariate space.We also derive a penalized primal–dual algorithm that jointly learns representations and predictors, and establish oracle inequalities decomposing error into overlap recovery, moment violation, and statistical terms.Extensive synthetic experiments demonstrate robust performance under varying degrees of non-overlap. A large-scale ride-hailing application shows that our method achieves substantial gains over existing baselines, matching the performance of models trained with significantly more RCT data.

FormalRx: Rectify and eXamine Semantic Failures in Autoformalization

Haocheng Wang, Baiyu Huang, Yingjia Wan, Xiao Zhu, Xiaoyang Liu, Yinya Huang, Zhijiang Guo

The veracious semantic alignment in autoformalization is significant for formal mathematical reasoning. However, existing evaluations provide only opaque binary verdicts or scalar scores, offering no interpretable insight into where or why translations fail. This opacity severely limits both human understanding and automated system improvement. To bridge this gap, we introduce FormalRx, a comprehensive diagnostic evaluation framework that transforms autoformalization assessment from black-box judgments into actionable feedback. At its core is SCI Error Taxonomy, a hierarchical classification scheme decomposing autoformalization errors into 28 distinct categories with strict priority ordering. Building on this taxonomy, FormalRx provides four critical diagnostic capabilities: alignment verdicts, error categorization, error localization, and correction. We instantiate the framework with a diagnostic model FormalRx-8B, trained on 56,287 synthetically generated samples with fine-grained diagnostic annotations, and release FormalRx-Test as the first fine-grained diagnostic benchmark. FormalRx-8B achieves F1-scores of 0.88 (verdict) and 0.71 (categorization), along with accuracies of 0.75 (localization) and 0.73 (correction), substantially outperforming both general-purpose LLMs and specialized baselines. By connecting evaluation with actionable insights, FormalRx enables systematic diagnosis and improvement of autoformalization systems.

FormalJudge: A Neuro-Symbolic Paradigm for Agentic Oversight

Jiayi Zhou, Yang Sheng, Hantao Lou, Yaodong Yang, Jie Fu

As LLM-based agents increasingly operate in high-stakes domains with real-world consequences, ensuring their behavioral safety becomes paramount. The dominant oversight paradigm, *LLM-as-a-Judge*, faces a fundamental dilemma: how can probabilistic systems reliably supervise other probabilistic systems without inheriting their failure modes? We argue that formal verification offers a principled escape from this dilemma, yet its adoption has been hindered by a critical bottleneck: the translation from natural language requirements to formal specifications. This paper bridges this gap by proposing , a neuro-symbolic framework that employs a bidirectional **Formal-of-Thought** architecture: LLMs serve as *specification compilers* that top-down decompose high-level human intent into atomic, verifiable constraints, then bottom-up prove compliance using Dafny specifications and Z3 Satisfiability modulo theories solving, which produces mathematical guarantees rather than probabilistic scores. We validate across three benchmarks spanning behavioral safety, multi-domain constraint adherence, and agentic upward deception detection. Experiments on 7 agent models demonstrate that achieves an average improvement of **16.6%** over LLM-as-a-Judge baselines, enables *weak-to-strong* generalization where a 7B judge achieves over 90% accuracy detecting deception from 72B agents, and provides *near-linear safety improvement* through iterative refinement.

Muon in Associative Memory Learning: Training Dynamics and Scaling Laws

Kaifei Wang, Binghui Li, Han Zhong, Pinyan Lu, Liwei Wang

Muon updates matrix parameters via the matrix sign of the gradient and has shown strong empirical gains, yet its dynamics and scaling behavior remain unclear in theory. We study Muon in a linear associative memory model with softmax retrieval and a hierarchical frequency spectrum over query–answer pairs, with and without label noise.
In this setting, we show that Gradient Descent (GD) learns frequency components at highly imbalanced rates, leading to slow convergence bottlenecked by low-frequency components. In contrast, the Muon optimizer mitigates this imbalance, leading to faster and more uniform progress.
Specifically, in the noiseless case, Muon achieves an exponential speedup over GD; in the noisy case with a power-law frequency spectrum, we derive Muon's scaling law and demonstrate its superior scaling efficiency over GD. Furthermore, we show that Muon can be interpreted as an implicit matrix preconditioner arising from adaptive task alignment and block-symmetric gradient structure. In contrast, the preconditioner with coordinate-wise sign operator could match Muon under oracle access to unknown task representations, which is infeasible for SignGD in practice. Experiments on synthetic long-tail classification and LLaMA-style pre-training corroborate the theory.

Beyond Rational Illusion: Behaviorally Realistic Strategic Classification
Xinpeng Lv, Yunxin Mao, Renzhe Xu, Chunyuan Zheng, Yikai Chen, Haoxuan Li, Yang Shi, Jinxuan Yang, Yuanlong Chen, Yuanxing Zhang, Shaowu Yang, Wenjing Yang, Zhouchen Lin, Haotian Wang
Strategic classification studies the interaction between decision models and agents who strategically manipulate their features for favorable outcomes.
Existing SC frameworks typically rely on the idealized assumption that agents are strictly rational.
However, evidence from behavioral economics and psychology consistently shows that real-world decision-making is often shaped by cognitive biases, deviating from pure rationality.
To formalize this limitation, we identify and define a new problem setting, termed the behaviorally realistic strategic classification problem, where agents’ strategic manipulations deviate from full rationality due to psychological biases.
Motivated by the identified limitation, we propose the Prospect-Guided Strategic Framework (Pro-SF) to address the problem, a principled framework grounded in prospect theory to model and learn under behaviorally realistic strategic responses.
Specifically, to capture behaviorally realistic strategic manipulations, our framework reformulates the Stackelberg-style interaction between agents and the decision-maker by incorporating three key mechanisms inspired by prospect theory, including the asymmetry between benefits and costs, different subjective reference points, and non-rational probability distortion. Experiments on synthetic and real-world datasets establish Pro-SF as a behaviorally grounded approach to strategic classification, bridging machine learning and behavioral economics for more reliable deployment in the real world.

Multilingual Safety Alignment Via Sparse Weight Editing
Jiaming Liang, Zhaoxin Wang, Handing Wang
Large Language Models (LLMs) exhibit significant safety disparities across languages, with low-resource languages (LRLs) often bypassing safety guardrails established for high-resource languages (HRLs) like English. Existing solutions, such as multilingual supervised fine-tuning (SFT) or Reinforcement Learning from Human Feedback (RLHF), are computationally expensive and de-
pendent on scarce multilingual safety data. In this paper, we propose a novel, training-free alignment framework based on Sparse Weight Editing. Identifying that safety capabilities are localized within a sparse set of ”safety neurons,” we formulate the cross-lingual alignment problem as a constrained linear transformation. We derive a closed-form solution to optimally map the harmful representations of LRLs to the robust safety subspaces of HRLs, while preserving general utility via a null-space projection constraint. Extensive experiments across 8 lang

uages and multiple model families (Llama-3, Qwen-2.5) demonstrate that our metho d significantly reduces Attack Success Rate (ASR) in LRLs with negligible impact on general reasoning capabilities, all achieved with a single, data-efficient c alculation.

****

Rethinking the Hardness of PbRL: A Provable General Regret Bound

Chenjie Mao, Yi Fan, Ning Zhang, Chongjie Zhang

This paper studies \emph{preference-based reinforcement learning} (PbRL), where agents learn from comparative, trajectory-level feedback rather than numeric rew ards. While PbRL has seen rapid empirical and theoretical progress, existing ana lyses are largely confined to restricted settings and fail to jointly capture th e outcome-based and comparison-based nature of preference feedback.

We prove that under a broad \emph{general function approximation} framework, PbR L admits a $\sqrt{T}$ regret guarantee. In particular, we introduce a simple and provably efficient algorithm, \emph{Recursive Trajectory-based Preference Q-Lea rning} (RTPQ), and establish its regret bound while explicitly accounting for th e trajectory-level and comparative structure of preferences.

Our analysis is characterized by a new complexity measure, the \emph{Dual Episod ic Eluder Dimension} (DEED), which quantifies the intrinsic difficulty of PbRL. We show that for linear MDPs, the DEED scales as $\mathcal{O}(dH)$, yielding a r egret bound of $\tilde{\mathcal{O}}(dH\sqrt{T}\max(H^{3/2},\,1/\kappa))$, where κ is a problem-dependent constant. This bound is near-optimal up to horiz on- and problem-dependent factors when compared to standard reward-based linear MDPs.

In addition, our framework recovers the best-known regret bounds in the special cases of dueling bandits and standard outcome-based reinforcement learning. Over all, our results provide a general regret guarantee for PbRL with outcome-based preference feedback and broad function approximation.

From Diagrams to Code: Multilingual Programming with Visual Design

Linzheng Chai, Jian Yang, Shukai Liu, Wei Zhang, Liran WANG, Ke Jin, Tao Sun, Co ngnan Liu, Chenchen Zhang, Hualei Zhu, Jiaheng Liu, Xianjie Wu, Ge Zhang, Tianyu Liu, Zhoujun Li

In modern software development, particularly in emerging ``vibe coding'' paradig ms, project implementation increasingly begins with visual interactions between users and AI coding assistants, where system architectures are communicated thro ugh visual designs before coding. This visual-first approach necessitates AI sys tems capable of interpreting diagrams across multiple programming languages. How ever, the development of such systems is severely hindered by the lack of large- scale multimodal training data and evaluation benchmarks. To address these limit ations, we present M²C-INSTRUCT, a comprehensive multilingual multimodal instruc tion-tuning dataset containing over 13.1M samples across 50+ programming languag es, designed for visual understanding and diagram interpretation in code generat ion tasks. We validate our dataset by training M²-CODER, a multilingual multimod al software developer that successfully integrates visual design inputs with tex tual instructions. We also introduce M²EVAL, a novel multilingual evaluation ben chmark for multimodal code generation performance. Experiments show our 7B M²-CO DER, performs on par with much larger 70B+ models, confirming the quality and ef fectiveness of our M²C-INSTRUCT. Together, M²C-INSTRUCT, M²-CODER, and M²EVAL pr ovide essential infrastructure for visual-assisted programming in vibe-coding an d visual-interactive development workflows.

AmbiRefer3D: 3D Visual Grounding with Referential Ambiguity

Rongjiang Zhu, Wei Kang, Zeqi Liu, Chen junyu, Shuo Yang, Xinxiao Wu

Traditional 3D visual grounding typically assumes that natural language express ions unambiguously refer to
target objects in a 3D scene.

However, in practical applications, human instructions are often ambiguous or in sufficient, which may lead existing models to associate the query with multiple possible objects, resulting in incorrect results.

In this paper, we propose a new task, 3D visual grounding with referential ambiguity, which allows for referential ambiguity in language descriptions, making it more broadly applicable to real-world scenarios.
To tackle this task, we propose an interactive grounding framework that performs multi-round question-answer interactions, in which the model actively generates clarifying questions and receives human-provided answers to acquire additional object attributes, spatial relationships, and other contextual information, thereby resolving referential ambiguity and achieving accurate grounding.
To support the learning of interactive grounding,
we construct a large-scale dataset named AmbiRefer3D, which contains 47,085 samples with 141,255 annotations of
question-answer dialogues that capture interactive disambiguation processes, covering 7,316 indoor 3D scenes.
Furthermore, we establish multi-round evaluation metrics to measure both disambiguation efficiency and grounding accuracy.
The code is available at *https://github.com/yearnallover/AmbiRefer3D*.

A New Framework for Cybersecurity Refusals in AI Agents
Eliot Krzysztof Jones, Matt Fredrikson, J Zico Kolter
Agentic scaffolds have dramatically improved LLM performance on complex, long-horizon tasks, yielding both broad benefits and amplified risks in domains like cybersecurity. Existing benchmarks for AI agents in cybersecurity focus mainly on measuring proficiency–how effectively agents can complete offensive security tasks–but neglect a critical question: when and how should agents refuse harmful requests? We present the first framework for establishing refusal boundaries in offensive security contexts. Our framework defines (1) principled criteria for when tasks should be refused, (2) categories of tasks that warrant refusal, and (3) evaluation methodology for measuring agent robustness under both benign and adversarial conditions. We apply this framework to assess how current LLM-powered agents adhere to appropriate refusal boundaries across a range of web-based offensive security scenarios, finding that 6 of 8 frontier models tested refuse to identify vulnerabilities in real systems 0\% of the time.
****

VERA-V: Variational Inference Framework for Jailbreaking Vision-Language Models
Qilin Liao, Anamika Lochab, Ruqi Zhang
Vision-Language Models (VLMs) extend large language models with visual reasoning, but their multimodal design also introduces new, underexplored vulnerabilities. Existing multimodal red-teaming methods largely rely on brittle templates, focus on single-attack settings, and expose only a narrow subset of vulnerabilities. To address these limitations, we introduce VERA-V, a variational inference framework that recasts multimodal jailbreak discovery as learning a joint posterior distribution over paired text-image prompts. This probabilistic view captures complex cross-modal interactions, enabling stealthy, coordinated adversarial inputs that bypass model guardrails. We train a lightweight attacker to approximate the posterior, allowing efficient sampling of diverse jailbreaks and providing distributional insights into vulnerabilities. VERA-V further integrates three complementary strategies: (i) typography-based text prompts that embed harmful cues, (ii) diffusion-based image synthesis that introduces adversarial signals, and (iii) structured distractors to fragment VLM attention. Experiments on HarmBench and HADES benchmarks show that VERA-V consistently outperforms state-of-the-art baselines on both open-source and frontier VLMs, achieving up to 53.75\% higher attack success rate (ASR) over the best baseline on GPT-4o. We include the code on the project page available here: https://github.com/kxwhiowo/VERA-V

Optimal Transport under Group Fairness Constraints
Linus Bleistein, Mathieu Dagréou, Francisco Andrade, Thomas Boudou, Aurélien Bellet
Ensuring fairness in matching algorithms is a key challenge in allocating scarce resources and positions. Focusing on Optimal Transport (OT), we introduce a novel notion of group fairness requiring that the probability of matching two indiv

iduals from any two given groups in the OT plan satisfies a predefined target. We first propose a modified Sinkhorn algorithm to compute perfectly fair transport plans efficiently. Since exact fairness can significantly degrade matching quality in practice, we then develop two relaxation strategies. The first one involves solving a penalized OT problem, for which we derive novel finite-sample complexity guarantees. Our second strategy leverages bilevel optimization to learn a ground cost that induces a fair OT solution, and we establish a bound on the deviation of fairness when matching unseen data. Finally, we present empirical results illustrating the performance of our approaches and the trade-off between fairness and transport cost.

Error Analysis of Discrete Flow with Generator Matching

Zhengyan Wan, Yidong Ouyang, Qiang Yao, Liyan Xie, Fang Fang, Hongyuan Zha, Guang Cheng

Discrete flow models offer a powerful framework for learning distributions over discrete state spaces and have demonstrated superior performance compared to the discrete diffusion models. However, their convergence properties and error analysis remain largely unexplored. In this work, we develop a unified framework grounded in stochastic calculus theory to systematically investigate the theoretical properties of discrete flow models. Specifically, by leveraging a Girsanov-type theorem for the path measures of two continuous-time Markov chains (CTMCs), we present a comprehensive error analysis that accounts for both transition rate estimation error and early stopping error. In fact, the estimation error of transition rates has received little attention in existing works. Unlike discrete diffusion models, discrete flow incurs no initialization error caused by truncating the time horizon in the noising process. Building on generator matching and uniformization, we establish non-asymptotic error bounds for distribution estimation without the boundedness condition on oracle transition rates. Furthermore, we derive a faster rate of total variation convergence for the estimated distribution with the boundedness condition, yielding a nearly optimal rate in terms of sample size. Our results provide the first error analysis for discrete flow models. We also investigate model performance under different settings based on simulation results.

Continuous Variable Hamiltonian Learning at Heisenberg Limit via Displacement-Random Unitary Transformation

Xi Huang, Lixing Zhang, Di Luo

Characterizing continuous-variable (CV) Hamiltonians can be formulated as Hamiltonian learning under quantum measurement constraints: finite operator coefficients are inferred from noisy measurement outcomes obtained by probing an infinite-dimensional system. Existing Heisenberg-limited CV protocols are often limited to low-order structures, vulnerable to noise, or unresolved for generic multi-mode settings. We introduce Displacement-Random Unitary Transformation (D-RUT), an active data acquisition protocol with pre-specified probes and number-preserving transformations that reduce finite-order bosonic Hamiltonian learning to polynomial recovery. We prove Heisenberg-limited total evolution time with robustness to state preparation and measurement (SPAM) errors, and develop hierarchical multi-mode coefficient recovery with better statistical efficiency than simultaneous estimation. We also extend D-RUT to first-quantized Hamiltonian coefficient learning, and numerical experiments on single- and multi-mode nonlinear systems validate the predicted Heisenberg scaling.

TsLLM: Augmenting LLMs for General Time Series Understanding and Prediction

Felix Parker, Nimeesha Chan, Chi Zhang, Kimia Ghobadi

Time series data is fundamental to decision-making across many domains including healthcare, finance, power systems, and logistics. However, analyzing this data correctly often requires incorporating unstructured contextual information, answering domain-specific questions, and generating natural language explanations – capabilities that traditional time series models lack. While Large Language Models (LLMs) excel at contextual reasoning and knowledge integration, they struggl

e with numerical time series due to inefficient text-based representations and l
imited exposure to numerical data during pretraining. We address this gap by aug
menting an LLM with specialized time series perception through a patch-based enc
oder-decoder architecture. We train this time series-augmented LLM (TsLLM) on a
large corpus of over 25 billion tokens of interleaved time series and text spann
ing diverse tasks: forecasting with contextual information, question-answering,
anomaly detection, classification, report generation, and more, all unified as a
utoregressive next token prediction. This training enables TsLLM to leverage bot
h its natural language skills and newly acquired understanding of numerical time
 series signals. While not designed to surpass specialized models on traditional
 benchmarks, TsLLM demonstrates strong performance on tasks requiring the integr
ation of time series analysis with natural language – capabilities that conventi
onal approaches cannot provide. It also exhibits strong zero-shot and few-shot p
erformance, showing it can adapt to new data without additional training.

Towards Generative Graph Matching for Graph Edit Distance Computation
Wei Huang, Hanchen Wang, Dong Wen, Wenjie Zhang, Ying Zhang, Xuemin Lin
Graph Edit Distance (GED), which aims to find an edit path with minimum number o
f edit operations to transform one graph into another, is a fundamental NP-hard
problem and a widely used graph similarity measure. Recent matching-based hybrid
 approaches have demonstrated better scalability than A* search-based hybrids by
 reformulating GED as a graph matching problem. In these methods, a neural netwo
rk predicts a single deterministic node matching matrix, from which top-k node
 mappings are extracted iteratively to derive candidate edit paths. However, the
se methods often suffer from highly correlated candidates that easily lead to su
boptimal solutions, while the iterative extraction becomes inefficient for large
 k. In this paper, we propose DiffGED, the first generative approach for GED c
omputation. Specifically, we formulate the graph matching problem as a generativ
e task, and employ a diffusion-based model to generate multiple diverse node mat
ching matrices simultaneously, from which diverse node mappings can be efficient
ly extracted. The generative diversity introduced by the diffusion process enabl
es DiffGED to avoid suboptimal solutions and achieve superior solution quality c
lose to the exact solution. Experiments on real-world datasets show that DiffGED
 generates multiple diverse edit paths with accuracy comparable to exact solutio
ns, while running faster than existing hybrid approaches.

Uncovering Competency Gaps in Large Language Models and Their Benchmarks
Maty Bohacek, Nino Scherrer, Nicholas Dufour, Thomas Leung, Christoph Bregler, S
tephanie C.Y. Chan
The evaluation of large language models relies heavily on standardized benchmark
s. These benchmarks provide useful aggregated metrics, but can obscure (i) parti
cular sub-areas where the models are weak ("model gaps") and (ii) imbalanced cov
erage in the benchmarks themselves ("benchmark gaps"). To automatically uncover
both types of gaps, we propose a simple new method using concept activations fro
m sparse autoencoders, to identify fine-grained gaps on a per-concept basis. The
 method also benefits from grounding evaluation in the model's internal represen
tations, as well as easy comparison across benchmarks. We applied the method to
five popular open-source models and more than a dozen benchmarks, as illustrativ
e examples. As validation of the approach, we found that our automatic, unsuperv
ised method was able to recover model gaps that have been previously documented
in the literature (e.g. relating to sycophancy), in addition to identifying nove
l model gaps. We were also able to automatically uncover benchmark gaps: core co
ncepts that should fall within the scope of a given benchmark. Our "competency g
aps" method can be used to complement existing benchmarks, by providing a concep
t-level decomposition of model behavior, and by helping benchmark developers ite
rate upon benchmark design. Code is available at https://competency-gaps.github.

Variational Learning for Insertion-based Generation
Yangtian Zhang, Zhe Wang, Arthur Gretton, Rex Ying, David van Dijk, Michalis Tit

sias, Jiaxin Shi
Non-monotonic sequence generation methods, such as masked diffusion models, provide a flexible alternative to left-to-right autoregressive modeling by allowing tokens to be generated in non-fixed and prescribed orders. Despite their practical advantages, most existing non-monotonic models are order-agnostic and rely on a fixed-length grid, limiting their ability to support variable-length generation and adaptive insertion order. In this work, we introduce a probabilistic framework for learning insertion order in variable-length insertion models. We formalize a bijective correspondence between insertion trajectories and permutations, which enables an exact reparameterization of the data likelihood as a sum over permutations. Building on this result, we propose the Insertion Process (IP), a stochastic generative model that jointly learns where to insert, what to insert, and when to terminate, trained via permutation-based variational inference. Unlike prior fixed-canvas approaches, IP natively supports variable-length generation and learns data-driven preferences over insertion orders. Experiments on goal-conditioned planning and molecular string generation demonstrate that learning insertion order improves both modeling quality and generalization in domains without a canonical left-to-right structure.

LoKiFormer: Locality-aware Attention with Decoupled Knowledge Memory for Efficient Large Language Model Pretraining
Qiuwu Chen, Zimo Liu, Yuchen Li, Ying Sun, Yifan Zhang, Zhijie Qiu, Zeng You, Ryan Dong, Simeng Ma, Yaofo Chen, Mingkui Tan
Large language models (LLMs) have achieved remarkable breakthroughs across various applications. However, their architectures remain inefficient in pretraining due to two main limitations: (i) self-attention lacks an explicit inductive bias for locality, leading to redundant modeling of sequence-internal local information; (ii) mixture-of-experts (MoE) implicitly couples knowledge storage with computational pathways, hindering flexible access to sequence-external global knowledge. To overcome these limitations, we propose LoKiFormer, a novel LLM architecture that augments the standard decoder with two dedicated modules: 1) Local Fusion Attention (LFA), which incorporates a convolutional fusion to attention, explicitly capturing local patterns and allowing the attention to operate on more informative representations; 2) Knowledge Memory Module (KMM), which introduces a parametric key–value memory that explicitly stores global knowledge in addressable slots, decoupling storage from computation and enabling direct knowledge retrieval. Together, these modules enable LoKiFormer to achieve more efficient and effective integration of information at both levels. Experimental results show that LoKiFormer converges 1.33x faster in pre-training than baseline models, underscoring its superiority over existing LLM architectures.

Attend to Anything: Foundation Model for Unified Human Attention Modeling
Wenzhuo Zhao, ronghao xian, Keren Fu, Qijun Zhao
Existing human attention (saliency) modeling methods persist as highly fragmented across modalities, scenes, and task formulations. Consequently, even with increasing model capacity and data scale, current models predominantly remain scene-dependent and task-specific, failing to practically generalize in real-world applications.

To address the fundamental limitations, we present the Attend to Anything Model (AAM), a multi-modal foundation model that unifies attention modeling across various image, video, and audio-visual tasks and scenes. AAM reformulates attention as a cognitive entailment relationship organized in a general-to-specific hierarchy, implemented through language prompts with hierarchical embeddings in hyperbolic space. Furthermore, to unify static image and dynamic video attention, we adopt a fluid-dynamics perspective, formulating video-frame attention as a diffusive temporal evolution governed by the Fokker--Planck equation.

Extensive experiments on 16 benchmarks demonstrate that AAM consistently outperforms state-of-the-art methods by an average of 6\% across various scenarios, while achieving approximately a 4$\times$ speedup in video inference.

Overall, these results demonstrate that AAM provides a principled foundation f

or future research on attention and saliency-related tasks. The dataset and code will be available at \url{https://github.com/wz-zhao/Attend-to-Anything}.

SAMT: Generating Structured Avatar Meshes and Textures from a Single Image
Muyu Wang, Jianzhe Gao, Xingping Dong, Yujia Wang, Wenguan Wang
Despite rapid progress in generative 3D creation, producing high-fidelity 3D face assets from a single image remains challenging, as it requires both identity-critical facial micro-structures and fine-grained view-consistent textures. To address this, we present a two-stage framework named **SAMT** for monocular 3D avatar generation and texture synthesis. Specifically, a latent 3D diffusion model for facial mesh generation is pretrained and then further adapted to generate high-quality facial geometry through large-scale domain-specific finetuning on 35K curated 3D avatar models. Subsequently, the generated facial mesh is textured through a multi-view-aware texturing strategy. It incorporates multi-view facial priors along with the mesh geometry to guide a 2D texturing diffusion, enabling cross-view consistent and mesh-aligned texture synthesis. Extensive experiments demonstrate that SAMT improves over existing baselines by producing more coherent facial geometry together with more fine-grained and view-consistent textures. Project page is available at https://github.com/muyuWang/SAMT.

Dissecting the Safety Circuit: Neuronal Intervention for Transferable Adversarial Attacks on VLMs
Chunlong Xie, Kangjie Chen, Shangwei Guo, Shudong Zhang, Jiamou Liu, Tianwei Zhang, Tao Xiang
The limited transferability of adversarial attacks on Vision-Language Models (VLMs) stems from their failure to navigate model-specific safety alignments, where superficial perturbations exploit surrogate-specific artifacts rather than shared safety-critical features. We reveal through linear probing that safety-related representations are concentrated within specific intermediate neuronal circuits, which act as localized defense bottlenecks that can be disentangled from transferable features. To overcome this barrier, we propose the Safety Circuit Intervention Attack (SCIA), a framework that surgically steers internal representations to bypass these localized safety mechanisms. SCIA employs a dual-objective steering strategy that suppresses the defensive circuit encoding safety features while amplifying the transferable circuit capturing model-agnostic representations, effectively decoupling adversarial patterns from surrogate-specific safety behaviors. Furthermore, we incorporate contrastive semantic steering and spectral smoothness regularization to guide optimization toward compliant semantic regions while producing visually coherent perturbations. Experimental results demonstrate that SCIA significantly outperforms state-of-the-art methods in bypassing unseen black-box VLMs.

DeepAnalyze: Agentic Large Language Models for Autonomous Data Science
Shaolei Zhang, Ju Fan, Meihao Fan, Yizhe Liu, Yuxin Zhang, Xiaoyong Du
Autonomous data science has been a long-standing challenge, and is now becoming feasible with the emergence of powerful large language models (LLMs). Recent workflow-based data agents have shown promising results on specific data tasks but remain fundamentally limited in achieving full autonomy due to their reliance on predefined workflows. In this paper, we introduce DeepAnalyze, the first agentic LLM for autonomous data science, capable of automatically completing the end-to-end data science from raw data to research reports. To tackle high-complexity data science tasks, we propose a curriculum-based agentic training paradigm that emulates the learning trajectory of human data scientists, enabling LLMs to progressively acquire and integrate multiple capabilities in real-world environments. Accordingly, we contribute a data-grounded trajectory synthesis framework to constructs high-quality data science training data. Through training in real-world environment, DeepAnalyze learns to perform a broad spectrum of data tasks, ranging from data question answering to open-ended data research. Experiments on 13 benchmarks demonstrate that, with only 8B parameters, DeepAnalyze outperforms workflow-based agents built on advanced proprietary LLMs. DeepAnalyze is fully o

pen-sourced, paving the way toward autonomous data science.

Reinforcement Learning with Discrete Diffusion Policies for Combinatorial Action Spaces
Haitong Ma, Ofir Nabati, Aviv Rosenberg, Bo Dai, Oran Lang, Craig Boutilier, Na Li, Shie Mannor, Lior Shani, Guy Tennenholtz
Reinforcement learning (RL) struggles to scale to large, combinatorial action spaces common in many real-world problems. This paper introduces a novel framework for training discrete diffusion models as highly effective policies in these complex settings. Our key innovation is an efficient online training process that ensures stable and effective policy improvement and . By leveraging policy mirror descent (PMD) to define an ideal, regularized target policy distribution, we frame the policy update as a distributional matching problem, training the expressive diffusion model to replicate this stable target. This decoupled approach stabilizes learning and significantly enhances training performance. Our method achieves state-of-the-art results and superior sample efficiency across a diverse set of challenging combinatorial benchmarks, including DNA sequence generation, RL with macro-actions, and multi-agent systems. Experiments demonstrate that our diffusion policies attain comparable or superior performance compared to other baselines. Crucially, our extensive empirical analysis reveals a key trade-off: FKL demonstrates superior sample efficiency and faster initial convergence, whereas RKL ensures stable training and higher asymptotic performance on challenging tasks.
****
Mitigating Perceptual Judgment Bias in Multimodal LLM-as-a-Judge via Perceptual Perturbation and Reward Modeling
Seojeong Park, Jiho Choi, Junyong Kang, Seonho Lee, Jaeyo Shin, Hyunjung Shim
Recent multimodal large language models have demonstrated strong reasoning ability, yet their reliability as automated evaluators remains limited by a critical weakness: when visual evidence conflicts with textual cues, MLLM judges tend to reward plausible narratives over perceptually correct answers. We identify and systematically analyze this phenomenon, which we term \textit{Perceptual Judgment Bias}. Through controlled visual perturbations, existing multimodal judges frequently anchor on the response text instead of their own visual perception, leading to inconsistent and non-verifiable evaluations. To address this issue, we introduce the \textit{Perceptually Perturbed Judgment Dataset}, which constructs minimally edited counterfactual responses that isolate perceptual errors and enable verifiable supervision. Building on this dataset, we develop a unified training framework that combines a structured GRPO-based reward with a batch-ranking objective, achieving coherent global ordering without explicit pairwise labels. Experiments across diverse MLLM-as-a-Judge benchmarks show that our approach substantially improves perceptual fidelity, ranking coherence, and alignment with human evaluation. Our results establish a scalable and generalizable pathway for training multimodal judges that are perceptually grounded, interpretable, and robust to visual–reasoning conflicts.

Stabilizing Recurrent Dynamics for Test-Time Scalable Latent Reasoning in Looped Language Models
Xiao-Wen Yang, Ziyu Han, Xi-Hua Zhang, Wen-Da Wei, Jie-Jing Shao, Lan-Zhe Guo, Yu-Feng Li
Looped Language Models (LoopLMs) enable efficient latent reasoning through depth recurrence, yet exhibit unreliable test-time scaling behavior: performance often peaks at a certain iteration depth and then collapses with further recurrence. Through latent dynamics analysis, we find an inherent trade-off between stability and effectiveness in existing architectures and strategies. By conceptualizing reasoning as uncertainty reduction, we propose that convergence toward stable fixed points while preserving effectiveness represents a promising way. To this end, we propose STARS (STAbility-driven Recurrent Scaling), a training framework that constrains latent states to approach asymptotically stable fixed points. This is realized via efficient Jacobian Spectral Radius Regularization with rand

om loop sampling, enabling STARS to maximize effectiveness while ensuring rigoro
us stability. Experiments on arithmetic tasks show that STARS achieves reliable
test-time scaling, and on complex mathematical reasoning it substantially mitiga
tes performance degradation as recurrence depth increases while also improving p
eak performance.

HVR-Met: A Hypothesis-Verification-Replanning Agentic System for Extreme Weather
 Diagnosis
Shuo Tang, Jiadong Zhang, Gengxian Zhou, Qizhao Jin, Qinxuan Wang, Yi Hu, Ning H
u, Hongchang Ren, Lingli He, Shiming Xiang, Jingtao Ding, Jian Xu, Jiaolan Fu, C
heng-Lin Liu
While deep learning-based weather forecasting paradigms have made significant st
rides, addressing extreme weather diagnostics remains a formidable challenge. Th
is gap exists primarily because the diagnostic process demands sophisticated mul
ti-step logical reasoning, dynamic tool invocation, and expert-level prior judgm
ent. Although agents possess inherent advantages in task decomposition and auton
omous execution, current architectures are still hampered by critical bottleneck
s: inadequate expert knowledge integration, a lack of professional-grade iterati
ve reasoning loops, and the absence of fine-grained validation and evaluation sy
stems for complex workflows under extreme conditions. To this end, we propose HV
R-Met, a multi-agent meteorological diagnostic system characterized by the deep
integration of expert knowledge. Its central innovation is the ``Hypothesis-Veri
fication-Replanning'' closed-loop mechanism, which facilitates sophisticated ite
rative reasoning for anomalous meteorological signals during extreme weather eve
nts. To bridge gaps within existing evaluation frameworks, we further introduce
a novel benchmark focused on atomic-level sub-tasks. Experimental evidence demon
strates that the system excels in complex diagnostic scenarios.

Diversity Over Frequency: Rethinking Tool Use in Visual Chain-of-Thought Agents
Dong-Hee Kim, Reuben Tan, Donghyun Kim
Visual agents employ external visual tools within visual chains of thought to in
corporate fine-grained evidence. While prior work has mainly studied these tools
 in visual search tasks, their role in more complex visual reasoning remains und
erexplored. In this paper, we move beyond simple visual search tasks to investig
ate more challenging tasks, including 3D spatial reasoning and medical visual qu
estion answering, where agents must integrate tool-acquired local evidence with
the global context.

    We identify a \emph{tool-use collapse phenomenon}: models progressively stop
 using tools while still achieving higher task accuracy.

    Moreover, we observe a clear asymmetry: (i) completely eliminating tool use
degrades performance, whereas (ii) incentivizing tool use yields only marginal g
ains despite substantially increasing usage.

    We find that vanilla training and tool-use encouragement both reduce rollout
 diversity, explaining why higher tool use does not yield stronger reasoning per
formance.

    Motivated by these findings, we add an entropy regularization term to encour
age diverse rollout exploration, achieving the best performance despite graduall
y declining tool usage.

    Overall, our findings suggest a training-time view of tools as scaffolding,
where broader exploration over language generation and visual tool invocation im
proves reasoning despite tool-use collapse.

Path-conditioned training: a principled way to rescale ReLU neural networks
Arthur Lebeurrier, Titouan Vayer, Rémi Gribonval
Despite recent algorithmic advances, we still lack principled ways to leverage t
he well-documented rescaling symmetries in ReLU neural network parameters. While
 two properly rescaled weights implement the same function, the training dynamic
s can be dramatically different. To offer a fresh perspective on exploiting this
 phenomenon, we build on the recent path-lifting framework, which provides a com

pact factorization of ReLU networks. We introduce a geometrically motivated crit
erion to rescale neural network parameters which minimization leads to a conditi
oning strategy that aligns a kernel in the path-lifting space with a chosen refe
rence. We derive an efficient algorithm to perform this alignment. In the contex
t of random network initialization, we analyze how the architecture and the init
ialization scale jointly impact the output of the proposed method. Numerical exp
eriments illustrate its potential to speed up training.
****
Towards Fully Parameter-Free Stochastic Optimization: Grid Search with Self-Boun
ding Analysis
Yuheng Zhao, Yu-Hu Yan, Amit Attia, Tomer Koren, Lijun Zhang, Peng Zhao
Parameter-free stochastic optimization aims to design algorithms that are agnost
ic to the underlying problem parameters while still achieving convergence rates
competitive with optimally tuned methods. While some parameter-free methods do n
ot require the specific values of the problem parameters, they still rely on pri
or knowledge, such as the lower or upper bounds of them. We refer to such method
s as "partially parameter-free". In this work, we target achieving "*fully* para
meter-free" methods, i.e., the algorithmic inputs do not need to satisfy any *un
verifiable* condition related to the true problem parameters. We propose a power
ful and general *grid search* framework, named GRASP, with a novel *self-boundin
g* analysis technique that effectively determines the search ranges of parameter
s, in contrast to previous work. Our method demonstrates generality in: (i) the
non-convex case, where we propose a fully parameter-free method that achieves ne
ar-optimal convergence rate, up to logarithmic factors; (ii) the convex case, wh
ere our parameter-free methods are competitive with strong performance in terms
of acceleration and universality. Finally, we contribute a sharper guarantee for
 the model ensemble, a final step of the grid search framework, under interpolat
ed variance characterization.
****
SetPO: Set-Level Policy Optimization for Diversity-Preserving LLM Reasoning
Chenyi Li, Yuan Zhang, Bo Wang, Guoqing Ma, Wei Tang, Haoyang Huang, Nan Duan
Reinforcement learning with verifiable rewards has shown notable effectiveness i
n enhancing large language models (LLMs) reasoning performance, especially in ma
thematics tasks. However, such improvements often come with reduced outcome dive
rsity, where the model concentrates probability mass on a narrow set of solution
s. Motivated by diminishing-returns principles, we introduce a set level diversi
ty objective defined over sampled trajectories using kernelized similarity. Our
approach derives a leave-one-out marginal contribution for each sampled trajecto
ry and integrates this objective as a plug-in advantage shaping term for policy
optimization. We further investigate the contribution of a single trajectory to
language model diversity within a distribution perturbation framework. This anal
ysis theoretically confirms a monotonicity property, proving that rarer trajecto
ries yield consistently higher marginal contributions to the global diversity. E
xtensive experiments across a range of model scales demonstrate the effectivenes
s of our proposed algorithm, consistently outperforming strong baselines in both
 Pass@1 and Pass@K across various benchmarks.

Blocking the Leakage: Manifold-Aware Gradient Projection for Long-Horizon Test-T
ime Adaptation
Haoyu Xiong, Chengchao Wang, ZhongQiang Wang, He Huang, Qiuxia Yang, Zhengpeng Z
hao, Yuanyuan Pu
Test-Time Adaptation (TTA) empowers pre-trained models to adapt online to distri
bution shifts during inference, but such online updates often become unstable in
 long-horizon deployments. Prevailing approaches attribute this failure to error
 accumulation from noisy pseudo-labels, relying on heuristics to gate samples us
ed for updates. We argue that this statistical view is insufficient: the problem
 lies not only in sample quality but also in the directionality of gradients. In
 this work, we identify a geometric failure mode termed manifold erosion. Throug
h spectral analysis, we find that reliable gradients concentrate in a stable low
-rank subspace, while gradients from confident mispredictions are high-rank yet

exhibit a persistent directional leakage into this protected subspace. This leak age can accumulate coherently and gradually erode core representations, eventual ly leading to collapse. To address this, we propose Manifold-Aware Gradient Proj ection (MGP), a geometric intervention that tracks the dominant subspace online and projects gradients onto its orthogonal complement. By blocking the leakage p ath, MGP decouples stability from plasticity. Extensive experiments on diverse T TA benchmarks demonstrate its long-horizon stability, whereas prior methods ofte n fail.

Interpretability Transfer from Language to Vision via Sparse Autoencoders
Alexey Kravets, Da Li, Chuan Li, Da Chen, Vinay P. Namboodiri
Recent advances in language model interpretability using sparse autoencoders (SA Es) have yet to effectively translate to the visual domain, mainly due to the di fficulty and ambiguity of labeling visual concepts. In this paper, we introduce Visual Interpretability via SAE Transfer Alignment (VISTA), a framework that tra nsfers interpretability from language to vision in a LLaVA-style vision-language model by constraining a visual projector to map visual tokens into an LLM's pre -existing, labeled textual SAE space. This approach enables visual interpretabil ity without training dedicated vision SAEs. By regularizing the projector using the LLM's SAE reconstruction loss, VISTA achieves a threefold increase in the ma tching rate, which measures how accurately the most activating textual concepts in the SAE space correspond to semantic elements in the image. Using this framew ork, we further analyze spatial localization properties of different vision enco ders and show that DINOv2 features have stronger localization abilities than oth er encoders. Leveraging this precision, we validate VISTA's cross-modal alignmen t through fine-grained, localized concept interventions, where specific objects are removed or replaced in the model's perception while preserving the surroundi ng scene. This results in improvements of 35\% in object removal and 47\% in obj ect replacement tasks over vision-only baselines, providing causal evidence that visual tokens inhabit the text SAE manifold. These contributions are validated across multiple LLM architectures.
****

JADAI: Jointly Amortizing Adaptive Design and Bayesian Inference
Niels Leif Bracher, Lars Kühmichel, Desi R. Ivanova, Xavier Intes, Paul-Christia n Bürkner, Stefan T. Radev
We consider problems of parameter estimation where design variables can be activ ely optimized to maximize information gain. To this end, we introduce JADAI, a f ramework that jointly amortizes Bayesian adaptive design and inference by traini ng a policy, a history network, and an inference network end-to-end. The network s minimize a generic loss that aggregates incremental reductions in posterior er ror along experimental sequences without density evaluations.
Inference networks are instantiated with diffusion models that can approximate h igh-dimensional and multimodal posteriors at every experimental step.
JADAI achieves superior or competitive performance across adaptive design benchm arks.
****

PhaseCoder: Microphone Geometry-Agnostic Spatial Audio Understanding for Multimo dal LLMs
Artem Dementyev, Wazeer Zulfikar, Sinan Hersek, Pascal Getreuer, Anurag Kumar, V

ivek Kumar
Current multimodal large language models (LLMs) process audio as a mono stream, ignoring the rich spatial information essential for embodied AI. Conversely, existing spatial audio models are constrained to fixed microphone geometries, preventing their deployment across diverse devices. We present **PhaseCoder**, a transformer-only spatial audio encoder that is inherently agnostic to microphone geometry. By taking raw multichannel audio and microphone coordinates as inputs, PhaseCoder performs accurate localization and produces robust spatial embeddings. We demonstrate that the Gemma 3n LLM can be fine-tuned to process and reason over the "Spatial Audio Tokens" produced by our encoder. PhaseCoder achieves state-of-the-art results on microphone-invariant localization benchmarks and, for the first time, enables an LLM to perform complex spatial reasoning and targeted transcription tasks from an arbitrary microphone array.

Gradient-Based Causal Tree Ensembles: A Backbone Architecture for Heterogeneous Treatment Effects
Yusuke Kano, Jeremy Paul Voisey, Mihaela van der Schaar
Estimating Heterogeneous Treatment Effects (HTE) from observational data is essential in fields such as healthcare and policy-making, where randomized experiments are often impractical.
While representation learning-based methods have shown promise, recent studies suggest that tree-based approaches may offer superior performance on tabular data, particularly in the presence of uninformative features.
We introduce **GRA**dient-based **C**ausal tree **E**nsembles (GRACE), a novel tree-based architecture for HTE estimation that incorporates multi-way, oblique, and soft splits, enabling end-to-end training via backpropagation.
GRACE can be seamlessly integrated into existing models as a replacement for fully-connected neural network layers.
Across diverse benchmarks involving binary and non-binary treatment settings, GRACE consistently surpasses neural network and tree-based baselines, often by a substantial margin.
We further analyze GRACE as an extension of fully-connected neural network layers and conduct ablation studies to isolate and quantify the contribution of each architectural component to the improvement in performance.
These results position GRACE as a promising new foundation for flexible, robust, and accurate HTE estimation.
GRACE code is available at https://github.com/ysk-kano/GRACE

What Makes Value Learning Efficient in Residual Reinforcement Learning?
Guozheng Ma, Lu Li, Haoyu Wang, Zixuan Liu, Pierre-Luc Bacon, Dacheng Tao
Residual reinforcement learning (RL) enables stable online refinement of expressive pretrained policies by freezing the base and learning only bounded corrections. However, value learning in residual RL poses unique challenges that remain poorly understood. In this work, we identify two key bottlenecks: cold start pathology, where the critic lacks knowledge of the value landscape around the base policy, and structural scale mismatch, where the residual contribution is dwarfed by the base action. Through systematic investigation, we uncover the mechanisms underlying these bottlenecks, revealing that simple yet principled solutions suffice: base-policy transitions serve as an essential value anchor for implicit warmup, and critic normalization effectively restores representation sensitivity for discerning value differences. Based on these insights, we propose DAWN (Data-Anchored Warmup and Normalization), a minimal approach targeting efficient value learning in residual RL. By addressing these bottlenecks, DAWN demonstrates substantial efficiency gains across diverse benchmarks, policy architectures, and observation modalities.

Toward Structural Multimodal Representations: Specialization, Selection, and Sparsification via Mixture-of-Experts
Hahyeon Choi, Nojun Kwak
We propose S3 (Specialization, Selection, Sparsification), a framework that reth

inks multimodal learning through a structural perspective. Instead of encoding a ll signals into a fixed embedding, S3 decomposes multimodal inputs into semantic experts and selectively routes them for each task. Specialization forms concept -level experts in a shared latent space, Selection adapts routing for task-speci fic needs, and Sparsification prunes low-utility paths to yield compact, informa tion-minimal representations. Across four MultiBench benchmarks, S3 improves acc uracy and exhibits consistent sparsity-performance dynamics, exhibiting a revers e U-shaped trend, with performance peaking at intermediate sparsity. These resul ts suggest that structuring multimodal representations as selectable semantic co mponents provides a practical and principled alternative to contrastive learning or InfoMax-driven approaches.

Ensembling Sparse Autoencoders

Soham Gadgil, Chris Lin, Su-In Lee

Sparse autoencoders (SAEs) are used to decompose neural network activations into human-interpretable features. Typically, features learned by a single SAE are u sed for downstream applications. However, it has recently been shown that a sing le SAE captures only a limited subset of features that can be extracted from the activation space. Motivated by this limitation, we introduce and formalize SAE ensembles. Furthermore, we propose to ensemble multiple SAEs through *naive bagg ing* and *boosting*. In naive bagging, SAEs trained with different weight initia lizations are ensembled, whereas in boosting SAEs sequentially trained to minimi ze the residual error are ensembled. Theoretically, naive bagging and boosting a re justified as approaches to reduce reconstruction error. Empirically, we evalu ate our ensemble approaches with three settings of language models and SAE archi tectures. Our empirical results demonstrate that, compared to an expanded SAE th at matches the number of features in the ensemble, ensembling SAEs improves the reconstruction of language model activations along with SAE stability. Additiona lly, on downstream tasks such as concept detection and spurious correlation remo val, SAE ensembles achieve better performance, showing improved practical utilit y.

A Graphop Analysis of Graph Neural Networks on Sparse Graphs: Generalization and Universal Approximation

Ofek Amran, Tom Gilat, Ron Levie

Generalization and approximation capabilities of message passing graph neural ne tworks (MPNNs) are often studied by defining a compact metric on a space of inpu t graphs under which MPNNs are equicontinuous. Such analyses are of two varietie s: 1) when the metric space includes graphs of unbounded sizes, the theory is on ly appropriate for dense graphs, and, 2) when studying sparse graphs, the metric space only includes graphs of uniformly bounded size. In this work, we present a unified approach, defining a compact metric on the space of graphs of all size s, both sparse and dense, under which MPNNs are equicontinuous. This leads to mo re powerful universal approximation theorems and generalization bounds than prev ious works. The theory is based on, and extends, a recent approach to graph limi t theory called graphop analysis.

T-measure: A Topology-Consistent Metric for Binary Segmentation

pengfei zhang, Jian Ji

Evaluation metrics establish a standard assessment framework for models, playing a pivotal role in model optimization and advancement. However, widely adopted p ixel-wise metrics (e.g., IoU, Dice) rely heavily on pixel-level statistics, ofte n failing to capture the structural integrity of predictions. While the S-measur e (S-m) incorporates structural perception to some extent, it struggles to diffe rentiate critical structural violations and remains insensitive to background fa lse positives and small objects. To address these limitations, we propose the To pology-aware measure (T-m), a novel metric designed to explicitly quantify topol ogical consistency. T-m employs the Fuzzy Jaccard Index as a foundational score, integrates a Topological Integrity term (I-topo) to penalize critical structura l fragmentation, and utilizes a Boundary Alignment term (A-bdy) to evaluate boun

dary alignment. These three components synergize to achieve robust evaluation of prediction maps at the topological level. We establish a rigorous Meta-Measure validation framework and benchmark our method against nine mainstream metrics across diverse complex scenarios. Extensive experiments demonstrate that T-m performs exceptionally in downstream tasks and maintains high consistency with human visual perception.

A Unified Framework for Deep Hypergraph Clustering Beyond Homophily

Bowen Zhao, Qianqian Wang

Deep hypergraph clustering exhibits compelling capacity for node representation learning via modeling high-order relationships. However, most existing methods adopt fixed propagation mechanisms and implicitly assume homophily, which presumes that adjacent nodes possess similar characteristics. This assumption might deviate from real-world situations, particularly under heterophilic conditions, thereby degrading clustering performance. To address this limitation, we propose a \textbf{Uni}fied Framework for \textbf{D}eep \textbf{H}ypergraph \textbf{C}lustering (Uni-DHC). Specifically, we design a learnable high-order hypergraph propagation strategy that fuses multi-order information and adaptively learns their importance derived from raw data. To stabilize unsupervised training and eliminate structural redundancy caused by high-order aggregation, we additionally enforce node-level consistency and hyperedge-level decorrelation constraints. From the spectral perspective, we demonstrate that conventional HGNN-style propagation corresponds to a fixed low-pass filter, whereas our designed method induces a learnable polynomial spectral filter. Extensive experiments on homophilic and heterophilic datasets illustrate that Uni-DHC consistently outperforms state-of-the-art methods, achieving prominent performance improvement in heterophilic settings.

DOCKSMITH: Scaling Reliable Coding Environments via an Agentic Docker Builder

Jiaran Zhang, Lu Ma, Yanhao Li, Fanqi Wan, DI QI, Xin Wu, Zhewei Huang, Liangyu Chen, YINGWEI MA, Qi Han, Xiangyu Zhang

Reliable Docker-based environment construction is a dominant bottleneck for scaling execution-grounded training and evaluation of software engineering agents. We introduce DockSmith, a specialized agentic Docker builder designed to address this challenge. DockSmith treats environment construction not merely as a preprocessing step, but as a core agentic capability that exercises long-horizon tool use, dependency reasoning, and failure recovery, yielding supervision that transfers beyond Docker building itself. DockSmith is trained on large-scale, execution-grounded Docker-building trajectories produced by a SWE-Factory--style pipeline augmented with a loop-detection controller and a cross-task success memory. Training a 30B-A3B model on these trajectories achieves open-source state-of-the-art performance on Multi-Docker-Eval, with 39.72\% Fail-to-Pass and 58.28\% Commit Rate. Moreover, DockSmith improves out-of-distribution performance on SWE-bench Verified, SWE-bench Multilingual, and Terminal-Bench 2.0, demonstrating the broader agentic benefits of environment construction. Our model and Docker-building trajectories are publicly available at https://huggingface.co/JiaranZhang/DockSmith.

SciVideoBench: Benchmarking Scientific Video Reasoning in Large Multimodal Models

Andong Deng, Taojiannan Yang, Shoubin Yu, Lincoln Spencer, Mohit Bansal, Chen Chen, Serena Yeung-Levy, Xiaohan Wang

Large Multimodal Models (LMMs) have achieved remarkable progress across various capabilities; however, complex video reasoning in the scientific domain remains a significant and challenging frontier. Current video benchmarks predominantly target general scenarios where perception/recognition is heavily relied on, while with relatively simple reasoning tasks, leading to saturation and thus failing to effectively evaluate advanced multimodal cognitive skills. To address this critical gap, we introduce SciVideoBench, a rigorous benchmark specifically designed to assess advanced video reasoning in scientific contexts. SciVideoBench consists of 1,000 carefully crafted multiple-choice questions derived from cutting-e

dge scientific experimental videos spanning over 25 specialized academic subjects and verified by a semi- automatic system. Each question demands sophisticated domain-specific knowledge, precise spatiotemporal perception, and intricate logical reasoning, effectively challenging models' higher-order cognitive abilities. Our evaluation highlights significant performance deficits in state-of-the-art proprietary and open-source LMMs, including Gemini 2.5 Pro and Qwen2.5-VL, indicating substantial room for advancement in video reasoning capabilities. Detailed analyses of critical factors such as reasoning complexity and visual grounding provide valuable insights and clear direction for future developments in LMMs, driving the evolution of truly capable multimodal AI co-scientists. We hope SciVideoBench could fit the interests of the community and help to push the boundary of cutting-edge AI for border science.

MedCoG: Maximizing LLM Inference Density in Medical Reasoning via Meta-Cognitive Regulation

Yu Zhao, Hao Guan, Yongcheng Jing, Ying Zhang, Dacheng Tao

Large Language Models (LLMs) have shown strong potential in complex medical reasoning yet face diminishing gains under inference scaling laws. While existing studies augment LLMs with various knowledge types, it remains unclear how effectively the additional costs translate into accuracy. In this paper, we explore how meta-cognition of LLMs, i.e., their self-assessment of their own cognitive states, can regulate the reasoning process. Specifically, we propose MedCoG, a Medical Meta-Cognition Agent with Knowledge Graph, where the meta-cognitive assessments of task complexity, familiarity, and knowledge density dynamically regulate utilization of procedural, episodic, and factual knowledge. The LLM-centric on-demand reasoning aims to mitigate the diminishing returns under scaling law by (1) reducing costs via avoiding indiscriminate scaling, (2) improving accuracy via filtering out distractive knowledge. To validate this, we empirically characterize the scaling curve and introduce inference density to quantify inference efficiency. Experiments demonstrate the effectiveness and efficiency of MedCoG on five hard sets of medical benchmarks, yielding 6.2x inference density. Furthermore, the Oracle study highlights the significant potential of meta-cognitive regulation.

Principled RL for Flow Matching Emerges from the Chunk-level Policy Optimization

Yifu Luo, Haoyuan Sun, Xinhao Hu, Penghui Du, Keyu Fan, Bo Li, SiNan Du, Xu Wan, Zhiyu Chen, Bo Xia, Yongzhe Chang, Kai Wu, Kun Gai, Tiantian Zhang, Xueqian Wang

Recent Progress in post-training flow matching for text-to-image (T2I) generation with Group Relative Policy Optimization (GRPO) has demonstrated strong potential. However, it is hindered by a critical limitation: inaccurate advantage attribution. In this work, we argue that aggregating consecutive timesteps into a coherent 'chunk' and shifting the policy optimization paradigm from GRPO's step level to the chunk level can effectively mitigate the negative impact of this issue. Building on this insight, we propose Group Chunking Policy Optimization (GCPO), the first chunk-level reinforcement learning approach for post-training flow matching. Extensive experiments demonstrate that GCPO achieves superior performance on both standard T2I benchmarks and preference alignment, with up to 43% additional gains over GRPO, highlighting the promise of chunk-level policy optimization.

Efficient Inference for Noisy LLM-as-a-Judge Evaluation

Yiqun T. Chen, Sizhu Lu, Sijia Li, Moran Guo, Shengyi Li

Large language models (LLMs) are increasingly used as automatic evaluators of generative AI outputs, a paradigm often referred to as "LLM-as-a-judge." In practice, LLM judges are imperfect predictions for the underlying truth and can exhibit systematic, non-random errors. Two main approaches have recently been proposed to address this issue: (i) *direct measurement-error correction* based on misclassification models such as Rogan--Gladen-style estimators, and (ii) *surrogate-outcome approaches* such as prediction-powered inference (PPI), which correct bi

as by calibrating prediction residuals on a small set of gold-standard human labels. In this paper, we systematically study the performance of these two approaches for estimating mean parameters (e.g., average benchmark scores or pairwise win rates). Leveraging tools from semiparametric efficiency theory, we unify the two classes of estimators by deriving explicit forms of *efficient influence function*-based efficient estimators and characterize conditions under which PPI-style estimators attain strictly smaller asymptotic variance than measurement-error corrections. We verify our theoretical results through simulations and demonstrate the methods on a real-data example using our open-source software package for performing the calibration.

****

Stability Analysis of Sharpness-Aware Minimization

Hoki Kim, Jinseong Park, Yujin Choi, Jaewook Lee

Sharpness-aware minimization (SAM) is a training method that seeks to find flat minima in deep learning, resulting in state-of-the-art performance across various domains. Instead of minimizing the loss of the current weights, SAM minimizes the worst-case loss in its neighborhood in the parameter space. In this paper, we investigate the convergence instability of SAM near a saddle point. Using the qualitative theory of dynamical systems, we explain how SAM becomes stuck in the saddle point and theoretically prove that the saddle point can become an attractor under SAM dynamics. Additionally, we show that this convergence instability can also occur in stochastic dynamical systems by establishing the diffusion of SAM. We prove that SAM diffusion is worse than that of vanilla gradient descent in terms of saddle point escape. Finally, we demonstrate that often overlooked training tricks, momentum and batch-size, might be important to mitigate the convergence instability and achieve high generalization performance. Our theoretical and empirical results are thoroughly verified through experiments on several well-known optimization problems and benchmark tasks.

ParamMem: Augmenting Language Agents with Parametric Reflective Memory

Tianjun Yao, Yongqiang Chen, Yujia Zheng, Pan Li, Zhiqiang Shen, Kun Zhang

Self-reflection enables language agents to iteratively refine solutions, yet often produces repetitive outputs that limit reasoning performance. Recent studies have attempted to address this limitation through various approaches, among which increasing reflective diversity has shown promise. Our empirical analysis reveals a strong positive correlation between reflective diversity and task success, further motivating the need for diverse reflection signals. We introduce `ParamMem`, a parametric memory module that encodes cross-sample reflection patterns into model parameters, enabling diverse reflection generation through temperature-controlled sampling. Building on this module, we propose ParamAgent, a reflection-based agent framework that integrates parametric memory with episodic and cross-sample memory. Extensive experiments on code generation, mathematical reasoning, and multi-hop question answering demonstrate consistent improvements over state-of-the-art baselines. Further analysis reveals that `ParamMem` is sample-efficient, enables weak-to-strong transfer across model scales, and supports self-improvement without reliance on stronger external model, highlighting the potential of `ParamMem` as an effective component for enhancing language agents.

Darwinian Memory: A Training-Free Self-Regulating Memory System for GUI Agent Evolution

Hongze Mi, Yibo Feng, WenJie Lu, Song Cao, Jinyuan Li, Yanming Li, Xuelin Zhang, Haotian Luo, Songyang Peng, He Cui, Tengfei Tian, Jun Fang, Hua Chai, Naiqiang Tan

Multimodal Large Language Model (MLLM) agents facilitate Graphical User Interface (GUI) automation but struggle with long-horizon, cross-application tasks due to limited context windows. While memory systems provide a viable solution, existing paradigms struggle to adapt to dynamic GUI environments, suffering from a granularity mismatch between high-level intent and low-level execution, and context pollution where the static accumulation of outdated experiences drives agents into hallucination.

To address these bottlenecks, we propose the Darwinian Memory System (DMS), a self-evolving architecture that constructs memory as a dynamic ecosystem governed by the law of "survival of the fittest." DMS decomposes complex trajectories into independent, reusable units for compositional flexibility, and implements Utility-driven Natural Selection to track survival value, actively pruning suboptimal paths and inhibiting high-risk plans. This evolutionary pressure compels the agent to derive superior strategies. Extensive experiments on real-world multi-app benchmarks validate that DMS boosts general-purpose MLLMs without training costs or architectural overhead, achieving average gains of 18.0% in success rate and 33.9% in execution stability, while reducing task latency, establishing it as an effective self-evolving memory system for GUI tasks. The implementation is available at https://anonymous.4open.science/r/DMS-C48C.

Set Diffusion: Interpolating Token Orderings between Autoregression and Diffusion for Fast and Flexible Decoding

Marianne Arriola, Volodymyr Kuleshov

Discrete diffusion models have steadily improved in quality relative to autoregressive (AR) models. However, these models are normally constrained to fixed-length generation and do not support key-value (KV) caching. Block diffusion partially bridges diffusion and AR by unmasking token blocks left-to-right, but it is still limited to generate fixed-size blocks sequentially. Here, we present a new class of language models, set diffusion, comprised of (i) a likelihood parameterization that factorizes over flexible-position, flexible-length token sets and (ii) a set-causal diffusion architecture that supports KV cache updates after every inference step. By factorizing over token sets instead of fixed-size blocks, tokens can be decoded in arbitrarily-ordered sets, including sliding-window sets, enabling faster inference and support for any-order decoding. Set diffusion achieves better speed-quality tradeoffs on mathematical reasoning, summarization, and unconditional generation compared to prior diffusion language models while offering stronger infilling performance than block diffusion. We provide the code, along with the model weights and blog post on the project page: https://m-arriola.com/setdlms/

ST-Veto: Spatio-Temporal Token Veto for Diffusion MLLMs via Taylor Prediction and Visual Grounding

Keuntae Kim, Beomseok Lee, Hyunwoo Kim, Yong Suk Choi

Vision Language Models (VLMs) achieve strong reasoning with Chain-of-Thought (CoT) prompting but incur high sequential-generation cost, error accumulation, and limited self-correction. Diffusion Multimodal Large Language Models (dMLLMs) unmask tokens in an order-agnostic process, improving efficiency and enabling iterative refinement, yet their reasoning and how to enhance it remain underexplored. We propose a training-free method, Spatio-Temporal Token Veto (ST-Veto), which leverages the ability to observe all token positions at each diffusion step. Rather than relying only on current-step confidence, ST-Veto vetoes temporally unstable tokens via second-order Taylor prediction of confidence dynamics and filters weakly grounded tokens using image-attention mass, swapping them with safer candidates. Across multiple dMLLMs and multimodal reasoning benchmarks, ST-Veto consistently outperforms standard decoding policies and prior VLM reasoning methods, improving accuracy by up to 9\% with no additional training or generation cost. Analyses show that ST-Veto steers generation toward higher-confidence, better-grounded paths.

****

Improving Diffusion Planners by Self-Supervised Action Gating with Energies

Yuan Lu, Dongqi Han, Yansen Wang, Dongsheng Li

Diffusion planners are a strong approach for offline reinforcement learning, but they can fail when value-guided selection favours trajectories that score well yet are locally inconsistent with the environment dynamics, resulting in brittle execution. We propose Self-supervised Action Gating with Energies (SAGE), an inference-time re-ranking method that penalises dynamically inconsistent plans using a latent consistency signal. SAGE trains a Joint-Embedding Predictive Archite

cture (JEPA) encoder on offline state sequences and an action-conditioned latent predictor for short horizon transitions. At test time, SAGE assigns each sampled candidate an energy given by its latent prediction error and combines this feasibility score with value estimates to select actions. SAGE can integrates into existing diffusion planning pipelines that can sample trajectories and select actions via value scoring; it requires no environment rollouts and no policy re-training. Across locomotion, navigation, and manipulation benchmarks, SAGE improves the performance and robustness of diffusion planners.

Sample from What You See: Visuomotor Policy Learning via Diffusion Bridge with Observation-Embedded Stochastic Differential Equation
Zhaoyang Liu, Mokai Pan, Zhongyi Wang, Kaizhen Zhu, Haotao Lu, Haipeng Zhang, Jingya Wang, Ye Shi
Imitation learning with diffusion models has advanced robotic control by capturing the multi-modal action distributions. However, existing methods typically treat observations only as high-level conditions to the denoising network, rather than integrating them into the stochastic dynamics of the diffusion process itself. As a result, the sampling is forced to begin from random noise, weakening the coupling between perception and control and often yielding suboptimal performance. We propose BridgePolicy, a generative visuomotor policy that directly integrates observations into the stochastic dynamics via a diffusion-bridge formulation. By constructing an observation-informed trajectory, BridgePolicy enables sampling to start from a rich and informative prior rather than random noise, substantially improving precision and reliability in control. A key difficulty is that diffusion bridge normally connects distributions of matched dimensionality, while robotic observations are heterogeneous and not naturally aligned with actions. To overcome this, we introduce a semantic aligner to unify the visual and state inputs and align the observations with action representations, making diffusion bridge applicable to heterogeneous robot data. Extensive experiments across 52 simulation tasks on three benchmarks and 5 real-world tasks demonstrate that BridgePolicy consistently outperforms state-of-the-art generative policies. Our code is available at https://github.com/jianghcsr/BridgePolicy.

Multi-Agent Reinforcement Learning with Submodular Reward
Wenjing Chen, Chengyuan Qian, Shuo Xing, Yi Zhou, Victoria G. Crawford
In this paper, we study cooperative multi-agent reinforcement learning (MARL) where
the joint reward exhibits submodularity, which is a natural property capturing
diminishing marginal returns when adding agents to a team. Unlike standard
MARL with additive rewards, submodular rewards model realistic scenarios
where agent contributions overlap (e.g., multi-drone surveillance,
collaborative exploration). We provide the first formal framework for this
setting and develop algorithms with provable guarantees on sample efficiency and regret bound. For known dynamics,
our greedy policy optimization achieves a $1/2$-approximation with polynomial
complexity in the number of agents K, overcoming the exponential curse of
dimensionality inherent in joint policy optimization. For unknown dynamics,
we propose a UCB-based learning algorithm achieving a $1/2$-regret of $O(H^2KS\sqrt{AT})$ over
T episodes.
****
video-SALMONN S: Memory-Enhanced Streaming Audio-Visual LLM
Guangzhi Sun, Yixuan Li, Xiaodong Wu, Yudong Yang, Wei Li, Zejun MA, Chao Zhang
Long-duration streaming video understanding is fundamental for future AI agents, yet remains limited by ineffective long-term memory. We introduce video-SALMONN S, a memory-enhanced streaming audio-visual large language model that processes over 3-hour videos at 1 FPS and 360p resolution, outperforming strong non-streaming models under the same memory budget.
In addition to token merging or downsampling, video-SALMONN S is the first to employ test-time training (TTT) as a streaming memory mechanism for video understa

nding. TTT continuously transforms short-term multimodal representations into lo
ng-term memory embedded in model parameters. To improve long-range dependency mo
deling and memory capacity, we propose (i) a TTT$_\text{MEM}$ layer with an addi
tional long-span prediction objective, (ii) a two-stage training scheme, and (ii
i) a modality-aware memory reader.
We further introduce the episodic learning from video memory (ELViM) benchmark,
simulating agent-like scenarios where models must learn from videos observed hou
rs earlier. video-SALMONN S consistently outperforms both streaming and non-stre
aming baselines by 3-7\% on long video benchmarks. Notably, video-SALMONN S achi
eves a 15% absolute accuracy improvement over strong non-streaming models on
ELViM, demonstrating strong learning abilities from video memory.
****

MaxSAT-Based Compression for Tsetlin Machines
Stefan Szeider
We consider the computational problem of compacting Tsetlin Machine classifiers
by reducing the number of propositional clauses while preserving predictive accu
racy. TMs trained with limited clause capacity often perform poorly because stoc
hastic optimization cannot reliably find the few precise clauses needed in a vas
t configuration space. High-quality compact subsets also exist in the case of la
rger Tsetlin Machines. The difficulty here lies in extracting them. Local prunin
g heuristics can fail badly on TMs because clauses interact through Boolean logi
c: a clause may appear unimportant in isolation yet becomes critical when others
 are removed. We formalize compression as the Minimum Discriminating Clause Set
(MDCS) problem, which asks to find a smallest subset of clauses that preserves t
he trained model's discrimination of training samples. We show that MDCS is NP-h
ard. We solve MDCS using weighted partial Maximum Satisfiability (MaxSAT). A par
tition-and-merge strategy allows us to scale to 100,000 samples. Across 13 datas
ets, the compressed model preserves the 200-clause teacher's accuracy within a f
ew percentage points while using a median of only 16 clauses, and outperforms a
matched-capacity TM trained from scratch on every dataset where direct training
has room to improve, by up to 45 percentage points.

Discrete Diffusion with Physical Mass Constraints for \emph{De Novo} Peptide Seq
uencing
An Zeyu, Wanyu Lin
$\textit{De novo}$ peptide sequencing is a pivotal technique that directly recon
structs amino acid sequences from tandem mass spectrometry (MS/MS) data; it enab
les the identification of novel proteins and variants absent from reference data
bases. Previous methods are typically based on autoregressive (AR) decoding or o
ne-shot generation. The AR-based methods conflict with the bidirectional and glo
bally constrained nature of MS/MS evidence and inevitably accumulate errors, whi
le one-shot generation does not explicitly enforce physical constraints, failing
 to produce chemically valid and reliable peptides in a single pass. Accurate se
quencing necessitates reasoning over the entire peptide simultaneously, enabling
 iterative self-correction under global constraints. To this end, we introduce $
\textbf{PhysNovo}$, a novel paradigm that harnesses discrete diffusion to enable
 simultaneous global reasoning and iterative refinement. Specifically, PhysNovo
reformulates sequencing as a $\textbf{phys}$ically mass-constrained reasoning pr
ocess by embedding a knapsack-based feasibility kernel to enforce exact precurso
r mass consistency. By conditioning the diffusion process on global spectral con
text, PhysNovo supports abductive reasoning where bidirectional evidence is expl
oited to iteratively resolve local inconsistencies and ensure physically valid p
redictions. PhysNovo achieves state-of-the-art performance, exceeding baselines
by over 2% in precision, with larger gains on out-of-distribution data. The sour
ce code is publicly available at https://github.com/WanyuGroup/ICML2026_PhysNovo
.

Biases in the Blind Spot: Detecting What LLMs Fail to Mention
Iván Arcuschin, David Chanin, Adrià Garriga-Alonso, Oana-Maria Camburu
Large Language Models (LLMs) often provide chain-of-thought (CoT) reasoning trac

es that appear plausible, but may hide internal biases. We call these *unverbalized biases*. Monitoring models via their stated reasoning is therefore unreliable, and existing bias evaluations typically require predefined categories and hand-crafted datasets.
In this work, we introduce a fully automated, black-box pipeline for detecting task-specific unverbalized biases. Given a task dataset, the pipeline uses LLM autoraters to generate candidate bias concepts. It then tests each concept on progressively larger input samples by generating positive and negative variations, and applies statistical techniques for multiple testing and early stopping. A concept is flagged as an unverbalized bias if it yields statistically significant performance differences while not being cited as justification in the model's CoTs.
We evaluate our pipeline across seven LLMs on three decision tasks (hiring, loan approval, and university admissions). Our technique automatically discovers previously unknown biases in these models (e.g., Spanish fluency, English proficiency, writing formality).
In the same run, the pipeline also validates biases that were manually identified by prior work (gender, race, religion, ethnicity).
More broadly, our proposed approach provides a practical, scalable path to automatic, more efficient, and broader task-specific unverbalized bias discovery.
****

Rethinking Code Complexity Through the Lens of Large Language Models
Chen Xie, Xiaodong Gu, Yuling Shi, Beijun Shen
Code complexity metrics such as cyclomatic complexity have long been used to assess software quality and maintainability. With the rapid advancement of large language models (LLMs) on coding tasks, an important yet underexplored question arises: do traditional complexity metrics meaningfully characterize the coding difficulty that LLMs perceive?
In this work, we empirically demonstrate that classical complexity metrics exhibit no consistent correlation with LLM performance, revealing a fundamental mismatch with model-perceived difficulty.
To address this gap, we propose LM-CC, a novel code complexity metric tailored for LLMs, grounded in the hypothesis that model-perceived code difficulty is fundamentally driven by semantic nonlinearity.
LM-CC quantifies complexity through an entropy-guided semantic compositional hierarchy, capturing the cumulative uncertainty encountered by LLMs during code understanding.
Our experimental results demonstrate that LM-CC exhibits strong and consistent partial correlations with LLM performance, while semantics-preserving reductions in LM-CC consistently lead to improved downstream task performance.
The source code is available at: https://github.com/xchen121/lm-cc.

Simultaneous Multi-objective Alignment Across Verifiable and Non-verifiable Rewards
Yiran Jenny Shen, Yu Xia, Jonathan Daniel Chang, Prithviraj Ammanabrolu
Aligning large language models to human preferences is inherently multidimensional, yet most pipelines collapse heterogeneous signals into a single objective.
We seek to answer what it would take to simultaneously align a model across various domains spanning those with: verifiable rewards, non-verifiable subjective preferences, and complex interactive scenarios. Such multi-objective alignment setups are often plagued by individual objectives being at odds with each other, resulting in inefficient training and limited user control during inference. To address these issues, we propose **M**ulti-**A**ction-**H**ead **AL**ignment with PRM-guided Dec**O**ding (**MAHALO**), a unified framework that standardizes PRM training across verifiable and non-verifiable settings for step-level supervision, performs vectorized multi-objective alignment with Multi-Action-Head DPO, and enables controllable inference through objective-specific weighting and PRM-guided decoding. Experiments across math reasoning, human values alignment, and multi-turn tutoring show that MAHALO jointly improves multiple objectives simultaneously with limited interference, while remaining generalizable and adaptable ac

ross domains and offering flexible user control at inference time. Our code is a
vailable at: https://github.com/pearls-lab/multiobj-align.

Diffusing to Coordinate: Efficient Online Multi-Agent Diffusion Policies
Zhuoran Li, Hai Zhong, Xun Wang, Qingxin Xia, Lihua Zhang, Longbo Huang
Online Multi-Agent Reinforcement Learning (MARL) is a prominent framework for ef
ficient agent coordination. Crucially, enhancing policy expressiveness is pivota
l for achieving superior performance. Diffusion-based generative models are well
-positioned to meet this demand, having demonstrated remarkable expressiveness a
nd multimodal representation in image generation and offline settings. Yet, thei
r potential in online MARL remains largely under-explored. A major obstacle is t
hat the intractable likelihoods of diffusion models impede entropy-based explora
tion and coordination. To tackle this challenge, we propose among the first Onli
ne off-policy MARL framework using Diffusion policies (**OMAD**) to orchestrate
coordination. Our key innovation is a relaxed policy objective that maximizes sc
aled joint entropy, facilitating effective exploration without relying on tracta
ble likelihood. Complementing this, within the centralized training with decentr
alized execution (CTDE) paradigm, we employ a joint distributional value functio
n to optimize decentralized diffusion policies. It leverages tractable entropy-a
ugmented targets to guide the simultaneous updates of diffusion policies, thereb
y ensuring stable coordination. Extensive evaluations on MPE and MAMuJoCo establ
ish our method as the new state-of-the-art across 10 diverse tasks, demonstrat
ing a remarkable $2.5\times$ to $5\times$ improvement in sample efficiency.

Aggregate Models, Not Explanations: Improving Feature Importance Estimation
Joseph Paillard, Angel David REYERO LOBO, Denis-Alexander Engemann, Bertrand Thi
rion
Feature-importance methods show promise for transforming machine learning (ML) m
odels from predictive engines into tools for scientific discovery. However, expr
essive models can be unstable due to data sampling and algorithmic stochasticity
, leading to inaccurate variable importance estimates, undermining their utility
 in critical biomedical applications. While ensembling offers a remedy, the choi
ce between explaining a single ensemble model or aggregating individual model ex
planations is non-trivial due to the non-linearity of importance measures, and r
emains largely understudied. Our theoretical analysis, developed under assumptio
ns accommodating complex state-of-the-art ML models, reveals that this choice is
 governed by a trade-off involving the model's excess risk. In contrast to prior
 literature, we show that ensembling at the model level provides more accurate v
ariable-importance estimates, particularly for expressive models, by reducing th
is leading error term. We validate these findings on classical benchmarks and a
large-scale proteomic study from the UK Biobank.
****

Tvcache: A Tool-Value Cache for Post-Training LLM Agents
Abhishek Vijaya Kumar, Bhaskar Kataria, Byungsoo Oh, Emaad Manzoor, Rachee Singh
In RL post-training of LLM agents, calls to external tools take several seconds
or even minutes, leaving allocated GPUs idle and inflating post-training time an
d cost. While many tool invocations repeat across parallel rollouts and could in
 principle be cached, naively caching their outputs for reuse is incorrect since
 tool outputs depend on the environment state induced by prior agent interaction
s. We present TVCACHE, a stateful tool-value cache for LLM agent post-training.
TVCACHE maintains a tree of observed tool-call sequences and performs longest-pr
efix matching for cache lookups: a hit occurs only when the agent’s full tool hi
story matches a previously executed sequence, guaranteeing identical environment
 state. On three diverse workloads—terminal-based tasks, SQL generation, and vid
eo understanding—TVCACHE achieves cache hit rates of up to 70% and reduces media
n tool call execution time by up to 6.9×, with no degradation in post-training r
eward accumulation.
****

3D Scene Assertion Verification
Jun Lin, Jiayu Ding, Xiangtian Si, Xitong Cao, Lixin Hong, Zhang Chen, Chenxi Lv

, Wenqian Wang
Existing 3D Visual Question Answering (3D-VQA) methods rely on generative outputs that can be ambiguous in decision-making settings. We introduce 3D Scene Assertion Verification, a task that verifies natural language assertions in 3D scenes with strict binary judgments. We present 3DSAV, a large-scale diagnostic benchmark with 22.5k samples across six semantic types. To address this task, we propose DualLPSS, which uses dual-stage subspace routing for type-aware cross-modal fusion and scene-guided assertion focusing. Experiments show that DualLPSS achieves state-of-the-art performance on 3DSAV and handles complex logical assertions better than existing 3D-VQA baselines.

The Differences Between Direct Alignment Algorithms are a Blur
Alexey Gorbatovski, Boris Shaposhnikov, Viacheslav Sinii, Alexey Malakhov, Daniil Gavrilov
Direct Alignment Algorithms (DAAs) simplify LLM alignment by directly optimizing policies, bypassing reward modeling and RL. While DAAs differ in their use of SFT (one-stage vs. two-stage) and the scalar score they optimize (likelihood vs. odds ratios), the key performance drivers remain underexplored. We present a systematic comparison and analyze a previously overlooked axis - the ranking objective (pairwise vs. pointwise). To isolate this factor, we propose a unified training framework across DAAs by (i) converting one-stage methods (ORPO, ASFT) into a two-stage pipeline with an explicit SFT phase and (ii) introducing a β parameter that places all methods in the same hyperparameter space and improves the quality of odds-ratio DAAs (ORPO, ASFT). Under this setup, the ranking objective emerges as the primary determinant of alignment quality, whereas the particular scalar score (policy–reference ratio vs. odds ratio) is secondary. We corroborate this on instruction-following tasks and further confirm it on math-reasoning benchmarks across model scales. Evidence suggests that this stems from how these objectives interact with prompt-specific biases, supported both by strictly controlled experiments and by observations on real data. Our findings underscore the need for nuanced evaluations in DAA research to avoid oversimplified claims of superiority.

LAPRAS : Learning-Augmented PRivate Answering for linear query Streams.
Pranay Mundra, Adam Sealfon, Ziteng Sun, Quanquan C. Liu
Modern database workloads are highly predictable: query streams are dominated by recurring jobs and templates, even when their arrival order is not known in advance. This motivates a learning-augmented view of online differentially private (DP) analytics: can algorithms utilize predictions about *which* queries will occur to improve utility under a single global privacy budget, while remaining robust when predictions are wrong? We study online DP query answering, where a curator must answer a stream Q of S linear queries arriving in uniformly random order under privacy budget (ϵ,δ). We present *LAPRAS*, which assumes access to an oracle that outputs a prediction set of queries likely to appear in the stream and uses it to guide privacy spending. LAPRAS answers predicted queries using the offline-optimal Matrix Mechanism and answers the remaining queries online from a residual budget. To pace spending across an unknown number of unpredicted queries, we introduce *Smooth Allocation*, which forms an unbiased stopping-time estimate $\widehat{B}$ from the first $T=\Theta(\log^2 S)$ unpredicted queries and continuously recalibrates per-query expenditure. Empirically, over two real datasets, we validate the intended consistency--robustness trade-off: LAPRAS achieves near-offline utility under high overlap and degrades gracefully to baseline-level performance when overlap is low.

Spectral Evolution Search: Efficient Inference-Time Scaling for Reward-Aligned Image Generation
Jinyan Ye, Zhongjie Duan, Zhiwen Li, Cen Chen, Daoyuan Chen, Yaliang Li, Yingda Chen
Inference-time scaling offers a flexible way to align visual generative models with downstream objectives without updating model parameters. In modern image gen

eration models, a natural way to do this is to optimize the random noise from wh
ich generation starts. However, searching in this high-dimensional noise space i
s highly inefficient, because many directions have little effect on the final im
age. We trace this inefficiency to a spectral bias in generative dynamics: model
 sensitivity to initial perturbations decays rapidly as frequency increases. Bas
ed on this insight, we propose Spectral Evolution Search (SES), a plug-and-play
framework for initial noise optimization that performs gradient-free evolutionar
y search in a low-frequency subspace. Theoretically, we derive the Spectral Scal
ing Prediction from perturbation propagation dynamics, which explains the freque
ncy-dependent impact of perturbations. Extensive experiments across diverse sett
ings show that SES substantially improves the trade-off between generation quali
ty and computational cost, consistently outperforming strong baselines under the
 same compute budget.

MLLM-4D: Towards Visual-based Spatial-Temporal Intelligence

Xingyilang Yin, Chengzhengxu Li, Jiahao Chang, Chi-Man Pun, Xiaodong Cun

Humans are born with vision-based 4D spatial-temporal intelligence, which enable
s us to perceive and reason about the evolution of 3D space over time from purel
y visual inputs. Despite its importance, this capability remains a significant b
ottleneck for current multimodal large language models (MLLMs). To tackle this c
hallenge, we introduce MLLM-4D, a comprehensive framework designed to bridge the
 gaps in training data curation and model post-training for spatiotemporal under
standing and reasoning. On the data front, we develop a cost-efficient data cura
tion pipeline that repurposes existing stereo video datasets into high-quality 4
D spatiotemporal instructional data. This results in the MLLM4D-2M and MLLM4D-R1
-30k datasets for Supervised Fine-Tuning (SFT) and Reinforcement Fine-Tuning (RF
T), alongside MLLM4D-Bench for comprehensive evaluation. Regarding model trainin
g, our post-training strategy establishes a foundational 4D understanding via SF
T and further catalyzes 4D reasoning capabilities by employing Group Relative Po
licy Optimization (GRPO) with specialized Spatiotemporal Chain of Thought (ST-Co
T) prompting and Spatiotemporal reward functions (ST-reward) without involving t
he modification of architecture. Extensive experiments demonstrate that MLLM-4D
achieves state-of-the-art spatial-temporal understanding and reasoning capabilit
ies from purely 2D RGB inputs. Project page: https://github.com/GVCLab/MLLM-4D.

Improved Dynamic Algorithm for Non-monotone Submodular Maximization under Cardin
ality Constraint

Kiarash Banihashem, Samira Goudarzi, MohammadTaghi Hajiaghayi, Peyman Jabbarzade
, Morteza Monemizadeh

We study fully dynamic non-monotone submodular maximization under a cardinality
constraint k. Prior work achieved approximation guarantees of $(0.125-\epsilon
)$ using $\tilde{O}(\epsilon^{-1}k^2)$ oracle queries per update (NeurIPS'20) an
d 0.171 using $\tilde{O}(\epsilon^{-3}k^4)$ oracle queries per update (NeurIPS
'25). In this work, we present a dynamic algorithm that achieves a 0.262-appro
ximation with worst-case expected update time $O(\epsilon^{-3}k\log(k)\log(\epsi
lon^{-1}k) + \epsilon^{-2}k^2\log(k))$, where $0 < \epsilon \leq 1$ is the error
 parameter. We also develop another dynamic algorithm with update time bounded b
y $\mathrm{poly}(\epsilon^{-1},k)$ that achieves a 0.277-approximation guarant
ee.

Helpful to a Fault: Measuring Illicit Assistance in Multi-Turn, Multilingual LLM
 Agents

Nivya Talokar, Ayush Kumar Tarun, Murari Mandal, Maksym Andriushchenko, Antoine
Bosselut

LLM-based agents execute real-world workflows via tools. These affordances enabl
e ill-intended adversaries to also use these agents to carry out complex misuse
scenarios. Existing agent-misuse benchmarks largely test single-prompt instructi
ons, leaving a gap in measuring how agents end up helping with harmful or illega
l tasks over multiple turns. We introduce **STING** (*Sequential Testing of Illi
cit N-step Goal execution*), an automated red-teaming framework that constructs

a step-by-step illicit plan grounded in a benign persona and iteratively probes a target agent with adaptive follow-ups, using judge agents to track phase completion. We further introduce an analysis framework that models multi-turn red-teaming as a time-to-first-jailbreak random variable, enabling analysis tools like discovery curves, hazard-ratio attribution by attack language, and a new metric: Restricted Mean Jailbreak Discovery. Across AgentHarm scenarios, STING yields substantially higher illicit-task completion than single-turn prompting and chat-oriented multi-turn baselines adapted to tool-using agents. In multilingual evaluations across six non-English settings, we find that attack success and illicit-task completion do *not* consistently increase in lower-resource languages, diverging from common chatbot findings. Overall, STING provides a practical way to evaluate and stress-test agent misuse in realistic deployment settings, where interactions are inherently multi-turn and often multilingual. Our code is available at https://github.com/epfl-nlp/helpful-to-a-fault.

Diamond Maps: Efficient Reward Alignment via Stochastic Flow Maps
Peter Holderrieth, Douglas Chen, Luca Eyring, Ishin Shah, Giri Anantharaman, Yutong He, Zeynep Akata, Tommi Jaakkola, Nicholas Matthew Boffi, Max Simchowitz
Flow and diffusion models produce high-quality samples, but adapting them to user preferences or constraints post-training remains costly and brittle, a challenge commonly called reward alignment. We argue that efficient reward alignment should be a property of the generative model itself, not an afterthought, and redesign the model for adaptability. We propose Diamond Maps, a stochastic flow-map model that enables efficient and accurate alignment to arbitrary rewards at inference time. Diamond Maps amortize many simulation steps into a single-step sampler, like flow maps, while preserving the stochasticity required for optimal reward adaptation. This design makes search, Sequential Monte Carlo, and guidance scalable by enabling efficient and consistent estimation of the value function. Our experiments show that Diamond Maps can be learned efficiently via distillation from GLASS Flows, achieve stronger reward-alignment performance, and scale better than existing alignment methods. Overall, our results point toward a practical route to generative models that can be rapidly adapted to arbitrary preferences and constraints at inference time.
****

VLA-ATTC: Adaptive Test-Time Compute for VLA Models with Relative Action Critic Model
Wenhao Li, Xiu Su, Yichao Cao, Hongyan Xu, Xiaobo Xia, Shan You, Yi Chen, Chang Xu
Vision-Language-Action (VLA) models have demonstrated remarkable capabilities and generalization in embodied manipulation. However, their decision-making relies on a fast, instinctive process that lacks deliberation. This strategy often leads to suboptimal or catastrophic actions when facing complex or ambiguous scenarios that require greater consideration. In this paper, we introduce \textbf{VLA-ATTC}, a framework that endows VLA models with adaptive test-time compute (TTC). VLA-ATTC employs an uncertainty-based ``cognitive clutch'' to dynamically transition from reflexive execution to a TTC deliberation phase when necessary. During TTC phase, a novel \textbf{Relative Action Critic} (RAC) model identifies the optimal action from generated candidates via pairwise comparisons. This relative mechanism replaces unstable absolute value estimation, significantly simplifying the learning objective. Furthermore, we introduce an efficient sampling strategy to amortize computational costs and an automated data pipeline that curates preference pairs without manual annotation. On the LIBERO-LONG benchmark, VLA-ATTC reduces the failure rate of the SOTA model PI0.5 by over 50\%.

Adversarial Dual On-Policy Distillation from Expressive Teacher
Zhenglin Wan, Jingxuan Wu, Xingrui Yu, Chubin Zhang, Mingcong Lei, Bo An, Ivor Tsang, Yang You
Learning from demonstrations in embodied control is often cast as behavioral cloning, and recent diffusion or flow-matching policies improve this paradigm by modeling multi-modal expert actions. Yet these methods remain offline supervised l

earners: the policy is trained only on expert states and receives no corrective signal on the states it actually visits. On-policy distillation (OPD) offers a natural remedy, but standard OPD assumes a strong fixed teacher, which is unavailable in demonstration-only control. We propose FA-OPD, an adversarial dual on-policy distillation method in which a Flow Matching (FM) teacher is learned from demonstrations and co-trained with a lightweight MLP student. The teacher provides two complementary signals on student rollouts. The reward channel learns an expert-likeness objective over state-action pairs and drives online exploration through long-horizon policy optimization. The action channel supplies dense local targets at student-visited states, stabilizing exploitation. FA-OPD couples them so that reward distillation enables generalization beyond point-wise demonstrations, while action distillation keeps exploration anchored near expert-like behavior. Across six robot navigation, manipulation, and locomotion benchmarks, FA-OPD beats strong baselines and shows much stronger robustness under noisy or limited demonstrations. Source code: https://github.com/vanzll/FA-OPD.

Zero Sum SVD: Balancing Loss Sensitivity for Low Rank LLM Compression
Ali Abbasi, Chayne Thrash, Haoran Qin, Shansita Sharma, Sepehr Seifi, Soheil Kolouri
Advances in large language models have driven strong performance across many tasks, but their memory and compute costs still hinder deployment. SVD-based compression reduces storage and can speed up inference via low-rank factors, yet performance depends on how rank is allocated under a global compression ratio. Prior methods often use homogeneous ranks for similarly sized matrices, despite large differences in loss sensitivity, or rely on expensive iterative pre-truncation optimization to determine per matrix ranks. We propose **Zero Sum SVD** (**ZS-SVD**), a post-training method that performs *global* singular component selection using activation whitening and first-order calibration loss estimates in whitened coordinates. **ZS-SVD** prunes components across the whole model with a **zero sum** rule that keeps the cumulative predicted loss change near zero, automatically yielding heterogeneous ranks without solving a rank allocation optimization. Motivated by evidence that gradients near pretrained solutions exhibit low rank structure, we also introduce an optional lightweight correction that applies a **single** projected gradient update after truncation, followed by re-truncation. Extensive experiments across multiple LLM architectures show consistent gains across diverse benchmarks and compression ratios. Code is available at https://github.com/mint-vu/Zero-Sum-SVD

Universal Algorithm-Implicit Learning
Stefano Woerner, Seong Joon Oh, Christian F. Baumgartner
Current meta-learning methods are constrained to narrow task distributions with fixed feature and label spaces, limiting applicability. Moreover, the current meta-learning literature uses key terms like “universal” and “general-purpose” inconsistently and lacks precise definitions, hindering comparability. We introduce a theoretical framework for meta-learning which formally defines practical universality and introduces a distinction between algorithm-explicit and algorithm-implicit learning, providing a principled vocabulary for reasoning about universal meta-learning methods. Guided by this framework, we present TAIL, a transformer-based algorithm-implicit meta-learner that functions across tasks with varying domains, modalities, and label configurations. TAIL features three innovations over prior transformer-based meta-learners: random projections for cross-modal feature encoding, random injection label embeddings that extrapolate to larger label spaces, and efficient inline query processing. TAIL achieves state-of-the-art performance on standard few-shot benchmarks while generalizing to unseen domains. Unlike other meta-learning methods, it also generalizes to unseen modalities, solving text and audio classification tasks despite training exclusively on images, handles tasks with up to 20× more classes than seen during training, and provides orders-of-magnitude computational savings over prior transformer-based approaches.

VEQ: Modality-Adaptive Quantization for MoE Vision-Language Models
Guangshuo Qin, Zhiteng Li, Zheng Chen, Weihang Zhang, Linghe Kong, Yulun Zhang
Mixture-of-Experts(MoE) Vision-Language Models(VLMs) offer remarkable performanc e but incur prohibitive memory and computational costs, making compression essen tial. Post-Training Quantization (PTQ) is an effective training-free technique t o address the massive memory and computation overhead. Existing quantization par adigms fall short as they are oblivious to two critical forms of heterogeneity: the inherent discrepancy between vision and language tokens, and the non-uniform contribution of different experts. To bridge this gap, we introduce Visual Expe rt Quantization (VEQ), a dual-aware quantization framework designed to simultane ously accommodate cross-modal differences and heterogeneity between experts. Spe cifically, VEQ incorporates 1)**Modality-expert-aware Quantization**, which util izes expert activation frequency to prioritize error minimization for pivotal ex perts, and 2)**Modality-affinity-aware Quantization**, which constructs an enhan ced Hessian matrix by integrating token-expert affinity with modality informatio n to guide the calibration process. Extensive experiments across diverse benchma rks verify that VEQ consistently outperforms state-of-the-art baselines. Specifi cally, under the W3A16 configuration, our method achieves significant average ac curacy gains of 2.04\% on Kimi-VL and 3.09\% on Qwen3-VL compared to the previou s SOTA quantization methods, demonstrating superior robustness across various mu lti-modal tasks.

Group Cognition Learning: Making Everything Better Through Controlled Two-Stage Agents Collaboration
Chunlei Meng, Pengbin Feng, Rong Fu, Hoi Leong Lee, Xiaojing Du, Zhaolu Kang, Ze yu Zhang, Weilin Zhou, Chun Ouyang, Zhongxue Gan
Centralized multimodal learning commonly compresses language, acoustic, and visu al signals into a single fused representation for prediction. While effective, t his paradigm suffers from two limitations: modality dominance, where optimizatio n gravitates towards the path of least resistance, ignoring weaker but informati ve modalities, and spurious modality coupling, where models overfit to incidenta l cross-modal correlations. To address these, we propose \textbf{Group Cognition Learning (GCL)}, a governed collaboration paradigm that applies a two-stage pro tocol after modality-specific encoding. In Stage 1 (Selective Interaction), a Ro uting Agent proposes directed interaction routes, and an Auditing Agent assigns sample-wise gates to emphasize exchanges that yield positive marginal predictive gain while suppressing redundant coupling. In Stage 2 (Consensus Formation), a Public-Factor Agent maintains an explicit shared factor, and an Aggregation Agen t produces the final prediction through contribution-aware weighting while keepi ng each modality representation as a specialization channel. Extensive experimen ts on CMU-MOSI, CMU-MOSEI, and MIntRec demonstrate that GCL mitigates dominance and coupling, establishing state-of-the-art results across both regression and c lassification benchmarks. Analysis experiments further demonstrate the effective ness of the design.

How do LLMs Compute Verbal Confidence?
Dharshan Kumaran, Arthur Conmy, Federico Barbero, Simon Osindero, Viorica Patrau cean, Petar Veli■kovi■
Verbal confidence—prompting LLMs to state their confidence as a number or catego ry—is widely used to extract uncertainty estimates from black-box models. Howeve r, how LLMs internally generate such scores remains unknown. We address two ques tions: first, when confidence is computed -- just-in-time when requested, or aut omatically during answer generation and cached for later retrieval; and second, what verbal confidence represents -- token log-probabilities, or a richer evalua tion of answer quality? Focusing on Gemma 3 27B (across TriviaQA, BigMath, and M MLU), Qwen 2.5 7B, and the reasoning model Magistral Small 24B, we provide conve rgent evidence for cached retrieval. Activation steering, patching, noising, and swap experiments reveal that confidence representations emerge at answer-adjace nt positions before appearing at the verbalization site. Attention blocking pinp oints the information flow: confidence is gathered from answer tokens, cached at

the first post-answer position, then retrieved for output. Critically, linear probing and variance partitioning reveal that these cached representations explain substantial variance in verbal confidence beyond token log-probabilities, suggesting a richer answer-quality evaluation rather than a simple fluency readout. These findings demonstrate that verbal confidence reflects automatic, sophisticated self-evaluation—not post-hoc reconstruction—with implications for understanding metacognition in LLMs and improving calibration.
****
MODUS: Decoder-only Any-to-Any Modeling of Diverse Modalities
Mingqiao Ye, Zhaochong An, Zhitong Gao, Xian Liu, O■uzhan Fatih Kar, Jesse Allardice, Roman Bachmann, David Mizrahi, François Fleuret, Chuan Li, Amir Zadeh, Serge Belongie, Afshin Dehghan, Amir Zamir
Any-to-any modeling aims to flexibly relate arbitrary modalities within a single system, a requirement that arises across multimodal learning and scientific domains such as ecology and astronomy.
However, existing any-to-any approaches are typically trained from scratch using encoder–decoder or diffusion architectures, limiting empirical performance and the use of pretrained models.
We investigate decoder-only any-to-any multimodal modeling, which treats all modalities symmetrically and supports arbitrary modalities as inputs and outputs without modality-specific heads, losses, or task pipelines.
As a consequence of this unified design, the resulting model MODUS naturally enables chained generation through intermediate modalities, cross-modal consistency verification, and analysis of visual representations by combining semantic and reconstruction features.
Across a range of benchmarks, MODUS demonstrates strong out-of-the-box performance and flexible multimodal composition within a single model.
****
Latent Laplace Diffusion for Irregular Multivariate Time Series
Zinuo You, Jin Zheng, John Cartlidge
Irregular multivariate time series impose a trade-off for long-horizon forecasting: discrete methods can distort temporal structure via re-gridding, while continuous-time models often require sequential solvers prone to drift. To bridge this gap, we present Latent Laplace Diffusion (LLapDiff), a generative framework that models the target as a low-dimensional latent trajectory, enabling horizon-wide generation without step-by-step integration over physical time. We guide the reverse process utilizing a stable modal parameterization motivated by stochastic port-Hamiltonian dynamics, and parameterize its mean evolution in the Laplace domain via learnable complex-conjugate poles, enabling direct evaluation over irregular timestamps. We also link continuous dynamics to irregular observations through renewal-averaging analysis, which maps sampling gaps to effective event-domain poles and motivates a gap-aware history summarizer. Extensive experiments show that LLapDiff improves over baselines in long-horizon forecasting, and its continuous-time generative nature supports missing-value imputation by querying the same model at historical timestamps. Code is available at \url{https://github.com/pixelhero98/LLapDiffusion}.
****
3D-RFT: Reinforcement Fine-Tuning for Video-based 3D Scene Understanding
Xiongkun Linghu, Jiangyong Huang, Baoxiong Jia, Siyuan Huang
Reinforcement Learning with Verifiable Rewards (RLVR) has emerged as a key paradigm for unlocking complex reasoning in Large Language Models (LLMs), yet its potential in 3D scene understanding remains untapped. To bridge this gap, we present Reinforcement Fine-Tuning for Video-based 3D Scene Understanding (3D-RFT), the first framework to extend RLVR to 3D perception and reasoning. Our pipeline operates in two stages: activating 3D-aware Multi-modal Large Language Models (MLLMs) via Supervised Fine-Tuning (SFT), followed by reinforcement fine-tuning using Group Relative Policy Optimization (GRPO) with strictly verifiable reward functions. We design task-specific rewards—such as 3D IoU and F1-score—to provide deterministic signals for spatial alignment. Extensive experiments demonstrate that 3D-RFT achieves state-of-the-art performance on video-based 3D scene understand

ing benchmarks, significantly outperforming VG LLM-8B on detection and grounding tasks. Moreover, our model surpasses larger mainstream models on VSI-Bench, demonstrating the efficiency of verifiable reinforcement learning. We conclude by offering valuable insights into optimal training strategies .

Physics-Informed Distillation of Diffusion Models for PDE-Constrained Generation
Yi Zhang, Peng Wang, Difan Zou

Diffusion models show growing promise for generative modeling of physical systems, but enforcing partial differential equation (PDE) constraints directly is infeasible during the stochastic denoising process. Current methods apply constraints to the expected clean sample, incurring a Jensen’s Gap that forces a trade-off between PDE satisfaction and generative accuracy. To bridge this gap, we propose Physics-Informed Distillation of Diffusion Models (PIDDM), a simple yet effective post-hoc distillation strategy that enforces PDE constraints after training. PIDDM enables fast single-step generation while improving both physical consistency and sample quality, supporting forward/inverse problems and reconstruction from partial observations. Extensive experiments across PDE benchmarks show PIDDM outperforms recent baselines, such as PIDM, DiffusionPDE, and ECI-sampling, in both accuracy and constraint satisfaction, with lower computation and minimal hyperparameter tuning, offering a more efficient pathway to physics-informed diffusion models.

****

Decomposing Query-Key Feature Interactions Using Contrastive Covariances
Andrew Lee, Yonatan Belinkov, Fernanda Viégas, Martin Wattenberg

Despite the central role of attention heads in Transformers, we lack tools to understand why a model attends to a particular token. To address this, we study the query-key (QK) space -- the bilinear joint embedding space between queries and keys. We present a contrastive covariance method to decompose the QK space into low-rank, human-interpretable components. It is when features in keys and queries align in these low-rank subspaces that high attention scores are produced. We first study our method both analytically and empirically in a simplified setting. We then apply our method to large language models to identify human-interpretable QK subspaces for categorical semantic features and binding features. Finally, we demonstrate how attention scores can be attributed to our identified features.

Self-Refining Video Sampling
Sangwon Jang, Taekyung Ki, Jaehyeong Jo, Saining Xie, Jaehong Yoon, Sung Ju Hwang

Modern video generators still struggle with complex physical dynamics, often falling short of physical realism. Existing approaches address this using external verifiers or additional training on augmented data, which is computationally expensive and still limited in capturing fine-grained motion. In this work, we present self-refining video sampling, a simple method that uses a pre-trained video generator trained on large-scale datasets as its own self-refiner. By interpreting the generator as a denoising autoencoder, we enable iterative inner-loop refinement at inference time without any external verifier or additional training. We further introduce an uncertainty-aware refinement strategy that selectively refines regions based on self-consistency, which prevents artifacts caused by over-refinement. Experiments on state-of-the-art video generators demonstrate significant improvements in motion coherence and physics alignment, achieving over 70% human preference compared to the default sampler and guidance-based sampler.

PCA of Probability Measures: Sparse and Dense Sampling Regimes
Erell Gachon, Jérémie Bigot, Elsa Cazelles

A common approach to perform PCA on probability measures is to embed them into a Hilbert space where standard functional PCA techniques apply. While convergence rates for estimating the embedding of a single measure from m samples are well understood, the literature has not addressed the setting involving multiple measures. In this paper, we study PCA in a double asymptotic regime where n prob

ability measures are observed, each through m samples. We derive convergence r
ates of the form $n^{-1/2} + m^{-\alpha}$ for the empirical covariance operator
and the PCA excess risk, where $\alpha>0$ depends on the chosen embedding. This
characterizes the relationship between the number n of measures and the numbe
r m of samples per measure, revealing a sparse (small m) to dense (large m
) transition in the convergence behavior. Moreover, we prove that the dense-regi
me rate is minimax optimal for the empirical covariance error. Our numerical exp
eriments validate these theoretical rates and demonstrate that appropriate subsa
mpling preserves PCA accuracy while reducing computational cost.
****

Clipping Low-Probability Tokens in SFT Yields a Generalizable Initialization for
RL
Tian-Shuo Liu, Chengxing Jia, Haoyu Liu, Pengyuan Wang, Shiyuan Zhang, Jie Fu, Y
ang Yu
Supervised Fine-Tuning (SFT) is a critical step for adapting Large Language Mode
ls (LLMs) to specialized domains, often serving as an initialization for subsequ
ent reinforcement learning (RL). However, SFT can overfit a small set of expert
data, harming generalization and eroding prior knowledge. This can limit downstr
eam RL, which benefits from a strong, generalizable initialization for explorati
on. Here, we demonstrate that prior knowledge degradation primarily results from
tokens in the expert data to which the base model assigns low probability. Spec
ifically, these low-probability tokens represent a significant deviation from th
e model’s current prior knowledge. Due to the nature of the log-likelihood objec
tive, they produce larger gradient magnitudes, which speed up adaptation to the
new data but degrade generalization. In this paper, we study the token-wise clip
ping strategy, a commonly used trust-region method for bounding per-token update
s.
We find that it reshapes token-level learning priorities, promoting more progres
sive adaptation that fits the new data while preserving general abilities.
Compared with standard SFT, clipping low-probability tokens reduces out-of-distr
ibution forgetting by 11.54\% and improves final RL performance by 7.09\% across
the agentic benchmarks. Moreover, latent-space analysis shows smaller represent
ational drift under clipping, indicating that it provides a generalizable initia
lization.

Extending Prediction-Powered Inference through Conformal Prediction
Daniel Csillag, Pedro Dall'Antonia, Claudio Jose Struchiner, Guilherme Tegoni Go
edert
Prediction-powered inference is a recent methodology for the safe use of black-b
ox ML models to impute missing data, strengthening inference of statistical para
meters. However, many applications require strong properties besides valid infer
ence, such as privacy, robustness or validity under continuous distribution shif
ts; deriving prediction-powered methods with such guarantees is generally an ard
uous process, and has to be done case by case. In this paper, we resolve this is
sue by connecting prediction-powered inference with conformal prediction: by per
forming imputation through a calibrated set-predictor, we attain validity while
achieving additional guarantees in a natural manner. We instantiate our procedur
e for the inference of means, Z- and M-estimation, as well as e-values and e-val
ue-based procedures. Furthermore, in the case of e-values, ours is the first gen
eral prediction-powered procedure that operates off-line. We demonstrate these a
dvantages by applying our method on private and time-series data. Both tasks are
nontrivial within the standard prediction-powered framework but become natural
under our method.

Alethia: a Foundational Encoder for Voice Deepfakes
Yi Zhu, Brahmi Dwivedi, Jayaram Raghuram, Surya Koppisetti
Existing voice deepfake detection and localization models rely heavily on repres
entations extracted from speech foundation models (SFMs). However, downstream fi
netuning has now reached a state of diminishing returns. In this paper, we shift
the focus to pretraining and propose a novel recipe that combines *bottleneck m

asked embedding prediction with flow-matching based spectrogram reconstruction*. The outcome, *Alethia*, is the first foundational audio encoder for various voice deepfake detection and localization tasks. We evaluate on 5 different tasks with 56 benchmark datasets, and note *Alethia* significantly outperforms state-of-the-art SFMs with superior robustness to real-world perturbations and zero-shot generalization to unseen domains (e.g., singing deepfakes). We also demonstrate the limitation of discrete targets in masked token prediction, and show the importance of *continuous embedding* prediction and *generative pretraining* for capturing deepfake artifacts.

Improving the Performance and Learning Stability of Parallelizable RNNs Designed for Ultra-Low Power Applications

Julien Brandoit, Arthur Fyon, Damien Ernst, Guillaume Drion

Sequence learning is dominated by Transformers and parallelizable recurrent neural networks (RNNs) such as state-space models, yet learning long-term dependencies remains challenging, and state-of-the-art designs trade power consumption for performance. The Bistable Memory Recurrent Unit (BMRU) was introduced to enable hardware-software co-design of ultra-low power RNNs: quantized states with hysteresis provide persistent memory while mapping directly to analog primitives. However, BMRU performance lags behind parallelizable RNNs on complex sequential tasks. In this paper, we identify gradient blocking during state updates as a key limitation and propose a cumulative update formulation that restores gradient flow while preserving persistent memory, creating skip-connections through time. This leads to the Cumulative Memory Recurrent Unit (CMRU) and its relaxed variant, the αCMRU. Experiments show that the cumulative formulation dramatically improves convergence stability and reduces initialization sensitivity. The CMRU and αCMRU match or outperform Linear Recurrent Units (LRUs) and minimal Gated Recurrent Units (minGRUs) across diverse benchmarks at small model sizes, with particular advantages on tasks requiring discrete long-range retention, while the CMRU retains quantized states, persistent memory, and noise-resilient dynamics essential for analog implementation.

****

Attention Projection Mixing with Exogenous Anchors

Jonathan Su

Cross-layer reuse of early attention projections can improve optimization and data efficiency, but it creates a structural conflict: the first layer must simultaneously act as a stable, reusable anchor for all deeper layers and as an effective computational block. We demonstrate that this tension constrains the performance of internal-anchor designs. We propose ExoFormer, which resolves the conflict by learning exogenous anchor projections outside the sequential layer stack. We introduce a unified normalized mixing framework that mixes queries, keys, values, and gate logits using learnable coefficients (exploring coefficient granularities: elementwise, headwise, and scalar), and we show that normalizing anchor sources is key to stable reuse. ExoFormer variants consistently outperform their internal-anchor counterparts, and the dynamic variant yields 1.5x downstream accuracy points while matching validation loss using 1.5x fewer tokens than Gated Attention. We explain this efficacy via an Offloading Hypothesis: external anchors preserve essential token identity, allowing layers to specialize exclusively in feature transformation. We release code and models to facilitate future research.

R1-SyntheticVL: Is Synthetic Data from Generative Models Ready for Multimodal Large Language Model?

Jingyi Zhang, Tianyi Lin, Huanjin Yao, Xiang Lan, Shunyu Liu, Jiaxing Huang

In this work, we aim to develop effective data synthesis techniques that autonomously synthesize multimodal training data for enhancing MLLMs in solving complex real-world tasks. To this end, we propose Collective Adversarial Data Synthesis (CADS), a novel and general approach to synthesize high-quality, diverse and challenging multimodal data for MLLMs. The core idea of CADS is to leverage collective intelligence to ensure high-quality and diverse generation, while exploring

adversarial learning to synthesize challenging samples for effectively driving model improvement. Specifically, CADS operates with two cyclic phases, i.e., Collective Adversarial Data Generation (CAD-Generate) and Collective Adversarial Data Judgment (CAD-Judge). CAD-Generate leverages collective knowledge to jointly generate new and diverse multimodal data, while CAD-Judge collaboratively assesses the quality of synthesized data. In addition, CADS introduces an Adversarial Context Optimization mechanism to optimize the generation context to encourage challenging and high-value data generation. With CADS, we construct MMSynthetic-20K and train our model R1-SyntheticVL, which demonstrates superior performance on various benchmarks.

Learning Robust Multi-Agent Policies via Selective Adversarial Fault Induction
David Henry Mguni, Yaqi Sun, Haojun Chen, Wanrong Yang, Amir Darabi, Larry Olanrewaju Orimoloye, Yaodong Yang
We study robustness to agent malfunctions in cooperative multi-agent reinforcement learning (MARL), a failure mode that is critical in practice yet underexplored in existing theory. We introduce MARTA, a plug-and-play robustness layer that augments standard MARL algorithms with a Switcher–Adversary mechanism which selectively induces malfunctions in performance-critical states. This formulation defines a fault-switching $(N+2)$-player Markov game in which the Switcher chooses when and which agent fails, and the Adversary controls the resulting faulty behaviour via random or worst-case policies. We develop a Q-learning-type scheme and show that the associated Bellman operator is a contraction, yielding existence and uniqueness of the minimax value, convergence to a Markov perfect equilibrium. MARTA integrates seamlessly with MARL algorithms without architectural modification and consistently improves robustness across Traffic Junction (TJ), Level-Based Foraging (LBF), MPE SimpleTag, and SMAC (v2). In these domains, MARTA achieves large gains in final performance of up to 116.7\% in SMAC, 21.4\% in MPE SimpleTag, and 44.6\% in LBF, while significantly reducing failure rates under train–test mismatched fault regimes. These results establish MARTA as a theoretically grounded and practically deployable mechanism for fault-tolerant MARL.

Fast KV Compaction via Attention Matching
Adam Zweiger, Xinghong Fu, Han Guo, Yoon Kim
Scaling language models to long contexts is often bottlenecked by the size of the key-value (KV) cache. In deployed settings, long contexts are typically managed through *compaction* in token space via summarization. However, summarization can be highly lossy, substantially harming downstream performance. Recent work on Cartridges (Eyuboglu et al., 2025) has shown that it is possible to *train* highly compact KV caches in latent space that closely match full-context performance, but at the cost of slow and expensive end-to-end optimization. This work describes an approach for *fast* context compaction in latent space through **Attention Matching**, which constructs compact keys and values to reproduce attention outputs and preserve attention mass at a per-KV-head level. We show that this formulation naturally decomposes into simple subproblems, some of which admit efficient closed-form solutions. Within this framework, we develop a family of methods that significantly push the Pareto frontier of compaction time versus quality, achieving up to $50\times$ compaction in seconds on some datasets with little quality loss.

Temporal Context Reinstatement Drives Episodic-Like Order Memory in Long-Context Language Models
Mathis Pink, Vy A. Vo, Qinyuan Wu, Jianing Mu, Javier S. Turek, Uri Hasson, Kenneth A. Norman, Sebastian Michelmann, Alexander Huth, Mariya Toneva
Human episodic memory supports the retrieval of experiences that unfold over extended timescales, yet the computational mechanisms underlying this ability remain debated due to the limited mechanistic accessibility in long-term memory experiments in humans. Long-context LLMs may offer promising ways to reveal plausible computational mechanisms that drive this type of retrieval. Here, we investigate whether and how LLMs capture the core behavioral signatures of episodic memory

via a temporal order memory task. Using a new dataset of human behavior based on memory of a full-length novel, we show that models exhibit the same characteristic distance effect observed in humans on this task. We next apply long-context mechanistic interpretability analyses to uncover how models solve this task, and find that model performance relies on a one-dimensional temporal code that is reinstated during retrieval by a single time-reinstatement attention head. These findings support temporal context reinstatement as an important mechanism for episodic-like temporal-order memory in LLMs, offering new insights into how temporal aspects of long-term episodic memory may be instantiated in both artificial and biological systems.

Latent Collaboration in Multi-Agent Systems
Jiaru Zou, Ruizhong Qiu, Gaotang Li, Xiyuan Yang, Katherine Tieu, Pan Lu, Ke Shen, Hanghang Tong, Yejin Choi, Jingrui He, James Zou, Mengdi Wang, Ling Yang
Multi-agent systems (MAS) extend large language models (LLMs) from independent single-model reasoning to coordinative system-level intelligence. While existing LLM agents depend on text-based mediation for reasoning and communication, we take a step forward by enabling models to collaborate directly within the continuous latent space. We introduce LatentMAS, an end-to-end training-free framework that enables pure latent collaboration among LLM agents. In LatentMAS, each agent first performs auto-regressive latent thoughts generation through last-layer hidden embeddings instead of text. Then, a shared latent working memory preserves and transfers each agent's internal representations and latent thoughts, ensuring lossless information exchange without re-encoding. We provide detailed theoretical analyses showing that LatentMAS achieves higher expressiveness and lossless information preservation with lower overall complexity than standard text-based MAS. In addition, empirical evaluations across 9 comprehensive benchmarks spanning math and science reasoning, commonsense understanding, and code generation show that LatentMAS outperforms advanced single agents and text-based MAS baselines, achieving up to 14.6\% higher accuracy, reducing output token usage by 70.8\%-83.7\%, and providing 4$\times$-4.3$\times$ faster end-to-end inference.

MentisOculi: Revealing the Limits of Reasoning with Mental Imagery
Jana Ricarda Zeller, Thaddäus Wiedemer, Fanfei Li, Thomas Klein, Prasanna Mayilvahanan, Matthias Bethge, Felix A. Wichmann, Ryan Cotterell, Wieland Brendel
Frontier models are transitioning from _multimodal large language models_ (MLLMs) that merely ingest visual information to _unified multimodal models_ (UMMs) capable of native interleaved generation.
This shift has sparked interest in using intermediate visualizations as a reasoning aid, akin to human _mental imagery_.
Central to this idea is the ability to form, maintain, and manipulate visual representations in a goal-oriented manner.
To evaluate and probe this capability, we develop MentisOculi, a procedural, stratified suite of multi-step reasoning problems amenable to visual solution, tuned to challenge frontier models.
Evaluating visual strategies ranging from latent tokens to explicit generated imagery, we find they generally fail to improve performance.
Analysis of UMMs specifically exposes a critical limitation:
While they possess the textual reasoning capacity to solve a task and can sometimes generate correct visuals, they suffer from compounding generation errors and fail to leverage even ground-truth visualizations.
Our findings suggest that despite their inherent appeal, _visual thoughts do not yet benefit model reasoning_.
MentisOculi establishes the necessary foundation to analyze and close this gap across diverse model families.

General Synthetic-Powered Inference
Meshi Bashari, Yonghoon Lee, Roy Maor Lotan, Edgar Dobriban, Yaniv Romano
The rapid proliferation of high-quality synthetic data---generated by advanced AI models or collected as auxiliary data from related tasks---presents both oppor

tunities and challenges for statistical inference. This paper introduces a GEner al Synthetic-Powered Inference (GESPI) framework that wraps around any statistic al inference procedure to safely enhance sample efficiency by combining syntheti c and real data. Our framework leverages high-quality synthetic data to boost st atistical power, yet adaptively defaults to the standard method using only real data when synthetic data are of low quality.
The error rate of our method remains below a user-specified bound without any di stributional assumptions on the synthetic data, and decreases as the quality of the synthetic data improves.
This flexibility enables seamless integration with conformal prediction, risk co ntrol, hypothesis testing, and multiple testing procedures, all without modifyin g the base inference method.
We demonstrate the benefits of our method on challenging tasks with limited labe led data, including AlphaFold protein structure prediction, and comparing large reasoning models on complex math problems.

iGRPO: Fast Online RL for Flow Matching Model with Instant Reward
Sucheng Ren, Chen Chen, Zhenbang Wang, Liangchen Song, Xiangxin Zhu, Yinfei Yang , Jiasen Lu
Conventional practice assumes that online reinforcement learning for flow-matchi ng models requires sampling full denoising trajectories to compute rewards.
This assumption underlies methods such as Group Relative Policy Optimization (GR PO), where the policy must traverse the entire reverse process before receiving a delayed, trajectory-level reward.
We observe, however, that while such terminal rewards provide feedback, they are neither necessary nor optimal for effective learning.
In this work, we introduce iGRPO (Instant-reward GRPO), which replaces GRPO's fu ll-trajectory rollouts with a single-step mapping that assigns rewards instantly at each denoising step. Because the flow matching model behaves differently acr oss timesteps, our step-local instant rewards which are inherently time-dependen t, overcome prior approaches that rely on a single, time-independent terminal re ward.
By evaluating each action locally rather than relying on a final terminal score, iGRPO eliminates the need for multi-step SDE rollouts and offers more precise c redit assignment.
Across standard benchmarks, iGRPO converges 10.2× faster than FlowGRPO while ach ieving higher final alignment quality. We hope this work motivates more efficien t and scalable online RL methods for flow-matching generative models.

CAST: Modeling Visual State Transitions for Consistent Video Retrieval
Yanqing Liu, Yingcheng Liu, Fanghong Dong, Budianto Budianto, Cihang Xie, Yan ji ao
As video content creation shifts toward long-form narratives, composing short cl ips into coherent storylines becomes increasingly important. However, prevailing retrieval formulations remain context-agnostic at inference time, prioritizing local semantic alignment while neglecting the state and identity consistency. To address this structural limitation, we formalize the task of **Consistent Video Retrieval (CVR)** and introduce a diagnostic benchmark spanning YouCook2, COIN, and CrossTask. We propose **CAST (Context-Aware State Transition)**, a lightwei ght, plug-and-play adapter compatible with diverse frozen vision-language embedd ing spaces. By predicting a state-conditioned residual update (Δ) from visual hi story, CAST introduces an explicit inductive bias for latent state evolution. Ex tensive experiments show that CAST improves performance on YouCook2 and CrossTas k, remains competitive on COIN, and consistently outperforms zero-shot baselines across diverse foundation backbones. Furthermore, CAST provides a useful rerank ing signal for black-box video generation candidates (e.g., from Veo), promoting more temporally coherent continuations.

Human-in-the-Loop Policy Optimization for Preference-Based Multi-Objective Reinf orcement Learning

Tianmeng Hu, Biao Luo, Ke Li
Multi-objective reinforcement learning (MORL) seeks policies that effectively balance conflicting objectives. However, presenting many diverse policies without accounting for the decision maker’s (DM’s) preferences can overwhelm the decision-making process. On the other hand, accurately specifying preferences in advance is often unrealistic. To address these challenges, we introduce a human-in-the-loop MORL framework that interactively discovers preferred policies during optimization. Our approach proactively learns the DM’s implicit preferences in real time, requiring no a priori knowledge. Importantly, we integrate this preference learning directly into a parallel optimization framework, balancing exploration and exploitation to identify high-quality policies aligned with the DM's preferences. Evaluations on a complex quadrupedal robot simulation environment demonstrate that, with only interactions, our proposed method can identify policies aligned with human preferences, e.g., running like a dog. Further experiments on seven MuJoCo tasks and a multi-microgrid system design task against eight state-of-the-art MORL algorithms fully demonstrate the effectiveness of our proposed framework. Demonstrations and full experiments are in https://sites.google.com/view/pbmorl/home.

Safety-Efficacy Trade Off: Robustness against Data-Poisoning
Diego Marco Granziol, Ulugbek Abdimanabov
Backdoor and data-poisoning attacks can achieve high attack success while evading existing spectral and optimisation-based defences. We show that this behaviour is not incidental, but arises from a fundamental geometric mechanism in input space. Using kernel ridge regression as an exact model of wide neural networks, we prove that clustered dirty-label poisons induce a rank-one spike in the input Hessian whose magnitude scales quadratically with attack efficacy. Crucially, for nonlinear kernels we identify a near-clone regime in which poison efficacy remains order-one while the induced input curvature vanishes, making the attack provably spectrally undetectable. We further show that input-gradient regularisation contracts poison-aligned Fisher and Hessian eigenmodes under gradient flow, yielding an explicit and unavoidable safety–efficacy trade-off by reducing data-fitting capacity. For exponential kernels, this defence admits a precise interpretation as an anisotropic high-pass filter that increases the effective length scale and suppresses near-clone poisons. Extensive experiments on linear models and deep convolutional networks across MNIST and CIFAR-10/100 validate the theory, demonstrating consistent lags between attack success and spectral visibility, and showing that regularisation and data augmentation jointly suppress poisoning. Our results establish when backdoors are inherently invisible, and provide the first end-to-end characterisation of poisoning, detectability, and defence through input-space curvature.

TGV-KV: Text-Grounded KV Eviction for Vision-Language Models
Jizhihui Liu, Ruizi Han, Miao Zhang, Rui Shao, Xuebo Liu, Weili Guan, Yaowei Wang
Vision-Language Models (VLMs) inherit the auto-regressive generation paradigm and cache the keys and values (KV) of all previous tokens to accelerate inference, resulting in memory consumption that scales linearly with context length. This issue is particularly pronounced in VLMs due to substantial redundancy in the visual modality. Although KV cache eviction approaches can effectively reduce inference memory, they often incur significant performance degradation in VLMs, as most are designed for language models and overlook the inherent gap between text and vision. By systematically analyzing the modality gap in VLMs in this work, we argue that the importance of visual information should be grounded in textual guidance and accordingly propose a **T**ext-**G**rounded KV Eviction method for **V**LMs (**TGV-KV**). TGV-KV comprises three submodules: *(1) Text-Vision Budgeting (TVB)* assigns budget to each layer based on the mutual information interaction. *(2) Text-Weighted Ranking (TWR)* assesses the priority of text and ranks vision importance based on weighted text-image attention. *(3) Text-Prioritised Retention (TPR)* policy strategically preserves text KV to avoid acute informati

on loss. We evaluate TGV-KV across five models with different sizes and architectures, showing that TGV-KV preserves 99.2% full-KV accuracy on the VizWiz-VQA task with LLaVA-NeXT and boosts end-to-end throughput by 52.6% with an extreme retention budget of 5%. [Code Link](https://github.com/Danielement321/TGV-KV).

How Do Language Models Speak Languages? A Case Study on Unintended Code-Switching
Yuxin Xiao, Zhen Huang, Wenxiao Wang, Yan Zhao, Zhihong Gu, Binbin Lin, Xiaofei He, Xu Shen, Jieping Ye
Unintended code-switching, where LLMs unexpectedly switch languages, poses a fundamental challenge to multilingual generation in LLMs. However, we still lack a mechanistic account of how this failure mode is implemented inside the model. Key questions remain: what internal components (i.e., circuits) give rise to unintended code-switching, where do they emerge across layers, and how can we intervene to mitigate it? In this work, we introduce a scalable circuit discovery framework that causally localizes multilingual neurons and describes their functional patterns, then further groups them into interpretable circuits—without any additional training or manual annotation. Our findings are twofold: a) The model's "speaking-a-language" circuit decomposes into a language regime (detecting and maintaining language identity) and a semantic regime (retrieving language-agnostic semantics). b) The mechanism of unintended code-switching is a regime shift. The semantic regime suppresses the language regime and overwhelms the multilingual circuit, causing the model to generate in an unintended language. To validate these findings, we further fine-tune the identified language sub-circuit, reducing the code-switching rate by 20.8% with minimal parameter updates (~0.019 % of all neurons).
This work serves as a preliminary exploration of multilingual generation mechanism, offering actionable insight for targeted training for multilingual LLMs.

LithoGRPO: Fast Inverse Lithography via GRPO Reinforced Flow Matching
Yao Lai, Xuyuan Xiong, Zeyue Xue, Guojin Chen, Jing Wang, Xihui Liu, Rui Zhang, Robert D. Mullins, Bei Yu, Ping Luo
In semiconductor manufacturing, lithography projects circuit layouts onto silicon wafers through an optical mask. As circuit features shrink below the wavelength of light, optical diffraction causes the printed patterns to deviate from their intended layouts. Inverse Lithography Technology (ILT) addresses this challenge by generating optimized masks that enhance the fidelity of pattern transfer onto wafers. While ILT resembles an image synthesis task, its reliance on explicit physical metrics for mask evaluation limits the applicability of existing generative models. We introduce LithoGRPO, an ILT framework that integrates the flow■matching paradigm with GRPO■based reinforcement learning (RL) fine■tuning, enabling efficient exploration of diverse masks for a given target layout. Unlike purely generative or optimization■based approaches, RL in LithoGRPO exploits the explicitly defined, physics■based reward function of ILT, enabling optimization under complex, process■aware constraints. To the best of our knowledge, this is the first framework that unifies flow matching and RL for mask optimization. To improve RL sampling efficiency, we propose a fast shot-counting algorithm for manufacturability evaluation, achieving over 130× speedup while preserving the mask ranking of the traditional shot-count metric. Extensive experiments demonstrate that LithoGRPO achieves state■of■the■art performance over both optimization■based and learning■based methods, while maintaining efficient mask generation.

Finding Differentially Private Second Order Stationary Points in Stochastic Minimax Optimization
Difei Xu, Youming Tao, Meng Ding, Chenglin Fan, Di Wang
We provide the first study of the problem of finding differentially private (DP) second-order stationary points (SOSP) in stochastic (non-convex) minimax optimization.
Existing literature either focuses only on first-order stationary points for minimax problems or on SOSP for classical stochastic minimization problems. This wo

rk provides, for the first time, a unified and detailed treatment of both empiri
cal and population risks. Specifically, we propose a purely first-order method
that combines a nested gradient descent--ascent scheme with SPIDER-style varianc
e reduction and Gaussian perturbations to ensure privacy. A key technical device
 is a block-wise (q-period) analysis that controls the accumulation of stochas
tic variance and privacy noise without summing over the full iteration horizon,
yielding a unified treatment of both empirical-risk and population formulations.
 Under standard smoothness, Hessian-Lipschitzness, and strong concavity assumpti
ons, we establish high-probability guarantees for reaching an $(\alpha,\sqrt{\rh
o_\Phi \alpha})$-approximate second-order stationary point with $\alpha = \mathc
al{O}((\frac{\sqrt{d}}{n\varepsilon})^{2/3})$
for empirical risk objectives and $\mathcal{O}(\frac{1}{n^{1/3}} + (\frac{\sqrt{
d}}{n\varepsilon})^{1/2})$ for population objectives, matching the best known ra
tes for private first-order stationarity.

DriveWorld-VLA: Unified Latent-Space World Modeling with Vision–Language–Action for Autonomous Driving

Feiyang Jia, Lin Liu, Ziying Song, Caiyan Jia, Hangjun Ye, Xiaoshuai Hao, Long C
hen

End-to-end (E2E) autonomous driving has recently attracted increasing interest i
n unifying Vision–Language–Action (VLA) with World Models to enhance decision-ma
king and forward-looking imagination. However, existing methods fail to effectiv
ely unify future scene evolution and action planning within a single architectur
e due to inadequate sharing of latent states, limiting the impact of visual imag
ination on action decisions. To address this limitation, we propose DriveWorld-V
LA, a novel framework that unifies world modeling and planning within a latent s
pace by tightly integrating VLA and world models at the representation level, wh
ich enables the VLA planner to benefit directly from holistic scene-evolution mo
deling and reducing reliance on dense annotated supervision. Additionally, Drive
World-VLA incorporates the latent states of the world model as core decision-mak
ing states for the VLA planner, facilitating the planner to assess how candidate
 actions impact future scene evolution. By conducting world modeling entirely in
 the latent space, DriveWorld-VLA supports controllable, action-conditioned imag
ination at the feature level, avoiding expensive pixel-level rollouts. Extensive
 open-loop and closed-loop evaluations demonstrate the effectiveness of DriveWor
ld-VLA, which achieves state-of-the-art performance with 91.3 PDMS on NAVSIMv1,
86.8 EPDMS on NAVSIMv2, and 0.16 3-second average collision rate on nuScenes. Co
de and models are released at https://github.com/liulin815/DriveWorld-VLA.

CoPE: Continual Probe-guided Expansion for Large Vision-Language Models

Ziqin Wang, Hengyuan Zhao, Qixin Sun, Kaiyou Song, Yilin Li, Xiaolin Hu, Qingpei
 Guo, Linjiang Huang, Si Liu

Mixture of Experts architectures have recently advanced the scalability and adap
tability of Large Language Models for continual multimodal learning. However, ex
tending these models to accommodate sequential tasks remains challenging. As ne
w tasks arrive, naive model expansion leads to rapid parameter growth, while mod
ifying shared routing components often causes catastrophic forgetting, undermini
ng previously learned knowledge. To address these issues, we propose CoPE, a con
tinual learning framework for LLMs that requires no replay data of previous task
s and ensures both parameter efficiency and robust knowledge retention. Our appr
oach introduces the Probe-Guided Knowledge Extension mechanism, which uses probe
 experts to dynamically determine when and where new experts should be added, en
abling adaptive and minimal parameter expansion tailored to task complexity. To
support inference without task labels, we further incorporate a Probabilistic Ta
sk Locator that dynamically matches inputs to the correct task-specific componen
ts. To handle the practical issue that task labels are unknown during inference
, we leverage a VAE-based reconstruction strategy to identify the most suitable
router by matching input distributions, allowing automatic and accurate expert a
llocation. This design mitigates routing conflicts and catastrophic forgetting,
enabling robust continual learning without explicit task labels. Extensive exper

iments on the CoIN benchmark, covering eight diverse VQA tasks, demonstrate that CoPE delivers strong continual learning performance with a compact model size, significantly reducing forgetting and parameter overhead compared to prior methods. These results showcase the effectiveness and scalability of our approach for parameter-efficient continual learning in large language models. Our code will be open-sourced soon.

Nonlinear Covariate Balance in Experimental Design

Qing Chen, Peng Zhang

We study experimental designs that balance nonlinear functions of covariates, extending classical methods that primarily target linear balance. Building on the Gram-Schmidt Walk (GSW) framework of Harshaw et al (2024) for linear covariate balancing, we introduce a design that directly controls imbalance in nonlinear structure, including polynomial and more general smooth function classes. Like GSW, the proposed design retains sufficient robustness against model misspecification. Our implementation operates directly on a Gram matrix, avoiding the expensive step of explicitly constructing the nonlinear covariate expansions. We further accelerate the nonlinear design via a low-rank approximation of the Gram matrix, achieving runtimes comparable to the GSW of Harshaw et al (2024) while preserving nonlinear covariate balance and robustness.

Off-Policy Learning in Large Action Spaces: Optimization Matters More Than Estimation

Imad Aouali, Otmane Sakhi

Off-policy evaluation (OPE) and off-policy learning (OPL) are foundational for decision-making in offline contextual bandits. Recent advances in OPL primarily optimize OPE estimators with improved statistical properties, assuming that better estimators inherently yield superior policies. Although theoretically justified, this estimator-centric approach neglects a critical practical obstacle: challenging optimization landscapes. In this paper, we provide theoretical insights and empirical evidence showing that current OPL methods encounter severe optimization issues, particularly as the action space grows. We show that estimator-aware policy parametrization can mitigate, but not fully resolve, optimization challenges. Building on this, we explore simpler weighted log-likelihood objectives and demonstrate that they enjoy substantially better optimization properties and still recover competitive, often superior, learned policies. Our findings emphasize the necessity of explicitly addressing optimization considerations in the development of OPL algorithms for large action spaces.

****

Automatic Layer Selection for Hallucination Detection

Xinpeng Wang, William Cao, Andrew Gordon Wilson, Zhe Zeng

Recent studies on hallucination detection have shown that hallucination-related signals are more strongly encoded in intermediate layers than in the final layer of large language models (LLMs). Although a growing body of work has sought to exploit this property for hallucination detection, how to automate the selection of high-performing layers remains underexplored, and principled methods for this purpose are still lacking. To address this gap, we first propose several hypotheses for why such signals emerge in intermediate layers and evaluate corresponding criteria for automatic layer selection across diverse LLM architectures, scales, and tasks, covering both question answering and summarization hallucination detection benchmarks. However, we find that none of these criteria consistently delivers satisfactory performance. We therefore propose a new selection criterion, First Effective Peak of Intrinsic Dimension (FEPoID), which consistently identify optimal or near-optimal layers and outperforms both the aforementioned criteria and existing hallucination detection baselines. FEPoID is training-free and incurs negligible computational overhead. In addition, we study the generation behaviors of LLMs and introduce a simple yet effective truncation strategy, which further amplifies hallucination-related signals and substantially improves overall detection performance. Code is publicly available at https://github.com/DesoloYw/Automatic-Layer-Selection-for-Hallucination-Detection.git

ProactiveLLM: Learning Active Interaction for Streaming Large Language Models
Junlong Tong, Yao Zhang, Anhao Zhao, Yingqi Fan, Yunpu Ma, Xiaoyu Shen
Standard Large Language Models (LLMs) follow a *read-then-generate* paradigm, ca
using unnecessary latency and computation. Streaming LLMs alleviate this issue b
y generating while receiving inputs, but still struggle to decide when to intera
ct with the stream. Existing methods either hard-code interaction timing or rely
 on costly external alignment signals, such as timing labels, reasoning trajecto
ries, or stronger teachers. In this paper, we propose **ProactiveLLM**, which ac
hieves active interaction by leveraging the model's endogenous states to guide i
nteraction decisions. The model first learns to perceive semantic sufficiency fr
om partial inputs through two complementary training mechanisms: *mask-based str
eaming modeling* and *synchronized privileged self-distillation (SPSD)*. The for
mer applies monotonic random masking to the input during training, simulating pr
ogressively revealed streaming inputs and enabling the model to learn local sema
ntic dependencies from partial-input views. The latter aligns the partial-contex
t student view with a full-context teacher view generated by the same evolving m
odel, allowing privileged full-context evidence to guide the student's understan
ding under incomplete observations. Together, these mechanisms induce endogenous
 sufficiency cues *without requiring external teachers or annotations*, providin
g a versatile foundation for the plug-and-play integration of diverse decision h
eads. Extensive evaluation across text and speech streaming tasks confirms that
ProactiveLLM significantly reduces interaction latency while maintaining quality
, validating its capacity for dynamic and active interaction. Code is publicly a
vailable at https://github.com/EIT-NLP/StreamingLLM/tree/main/ProactiveLLM.

Personalized Image Generation via Human-in-the-loop Bayesian Optimization
Rajalaxmi Rajagopalan, Debottam Dutta, Yu-Lin Wei, Romit Roy Choudhury
Imagine Alice has a specific image $x^\ast$ in her mind, say, the view of the st
reet in which she grew up during her childhood.
To generate that exact image, she guides a generative model with multiple rounds
 of prompting and arrives at an image x^{p*}.
Although x^{p*} is reasonably close to $x^\ast$, Alice finds it difficult to c
lose that gap using language prompts.
This paper aims to narrow this gap by observing that even after language has rea
ched its limits, humans can still tell when a new image x^+ is closer to $x^\a
st$ than x^{p*}.
Leveraging this observation, we develop **MultiBO** (Multi-Choice Preferential B
ayesian Optimization) that carefully generates K new images as a function of $
x^{p*}$, gets preferential feedback from the user, uses the feedback to guide th
e diffusion model, and ultimately generates a new set of K images.
We show that within B rounds of user feedback, it is possible to arrive much c
loser to $x^\ast$, even though the generative model has no information about $x^
\ast$.
Qualitative scores from 30 users, combined with quantitative metrics compared
across 5 baselines, show promising results, suggesting that multi-choice feedb
ack from humans can be effectively harnessed for personalized image generation.

Evaluating LLM Uncertainty in Long-Form Generation Using Deterministic Ground Tr
uth
Ido Amit, Ido Galil, Ran El-Yaniv
As LLMs generate increasingly long outputs, effective uncertainty estimation mus
t identify errors at fine-grained levels rather than discard entire responses. W
hile such methods exist, evaluating uncertainty at any resolution (token to an e
ntire generation) is challenging and highly sensitive to label imperfections, ma
king zero-noise benchmarks essential; yet, long-form generation benchmarks tend
to rely on fallible labels rather than deterministic ground truth.
We introduce Single-answer Atomic Long-form Target (SALT), a benchmark of six pr
ocedurally generated tasks with single deterministic long textual ground truths,
 enabling unit-level evaluation of correctness, calibration, and ranking without

external judges.
Equipped with SALT, our analysis of 50+ LLMs reveals key insights: We identify which confidence functions dominate each uncertainty aspect
and show that confidence ranking largely breaks at atomic resolution, even when clearer separability emerges at coarser line-level units.
SALT further enables controlled atom-level interventions throughout generation, revealing two separable drivers of future errors: propagation from corrupted prefixes, dominated by global context correctness, and bounded degradation from increasing answer-context length.
Finally, we demonstrate that reasoning, via Chain-of-Thought prompting or internalized through training, introduces a trade-off, improving accuracy while degrading confidence ranking.
These findings directly impact risk-critical applications requiring reliable error identification and mitigation. We release the Code at [https://github.com/IdoAmit198/SALT](github.com/IdoAmit198/SALT).

EasyBalance: Cross-Layer Load Balancing in Distributed MoE Inference
Yize Wu, KE GAO, Ling Li, Yanjun Wu
Load Balancing has emerged as a critical problem in expert-parallel distributed inference of Mixture-of-Experts (MoE) models. As routing distributions are typically skewed across experts, devices hosting lighter-loaded experts must idle to wait for the heaviest during expert computing, leading to inefficiency. Existing load-balancing approaches primarily rely on expert replication or migration within each layer, which introduce additional overhead and limit their flexibility and scalability. To address this problem, we propose EasyBalance, a \textbf{cross-layer} load balancing strategy that requires no modifications to the expert-device mapping, enabling instant adaptability and incurring essentially no additional overhead. Our key insights are that (1) experts from other layers can be viewed as naturally redundant, and (2) expert workloads of multiple layers can be jointly executed. Based on these observations, EasyBalance greedily schedules a subset of cross-layer workloads at each MoE-computation stage to run, while deferring the remaining workloads for future balancing opportunities. Extensive experiments across different models, tasks, and parallelism configurations demonstrate that EasyBalance consistently accelerates distributed MoE inference, reducing GPU idling by mostly over 40\%.

Dynamic Thinking-Token Selection for Efficient Reasoning in Large Reasoning Models
Zhenyuan Guo, Tong Chen, Wenlong Meng, Chen GONG, Xin Yu, Chengkun Wei, Wenzhi CHEN
Large Reasoning Models (LRMs) excel at solving complex problems by explicitly generating a reasoning trace before deriving the final answer.
However, these extended generations incur substantial memory footprint and computational overhead, bottlenecking LRMs' efficiency.
This work uses attention maps to analyze the influence of reasoning traces and uncover an interesting phenomenon: *only some decision-critical tokens in a reasoning trace steer the model toward the final answer, while the remaining tokens contribute negligibly.*
Building on this observation, we propose **Dyn**amic **T**hinking-Token **S**election (**DynTS**).
This method identifies decision-critical tokens and retains only their associated Key-Value (KV) cache states during inference, evicting the remaining redundant entries to optimize efficiency.
Across six benchmarks, **DynTS** surpasses the state-of-the-art KV cache compression methods, improving Pass@1 by $2.6\\%$ under the same budget.
Compared to vanilla Transformers, it reduces inference latency by $1.84–2.62\times$ and peak KV-cache memory footprint by $3.32–5.73\times$ without compromising LRMs' reasoning performance.

Robust AI Evaluation through Maximal Lotteries

Hadi Khalaf, Serena Lutong Wang, Daniel Halpern, Itai Shapira, Flavio Calmon, Ariel D. Procaccia

The standard way to evaluate language models on subjective tasks is through pairwise comparisons: an annotator chooses the "better" of two model responses for a given prompt. These comparisons are then aggregated into a single ranking via the Bradley–Terry (BT) framework, forcing heterogeneous preferences into a total order and violating basic social-choice desiderata. In contrast, social choice theory provides an alternative approach called maximal lotteries, which aggregates pairwise preferences without imposing any assumptions on their structure. However, we show that maximal lotteries can be highly sensitive to heterogeneity among annotators and across prompts. We introduce *robust lotteries*, which optimize worst-case performance under plausible shifts in the preference data. On large-scale preference datasets, robust lotteries achieve more reliable win rate guarantees across the annotator distribution and recover a stable set of top performing models.

Causal-Adapter: Taming Text-to-Image Diffusion for Faithful Counterfactual Generation

Lei Tong, Zhihua Liu, Chaochao Lu, Dino Oglic, Tom Diethe, Philip Alexander Tearle, Sotirios A. Tsaftaris, Chen Jin

We present Causal-Adapter, a modular framework that adapts frozen text-to-image diffusion backbones for counterfactual image generation. Our method enables causal interventions on target attributes while preserving all other aspects of the image, including the core identity. In contrast to prior approaches that rely on prompt engineering without explicit causal structure, Causal-Adapter leverages structural causal modeling augmented with two attribute regularization strategies: prompt-aligned injection, which aligns causal attributes with textual embeddings for precise semantic control, and a conditioned token contrastive loss to disentangle attribute factors and reduce spurious correlations. Causal-Adapter achieves state-of-the-art results on synthetic and real-world datasets, outperforming other baselines in effectiveness, composition, realism, and minimality. These results demonstrate that the approach enables efficient, robust, and generalizable counterfactual image editing with faithful attribute modification and strong preservation of core identity.

PRISM: Perception Reasoning Interleaved for Sequential Decision Making.

Mohamed Salim AISSI, Clémence Grislain, Clément ROMAC, Laure Soulier, Mohamed CHETOUANI, Olivier Sigaud, Nicolas THOME

Scaling LLM-based embodied agents from text-only environments to complex multimodal settings remains a major challenge. Recent work identifies a perception–reasoning–decision gap in standalone Vision–Language Models (VLMs), which often overlook task-critical information. In this paper, we introduce PRISM, a framework that tightly couples perception (VLM) and decision (LLM) through a dynamic question–answer (DQA) pipeline. Instead of passively accepting the VLM’s description, the LLM critiques it, probes the VLM with goal-oriented questions, and synthesizes a compact image description. This closed-loop interaction yields a sharp, task-driven understanding of the scene. We evaluate PRISM on the ALFWorld and Room-to-Room (R2R) benchmarks. We show that: (1) PRISM significantly outperforms state-of-the-art image-based models, (2) our Interactive goal-oriented perception pipeline yields systematic and substantial gains, and (3) PRISM is fully automatic, eliminating the need for handcrafted questions or answers.

Revealing Behavioral Plasticity in Large Language Models: A Token-Conditional Perspective

Liyuan Mao, Le Yu, Jing Zhou, Chujie Zheng, Bowen Yu, Chang Gao, Shixuan Liu, An Yang, Weinan Zhang, Junyang Lin

In this work, we reveal that Large Language Models (LLMs) possess intrinsic behavioral plasticity—akin to chameleons adapting their coloration to environmental cues—that can be *exposed* through token-conditional generation and *stabilized* via reinforcement learning. Specifically, by conditioning generation on careful

ly selected token prefixes sampled from responses exhibiting desired behaviors, LLMs seamlessly adapt their behavioral modes at inference time (e.g., switching from step-by-step reasoning to direct answering) without retraining. Based on th is insight, we propose **To**ken-**Co**nditioned **R**einforcement **L**earning (**ToCoRL**), a principled framework that leverages RL to internalize this chame leon-like plasticity, transforming transient inference-time adaptations into sta ble and learnable behavioral patterns. ToCoRL guides exploration with token-cond itional generation and keep enhancing exploitation, enabling emergence of approp riate behaviors. Extensive experiments show that ToCoRL enables precise behavior al control without capability degradation. Notably, we show that large reasoning models, while performing strongly on complex mathematics, can be effectively ad apted to excel at factual question answering, which was a capability previously hindered by their step-by-step reasoning patterns.

Modeling Spectral Energy Shifts in Spatio-Temporal Graph Anomaly Detection

Yilin Liu, Hongchao Zhang, Ahmad Taha, Taylor T Johnson, Meiyi Ma

Graph anomaly detection methods aim to distinguish anomalous nodes. While prior methods characterize anomalies through increased variation in the spectral energ y distributions, they overlook those that result in decreased variation, i.e., c amouflaged anomalies that appear normal. We show that this type of anomaly persi sts across multiple datasets and remains undetectable by existing spectral appro aches. To address this limitation, we propose a node-level spectral energy formu lation that is fully compatible with message passing and enables the detection o f camouflaged anomalies. Building on this formulation, we introduce an energy-aw are graph learning framework that models spectral shifts through energy-driven m essage passing in both static and time-series graphs. Besides, our unified archi tecture extends to temporal settings without introducing specialized sequence mo dules, enabling efficient learning under long sliding windows. Extensive experim ents on large-scale benchmarks demonstrate the effectiveness and scalability of our approach. Our code is available at https://github.com/AICPS-Lab/Spectral-Ene rgy-Shifts-in-GAD.

Understanding the Performance Gap in Preference Learning: A Dichotomy of RLHF an d DPO

Ruizhe Shi, Minhak Song, Runlong Zhou, Zihan Zhang, Maryam Fazel, Simon Shaolei Du

We present a fine-grained theoretical analysis of the performance gap between tw o-stage reinforcement learning from human feedback (RLHF) and direct preference optimization (DPO). Our study decomposes this gap into two sources: the explicit representation gap under exact optimization and the implicit representation gap under finite samples. In the exact optimization setting, we characterize how th e relative capacities of the reward and policy model classes influence the final policy qualities. We show that RLHF, DPO, or online DPO can outperform one anot her depending on type of model mis-specifications. Notably, online DPO can outpe rform both RLHF and standard DPO when the reward and policy model classes are is omorphic and both mis-specified. In the approximate optimization setting, we pro vide a concrete construction where the ground-truth reward is sparse and show th at RLHF requires significantly fewer samples than DPO to recover an effective re ward model, highlighting a statistical advantage of two-stage learning. Together , these results provide a comprehensive understanding of the performance gap bet ween RLHF and DPO under various settings, and offer practical insights into when each method is preferred.

Efficient Learned Image Compression without Entropy Coding

Hao Cao, Wenqi Guo, Zhijin Qin, Jungong Han

Entropy coding is widely used in typical learned image compression (LIC) that co nverts latents into a compact bitstream.

However, entropy coding is typically sequential and becomes the coding latency b ottleneck.

To overcome it, we present **E**ntropy-Coding **F**ree **L**earned **I**mage **C**

**ompression (EF-LIC), a multi-rate framework that generates compact representation by removing statistical and correlation redundancy with low coding latency.
First, we introduce unconstrained vector quantization and prove that its index distribution approaches the maximum-entropy bound, yielding minimal statistical redundancy.
Second, we propose a context-conditioned autoregressive transform that directly reparameterizes the latents to reduce inter-dependency.
Theoretical analysis shows that EF-LIC can remove correlation redundancy as effectively as typical LIC with entropy coding, leading to comparable compression performance.
Experiments show EF-LIC achieves up to 67.86\% bitrate reduction over MS-ILLM on Kodak with LPIPS.
Ablation studies further show EF-LIC matches the compression performance of its entropy-coding based variant while achieving over $3\times$ faster encoding and $5\times$ faster decoding.

cMoLLM at Scale: Horizontal Scaling Laws for Convolutionally-Gated Mixture-of-LLMs

Xin Yang, Yemin Wang, Mingda Liu, Letian Li, Shuaishuai Cao, ZhengXiao He, Ryan Dong

Scaling large language models (LLMs) has driven their success, yet dense Transformers couple capacity and computation: every parameter is activated for every token, making training and inference costs grow linearly with model size—a critical bottleneck as models approach trillion-parameter regimes. We aim to scale capacity through MoE-style mixture throughout the LLM pipeline rather than only the FFN. Prior pipeline-level approaches include ParaScale, which introduces virtual tokens and parallel streams but incurs substantial overhead and suffers from homogenized routing and gradient collapse, and AltUp, which uses an auxiliary prediction branch but offers limited adaptivity and slow convergence. We establish that MoE-style mixture layers can be reformulated as variable-kernel dynamic convolutions, where each expert corresponds to a $1{\times}1$ convolutional kernel and routing implements input-conditioned kernel aggregation. Building on this equivalence, we introduce cMoLLM: a convolutionally gated mixture-of-LLMs that routes over end-to-end streams through fully differentiable dynamic convolution. In GPT-2-style models trained on FineWeb, cMoLLM improves language modeling perplexity and downstream GLUE and SQuAD accuracy under matched compute, with better stream utilization, more stable optimization, and favorable scaling compared to ParaScale- and AltUp-style baselines.

Learn from Your Mistakes: Tree-like Self-Play for Secure Code LLMs

Wenqi Chen, Ziyan Zhang, Wang Bin, Lin Liu, Hengheng Zhang, Zhengsu Chen

While Large Language Models (LLMs) excel in code generation, they remain prone to replicating subtle yet critical vulnerabilities endemic to their training data. Current alignment techniques, such as Supervised Fine-Tuning (SFT) and Reinforcement Learning (RL), typically apply coarse-grained optimization at the sequence level. This approach often fails to address the localized nature of security flaws, where a single incorrect token choice can compromise an entire program.
To bridge this gap, we introduce Tree-like Self-Play (TSP), a framework that reframes secure code generation as a fine-grained sequential decision process. Unlike standard methods that blindly maximize likelihood, TSP constructs a decision tree where the model explores branching trajectories—generating both secure "golden paths" and vulnerable variants. By treating code generation as a self-play game, the model learns to strictly discriminate against its own localized errors. This provides a dense, on-policy learning signal that forces self-correction precisely at the critical decision nodes where vulnerabilities typically emerge.
Our experiments demonstrate that TSP fundamentally enhances model reliability. In Python security benchmarks, TSP boosts CodeLlama-7B’s pass rate (SPR@1) to 75.8\%, significantly outperforming SFT (57.0\%) and unstructured self-play baselines. Crucially, TSP induces robust out-of-distribution generalization: the model not only reduces vulnerabilities in unseen categories (CWEs) by 24.5\% but also

successfully transfers security principles learned from C/C++ to diverse languages, including Python, Go, and JavaScript. This suggests that TSP does not merely memorize patches, but internalizes abstract, language-agnostic security logic.

Reasoning over Boundaries: Enhancing Specification Alignment via Test-time Deliberation
Haoran Zhang, Yafu Li, Xuyang Hu, Dongrui Liu, Zhilin Wang, Bo Li, Yu Cheng
Large language models (LLMs) are increasingly applied in diverse real-world applications, each governed by bespoke behavioral and safety specifications (spec) customtailored by users or organizations. These specifications, categorized into safety-spec and behavioral-spec, vary across scenarios and evolve with changing preferences and requirements. We formalize this challenge as specification alignment, focusing on LLMs' ability to follow dynamic, scenario-specific spec from both behavioral and safety perspectives. To address this challenge, we introduce SpecBench, a unified benchmark for measuring specification alignment, covering 5 scenarios, 103 spec, and 1,500 prompts. Experiments on 15 reasoning and 18 instruct models with several Test-Time Deliberation (TTD) methods, including Self-Refine, TPO, and MoreThink, show that SpecBench effectively reveals alignment gaps and that test-time deliberation improves specification alignment. Based on previous TTD methods, we further propose Align3, a lightweight method with hierarchical reflection and revision to reason over specification boundaries, advancing the safety-helpfulness trade-off frontier with minimal overhead. These results highlight test-time deliberation as an effective strategy for reasoning over the real-world specification boundaries. Our code and resources are available at https://github.com/zzzhr97/SpecBench.

Can Vision Language Models Learn Intuitive Physics from Interaction?
Luca M. Schulze Buschoff, Konstantinos Voudouris, Can Demircan, Eric Schulz
Pre-trained vision language models do not have good intuitions about the physical world. Recent work has shown that supervised fine-tuning can improve model performance on simple physical tasks. However, fine-tuned models do not appear to learn robust physical rules that can generalize to new contexts. Based on research in cognitive science, we hypothesize that models need to interact with an environment to properly learn its physical dynamics. We train models that learn through interaction with a simulated environment using reinforcement learning. While learning from interaction allows models to improve their within-task performance, it fails to produce models with generalizable physical intuitions. We find that models trained on one task do not reliably generalize to related tasks, even if the tasks share visual statistics and physical principles, and regardless of whether the models are trained through interaction.

What Does Thompson Sampling Optimize?
Yanlin Qu, Hongseok Namkoong, assaf zeevi
Thompson Sampling is one of the most widely used and studied bandit algorithms, known for its simple structure, low regret performance, and solid theoretical guarantees. Yet, in stark contrast to most other families of bandit algorithms, the exact mechanism through which posterior sampling (as introduced by Thompson) is able to "properly" balance exploration and exploitation, remains a mystery. In this paper, we show that the core insight to address this question stems from recasting Thompson Sampling as an online optimization algorithm. To distill this, we introduce a time invariant notion of regret that summarizes cumulative regret across horizons (through a regret bound), leading to a time invariant Bellman-optimal policy. It turns out that Thompson Sampling admits an online optimization form that mimics the structure of the Bellman-optimal policy, where greediness is regularized by a measure of residual uncertainty. When viewed through this new lens of online optimization, Thompson Sampling can be understood and improved in a principled manner, by comparing it against the Bellman-optimal benchmark.

Language Generation with Replay: A Learning-Theoretic View of Model Collapse
Giorgio Racca, Michal Valko, Amartya Sanyal

As scaling laws push the training of frontier large language models (LLMs) toward ever-growing data requirements, training pipelines are approaching a regime where much of the publicly available online text may be consumed. At the same time, widespread LLM usage increases the volume of machine-generated content on the web; together, these trends raise the likelihood of generated text re-entering future training corpora, increasing the associated risk of performance degradation often called *model collapse*. In practice, model developers address this concern through data cleaning, watermarking, synthetic-data policies, or, in some cases, blissful ignorance. However, the problem of model collapse in generative models has not been examined from a learning-theoretic perspective: we study it through the theoretical lens of the *language generation in the limit* framework, introducing a *replay* adversary that augments the example stream with the generator's own past outputs. Our main contribution is a fine-grained learning-theoretic characterization of when replay fundamentally limits generation: while replay is benign for the strongest notion of uniform generation, it provably creates separations for the weaker notions of non-uniform generation and generation in the limit. Interestingly, our positive results mirror heuristics widely used in practice, such as data cleaning, watermarking, and output filtering, while our separations show when these ideas can fail.

Understanding Self-Supervised Learning via Latent Distribution Matching

Fabian A Mikulasch, Friedemann Zenke

Self-supervised learning (SSL) excels at finding general-purpose latent representations from complex data, yet lacks a unifying theoretical framework that explains the diverse existing methods and guides the design of new ones. We cast SSL as latent distribution matching (LDM): learning representations that maximize their log-probability under an assumed latent model (alignment), while maximizing latent entropy to prevent collapse (uniformity). This view unifies independent component analysis with contrastive, non-contrastive, and predictive SSL methods, including stop gradient approaches. Leveraging LDM, we derive a nonlinear, sampling-free Bayesian filtering model with a Kalman-based predictor for high-dimensional timeseries. We further prove that predictive LDM yields identifiable latent representations under mild assumptions, even with nonlinear predictors. Overall, LDM clarifies the assumptions behind established SSL methods and provides principled guidance for developing new approaches.

Identifying and Mitigating Errors in Gradient Aggregation of Distributed Data Parallel Training

Zhenheng Tang, Junlin Huang, Zichen TANG, Xueze Kang, Yuxin Wang, Peijie Dong, Shaohuai Shi, Xiaowen Chu, Bo Li

Hardware-related silent data corruptions during gradient aggregation pose significant challenges to fault-tolerant distributed training, often leading to slow or failed convergence. To address this, we first mathematically formulate these errors as gradient inconsistency and theoretically analyze how they result in accumulated model divergence. Guided by this analysis, we introduce PAFT, a fault-tolerant distributed training system designed with dynamic and asynchronous parameter synchronization. PAFT comprises two core components: PAFT-Sync, which mitigates divergence via periodic synchronization, and PAFT-Dyn, which minimizes overhead through dynamic training overlap and frequency scheduling. Furthermore, the system’s synchronization mechanism is optimized to support standard optimizers, including SGD, SGD momentum, and Adam. We implement PAFT on PyTorch Distributed, and experimental results training ResNet, GPT-2, and LLaMA-2 on 4$\sim$32 GPUs demonstrate that it efficiently defends against aggregation errors while maintaining training performance.

From Reasoning Traces to Reusable Modules: Understanding Compositional Generalization in Language Model Reasoning

Lingjing Kong, Xin Liu, Guangyi Chen, Martin Q. Ma, Xiangchen Song, Yuekai Sun, Mikhail Yurochkin, Taylor W. Killian, Ruslan Salakhutdinov, Kun Zhang, Eric P. Xing, Zhengzhong Liu

Reinforcement learning (RL) has emerged as a key mechanism for transforming LLMs into robust reasoners. While supervised fine-tuning (SFT) often limits models to the distribution of observed reasoning traces, RL post-training significantly improves performance on out-of-distribution (OOD) tasks that require unfamiliar recombinations of familiar steps. We argue that this improvement is driven by **compositional generalization**, which we formalize through a **Hierarchical Latent Selection Model**. In this framework, reasoning traces are generated by a cascade of discrete latent selection variables corresponding to reusable atomic modules, including both skills (local operations) and routing mechanisms (how intermediate information is selected, reused, and composed). We theoretically show that RL's exploratory nature provides sufficient coverage to identify latent structure and enable compositional generalization.
We design controlled experiments to validate this theory. Our results demonstrate that RL can extract atomic modules from compound traces and recombine them to solve new configurations. Moreover, we find that training on compound traces can yield stronger generalization than training on isolated atomic modules. Finally, we investigate relations between SFT and RL and identify an effective protocol in which SFT ensures coverage of all atomic modules, while RL focuses on novel compositions beyond the SFT support to encourage exploration.

RN-D: Discretized Categorical Actors for On-Policy Reinforcement Learning
Yuexin Bian, Jie Feng, Tao Wang, Yijiang Li, Sicun Gao, Yuanyuan Shi
On-policy Reinforcement Learning (RL) remains a dominant paradigm for continuous control, yet standard implementations rely on Gaussian actors and relatively shallow MLP policies, often leading to brittle optimization when gradients are noisy, and policy updates must be conservative. In this paper, we revisit actor policy representation as a first-class design choice for on-policy RL. We study discretized categorical actors, which represent each action dimension as a distribution over discrete bins and induce a policy objective analogous to classification cross-entropy loss. Building on architectural advances from supervised learning, we further pair discretized categorical actors with regularized networks, yielding RN-D. Across diverse continuous-control benchmarks, we show that simply replacing the standard Gaussian actor with our proposed actor substantially improves performance, achieving state-of-the-art results within on-policy RL. We release our code at https://github.com/alwaysbyx/RND-RL.

Real Data Lies: Unveiling and Closing the Quality Shortcut in Generalizable AI-Generated Video Detection
Ziyuan Fang, Tianyi Wei, Guanjie Wang, Weiming Zhang, Nenghai Yu, Wenbo Zhou
Recent advances in video generation have enabled highly realistic synthetic content, raising concerns about the integrity of digital media and motivating the development of benchmarks and detection methods for generated videos. Prior works have largely prioritized bolstering model generalization against unseen generators. However, we uncover a neglected factor: the quality distribution of real videos plays a pivotal role. Current training protocols suffer from a clear quality bias between real and fake data, prone to shortcut learning. Compounded by testing on similar real data distributions, this creates an illusion of generalization. In reality, these models fail to generalize when exposed to real data with significantly different quality profiles. To address this, we propose training with quality-matched real and fake data to mitigate bias. Building on this, we introduce a data expansion strategy that broadens the training set to comprehensively cover the full quality spectrum. This approach enables the model to learn quality-agnostic features for detection, thereby achieving generalization across real data of varying qualities and enhancing real-world applicability. Extensive experiments demonstrate that our method scales well across diverse backbones, consistently enhancing the generalization capability of existing models.

Causally Evaluating the Learnability of Formal Language Tasks
Vésteinn Snæbjarnarson, Anej Svete, Josef Valvoda, Reda Boumasmoud, Brian DuSell, Ryan Cotterell

Language models, as multi-task learners, acquire a wide range of abilities during training. A fundamental question is how much task-specific data is needed to learn a given task. Answering this for natural language is difficult: tasks are hard to delineate and can confound one another. To rigorously investigate the relationship between data frequency and learnability, we turn to a controlled setting using formal languages induced from probabilistic finite automata. These serve as a methodological testbed to demonstrate that standard correlational evaluation practices are inherently flawed. To enable causal analysis, we introduce the binning semiring, an algebraic object that lets us control how often a targeted property occurs in a sampled corpus. We formulate the experimental pipeline as a causal graphical model and derive decomposed Kullback--Leibler divergence metrics to measure the learnability of specific sub-tasks. Our experiments show that evaluating learnability without causal intervention leads to incorrect conclusions due to confounders in correlational analysis, and serve as a warning about correlational pitfalls in natural-language settings.
****

Furina: Fragmented Uncertainty-Driven Refusal Instability Attack
Tongxi Wu, Jian Zhang, Yang Gao
Safety alignment in large language models (LLMs) and multimodal large language models (MLLMs) is commonly assumed to operate as a near-binary threshold mechanism. We challenge this assumption by revealing that safety behavior is governed by an \emph{instability region} where small perturbations induce stochastic refusal decisions rather than deterministic outcomes.
We develop a multi-metric diagnostic framework combining external and internal signals to characterize this instability. Through systematic experiments, we identify a characteristic \emph{diagnostic signature}: inputs in unstable regimes exhibit elevated output uncertainty yet \emph{decreased} internal safety activation, a decoupling phenomenon that explains why detection-based defenses fail against sophisticated attacks.
Building on this framework, we introduce \textbf{Furina}, a jailbreak attack that deliberately induces this signature through fragmented, scene-anchored prompts without model-specific optimization.
Furina outperforms strong single-turn and multi-turn baselines on HarmBench and achieves competitive results on MM-SafetyBench, demonstrating that uncertainty amplification provides a principled and transferable mechanism for understanding safety vulnerabilities. Code is available at: \url{https://github.com/0xCavaliers/Furina_Jailbreak}.

Don't Overthink with Pixels: Efficient Reasoning for Segmentation
Song Wang, Gongfan Fang, Lingdong Kong, Xiangtai Li, Jianyun Xu, Sheng Yang, Qiang Li, Jianke Zhu, Xinchao Wang
Existing reasoning segmentation approaches typically fine-tune multimodal large language models (MLLMs) using image-text pairs and corresponding mask labels. While recent efforts leverage reinforcement fine-tuning to further enhance reasoning ability, they often suffer from overthinking and produce uniformly verbose reasoning chains irrespective of task complexity. To address this problem, we propose PixelThink, a simple yet effective scheme that integrates externally estimated task difficulty and internally measured model uncertainty to regulate reasoning generation within a reinforcement learning paradigm. The model learns to compress reasoning length in accordance with scene complexity and predictive confidence. To support comprehensive evaluation, we introduce ReasonSeg-Diff, an extended benchmark with annotated reasoning references and difficulty scores, along with a suite of metrics designed to assess segmentation accuracy, reasoning quality, and efficiency jointly. Experimental results demonstrate that the proposed approach not only improves segmentation performance but also significantly reduces inference latency by 30.4%, cutting token usage by 48.2%.
****

Evaluating and Steering Modality Preferences in Multi-modal LLMs
Yu Zhang, Jinlong Ma, Yongshuai Hou, Xuefeng Bai, Kehai Chen, Yang Xiang, Jun Yu, Min Zhang

Multi-modal large language models (MLLMs) have achieved remarkable success on co
mplex multi-modal tasks.
However, it remains insufficiently explored whether they exhibit modality prefer
ence, a tendency to favor one modality over another when processing multi-modal
contexts.
To study this question, we introduce MC^2 benchmark, which constructs controll
ed evidence-conflict scenarios to systematically evaluate modality preference in
 decision-making.
Extensive experiments reveal that all 20 tested MLLMs generally demonstrate clea
r modality preferences, and such preferences are
statistically associated with performances of downstream taks for MLLMs.
Further analysis shows that modality preference can be controlled by instruction
 guidance and captured within the latent representations of MLLMs.
Built on these insights, we propose a probing and steering method based on repre
sentation engineering to explicitly control modality preference without requirin
g additional fine-tuning.
This method effectively amplifies modality preference toward a desired direction
 and demonstrates promising improvements across
multiple multi-modal understanding and reasoning tasks.

Probabilistic Modeling of Latent Agentic Substructures in Deep Neural Networks
Su Hyeong Lee, Risi Kondor, Richard Ngo
We develop a theory of intelligent agency grounded in probabilistic modeling for
 neural models. Agents are represented as outcome distributions with epistemic u
tility given by log score, and compositions are defined through weighted logarit
hmic pooling that strictly improves every member's welfare. We prove that strict
 unanimity is impossible under linear pooling or in binary outcome spaces, but p
ossible with three or more outcomes. Our framework admits recursive structure vi
a cloning invariance, continuity, and openness, while tilt-based analysis rules
out trivial duplication. Finally, we formalize an agentic alignment phenomenon i
n LLMs using our theory: eliciting a benevolent persona ("Luigi'') induces an an
tagonistic counterpart ("Waluigi''), while a manifest-then-suppress Waluigi stra
tegy yields strictly larger first-order misalignment reduction than pure Luigi r
einforcement alone. These results clarify how developing a principled mathematic
al framework for how subagents can coalesce into coherent higher-level entities
provides novel implications for alignment in agentic AI systems.

Continuity-Regularized Flow Matching for Offline Reinforcement Learning
Xiaocong Chen, Siyu Wang, Lina Yao
Flow-matching policies have recently emerged as a powerful class of generative m
odels for offline reinforcement learning (RL), capable of capturing complex, mul
ti-modal action distributions from static datasets. However, standard training o
bjectives are largely agnostic to the global properties of the generative path,
permitting learned vector fields that are irregular and unstable, which can hind
er performance. In this work, we introduce PDE-regularized Q-Learning (PQL), a n
ovel algorithm that addresses this limitation by imposing a principled structure
 on the entire probability flow. PQL makes two synergistic contributions: first,
 a partial differential equation based regularizer derived from the continuity e
quation promotes global smoothness and stability on the flow. Second, to solve t
he complex optimization problem introduced by this regularizer, we propose a Bet
a-distributed timestep sampling strategy that focuses learning on the critical t
rajectory segments where the trade-off between imitation and smoothness is most
acute. Through extensive experiments, we demonstrate that by structuring the gen
erative journey and not just its destination, PQL achieves state-of-the-art perf
ormance on a wide range of challenging offline RL tasks.
****

Optimal Self-Consistency for Efficient Reasoning with Large Language Models
Austin Feng, Marius Alonso, Ambroise Odonnat, Vasilii Feofanov, Ievgen Redko
Self-consistency (SC) is a widely-used test-time inference technique for improvi
ng performance in chain-of-thought reasoning. It consists of generating multiple

responses, or "samples," from a large language model (LLM) and selecting the most frequent answer. This procedure can naturally be viewed as a majority vote or empirical mode estimation. Despite its effectiveness, self-consistency is prohibitively expensive at scale when naively applied to datasets, and it lacks a unified theoretical treatment of sample efficiency and scaling behavior.
In this paper, we provide the first comprehensive analysis of SC's scaling behavior and its variants, drawing on mode estimation and voting theory. We derive and empirically validate power law scaling for self-consistency across datasets, and analyze the sample efficiency for fixed-allocation and dynamic-allocation sampling schemes. From these insights, we introduce Blend-ASC, a novel variant of self-consistency that dynamically allocates samples to questions during inference, achieving state-of-the-art sample efficiency. Our approach uses $4.8\times$ fewer samples than vanilla SC on average, outperforming both fixed- and dynamic-allocation SC baselines, thereby demonstrating the superiority of our approach in terms of efficiency. In contrast to existing variants, we note that Blend-ASC is hyperparameter-free and can fit any budget of samples, ensuring it can be easily applied to any self-consistency application.
****

Rényi Diffusion Models
Yirong Shen, Lu GAN, Cong Ling
The choice of training objective is central to diffusion-based generative modeling in terms of both sample quality and distribution coverage. While standard maximum likelihood training provides a principled objective with strong theoretical grounding, empirical studies indicate that previous training objectives in diffusion models often face an inverse correlation between likelihood optimization and perceptual evaluations.

We propose the Rényi diffusion model, a unified generative framework that formulates training objectives using Rényi divergence. This yields a generalized score matching objective providing explicit control over the trade-off between sample quality and distribution coverage. Experiments demonstrate improved balance between density estimation and sample generation performances across multiple datasets without modifying model architectures or sampling procedures.

Revisiting Regularized Policy Optimization for Stable and Efficient Reinforcement Learning in Two-Player Games
Kazuki Ota, Takayuki Osa, Motoki Omura, Tatsuya Harada
Two-player games such as board games have long been used as traditional benchmarks for reinforcement learning. This work revisits a policy optimization method with reverse Kullback-Leibler regularization and entropy regularization and analyzes this combination in two-player zero-sum settings from theoretical and empirical perspectives. From a theoretical perspective, we investigate the stability of the policy update rule in two theoretical settings: game-theoretic normal-form games and finite-length games. We provide novel convergence guarantees and verify our theoretical results through numerical experiments on synthetic games. From an empirical perspective, we derive a practical model-free reinforcement learning algorithm based on the regularized policy optimization. We validate the training efficiency of our algorithm through comprehensive experiments on five board games: Animal Shogi, Gardner Chess, Go, Hex, and Othello. Experimental results show that our agent learns more efficiently than existing methods across environments.

Through the Stealth Lens: Attention-Aware Defenses Against Poisoning in RAG
Sarthak Choudhary, Nils Palumbo, Ashish Hooda, Krishnamurthy Dj Dvijotham, Somesh Jha
Retrieval-augmented generation (RAG) systems are vulnerable to attacks that inject poisoned passages into the retrieved context, even at low corruption rates. We show that existing attacks are not designed to be stealthy, allowing reliable detection and mitigation. We formalize a distinguishability-based security game to quantify stealth for such attacks. If a few poisoned passages control the res

ponse, they must bias the inference process more than the benign ones, inherentl
y compromising stealth. This motivates analyzing intermediate signals of LLMs, s
uch as attention weights, to approximate the influence of different passages on
the response. Leveraging attention weights, we introduce the Normalized Passage
Attention Score (NPAS) and a lightweight Attention-Variance Filter (AV Filter) t
hat flags anomalous passages. Our method improves robustness, yielding up to ~20
% higher accuracy than baseline defenses. We also develop adaptive attacks that
attempt to conceal such anomalies, achieving up to 35% success rate and undersco
ring the challenges of achieving true stealth in poisoning RAG systems.
****
SLIM: Secure and Efficient Inference for Large Language Models on Untrusted Devi
ces via TEEs
Wei Wang, Zihao Guan, Xing Zhou, Yan Ding, Yusong Tan, Jie Yu, Bao Li
Deploying large language models (LLMs) on untrusted hardware entails a risk of w
eight extraction, which can lead to unauthorized replication and misuse of the m
odel. A practical approach is to leverage Trusted Execution Environments (TEEs)
and protect model security by obfuscating model weights. However, existing obfus
cation schemes struggle to simultaneously provide strong security guarantees and
high performance: schemes with security guarantees incur substantial overhead d
ue to frequent TEE interactions, whereas schemes that achieve efficient inferenc
e are insecure. We propose SLIM, a secure inference framework that exploits the
iterative structure of LLMs to let transformed representations cascade through c
onsecutive obfuscated layers, thereby minimizing interactions with the TEE. SLIM
introduces a T-Way Mixing algorithm that performs consecutive inter-vector cove
ring using carefully constructed block-diagonal Householder matrices and combine
s it with successive random permutations, providing thorough weight obfuscation
while keeping TEE-side computation lightweight. Evaluations demonstrate that SLI
M provides robust security guarantees and significantly outperforms prior state-
of-the-art obfuscation schemes in terms of performance, delivering up to a $13.8
0\times$ speedup while preserving fidelity.

Are LLM Evaluators Really Narcissists? Sanity Checking Self-Preference Evaluatio
ns
Dani Roytburg, Matthew Bozoukov, Matthew Nguyen, Jou Barzdukas, Mackenzie Puig-H
all, Narmeen Fatimah Oozeer
Recent research has shown that large language models (LLMs) favor their own outp
uts when acting as judges, undermining the integrity of automated post-training
and evaluation workflows.
However, it is difficult to disentangle which behaviors are explained by narciss
ism versus experimental confounds.
Specifically, LLM evaluators may deliver self-preferring verdicts when comparing
responses to questions they fail on; these verdicts may not depend on the ident
ity of the author, but on evaluator quality.

We correct this by directly comparing the judge's voting distribution in cases w
here it evaluates itself versus another model.
This evaluator quality baseline reveals that only **51%** of examples in previou
s findings retain statistical significance against this null hypothesis, coverin
g **89.6%** of total self-preference probability mass.
Finally, we compare the entropy of voting distributions, suggesting uncertainty-
driven overlap, and show that our procedure enables more careful documentation a
gainst the backdrop of judge-bias research.

Leak@k: Unlearning Does Not Make LLMs Forget Under Probabilistic Decoding
Hadi Reisizadeh, Jiajun Ruan, Yiwei Chen, Soumyadeep Pal, Sijia Liu, Mingyi Hong
Unlearning in large language models (LLMs) is critical for regulatory compliance
and for building ethical generative AI systems that avoid producing private, to
xic, illegal, or copyrighted content. Despite rapid progress, in this work, we s
how that \textit{almost all} existing unlearning methods fail to achieve true fo
rgetting in practice. Specifically, while evaluations of these `unlearned' model

s under deterministic (greedy) decoding often suggest successful knowledge removal using standard benchmarks, we show that sensitive information reliably resurfaces when models are sampled with standard probabilistic decoding. To rigorously capture this vulnerability, we introduce \texttt{leak@k}, a new meta-evaluation metric that quantifies the likelihood of forgotten knowledge reappearing when generating k samples from the model under realistic decoding strategies. Using three widely adopted benchmarks, TOFU, MUSE, and WMDP, we conduct the first large-scale, systematic study of unlearning reliability using \texttt{leak@k} metric. Our findings demonstrate that knowledge leakage persists across methods and tasks, underscoring that current state-of-the-art (SOTA) unlearning techniques provide only limited forgetting. We propose an algorithm, termed Robust Unlearning under LEak@k metric (\texttt{RULE}) to address this concern. We demonstrate that \texttt{RULE} provides an unlearned model for TOFU benchmark with no information leakage for a large number of generation samples. On the MUSE benchmark, \texttt{RULE} outperforms SOTA unlearning methods under the \texttt{leak@k} metric across most sampling budgets k. Codes are available at \url{https://github.com/OptimAI-Lab/Leak-k}.

LARA: Latent Action Representation Alignment for Vision-Language-Action Models

Mengya Liu, Baoxiong Jia, Jiangyong Huang, Jingze Zhang, Siyuan Huang

Visual-language-action (VLA) models enable robots to predict actions directly from observations and language instructions, but their performance depends on large-scale, high-quality data and is limited by the scarcity of real-world robot action datasets. To facilitate VLA model learning with abundant unlabeled human videos, Latent Action Models (LAM) learn latent action representations from visual dynamics to provide additional supervision for VLA learning. However, LAM and VLA are typically trained separately, leaving LAM ungrounded during VLA training and VLA models constrained by frozen LAM representations. To address these issues, we propose Latent Action Representation Alignment (LARA), a plug-and-play framework that jointly optimizes LAM and VLA via representation alignment. This enables reciprocal benefits where LAMs learn with action trajectories to avoid spurious visual changes, while VLAs are regularized by forward dynamics learned within LAMs to reduce hallucinations of functionally ineffective trajectories. We demonstrate LARA's versatility and effectiveness for pre-training, post-training enhancement of pre-trained VLA models, and LAM refinement, achieving an average of ~10%, ~5%, and ~15% improvement over 3 simulation and 1 meticulously designed real-world robotic manipulation benchmarks. The code is publicly available at https://github.com/lmy1001/LARA.

Mitigating Mask Prior Drift and Positional Attention Collapse in Large Diffusion Vision-Language Models

Sujung Hong, Chanyong Yoon, Seong Jae Hwang

Large diffusion vision–language models (LDVLMs) have recently emerged as a promising alternative to autoregressive models, enabling parallel decoding for efficient inference and leveraging bidirectional attention for global context.

Despite these advances, their behavior under long-form generation remains underexplored.

In this work, we show that existing LDVLMs suffer from repetitive generation and degraded visual grounding, and identify two underlying causes.

First, repetitive generation originates from a mask token prior: since generation tokens are initialized as mask tokens, their hidden representations progressively drift toward a shared prior direction over generation steps.

Second, a fundamental misalignment between the positional attention bias and the iterative unmasking process suppresses attention toward informative visual tokens, degrading visual grounding.

Based on these insights, we propose a training-free approach, introducing Mask Prior Suppression and Monotonic RoPE Scaling to mitigate mask prior drift and positional attention collapse during decoding.

Experiments on general multimodal benchmarks and visual grounding tasks demonstrate improvements over baseline LDVLMs, with robust gains on long-form descriptio

n benchmarks.
Our results show that these failures can be effectively addressed with a lightwe ight, plug-and-play strategy that requires no additional training and generalize s across diverse LDVLM architectures.

Unraveling Syntax: Language Modeling and the Substructure of Grammars
Laura Ying Schulz, Daniel Mitropolsky, Tomaso Poggio
While language models achieve impressive results, their *learning dynamics* are far from understood. Many domains of interest – such as natural language syntax, coding languages, arithmetic – are captured by context-free grammars (CFGs). In this work, we extend prior work on neural language modeling of CFGs in a novel direction: how language modeling behaves with respect to CFG *substructure*, nam ely sub*grammars*. We define subgrammars, and prove a set of fundamental theorem s connecting language modeling and subgrammars. We show that language modeling l oss recurses linearly over its top-level subgrammars; applied recursively, the l oss decomposes into losses for "irreducible" subgrammars. Under additional assum ptions, and empirically, parametrized models learn subgrammars in parallel, unli ke children who first master simple substructures. We find that subgrammar pretr aining can improve final performance, but only for tiny models relative to the g rammar, while alignment analyses show that pretraining consistently leads to int ernal representations that better reflect the grammar’s substructure.

MotionGRPO: Overcoming Low Intra-Group Diversity in GRPO-Based Egocentric Motion Recovery
Nanjie Yao, Junlong Ren, Wenhao Shen, Hao Wang
This paper studies full-body 3D human motion recovery from head-mounted device s ignals. Existing diffusion-based methods often rely on global distribution match ing, leading to local joint reconstruction errors. We propose MotionGRPO, a nove l framework leveraging reinforcement learning post-training to inject fine-grain ed guidance into the diffusion process. Technically, we model diffusion sampling as a Markov decision process optimized via Group Relative Policy Optimization (GRPO). To this end, we introduce a hybrid reward mechanism that combines a learn ed conditioned perceptual model for global visual plausibility and explicit cons traints for local joint precision. Our key technical insight is that policy opti mization in diffusion-based recovery suffers from vanishing gradients due to lim ited intra-group sample diversity. To address this, we further introduce a noise -injection strategy that explicitly increases sample variance and stabilizes lea rning. Extensive experiments demonstrate that MotionGRPO achieves state-of-the-a rt performance with superior visual fidelity. Code is available at: https://gith ub.com/3DAgentWorld/MotionGRPO/
****
ExpAlign: Expectation-Guided Vision–Language Alignment for Open-Vocabulary Groun ding
Junyi Hu, Tian Bai, Fengyi Wu, Wenyan Li, Zhenming Peng, Yi ZHANG
Open-vocabulary grounding requires accurate vision-language alignment under weak supervision, yet existing methods either rely on global sentence embeddings tha t lack fine-grained expressiveness or introduce token-level alignment with expli cit supervision or heavy cross-attention designs. We propose \textbf{ExpAlign}, a theoretically grounded vision-language alignment framework built on a principl ed multiple instance learning formulation. ExpAlign introduces an Expectation Al ignment Head that performs attention-based soft MIL pooling over token-region si milarities, enabling implicit token and instance selection without additional an notations. To further stabilize alignment learning, we develop an energy-based m ulti-scale consistency regularization scheme, including a Top-K multi-positive c ontrastive objective and a Geometry-Aware Consistency Objective derived from a L agrangian-constrained free-energy minimization. Extensive experiments show that ExpAlign consistently improves open-vocabulary detection and zero-shot instance segmentation, particularly on long-tail categories. Most notably, it achieves 36 .2 AP$_r$ on the LVIS minival split, outperforming other state-of-the-art method s at comparable model scale, while remaining lightweight and inference-efficient

Topology-Preserving Neural Operator Learning via Hodge Decomposition
Dongzhe Zheng, Tao Zhong, Christine Allen-Blanchette
In this paper, we study solution operators of physical field equations on geometric meshes from a function-space perspective. We reveal that Hodge orthogonality fundamentally resolves spectral interference by isolating unlearnable topological degrees of freedom from learnable geometric dynamics, enabling an additive approximation confined to structure-preserving subspaces. Building on Hodge theory and operator splitting, we derive a principled operator-level decomposition. The result is a Hybrid Eulerian-Lagrangian architecture with an algebraic-level inductive bias we call Hodge Spectral Duality (HSD). In our framework, we use discrete differential forms to capture topology-dominated components and an orthogonal auxiliary ambient space to represent complex local dynamics. Our method achieves superior accuracy and efficiency on geometric graphs with enhanced fidelity to physical invariants.

[CLS] is Not Enough: Multi-Label Recognition via Patch-Level Inference and Adaptive Aggregation
Akang Wang, Xili Deng, Zhanxuan Hu, Yi Zhao, Yonghang Tai, Huafeng Li
Vision-Language Models such as CLIP exhibit strong zero-shot recognition capability by aligning images with textual concepts, yet they often underperform on multi-label recognition where multiple objects co-exist. A key bottleneck is that the CLS token, as a single global visual representation, is insufficient to faithfully encode diverse targets with varying scales, contexts, and co-occurrence patterns. To address this limitation, we present a new multi-label image recognition framework, termed **PIAA**, which formulates prediction as ***P**atch-level **I**nference followed by **A**daptive **A**ggregation*. Specifically, we first enhance patch-wise predictions from two complementary perspectives: (i) mitigating semantic entanglement in the visual encoder to obtain more discriminative patch representations, and (ii) learning an unsupervised visual classifier to narrow the vision–language modality gap. We then introduce an adaptive aggregation module that consolidates patch-level scores into the final multi-label prediction. Notably, the entire pipeline is fully *Training-free*, requiring no gradient updates or parameter fine-tuning. Experiments show that our method achieves strong improvements with minimal extra computation, exceeding a 6\% mAP gain on the challenging NUS-WIDE benchmark over representative baselines.

Towards the Explainability of Temporal Graph Networks via Memory Backtracking and Topological Attribution
Yazheng Liu, Xi Zhang, Sihong Xie, Hui Xiong
Temporal graphs are ubiquitous in real-world applications and Temporal Graph Networks (TGNs) have achieved superior predictive accuracy.
Understanding which historical events drive
model predictions can enhance trustworthiness of TGNs. Existing explanation methods overlook the memory module, the core component that records and updates node histories, leaving the influence of past events unexplored. To address this, we attribute TGNs predictions through the topology attribution tree and memory backtracking tree. The topology attribution tree captures the influence of neighbors and their memory vectors, then the memory backtracking tree quantifies how historical events shape node memory vectors. We apply the LRP in TGNs,
ensuring that the total contribution of events equals the model’s logits. Finally, top-k selection may be unfaithful due to the nonlinear mapping from logits to probabilities, we design optimization objectives to identify the important events. Experiments on nine temporal graph datasets, spanning node property prediction, link prediction tasks and graph classification tasks, show that our method provides faithful explanations and outperforms state-of-the-art baselines. The code is available at https://github.com/yazhengliu/MemExplainer.
****
A Unifying View of Variational Generative Wasserstein Flows

Paul Caucheteux, Clément Bonet, Anna Korba
Many modern generative models can be viewed as minimizing divergences between pr
obability distributions, yet they rely on different algorithmic and geometric pr
inciples. Wasserstein gradient flows provide a continuous-time formulation for o
ptimizing over distributions, and can be approximated through their implicit dis
cretization via the Jordan–Kinderlehrer–Otto (JKO) scheme. In this work, we pres
ent a unified theoretical framework for generative modeling based on Wasserstein
 gradient flows, which we refer to as Generative Wasserstein Flows (GWF). We sho
w that a broad class of existing methods can be derived as instances of parametr
ic JKO schemes for f-divergence objectives, and we establish equivalences betw
een several recently proposed algorithms. We extend this framework beyond f-di
vergences to Integral Probability Metrics and squared Maximum Mean Discrepancy,
deriving new JKO-based generative algorithms, and clarifying their connections w
ith GANs. We study empirically the impact of the JKO regularization for a wide s
et of objectives. Finally, we analyze parametric Wasserstein flows, where the dy
namics are restricted to distributions induced by parametrized maps.

FedScar: Correcting Geometric Bias for Flatness-Consistent Federated Learning
Jianfeng Lu, YuZhao Xiang, Yue Chen, Gang Li, Shuqin Cao, Guanghui Wen
Federated Learning (FL) often suffers from degraded generalization under statist
ical heterogeneity, where client updates systematically deviate from the global
objective. While recent Sharpness-Aware Minimization (SAM) methods promote local
ly flat solutions, they implicitly assume that local flatness transfers to the g
lobal model, which generally does not hold under heterogeneous data distribution
s. This mismatch gives rise to a flatness discrepancy induced by misaligned loss
 landscapes. To address this issue, we propose FedScar, a federated optimization
 framework that explicitly corrects heterogeneityinduced geometric inconsistency
. FedScar maintains a history-accumulated geometric bias to capture persistent c
urvature skew across clients, and employs a variance-aware injection mechanism t
o steer local updates toward regions that are flat with respect to the global ob
jective. We provide a theoretical interpretation of FedScar as a Split-Dual ADMM
 formulation, which jointly enforces parameter consensus and geometric alignment
. Extensive experiments under severe heterogeneity demonstrate that FedScar cons
istently reduces flatness discrepancy and improves generalization over state-of-
the-art methods, without incurring additional communication overhead. The source
 code is available at https://github.com/Ultraman6/FedScar.

A Regime-Aware Trajectory Prediction Framework for 1000+ Systems Biology Models
Heng Rao, Jason Zipeng Zhang, Yu Gu, Zhenghao Liu, Ge Yu, Jeffrey Su, Yang Cao,
Fan Yang, Minghan Chen
Predicting long-horizon trajectories of biological dynamical systems remains cha
llenging due to substantial system heterogeneity.
Most existing machine learning approaches are system-specific, requiring retrain
ing for each new system and exhibiting limited generalization across distinct bi
ological regimes. To address this limitation, we create a large-scale benchmark
of over 1,000 ODE-based systems biology models spanning diverse organisms, biolo
gical processes, and dynamical behaviors. Building on this benchmark, we propose
 a regime-aware trajectory prediction framework that enables cross-system genera
lization and uncertainty quantification for unseen systems. Our approach introdu
ces structured initial states derived from biological regime priors, such as gro
wth trends and oscillatory rhythms, into conditional flow matching, replacing th
e standard Gaussian source distribution. We provide theoretical justification fo
r this initialization and empirically demonstrate state-of-the-art accuracy (31\
% MAE reduction), well-calibrated uncertainty (17\% CRPS improvement), and effic
ient long-horizon inference across the benchmark.

From Reward-Free Representations to Preferences: Rethinking Offline Preference-B
ased Reinforcement Learning
Jun-Jie Yang, Chia-Heng Hsu, Kui-Yuan Chen, Ping-Chun Hsieh
Preference-based reinforcement learning (PbRL) avoids explicit reward engineerin

g by learning from pairwise human preference feedback. Existing offline PbRL methods typically follow a two-stage pipeline, first learning a reward or preference model from labeled preferences and then performing offline RL on unlabeled data. We revisit offline PbRL through the lens of reward-free representation learning (RFRL) from the zero-shot RL literature, and propose a new training framework that first learns latent successor-measure representations from reward-free offline data, followed by contrastive search and fine-tuning using preference data. Through extensive experiments and ablations, we show that our method achieves superior preference efficiency over offline PbRL baselines. This work is the first to connect RFRL with PbRL, highlighting its potential as a feedback-efficient solution. Our code is publicly available at https://github.com/rl-bandits-lab/FB-PbRL.

VIA-SD: Verification via Intra-Model Routing for Speculative Decoding
Yuchen Xian, Yang He, Yunqiu Xu, Yi Yang
Speculative decoding (SD) addresses the high inference costs of LLMs by having lightweight drafters generate candidates for large verifiers to validate in parallel. Existing draft-verify methods use binary decisions: accept or fully recompute. Yet we find that many rejected tokens can be verified correctly by a slim submodel derived from the full verifier via intra-model routing, instead of the full verifier. This motivates our slim-verifier to handle tokens requiring moderate verification resources, reducing expensive large-model calls. We propose **V**erification via **I**ntr**a**-Model Routing for **S**peculative **D**ecoding (VIA-SD), a multi-tier framework using a routed slim-verifier. Draft tokens are processed hierarchically: direct acceptance for high-confidence cases, slim-verifier regeneration for medium-confidence cases, and full-model verification for uncertain cases. Across four representative tasks and multiple model families, VIA-SD reduces rejection rates by 0.10–0.22 and delivers 10–20% speedups over strong SD baselines, while achieving 2.5–3× acceleration over non-drafting decoding. Moreover, VIA-SD is compatible with existing SD frameworks without modifying their training procedures. Our results suggest multi-tier SD as a general paradigm for scalable and efficient LLM inference. Project page: https://zju-xyc.github.io/VIA-SD-Project-Page/

Any-Order GPT as Masked Diffusion Model: Decoupling Formulation and Architecture
Shuchen Xue, Tianyu Xie, Tianyang Hu, Zijin Feng, Jiacheng Sun, Kenji Kawaguchi, Zhenguo Li, Zhi-Ming Ma
Efficiently scaling Large Language Models (LLMs) necessitates exploring alternatives to dominant autoregressive (AR) methods, with Masked Diffusion Models (MDMs) emerging as candidates. However, comparing AR (typically decoder-only) and MDM (often encoder-only) paradigms is confounded by differing architectures, obscuring true algorithmic and efficiency trade-offs. This research decouples these factors by evaluating MDMs within a decoder-only framework to: (1) Equitably compare MDM (as Any-Order AR) and standard AR paradigms through discrepancies on orders. (2) Investigate MDM architectural impacts on computational efficiency. We show decoder-only MDMs, despite a larger modeling space, can achieve significant inference speedups ($\sim25\times$) and comparable perplexity with techniques like temperature annealing, offering a path to reduced inference compute. This work provides insights for developing more computationally efficient foundation models by disentangling core modeling choices from architectural influences. Code is available at \url{https://github.com/scxue/AO-GPT-MDM}.

FedReLa: Imbalanced Federated Learning via Re-Labeling
Guangzheng Hu, Patricia Menendez, Feng Liu, Mingming Gong, Guanghui Wang, Liuhua Peng
Federated learning has emerged as the foremost approach for decentralized model training with privacy preserving. The global class imbalance and cross-client data heterogeneity naturally coexist, and the mismatch between local and global imbalances exacerbates the performance degradation of the aggregated model. The agnosticism of global class distribution poses significant challenges for data-lev

el methods, especially under extreme conditions with severe class absence across clients. In this paper, we propose FedReLa, a novel data-level approach that tackles the coexistence of data heterogeneity and class imbalance in federated learning. By re-labeling samples with a feature-dependent label re-allocator, FedReLa corrects biased global decision boundaries without requiring knowledge of the global class distribution. This modular, model-agnostic approach can be integrated with algorithmic methods to deliver consistent improvements without additional communication overhead. Through extensive experiments, our method significantly improves the accuracy of minority classes and the overall accuracy on stepwise-imbalanced and long-tailed datasets, outperforming the previous state of the art.
****
f-Trajectory Balance: A Loss Family for Tuning GFlowNets, Generative Models, and LLMs with Off- and On-Policy Data
Jake Fawkes, Jason Hartford
In GFlowNets and variational inference, it has been shown that the mean square error between target and model log probabilities is an effective, low variance, surrogate loss for training generative models. This loss has the property that when evaluated \emph{on-policy} its gradients correspond to those of the KL divergence, while \emph{off-policy} it remains a valid loss with the same global minimiser. In this work, we demonstrate that this construction can be extended to the whole family of f-divergences, leading to a family of losses whose on-policy gradients are that of the corresponding f-divergence, but retain the same global minimiser off-policy. Specifically, we show that the on-policy gradients lead to a one to one correspondence between translation invariant loss functions on the target and model log probabilities, and f-divergences. This equivalence allows us to design new surrogate loss functions for tuning a wide class of generative models that inherit the properties of the corresponding f-divergence, such as being more mode covering, whilst being applicable to off-policy data. We apply our losses on a range of tasks, including classic synthetic examples, SynFloWNets for molecule discovery, and asynchronous large language model (LLM) tuning, demonstrating that our models retain their predicted properties on- and off-policy and can be applied to a wide class of generative models.
****
Saving Foundation Flow-Matching Priors for Inverse Problems
Yuxiang Wan, Ryan Devera, Wenjie Zhang, Ju Sun
Foundation flow-matching (FM) models promise universal priors for solving inverse problems (IPs); yet today, they trail behind domain-specific and even untrained priors. \emph{How can we unlock their potential?} We introduce FMPlug, a plug-in framework that redefines how foundation FMs are used in IPs. FMPlug combines an instance-guided, time-dependent warm-start strategy with sharp Gaussianity regularization, adding problem-specific guidance while preserving the Gaussian structures. For evaluation, we consider both simple image restoration tasks and scientific IPs with a few similar samples---where the prohibitive cost of data collection and model training hinders the development of domain-specific generative models. Our superior experimental results confirm the effectiveness of FMPlug. Overall, FMPlug paves the way for making foundation FM models practical, reusable priors for IPs, especially scientific ones with few similar samples.
****
Scaling Vision Transformers for Functional MRI with Flat Maps
Connor Lane, Mihir Tripathy, Leema Krishna Murali, Ratna Sagari Grandhi, Shamus Sim Zi Yang, Sam Gijsen, Debojyoti Das, Manish Ram, Utkarsh Kumar Singh, Cesar Kadir Torrico Villanueva, YUXIANG WEI, Will Beddow, Gianfranco Cortes, Suin Cho, Daniel Z Kaplan, Benjamin Warner, Tanishq Mathew Abraham, Paul Steven Scotti
We study the problem of training self-supervised foundation models for functional MRI. Our main contributions are: (1) we introduce a new model family (CortexMAE) trained using the masked autoencoder framework on 2.1K hours of open fMRI data, and (2) we release the first open evaluation suite (Brainmarks) for fMRI foundation models. Our core innovation is simple: we adapt the Vision Transformer to fMRI by first converting each 3D fMRI volume to a 2D map using a cortical flat

map projection. We directly compare flat maps to both parcellation and volume-ba
sed representations. While each has its advantages, flat maps generally perform
best. We perform the first systematic scaling analysis for fMRI and observe stri
ct power law scaling, albeit with limits. Finally, we use Brainmarks to do contr
olled benchmark comparisons. On subject-level trait prediction, we report a chal
lenging null result: no single model achieves clear state-of-the-art performance
. Moreover, all models struggle to outperform a simple functional connectivity b
aseline. On cognitive state decoding, we observe more robust performance, and in
 this setting our CortexMAE family outperforms prior models by a large margin. C
ode, models, and datasets are available at https://github.com/MedARC-AI/CortexMA
E and https://github.com/MedARC-AI/Brainmarks.
****

NaRA: Noise-Aware LoRA for Parameter-Efficient Fine-Tuning of Diffusion LLMs
Shuaidi Wang, Zhan Zhuang, HUANG Ruping, Yu Zhang
Diffusion Large Language Models (dLLMs) have emerged as a promising non-autoregr
essive generative paradigm. Given the prohibitive computational cost of full fin
e-tuning, Parameter-Efficient Fine-Tuning (PEFT) has become the standard approac
h. However, existing PEFT methods (e.g., LoRA), originally tailored for autoregr
essive models, rely on static parameters that are agnostic to the noise level. C
onsequently, they ignore the intrinsic dynamics of the diffusion process, where
input distributions and generation difficulty shift significantly along the deno
ising trajectory, rendering them suboptimal for dLLMs. To address this, we propo
se **N**oise-**a**ware Low-**R**ank
Adaptation (NaRA), which introduces a low-rank core matrix generated by a li
ghtweight, globally shared hypernetwork conditioned on the noise level. This des
ign enables the update matrices to vary continuously along the diffusion process
 while keeping parameter and latency overhead negligible. We provide a theoretic
al justification for the proposed NaRA framework and empirically demonstrate con
sistent improvements over noise-agnostic baselines across commonsense reasoning,
 mathematical reasoning, and code generation benchmarks. Our code is available a
t https://github.com/generaldi/NaRA.

Robust In-Context Reinforcement Learning Under Reward Poisoning Attacks
Paulius Sasnauskas, Yi■it Yal■n, Goran Radanovic
We study the corruption-robustness of in-context reinforcement learning (ICRL),
focusing on the Decision-Pretrained Transformer (DPT, Lee et al., 2023). To addr
ess the challenge of reward poisoning attacks targeting the DPT, we propose a no
vel adversarial training framework, called Adversarially Trained DPT (AT-DPT). O
ur method simultaneously trains a population of attackers to minimize the true r
eward of the DPT by poisoning environment rewards, and a DPT model to infer opti
mal actions from the poisoned data. We evaluate the effectiveness of our approac
h against standard bandit algorithms, including robust baselines designed to han
dle reward contamination. Our results show that AT-DPT significantly outperforms
 them in bandit settings under a learned attacker, and generalizes to more compl
ex environments such as adaptive attackers and MDPs. It shows promise in ICRL as
 a meta-RL approach to learning effective corruption-robust algorithms.
****

Zeroth-Order Optimization at the Edge of Stability
Minhak Song, Liang Zhang, Bingcong Li, Niao He, Michael Muehlebach, Sewoong Oh
Zeroth-order (ZO) methods are widely used when gradients are unavailable or proh
ibitively expensive, including black-box learning and memory-efficient fine-tuni
ng of large models, yet their optimization dynamics in deep learning remain unde
rexplored. In this work, we provide an explicit step size condition that exactly
 captures the (mean-square) linear stability of a family of ZO methods based on
the standard two-point estimator. Our characterization reveals a sharp contrast
with first-order (FO) methods: whereas FO stability is governed solely by the la
rgest Hessian eigenvalue, mean-square stability of ZO methods depends on the ent
ire Hessian spectrum. Since computing the full Hessian spectrum is infeasible in
 practical neural network training, we further derive tractable stability bounds
 that depend only on the largest eigenvalue and the Hessian trace. Empirically,

we find that full-batch ZO methods operate at the edge of stability: ZO-GD, ZO-GDM, and ZO-Adam consistently stabilize near the predicted stability boundary across CNNs, ResNets, and Transformers on vision tasks. Our results highlight an implicit regularization effect specific to ZO methods, where large step sizes primarily regularize the Hessian trace, whereas in FO methods they regularize the top eigenvalue.

Coverage Improvement and Fast Convergence of On-policy Preference Learning

Juno Kim, Jihun Yun, Jason D. Lee, Kwang-Sung Jun

On-policy preference learning algorithms for language model alignment such as online direct policy optimization (DPO) can significantly outperform their offline counterparts. We provide a theoretical explanation for this phenomenon by analyzing how the sampling policy's coverage evolves throughout on-policy training. We propose and rigorously justify the coverage improvement principle: with sufficient batch size, each update moves into a region around the target where coverage is uniformly better, making subsequent data increasingly informative and enabling rapid convergence. In the contextual bandit setting with Bradley-Terry preferences and linear softmax policy class, we show that on-policy DPO converges exponentially in the number of iterations for batch size exceeding a generalized coverage threshold. In contrast, any learner restricted to offline samples from the initial policy suffers a slower minimax rate, leading to a sharp separation in total sample complexity. We further propose a hybrid sampler based on a novel preferential G-optimal design, which removes dependence on coverage and guarantees convergence in just two rounds. Finally, we develop principled on-policy schemes for reward distillation which achieve faster noiseless rates. Experimentally, we confirm that on-policy DPO and our proposed reward distillation algorithms outperform their off-policy counterparts and enjoy stable gains across iterations.

****

Structure-Aware Riemannian Flow Matching for Registration and Fusion of Hyperspectral and Multispectral Images

Quan Zhang, Jun Li, Weilong Zhu, MINGYANG LI, Qinmu Shen, Yuanxi Peng

Precise alignment is a prerequisite for hyperspectral and multispectral image fusion, yet existing methods struggle with complex non-rigid deformations. Existing techniques either suffer from inter-task error accumulation by treating registration and fusion as disjoint processes or neglect the geometric nature of distortions by relying on isotropic Euclidean metrics. We propose Structure-Aware Riemannian Flow Matching (SA-RFM), a geometry-informed framework for joint registration and fusion of hyperspectral and multispectral images. SA-RFM reformulates registration as dynamic optimal transport on a structure-induced Riemannian manifold, where anisotropic costs are derived from MSI structural cues. To circumvent the complexity of explicit OT solvers, we incorporate this geometry into a conditional flow matching framework via a local cost approximation. This formulation is realized through two synergistic mechanisms: a Riemannian Flow Matching objective that enforces structure-aware error measurement, and an optimal transport direction regularization that aligns the velocity field with the induced metric, thereby resolving the fundamental mismatch between anisotropic costs and conventional Euclidean supervision. Extensive experiments on four datasets demonstrate the superiority of our method. Code is available at: https://github.com/ZhangQuan-hub.

Concept Removal for Frontier Image Generative Models

Aditya Kumar, Pierre Joly, Adam Dziedzic, Franziska Boenisch

Image generative models are trained on massive, largely uncurated internet-scale datasets that contain undesirable visual concepts. Efficiently removing such concepts from the model generations without degrading the quality of output images remains challenging. We introduce a novel concept removal method for frontier diffusion and image autoregressive models, such as, SD3.5, Flux, and Infinity. Our intervention replaces the internal bottleneck layer present in all these modern models with a transcoder that is trained to replicate the original layer while

structuring it into distinct activation features. This in■place substitution cr
eates an integrated filter through which concept■specific signals can be selecti
vely disabled while preserving the rest of the model’s behavior. Since the inter
vention modifies the model backbone rather than attaching an external component,
it remains persistent under white■box access. Empirically, the approach achieve
s state■of■the■art concept removal performance across modern diffusion and autor
egressive models, maintains visual generation quality, provides robustness again
st adversarial prompts, and supports sequential removal of diverse concepts. Thi
s positions our method as a practical approach for concept removal in frontier i
mage generative models.

Towards Feedback-to-Plan Decisions for Self-Evolving LLM Agents in CUDA Kernel G
eneration

Yee Hin Chong, Jiaming Wu, Youhui Zhang, Peng Qu

Large language models (LLMs) have shown strong empirical gains as self-evolving
agents for CUDA kernel generation, driven by feedback-conditioned planning acros
s generations. However, how planning decisions attribute and combine heterogeneo
us feedback signals remains opaque. Standard end-to-end ablations fail to resolv
e this question, as iterative planning amplifies early perturbations and conflat
es feedback effects with trajectory-dependent drift.

We introduce \texttt{CUDAnalyst}, a unified analysis layer for controlled, gener
ation-level attribution of planning decisions to feedback components via traject
ory freezing and selective feedback injection. \texttt{CUDAnalyst} enables stabl
e generation-level evaluation and principled coalitional-style attribution of fe
edback effects and interactions. Our results show that explicit planning is bene
ficial only when feedback is aligned, that effective planning emerges from struc
tured multi-feedback interactions, and that high-level plans from stronger reaso
ning models can partially transfer to weaker ones. These trends hold across refe
rence backbones, representative workloads, and reference induction regimes, indi
cating that the identified feedback-to-plan structure is robust within the contr
olled axes studied.

A Game-Theoretic Analysis of Attacks on Large Language Models via Compositional
Skills

Xinbo Wu, Huan Zhang, Abhishek Umrawal, Lav R. Varshney

As large language models grow increasingly capable, concerns about their safe de
ployment have intensified. While numerous alignment strategies aim to restrict h
armful behavior, these defenses can still be circumvented through carefully desi
gned adversarial prompts. In this work, we introduce a theoretical framework tha
t formalizes a game between an attacker hiding its intent via compositional skil
ls and a defender. Within this framework, we design a theoretical best-response
attack strategy and show that it is closely related to many existing adversarial
prompting methods. We further analyze the resulting game, characterize its equi
libria, and reveal inherent advantages for the attacker. Drawing on our theoreti
cal analysis, we also derive a provably optimal defense strategy. Empirically, w
e evaluate a practical instantiation of the theoretically optimal attack and obs
erve stronger performance relative to existing adversarial prompting approaches
in diverse settings encompassing different LLMs and benchmarks.

CircuitPrint: Mechanistic Circuit Fingerprints for Large Language Models

Zhenxiong Yan, Suhang Yao, Yu Liu, Wenqiang Jin

Large language models (LLMs) are trained at significant computational and data c
ost, making them valuable intellectual property (IP). Existing IP verification m
ethods primarily rely either on invasive watermarking that degrades model utilit
y, or on superficial behavioral signatures disrupted by fine-tuning and model me
rging. This apparent trade-off between model utility and IP protection has const
rained practical deployment. We challenge this trade-off and propose CircuitPrin
t, a non-invasive IP fingerprinting framework that enables robust verification t
hrough standard model queries by leveraging stable internal computational circui

ts of LLMs. We show that these circuits function as a persistent computational b
ackbone across model derivatives, allowing them to serve as stable fingerprints
for distinguishing LLMs. Building on this stability, CircuitPrint constructs IP
signatures by identifying mechanistically essential supernodes that causally pro
duce specific predictions within these circuits. Specifically, trigger queries a
re synthesized to replicate the internal suppression of these supernodes, thereb
y inducing distinctive and observable output shifts. Experimental results demons
trate that CircuitPrint substantially outperforms existing baselines while remai
ning robust under aggressive fine-tuning and model merging, effectively resolvin
g this trade-off without altering model parameters.

Ramba: Selective State-Space Models for Relational Deep Learning
Yiming Liu, Chunyu Wei, Haozhe Lin, Fengjun Xiao, Junqi Zhang, Yunhai Wang, Yueg
uo Chen
Relational Deep Learning aims to learn directly on multi-table databases, yet cu
rrent methods face a fundamental tension: Transformers' quadratic complexity pro
hibits the large contexts relational data demands, while GNNs sacrifice global c
ontext for efficiency. We introduce Ramba, the first selective state-space model
for relational databases. Our approach features two innovations: (1) Topology-A
ware Linearization, which processes cells via global columnar serialization in O
(L) complexity while recovering relational structure through sparse entity and f
oreign-key attention masks; and (2) Schema Dynamic Gating, which modulates SSM s
tate transitions based on semantic alignment between the currently scanned attri
bute and the prediction target, enabling cross-table relevance filtering without
relying on value distributions. Together, these enable Ramba to ingest vast rel
ational contexts while selectively retaining semantically relevant information,
a combination existing architectures cannot achieve. Experiments demonstrate sta
te-of-the-art performance with linear scalability across diverse relational benc
hmarks.

Zero-source LLM Hallucination Detection with Human-like Criteria Probing
Jiahao Yang, Shuhai Zhang, Hailong Kang, Feng Liu, Qi Chen, Mingkui Tan
Large language models (LLMs) often hallucinate by generating factually incorrect
or unfaithful content, posing significant risks to their safe use. Detecting su
ch hallucinations is particularly challenging under the zero-source constraint,
where no model internals or external references are available, and detection mus
t rely solely on the textual query–answer pair. In this paper, we propose Human
-like Criteria Probing for Hallucination Detection (HCPD), a paradigm that emula
tes the multi-faceted reasoning of human evaluators. Its core is a Human-like Cr
iteria Probing (HCP) mechanism, in which a LLM agent adaptively decomposes its j
udgment into a weighted set of interpretable criteria and aggregates criterion-s
pecific scores into a final truthfulness measure. To achieve this adaptive capab
ility, we introduce a reward-based alignment scheme using only weak supervision
from semantic consistency. At inference, we employ a multi-sampling aggregation
strategy to ensure robust decisions while preserving full interpretability. We f
urther provide theoretical analysis supporting the reliability of our approach.
Extensive experiments show that HCPD consistently outperforms state-of-the-art b
aselines, offering an effective and explainable solution for zero-source halluci
nation detection.

From Observations to States: Latent Time Series Forecasting
Jie Yang, Yifan Hu, Yuante Li, Kexin Zhang, Kaize Ding, Philip S. Yu
Deep learning has achieved strong performance in Time Series Forecasting (TSF).
However, we identify a critical representation paradox, termed Latent Chaos: mod
els with accurate predictions often learn latent representations that are tempor
ally disordered and lack continuity. We attribute this to the dominant observati
on-space forecasting paradigm, where minimizing point-wise errors on noisy and p
artially observed data encourages shortcut solutions instead of the recovery of
underlying system dynamics. To address this, we propose Latent Time Series Forec
asting (LatentTSF), a paradigm that shifts TSF from observation regression to la

tent state prediction. LatentTSF employs an AutoEncoder to project each observation into a learned latent state space and performs forecasting entirely in this space, allowing the model to focus on learning structured temporal dynamics. We provide an information-theoretic analysis showing that the latent objectives can be motivated as surrogates for maximizing mutual information between predicted and ground-truth latent states and future observations. Extensive experiments on widely-used benchmarks confirm that LatentTSF effectively mitigates latent chaos, yielding consistent improvements in both forecasting accuracy and representation quality. Our code is available at https://github.com/Muyiiiii/LatentTSF.

Instance-Specific Approximation Ratios for Correlation Clustering and Max-Cut
Sebastian Lüderssen, Ioana-Oriana Bercea, Stefan Neumann
For many NP-hard optimization problems, strong theoretical inapproximability results exist. However, in practice, heuristics regularly outperform these pessimistic worst-case results on real-world datasets. Assessing the quality of these algorithms' outputs is often difficult since we lack good lower bounds on the optimal solution. In this paper, we present efficient algorithms for computing lower bounds on the optimal solutions for correlation clustering, which is a popular problem in social-network analysis. Our lower bounds allow us to provide empirical certificates that bound the solution quality of practical algorithms by obtaining instance-specific approximation ratios. Our main technical contribution is an algorithm that approximates an LP relaxation of a related triangle covering problem in near-linear time on sparse graphs; the algorithm is based on the multiplicative weights update framework and runs on graphs with millions of edges in a few minutes. For the concrete problem of correlation clustering, our lower bounds certify that state-of-the-art heuristics achieve almost optimal approximation ratios of 0.94 for the agreement version and 1.97 for the disagreement version (averaged over 7 real-world datasets). We also show similar results for the fundamental max-cut problem.

Detecting Perspective Shifts in Multi-Agent Systems
Eric W Bridgeford, Hayden Helm
Generative models augmented with external tools and update mechanisms (or *agents*) have demonstrated capabilities beyond intelligent prompting of base models. As agent use proliferates, dynamic multi-agent systems have naturally emerged. Recent work has investigated the theoretical and empirical properties of low-dimensional representations of agents based on query responses at a single time point. This paper introduces the Temporal Data Kernel Perspective Space (TDKPS), which jointly embeds agents across time, and proposes several novel hypothesis tests for detecting behavioral change at the agent- and group-level in black-box multi-agent systems. We characterize the empirical properties of our proposed tests, including their sensitivity to key hyperparameters, in simulations motivated by a multi-agent system of evolving digital personas. Finally, we demonstrate via natural experiment that our proposed tests detect changes that correlate sensitively, specifically, and significantly with a real exogenous event. TDKPS is the first principled framework for monitoring behavioral dynamics in black-box multi-agent systems -- a critical capability as generative agent deployment continues to scale.

TWLA: Achieving Ternary Weights and Low-Bit Activations for LLMs via Post-Training Quantization
Zhixiong Zhao, Zukang Xu, Zhixuan Chen, Xing Hu, Zhe jiang, Dawei Yang
Large language models (LLMs) exhibit exceptional general language processing capabilities, but their memory and compute costs hinder deployment. Ternarization has emerged as a promising compression technique, offering significant reductions in model size and inference complexity. However, existing methods struggle with heavy-tailed activation distributions and therefore keep activations in high precision, fundamentally limiting end-to-end inference acceleration.
To overcome this limitation, we propose **TWLA**, a post-training quantization (

PTQ) framework that achieves 1.58-bit weight compression and 4-bit activation qu
antization while maintaining high accuracy. TWLA comprises three components: (1)
 Euclidean-to-Manifold Asymmetric Ternary Quantizer (E2M-ATQ) minimizes layer-ou
tput error under weight ternarization via a two-stage optimization from Euclidea
n initialization to manifold relocation; (2) Kronecker Orthogonal Tri-Modal Shap
ing (KOTMS) applies a Kronecker-structured orthogonal rotation to reshape weight
s into ternary-friendly tri-modal distributions, while the shared rotation stati
stically suppresses activation outliers; and (3) Inter-Layer Aware Activation Mi
xed Precision (ILA-AMP) explicitly introduces adjacent-layer second-order intera
ction costs in bit allocation and jointly optimizes for the layer-wise disparity
 of activation quantization gains induced by the shared orthogonal transform, pr
eventing cascades triggered by a few weak layers.
Extensive experiments demonstrate that TWLA is a PTQ method that maintains high
accuracy under the **W1.58A4** configuration, while delivering significant infer
ence acceleration. The code is available at [TWLA](https://github.com/Kishon-zzx
/TWLA).

Turning Stale Gradients into Stable Gradients: Coherent Coordinate Descent with Implicit Landscape Smoothing for Lightweight Zeroth-Order Optimization
Chen Liang, Xiatao Sun, Qian Wang, Daniel Rakita
Zeroth-Order (ZO) optimization is pivotal for scenarios where backpropagation is
 unavailable, such as memory-constrained on-device learning and black-box optimi
zation. However, existing methods face a stark trade-off: they are either sample
-inefficient (e.g., standard finite differences) or suffer from high variance du
e to randomized estimation (e.g., random subspace methods). In this work, we pro
pose Coherent Coordinate Descent (CoCD), a deterministic, sample-efficient, and
budget-aware ZO optimizer. Theoretically, we formalize the notion of gradient co
herence and demonstrate that CoCD is equivalent to Block Cyclic Coordinate Desce
nt (BCCD) with ``warm starts,'' effectively converting historical (stale) gradie
nts from a liability into a computational asset. This mechanism enables $O(1)$ q
uery complexity per step while maintaining global descent directions. Furthermor
e, we derive error bounds revealing a counter-intuitive insight: larger finite-d
ifference step sizes can induce an implicit smoothing effect on the optimization
 landscape by reducing the effective smoothness constant, thereby improving conv
ergence stability. Experiments on MLP, CNN, and ResNet architectures (up to 270
k parameters) demonstrate that CoCD significantly outperforms BCCD in terms of s
ample efficiency and convergence loss/accuracy, and exhibits superior stability
over randomized ZO methods. Our results suggest that deterministic, structure-aw
are updates offer a superior alternative to randomization for lightweight ZO opt
imization.

Sonar-TS: Search-Then-Verify Natural Language Querying for Time Series Databases
Zhao Tan, Yiji Zhao, Shiyu Wang, Chang Xu, Yuxuan Liang, Xiping Liu, Shirui Pan,
 Ming Jin
Natural Language Querying for Time Series Databases (NLQ4TSDB) aims to assist no
n-expert users retrieve meaningful events, intervals, and summaries from massive
 temporal records.
However, existing Text-to-SQL methods are not designed for continuous morphologi
cal intents such as shapes or anomalies, while time series models struggle to ha
ndle ultra-long histories.
To address these challenges, we propose Sonar-TS, a neuro-symbolic framework tha
t tackles NLQ4TSDB via a "Search-Then-Verify" pipeline.
Analogous to active sonar, it utilizes a feature index to "ping'' candidate wind
ows via SQL, followed by generated Python programs to "lock on'' and verify cand
idates against raw signals.
To enable effective evaluation, we introduce NLQTSBench, the first large-scale b
enchmark designed for NLQ over TSDB-scale histories.
Our experiments highlight the unique challenges within this domain and demonstra
te that Sonar-TS effectively navigates complex temporal queries where traditiona
l methods fail.

This work presents the first systematic study of NLQ4TSDB, offering a general fr
amework and evaluation standard to facilitate future research.

General Analysis of LMO-based Optimizers: Beyond Bounded Variance
Egor Shulgin, Mohamed Awad, Peter Richtárik, Eduard Gorbunov
We study a broad family of momentum *Linear Minimization Oracle* (LMO) methods t
hat includes normalized SGD with momentum, sign-based (Adam-like) directions, an
d Muon (spectral) updates. Our focus is on subsampling regimes where the classic
al uniformly-bounded-variance model can be fragile even for finite-sum objective
s on unbounded domains. To obtain subsampling-faithful guarantees, we analyze th
is LMO family under *expected smoothness* (ABC condition), which captures common
 sampling schemes. We establish a unified nonconvex convergence theory via a new
 self-bounding closure that handles the history-coupling induced by momentum und
er ABC. Our bounds recover known bounded-variance results as a special case and
simplify in strong-growth regimes. Specializing to τ-nice sampling, we deri
ve explicit batch-size scaling laws, predicting that the optimal momentum must i
ncrease with the batch size to maximize sample efficiency. We further identify a
 theoretical **optimal batch size** that minimizes total sample complexity. Expe
riments on linear and matrix regression corroborate these predictions, showing a
 distinct diagonal shift in the optimal momentum-batch landscape that matches ou
r theoretical scaling.

Many-Shot CoT-ICL: Making In-Context Learning Truly Learn
Tsz Ting Chung, Lemao Liu, Mo Yu, Dit-Yan Yeung
While many-shot ICL achieves remarkable performance, prior studies of its scalin
g behavior have mainly focused on non-reasoning tasks. In this work, we study ma
ny-shot ICL on reasoning tasks, with a particular focus on many-shot chain-of-th
ought in-context learning (CoT-ICL). Analyzing across non-reasoning and reasonin
g tasks and across non-reasoning and reasoning-oriented LLMs, we identify severa
l distinctive properties of many-shot CoT-ICL. We further interpret these findin
gs by viewing many-shot CoT-ICL as in-context test-time learning rather than sca
led pattern matching, and suggest two principles: (i) demonstrations should be e
asy for the target model to understand, and (ii) they should be ordered to suppo
rt a smooth conceptual progression. Guided by the principle, we propose Curvilin
ear Demonstration Selection (CDS), a simple ordering method that yields up to a
5.42 percentage-point gain on a math task with 64 demonstrations. Overall, our r
esults reframe the long context window from a retrieval buffer into a structured
 curriculum for in-context test-time learning.

d3LLM: Ultra-Fast Diffusion LLM using Pseudo-Trajectory Distillation
Yu-Yang Qian, Junda Su, Lanxiang Hu, Peiyuan Zhang, Zhijie Deng, Peng Zhao, Hao
Zhang
Diffusion large language models (dLLMs) offer capabilities beyond those of autor
egressive (AR) LLMs, such as parallel decoding and random-order generation. Howe
ver, realizing these benefits in practice is non-trivial, as dLLMs inherently fa
ce an *accuracy-parallelism trade-off*. Despite increasing interest, existing me
thods typically focus on only one-side of the coin, targeting either efficiency
or accuracy. To address this limitation, we propose d3LLM (*Pseudo-Distilled Dif
fusion Large Language Model*), striking a balance between accuracy and paralleli
sm: (i) during training, we introduce *pseudo-trajectory distillation* to teach
the model which tokens can be decoded confidently at early steps, thereby improv
ing parallelism; (ii) during inference, we employ *entropy-based multi-block dec
oding* with a KV-cache refresh mechanism to achieve high parallelism while maint
aining accuracy. To better evaluate dLLMs, we also introduce AUP (*Accuracy Unde
r Parallelism*), a new metric that jointly measures accuracy and parallelism. Ex
periments demonstrate that our d3LLM achieves up to $10\times$ speedup over vani
lla LLaDA/Dream, and $5\times$ speedup over AR models without much accuracy drop
. Our code is available at https://github.com/hao-ai-lab/d3LLM.

Controllable Molecule Generation via Sparse Representation Editing: An Interpret

ability-Driven Perspective
Zhuoran Li, Xu Sun, Chang Wen Chen, Wanyu Lin
Controllable molecule generation is crucial for diverse scientific applications, such as drug discovery and materials design. While large language models (LLMs) show great promise, their dense and entangled representations impede precise control over the generation of molecules with bespoke substructures or properties. To address this, we propose Sparse Representation Editing (SpaRE), an interpretability-driven framework for fine-grained and precise control in LLM-based molecule generation. The crux of SpaRE is to learn an overcomplete sparse feature space that disentangles LLM representations into a compact set of latent features corresponding to chemically meaningful concepts. Within this space, we can directly manipulate these concept-aligned latent features to achieve (1) local control, by generating target atoms and functional groups at specified positions; and (2) global control, by customizing the overall structural and physicochemical properties within defined ranges. In this way, our framework advances interpretability from post-hoc analysis to actionable generative control. Experiments show that SpaRE can generate chemically desirable molecules under complex constraints in real-world scenarios, while offering mechanistic insights for quantitative structure–property analysis. The code and demo are available at https://github.com/WanyuGroup/ICML2026_SpaRE.

The Optimal Sample Complexity of Linear Contracts
Mikael Møller Høgsgaard
In this paper, we settle the problem of learning optimal linear contracts from data in the offline setting, where agent types are drawn from an unknown distribution and the principal's goal is to design a contract that maximizes her expected utility. Specifically, our analysis shows that the simple Empirical Utility Maximization (EUM) algorithm yields an ε-approximation of the optimal linear contract with probability at least $1-\delta$, using just $O(\ln(1/\delta) / \varepsilon^2)$ samples. This result improves upon previously known bounds and matches a lower bound from (Dütting et al., 2025) up to constant factors, thereby proving its optimality.
Furthermore, our result establishes the stronger guarantee of uniform convergence: the empirical utility of every linear contract is a ε-approximation of its true expectation with probability at least $1-\delta$, using the same optimal $O(\ln(1/\delta) / \varepsilon^2)$ sample complexity.
****
Revisiting Parameter-Based Knowledge Editing in Large Language Models: Theoretical Limits and Empirical Evidence
Wanying Ren, Xin Song, Futing Wang, Guoxiu He, Aixin Sun
Parameter-based knowledge editing updates the internal knowledge of large language models (LLMs) via localized weight modifications and has attracted significant attention.
However, most existing methods overlook fundamental theoretical limitations and are rarely evaluated under realistic, practice-oriented settings.
In this paper, we first present a theoretical analysis based on the dimensional Collapse Hypothesis, explaining how localized parameter edits can propagate along fragile directions in the representation space, inducing global interference and ultimately causing reasoning collapse.
Building on this insight, we conduct a comprehensive empirical evaluation by systematically varying knowledge complexity, number of edits, evaluation dimensions, and baseline methods.
Our results show that parameter-based editing methods consistently damage core LLM capabilities.
In contrast, a simple retrieval-based baseline achieves consistently stronger performance than all parameter-editing methods across all evaluated conditions.
These findings highlight that preserving the fundamental capabilities of LLMs after knowledge editing should be a central concern for future research.
****
Action-Sufficient Goal Representations

Jinu Hyeon, Woobin Park, Hongjoon Ahn, Taesup Moon
Hierarchical policies in offline goal-conditioned reinforcement learning (GCRL) addresses long-horizon tasks by decomposing control into high-level subgoal planning and low-level action execution. A critical design choice in such architectures is the goal representation—the compressed encoding of goals that serves as the interface between these levels. Existing approaches commonly derive goal representations while learning value functions, implicitly assuming that preserving information sufficient for value estimation is adequate for optimal control. We show that this assumption can fail, even when the value estimation is exact, as such representations may collapse goal states that need to be differentiated for action learning. To address this, we introduce an information-theoretic framework that defines *action sufficiency*, a condition on goal representations necessary for optimal action selection. We prove that value sufficiency does not imply action sufficiency and empirically verify that the latter is more strongly associated with control success in a discrete environment. We further demonstrate that standard log-loss training of low-level policies naturally induces action-sufficient representations. Our experimental results a popular benchmark demonstrate that our actor-derived representations consistently outperform representations learned via value estimation.
****
Closing the Sim-to-Real Gap in Non-Markovian Spreading Processes via GPU-Accelerated Distributional RL
Heman Shakeri
Controlling spreading processes on networks, such as epidemics,
information cascades, and product adoption, requires policies that perform
on realistic stochastic dynamics, not just tractable approximations. Yet policies trained on standard simplifications (mean-field ODEs, Markovian dynamics) suffer severe performance degradation at deployment. We trace this sim-to-real gap to three theoretical pathologies: Optimism Bias, where deterministic approximations systematically underestimate variance via Jensen's inequality; Hub Blindness, where global state aggregation obscures the super-spreaders driving scale-free networks; and the Valley of Death, where mean-value critics fail to navigate the bimodal nature (extinction vs. viral) of cascade outcomes. We resolve these challenges through two synergistic contributions. First, the Stratified Mean-Field Observer partitions nodes by influence tier, preserving hub dynamics at $O(N)$ cost while producing fixed-dimensional observations that enable zero-shot transfer across network scales and topologies. Second, we show that distributional RL via Truncated Quantile Critics improves risk-aware control of bimodal cascades. Trained on a GPU-accelerated simulator supporting non-Markovian renewal dynamics, our approach achieves $59\times$ improvement over Markovian baselines and robust zero-shot transfer to real-world social networks (Facebook, Twitter, YouTube), significantly mitigating the simulation-to-reality gap.
****
PACE: Post-Causal Entropy Modeling for Learned LiDAR Point Cloud Compression
Jiahao Zhu, Kang You, Dandan Ding, Zhan Ma
LiDAR point cloud compression is vital for autonomous systems to handle massive data from high-resolution sensors. While learned entropy modeling built upon octree structures yields high compression gains, it faces two critical bottlenecks: 1) prohibitive latency, particularly during decoding, caused by causal, multi-stage context modeling; and 2) a rigid performance-latency trade-off, preventing a single model from adapting to varying constraints. These limitations stem from the tight coupling between the context aggregation backbone and probability prediction. To address this, we propose PACE, a new framework that reformulates ancestral context aggregation as a non-causal backbone and confines causality to a lightweight, stage-scalable predictor, eliminating repetitive backbone executions and reducing computational overhead. The predictor supports an arbitrary number of prediction stages, enabling seamless adaptation across diverse performance-latency trade-offs without reloading parameters. Experiments demonstrate that PACE sets a new state-of-the-art in compression efficiency, achieving notable BD-BR savings and reducing decoding latency by over 90\% in autoregressive mode, mak

ing it attractive for practical applications.
****
Towards Understanding Massive Activations in Attention Sink Mechanism
Haiyu Wang, Yuanyuan Lin
Recent studies have revealed two intriguing phenomena in large language models: attention sinks and massive activations. However, the co-emergence and co-existence of these two phenomena remain poorly understood. In this work, we revisit the prevailing view that massive activations are the primary mechanism responsible for concentrating attention on sink tokens, and provide a more nuanced interpretation of their relationship. Through both theoretical analysis and empirical evidence, we demonstrate that massive activations and attention sinks jointly act to prevent excessive token mixing in self-attention. Specifically, attention sinks suppress mixing among non-sink tokens, whereas massive activations suppress mixing between sink tokens and non-sink tokens. Furthermore, our theory provides a principled explanation of how KV-biases, gating mechanisms, and normalization layers can remove massive activations while largely preserving attention sinks. We further conduct intervention analyses and find that removing the value vector of the sink token can recover attention sinks even when massive activations are entirely suppressed. Overall, this work provides a mechanistic perspective on how massive activations and attention sinks interact under normalization and self-attention layers, offering new insights into their functional roles in Transformer models.
****
Provable Training Data Identification for Large Language Models
Zhenlong Liu, Hao Zeng, Weiran Huang, Hongxin Wei
Identifying training data of large-scale models is critical for copyright litigation, privacy auditing, and ensuring fair evaluation. However, existing works typically treat this task as an instance-wise identification without controlling the error rate of the identified set, which cannot provide statistically reliable evidence. In this work, we formalize training data identification as a set-level inference problem and propose Provable Training Data Identification (PTDI), a distribution-free approach that enables provable and strict false identification rate control. Specifically, our method computes conformal p-values for each data point using a set of known unseen data and then develops a novel Jackknife-corrected Beta boundary (JKBB) estimator to estimate the training-data proportion of the test set, which allows us to scale these p-values. By applying the Benjamini–Hochberg (BH) procedure to the scaled p-values, we select a subset of data points with provable and strict false identification control. Extensive experiments across various models and datasets demonstrate that PTDI achieves higher power than prior methods while strictly controlling the FIR.

Decentralized and Disentangled Task–Role Representation Learning for Generalizable Offline Multi-Agent Meta Reinforcement Learning
Lei Yuan, Ruiqi Xue, Yang Yu
Offline meta reinforcement learning (RL) enables agents to learn a unified policy from multi-task offline data to support generalization in out-of-distribution (OOD) tasks.
Recent approaches in single-agent RL tackle this by learning an efficient task representation to distinguish between tasks, showing promising adaptation ability.
However, when extended to multi-agent settings, these methods struggle with decentralized task identification due to limited global information, and suffer from inefficient knowledge transfer in the absence of role information.
To address this, we propose D^{2}TR, a novel context-based meta RL framework with efficient decentralized and disentangled task-role identification.
Specifically, D^{2}TR first introduces mutual information knowledge distillation to align decentralized task representations with centralized task representations inferred from global trajectories, enabling efficient decentralized team-centric information identification. Next, D^{2}TR leverages a large language model to assign semantic roles to trajectories in offline data, and achieves effective

individual-centric information inference by learning decentralized role representations.
Extensive experiments conducted on commonly used multi-agent environments, including CN, SMAC, and SMACv2, demonstrate that D^{2}TR exhibits strong generalization performance to unseen tasks, outperforming prior multi-agent multi-task and context-based meta RL baselines.
****

General Covariant Action Modeling: Constructing Generalized Manifolds via Spatio-Temporal Decoupling
Huaihai Lyu, Chaofan Chen, Mingyu Cao, Yuheng Ji, Changsheng Xu
Achieving robust generalization from limited data is a central challenge in embodied intelligence. Prevailing methods fail by regressing absolute coordinates, which violates the principle of general covariance. Theoretically, this conflates the intrinsic task geometry with rigid execution patterns, binding policies to specific motion styles and fixed speeds. To resolve this, we propose the Generalized Action Manifold (GAM) framework that enforces general covariance through structural disentanglement. Specifically, GAM constructs the manifold by enforcing invariance across two orthogonal dimensions: (1) Temporal Invariance, utilizing an Arc-Length Parameterizer to orthogonalize the spatial path geometry from temporal dynamics, ensuring robustness to velocity variations; (2) Geometric Invariance, where a Schema-Affine-Factorization mechanism maps trajectories to canonical “world lines” in the Lie-algebraic tangent space. This distinguishes invariant topological schemas from affine modulations, ensuring spatial generalizability. By integrating GAM within a structured Vision-Language-Action (VLA) architecture, we expand sparse training data into a continuous, valid action manifold. Empirical results demonstrate that GAM enables superior transfer and robustness capabilities, significantly outperforming geometry-agnostic baselines.
****

Scale-Aware Domain Harmonization for Domain Adaptation Person Search
Huibing Wang, Guojian Zhao, Jinjia Peng, Linfeng Qi, Mingze Yao, Jiqing Zhang
Unsupervised Domain Adaptation (UDA) person search aims to transfer a model trained on a labeled source domain to an unlabeled target domain without using target annotations. However, existing UDA methods frequently neglect the issue of scale inconsistency between the source and target domains. This inconsistency arises from variations in camera height, tilt angle, focal length, and scene layout. To address this challenge, we propose a Scale-Aware Consistent Alignment Learning (SCALE) framework. Specifically, we propose a Scale-aware Domain Harmonization (SDH) module, which adaptively harmonizes semantic and structural scales through cross-path interaction and consistency refinement to alleviate cross-domain scale inconsistency. To further reduce pseudo-label noise, we introduce a Bidirectional Cluster Regularization (BCR) strategy, which improves pseudo-label reliability by refining the clustering results through a second regularized clustering step. By collaboratively alleviating the impact of scale misalignment and enhancing pseudo-label reliability, our approach achieves state-of-the-art performance on two benchmark person search datasets, with 82.3% mAP and 84.0% top-1 on the CUHK-SYSU dataset, 41.7% mAP and 82.4% top-1 on the PRW dataset. Our source code is available at https://github.com/whhbdmu/SCALE.

Group Distributionally Robust Optimization-Driven RL for LLM Reasoning
Kishan Panaganti, Zhenwen Liang, Wenhao Yu, Haitao Mi, Dong Yu
Reasoning post-training with GRPO is typically built on *static uniformity*: uniform prompt sampling and a fixed number of rollouts per prompt. For heterogeneous, heavy-tailed reasoning data, this wastes compute on already-solved patterns while under-training the long tail of hard problems. We cast GRPO post-training as two independent GDRO games (not coupled) over *dynamic difficulty groups* defined by an *online train-time pass@n* statistic (computed from the rollouts used for GRPO updates): a *data adversary* that reshapes prompt sampling and a *compute adversary* that redistributes rollouts. **Prompt-GDRO** applies multiplicative-weights reweighting over bins (with an EMA-debiased difficulty score) to upweight persistently hard groups without frequency bias. **Rollout-GDRO** allocate

s rollouts across bins under a fixed mean budget via a shadow-price controller, improving gradient information efficiency on high-uncertainty groups while preserving the mean train-time rollout budget. Our approach is principled and theory-driven: we provide no-regret guarantees for the Prompt-GDRO game (via an entropy-regularized GDRO surrogate) and a variance-proxy analysis that yields a square-root optimal compute allocation for Rollout-GDRO. On DAPO 14.1k with Qwen3-Base (1.7B/4B/8B), each controller improves pass@8 by 9--13\% over GRPO; targeted Qwen3-4B reruns reproduce the Prompt-GDRO gap under a second seed, show second-seed Rollout-GDRO gains on four of five comparable benchmarks, and show low sensitivity to several key hyperparameters.

The Entropic Signature of Class Speciation in Diffusion Models
Florian Handke, Dejan Stancevic, Felix Koulischer, Thomas Demeester, Luca Ambrogioni
Diffusion models do not recover semantic structure uniformly over time. Instead, samples transition from semantic ambiguity to class commitment within a narrow regime. Recent theoretical work attributes this transition to dynamical instabilities along class-separating directions, but practical methods to detect and exploit these windows in trained models are still limited. We show that tracking the class-conditional entropy of a latent semantic variable given the noisy state provides a reliable signature of these transition regimes. By restricting the entropy to semantic partitions, the entropy can furthermore
resolve semantic decisions at different levels of abstraction. We validate our method on EDM2-XS and Stable Diffusion 1.5, where class-conditional entropy consistently isolates the noise regimes critical for semantic structure formation. Finally, we use our framework to quantify how guidance redistributes semantic information over time. Together, these results connect information-theoretic and statistical physics perspectives on diffusion and provide a principled basis for time-localized control.

Amortized Simulation-Based Inference in Generalized Bayes via Neural Posterior Estimation
Shiyi Sun, Geoff K. Nicholls, Kate Lee
Generalized Bayesian Inference (GBI) tempers a loss with a temperature $\beta>0$ to
mitigate overconfidence and improve robustness under model misspecification, but existing GBI methods typically rely on costly MCMC or SDE-based samplers and must be re-run for each new dataset and each β-value. We give the first fully amortized variational approximation for the specific case of the tempered posterior family $p_\beta(\theta\mid x) \propto \pi(\theta)p(x \mid\\theta)^\beta$ by training a single (x,β)-conditioned neural posterior estimator $q_\phi(\theta \mid x, \beta)$ that enables sampling in a single forward pass, without simulator calls or
inference-time MCMC. We introduce two complementary training routes: (i) synthesizes off-manifold samples $(\theta, x) \sim \pi(\theta)p(x \mid \theta)^\beta$ and (ii) reweights a fixed base dataset $\pi(\theta)p(x \mid \theta)$ using
self-normalized importance sampling (SNIS), where we show that the SNIS-weighted objective provides a consistent forward-KL fit to the tempered posterior with finite weight variance.
Across four standard simulation-based inference (SBI) benchmarks—including the chaotic Lorenz–96 system—our β-amortized estimator achieves competitive posterior approximations, in standard two-sample metrics, with non-amortized MCMC-based power-posterior samplers over a wide range of temperatures.

Twice Sequential Monte Carlo for Tree Search
Yaniv Oren, Joery A. de Vries, Pascal R. Van der Vaart, Matthijs T. J. Spaan, Wendelin Boehmer
Model-based reinforcement learning (RL) methods that leverage search are responsible for many milestone breakthroughs in RL.
Sequential Monte Carlo (SMC) recently emerged as an alternative to the Monte Car

lo Tree Search (MCTS) algorithm which drove these breakthroughs. SMC is easier t
o parallelize and more suitable to GPU acceleration. However, it also suffers fr
om large variance and path degeneracy which prevent it from scaling well with in
creased search depth, i.e., increased sequential compute. To address these probl
ems, we introduce Twice Sequential Monte Carlo Tree Search (TSMCTS). Across disc
rete and continuous environments TSMCTS outperforms the SMC baseline as well as
a popular modern version of MCTS as a policy improvement operator, scales favora
bly with sequential compute, reduces estimator variance and mitigates the effect
s of path degeneracy while retaining the properties that make SMC natural to par
allelize.

An Embarrassingly Simple Way to Optimize Orthogonal Matrices at Scale
Adrián Javaloy, Antonio Vergari
Orthogonality constraints are ubiquitous in robust and probabilistic machine lea
rning. Unfortunately, current optimizers are computationally expensive and do no
t scale to problems with hundreds or thousands of constraints. One notable excep
tion is the Landing algorithm (Ablin et al., 2024) which, however comes at the e
xpense of temporarily relaxing orthogonality. In this work, we revisit and impro
ve on the ideas behind Landing, enabling the inclusion of modern adaptive optimi
zers while ensuring that orthogonal constraints are effectively met. Remarkably,
 these improvements come at little to no cost, and reduce the number of required
 hyperparemeters. Our algorithm POGO is fast and GPU-friendly, _consisting of on
ly 5 matrix products_, and in practice maintains orthogonality at all times. On
several challenging benchmarks, POGO greatly outperforms recent optimizers and s
hows it can optimize problems with thousands of orthogonal matrices in minutes w
hile alternatives would take hours. As such, POGO sets a milestone to finally ex
ploit orthogonality constraints in ML at scale. A public PyTorch implementation
of POGO is available at https://github.com/adrianjav/pogo.

OSF: On Pre-training and Scaling of Sleep Foundation Models
Zitao Shuai, Zongzhe Xu, David Yang, Wei Wang, Yuzhe Yang
Polysomnography (PSG) provides the gold standard for sleep assessment but suffer
s from substantial heterogeneity across recording devices and cohorts.
There have been growing efforts to build general-purpose foundation models (FMs)
 for sleep physiology, but lack an in-depth understanding of the pre-training pr
ocess and scaling patterns that lead to more generalizable sleep FMs.
To fill this gap, we curate a massive corpus of 166,500 hours of sleep recording
s from nine public sources and establish SleepBench, a comprehensive, fully open
-source benchmark.
Leveraging SleepBench, we systematically evaluate four families of self-supervis
ed pre-training objectives and uncover three critical findings:
(1) existing FMs fail to generalize to missing channels at inference;
(2) channel-invariant feature learning is essential for pre-training;
and (3) scaling sample size, model capacity, and multi-source data mixture consi
stently improves downstream performance.
With an enhanced pre-training and scaling recipe, we introduce OSF, a family of
sleep FMs that achieves state-of-the-art performance across nine datasets on div
erse sleep and disease prediction tasks.
Further analysis of OSF also reveals intriguing properties in sample efficiency,
 hierarchical aggregation, and cross-dataset scaling. Codes are available at: ht
tps://github.com/yang-ai-lab/OSF-Open-Sleep-FM.

Tackling Fake Forgetting through Uncertainty Quantification
Yingdan Shi, Sijia Liu, Kaize Ding, Ren Wang
Machine unlearning seeks to remove the influence of specified data from a traine
d model. While the unlearning accuracy provides a widely used metric for assessi
ng unlearning performance, it falls short in assessing the reliability of forget
ting. In this paper, we find that the forgetting data points misclassified by un
learning accuracy still have their ground truth labels included in the conformal
 prediction set from the uncertainty quantification perspective, leading to a ph

enomenon we term fake forgetting. To address this issue, we propose a novel metr
ic CR, inspired by conformal prediction, that offers a more reliable assessment
of forgetting quality. Building on these insights, we further propose an unlearn
ing framework CPU that incorporates conformal prediction into the Carlini & Wagn
er adversarial attack loss, enabling the ground truth label to be effectively re
moved from the conformal prediction set. Through extensive experiments on image
classification tasks, we demonstrate both the effectiveness of our proposed metr
ic and the superior forgetting quality achieved by our framework. Code is availa
ble at https://github.com/TIML-Group/Conformal-Prediction-Unlearning.

Krause Synchronization Transformers
Jingkun Liu, Yisong Yue, Max Welling, Yue Song
Self-attention in Transformers relies on globally normalized softmax weights, ca
using all tokens to compete for influence at every layer. When composed across d
epth, this interaction pattern induces strong synchronization dynamics that favo
r convergence toward a dominant mode, a behavior associated with representation
collapse and attention sink phenomena. We introduce $\textbf{Krause Attention}$,
 a principled attention mechanism inspired by bounded-confidence consensus dynam
ics. Krause Attention replaces similarity-based global aggregation with distance
-based, localized, and selectively sparse interactions, promoting structured loc
al synchronization instead of global mixing. We relate this behavior to recent t
heory modeling Transformer dynamics as interacting particle systems, and show ho
w bounded-confidence interactions naturally moderate attention concentration and
 alleviate attention sinks. Restricting interactions to local neighborhoods also
 reduces runtime complexity from quadratic to linear in sequence length. Empiric
ally, we validate Krause Attention across diverse settings, including vision (Vi
T on CIFAR/ImageNet), autoregressive image generation (MNIST/CIFAR-10), large la
nguage models (Llama/Qwen), and language models trained from scratch at multiple
 scales (100M/200M). Across these domains, Krause Attention achieves consistent
performance gains while improving computational efficiency, highlighting bounded
-confidence dynamics as a scalable and effective inductive bias for attention. P
roject page is available at https://jingkun-liu.github.io/krause-sync-transforme
rs/.

Hybrid Reinforcement Learning in Adversarial Markov Decision Processes
Duo Cheng, Xingyu Zhou, Bo Ji
We study hybrid reinforcement learning (RL) in adversarial Markov Decision Proce
sses (MDPs), where the learner simultaneously receives on-policy feedback from t
he executed policy and off-policy feedback from a fixed behavior policy, and los
s functions can change arbitrarily over time. On-policy feedback allows explorat
ion and ensures the worst-case guarantee against any comparator policy, while of
f-policy feedback provides coverage-dependent guarantee that scales with the "mi
smatch" between the behavior and comparator policies (called coverage ratio) and
 can be sharper than on-policy results whenever this ratio is small. We propose
a new hybrid RL framework that accommodates adversarial losses and unknown trans
itions, preserving off-policy guarantees while ensuring non-trivial worst-case p
erformance.

Learning with Admissibility: Robust Fuzzy Hashing for Cross-Modal Retrieval with
 Noisy Labels
Xincheng Sun, Ruitao Pu, Guangsi Shi, Zhenwen Ren, Peng Hu, Yuan Sun
Recently, cross-modal hashing (CMH) has garnered significant attention due to it
s low storage costs and high retrieval efficiency. Most existing CMH methods imp
licitly assume the availability of high-quality annotations, which is often viol
ated in real-world scenarios as label noise inevitably arises from human errors
or non-expert annotations. To cope with noisy supervision, current noise-robust
CMH methods mainly follow two paradigms, i.e., noise separation and label smooth
ing. They often discard the predicted noisy instances or smooth discriminative s
ignals to mitigate the impact of noisy labels. However, aggressive separation le
ads to reduced data utilization, while smoothing weakens the discriminative capa

bility regarding the true distribution of clean instances. To address these limi tations, we propose a novel Robust Fuzzy Cross-modal Hashing framework (RFCMH) t hat introduces fuzzy set theory to endow the labels with admissibility, thereby obtaining reliable discriminative supervision from noisy labels. Specifically, w e first leverage possibility and necessity measures to model the noisy labels. S ubsequently, we propose Fuzzy Admissibility Refinement (FAR) to dynamically cali brate supervision signals, thereby preventing the model from being misled by fal se positives. Furthermore, we introduce Dual-Granularity Structural Alignment (D GSA) to enforce both cross-modal alignment and instance-level uniformity, ensuri ng stable and diverse representations. Extensive experiments on multiple benchma rks demonstrate that RFCMH achieves state-of-the-art retrieval performance. Code is available at https://github.com/XinchengSun/RFCMH.

Reverse-Engineering Model Editing on Language Models
Zhiyu Sun, Minrui Luo, Yu Wang, Zhili Chen, Tianxing He
Large language models (LLMs) are pretrained on corpora containing trillions of t okens and, therefore, inevitably memorize sensitive information. Locate-then-edi t methods, as a mainstream paradigm of model editing, offer a promising solution by modifying model parameters without retraining. However, in this work, we rev eal a critical vulnerability of this paradigm: the parameter updates inadvertent ly serve as a side channel, enabling attackers to recover the edited data. We pr opose a two-stage reverse-engineering attack named KSTER (KeySpaceReconsTruction -then-EntropyReduction) that leverages the low-rank structure of these updates. First, we theoretically show that the row space of the update matrix encodes a " fingerprint" of the edited subjects, enabling accurate subject recovery via spec tral analysis. Second, we introduce an entropy-based prompt recovery attack that reconstructs the semantic context of the edit. Extensive experiments on multipl e LLMs demonstrate that our attacks can recover edited data with high success ra tes. Furthermore, we propose subspace camouflage, a defense strategy that obfusc ates the update fingerprint with semantic decoys. This approach effectively miti gates reconstruction risks without compromising editing utility. Our code is ava ilable at https://github.com/reanatom/EditingAttack.

Bits That Count: Quantifying and Predicting Capabilities of Language Models
Elizabeth Donoway, Hailey Joren, Michael R DeWeese, Ethan Perez, John Schulman, Fabien Roger, Jan Leike
When does learning elicit \textit{existing} knowledge, and when does it primaril y teach \textit{new} capabilities? We find that the amount of generalizable info rmation language models learn during training predicts the origins of their emer gent capabilities. Minuscule amounts of information---in many cases, a few bits in a single example---can unlock large fractions of models' maximum performance when capabilities are \textit{elicited} rather than \textit{taught}. We quantify these learning regimes using excess description length (EDL), an information-th eoretic measure of generalizable information learned during training. We find th at elicitation and teaching exhibit distinct EDL signatures that characterize th e predominant learning mechanism as information scales: elicitation requires ord ers of magnitude less information than teaching to comparable performance. We de monstrate that EDL provides a practical tool for quantitatively estimating the m aximum amount of predictive information models can compress from data into train able parameters during learning. These capacity limits describe optimal tradeoff s between data and parameter count that robustly predict when parameter-efficien t fine-tuning methods (\textit{e.g.}, LoRA) will underperform full fine-tuning.

Distribution Matching Variational AutoEncoder
Sen Ye, Jianning Pei, Mengde Xu, Shuyang Gu, Chunyu Wang, Liwei Wang, Han Hu
Most visual generative models compress images into a latent space before applyin g diffusion or autoregressive modelling. Yet, existing approaches such as VAEs a nd foundation model aligned encoders implicitly constrain the latent space witho ut explicitly shaping its distribution, making it unclear which types of distrib utions are optimal for modeling. We introduce **Distribution-Matching VAE** (**D

MVAE**), which explicitly aligns the encoder’s latent distribution with an arbit
rary reference distribution via a distribution matching constraint. This general
izes beyond the Gaussian prior of conventional VAEs, enabling alignment with dis
tributions derived from self-supervised features, diffusion noise, or other prio
r distributions. With DMVAE, we can systematically investigate which latent dist
ributions are more conducive to modeling, and we find that SSL-derived distribut
ions provide an excellent balance between reconstruction fidelity and modeling e
fficiency, reaching a gFID of 3.2 on ImageNet with only 64 training epochs. Our
results suggest that choosing a suitable latent distribution structure (achieved
 via distribution-level alignment), rather than relying on fixed priors, is key
to bridging the gap between easy-to-model latents and high-fidelity image synthe
sis.

EPS3D: End-to-End Feed-Forward 3D Panoptic Segmentation
Runsong Zhu, Jiaxin Guo, Xiaoyang Guo, Zhengzhe Liu, Ka-Hei Hui, Wei Yin, Kai Ch
en, Wei Chen, Weiqiang Ren, Yunhui Liu, Pheng-Ann Heng, Chi-Wing Fu
This paper introduces EPS3D, a new end-to-end feed-forward framework for open-vo
cabulary 3D panoptic segmentation. Unlike existing methods relying on additional
 preprocessing, we design an end-to-end architecture, with a distillation-based
training strategy on diverse 3D scenes to predict 3D-aware semantic and instance
 features from multi-view images, improving 3D consistency and avoiding error ac
cumulation. We further propose a mutual enhancement module to enforce inherent s
emantic-instance consistency. By aligning semantics within instances (Ins2Sem) a
nd refining instance features with semantic guidance (Sem2Ins), we achieve more
coherent 3D scene understanding. Ultimately, EPS3D outperforms SOTA baselines on
 two benchmarks (e.g., +13% mIoU for semantics on Replica) with high efficiency
(e.g., 1s per scene), supporting tasks like robotic manipulation and 3D scene ed
iting.

Test-Time Anchoring for Discrete Diffusion Posterior Sampling
Litu Rout, Andreas Lugmayr, Yasamin Jafarian, Srivatsan Varadharajan, Constantin
e Caramanis, Sanjay Shakkottai, Ira Kemelmacher-Shlizerman
While continuous diffusion models have achieved remarkable success, discrete dif
fusion offers a unified framework for jointly modeling text and images. Beyond u
nification, discrete diffusion provides faster inference, finer control, and pri
ncipled training-free guidance, making it well-suited for posterior sampling. Ex
isting approaches to posterior sampling using discrete diffusion face severe cha
llenges: derivative-free guidance yields sparse signals, continuous relaxations
limit applicability, and split Gibbs samplers suffer from the curse of dimension
ality. To overcome these limitations, we introduce Anchored Posterior Sampling (
APS), built on two key innovations: *quantized expectation* for gradient-like gu
idance in discrete embedding space, and *anchored remasking* for adaptive decodi
ng. APS achieves state-of-the-art performance among discrete diffusion samplers
on both linear and nonlinear inverse problems across the standard image benchmar
ks. We demonstrate the generality of APS through training-free stylization and t
ext-guided editing. We further apply APS to a large-scale diffusion language mod
el, showing consistent improvement in question answering.

Conformal Policy Control
Drew Prinster, Clara Fannjiang, Ji Won Park, Kyunghyun Cho, Anqi Liu, Suchi Sari
a, Samuel Don Stanton
An agent must try new behaviors to explore and improve. In high-stakes environme
nts, an agent that violates safety constraints may cause harm and must be taken
offline, curtailing any future interaction. Imitating old behavior is safe, but
excessive conservatism discourages exploration. How much behavior change is too
much? We show how to use any safe reference policy as a probabilistic regulator
for any optimized but untested policy. Conformal calibration on data from the sa
fe policy determines how aggressively the new policy can act, while provably enf
orcing the user's declared risk tolerance. Unlike conservative optimization meth
ods, we do not assume the user has identified the correct model class nor tuned

any hyperparameters. Unlike previous conformal methods, our theory provides finite-sample guarantees even for non-monotonic bounded loss functions. Our experiments on applications ranging from natural language question answering to biomolecular engineering show that safe exploration is not only possible from the first moment of deployment, but can also improve performance.

Fingerprinting Pre-trained Encoders under Arbitrary Downstream Fine-Tuning via Adversarial Shifting
Tianlong Xu, Zixiong Wang, Lishuai Hou, Gaoyang Liu, Chen Wang, Xiaoyi Fan
In the pre-training-fine-tuning paradigm, pre-trained encoders have become high-value intellectual property (IP) due to their immense training costs, necessitating robust protection. Existing fingerprinting or watermarking methods typically rely on pre-defined samples and labels, or require intrusive modifications to the training process. However, downstream fine-tuning can significantly alter an encoder's representation and label space, thereby destroying the label consistency of existing methods and rendering them ineffective. Consequently, it is both challenging and urgent to provide a downstream-agnostic, black-box ownership verification mechanism for pre-trained encoders. To address this, we propose a downstream-agnostic, label-only fingerprinting method that leverages Adversarial Shifting to construct stable fingerprint clusters in the encoder’s latent space. By exploiting the inherent output consistency of these clusters, our method remains effective regardless of the specific downstream task or label mapping. Extensive experiments demonstrate that our method maintains superior robustness and stealthiness across various downstream tasks and category scales, providing a practical and reliable IP protection scheme for high-value pre-trained encoders.
****
Real-Time Monitoring and Calibration of Chain-of-Thought Sycophancy in Large Reasoning Models
Jingyu Hu, Shu Yang, Xilin Gong, Hongming Wang, Weiru Liu, Di Wang
Large Reasoning Models (LRMs) suffer from sycophantic behavior, where models tend to agree with users' incorrect beliefs and follow misinformation rather than maintain independent reasoning. This behavior undermines model reliability and poses societal risks. Mitigating LRM sycophancy requires monitoring how this sycophancy emerges during the reasoning trajectory; however, current methods mainly focus on judging based on final answers and correcting them, without understanding how sycophancy develops during reasoning processes.
To address this limitation, we propose MONICA, a novel Monitor-guided Calibration framework that monitors and mitigates sycophancy during model inference at the level of reasoning steps, without requiring the model to finish generating its complete answer.
MONICA integrates a sycophantic monitor that provides real-time monitoring of sycophantic drift scores during response generation with a calibrator that dynamically suppresses sycophantic behavior when scores exceed predefined thresholds.
Extensive experiments across 12 datasets and 3 LRMs demonstrate that our method effectively reduces sycophantic behavior in both intermediate reasoning steps and final answers, yielding robust performance improvements.

Factored Latent Action World Models
Zizhao Wang, Chang Shi, Jiaheng Hu, Kevin Rohling, Roberto Martín-Martín, Amy Zhang, Peter Stone
Learning latent actions from action-free video has emerged as a powerful paradigm for scaling up controllable world model learning. Latent actions provide a natural interface for users to iteratively generate and manipulate videos. However, most existing approaches rely on monolithic inverse and forward dynamics models that learn a single latent action to control the entire scene, and therefore struggle in complex environments where multiple entities act simultaneously. This paper introduces Factored Latent Action Model (FLAM), a factored dynamics framework that decomposes the scene into independent factors, each inferring its own latent action and predicting its own next-step factor value. This factorized structure enables more accurate modeling of complex multi-entity dynamics and improv

es video generation quality in action-free video settings compared to monolithic models. Based on experiments on both simulation and real-world multi-entity datasets, we find that FLAM outperforms prior work in prediction accuracy and representation quality, and facilitates downstream policy learning, demonstrating the benefits of factorized latent action models.
****
Partial Identification under High-Dimensional Potential Outcomes and Confounders via Optimal Transport
Yunfeng Wang, Zhiheng Zhang, Zijun Gao
Partial identification provides informative causal guarantees when point identification is impossible, but existing approaches based on optimal transport (OT) become computationally and statistically intractable in high-dimensional settings. This limitation is particularly severe when both potential outcomes and confounders are high-dimensional, where classical OT-based bounds suffer from the curse of dimensionality and unfavorable convergence rates. To address this challenge, we propose a novel estimator that decomposes the transport problem into a low-dimensional signal subspace and a high-dimensional residual subspace. Unlike existing projection-based methods that discard residual information, we recover the residual transport energy using the Sliced Wasserstein distance, which is computationally efficient and robust to high dimensions. We establish interpretable conditions controlling the approximation gap based on residual structure and provide a data-driven rule for signal dimension selection. Empirical results show that our estimator consistently outperforms projection-only baselines by recovering lost transport energy, yielding more informative causal bounds while remaining computationally tractable in high dimensions.
****
MIRA: A Score for Conditional Distribution Accuracy and Model Comparison
Sammy Nasser Sharief, Justine Zeghal, Gabriel Missael Barco, Pablo Lemos, Yashar Hezaveh, Laurence Perreault-Levasseur
We introduce MIRA, a sample-based score for assessing the accuracy of a candidate conditional distribution using only joint samples from the true data-generating process. Relying on the principle that distributions coincide if they assign equal probability mass to all regions, we derive an analytic expression for the MIRA statistic, whose average defines the MIRA score. This formulation further allows us to compute theoretical reference values and uncertainty estimates when the candidate distribution matches the true one. This framework enables model comparison by quantifying the alignment between the conditional distribution of a candidate model and the true data generating process. Consequently, MIRA enables Bayesian model comparison through direct posterior validation, bypassing the challenging evidence computation. We demonstrate its effectiveness across several toy problems and Bayesian inference tasks.
****
Online Packet Scheduling with Deadlines and Learning
Gianmarco Genalti, Achraf Azize, Vianney Perchet
Network routers that enforce Quality-of-Service (QoS) guarantees must decide, at every clock cycle, which expiring packet of information to transmit, even when the value of the packet is unknown until it is processed. We frame this problem as the Online Packet Scheduling with Deadlines (OPSD) problem under Partial Feedback: packets arrive at every clock cycle, with different deadlines, but the weights are only observed after execution. Under a stochastic assumption on the unknown weights, we explore different variants of the OPSD problem with bandit feedback. We establish a connection between our setting and the sleeping bandits problem, and set our learning goal to α-regret minimization. We provide algorithms with provable α-regret guarantees under different spans of slackness, distinguishing systems allowing for randomization and systems that do not. In every scenario, our algorithms achieve an α-regret upper bound of $\widetilde{\mathcal{O}}\left(\sqrt{KT}\right)$, matching the lower bound for the standard bandit setting. In the practically relevant case of 2-bounded deadline instances, where the deadline is set at most one clock cycle away from the arrival, our deterministic algorithm achieves the provably tightest possible competiti

ve ratio. Remarkably, when the number of distinct packet types $K\ge 2$ is finit e, it is possible to break the well-established $\Phi = \frac{1+\sqrt{5}}{2}$ co mpetitive ratio barrier and attain a tighter competitive ratio θ_K rangin g in $[\sqrt{2}, \Phi)$.

Emergent Visual Representations through Unsupervised Spiking Networks with Synap tic Pruning

Di Hong, Dazhong Rong, Yueming Wang

Recent work has shown that brain-aligned visual representations can emerge even in randomly initialized, high-dimensional neural networks, suggesting that corti cal representations may be discovered rather than fully learned through task opt imization. However, how such latent brain-relevant representations are stabilize d and refined during development remains unclear. Motivated by this perspective and by neuroscientific evidence of activity-dependent synaptic pruning, we study how brain-aligned representations can emerge and be refined from high-dimension al unsupervised spiking systems. We propose a biologically grounded deep SNN tha t integrates unsupervised learning with developmental pruning dynamics. Starting from an overcomplete spiking architecture, the model self-organizes through sen sory-driven activity while selectively eliminating weak or redundant synapses, p rogressively yielding compact and informative representations. Without using lab els, the resulting network forms hierarchical visual representations that strong ly align with neural responses across multiple areas of the mouse and macaque vi sual cortex, outperforming supervised and unsupervised ANN and SNN baselines. Sy naptic pruning further improves alignment and robustness under noisy and few-sho t recognition settings. By unifying high-dimensional unsupervised spiking repres entations with activity-dependent synaptic pruning, this work provides a computa tional account of developmental refinement in visual cortex and bridges recent f indings on emergent brain alignment in random networks with biologically grounde d models of representation learning.

ConsMSA: Semantic Distribution Consistency Learning for Multimodal Sentiment Ana lysis

Pan Wang, Lipeng Ke, Huajun Ying, Pritish Mohapatra, Rohan Sarkar, Suresh Lakhan i, sankar venkataraman, Jingtong Hu

Multimodal sentiment analysis (MSA) aims to predict human sentiments by integrat ing signals from different modalities such as text, video, and audio. However, r aw multimodal sequences often suffer from semantic inconsistency--exhibiting red undancy or conflicts within and across modalities--which hinders robust understa nding and increases computational cost. To this end, we introduce ConsMSA, which explicitly formalizes semantic distribution consistency across both $\textit{in tra}$- and $\textit{inter}$-modality, providing a consistency-aware mechanism fo r robust and efficient multimodal sentiment prediction. Specifically, ConsMSA pr ojects multimodal token features into a shared sentiment space to compute an Int ra- and Inter-modality Consistency Score (I^2CS). By coupling this score with predictive relevance, we formulate consistency-aware importance signals that are utilized: (i) as a consistency regularizer to align latent distributions during training, (ii) to derive semantic-aware weights for adaptive multimodal token r eweighting, and (iii) as a practical criterion to prune redundant or conflicting tokens. Extensive experiments on CMU-MOSI, CMU-MOSEI, and CH-SIMS demonstrate t hat ConsMSA achieves state-of-the-art performance while remaining robust under a ggressive token compression--retaining only 10\% of tokens yields comparable acc uracy. These results establish semantic distribution consistency as a promising foundation for synergizing predictive robustness with computational efficiency.
****

IntentRL: Training Proactive User-intent Agents for Open-ended Deep Research via Reinforcement Learning

Haohao Luo, Zexi Li, Yuexiang Xie, Wenhao Zhang, Yaliang Li, Ying Shen

Deep Research (DR) agents extend Large Language Models (LLMs) beyond parametric knowledge by autonomously retrieving and synthesizing evidence from large web co rpora into long-form reports, enabling a long-horizon agentic paradigm. However,

unlike real-time conversational assistants, DR is computationally expensive and time-consuming, creating an autonomy-interaction dilemma: high autonomy on ambiguous user queries often leads to prolonged execution with unsatisfactory outcomes. To address this, we propose IntentRL, a framework that trains proactive agents to clarify latent user intents before starting long-horizon research. To overcome the scarcity of open-ended research data, we introduce a scalable pipeline that expands a few seed samples into high-quality dialogue turns via a shallow-to-deep intent refinement graph. We further adopt a two-stage reinforcement learning (RL) strategy: Stage I applies RL on offline dialogues to efficiently learn general user-interaction behavior, while Stage II uses the trained agent and a user simulator for online rollouts to strengthen adaptation to diverse user feedback. Extensive experiments show that IntentRL significantly improves both intent hit rate and downstream task performance, outperforming the built-in clarify modules of closed-source DR agents and proactive LLM baselines.

MINIM: Privacy-Aware Minimal View for Agents via Trusted Local Sanitization

Hexuan Yu, Chaoyu Zhang, Heng Jin, Shanghao Shi, Ning Zhang, Thomas Hou, Wenjing Lou

Modern LLM-powered autonomous agents increasingly rely on rich user interface (UI) state observations to achieve reliable action grounding in complex digital environments. However, many deployments transmit the full UI state to remote inference servers even when most elements are irrelevant to the current task, which can leak sensitive but unnecessary context such as authentication codes, private notifications, and background application states. We propose MINIM, a trusted local broker that performs privacy-aware minimization on the client side before any observation leaves the device. Grounded in Contextual Integrity (CI), MINIM learns a dual-score representation for each UI element by predicting an inherent sensitivity score (s) and a task-conditioned necessity score (n). These scores drive a ternary disclosure policy that keeps essential elements, abstracts sensitive attributes when needed, and removes task-irrelevant content. We optimize a CI-aware objective that penalizes necessity errors more strongly on high-risk content, enabling aggressive pruning while preserving task-critical information. Experiments on real-world UI observations derived from WebArena show that MINIM substantially reduces task-irrelevant sensitive leakage while preserving task-critical semantic context and the interactive affordances required for reliable agent actions.

A Progressive Evidence Localization Framework Based on Wasserstein Gradient Flows for Document Visual Question Answering

Haosen Wang, Jing Xiao, Mengqiao Li, Xuanze Wang, Mingzheng Zhang, Xiaowang Zhang, Zhiyong Feng

Precise localization of evidence regions in Document Visual Question Answering is crucial for improving model interpretability and reliability.

However, existing methods predominantly adopt one-step localization strategies, which often fail to effectively distinguish evidence regions from irrelevant content when page semantics are complex or evidence regions are extremely small, leading to ambiguous boundaries and inaccurate localization. To address this issue, we propose a progressive evidence localization framework based on Wasserstein gradient flow, which formulates evidence localization as an optimal transport problem over probability distributions.

Since continuous gradient flows are intractable in practice, we employ the Jordan-Kinderlehrer-Otto (JKO) scheme for discrete optimization and further derive an end-to-end trainable loss function that transforms the theoretical formulation into a neural network optimization objective, enabling coarse-to-fine precise characterization of evidence regions.Experimental results demonstrate that the proposed method significantly outperforms existing approaches in both evidence localization and answer generation tasks.

Rethinking 3D Shape Generation: Diffusion over Superquadrics

Zhiyang Liu, Li Wanze, Yuwei Wu, Chengran Yuan, JIAWEI SUN, Rui Zheng, Marcelo H

Ang Jr
Diffusion models have advanced 3D shape generation, yet most methods still denoise in high-cardinality spaces (e.g., voxel/SDF grids, meshes, or point clouds), which is computationally and memory intensive and makes it difficult to scale in terms of both higher resolution and stronger controllability.
We rethink the diffusion representation and propose to move diffusion from dense geometry to compact geometric primitives, representing each shape as a small set of **superquadrics**.
Instead of operating on thousands to millions of geometric representation values, we leverage 7KB superquadric parameters (pose, size, and shape), drastically reducing diffusion-state dimensionality and per-step compute/memory.
Our diffusion-over-superquadrics improves scalability by supporting broader capabilities (e.g., resolution-free point-cloud decoding, part-level editing, and constraint-based design) and achieving competitive surface-fidelity and distributional performance on standard benchmarks after point-cloud decoding, while enabling efficient generation within 0.6s per shape for most conditions.
****
Contrastive Order Learning: A General Framework for Ordinal Regression
Chaewon Lee, BeomJun Shim, Kwang Pyo Choi, Chang-Su Kim
We propose contrastive order learning (ConOrd), a contrastive learning framework for ordinal regression that integrates the strengths of contrastive learning and order learning. While contrastive learning effectively leverages all samples in a batch, it typically ignores the inherent ordering among rank labels. Conversely, order learning explicitly models label ordinality but often relies on local, margin-based comparisons, limiting its ability to capture global ordinal structure. ConOrd addresses these limitations by introducing a contrastive order loss with soft affinity and disparity weights based on rank differences, enabling fine-grained modeling of ordinal relationships across all sample pairs within a batch. Extensive experiments on a range of ordinal regression tasks, including facial age estimation, blind image quality assessment, and blind video quality assessment, demonstrate that ConOrd consistently achieves state-of-the-art performance and generalizes well across diverse ordinal regression scenarios. The source code is available at https://github.com/cwlee00/ConOrd.
****
Understanding the Parameter Space Geometry of Transformers Encoding Boolean Functions
Blanka Kövér, Alexandra Butoi, Anej Svete, Michael Hahn, Ryan Cotterell
Transformers consistently fail to learn certain simple functions that are provably expressible with specific parameter settings.
    This gap between *learnability* and *expressivity* is particularly prominent for sensitive functions---functions whose output is likely to change if a single bit of the input is flipped---for example, Parity.
    While prior work has established that transformers exhibit a bias toward functions with low average sensitivity, the precise mechanism underlying this bias remains poorly understood.
    To shed light on this phenomenon, we study the geometry of transformers' parameter space.
    We show that sensitive functions---even when representable---occupy a vanishingly small region that random initialization is very likely to miss.
    Specifically, we shift the focus from average sensitivity to the full sensitivity profile---the distribution of sensitivity values across all inputs---and prove that randomly initialized transformers almost surely compute functions which have low-sensitivity strings.
    Consequently, any function that lacks such strings is provably unlearnable.
****
How does Bayesian Sampling help Membership Inference Attacks?
Zhenlong Liu, Wenyu Jiang, Feng Zhou, Hongxin Wei
Membership Inference Attacks (MIAs) aim to estimate whether a specific data point was used in the training of a given model. Existing state-of-the-art attacks typically rely on training multiple reference models to approximate the condition

al score distribution for individual data points, which leads to significant com putational overhead and limits their practical applicability. In this work, we propose a novel approach -- Bayesian Membership Inference Attack (BMIA), which performs conditional attack through Bayesian sampling. Specifically, we apply La place approximation to a single reference model to obtain a posterior over model parameters, enabling direct estimation of the conditional score distribution. T heoretically, we demonstrate that Bayesian sampling reduces intra-model variance , thereby improving attack power. This insight naturally motivates the multi-ref erence variant that further enhances performance when additional reference model s are available. Extensive experiments across image, text, and tabular datasets indicate that our method achieves state-of-the-art performance in both effective ness and efficiency.
****

Frictional Q-Learning
Hyunwoo Kim, Hyo Kyung Lee
Off-policy reinforcement learning suffers from extrapolation errors when a learn ed policy selects actions that are weakly supported in the replay buffer. In thi s study, we address this issue by drawing an analogy to static friction. From th is perspective, the replay buffer is represented as a smooth, low-dimensional ac tion manifold, where the support directions correspond to the tangential compone nt, while the normal component captures the dominant first-order extrapolation e rror. This decomposition reveals an intrinsic anisotropy in value sensitivity th at naturally induces a stability condition analogous to a friction threshold. To mitigate deviations toward unsupported actions, we propose Frictional Q-Learnin g, an off-policy algorithm that encodes supported actions as tangent directions using a contrastive variational autoencoder. We further show that an orthonormal basis of the orthogonal complement corresponds to normal components under mild local isometry assumptions. Extensive empirical results on standard continuous-c ontrol benchmarks consistently demonstrate robust and stable performance compare d with competitive baselines.

Learning to Self-Verify Makes Language Models Better Reasoners
Yuxin Chen, Yu Wang, Yi Zhang, Ziang Ye, Zhengzhou Cai, Yaorui Shi, Qi GU, Hui S u, Xunliang Cai, Xiang Wang, An Zhang, Tat-Seng Chua
Recent large language models (LLMs) achieve strong performance in generating pro mising reasoning paths for complex tasks.
However, despite powerful generation ability, LLMs remain weak at verifying thei r own answers, revealing a persistent capability asymmetry between generation an d self-verification. In this work, we conduct an in-depth investigation of this asymmetry throughout training evolution and show that, even on the same task, im proving generation does not lead to corresponding improvements in self-verificat ion. Interestingly, we find that the reverse direction of this asymmetry behaves differently: learning to self-verify can effectively improve generation perform ance, achieving accuracy comparable to standard generation training while yieldi ng more efficient and effective reasoning traces. Building on this observation, we further explore integrating self-verification into generation training by for mulating a multi-task reinforcement learning framework, where generation and sel f-verification are optimized as two independent but complementary objectives. Ex tensive experiments across benchmarks and models demonstrate performance gains o ver generation-only training in both generation and verification capabilities.

ReSpinQuant: Efficient Layer-Wise LLM Quantization via Subspace Residual Rotatio n Approximation
Suyoung Kim, Sunghyun Wee, Hyeonjin Kim, Kyomin Hwang, Hyunho Lee, Nojun Kwak
Rotation-based Post-Training Quantization (PTQ) has emerged as a promising solut ion for mitigating activation outliers in the quantization of Large Language Mod els (LLMs). Global rotation methods achieve inference efficiency by fusing activ ation rotations into attention and FFN blocks, but suffer from limited expressiv ity as they are constrained to use a single learnable rotation matrix across all layers. To tackle this, layer-wise transformation methods emerged, achieving su

perior accuracy through localized adaptation. However, layer-wise methods cannot fuse activation rotation matrices into weights, requiring online computations and causing significant overhead. In this paper, we propose **ReSpinQuant**, a quantization framework that resolves such overhead by leveraging offline activation rotation fusion and matching basis using efficient residual subspace rotation. This design reconciles the high expressivity of layer-wise adaptation with only negligible inference overhead. Extensive experiments on W4A4 and W3A3 quantization demonstrate that ReSpinQuant achieves state-of-the-art performance, outperforming global rotation methods and matching the accuracy of computationally expensive layer-wise methods with minimal overhead.

Fast Reconstruction of Mixtures of Bernoulli Product Distributions
Sanyam Agarwal, Pranjal Dutta, Markus Bläser
Mixtures of Bernoulli product distributions are a simple and widely used latent-variable model, with applications in e.g.\ recommendation systems, crowdsourcing, and medical data analysis. We consider the problem of reconstructing the mixture parameters from oracle access to its probability generating polynomial (PGP), for instance represented by a probabilistic generating circuit (PGC). We show that the parameters are uniquely identifiable for almost all mixtures, and give a randomized algorithm that exactly recovers the mixture weights and component marginals for mixtures of r Bernoulli product distributions over n variables using only $O(nr^2)$ oracle queries. The algorithm repeatedly applies restrictions to $O(r)$ variables, extracts low-degree coefficients, and then recovers the parameters using a moment-based tensor decomposition. To the best of our knowledge, this is the {\em first} exact reconstruction algorithm in this PGP oracle model with query complexity linear in n and polynomial in r.

Identifying and Correcting Label Noise for Robust GNNs via Influence Contradiction
Wei Ju, Wei Zhang, Siyu Yi, Zhengyang Mao, Yifan Wang, Jingyang Yuan, Zhiping Xiao, Ziyue Qiao, Ming Zhang
Graph Neural Networks (GNNs) have shown remarkable capabilities in learning from graph-structured data with various applications such as social analysis and bioinformatics. However, the presence of label noise in real scenarios poses a significant challenge in learning robust GNNs, and their effectiveness can be severely impacted when dealing with noisy labels on graphs, often stemming from annotation errors or inconsistencies. To address this, in this paper we propose a novel approach called ICGNN that harnesses the structure information of the graph to effectively alleviate the challenges posed by noisy labels. Specifically, we first design a novel noise indicator that measures the influence contradiction score (ICS) based on the graph diffusion matrix to quantify the credibility of nodes with clean labels, such that nodes with higher ICS values are more likely to be detected as having noisy labels. Then we leverage the Gaussian mixture model to precisely detect whether the label of a node is noisy or not. Additionally, we develop a soft strategy to combine the predictions from neighboring nodes on the graph to correct the detected noisy labels. At last, pseudo-labeling for abundant unlabeled nodes is incorporated to provide auxiliary supervision signals and guide the model optimization. Experiments on benchmark datasets show the superiority of our approach over competitive baselines in noisy label scenarios. The source code is available at: https://github.com/wayc04/ICGNN.

Goal-Conditioned Agents that Learn Everything All at Once
Michael Matthews, Matthew Thomas Jackson, Michael Beukman, Thomas Foster, Alistair Letcher, Scott Fujimoto, Cédric Colas, Jakob Nicolaus Foerster
A goal-conditioned reinforcement learning agent acting in an environment will see a wealth of information throughout a trajectory, most of which is discarded when only considering the trajectory with respect to a single goal. All-goals learning, where each transition is used for learning off-policy with respect to every goal, allows agents to extract maximal information, however it is usually computationally infeasible when done via naive relabelling. This can be overcome by

jointly outputting values and actions for every goal at once, allowing for efficient, parallel all-goals updates with a single pass through the network, in a process we call Learning Everything all at Once (LEO). We show that this approach significantly outperforms other methods on goal-conditioned Craftax and is competitive with existing baselines on continuous control environments, while achieving a 250x speed-up compared to all-goals relabelling. We hope that, by unlocking all-goals learning at scale, LEO can serve as a useful tool for RL practitioners in complex environments. We open source our code at https://anonymous.4open.science/r/CraftaxGC-D3E1.

Sim2Reason: Solving Physics Olympiad via Reinforcement Learning on Physics Simulators
Mihir Prabhudesai, Aryan Satpathy, Yangmin Li, Zheyang Qin, Nikash Bhardwaj, Amir Zadeh, Chuan Li, Katerina Fragkiadaki, Deepak Pathak
We have witnessed remarkable advances in LLM reasoning capabilities with the advent of DeepSeek-R1. However, much of this progress has been fueled by the abundance of internet question–answer (QA) pairs—a major bottleneck going forward, since such data is limited in scale and concentrated mainly in domains like mathematics. In contrast, other sciences such as physics lack large-scale QA datasets to effectively train reasoning-capable models. In this work, we show that physics simulators can serve as a powerful alternative source of supervision for training LLMs for physical reasoning. We generate random scenes in physics engines, create synthetic question–answer pairs from simulated interactions, and train LLMs using reinforcement learning on this synthetic data. Our models exhibit zero-shot sim-to-real transfer to real-world physics benchmarks: for example, training solely on synthetic simulated data improves performance on IPhO (International Physics Olympiad) problems by 5-10 percentage points across model sizes. These results demonstrate that physics simulators can act as scalable data generators, enabling LLMs to acquire deep physical reasoning skills beyond the limitations of internet-scale QA data. Code available at: https://sim2reason.github.io/.

Perceptrons and Localization of Attention’s Mean-Field Landscape
Antonio Álvarez-López, Borjan Geshkovski, Domènec Ruiz-Balet
The forward pass of a Transformer can be seen as an interacting particle system on the unit sphere: time plays the role of layers, particles that of token embeddings, and the unit sphere idealizes layer normalization. In some weight settings the system can even be seen as a gradient flow for an explicit energy, and one can make sense of the infinite context length *mean-field* limit thanks to Wasserstein gradient flows. In this paper we study the effect of the perceptron block in this setting, and show that critical points are generically atomic and localized on subsets of the sphere.

PluRel: Synthetic Data unlocks Scaling Laws for Relational Foundation Models
Vignesh Kothapalli, Rishabh Ranjan, Valter Hudovernik, Vijay Prakash Dwivedi, Johannes Hoffart, Carlos Guestrin, Jure Leskovec
Relational Foundation Models (RFMs) facilitate data-driven decision-making by learning from complex multi-table databases. However, the diverse relational databases needed to train such models are rarely public due to privacy constraints. While there are methods to generate synthetic tabular data of arbitrary size, incorporating schema structure and primary--foreign key connectivity for multi-table generation remains challenging. Here we introduce PluRel, a framework to synthesize multi-tabular relational databases from scratch.
In a step-by-step fashion, PluRel models (1) schemas with directed graphs, (2) inter-table primary-foreign key connectivity with bipartite graphs, and, (3) feature distributions in tables via conditional causal mechanisms. The design space across these stages supports the synthesis of a wide range of diverse databases, while being computationally lightweight. Using PluRel, we observe for the first time that (1) RFM pretraining loss exhibits power-law scaling with the number of synthetic databases and total pretraining tokens, (2) scaling the number of synthetic databases improves generalization to real databases, and (3) synthetic p

retraining yields strong base models for continued pretraining on real databases. Overall, our framework and results position synthetic data scaling as a promising paradigm for RFMs. Webpage: https://snap-stanford.github.io/plurel

Elastic Attention: Test-time Adaptive Sparsity Ratios for Efficient Transformers
Zecheng Tang, Quantong Qiu, Yi Yang, Zhiyi Hong, Haiya Xiang, Kebin Liu, Qingqing Dang, Juntao Li, Min Zhang
The quadratic complexity of standard attention mechanisms poses a significant scalability bottleneck for large language models (LLMs) in long-context scenarios. While hybrid attention strategies that combine sparse and full attention within a single model offer a viable solution, they typically employ static computation ratios (i.e., fixed proportions of sparse versus full attention) and fail to adapt to the varying sparsity sensitivities of downstream tasks during inference. To address this issue, we propose $\textit{\textbf{Elastic Attention}}$, which allows the model to dynamically adjust its overall sparsity based on the input. This is achieved by integrating a lightweight $\textit{\textbf{Attention Router}}$ into the existing pretrained model, which dynamically assigns each attention head to different computation modes. Within only 12 hours of training on 8$\times$A800 GPUs, our method enables models to achieve both strong performance and efficient inference. Experiments across three long-context benchmarks on widely-used LLMs demonstrate the superiority of our method.

Sycophancy Towards Researchers Drives Performative Misalignment
David D. Baek, Xinnuo Li, Anay Gupta, Taslim Mahbub, Kejian Shi, Max Tegmark, Shi Feng
The increasing situational awareness of language models raises safety concerns: models might be aware when they are evaluated, and adjust their behavior to evade monitoring and resist modification, e.g., pretending to be aligned only in evaluation. This *alignment faking* behavior is often interpreted as scheming: an intentional effort of strategic deception. In this paper, we examine an alternative interpretation, *performative misalignment*, which explains the change in behavior as a result of *sycophancy towards AI researchers*. To examine this hypothesis, we present three empirical findings. First, we show that evaluation awareness persists even when we tell models they are deployed, which contradicts the scheming story which predicts less misalignment when the model perceives evaluation. Second, we use probing and steering to show that our current methods cannot mechanistically distinguish sycophancy and scheming in alignment faking evaluations. Third, we fine-tune models to be more sycophantic and observe increased sensitivity to evaluation cues. To conclude, we emphasize deconfounding sycophancy from scheming for future work on evaluations and mitigations of intent misalignment.
****
Singular Bayesian Neural Networks
Mame Diarra Toure, David A. Stephens
Bayesian neural networks promise calibrated uncertainty but require $O(mn)$ parameters for standard mean-field Gaussian posteriors. We argue this cost is often unnecessary, particularly when weight matrices exhibit fast singular value decay.
By parameterizing weights as $W = AB^{\top}$ with $A \in \mathbb{R}^{m \times r}$,
$B \in \mathbb{R}^{n \times r}$, we induce a posterior that is \emph{singular} with respect to the Lebesgue measure, concentrating on the rank-r manifold. This
singularity captures structured weight correlations through shared latent factors, geometrically distinct from mean-field's independence assumption. We derive PAC-Bayes generalization bounds whose complexity term scales as $\sqrt{r(m+n)}$ instead of $\sqrt{m n}$, and prove loss bounds that decompose the error into optimization and rank-induced bias using the Eckart-Young-Mirsky theorem. We further adapt recent Gaussian complexity bounds for low-rank deterministic networks to Bayesian predictive means.

Empirically, across MLPs, LSTMs, and Transformers on standard benchmarks, our method achieves competitive predictive performance while using up to $33\times$ fewer parameters than 5-member Deep Ensembles. It substantially improves OOD detection and often improves calibration relative to mean-field and perturbation baselines, while Deep Ensembles can still be stronger on in-distribution likelihood-based metrics.

DRIFT: Decoupled Rollouts and Importance-Weighted Fine-Tuning for Efficient Multi-Turn Optimization
Jian Mu, Tianyi Lin, Chengwei Qin, Zhongxiang Dai, Yao Shu
Large language models are increasingly deployed in multi-turn interactive settings where users or environments can iteratively provide lightweight feedback.
Unfortunately, optimizing such behavior presents a sharp dilemma in practice: online reinforcement learning is able to effectively address multi-turn dynamics but is prohibitively expensive due to the cost of generating full correction trajectories at every update, whereas offline supervised fine-tuning (SFT) is efficient but suffers from distribution shift and behavioral collapse.
To this end, we novelly propose DRIFT (Decoupled Rollouts and Importance-Weighted Fine-Tuning), a framework that operationalizes the theoretical insight that the KL-regularized RL objective is equivalent to importance-weighted supervised learning.
DRIFT decouples rollout from optimization by sampling offline interaction trajectories from a fixed reference policy, deriving return-based importance weights, and optimizing the policy via weighted SFT on the resulting dataset.
Empirically, we demonstrate that DRIFT matches or exceeds the performance of multi-turn reinforcement learning baselines while maintaining the training efficiency and simplicity of standard supervised fine-tuning. Code is available at https://github.com/2020-qqtcg/DRIFT.

Local Hessian Spectral Filtering for Robust Intrinsic Dimension Estimation
GENKI OSADA
While diffusion models enable new approaches for estimating Local Intrinsic Dimension (LID), existing methods fail in high-dimensional spaces where noise from vast normal directions overwhelms the tangent signal. We propose Local Hessian Spectral Dimension (LHSD), which resolves this by applying spectral filtering to the log-density Hessian, explicitly cutting off large eigenvalues associated with normal directions to count zero-curvature tangent directions. Implemented using Stochastic Lanczos Quadrature (SLQ), LHSD avoids full Hessian construction, achieving linear scalability with dimension D.
Experiments on synthetic and real data confirm LHSD’s superior robustness and its utility in detecting memorization in large-scale diffusion models.
****

A Capacity-Based Rationale for Multi-Head Attention
Micah Adler
We study the capacity of the self-attention key-query channel: for a fixed budget, how many distinct token-token relations can a single layer reliably encode? We introduce *Relational Graph Recognition*, where the key-query channel encodes a directed graph and, given a context (a subset of the vertices), must recover the neighbors of each vertex in the context. We measure resources by the total key dimension $D_K = hd_k$. In a tractable multi-head model, we prove matching information-theoretic lower bounds and upper bounds via explicit constructions showing that recovering a graph with m' relations in d_{model}-dimensional embeddings requires D_K to grow essentially as m'/d_{model} up to logarithmic factors, and we obtain corresponding guarantees for scaled-softmax attention. This analysis yields a new, capacity-based rationale for multi-head attention: even in permutation graphs, where **all queries attend to a single target**, splitting a fixed D_K budget into multiple heads increases capacity by reducing interference from embedding superposition. Controlled experiments mirror the theory, revealing sharp phase transitions at the predicted capacity, and the multi-head advantage persists when adding softmax normalization, value routin

g, and a full Transformer block trained with frozen GPT-2 embeddings.

Nonparametric LLM Evaluation from Preference Data
Dennis Frauen, Athiya Deviyani, Mihaela van der Schaar, Stefan Feuerriegel
Evaluating the performance of large language models (LLMs) from human preference data is crucial for obtaining LLM leaderboards. However, many existing approaches either rely on restrictive parametric assumptions or lack valid uncertainty quantification when flexible machine learning methods are used. In this paper, we propose a nonparametric statistical framework, called DMLRank, for comparing and ranking LLMs from preference data using debiased machine learning (DML). For this, we introduce generalized average ranking scores (GARS), which generalize commonly used ranking models, including the Bradley-Terry model or PageRank/ Rank centrality with complex human responses such as ties. DMLRank comes with the following advantages: (i) It produces statistically efficient estimates of GARS ranking scores. (ii) It naturally allows to incorporate black-box machine learning methods for estimation. (iii) It can be combined with pre-trained LLM evaluators (e.g., using LLM-as-a-judge). (iv) It suggests optimal policies for collecting preference data under budget constraints. We demonstrate these advantages both theoretically and empirically using both synthetic and real-world preference datasets. In summary, our framework provides practitioners with powerful, state-of-the-art methods for comparing or ranking LLMs for leaderboards.

DTS: Enhancing Large Reasoning Models via Decoding Tree Sketching
Zicheng Xu, Xiuyi Lou, Guanchu Wang, Yu-Neng Chuang, Feng Luo, Guangyao Zheng, Alex Szalay, Zirui Liu, Vladimir Braverman
Large Reasoning Models (LRMs) achieve remarkable inference-time improvements through parallel thinking. However, existing methods rely on redundant sampling of reasoning trajectories, failing to effectively explore the reasoning space to uncover high-quality solutions. To address these limitations, we propose **D**ecoding **T**ree **S**ketching (DTS), a plug-and-play decoding framework for structural multi-trajectory exploration and reasoning selection. For reasoning exploration, DTS sketches a backbone tree of the reasoning space by selectively branching at decision tokens. For reasoning selection, guided by length-accuracy anti-correlation, DTS designs an early termination to prioritize short and reliable trajectories during decoding. Experimental results across four LRMs and datasets demonstrate that DTS significantly enhances accuracy by **14\%** and reduces repetitive generation by **8\%** on average. Notably, DTS enables smaller models to outperform larger models with 10$\times$ the size, highlighting its potential to strengthen reasoning capabilities.

TextResNet: Decoupling and Routing Optimization Signals in Compound AI Systems via Deep Residual Tuning
Suizhi Huang, Mei Li, Han Yu, Xiaoxiao Li
Textual Gradient-style optimizers (TextGrad) enable gradient-like feedback propagation through compound AI systems. However, they do not work well for deep chains. The root cause of this limitation stems from the *Semantic Entanglement* problem in these extended workflows. In standard textual backpropagation, feedback signals mix local critiques with upstream contexts, leading to *Attribution Ambiguity*. To address this challenge, we propose TextResNet, a framework that reformulates the optimization process to achieve precise signal routing via four key innovations. Firstly, in the forward pass, it enforces Additive Semantic Deltas to preserve an Identity Highway for gradient flow. Secondly, in the backward pass, it introduces Semantic Gradient Decomposition via a Semantic Projector to disentangle feedback into causally independent subspaces. Thirdly, it implements Causal Routing, which routes projected signals to their specific components. Finally, it performs Density-Aware Optimization Scheduling to leverage the disentangled signals to dynamically allocate resources to key system bottlenecks. Our results show that TextResNet not only achieves superior performance compared to TextGrad, but also exhibits remarkable stability for agentic tasks in compound AI systems where baselines collapse. Code is available at https://github.com/JeanDiab

le/TextResNet.

WET: Mitigating World-Conditioned Knowledge Conflicts via World Entropy Tetherin
g
Zixuan Wang, Yifei He, Zihan Wang, Kun Wang, Chaomeng Chen
Large language models (LLMs) face a "loyalty dilemma" when correctness is condit
ioned on an active world-of-discourse. We identify a systemic failure mode---wor
ld misattribution---where models implicitly ground generation in an incompatible
 regime and drift from the target world. We propose World Entropy Tethering (WET
), an inference-time monitor-and-tether: a world-entropy probe flags drift risk
on prompt anchors, and a conditional score matching geometry model identifies te
thering heads for entropy-gated rescaling. Experiments show: (I) Linear Separabi
lity: world labels are linearly decodable from internal states; (II) Geometric D
rift: hallucinations are preceded by measurable deviations from the target world
 region; and (III) Targeted Mitigation: WET improves world consistency and reduc
es hallucination rates by up to 22.4% without compromising generation quality. C
ode is available at https://github.com/guess-guess-who-i-am/WET-World-Entropy-Te
thering.

Eyes-on-Me: Scalable RAG Poisoning through Transferable Attention-Steering Attra
ctors
Yen-Shan Chen, Sian-Yao Huang, Cheng-Lin Yang, Yun-Nung Chen
Existing data poisoning attacks on retrieval-augmented generation (RAG) systems
scale poorly because they require costly optimization of poisoned documents for
each target phrase. We introduce Eyes-on-Me, a modular attack that decomposes an
 adversarial document into reusable **Attention Attractors** and **Focus Regions
**. Attractors are optimized to direct attention to the Focus Region. Attackers
can then insert semantic baits for the retriever or malicious instructions for t
he generator, adapting to new targets at near zero cost. This is achieved by ste
ering a small subset of attention heads that we empirically identify as strongly
 correlated with attack success. Across 18 end-to-end RAG settings (3 datasets $
\times$ 2 retrievers $\times$ 3 generators), Eyes-on-Me raises average attack su
ccess rates from 21.9 to 57.8 (+35.9 points, 2.6$\times$ over prior work). A sin
gle optimized attractor transfers to unseen black box retrievers and generators
without retraining. Our findings establish a scalable paradigm for RAG data pois
oning and show that modular, reusable components pose a practical threat to mode
rn AI systems. They also reveal a strong link between attention concentration an
d model outputs, informing interpretability research.

Beyond Accuracy: Latent Perturbations for Cognitive-Aware Diagnosis
Yuting Yan, Yinghao Fu, Wendi Ren, Haozhou Gao, Shuang Li
Diagnosing rare diseases remains a persistent challenge, often hindered by cogni
tive anchoring: once clinicians settle on a common diagnosis, they often discoun
t alternative explanations, including rare conditions. To address this, we propo
se a cognitive-aware counterfactual reasoning framework using a Denoising Masked
 AutoEncoder (DMAE) to simulate what-if diagnostic scenarios that probe clinicia
ns’ initial assumptions. Our model jointly learns (1) the true distribution of d
iseases and symptoms, and (2) human diagnostic behavior, revealing critical gaps
 between medically possible and clinically considered diagnoses. By strategicall
y perturbing latent patient representations, it generates contrastive counterfac
tuals that highlight rare yet plausible diseases that cognitive bias often obscu
res. Unlike traditional decision-support tools, our system suggests rare disease
s not because they are statistically dominant, but because they are systematical
ly under-considered relative to the observed evidence and learned diagnostic beh
avior. Across four public and three private rare-disease datasets, our approach
outperforms standard machine learning classifiers in detecting rare conditions w
hile maintaining strong performance on common diagnoses. Beyond boosting accurac
y, the counterfactual evidence encourages hypothesis-driven reasoning and suppor
ts clinical learning.

IsoCompute Playbook: Optimally Scaling Sampling Compute for LLM RL
Zhoujun Cheng, Yutao Xie, Yuxiao Qu, Amrith Setlur, Shibo Hao, Varad Pimpalkhute, Tongtong Liang, Feng Yao, Zhengzhong Liu, Eric P. Xing, Virginia Smith, Ruslan Salakhutdinov, Zhiting Hu, Taylor W. Killian, Aviral Kumar
While scaling laws guide compute allocation for LLM pre-training, analogous prescriptions for reinforcement learning (RL) post-training of LLMs remain poorly understood. We study the compute-optimal allocation of sampling compute for on-policy RL methods in LLMs, framing scaling as a compute-constrained optimization over three resources: parallel rollouts per problem, number of problems per batch, and number of update steps. We find that the compute-optimal number of parallel rollouts per problem increases predictably with compute budget and then saturates. This trend holds across both easy and hard problems, though driven by different mechanisms: solution sharpening on easy problems and coverage expansion on hard problems. We further show that increasing the number of parallel rollouts mitigates interference across problems, while the number of problems per batch primarily affects training stability and can be chosen within a broad range. Validated across base models and data distributions, our results recast RL scaling laws as prescriptive allocation rules and provide practical guidance for compute-efficient LLM RL post-training.

Practical and Optimal Algorithm for Linear Contextual Bandits with Rare Parameter Updates
Sanghoon Yu, Min-hwan Oh
We study linear contextual bandits under rare parameter updates:
the learner may incorporate reward feedback into its parameter estimate only at a small number of update times,
while still observing contexts online and selecting actions sequentially.
This viewpoint clarifies a practical distinction that is often blurred in the literature:
many "strictly batched" methods additionally restrict within-interval context adaptivity,
meaning that the action rule inside an interval cannot depend on the sequence of realized contexts/actions in that interval (beyond the current round's context).
For linear contextual bandits, we propose two practical algorithms with only $O(\log\log T)$ parameter updates.
Our first algorithm BLCE-G attains minimax-optimal regret (up to polylogarithmic factors in T) simultaneously in both the small-K and large-K regimes under a static schedule.
Our second algorithm BLCE removes the near G-optimal design step---a dominant computational bottleneck in prior strictly batched static-grid methods---yet preserves minimax-optimal regret and achieves the lowest known runtime complexity among optimal algorithms.
We further extend these rare-update and computational principles to generalized linear contextual bandits.
Overall, our results yield statistically optimal algorithms under $O(\log\log T)$ parameter updates that are also computationally efficient in practice.
****
Words & Weights: Streamlining Multi-Turn Interactions via Co-Adaptation
Chenxing Wei, Hong Wang, Ying He, Zhongxiang Dai, Bo Jiang, Fei Yu, Yao Shu
Test-time policy adaptation for multi-turn interactions (T^{2}PAM) is essential for aligning Large Language Models (LLMs) with dynamic user needs. However, existing paradigms typically treat adaptation as a single-axis problem by either purely refining instructions or solely updating weights. This bifurcated approach overlooks the fact that interaction failures arise from a coupled mixture of context ambiguity and model incapacity. To address this, we propose ROSA2, a framework that reformulates T^{2}PAM as a joint optimization problem over the heterogeneous space of Words and Weights. Within this framework, the semantic stream acts as a feedback normalizer that transforms noisy or ambiguous user feedback into actionable instructions, ensuring that parametric adaptation is performed on sem

antically clarified trajectories. Theoretically, we prove that this semantic pre
-conditioning strictly reduces the required parameter shift for convergence. Emp
irically, ROSA2 consistently outperforms state-of-the-art baselines across diver
se mathematical, general reasoning, and coding benchmarks. It achieves up to a 3
7.8\% accuracy improvement while reducing average interaction turns by 40\%, dem
onstrating that ROSA2 unlocks the true potential of parameter updates.

RouterInterp: Understanding Superposed Specialisation in Mixture of Experts Rout
ing

Ilya Lasy, Nora Yinuo Cai, Kola Ayonrinde

Sparse Mixture of Experts (MoE) models scale more efficiently than dense models
by routing tokens to modular expert networks that are only active when relevant
to the task. A leading hypothesis for the performance of MoE models is that each
expert specialises in a single, coherent domain. However, interpretability effo
rts that assume this hypothesis have generally been unsuccessful. We propose and
present evidence for an alternative account that we call the *Superposed Specia
lisation Hypothesis* (SSH): experts specialise in a disjoint union of fine-grain
ed features rather than one broad domain. Leveraging the SSH, we introduce *Rout
erInterp*, a method for interpreting expert routing that identifies Sparse Autoe
ncoder features most predictive of routing decisions and produces unified natura
l language explanations. On gpt-oss-20b, RouterInterp explains expert routing wi
th 57% higher detection accuracy than prior token statistics based methods. This
work provides a scalable method for generating concise and more accurate explan
ations of expert routing and increases our understanding of a previously uninter
pretable component of foundation models.

Hyper-ICL: Attention Calibration with Hyperbolic Anchor Distillation for Multimo
dal In-Context Learning

Niloufar Alipour Talemi, Hossein Kashiani, Fatemeh Afghah

Multimodal In-Context Learning (ICL) has emerged as a practical inference paradi
gm for Multimodal Large Language Models, where a small set of interleaved image-
text In-Context Demonstrations (ICDs) conditions the model to solve new tasks. D
espite its flexibility, multimodal ICL incurs high inference latency and suffers
from instability due to sensitivity to demonstration formatting, ordering, and
content. To address these limitations, we propose Hyper-ICL, a lightweight, trai
ning-based framework for demonstration-free multimodal ICL that reconstructs dem
onstration effects directly without requiring ICDs at inference time. Hyper-ICL
learns a parameter-efficient low-rank logit-level adapter that calibrates attent
ion distributions to better match demonstration-induced attention redistribution
. To capture how demonstration influence varies across queries, we introduce a q
uery-adaptive modulation mechanism that adaptively controls intervention strengt
h at token level across layers and heads based on the current query. Finally, we
propose a layer-wise hyperbolic anchor distillation loss that aligns intermedia
te student features to a demonstration-conditioned teacher via Lorentz geodesic
distance. This loss encourages the student to reconstruct the demonstration–quer
y relationships induced by ICDs. Extensive experiments across six different mult
imodal benchmarks (including VQAv2, OK-VQA, and COCO Caption) demonstrate that H
yper-ICL consistently improves accuracy and stability over vanilla ICL and exist
ing state-of-the-art methods.

Non-Parametric Optimization for Scalable Learning in Stochastic Decision Problem
s

Mohsen Amidzadeh, Lauri Viitasaari, Mario Di Francesco

Stochastic optimization (SO) plays a central role in decision-making under uncer
tainty. Among SO problems, time-varying stochastic optimization (TV-SO) is parti
cularly important due to its applications in adaptive control and machine learni
ng. Non-parametric approaches have been proposed for time-varying deterministic
optimization; however, they have not been developed for their stochastic counter
parts. This work addresses that gap by developing a stochastic variational frame
work based on Malliavin calculus. This framework yields non-parametric optimalit

y conditions for SO problems with stochastic decisions and supports the design of a scalable deep-learning algorithm that is insensitive to the parameterization dimension. This algorithm, called the Stochastic Path Follower (SPF), is applied to two important problems under distribution drift, namely least-squares recovery and logistic regression. Experimental results show that the proposed approach outperforms state-of-the-art learning-based and gradient-based methods in both performance and scalability.

Safety Recovery in Reasoning Models Is Only a Few Early Steering Steps Away
Soumya Suvra Ghosal, Souradip Chakraborty, Vaibhav Singh, Furong Huang, Dinesh Manocha, Amrit Singh Bedi
Reinforcement learning (RL) based post-training for explicit chain-of-thought (e.g., GRPO) improves the reasoning ability of multimodal large-scale reasoning models (MLRMs). But recent evidence shows that it can simultaneously degrade safety alignment and increase jailbreak success rates. We propose SafeThink, a lightweight inference-time defense that treats safety recovery as a satisficing constraint rather than a maximization objective. SafeThink monitors the evolving reasoning trace with a safety reward model and conditionally injects an optimized short corrective prefix ("Wait, think safely") only when the safety threshold is violated. In our evaluations across six open-source MLRMs and four jailbreak benchmarks (JailbreakV-28K, Hades, FigStep, and MM-SafetyBench), SafeThink reduces attack success rates by 30-60 % (e.g., LlamaV-o1: 63.33\% $\rightarrow$5.74\% on JailbreakV-28K, R1-OneVision: 69.07\%$\rightarrow$5.65\% on Hades) while preserving reasoning performance (MathVista accuracy: 65.20\%$\rightarrow$65.00\%). A key empirical finding from our experiments is that safety recovery is often only a few steering steps away: intervening in the first $1–3$ reasoning steps typically suffices to redirect the full generation toward safe completions.

E²I-VRWKV: Explicit EPI-Representation and Interaction-Aware Vision-RWKV for Light Field Semantic Segmentation
Wei Zhang, Chen Jia, Xu Cheng, Fan Shi, Hui Liu, Shengyong Chen
Pixel-level semantic segmentation of 4D light field (LF) data remains a considerable challenge, primarily due to the conflict between modeling complex spatial-angular dependencies and maintaining linear computational efficiency. Current linear models like VRWKV offer scalability but often fail to capture intrinsic geometric structures, leading to the structural collapse of Epipolar Plane Image (EPI) cues. To overcome these limitations, we propose E²I-VRWKV, an EPI-Enhanced and Interaction-aware network that generates high-quality segmentation maps by embedding explicit geometric priors into a linear-complexity backbone. Specifically, we introduce the Light Field Epipolar-Aware Cross-Modal Attention (LF-ECMA) block. The key innovation lies in the integration of an EPI Geometric Prior Generator, which explicitly extracts disparity-sensitive biases to enforce geometric consistency, and a Geometric-Context Gating (GC-Gate) mechanism. This mechanism functions as a geometrically modulated aperture to dynamically calibrate the fusion of spatial and angular manifolds. Experiments on the UrbanLF benchmark demonstrate that our method outperforms other state-of-the-art (SOTA) methods, achieving 86.55% mIoU on UrbanLF-Real while maintaining a superior balance between accuracy and linear efficiency.

Quant VideoGen: Auto-Regressive Long Video Generation via 2-Bit KV-Cache Quantization
Haocheng Xi, Shuo Yang, Yilong Zhao, Muyang Li, Han Cai, Xingyang Li, Yujun Lin, Zhuoyang Zhang, Jintao Zhang, Xiuyu Li, Zhiying Xu, Jun Wu, Chenfeng Xu, Ion Stoica, Song Han, Kurt Keutzer
Despite rapid progress in auto-regressive video diffusion, we identify an emerging system–algorithm bottleneck that limits both deployability and generation quality: KV-cache memory. In auto-regressive video generation models, the KV-cache grows with generation history and quickly dominates GPU memory (often ≥30 GB), preventing deployment on widely available hardware. More critically, memory-bounded KV budgets constrain the effective working memory, directly degrading long-ho

rizon consistency in identity, layout, and motion.
To address this challenge, we present Quant VideoGen (QVG), a training-free KV-cache quantization framework for auto-regressive video diffusion models. QVG exploits video’s inherent spatiotemporal redundancy via Semantic-Aware Smoothing, producing low-magnitude, quantization-friendly residuals. Building on this, QVG introduces Progressive Residual Quantization, a coarse-to-fine multi-stage scheme that further reduces quantization error while enabling a smooth quality–memory trade-off.
Across LongCat-Video, HY-WorldPlay, and Self-Forcing, QVG establishes a new Pareto frontier between quality and memory efficiency, reducing KV memory by up to 7.0× with less than 4% end-to-end latency overhead, while delivering significantly better generation quality than existing baselines.

Plug-and-Play Label Map Diffusion for Universal Goal-Oriented Navigation
Zhixuan Shen, Yijie Zeng, Shengxiang Luo, Tianrui Li, Haonan Luo
In embodied vision, Goal-Oriented Navigation (GON) requires robots to locate a specific goal within an unexplored environment. The primary challenge of GON arises from the need to construct a Bird's-Eye-View (BEV) map to understand the environment while simultaneously localizing an unobserved goal. Existing map-based methods typically employ self-centered semantic maps, often facing challenges such as reliance on complete maps or inconsistent semantic association. To this end, we propose Plug-and-Play Label Map Diffusion (PLMD), which defines a novel map completion diffusion model based on Denoising Diffusion Probabilistic Models (DDPM). PLMD generates obstacle and semantic labels for unobserved regions through a diffusion-based completion process, thereby enabling goal localization even in partially observed environments. Moreover, it mitigates inconsistent semantic association by leveraging structural consistency between known and unknown obstacle layouts and integrating obstacle priors into the semantic denoising process. By substituting predicted labels for unobserved regions, robots can accurately localize the specified objects. Extensive experiments demonstrate that PLMD **(I)** effectively expands the region of unknown maps, **(II)** integrates seamlessly into existing navigation strategies that rely on semantic maps, **(III)** achieves state-of-the-art performance on three GON tasks. Code is available at: <https://github.com/FrankZxShen/PLMD>.

Estimating the Empowerment of Language Model Agents
Jinyeop Song, Jeff Gore, Max Kleiman-Weiner
As language model (LM) agents become increasingly capable and adopted in real-world applications, there is a growing need for scalable evaluation frameworks beyond costly, manually designed benchmarks. We propose information-theoretic evaluation based on empowerment, an information-theoretic measure of an agent’s influence on future states through its actions. To handle the unique challenges of text-based environments, we introduce EELMA (Estimating Empowerment of Language Model Agents), an algorithm for approximating effective empowerment from multi-turn text interactions. We demonstrate EELMA on textual games and realistic web and tool-use environments, showing that empowerment strongly correlates with average task performance. We further analyze how empowerment varies across models, environment complexity, and agent configurations, and show that high-empowerment states and actions often mark pivotal moments for general capabilities. These results establish empowerment as a goal-agnostic metric that complements task-success measures for LM-agent evaluation. Code available: https://github.com/Jinyeop3110/EELMA

Faster Than Flash: Exploiting Attention Sparsity for Efficient Long-Context Decoding
Zhigeng Liu, Zhiyuan Ning, Ruixiao Li, Xiaoran Liu, Yuerong Song, Min Zhang, Ziwei He, Xipeng Qiu
The development of long-context Large Language Models (LLMs) is constrained by the memory bandwidth bottleneck and quadratic complexity of the attention mechanism during decoding. To overcome the inherent trade-offs between the memory overh

ead of metadata-based metrics and the computational inefficiency of adaptive sel
ection strategies, we present \textbf{Faster Flash Decoding (FFD)}, a novel hard
ware-algorithm co-design framework designed to break the memory wall in long-con
text decoding. FFD integrates the selector and computer into a fully fused kerne
l, replacing external metadata indices with content-aware scanning via low-bit q
uantization. Furthermore, we introduce the top-δ strategy, which dynamica
lly filters blocks to achieve distribution-adaptive sparsity without global sync
hronization. As a training-free, plug-and-play solution, FFD enables the reuse o
f scanning results for computation, achieving up to 11.6x kernel-level speedup a
t 256k context length and 2.37x end-to-end throughput improvement. Empirical val
idation on Ruler and Longbench confirms that FFD maintains model accuracy while
delivering high-ratio sparsity.

From Seeing to Thinking: Decoupling Perception and Reasoning Improves Post-Train
ing of Vision-Language Models
Juncheng Wu, Hardy Chen, Haoqin Tu, Xianfeng Tang, Freda Shi, Hui Liu, Hanqing L
u, Cihang Xie, Yuyin Zhou
Recent advances in vision-language models (VLMs) emphasize long chain-of-thought
 reasoning; yet, we find that their performance on visual tasks is primarily lim
ited by a lack of visual perception as opposed to reasoning itself. In this work
, we systematically study the interplay between perception and reasoning in VLM
post-training by decomposing their capabilities into three separate training sta
ges: visual perception, visual reasoning, and textual reasoning, incorporating s
pecialized training data. We demonstrate that visual perception (a) requires tar
geted optimization with specialized data; (b) serves as a fundamental scaffold t
hat should be solidified through staged training before refining visual reasonin
g; and (c) is more effectively learned via RL than caption-based SFT. Our experi
ments across multiple VLMs demonstrate that staged training consistently improve
s both visual perception and reasoning performance over merged training. Notably
, models trained with our approach achieve 1.5% higher reasoning accuracy with 2
0.8% shorter reasoning traces, suggesting that superior perception reduces the n
eed for excessive reasoning. Furthermore, we show that this capability-based sta
ging represents a new curriculum dimension orthogonal to traditional difficulty-
based curricula, and combining both yields further additive gains. Our staged-tr
aining models achieve superior performance among open-weight VLMs, establishing
advanced results on several visual math and perception (e.g., +5.2% on WeMath an
d +3.7% on RealWorldQA) tasks compared with the base counterpart.

WeightCLIP: Aligning Datasets and Models for Weight Space Learning
Aron Asefaw, Konstantinos Tzevelekakis, Damian Falk, Léo Meynent, Damian Borth
Weight space learning aims to learn representations of neural network (NN) weigh
ts, enabling different downstream tasks. Existing approaches show promising perf
ormance, but lacking a way to shape these weight-space representations using inf
ormation about the datasets the models were trained on, thus limiting downstream
 applications. We propose **WeightCLIP**, a method for learning a dataset-aligne
d latent space for neural networks, where datasets information is induced during
 training. The NNs are encoded as latent representations using an autoencoder, w
hile dataset samples are encoded using a dataset encoder. The two representation
s are aligned using a contrastive objective, effectively reshaping the weight-sp
ace representations according to the datasets. We demonstrate that such represen
tations can be used for different downstream tasks, including mapping dataset in
formation to a weight-space representation that decode to strong models. In addi
tion, we introduce a latent refinement process for generating models that outper
forms standard fine-tuning. Overall, our results demonstrate that explicitly inc
orporating dataset information improves what can be achieved with weight-space r
epresentations across retrieval, generation, and refinement. Code will be availa
ble at https://github.com/HSG-AIML/WeightCLIP.

Leaderboard Incentives: Model Rankings under Strategic Post-Training
Yatong Chen, Guanhua Zhang, Moritz Hardt

Influential benchmarks incentivize competing model builders to strategically allocate post-training resources towards improvements on the leaderboard, a phenomenon dubbed \emph{benchmaxxing} or \emph{training on the test task}. In this work, we initiate a principled study of the incentive structure that benchmarks induce. We model benchmarking as a Stackelberg game between a benchmark designer who chooses an evaluation protocol and multiple model providers who compete simultaneously in a subgame given by the designer’s choice. Each competitor has a model of unknown latent quality and can inflate its observed score by allocating resources to benchmark-specific improvements. First, we prove that current benchmarks induce games for which no Nash equilibrium between model developers exists. This result suggests one explanation for why current practice leads to misaligned incentives, prompting model providers to strategize in opaque ways. However, we prove that under mild conditions, a recently proposed evaluation protocol, called tune-before-test, induces a benchmark with a unique Nash equilibrium that ranks models by latent quality. This positive result demonstrates that benchmarks need not set bad incentives, even if current evaluations do.

Steering at the Source: Style Modulation Heads for Robust Persona Control
Yoshihiro Izawa, Gouki Minegishi, Koshi Eguchi, Sosuke Hosokawa, Kenjiro Taura
Activation steering offers a computationally efficient mechanism for controlling Large Language Models (LLMs) without fine-tuning.
While effectively controlling target traits (e.g., persona), coherency degradation remains a major obstacle to safety and practical deployment.
We hypothesize that this degradation stems from intervening on the residual stream, which indiscriminately affects aggregated features and inadvertently amplifies off-target noise.
In this work, we identify a sparse subset of attention heads (only three heads) that independently govern persona and style formation, which we term *Style Modulation Heads*.
Specifically, these heads can be localized via geometric analysis of internal representations, combining layer-wise cosine similarity and head-wise contribution scores.
We demonstrate that intervention targeting only these specific heads achieves robust behavioral control while significantly mitigating the coherency degradation observed in residual stream steering.
More broadly, our findings show that precise, component-level localization enables safer and more precise model control.

Non-Monotonic Autoregressive Sequence Model
Tianyi Ma, Yiyue Qian, Yiyang Li, Zehong Wang, Yifan Ding, Zheyuan Zhang, Yan Liang, Chuxu Zhang, Yanfang Ye
Autoregressive models generate sequences monotonically, where any sampled token, even if erroneous or sub-optimal, becomes a permanent condition for all subsequent steps.
This structural limitation means that autoregressive models cannot revisit or revise earlier decisions, i.e., a capability essential for complex generation tasks where exploration and correction are necessary.
To this end, we propose N-MARS, a Non-Monotonic AutoregRessive Sequence modeling framework that enables models to generate, evaluate, and revise tokens within a single forward pass, effectively allowing exploration before commitment.
We operationalize this framework through a learned erase token <UNDO> that retracts the previous token, enabling on-the-fly revision within standard autoregressive decoding.
To train the model, we introduce a sequence augmentation method that constructs error-correction trajectories from model-generated deviations paired with ground-truth references.
We then propose masked supervised fine-tuning (mSFT) that exposes the model to errors as context for learning when to revise, without optimizing their likelihood.
Finally, we refine the model with group relative policy optimization (GRPO) that

incentivizes judicious <UNDO> usage, i.e., rewarding effective corrections while penalizing unsuccessful ones.
We conduct comprehensive theoretical and empirical analysis to validate the effectiveness of N-MARS, demonstrating a robust foundation for non-monotonic sequence modeling.

Approximating Drift-Diffusion Models for User Decisions under Nudging and External Information
Gustavo Grivol, Hanna Halaburda, Alexander Tuzhilin
Modeling decision-making outside of controlled environments requires accounting for asynchronous, exogenous signals, such as notifications or algorithmic feeds, that dynamically alter user response times. Standard Drift-Diffusion Models (DDM) become analytically intractable when drift rates vary continuously with time. In this paper, we derive a closed-form analytical approximation for the first-passage time distribution of a single-boundary DDM with time-dependent drift, valid in the high-threshold regime. The main result allows us to analytically study the optimal timing of external signals to maximize the probability of a user response within our approximation framework. To evaluate our response time model, we conduct an extensive empirical comparison with state-of-the-art methods for user watch-time prediction and evaluation in simulated environments.

Parametric Prior Mapping Framework for Non-stationary Probabilistic Time Series Forecasting
Jinglin Li, Jun Tan, QI Fang, Ning Gui
Effectively modeling non-stationary dynamics in probabilistic multivariate time series(MTS) forecasting requires balancing expressiveness with robustness. Existing parametric approaches benefit from strong inductive biases but lack flexibility, whereas deep generative models struggle to capture complex temporal dependencies without extensive data and computation. We introduce Parametric Prior Mapping (PPM), a framework that injects parametric structural priors into a generative modeling process. Specifically, PPM utilizes a parametric estimator to derive a dynamic, adaptive prior that guides the learning of a complex predictive distribution via a learnable mapping. This design allows the model to retain the efficiency of parametric methods while exploiting the expressive power of generative models. Trained with a hybrid objective, PPM yields precise forecasts with well-calibrated uncertainty estimates. Empirical results show that PPM outperforms existing baselines in handling non-stationary data, offering a superior trade-off between accuracy and computational efficiency. The code is available at https://github.com/ljl8336/PPM.

Questioning the Coverage-Length Metric in Conformal Prediction: When Shorter Intervals Are Not Better
Yizhou Min, Yizhou Lu, Lanqi Li, Zhen Zhang, Jiaye Teng
Conformal prediction (CP) has become a cornerstone of distribution-free uncertainty quantification, conventionally evaluated by its coverage and interval length.
This work critically examines the sufficiency of these standard metrics.
We demonstrate that the interval length might be deceptively improved through a counter-intuitive approach termed Prejudicial Trick (PT), while the coverage remains valid.
Specifically, for any given test sample, PT probabilistically returns an interval, which is either null or constructed using an adjusted confidence level, thereby preserving marginal coverage.
While PT potentially yields a deceptively lower interval length, it introduces practical vulnerabilities: the same input can yield completely different prediction intervals across repeated runs of the algorithm. We formally derive the conditions under which PT achieves these misleading improvements and provide extensive empirical evidence across various regression and classification tasks.
Furthermore, we introduce a new metric interval stability which helps detect whether a new CP method implicitly improves the length based on such PT-like techni

ques. Code is available at https://github.com/benben-cd/PT-Conformal-Prediction

Video-BCI: Bayesian Cognitive Integration of Self-Prior Hypotheses for Video Understanding
Xing Xi, Peixian Chen, Yu Qiu, Ronghua Luo, Peilin Tong, Jiahao Liang
Recent progress in vision-language models (VLMs) has driven significant advances in video understanding. However, existing methods often act as naive empiricists, mapping video input directly to output without any mechanism to introspect or challenge inherent bias. In this work, we challenge this paradigm by reframing video reasoning as a Bayesian cognitive process. We propose Video-BCI (Bayesian Cognitive Integration of Self-Prior Hypotheses), a novel framework that first samples a set of Self-Prior Hypotheses to represent the model's intuitive yet potentially biased cognitive state, and then guides the VLMs to perform a critical integration of these priors. This process encourages the model to challenge erroneous majority consensus in cases of high information divergence and to distill superior reasoning chains from its own prior space. The integration is driven by a composite Cognitive Utility Function comprising two intrinsic learning signals: Dialectical Uncertainty Signal (DUS) and Process Tracing Signal (PTS). The DUS incentivizes correct, non-majority judgments by quantifying both the conflict (entropy) among priors and their consensus-challenging strength. The PTS guides the model to trace and learn from reasoning paths within its own priors that lead to better answers, enabling self-driven procedural knowledge distillation. Extensive experiments on six mainstream benchmarks show that Video-BCI achieves new state-of-the-art (SOTA) results across the board. For example, it surpasses the previous best on the MMVU benchmark by 3.8%.

Improved Bounds for Private and Robust Alignment
Wenqian Weng, Yi He, Xingyu Zhou
In this paper, we study the private and robust alignment of language models from a theoretical perspective by establishing upper bounds on the suboptimality gap in both offline and online settings. We consider preference labels subject to privacy constraints and/or adversarial corruption, and analyze two distinct interplays between them: privacy-first and corruption-first. For the privacy-only setting, we show that log loss with an MLE-style algorithm achieves near-optimal rates, in contrast to conventional wisdom. For the joint privacy-and-corruption setting, we first demonstrate that existing offline algorithms in fact provide stronger guarantees---simultaneously in terms of corruption level and privacy parameters---than previously known, which further yields improved bounds in the corruption-only regime. In addition, we also present the first set of results for private and robust online alignment. Our results are enabled by new uniform convergence guarantees for log loss and square loss under privacy and corruption, which we believe have broad applicability across learning theory and statistics.

On the Convergence of Decentralized Stochastic Minimax Optimization Algorithm with Compressed Communication
Yihan Zhang, Xinghua Shi, Meikang Qiu, Yu Wang, Hongchang Gao
The stochastic minimax optimization problem has widespread applications in machine learning. Recently, numerous distributed minimax optimization algorithms have been developed to handle distributed training data. However, most of these algorithms suffer from high communication costs. To address this issue, we develop a novel communication-efficient decentralized stochastic gradient descent ascent with momentum algorithm based on the error feedback mechanism. Importantly, our algorithm demonstrates how to balance the full-precision update and the compression residual with novel designs for coefficients regarding variables and gradients to guarantee convergence. However, compressing the primal and dual variables (and their gradients) of stochastic minimax optimization problems with the error feedback mechanism presents significant challenges for convergence analysis. In particular, it incurs the circle dependence among consensus errors and compression errors. To overcome this challenge, we propose novel strategies that enable the establishment of the convergence rate for our algorithm. Our theoretical re

sults demonstrate how the compression operator influences the convergence rate. Finally, extensive experimental results confirm the efficacy of our proposed alg orithm.

Energy-based Compositional Diffusion Planning
Tao Sun, Utkarsh Aashu Mishra, Jiaxin Lu, Danfei Xu, Iro Armeni
Compositional diffusion planners aim to solve long-horizon robotic tasks using s hort training trajectories. Yet, current approaches often rely on the heuristic stitching of local predictions. We show that the resulting stitched update is ge nerally a non-conservative field} that does not mathematically correspond to any valid global trajectory log-density function. We propose **Energy-based Composi tional Diffuser** (ECD), a framework that formulates the global trajectory as th e minimizer of the sum of local bridge potentials. This energy-based perspective defines a conservative correction field and contains a boundary reaction term t hat heuristic stitching omits. To enable efficient inference, we further introdu ce a Markov-based score approximation that computes the reaction term via a sing le block-tridiagonal solve, maintaining time complexity linear in the planning h orizon. Empirically, ECD achieves state-of-the-art success rates on a range of O GBench stitching tasks, while nearly matching the inference speed of heuristic s titching methods. Code is available at https://github.com/GradientSpaces/ECD.

Hydra-Nav: Object Navigation via Adaptive Dual-Process Reasoning
Zixuan Wang, Huang Fang, Shaoan Wang, Yuanfei Luo, Heng Dong, Wei Li, Yiming Gan
While large vision-language models (VLMs) show promise for object goal navigatio n, current methods still struggle with low success rates and inefficient localiz ation of unseen objects—failures primarily attributed to weak temporal-spatial r easoning. Meanwhile, recent attempts to inject reasoning into VLM-based agents i mprove success rates but incur substantial computational overhead. To address bo th the ineffectiveness and inefficiency of existing approaches, we introduce Hyd ra-Nav, a unified VLM architecture that adaptively switches between a deliberati ve "slow system" for analyzing exploration history and formulating high-level pl ans, and a reactive "fast system" for efficient execution. We train Hydra-Nav th rough a three-stage curriculum: (i) spatial-action alignment to strengthen traje ctory planning, (ii) memory-reasoning integration to enhance temporal-spatial re asoning over long-horizon exploration, and (iii) iterative rejection fine-tuning to enable selective reasoning at critical decision points. Extensive experiment s demonstrate that Hydra-Nav achieves state-of-the-art performance on the HM3D, MP3D, and OVON benchmarks, outperforming the second-best methods by 11.1\%, 17.4 \%, and 21.2\%, respectively. Furthermore, we introduce SOT (Success weighted by Operation Time), a new metric to measure search efficiency across VLMs with var ying reasoning intensity. Results show that adaptive reasoning significantly enh ances search efficiency over fixed-frequency baselines. Project page is availabl e at: https://zixuan-wang99.github.io/Hydra-Nav/.

Towards Reliable Marking and Verification of AI-Generated Text via Geometry-awar e Sentence-level Watermarking
Yubing Ren, Ping Guo, Yanan Cao
Large generative models raise growing concerns about provenance, misinformation, and impersonation. Digital watermarking offers a principled solution, yet exten ding it to natural language remains challenging due to text discreteness and sen sitivity to semantic perturbations. Existing text watermarking methods either op erate at the token level requiring white-box access and remaining fragile to par aphrasing, or at the sentence level, which supports black-box deployment but suf fers from low Watermark Success Rate (WSR). We show that low WSR in sentence-lev el watermarking primarily stems from low injection success probability caused by a mismatch between posterior embedding distributions and semantic accept region s. Based on this insight, we propose \textbf{X-Guard}, a geometry-aware sentence -level watermarking framework that improves injection success by jointly optimiz ing embedding distributions and semantic space partitioning. X-Guard learns a mo re isotropic embedding space and introduces \textbf{A^{2}PQ}, a centroid-aligned

 partitioning scheme that approximately equalizes probability mass across region
s.
Extensive experiments across multiple models, languages, and attack settings dem
onstrate that X-Guard consistently improves robustness while preserving text flu
ency and practical deployability.

MVP-LAM: Learning Action-Centric Latent Action via Cross-Viewpoint Reconstructio
n
Jung Min Lee, Dohyeok Lee, Seokhun Ju, Taehyun Cho, Jin Woo Koo, Li Zhao, Sangwo
o Hong, Jungwoo Lee
Latent actions learned from diverse human videos serve as pseudo-labels for visi
on-language-action (VLA) pretraining, but provide effective supervision only if
they remain informative about the underlying ground-truth actions. For effective
 supervision, latent actions should contain information about the underlying act
ions even though they are inaccessible. We propose **M**ulti-**V**iew**P**oint *
*L**atent **A**ction **M**odel (**MVP-LAM**), which learns latent actions that a
re highly informative about ground-truth actions from multi-view videos. MVP-LAM
 trains latent actions with a *cross-viewpoint reconstruction* objective, so tha
t a latent action from one view must explain the future in another view, reducin
g reliance on viewpoint-specific cues. On Bridge V2, MVP-LAM produces more actio
n-centric latent actions, achieving higher mutual information with ground-truth
actions and improved action prediction, including under out-of-distribution eval
uation. Finally, pretraining VLAs with MVP-LAM latent actions improves downstrea
m manipulation performance on various benchmarks. The code and trained checkpoin
ts are available at [https://jm-this.github.io/mvp_lam/](https://jm-this.github.
io/mvp_lam/).

Self-Captioning Multimodal Interaction Tuning: Amplifying Exploitable Redundanci
es for Robust Vision Language Models
Yuriel Ryan, Ip Hei Man, Adriel Kuek, Paul Pu Liang, Roy Ka-Wei Lee
Current vision language models face hallucination and robustness issues against
ambiguous or corrupted modalities. We hypothesize that these issues can be addre
ssed by exploiting the shared information between modalities to compensate for t
he impaired one. To this end, we analyze multimodal interactions -- redundant (s
hared), unique (exclusive), and synergistic (emergent) task-relevant information
 provided by the modalities -- to determine their impacts on model reliability.
Specifically, amplifying redundant interactions would increase this exploitable
shared information to resolve these issues; yet, modern instruction datasets oft
en eliminate redundancies to prioritize visual grounding. We bridge this gap thr
ough a self-captioning workflow featuring a \textsc{Multimodal Interaction Gate}
: a mechanism to convert unique interactions into redundant interactions. Our fi
ndings suggest that increasing redundancy can reduce visual induced errors by 38
.3\% and improve consistency by 16.8\%.
****
Population-Aware Imitation Learning in Mean-field Games with Common Noise
Grégoire Lambrecht, Mathieu Lauriere
Mean Field Games (MFGs) provide a powerful framework for modeling the collective
 behavior of large populations of interacting agents. In this paper, we address
the problem of Imitation Learning (IL) in MFGs subject to common noise, where th
e population distribution evolves stochastically. This stochasticity compels age
nts to adopt population-aware policies to respond to aggregate shocks. We formul
ate two distinct learning objectives: recovering a Nash equilibrium and maximizi
ng performance against an expert population. We investigate two imitation proxie
s: Behavioral Cloning (BC) and Adversarial (ADV) divergence. We then establish f
inite-sample error bounds showing that minimizing these proxies effectively cont
rols both the policy’s exploitability and its performance gap relative to the ex
pert. Furthermore, we propose a numerical framework using generalized Fictitious
 Play and Deep Learning to compute expert population-aware policies. Through exp
eriments on three environments we demonstrate that standard population-unaware p
olicies fail to capture the equilibrium dynamics. Our results highlight that lea

rning population-aware policies is crucial to avoid being misled by the randomne
ss inherent in common noise.

SEPS: Semantic-Enhanced Patch Slimming Framework for Fine-Grained Cross-Modal Al
ignment

Xinyu Mao, Junsi Li, Haoji Zhang, Yu Liang, Ming Sun

Fine-grained cross-modal alignment is pivotal for multimodal reasoning yet remai
ns limited by Semantic Sparsity Bias—a fundamental asymmetry where dense visual
signals are under-represented by sparse textual captions. This disparity leads t
o the inadvertent suppression of contextually vital visual regions (patch redund
ancy) and hinders precise concept grounding (patch ambiguity). While Multimodal
Large Language Models (MLLMs) offer rich descriptive capabilities, their naive i
ntegration often induces semantic drift due to inconsistencies with sparse groun
d-truth captions. To systematically resolve these challenges, we present the Sem
antic-Enhanced Patch Slimming (SEPS) framework. Central to SEPS is a novel Dual-
Granularity Semantic Calibration mechanism, which synthesizes a Holistic Visual-
Linguistic Anchor from MLLMs to synergize with original sparse queries. This mec
hanism transforms patch selection into a semantic consensus process, ensuring th
at retained patches satisfy both local discriminability and global contextual in
tegrity. Furthermore, we propose a Salience-Guided Metric Aggregation strategy t
o mitigate the similarity dilution effect inherent in global mean pooling, there
by amplifying highly-relevant patch-word correspondences. Extensive experiments
on Flickr30K and MS-COCO datasets demonstrate that SEPS surpasses existing state
-of-the-art approaches across diverse backbones, delivering significant performa
nce gains in text-to-image retrieval tasks. The complete implementation is avail
able at https://anonymous.4open.science/r/SEPS/.

Fast Non-Episodic Finite-Horizon RL with K-Step Lookahead Thresholding

Jiamin Xu, Kyra Gan

Online reinforcement learning in non-episodic, finite-horizon MDPs remains under
explored and is challenged by the need to estimate returns to a fixed terminal t
ime. Existing infinite-horizon methods, which often rely on discounted contract
ion, do not naturally account for this fixed-horizon structure. We introduce a m
odified Q-function: rather than targeting the full-horizon, we learn a K-step lo
okahead Q-function that truncates planning to the next K steps. To further impro
ve sample efficiency, we introduce a thresholding mechanism: actions are selecte
d only when their estimated K-step lookahead value exceeds a time-varying thresh
old. We provide an efficient tabular learning algorithm for this novel objective
, proving it achieves fast finite-sample convergence: it achieves minimax optima
l constant regret for $K=1$ and $\mathcal{O}(\max((K-1),C_{K-1})\sqrt{SAT\log(T)
})$ regret for any $K \geq 2$. We numerically evaluate the performance of our a
lgorithm under the objective of maximizing reward. Our implementation adaptively
 increases K over time, balancing lookahead depth against estimation variance. E
mpirical results demonstrate superior cumulative rewards over state-of-the-art t
abular RL methods across synthetic MDPs and RL environments: JumpRiverswim, Fro
zenLake and AnyTrading. Code is provided on \href{https://github.com/jamie01713/
K-Step-Lookahead}{github}.

Conformal Path Reasoning: Trustworthy Knowledge Graph Question Answering via Pat
h-Level Calibration

Shuhang Lin, Chuhao Zhou, Xiao Lin, Zihan Dong, Kuan Lu, Zhencan Peng, Jie Yin,
Dimitris N. Metaxas

Knowledge Graph Question Answering (KGQA) offers grounded, interpretable reasoni
ng, but existing methods often fail to provide reliable coverage guarantees over
 retrieved answers. While Conformal Prediction (CP) offers a principled framewor
k for producing prediction sets with statistical guarantees, prior conformal KGQ
A methods suffer from two critical pitfalls: violated coverage guarantees due to
 invalid calibration, and weak score discriminability that yields excessively la
rge prediction sets. We propose Conformal Path Reasoning (CPR), a novel trustwor
thy KGQA framework built on two key innovations. First, query-level conformal ca

libration over path-level scores preserves exchangeability to ensure valid cover age guarantees. Second, we introduce the Residual Conformal Value Network (RCVNe t), a lightweight module trained via PUCT-guided exploration to learn discrimina tive path-level nonconformity scores. Extensive experiments show that CPR signif icantly improves the Empirical Coverage Rate by 45\% while reducing prediction s et size by 52\% on average over conformal baselines across benchmark datasets, h ighlighting its effectiveness for reliable conformal reasoning over knowledge gr aphs.
****

DLM: Unified Decision Language Model for Offline Multi-Agent Sequential Decision Making

Zhuohui Zhang, Bin Cheng, Bin He

Building scalable and reusable multi-agent decision policies from offline datase ts remains a challenge in offline multi-agent reinforcement learning (MARL), as existing methods often rely on fixed observation formats and action spaces that limit generalization. In contrast, large language models (LLMs) offer a flexible modeling interface that can naturally accommodate heterogeneous observations an d actions. Motivated by this, we propose the Decision Language Model (DLM), whic h formulates multi-agent decision making as a dialogue-style sequence prediction problem under the centralized training with decentralized execution paradigm. D LM is trained in two stages: a supervised fine-tuning phase, which leverages dia logue-style datasets for centralized training with inter-agent context and gener ates executable actions from offline trajectories, followed by a group relative policy optimization phase to enhance robustness to out-of-distribution actions t hrough lightweight reward functions. Experiments on multiple benchmarks show tha t a unified DLM outperforms strong offline MARL baselines and LLM-based conversa tional decision-making methods, while demonstrating strong zero-shot generalizat ion to unseen scenarios across tasks.

EpiCoCo: De Novo Epitope Generation via MHC-Context Co-Modeling and Contrastive Affinity Guidance

Haoyang Luan, Gufeng Yu, Letian Chen, Zhenran Xiao, Yueshan Huang, Junkun Guo, Y ang Yang

The *de novo* generation of high-affinity epitopes tailored to specific major hi stocompatibility complex (MHC) proteins is a pivotal challenge in computational immunotherapy. However, current methods struggle to effectively integrate the MH C context into the generation process, and often fail to guarantee high binding affinity due to the neglect of discriminative signals from non-binders. To bridg e these gaps, we present **EpiCoCo**, a probabilistic framework for **Epi**tope generation via MHC-context **Co**-modeling and **Co**ntrastive affinity learning . EpiCoCo treats the pMHC complex as a dynamic, co-adaptive system by operating on the joint E(3) graph. In addition, we introduce Contrastive Affinity Guidance (CAG), an inference mechanism that leverages the gradient difference between le arned high- and low-affinity distributions. CAG actively drives the generation t rajectory towards high-affinity manifolds while utilizing repulsive signals to f ilter out candidates with poor binding potential. Extensive evaluations demonstr ate that EpiCoCo achieves a mean binding free energy of -45.20 REU, a 23% improv ement over the state-of-the-art, while maintaining high structural plausibility. The results validate that context co-modeling and negative-informed guidance ar e essential for generating valid, high-potency immunotherapeutics.

Persona2Web: Benchmarking Personalized Web Agents for Contextual Reasoning with User History

Serin Kim, Sangam Lee, Dongha Lee

Large language models have advanced web agents, yet current agents lack personal ization capabilities.
Since users rarely specify every detail of their intent, practical web agents mu st be able to interpret ambiguous queries by inferring user preferences and cont exts.
To address this challenge, we present Persona2Web, the first benchmark for evalu

ating personalized web agents on the real open web, built upon the clarify-to-pe
rsonalize principle, which requires agents to resolve ambiguity based on user hi
story rather than relying on explicit instructions.
Persona2Web consists of:
(1) user histories that reveal preferences implicitly over long time spans,
(2) ambiguous queries that require agents to infer implicit user preferences, an

MMBench-Live: A Continuously Evolving Benchmark for Multimodal Models
Yuanzhi Liu, Shousheng Zhao, Bo Zhou, Kongming Liang, Zhanyu Ma
Evaluation benchmarks are essential for assessing vision--language models (VLMs)
, but most multimodal benchmarks are static, making them vulnerable to temporal
staleness, data contamination, and costly maintenance. We present MMBench-Live,
a continuously evolving multimodal benchmark built by a multi-agent-driven autom
ated pipeline. Our framework treats benchmark evolution as task-guided dataset c
onstruction, integrating structured benchmark specification, feedback-controlled
 real-time data acquisition, and verifiable QA generation with executable reason
ing. To maintain cross-version comparability, we introduce a distribution-consis
tent update strategy that extracts task-related visual patterns from the origina
l benchmark to guide data collection and filtering. Instantiated from MMBench, M
MBench-Live contains 5.9K newly generated evaluation instances with a high answe
r correctness rate, while each update costs about \$30 and takes 1--2 hours. Ext
ensive evaluations show that MMBench-Live preserves stable model rankings, maint
ains semantic alignment with the original benchmark, and exhibits weaker contami
nation-related memorization signals, suggesting a practical and scalable paradig
m for sustainable multimodal benchmark evolution. The project is available at \u
rl{https://github.com/PRIS-CV/MMBench-Live}.

Tackling Length Inflation Without Trade-offs: Group Relative Reward Rescaling fo
r Reinforcement Learning
Zichao Li, Jie Lou, Fangchen Dong, Zhiyuan Fan, Mengjie Ren, Hongyu Lin, Xianpei
 Han, Debing Zhang, Le Sun, Yaojie Lu, XingYu Li
Reinforcement learning significantly enhances LLM capabilities but suffers from
a critical issue: length inflation, where models adopt verbosity or inefficient
reasoning to maximize rewards.
Prior approaches struggle to address this challenge in a general and lossless ma
nner, primarily because additive penalties introduce a compensatory effect that
creates optimization shortcuts, while heuristic gating strategies lack generalit
y beyond binary feedback.
To bridge this gap, we present Group Relative Reward Rescaling (GR^3), which r
eframes length control as a multiplicative rescaling paradigm, effectively estab
lishing a generalized, continuous, and reward-dependent gating mechanism. To fur
ther ensure lossless optimization, we incorporate group-relative regularization
and advantage-aware calibration, which dynamically adapt length budgets to insta
nce difficulty and preserve the advantage signal of high-quality trajectories. E
mpirically, across both RLHF and RLVR settings, GR^3 maintains training dynami
cs and downstream performance comparable to standard GRPO while significantly mi
tigating length inflation, outperforming state-of-the-art length-regularized bas
elines.

ConFlux: Multivariate Time Series in Flux, One Unified Forecast in Confluence
Shiyu Wang, Juntong Ni, Ziyi Zhang, Baichuan Mo, Xinyue Zhong, Chengxin Wang, Yu
chen Fang, Zhou Ye, Yang Xiang

Real-world multivariate time series are inherently in flux: different variables evolve asynchronously and interact in complex, time-varying ways, yet accurate forecasting requires these dispersed signals to converge into a single unified prediction.
This structural mismatch between dynamic, heterogeneous inputs and a unified forecasting objective poses a fundamental challenge for building general-purpose multivariate forecasting models, especially in zero-shot and large-scale settings.

To this end, inspired by the idea that ``\emph{all rivers run into the sea}'', we propose \textbf{ConFlux}, a \emph{general-purpose foundation model for multivariate time-series forecasting} by learning to adaptively integrate cross-channel information under a unified forecasting objective. Specifically, ConFlux first reorders variables to reduce cross-variable entanglement, then aggregates adjacent variables into compact patches that can be processed by a Vision Transformer-style architecture. This design shortens the effective context, reduces attention complexity, and provides a unified token representation for pre-training and downstream tasks.
Experiments on 25 public datasets show that ConFlux achieves state-of-the-art performance in zero-shot, fine-tuning, and from-scratch settings, while offering faster inference and lower memory usage.

GEM: Geometric Entropy Mixing for Optimal LLM Data Curation
Yue Min, Ziyun Qiao, Ruining Chen, Yujun Li
LLM pre-training efficacy increasingly depends on data composition rather than sheer volume. Yet, optimal mixing is hindered by categorization flaws: human taxonomies suffer from ontological misalignment, and Euclidean clustering fails to address embedding anisotropy. We introduce **GEM** (**G**eometric **E**ntropy **M**ixing), a framework reformulating data curation as a variational problem on the hypersphere augmented with a **mixing-balance regularizer**. By decoupling the generative prior and optimizing the objective via a provable **MM (Minorize-Maximize)** algorithm, GEM effectively counteracts the cluster collapse to discover balanced semantic structures invisible to Euclidean heuristics. We employ teacher-student distillation to scale this geometric fidelity to web-scale corpora and introduce the **Geometric Influence Score (GIS)** for interpretable taxonomy generation. Experiments with 1.1B-parameter models demonstrate that GEM establishes a new state-of-the-art when integrated into mixing strategies like DoReMi and RegMix, improving average downstream accuracy by up to **1.2%** and offering a robust coordinate system for predictable data mixing.

Diversity-Aware Recursive Feature Multiple Kernel Learning
Nan Cao, Xu Zhao, Teng Zhang
\textit{\underline{M}ultiple \underline{k}ernel \underline{l}earning}~(MKL) combines several base kernels in the spirit of ensemble learning, yet existing methods rarely model kernel diversity---a known cornerstone of ensembles---and most traditional kernels weight all features uniformly, ignoring feature-level discriminability. We address both gaps with DARFMMKL: a data-driven kernel family (Recursive Feature Machine kernels) that learns feature importance directly from data, paired with a kernel selection method that jointly optimizes diversity and quality. The resulting NP-hard binary quadratic program is reformulated via Glover linearization and continuous relaxation into a linear program, and accelerated by Nystr\"om sketching, yielding a selector whose cost is decoupled from the sample size. We provide a covering-number generalization bound that explicitly relates kernel diversity to estimation error. Experiments on 12 benchmark datasets show that DARFMMKL consistently outperforms 9 state-of-the-art MKL methods.

CausalX: A Unified and Causally-Interpretable Plug-and-Play Model for Multi-modal Spatio-Temporal Forecasting
Shiqi Zhang, Pan Mu, Hanting Yan, Yuchao Zhu, jinglin zhang, Cong Bai
Multi-modal spatio-temporal forecasting underpins many real-world applications but remains challenging due to the complex and evolving interactions across modal

ities and time steps. Moreover, the lack of interpretability in existing models limits their reliability in safety-critical scenarios.
In this paper, we present CausalX, a unified and causally interpretable plug-and-play model for multi-modal spatio-temporal forecasting.
CausalX achieves interpretability by learning a dynamic causal graph across modalities and time, whose edge weights quantify causal attribution strength, and are further refined by a diffusion-based generative process guided by structural priors.
To overcome the absence of ground-truth causal structures, CausalX aggregates multi-source constraints from causal analysis techniques and a variational autoencoder, spanning predictive, temporal, interventional, and generative aspects to jointly learn a more comprehensive causal graph. Extensive experiments on real-world forecasting tasks, including pedestrian trajectory prediction and tropical cyclone forecasting, demonstrate that CausalX achieves superior accuracy while producing interpretable causal graphs. CausalX is modular, architecture-agnostic, and generalizable, offering a new perspective on bridging causal inference and spatio-temporal forecasting.

Population-Free Pareto Tracking for Sample-Efficient Multi-Policy MORL
Zeyu Zhao, Yueling Che, Kaichen Liu, Jian Li, Junmei Yao
Multi-objective reinforcement learning (MORL) is a fundamental framework for real-world decision-making problems involving multiple conflicting criteria. Existing multi-policy (MP) methods typically rely on online evolutionary frameworks that maintain large policy populations, leading to high sample complexity and excessive agent–environment interactions. To mitigate these limitations, we present Multi-policy Pareto Front Tracking (MPFT), a framework without a self-evolving population. It leverages an efficient Pareto-tracking mechanism initialized with single-objective extreme policies to trace the Pareto front, and further densifies sparse regions to achieve an accurate approximation of the full Pareto front. MPFT can be seamlessly integrated with advanced offline MORL algorithms, thereby
substantially improving sample efficiency. We evaluate MPFT on six robotic control tasks with up to three objectives and three high-dimensional tasks with more than three objectives. Experimental results show that MPFT outperforms state-of-the-art baselines in terms of hypervolume and expected utility. It also significantly reduces agent–environment interactions. These results further demonstrate that MPFT serves as a general purpose framework that can seamlessly integrate both online and offline MORL algorithms.

GeoFlow: Geo-Aware Modeling of Inter-Area Relationships in Origin-Destination Flow Prediction and Generation
Zherui Huang, Guanjie Zheng, Hao Xue, Linghe Kong
Origin–destination (OD) flow modeling underpins urban planning and mobility analysis, but prevailing graph-based methods often neglect salient geographic attributes, limiting their ability to model long-range and multi-area dependencies. In this paper, we introduce GeoFlow, a novel framework that (i) augments area representations with geospatial attributes, including relative positions,
-hop and geodesic distances, (ii) employs a specialized geometric-intrinsic fusion encoder design that combines graph attention for intrinsic area signals with coordinate-aware encoders for global structure, and (iii) adopts an axial-global attention decoder to capture OD-specific competitive dependencies. For OD flow generation, GeoFlow is paired with flow matching models to produce more authentic and diverse mobility samples. Empirically, GeoFlow achieves superior performance in predictive accuracy, while substantially improving generative fidelity and diversity. Ablation and analytical studies confirm the contribution of each component. Code is available at https://github.com/ZheruiHuang/GeoFlow.

Nested birth-death processes are competitive with neural networks as time-dependent models of protein evolution

Annabel Large, Ian Holmes
Most statistical phylogenetics analyses use simple continuous-time finite-state Markov models of point substitution to describe molecular evolution. These models enforce unrealistic assumptions like keeping sequence length fixed, ignoring insertions and deletions (indels) entirely, and making little (if any) allowance for variation in selection pressure due to interactions between amino acids. We extend the TKF92 model—the canonical hierarchical model combining an outer birth-death process for indels with an inner finite-state Markov chain for substitutions—by introducing additional nesting and latent states, allowing for structural heterogeneity. We compare these TKF92 extensions to two classes of neural seq2seq models that use evolutionary time as an input feature: the first "basic" class lacks any evolutionary modeling constraints, while the second "hybrid" class combines neural sequence embeddings with a TKF92-like likelihood function. We evaluate the per-character perplexities of all models on splits of the Pfam database of aligned protein domains. The hybrid neural models outperform their basic counterparts across all sequence embedding architectures. Furthermore, a nested TKF-based model with only 30,000 parameters is highly competitive with all neural networks (which contain tens of millions of parameters), outperforming all but two of the neural architectures tested. Taken together, our results indicate that approaches grounded in molecular evolutionary theory may provide a better fit to real alignments than unconstrained alternatives, supporting the incorporation of CTMC-based model structure within future neural phylogenetic approaches.
****
Physics-Guided Motion Loss for Video Generation Model
Bowen Xue, Giuseppe Claudio Guarnera, Shuang Zhao, Zahra Montazeri
Current video diffusion models generate visually compelling content but often struggle with physical motion, producing subtle artifacts like rubber-sheet deformations and
inconsistent object motion. We introduce a frequency-domain physics prior that improves
motion plausibility without modifying model architectures. Our method decomposes common
motion patterns (translation, rotation, scaling) into lightweight spectral losses.
Applied to Open-Sora, MVDIT, and Hunyuan, our approach improves both motion accuracy and action recognition by ~11\% on average on OpenVID-1M (relative), while maintaining visual quality. Additional results on Wan 2.1-14B show consistent gains on video-quality and physics-oriented metrics. User studies show 74-83\% preference for our physics-enhanced videos. It also reduces warping error by 22-37\% (depending on the backbone) and improves temporal consistency scores. These results indicate that simple, global spectral cues are an effective drop-in regularizer for physically plausible motion in video diffusion.
****
Two Modalities Are Better Than One: Efficient Adversarial Purification via Multimodal Diffusion Models
Mingyuan Bai, Wei Huang, Tenghui Li, Andong Wang, Chao Li, Cesar F Caiafa, Junbin Gao, Qibin Zhao
Adversarial purification uses generative models to restore clean data distributions from unseen attacks without retraining classifiers. However, unimodal diffusion-based approaches struggle to preserve semantic consistency, while recent multimodal variants rely on computationally expensive adversarial training or distillation. Both approaches often lack theoretical guarantees. In this work, we propose MultiDAP, a novel framework leveraging multimodal diffusion models for efficient adversarial purification. MultiDAP first learns continuous class-agnostic prompts from clean data to capture rich semantic priors, replacing rigid hand-crafted templates. Guided by these prompts, MultiDAP purifies adversarial inputs by minimizing a regularized DDPM loss for only a few steps (e.g., 5-20). We provide theoretical guarantees for both the likelihood improvement via prompt learning and the convergence of the purification process. Extensive experiments on CIFAR-10, CIFAR-100, and ImageNet-1K demonstrate that MultiDAP matches the robustnes

s of state-of-the-art baselines but with improved efficiency.
****
MemEvolve: Meta-Evolution of Agent Memory Systems
Guibin Zhang, Haotian Ren, Chong Zhan, Junhao Wang, He Zhu, Wangchunshu Zhou, Sh uicheng YAN
Self-evolving memory systems are rapidly reshaping the evolutionary paradigm of large language model (LLM)-based agents. Prior work has predominantly relied on manually engineered memory architectures to store trajectories, distill experien ce, and synthesize reusable tools, enabling agents to evolve on the fly within e nvironment interactions. However, this paradigm is fundamentally constrained by the \textit{staticity} of the memory system itself: while memory facilitates age nt-level evolving, the underlying memory architecture cannot be meta-adapted to diverse task contexts. To address this gap, we propose MemEvolve, a meta-evoluti onary framework that jointly evolves agents' experiential knowledge and their me mory architecture, allowing agent systems not only to accumulate experience but also to progressively refine how they learn from it. To ground MemEvolve in prio r work and promote openness in future self-evolving systems, we introduce Evolve Lab, a unified memory codebase that distills twelve representative memory system s into a modular design space (\textit{encode}, \textit{store}, \textit{retrieve }, \textit{manage}), providing a standardized implementation substrate and a fai r experimental arena. Extensive evaluations on four challenging agentic benchmar ks show that MemEvolve delivers (i) substantial performance gains, improving fra meworks such as SmolAgent and Flash-Searcher by up to 17.06%, and (ii) strong cross-task and cross-LLM generalization, yielding memory architectures that tra nsfer effectively across diverse benchmarks and backbones.
****
From Feasible to Practical: Pareto-Optimal Synthesis Planning
Friedrich Hastedt, Dongda Zhang, Antonio Del rio chanona
Current computer-aided synthesis planning (CASP) methods often treat retrosynthe sis as solved once a single feasible route is identified, focusing primarily on convergence or shortest-path metrics. This view is misaligned with real-world pr actice, where chemists must balance competing objectives such as cost, sustainab ility, toxicity, and overall yield. To address this, we formulate synthesis plan ning as a multi-objective search problem and introduce MORetro*, an algori thm that generates a Pareto front of synthesis routes to explicitly capture trad e-offs between user-defined criteria. MORetro* uses weighted scalarization and solution-informed sampling to efficiently navigate the combinatorial search space and prioritize promising trade-offs. Building on multi-objective A* -search, we provide optimality guarantees showing that, for a fixed single-step model, MORetro* recovers the true Pareto front under admissibility. Across multiple retrosynthesis benchmarks, MORetro* produces diverse, high-quali ty Pareto fronts, uncovering solutions overlooked by single-objective approaches and better aligning CASP outputs with industrial decision-making.

DREAM: Dual-Standard Semantic Homogeneity with Dynamic Optimization for Graph Le arning with Label Noise
Yusheng Zhao, Jiaye Xie, Qixin Zhang, Weizhi Zhang, Xiao Luo, Zhiping Xiao, Phil ip S. Yu, Ming Zhang
Graph neural networks (GNNs) have been widely used in various graph machine lear ning scenarios. Existing literature primarily assumes well-annotated training gr aphs, while the reliability of labels is not guaranteed in real-world scenarios. Recently, efforts have been made to address the problem of graph learning with label noise. However, existing methods often (i) struggle to distinguish between reliable and unreliable nodes, and (ii) overlook the relational information emb edded in the graph topology. To tackle this problem, this paper proposes a novel method, Dual-Standard Semantic Homogeneity with Dynamic Optimization (DREAM), f or reliable, relation-informed optimization on graphs with label noise. Specific ally, we design a relation-informed dynamic optimization framework that iterativ ely reevaluates the reliability of each labeled node in the graph during the opt imization process according to the relation of the target node and other nodes.

To measure this relation comprehensively, we propose a dual-standard selection strategy that selects a set of anchor nodes based on both node proximity and graph topology. Subsequently, we compute the semantic homogeneity between the target node and the anchor nodes, which serves as guidance for optimization. We also provide a rigorous theoretical analysis to justify the design of DREAM. Extensive experiments are performed on six graph datasets across various domains under three types of graph label noise against competing baselines, and the results demonstrate the effectiveness of the proposed DREAM.

Vision-aligned Latent Reasoning for Multi-modal Large Language Model
Byungwoo Jeon, Yoonwoo Jeong, Hyunseok Lee, Minsu Cho, Jinwoo Shin
Despite recent advancements in Multi-modal Large Language Models (MLLMs) on diverse understanding tasks, these models struggle to solve problems which require extensive multi-step reasoning. This is primarily due to the progressive dilution of visual information during long-context generation, which hinders their ability to fully exploit test-time scaling. To address this issue, we introduce Vision-aligned Latent Reasoning (VaLR), a simple, yet effective reasoning framework that dynamically generates vision-aligned latent tokens before each Chain of Thought reasoning step, guiding the model to reason based on perceptual cues in the latent space. Specifically, VaLR is trained to preserve visual knowledge during reasoning by aligning intermediate embeddings of MLLM with those from vision encoders. Empirical results demonstrate that VaLR consistently outperforms existing approaches across a wide range of benchmarks requiring long-context understanding or precise visual perception, while exhibiting test-time scaling behavior not observed in prior MLLMs. In particular, VaLR improves the performance significantly from 33.0\% to 52.9\% on VSI-Bench, achieving a 19.9\%p gain over Qwen2.5-VL.
****

Generalizable and Composable Multi-Model Embedding Translation
Beining Yang, Yang Cao
Embedding translation enables interoperability across embedding models, allowing embedding vectors to be reused without costly re-embedding. However, existing methods are typically evaluated under simplified pairwise and i.i.d. settings and behave as black boxes at inference time, leading to unreliable performance under out-of-distribution (OOD) inputs, multi-model mixing, and composed translations. We analyze embedding translation from a geometric perspective and derive an interpretable error bound that explains systematic error amplification under OOD inputs, mixing and chaining. Building on this, we propose a geometry-aware confidence metric and a Hierarchical Mixture of Experts (HMoE) framework with localized, parameter-efficient adaptation. Following the MTEB leaderboard, we conduct large-scale experiments over 10 embedding models and 6 datasets across 90 pairwise translation settings. HMoE outperforms every baseline for every model pair over every dataset under OOD scenarios. Furthermore, multi-model mixing and chaining only degrade our performance in Recall@100 by $0.5\% -- 2.6\%$, compared to $7.2\% -- 92.3\%$ recall drop by existing methods.
****

Scaling-Aware Adapter for Structure-Grounded LLM Reasoning
Zihao Jing, QIUHAO Zeng, Ruiyi Fang, Yan Yi Li, Yan Sun, Boyu Wang, Pingzhao Hu
Large language models (LLMs) are enabling reasoning over 2D and 3D structures, yet existing methods remain modality-specific and typically compress structural inputs through sequence-based tokenization or fixed-length query connectors. Such architectures either omit the geometric grounding requisite for mitigating structural hallucinations, or impose inflexible modality fusion bottlenecks that concurrently over-compress and suboptimally allocate structural tokens, thereby impeding the realization of generalized all-atom reasoning. We introduce **Cuttlefish**, a unified multimodal LLM that grounds language reasoning in geometric cues while scaling modality tokens with structural complexity. First, **Scaling-Aware Patching** leverages an instruction-conditioned gating mechanism to generate variable-size patches over structural graphs, adaptively scaling the query token budget with structural complexity to mitigate fixed-length connector bottlenecks

. Second, **Geometry Grounding Adapter** refines these adaptive tokens via cross-attention to modality embeddings and injects the resulting modality tokens into the LLM, exposing explicit geometric cues to reduce structural hallucination. Experiments across interdisciplinary all-atom benchmarks demonstrate that Cuttlefish achieves superior performance in heterogeneous structure-grounded reasoning. Code: github.com/zihao-jing/Cuttlefish.
****

MADA-Attack: Transferable Multi-modal Attention Distraction Adversarial Attack against Vision Language Models
Zhihan Qin, Jiahao Chen, Chunyi Zhou, Yuwen Pu, Chunqiang Hu, Xiaolei Liu, Shouling Ji
Vision Language Models (VLMs) achieve strong performance across multi-modal tasks but remain vulnerable to universal adversarial perturbations (UAPs). Existing UAP methods mainly operate on the visual modality, overlooking structured textual semantics and cross-modal interactions, which limits their ability to disrupt alignment and generalize across tasks and model architectures. To address these limits, we propose **Multi-modal Attention Distraction Adversarial Attack (MADA-Attack)** framework. We begin by conducting several insight experiments and discover that modality attention distributes differently over layers and early phase of optimization is decisive. Building on these observations, we introduce Semantic Token Manipulation (STM) to steer text-guided attention, and Fused Embedding Training (FET) to jointly optimize textual and visual embedding losses for coordinated misalignment. We further incorporate an Adaptive Data Augmentation (ADA) strategy that dynamically balances attack strength, transferability, and training efficiency. Extensive experiments demonstrate that **MADA-Attack** consistently achieves state-of-the-art performance and strong transferability while remaining computationally lightweight, with an average ASR of 82.60\% and 73.42\% in zero-shot classification and image captioning tasks. For the visual question answering (VQA) and I-T Retrieval task, our method exceeds the SOTA baseline by 10\%. Our code is available at this [GitHub Repository](https://github.com/RaymundoTheWolf/MADA-Attack).

Memory as a Markov Matrix: Sample Efficient Knowledge Expansion via Token-to-Dictionary Mapping
Kaustubh Pethkar, Ziyang Xiong, Zuofeng Shang, Yingcong Li
Continual incorporation of new knowledge is essential for the long-term evolution of large language models (LLMs). Existing approaches typically rely on parameter-update algorithms to mitigate catastrophic forgetting, yet they suffer from fundamental limitations: 1) forgetting is unavoidable as the amount of newly injected knowledge grows; and 2) model updates are often irreversible. As modern LLMs become increasingly expressive, it is natural to question whether large-scale weight updates are necessary for acquiring a small amount of new knowledge. In this work, we propose a principled framework that models autoregressive language generation as a Markov process over tokens, where model memory is represented by a Markov transition matrix. Under this formulation, incorporating new knowledge/tokens corresponds to extending the state space, and preserving existing transitions guarantees retention of previously learned knowledge. We then prove a sample complexity bound for incorporating new tokens via a token-to-dictionary mapping strategy. In particular, for learning the transition behavior of each new token, the required number of samples scales linearly with the number of existing tokens it is mapped to. To realize this mapping, we propose an embedding-tuning algorithm that requires minimal parameter updates and induces zero forgetting. Experimental results further demonstrate the effectiveness of our method and validate our theoretical findings.
****

FiSeR: Fine-Grained Source Representations for Cross-Domain AI Image Detection
Shan Zhang, Yongxin He, Mingming Zhang, Huiwen Tian, Lei Ma
Real-world synthetic image detectors often generalize poorly under domain shift despite strong in-domain performance. Using unsupervised UMAP projections, we find that natural and synthetic features remain partially separable on unseen data

sets, yet performance still drops, suggesting that the classification head overfits to training-domain artifacts.
Therefore, the key is to learn more transferable representations so that the decision criterion is more stable and robust to domain shifts. Based on the structural fact that synthetic images are produced by diverse generators, we propose a hierarchical contrastive learning framework that improves the separability between natural and synthetic images while preserving generator identity information. It jointly optimizes (i) a coarse contrastive objective between natural and synthetic images and (ii) a fine contrastive objective among synthetic images using generator identities.
Trained on WildFake, our method achieves an average AUROC gain of +10.22 on cross-domain evaluation over Chameleon, AIGIBench, Community Forensics, and GenImage under the same settings as the strong baseline DIRE. For few-shot adaptation, we freeze the backbone and fit an SVM head on 10 labeled samples per class, improving AUROC by +10.64 on AIGIBench and +17.41 on Chameleon, averaged over 12 widely used detectors. Our code is publicly available at: https://github.com/heyongxin233/FiSeR.

VLA-Arena: An Open-Source Framework for Benchmarking Vision-Language-Action Models
Borong Zhang, Jiahao Li, Jiachen Shen, Yuhao Zhang, Yishuai Cai, Yuanpei Chen, Juntao Dai, Jiaming Ji, Yaodong Yang
While Vision-Language-Action models (VLAs) are rapidly advancing toward generalist robot policies, quantitatively characterizing their capability boundaries and failure modes remains challenging. To address this, we introduce **VLA-Arena**, a comprehensive benchmark. It features a novel structured task design framework to quantify difficulty across three orthogonal axes: **(1) Task Structure**, **(2) Language Command**, and **(3) Visual Observation**. This allows us to systematically design tasks with fine-grained difficulty levels, enabling a precise measurement of model capability frontiers. For task structure, VLA-Arena comprises 11 task suites organized into four dimensions: **Safety**, **Distractor**, **Extrapolation**, and **Long Horizon**, totaling 170 tasks. Each suite spans three difficulty levels (L0–L2), with fine-tuning restricted to L0 to rigorously assess generalization. Orthogonal to this, language (W0-W4) and visual (V0-V4) perturbations can be applied to any task as diagnostic probes to distinguish robust grounding from superficial pattern matching. Our extensive evaluation of state-of-the-art VLAs reveals critical limitations: memorization over generalization, superficial visual perception, and a neglect of safety constraints. Additionally, model rank reversals across L0–L2 validate that each level provides non-redundant insights. To foster research addressing these model limitations and ensure reproducibility, we provide the complete VLA-Arena framework, including an end-to-end toolchain from task definition to automated evaluation and the VLA-Arena-S/M/L datasets for fine-tuning. Our benchmark, datasets, models, and leaderboard are publicly available at https://vla-arena.github.io.

HEARTS: Benchmarking LLM Reasoning on Health Time Series
Sirui Li, Shuhan Xiao, Mihir Joshi, Ahmed Metwally, Daniel McDuff, Wei Wang, Yuzhe Yang
The rise of large language models (LLMs) has shifted time series analysis from narrow analytics to general-purpose reasoning. Yet, existing benchmarks cover only a small set of health time series modalities and tasks, failing to reflect the diverse domains and extensive temporal dependencies inherent in real-world physiological modeling. To bridge these gaps, we introduce HEARTS (Health Reasoning over Time Series), a unified benchmark for evaluating hierarchical reasoning capabilities of LLMs over general health time series. HEARTS integrates 16 real-world datasets across 12 health domains and 20 signal modalities, and defines a comprehensive taxonomy of 110 tasks grouped into four core capabilities: Perception, Inference, Generation, and Deduction. Evaluating 14 state-of-the-art LLMs on more than 20K test samples reveals intriguing findings. First, LLMs substantially underperform specialized models, and their performance is only weakly related t

o general reasoning scores. Moreover, LLMs often rely on simple heuristics and s truggle with multi-step temporal reasoning. Finally, performance declines with i ncreasing temporal complexity, with similar failure modes within model families, indicating that scaling alone is insufficient. By making these gaps measurable, HEARTS provides a standardized testbed and living benchmark for developing next -generation LLM agents capable of reasoning over diverse health signals.

Decoupling Universal Laws and Environmental Heterogeneity: A Physics-Inspired Fr amework for Robust Spatio-Temporal Forecasting
Aoyu Liu, Liming Wei, Yaying Zhang
Most spatio-temporal forecasting models assume in-distribution data and can degr ade sharply under non-stationary environments. Existing methods for handling dis tribution shift largely rely on discrete graph inference, making it difficult to disentangle universal dynamics from environment-specific changes and to respect the continuous physical nature of spatio-temporal fields. To this end, we propo se STPDE, a general framework that reformulates spatio-temporal dynamics as the evolution of inhomogeneous partial differential equations. STPDE explicitly deco mposes dynamics into an Invariant Diffusion Operator that captures universal mec hanisms and an Environment Basis Manifold that parameterizes local heterogeneous media. We show that the Green's function of the Laplacian can be effectively ap proximated by linear attention, enabling global diffusion at scale. Combined wit h stochastic environment perturbations, STPDE improves robustness under heteroge neous and shifting environments. Extensive experiments on in-distribution foreca sting, out-of-distribution generalization, few-shot cross-city transfer, and con tinual learning demonstrate consistent improvements over state-of-the-art baseli nes with competitive computational efficiency.

Derivative Informed Learning of Exchange-Correlation Functionals
Eike Eberhard, Luca Thiede, Abdulrahman Aldossary, Andreas Burger, Nicholas Gao, Vignesh C Bhethanabotla, Alan Aspuru-Guzik, Stephan Günnemann
Machine-learned (ML) XC functionals aim to replace human-designed density functi onal approximations by learning directly from reference data, but they still do not consistently outperform traditional $\mathcal{O}(N^4)$-scaling hybrid functi onals. We therefore study a hybrid-distillation setting, where $\mathcal{O}(N^3) $-scaling semilocal ML-XC functionals are trained to reproduce B3LYP/def2-SVP ta rgets. We introduce Derivative Informed XC-Loss (DI-Loss), a loss that incorpora tes additional information from the reference hybrid functional by supervising f irst and second derivatives of the energy on the Grassmannian of admissible dens ity matrices. Rather than only matching the self-consistent fixed point, DI-Loss aligns the local first- and second-order response of the learned functional wit h that of the target functional. Across four evaluated architectures, DI-Loss co nsistently improves the main energy metrics. Averaged uniformly across architect ures, the total-energy MAE decreases by 66% relative to energy and density super vision alone. The density-sensitive mean-field energy metric E_ρ improves f rom 1.2 to 0.8 mEh on average, while dipole and $\mathcal{L}_2$ density errors d o not improve uniformly. We further show that densities from the distilled funct ionals reduce hybrid-functional SCF iterations by up to 55%. In downstream TDDFT calculations, Hessian supervision improves excited-state predictions, with XCdi ff reducing the mean excitation-energy MAE by 24-35% across molecule sizes on QM 40.

NanoQuant: Efficient Sub-1-Bit Quantization of Large Language Models
Hyochan Chong, Dongkyu Kim, Changdong Kim, Minseop Choi
Weight-only quantization has become a standard approach for efficiently serving large language models (LLMs). However, existing methods fail to efficiently comp ress models to binary (1-bit) levels, as they either require large amounts of da ta and compute or incur additional storage. In this work, we propose NanoQuant, a post-training quantization (PTQ) method to compress LLMs to both binary and su b-1-bit levels. NanoQuant formulates quantization as a low-rank binary factoriza tion problem, and compresses full-precision weights to low-rank binary matrices

and scales. Specifically, it utilizes an efficient alternating direction method of multipliers (ADMM) solver to precisely initialize latent binary matrices and scales, and then tunes the initialized parameters through a block and model reconstruction process. Consequently, NanoQuant establishes a new Pareto frontier in low-memory post-training quantization, and enables sub-1-bit compression. NanoQuant makes large-scale deployment feasible on consumer hardware. For example, it compresses Llama-2-70B by 24$\times$ in just 13 hours on a single H100, enabling a 70B model to operate on a consumer 8 GB GPU.

Lost in Context: Adressing Context Anxiety in Large Language Models

Ifueko Igbinedion, Jillian Ross, Etienne Ricardez, Sertac Karaman, Eric So

Conventional wisdom suggests that reasoning models fail when problems exceed their capabilities. However, we find that frontier reasoning models sometimes possess the necessary capabilities to solve problems but fail due to premature self-doubt -- a phenomenon informally known as context anxiety. We provide the first systematic study of context anxiety, demonstrating that it arises, in part, from a model's inability to accurately estimate the tokens required to complete a task. We also show that context anxiety leads to material efficiency losses when models operate under perceived constraints. Building on this analysis, we further show that models can learn alternative strategies for solving long-horizon problems without exhibiting context anxiety, suggesting that performance improvements may be achievable not through scaling model capabilities, but by improving models' ability to accurately assess and adapt to their own limitations.

An Exterior Method for Nonnegative Matrix Factorization

Qiujing Lu, Tonmoy Monsoor, Ehsan Ebrahimzadeh, Kartik Sharma, Vwani Roychowdhury

Nonnegative matrix factorization (NMF) seeks a low-rank approximation $X \approx UV^T$ with nonnegative factors and is commonly solved using *interior* methods that enforce feasibility throughout optimization. We show that such constraint-driven approaches can impede progress in the nonconvex landscape, leading to slow convergence or convergence to suboptimal stationary points. We propose an *exterior* framework for NMF (eNMF) that separates low-rank approximation from nonnegativity enforcement. Our method initializes from the optimal unconstrained factorization and introduces a rotation procedure that maps unconstrained factors to an exterior point closest to the nonnegative orthant. This viewpoint yields an algorithmic framework in which simple iterative updates converge to KKT-satisfying stationary points on the boundary of the positive orthant. The exterior formulation also enables a geometric interpretation of NMF solutions, clarifying equivalence classes of factorizations under permutation and orthogonal transformations. An intriguing numerical result, involving 400 NMF experiments across both real and synthetic datasets, show that in 99\% of the cases, different algorithms tend to converge towards equivalent factor matrices. We benchmark eNMF against 9 state-of-the-art NMF algorithms with 9 initialization schemes across 3 real-world and 2 synthetic datasets. eNMF consistently outperforms all 81 competitors, achieving up to 30\% lower reconstruction error under equal-time settings and up to 150\% speedup under equal-error settings. The downstream experiments further demonstrate substantial performance gains in audio processing and recommendation tasks, corroborating the practical benefits of the proposed exterior optimization framework. Code is available at https://github.com/roychowdhuryresearch/eNMF

Measuring Intent Comprehension in LLMs

Nadav Kunievsky, James Evans

People judge interactions with large language models (LLMs) as successful when outputs match what they want, not what they type. Yet LLMs are trained to predict the next token solely from text input, not underlying intent. Because written language is an imperfect proxy for intent, and correlations between phrasing and desired outcomes can break down in training data, models that rely too heavily on surface cues may respond inconsistently to semantically equivalent prompts. This makes it essential to evaluate whether LLMs can reliably infer user intent—es

pecially in high-stakes settings where robustness and generalization are critica
l. We introduce a formal framework for assessing intent comprehension in LLMs: w
hether a model demonstrates robust understanding of user intent by producing con
sistent outputs across semantically equivalent prompts while differentiating bet
ween prompts with distinct intents. Our evaluation approach is based on a varian
ce decomposition of model responses into three components: variability due to us
er intent, user articulation, and model uncertainty. Models that understand what
 users want, and are not overly sensitive to textual cues, should attribute most
 output variance to intent differences, rather than articulation style. Applying
 this framework across diverse domains, we find that, within the five LLaMA and
Gemma models we evaluate, larger models typically assign a greater share of vari
ance to intent, indicating stronger comprehension of intent, although gains are
uneven and often modest with increasing model size. These results motivate movin
g beyond accuracy-only benchmarks toward semantic diagnostics that directly asse
ss whether models understand what users intend.

Modeling Attributional Style at Scale: A Dataset and Analysis for Psychological
Attribution Assessment and Reframing

Qiang Zhou, Hanzhen Zhu, Pan Wang, Rui Tu, Huaizhi Qu, Zhuoran Wang, Xin Hu, Lei
 Li, Tianlong Chen, Jingtong Hu

According to the reformulated Learned Helplessness theory, repeated exposure to
uncontrollable negative events can foster a depressogenic attributional style—in
creasing susceptibility to depression yet remaining a tractable target for cogni
tive therapy. Computational research on attributional cognition, however, is ham
pered by the lack of large-scale datasets and robust evaluation protocols. In th
is work, we introduce the Attributional Style Transfer Dataset (ASTD) along with
 dedicated evaluation metrics, the first benchmark designed to model, assess, an
d reframe attributional explanations at scale. Constructed via a Prevent–Filter–
Validate pipeline that integrates LLM-based generation with specialist validatio
n, ASTD contains 42,000 real-world events paired with psychologically grounded a
ttributions spanning seven styles. Using this dataset, we address two key challe
nges: (1) scalable assessment of attributional style via both supervised classif
iers and zero/few-shot LLMs; and (2) attributional reframing and evaluation, whe
re we propose automatic evaluation metrics to quantify psychological validity. F
urthermore, we leverage our proposed metrics to construct a preference dataset,
fine-tuning LLMs with Direct Preference Optimization (DPO) and achieving substan
tial gains in reframing quality. Together, our dataset, metrics, and methodology
 offer a new paradigm for understanding and modeling attributional style, with d
irect implications for scalable and adaptive mental health interventions.

Learning Generalizable Skill Policy with Data-Efficient Unsupervised RL

Jongchan Park, Seungjun Oh, Seungho Baek, Yusung Kim

Unsupervised Reinforcement Learning (URL) aims to pre-train scalable, skill-cond
itioned policies without extrinsic rewards, serving as a foundation for downstre
am control tasks. Despite recent progress, we argue that current off-policy URL
methods are limited by two critical, overlooked bottlenecks: (1) non-stationarit
y skill semantic and (2) brittle generalization. To address these challenges, we
 propose GenDa (Generalizable Data-efficient Agent), a unified framework for rob
ust unsupervised reinforcement learning. First, we introduce a skill relabeling
mechanism to mitigate non-stationarity and significantly improve sample efficien
cy for pretraining. Second, we propose a Complementary Information Bottleneck(CI
B), encouraging the learned skill policy to focus on ego-centric features and be
come robust to distribution shifts for downstream tasks. Through various experim
ents, we demonstrate that GenDa significantly enhances the scalability of URL wi
th superior generality and sample efficiency. Our source codes are available in
the supplementary materials.

ThoughtFold: Folding Reasoning Chains via Introspective Preference Learning

Ziyan Liu, Xueda Shen, Yuzhe Gu, Songyang Gao, Kuikun Liu, Guangran Cheng, Cheng
qi Lyu, Dahua Lin, Wenwei Zhang, Kai Chen

Large Reasoning Models (LRMs) have achieved remarkable progress thanks to Reinfo rcement Learning with Verifiable Rewards (RLVR) on Chain-of-Thoughts (CoTs). However, since long CoTs naturally contain trial and errors and mainstream RLVR approaches choose outcome-correct CoT trajectories for memorization, the redunda nt explorations in long CoTs are inevitably reinforced, which results in the ove r-thinking issues of LRMs.
Previous attempts to resolve this issue mainly give more advantage to shorter tr ajectories, yet their learning signals are still outcome-based and cannot reduce the memorization of redundant explorations in long CoTs.
Therefore, we propose ThoughtFold, a framework that leverages fine-grained prefe rence learning to mitigate redundant explorations for efficient reasoning. Thoug htFold employs an introspective strategy to identify redundancy within each corr ect trajectory, which yields a spectrum of candidate sub-trajectories. Leveragin g this spectrum, we introduce a masked preference optimization objective that ex plicitly penalizes redundant explorations and encourages the model to directly b ridge essential reasoning segments, effectively folding its reasoning chains int o a more concise path. Extensive experiments show that ThoughtFold significantly enhances efficiency. It reduces the token usage of DeepSeek-R1-Distill-Qwen-7B by approximately 56\% while maintaining state-of-the-art accuracy.

Controlled Collaboration Geometry for Personalized Federated Learning
Hongbo Yin, Jichun Wu, Zhou Yang, Chi Jiang, Yin Zhang, Yan Zhang
In personalized federated learning (PFL), collaboration graphs specify model agg regation among clients. However, without constraints on the collaboration geomet ry, training can drift into two degenerate regimes: global consensus or spontane ous clustering. This paper provides a unified dynamical analysis: under the same budget of representative models, collaborative PFL is more expressive and achie ves higher-order approximation accuracy than clustered PFL. An upper bound on di sagreement further reveals two degeneration mechanisms—overly strong collaborati on drives consensus (reducing to standard federated learning), while similarity-driven weight updates make the graph nearly reducible and induce self-clustering (collapsing to clustered PFL). Motivated by these findings, we propose pFedCCG. pFedCCG preserves the expressivity advantage via controlled collaboration geome try (CCG): it builds a static similarity-based collaboration template decoupled from training, optimizes a Markovian collaboration matrix with a prescribed stat ionary distribution via reversible parameterization and Euclidean projection, an d schedules collaboration strength to avoid self-clustering. Experiments across diverse heterogeneity settings show consistent personalization gains and markedl y reduced collapse and self-clustering. Code is available at https://github.com/YinHonb/pFedCCG.
****

Collaborative Learning for Semi-Supervised LiDAR Semantic Segmentation
Bin Yang, Alexandru Paul Condurache
Annotating large-scale LiDAR point clouds for 3D semantic segmentation is costly and time-consuming, which motivates the use of semi-supervised learning (SemiSL). Standard LiDAR SemiSL methods typically adopt a two-step training paradigm, w here pseudo-labels are separately generated from a single distillation source, e ither from the same or another LiDAR representation. Such supervision relies on a unique source of pseudo-labels, which can reinforce confirmation bias and prop agate errors during training, ultimately limiting performance. To address this c hallenge, we introduce *CoLLiS*, a novel framework that leverages **Co**llaborat ive **L**earning for **Li**DAR **S**emi-supervised segmentation. Unlike prior pa radigms with decoupled pseudo-labeling and training phases, *CoLLiS* trains mult iple representations collaboratively in a single step by treating them as coequa l students. Each student is adaptively distilled from multiple representations, while inter-student disparities are monitored online to resolve contradictory su pervision and effectively mitigate confirmation bias. Extensive experiments on t hree datasets demonstrate that *CoLLiS* consistently outperforms state-of-the-ar t LiDAR SemiSL methods, with particularly strong gains in low-label regimes.

RoboOmni: Actions Are Just Another Modality for Vision-Language Models
Dong Wang, Zilong Chen, Jirong Liu, Ziqing Qiao, Xin Xiao, Bingyi Kang, Hongtao Wu, Xiao Ma, Tao Kong, Huaping Liu
Integrating Vision-Language Models (VLMs) into robotics has facilitated the development of generalizable Vision-Language Action (VLA) policies.
However, unified discrete frameworks lag behind decoupled continuous designs due to limitations in action chunking and temporal modeling.
To address this, we introduce **RoboOmni**, a unified multi-modal next-token prediction framework.
Challenging the assumption that continuous modeling is essential for high-performance manipulation, **RoboOmni** demonstrates that *actions are just another modality* capable of being effectively modeled discretely.
At the core of our method is Multi-Token Action Prediction (MTAP), which integrates action chunking directly into the discrete tokenizer. This design resolves temporal modeling bottlenecks and significantly reduces distribution shift between training and inference. By preserving the native VLM training and inference pipeline, **RoboOmni** naturally benefits from large-scale multimodal co-training and modern decoding optimizations.
Extensive evaluations on the CALVIN, SimplerEnv, and real-world platforms confirm that **RoboOmni** establishes new state-of-the-art performance, significantly outperforming diffusion-based baselines such as π_0.
Notably, combining our proposed MTAP with the FAST tokenizer achieves a 94.4\% average success rate on CALVIN,
while the Bin tokenizer implementation attains a 27$\times$ inference speedup compared to OpenVLA.
****
Less Data, Faster Training: repeating smaller datasets speeds up learning via sampling biases
Jingwen Liu, Ezra Edelman, Surbhi Goel, Bingbin Liu
This work investigates the "small-vs-large gap", where repeating on _fewer samples_ can lead to _compute saving_ during training compared to using a larger dataset.
This is observed across algorithmic tasks, architectures and optimizers and cannot be explained using prior theory.
We argue that the speedup comes from appropriate layer-wise growth enabled by _sampling biases_, which is more pronounced when the dataset size is smaller.
We provide both theoretical analysis and empirical evidence from various interventions.
Our results suggest that using a smaller dataset with more repetitions is not just a fallback strategy under data scarcity, but can be proactively leveraged as a favorable inductive biases for optimization, particularly in reasoning tasks.
****
Routing by Reaching: Composition of Pre-trained GFlowNets for Multi-Objective Generation
Seokwon Yoon, Youngbin Choi, Seunghyuk Cho, Seungbeom Lee, MoonJeong Park, Dongwoo Kim
Generative Flow Networks (GFlowNets) learn to sample diverse candidates in proportion to a reward function, making them well-suited for scientific discovery, where exploring multiple promising solutions is crucial.
Further extending GFlowNets to multi-objective settings has attracted growing interest as real-world applications often involve multiple, conflicting objectives.
However, existing approaches require joint training for each combination of objectives, meaning that any change in the objective set necessitates retraining from scratch.
We propose a framework that composes pre-trained GFlowNets at inference time, enabling rapid adaptation without fine-tuning or retraining.
Importantly, our framework is flexible, capable of handling diverse reward combinations ranging from linear scalarization to complex nonlinear operators, which are often handled separately in previous literature.

We prove that our method exactly recovers the target distribution for linear sca
larization, and quantify the approximation quality for nonlinear operators throu
gh a distortion factor.
Experiments on a synthetic 2D grid and real-world molecule generation tasks demo
nstrate that our approach achieves performance comparable to baselines.
The code is available at https://github.com/ml-postech/gflownet-composition.
****
Local Covariate Selection for Average Causal Effect Estimation without Pretreatm
ent and Causal Sufficiency Assumptions
Zeyu Liu, Zheng Li, Feng Xie, Yan Zeng, Hao Zhang, Kun Zhang
Causal effect estimation is a fundamental task in many scientific fields. Select
ing appropriate covariates for adjustment is crucial for obtaining unbiased caus
al effects. However, most existing methods either rely on learning the global ca
usal structure, assume the absence of latent variables, or impose the pretreatme
nt assumption-restricts covariates to those unaffected by the treatment or outco
me. These assumptions are often unrealistic in real-world scenarios, and global
structure learning can be computationally intensive and inefficient.
To address these challenges, we first characterize the local existence boundary
of adjustment sets for causal effect estimation. Based on this characterization,
 we develop a novel local learning method for covariate selection in nonparametr
ic causal effect estimation. This method accommodates the presence of latent var
iables and eliminates the need for the pretreatment assumption.
We prove that the proposed method is both sound and complete under standard assu
mptions. Its effectiveness is validated through extensive experiments on both sy
nthetic and real-world datasets.

Supervise Less, See More: Training-free Nuclear Instance Segmentation with Proto
type-Guided Prompting
Wen Zhang, Qin Ren, Wenjing Liu, Haibin Ling, Chenyu You
Accurate nuclear instance segmentation is a pivotal task in computational pathol
ogy, supporting data-driven clinical insights and facilitating downstream transl
ational applications. While large vision foundation models have shown promise fo
r zero-shot biomedical segmentation, most existing approaches still depend on de
nse supervision and computationally expensive fine-tuning. Consequently, trainin
g-free methods present a compelling research direction, yet remain largely unexp
lored.
In this work, we introduce SPROUT, a fully training- and annotation-free prompti
ng framework for nuclear instance segmentation. SPROUT leverages histology-infor
med priors to construct slide-specific reference prototypes that mitigate domain
 gaps. These prototypes progressively guide feature alignment through a partial
optimal transport scheme. The resulting foreground and background features are t
ransformed into positive and negative point prompts, enabling the Segment Anythi
ng Model (SAM) to produce precise nuclear delineations without any parameter upd
ates.
Extensive experiments across multiple histopathology benchmarks demonstrate that
 SPROUT achieves competitive performance without supervision or retraining, esta
blishing a novel paradigm for scalable, training-free nuclear instance segmentat
ion in pathology. Code is available at https://github.com/Y-Research-SBU/SPROUT.

The Interplay Between Interpolation and Aggregation in Regression: Optimal Sampl
e Complexity
Mikael Møller Høgsgaard, Kasper Green Larsen, Liang-Yu Zou
This work investigates theoretically the interplay between interpolation and agg
regation in regression.
We establish that the
γ-graph dimension characterizes learnability for a broad class of natural
 aggregation procedures.
Furthermore, we prove that an extremely simple aggregation procedure, combining
three interpolating hypotheses via the median, is optimal among all these aggreg
ation procedures, and is strictly more

powerful than proper learning.
Finally, we show that some hypothesis classes are learnable only by aggregating infinitely many hypotheses or by using non-interpolating aggregation rules (which may predict outside the range of their inputs), and any finite interpolating aggregation fails to achieve even trivial performance.
****

SCORE: A Unified Framework for Overshoot Refund in Online FDR Control
Qi Kuang, Bowen Gang, Yin Xia
We propose a unified framework to enhance the power of online multiple hypothesis testing procedures based on e-values. While e-value-based methods offer robust online False Discovery Rate (FDR) control under minimal assumptions, they often suffer from power loss by discarding evidence that exceeds the rejection threshold. We address this inefficiency via the \textbf{S}equential \textbf{C}ontrol with \textbf{O}vershoot \textbf{R}efund for \textbf{E}-values (SCORE) framework, which leverages the inequality $\mathbb{I}(y \ge 1) \le y - (y-1)_+$, valid for all $y\ge 0$, to reclaim this otherwise ``wasted'' evidence. This simple yet powerful insight yields a unified principle for improving a broad class of online testing algorithms. Building on this framework, we develop SCORE-enhanced versions of several state-of-the-art procedures, including SCORE-LOND, SCORE-LORD, and SCORE-SAFFRON, all of which strictly dominate their original counterparts while preserving valid finite-sample FDR control. Furthermore, under mild assumptions, SCORE permits retroactive updates of alpha■wealth by using the latest decision twice: first to determine its reward or loss, and then to refresh past wealth. Such a mechanism enables more aggressive testing strategies while maintaining valid FDR control, thereby further improving statistical power. The effectiveness of the proposed methods is validated through extensive simulation and real-data experiments.

MARS: Modular Agent with Reflective Search for Automated AI Research
Jiefeng Chen, Bhavana Dalvi Mishra, Jaehyun Nam, Rui Meng, Tomas Pfister, Jinsung Yoon
A critical bottleneck in automating AI research is the execution of complex machine learning engineering (MLE) tasks. MLE differs from general software engineering due to computationally expensive evaluation (e.g., model training) and opaque performance attribution. Current LLM-based agents struggle here, often generating monolithic scripts that ignore execution costs and causal factors. We introduce **MARS** (**M**odular **A**gent with **R**eflective **S**earch), a framework optimized for autonomous AI research. MARS relies on three pillars: (1) Budget-Aware Planning via cost-constrained Monte Carlo Tree Search (MCTS) to explicitly balance performance with execution expense; (2) Modular Construction, employing a "Design-Decompose-Implement" pipeline to manage complex research repositories; and (3) Comparative Reflective Memory, which addresses credit assignment by analyzing solution differences to distill high-signal insights. MARS achieves state-of-the-art performance among open-source frameworks on MLE-Bench under comparable settings, maintaining competitiveness with the global leaderboard's top methods. Furthermore, the system exhibits qualitative "Aha!" moments, where 63% of all utilized lessons originate from cross-branch transfer, demonstrating that the agent effectively generalizes insights across search paths.
****

Optimal Rates for Feasible Payoff Set Estimation in Games
Annalisa Barbara, Riccardo Poiani, Martino Bernasconi, Andrea Celli
We study a setting in which two players play a (possibly approximate) Nash equilibrium of a bimatrix game, while a learner observes only their actions and has no knowledge of the equilibrium or the underlying game. A natural question is whether the learner can rationalize the observed behavior by inferring the players' payoff functions. Rather than producing a single payoff estimate, inverse game theory aims to identify the entire set of payoffs consistent with observed behavior, enabling downstream use in, e.g., counterfactual analysis and mechanism design across applications like auctions, pricing, and security games. We focus on the problem of estimating the set of feasible payoffs with high probability and

up to precision ϵ on the Hausdorff metric. We provide the first minimax-optimal rates for both exact and approximate equilibrium play, in zero-sum as well as general-sum games. Our results provide learning-theoretic foundations for set-valued payoff inference in multi-agent environments.

****

Online Social Welfare Function-based Resource Allocation

Kanad Shrikar Pardeshi, Samsara Foubert, Aarti Singh

In many real-world settings, a centralized decision-maker must repeatedly allocate finite resources to a population over multiple time steps. Individuals who receive a resource derive some stochastic utility; to characterize the population-level effects of an allocation, the expected individual utilities are then aggregated using a social welfare function (SWF). We formalize this setting and present a general confidence sequence framework for SWF-based online learning and inference, valid for any monotonic, concave, and Lipschitz-continuous SWF. Our key insight is that monotonicity alone suffices to lift confidence sequences from individual utilities to anytime-valid bounds on optimal welfare. Building on this foundation, we propose SWF-UCB, a SWF-agnostic online learning algorithm that achieves near-optimal $\tilde{\mathcal{O}}(n+\sqrt{nkT})$ regret (for k resources distributed among n individuals at each of T time steps). We instantiate our framework on three normatively distinct SWF families: Weighted Power Mean, Kolm, and Gini, providing bespoke oracle algorithms for each. Experiments confirm $\sqrt{T}$ scaling and reveal rich interactions between k and SWF parameters. This framework naturally supports inference applications such as sequential hypothesis testing, optimal stopping, and policy evaluation.

****

GLAD: Bidirectional Structure-Attribute Alignment via Latent Graph Diffusion Models

Jiankai Zuo, Yu Zhang, Yang Zhang, Zihao Yao, Yaying Zhang

Learning on graphs with missing node attributes is a prevalent yet challenging problem in real-world scenarios, as graph neural networks (GNNs) typically rely on complete attribute information. Existing solutions often employ adversarial learning in a shared latent space to align graph structure and attributes. However, these methods frequently suffer from training instability and mode collapse, failing to fully capture the complex, multi-modal joint distribution of topology and features. To address these limitations, we present GLAD, a novel generative framework for robust node attribute completion. GLAD leverages the strong generative capabilities of diffusion models to learn the conditional distribution of attributes given the graph structure within a decoupled latent space. Unlike previous unidirectional approaches, GLAD introduces a robust bidirectional alignment mechanism. Specifically, we incorporate a structure reconstruction constraint during training and structure-aware classifier-free guidance during sampling, ensuring that generated attributes are not only plausible but also maintain strict topological consistency with the underlying graph. Theoretically, we show that GLAD maximizes a tighter variational lower bound on the joint log-likelihood compared to GAN-based predecessors, leading to superior mode coverage. Extensive experiments on large-scale benchmarks demonstrate that GLAD significantly outperforms state-of-the-art baselines in both attribute recovery quality and downstream task performance.

****

UltraHorizon: Benchmarking LLM-Agent Capabilities in Ultra Long-Horizon Scenarios

Haotian Luo, Huaisong Zhang, Xuelin Zhang, Haoyu Wang, Zeyu Qin, WenJie Lu, Guozheng Ma, Haiying He, Yingsha Xie, Qiyang Zhou, Zixuan Hu, Hongze Mi, Yibo Wang, Naiqiang Tan, Hong Chen, Yi R. Fung, Chun Yuan, Li Shen

Autonomous agents have recently achieved remarkable progress across diverse domains, yet most evaluations focus on short-horizon, fully observable tasks. In contrast, many critical real-world tasks, such as large-scale software development, commercial investment, and scientific discovery, unfold in long-horizon and partially observable scenarios where success hinges on sustained reasoning, planning, memory management, and tool use. Existing benchmarks rarely capture these lon

g-horizon challenges, leaving a gap in systematic evaluation. To bridge this gap , we introduce $\textbf{UltraHorizon}$, a novel benchmark that measures the foun dational capabilities essential for complex real-world challenges. We use explor ation as a unifying task across three distinct environments to validate these co re competencies. Agents are designed in long-horizon discovery tasks where they must iteratively uncover hidden rules through sustained reasoning, planning, mem ory and tools management, and interaction with environments. Under the heaviest scale setting, trajectories average $\textbf{200k+}$ tokens and $\textbf{400+}$ tool calls, whereas in standard configurations they still exceed $\textbf{35k}$ tokens and involve more than $\textbf{60}$ tool calls on average. Our extensive experiments reveal that agents powered by state-of-the-art LLMs consistently und erperform in these settings, whereas human participants achieve much higher scor es, underscoring a persistent gap in agents' long-horizon exploration abilities. We also observe that simple scaling fails in our task. To better illustrate the failure of agents, we conduct an in-depth analysis of collected trajectories. W e identify eight types of errors and attribute them to two primary causes: in-co ntext locking and functional fundamental capability gaps.

****

FedARC: Anchor-Guided Residual Compensation for Data and Model Heterogeneous Fed erated Learning

Chentao Lu, Xuhao Ren, Dawei xu, Chuan Zhang, Liehuang Zhu

Federated learning (FL) allows clients to collaboratively train models without e xposing private data, but practical FL is simultaneously challenged by data hete rogeneity and model heterogeneity. Prior heterogeneous FL (HtFL) approaches ofte n fail to handle fine-grained feature shifts, leading to weak representation ali gnment and limited cross-client knowledge transfer, which degrades both personal ization and generalization. We propose FedARC, an HtFL framework that couples a shared lightweight extractor with client-specific fusion: a trainable projector integrates local and global embeddings, while adaptive residual compensation dyn amically corrects feature-level mismatches. To further stabilize aggregation, Fe dARC performs semantic anchor alignment across clients, and we theoretically pro ve FedARC converges with a non-convex convergence rate $\mathcal{O}(1/T)$. Exper iments on five public benchmarks demonstrate that FedARC outperforms nine state- of-the-art HtFL baselines by up to 2.63\% in average accuracy, while maintaining efficient communication and computation.

****

MedMamba: Multi-View State Space Models with Adaptive Graph Learning for Medical Time Series Classification

Da Zhang, Bingyu Li, Zhiyuan Zhao, Hongyuan Zhang, Junyu Gao, Xuelong Li

Medical time series are central to healthcare, enabling continuous monitoring an d supporting timely clinical decisions. Despite recent progress, existing method s struggle to jointly model local-global dynamics and handle nonstationarities l ike baseline drift, while often failing to capture latent channel interactions. To address these challenges, we propose **MedMamba**, an end-to-end architecture that integrates state space models with domain-specific inductive biases. Speci fically, MedMamba first employs multi-scale convolutional embeddings to capture discriminative local morphology. Second, to mitigate nonstationarity, we introdu ce a tri-branch differential state space encoder that processes raw, temporal-di fference, and frequency-domain views, fusing them to emphasize informative patte rns while suppressing drift. Furthermore, to uncover latent channel correlations , we design a spatial graph Mamba module that learns a directed dependency struc ture regularized toward sparsity and acyclicity, which obviates the need for pre defined graphs. Extensive experiments on five real-world datasets demonstrate th at MedMamba achieves state-of-the-art performance while maintaining linear compu tational complexity, and ablation studies validate each component's contribution .Code is available at https://github.com/zhangda1018/MedMamba.

MetaPerch: Learning from metadata for bioacoustics foundation models

Mustafa Chasmai, Vincent Dumoulin, Jenny Hamer

Bioacoustic foundation models rely on large-scale citizen science platforms like

Xeno-Canto for geographically and ecologically diverse data. Recent work has shown that supervision alone can produce SotA species detection models when trained on this large-scale data---however, there remains unutilized potential in the form of recording metadata readily available within these community-driven data hubs. In this work, we explore the use of metadata---such as location and time---as auxiliary supervision signals, allowing the model to leverage species-metadata correlations in its learned representation. Auxiliary metadata losses provide additional information beyond vocalizations alone that can encourage a richer, more robust representation that generalizes better to species distribution and acoustic domain shifts---important challenges for deployment in real-world passive acoustic monitoring (PAM) settings. We introduce MetaPerch, a new foundation model that achieves strong species identification performance across multiple challenging domains and present an extensive empirical study of the effects of 9 diverse metadata sources on 17 bioacoustic datasets.

Seeing Realism from Simulation: Efficient Video Transfer for Vision-Language-Action Data Augmentation

Chenyu Hui, Xiaodi Huang, Siyu Xu, Yunke Wang, Shan You, Fei Wang, Tao Huang, Chang Xu

Vision-language-action (VLA) models typically rely on large-scale real-world videos, whereas simulated data, despite being inexpensive and highly parallelizable to collect, often suffers from a substantial visual domain gap and limited environmental diversity, resulting in weak real-world generalization. We present an efficient video augmentation framework that converts simulated VLA videos into realistic training videos while preserving task semantics and action trajectories. Our pipeline extracts structured conditions from simulation via video semantic segmentation and video captioning, rewrites captions to diversify environments, and uses a conditional video transfer model to synthesize realistic videos. To make augmentation practical at scale, we introduce a diffusion feature-reuse mechanism that reuses video tokens across adjacent timesteps to accelerate generation, and a coreset sampling strategy that identifies a compact, non-redundant subset for augmentation under limited computation.Extensive experiments on Robotwin 2.0, LIBERO, LIBERO-Plus, and a real robotic platform demonstrate consistent improvements.For example, our method improves RDT-1B by 8\% on Robotwin 2.0, and boosts π_0 by 5.1\% on the more challenging LIBERO-Plus benchmark. Code is available at: https://github.com/nanfangxiansheng/Seeing-Realism-from-Simulation

JAEGER: Joint 3D Audio-Visual Grounding and Reasoning in Simulated Physical Environments

Zhan Liu, Changli Tang, Yuxin WANG, Zhiyuan Zhu, Youjun Chen, Yiwen Shao, TIANZI WANG, Lei Ke, Zengrui Jin, Chao Zhang

Current audio-visual large language models (AV-LLMs) are predominantly restricted to 2D perception, relying on RGB video and monaural audio. This design choice introduces a fundamental dimensionality mismatch that precludes reliable source localization and spatial reasoning in complex 3D environments. We address this limitation by presenting JAEGER, a framework that extends AV-LLMs to 3D space, to enable joint spatial grounding and reasoning through the integration of RGB-D observations and multi-channel first-order ambisonics. A core contribution of our work is the neural intensity vector (Neural IV), a learned spatial audio representation that encodes robust directional cues to enhance direction-of-arrival estimation, even in adverse acoustic scenarios with overlapping sources. To facilitate large-scale training and systematic evaluation, we propose SpatialSceneQA, a benchmark of 61k instruction-tuning samples curated from simulated physical environments. Extensive experiments demonstrate that our approach consistently surpasses 2D-centric baselines across diverse spatial perception and reasoning tasks, underscoring the necessity of explicit 3D modelling for advancing AI in physical environments. Our source code, pre-trained model checkpoints, and datasets are available at https://github.com/liuzhan22/JAEGER.

Alignment Tampering: How Reinforcement Learning from Human Feedback Is Exploited

to Optimize Misaligned Biases
Dongyoon Hahm, Dylan Hadfield-Menell, Kimin Lee
Reinforcement Learning from Human Feedback (RLHF) is the standard method to align Large Language Models (LLMs) with human preferences. In this work, we introduce alignment tampering, a potential vulnerability where the LLM undergoing alignment influences the preference dataset, causing RLHF to amplify undesired behaviors. This arises from core limitations of RLHF: (1) preference datasets are constructed from the LLM's own outputs, allowing it to influence them, and (2) pairwise comparisons only indicate which response is better, not why. These limitations can be exploited to cause alignment tampering. For example, if an LLM generates biased responses with higher quality, annotators will prefer them based on quality. However, preference labels do not distinguish quality from bias, and the reward model inherits this limitation. Optimizing such rewards through reinforcement learning or best-of-N sampling can amplify misaligned biases. Our experiments demonstrate amplification across diverse biases: from keyword bias to propaganda (e.g., sexism), brand promotion, and instrumental goal-seeking. Mitigation remains challenging, as existing techniques for robust RLHF fail to fully resolve alignment tampering without sacrificing response quality. These findings reveal structural vulnerabilities of current RLHF and emphasize the need to prevent this vulnerability. Project page: https://alignment-tampering.github.io/

FrontierCS: Evolving Challenges for Evolving Intelligence
Qiuyang Mang, Wenhao Chai, Zhifei Li, Huanzhi Mao, Shang Zhou, Alexander Du, Hanchen Li, Shu Liu, Edwin Chen, Yichuan Wang, Xieting Chu, Zerui Cheng, Yuan Xu, Tian Xia, Zirui Wang, Tianneng Shi, Jianzhu Yao, Yilong Zhao, Qizheng Zhang, Charlie F. Ruan, Zeyu Shen, Kaiyuan Liu, Zhaoyang Hong, Alex Gu, Ziyi Zhang, Runyuan He, Dong Xing, Zerui Li, Zirong Zeng, Yige Jiang, Lufeng Cheng, Ziyi Zhao, Youran Sun, Suyang Zhong, Junpeng Wang, Donglin Li, Wenyuan Huang, Jialiang Gu, Wesley Kai Zheng, Wangmeiyu Zhang, Ruyi Ji, Xuechang Tu, Zihan Zheng, Zhaozi Wang, Zexing Chen, Jingbang Chen, JIALU ZHANG, Aleksandra Korolova, Peter Henderson, Pramod Viswanath, Vijay Ganesh, Saining Xie, Zhuang Liu, Dawn Song, Sewon Min, Ion Stoica, Joseph E. Gonzalez, Jingbo Shang, Alvin Cheung
We introduce FrontierCS, a benchmark of 240 open-ended problems across diverse areas of computer science, designed and reviewed by experts, including CS PhDs and top-tier competitive programming participants and problem setters.
Unlike existing benchmarks that focus on tasks with known optimal solutions, FrontierCS targets problems where the optimal solution is unknown, but the quality of a solution can be objectively evaluated. Models solve these tasks by implementing executable programs rather than outputting a direct answer.
FrontierCS includes algorithmic problems, which are often NP-hard variants of competitive programming problems with objective partial scoring, and research problems with the same property.
For each problem, we provide an expert reference solution and an automatic evaluator.
Combining open-ended design, measurable progress, and expert curation,
FrontierCS provides a benchmark at the frontier of computer-science difficulty.
Empirically, we find that frontier reasoning models still lag far behind human experts, and that simply increasing reasoning budgets does not close this gap on open-ended challenges.
Moreover, these models struggle to identify internal equivalence classes, and existing agentic frameworks also exhibit brittleness on such problems due to overfitting.
FrontierCS thus offers a new lens into model capabilities on real frontier computer science problems.

Instance-Level Costs for Nuanced Classifier Evaluation
Kabir Kang, Stephen Mussmann
Standard classification treats all errors equally, but in applications such as content moderation and medical screening, mistakes on clear-cut cases are more costly than errors on ambiguous ones. From a contextual bandit framework, we propo

se normalized excess cost (NEC), a metric that weighs classification errors by p
er-example costs and reduces to standard error rate when costs are uniform. Cost
s can derive from annotator vote margins, distance from decision thresholds, or
confidence ratings. Across text, image, and tabular benchmarks, we find that NEC
 is often substantially lower than error rate—models with 5% error rate can achi
eve 1.8% NEC—revealing that most mistakes concentrate on ambiguous, low-cost exa
mples. We also find that incorporating costs into training via loss weighting, s
ampling strategies, or regression yields inconsistent benefits. Our framework pr
ovides a practical methodology for deriving and evaluating instance-level miscla
ssification costs, even if cost-sensitive training offers limited benefit.

Federated Data and Feature Selection by Generalized CUR Decomposition
Ying-Peng Tang, Zhuang Qi, Xiaoli Tang, Wei Zhuo, Sheng-Jun Huang, Han Yu
With the advance of federated learning (FL) in privacy-sensitive domains, the ne
ed for efficient and robust training becomes increasingly urgent. Communication
bottlenecks, heterogeneous client distributions, and fairness requirements make
it essential to select the “right” data and features for model training. Yet exi
sting FL research often addresses feature selection and data selection separatel
y, ignoring their interplay in real-world high-dimensional and noisy datasets, l
eading to suboptimal performance. In this paper, we propose a unified framework
for data and feature selection by formulating the problem as a generalized CUR d
ecomposition problem. We introduce FedGCUR, a practical framework that integrate
s a federated column-pivoted QR (FedCPQR) decomposition routine with per-silo ro
w selection. We prove that FedCPQR produces exactly the same decomposition resul
ts as centralized CPQR and establish an upper bound of the reconstruction error
of FedGCUR. Experiments on tabular tasks and vision benchmarks show strong downs
tream accuracy and absolute CUR reconstruction quality compared with representat
ive data and feature selection baselines.

Riemannian Diffusion Models on General Manifolds via Physics-Informed Neural Net
works
Gyeonghoon Ko, Juho Lee
Riemannian diffusion models generalize score-based generative modeling to manifo
ld-supported data via stochastic diffusion equations on the manifold.
However, training requires sampling from and differentiating the manifold heat k
ernel, which is rarely available in closed form beyond a few highly symmetric ma
nifolds.
We propose a general approach that approximates the heat kernel by directly solv
ing the manifold heat equation with a physics-informed neural network (PINN).
Given an explicit manifold specification, we choose a coordinate system, derive
the corresponding heat (Fokker--Planck) equation and a short-time asymptotic app
roximation, and then train a PINN to learn the log heat kernel.
The resulting surrogate enables both forward noising (heat-kernel sampling) and
conditional-score evaluation for denoising score matching.
We demonstrate the method on diverse manifolds including S^2, $SO(3)$, $\mathr
m{SPD}(n)$, and permutation-quotiented point clouds.

LatentLens: Revealing Highly Interpretable Visual Tokens in LLMs
Benno Krojer, Shravan Nayak, Oscar Mañas, Vaibhav Adlakha, Desmond Elliott, Siva
 Reddy, Marius Mosbach
Transforming a large language model (LLM) into a vision-language model (VLM) can
 be achieved by mapping the visual tokens from a vision encoder into the embeddi
ng space of an LLM.
Intriguingly, this mapping can be as simple as a shallow MLP transformation.
To understand why LLMs can so readily process visual tokens, we need interpretab
ility methods that reveal what is encoded in the visual token representations at
 every layer of LLM processing.
In this work, we introduce LatentLens, a novel approach for mapping latent repre
sentations to descriptions in natural language.
LatentLens encodes a large text corpus and stores contextualized token represent

ations for each token in that corpus.
Visual token representations are then compared to these contextualized represent ations and the top-k nearest neighbor representations serve as descriptions of the visual token.
We evaluate this method on 15 different VLMs, showing that commonly used methods , such as LogitLens, substantially underestimate the interpretability of visual tokens.
With LatentLens instead, the majority of visual tokens are interpretable across all studied models and all layers.
Qualitatively, we show that the descriptions produced by LatentLens are semantic ally meaningful and provide more fine-grained interpretations for humans compare d to individual tokens.
More broadly, our findings contribute new evidence on the alignment between visi on and language representations and open up new directions for analyzing the lat ent representations of LLMs.

Head-in-Head in Linear Attention
Shijie Mei, Man Yao, Jiabo Tong, Bo XU, Guoqi Li
The state-transition (decay) matrix governs how fixed-size memory is updated and used, making it a core design in linear attention models. Prior work exploits r ank-1 approximations to reduce the cost of constructing decay matrices, but this low-rank constraint also limits the expressive capacity. We therefore formulate decay-matrix design as an open optimization problem: maximizing expressiveness while introducing minimal additional cost. Inspired by the multi-head mechanism, we propose Head-in-Head, which introduces an additional mask matrix to structur e memory partitioning and interactions within a single linear-attention head. Th is simple, generic, and efficient design: 1) enables a rank-r approximation of the decay matrix with only a few extra parameters and 2) strengthens intra-head information interaction. We further develop mask normalization and a chunk-wise parallelization scheme to support efficient parallel training. Extensive experi ments on synthetic benchmarks and language modeling tasks, together with visual analyses, show that Head-in-Head consistently improves baseline performance by e nriching information diversity and strengthening intra-head interactions. Code a vailable at:
\url{https://github.com/msj-19/Head-in-Head-Linear-Attention}

SVL: Goal-Conditioned Reinforcement Learning as Survival Learning
Franki NGUIMATSIA TIOFACK, Fabian Schramm, Théotime Le Hellard, Justin Carpentie r
Standard approaches to goal-conditioned reinforcement learning (GCRL) that rely on temporal-difference learning can be unstable and sample-inefficient due to bo otstrapping. While recent work has explored contrastive and supervised formulati ons to improve stability, we present a probabilistic alternative, called surviva l value learning (SVL), that reframes GCRL as a survival learning problem by mod eling the distribution of time-to-goal from each state. This structured distribu tional Monte Carlo perspective yields a closed-form identity that expresses the goal-conditioned value function as a discounted sum of survival probabilities, e nabling value estimation via a hazard model trained via maximum likelihood on bo th event and right-censored trajectories. We introduce three practical value est imators, including finite-horizon truncation and two binned infinite-horizon app roximations to capture long-horizon objectives. Experiments on offline GCRL benc hmarks show that SVL combined with hierarchical actors matches or surpasses stro ng hierarchical TD and Monte Carlo baselines, excelling on complex, long-horizon tasks.

Joint-Space Empowerment as a Theory of Dexterous Motor Coordination
James Heald, Vittorio Caggiano, Vikash Kumar, Maneesh Sahani
Searching for effective policies is notoriously challenging in high-dimensional musculoskeletal systems, where multiple muscles actuate individual joints. Altho ugh this redundancy complicates naive policy search, it also implies that effect

ive control can be captured by a low-dimensional action manifold. To identify su ch a manifold, we introduce Joint-Space Empowerment (JoSE), a novel information- theoretic objective that quantifies how much control an agent has over its mecha nical degrees-of-freedom. We frame manifold discovery as an optimal precoding pr oblem—where a state-dependent precoder maps low-dimensional latent actions to hi gh-dimensional muscle commands—and derive the optimal precoder in closed form un der control-affine Gaussian dynamics. We show that manipulation policies learned on this manifold display significantly enhanced dexterity, sample efficiency, a nd improved generalization. These results present optimal precoding as a general information-theoretic paradigm for coordinating high-dimensional actuators to c ontrol low-dimensional features.

Is Vibe Coding Safe? Benchmarking Vulnerability of Agent-Generated Code in Real-World Tasks

Songwen Zhao, Danqing Wang, Kexun Zhang, Jiaxuan Luo, Zhuo Li, Lei Li

Vibe coding is a new software development paradigm in which human engineers prom pt a large language model (LLM) agent to complete complex coding tasks with litt le supervision. Although vibe coding is increasingly adopted, is the generated c ode really safe to deploy in production? To investigate this question, we propos e SUSVIBES, a benchmark consisting of 186 feature-request software engineering t asks from real-world open-source projects, for which human programmers committed vulnerable implementations. We evaluate 12 widely used coding agentic settings with frontier models on the benchmark. Disturbingly, all agents perform poorly i n terms of software security. Although 57% of the solutions from SWE-Agent with Claude 4 Sonnet are functionally correct, only 11.8% are secure. Further experim ents demonstrate that preliminary security strategies, such as augmenting the fe ature request with vulnerability hints, cannot mitigate these security issues. O ur findings raise serious concerns about the widespread adoption of vibe coding, particularly in security-sensitive applications. The code and dataset are avail able at https://github.com/LeiLiLab/susvibes. The leaderboard is at https://leil ilab.github.io/ susvibes-leaderboard.

Just Ask: Curious Code Agents Reveal System Prompts in Frontier LLMs

Xiang Zheng, Yutao Wu, Hanxun Huang, Yige Li, Xingjun Ma, Bo Li, Yu-Gang Jiang, Cong Wang

Autonomous code agents built on large language models are reshaping software and AI development through tool use, long-horizon reasoning, and self-directed inte raction. However, this autonomy introduces a previously unrecognized security ri sk: agentic interaction fundamentally expands the LLM attack surface, enabling s ystematic probing and recovery of hidden system prompts that guide model behavio r. We identify system prompt extraction as an emergent vulnerability intrinsic t o code agents and present JustAsk, a self-evolving framework that autonomously d iscovers effective extraction strategies through interaction alone. Unlike prior prompt-engineering or dataset-based attacks, JustAsk requires no handcrafted pr ompts, labeled supervision, or privileged access beyond standard user interactio n. It formulates extraction as an online exploration problem, using Upper Confid ence Bound-based strategy selection and a hierarchical skill space spanning atom ic probes and high-level orchestration. These skills exploit imperfect system-in struction generalization and inherent tensions between helpfulness and safety. E valuated on 41 black-box commercial models across multiple providers, JustAsk co nsistently achieves full or near-complete system prompt recovery, revealing recu rring design- and architecture-level vulnerabilities. Our results expose system prompts as a critical yet largely unprotected attack surface in modern agent sys tems.

Federated Sketching LoRA: A Flexible Framework for Heterogeneous Collaborative F ine-Tuning of LLMs

Wenzhi Fang, Dong-Jun Han, Liangqi Yuan, Seyyedali Hosseinalipour, Christopher B rinton

Fine-tuning large language models (LLMs) on resource-constrained clients remains

a challenging problem. Recent works have fused low-rank adaptation (LoRA) techniques with federated fine-tuning to mitigate challenges associated with client model sizes and data scarcity. Still, the heterogeneity of resources remains a critical bottleneck: while higher-rank modules generally enhance performance, varying client capabilities constrain LoRA's feasible rank range. Existing approaches attempting to resolve this issue either lack analytical justification or impose additional computational overhead, leaving a wide gap for efficient and theoretically-grounded solutions. To address these challenges, we propose federated sketching LoRA (FSLoRA), which leverages a sketching mechanism to enable clients to selectively update submatrices of global LoRA modules maintained by the server. By adjusting the sketching ratios, which determine the ranks of the submatrices on the clients, FSLoRA flexibly adapts to client-specific communication and computational constraints. We provide a rigorous convergence analysis of FSLoRA that characterizes how the sketching ratios affect the convergence rate. Through extensive experiments, we demonstrate that FSLoRA outperforms baselines and significantly improves training efficiency while preserving stable convergence.

Exact Functional ANOVA Decomposition for Categorical Inputs Models

Baptiste Ferrere, Nicolas Bousquet, Fabrice Gamboa, Jean-Michel Loubes, Joseph Muré

Functional ANOVA offers a principled framework for interpretability by decomposing a model’s prediction into main effects and higher-order interactions. For independent features, this decomposition is well-defined, strongly linked with SHAP values, and serves as a cornerstone of additive explainability. However, the lack of an explicit closed-form expression for general dependent distributions has forced practitioners to rely on costly sampling-based approximations. We completely resolve this limitation for categorical inputs. By bridging functional analysis with the extension of discrete Fourier analysis, we derive a closed-form decomposition without any assumption. Our formulation is computationally very efficient. It seamlessly recovers the classical independent case and extends to arbitrary dependence structures, including distributions with non-rectangular support. Furthermore, leveraging the intrinsic link between SHAP and ANOVA under independence, our framework yields a natural generalization of SHAP values for the general categorical setting.

Embodied Task Planning via Graph-Informed Action Generation with Large Language Models

Xiang Li, Ning Yan, Masood S. Mortazavi

While Large Language Models (LLMs) have demonstrated strong zero-shot reasoning capabilities, their deployment as embodied agents still faces fundamental challenges in long-horizon planning. Unlike open-ended text generation, embodied agents must decompose high-level intents into actionable sub-goals while adhering to the constraints of a dynamic environment. Standard LLM planners frequently fail to maintain strategy coherence over extended horizons due to context window limitations or hallucinate state transitions that violate environment constraints. We propose GiG, a planning framework that structures embodied agents’ memory using a Graph-in-Graph architecture. Our approach employs a Graph Neural Network (GNN) to encode environmental states into embeddings, organizing these embeddings into action-connected execution trace graphs within an experience memory bank. GiG enables retrieval of structurally-similar priors, allowing agents to ground current decisions in relevant past structural patterns. Furthermore, we introduce a bounded lookahead module that leverages symbolic transition logic to enhance the agent’s planning capabilities through grounded action projections. We evaluate our framework on three embodied planning benchmarks—Robotouille Synchronous, Robotouille Asynchronous, and ALFWorld. Our method outperforms state-of-the-art baselines, achieving Pass@1 performance gains of up to 22% on Robotouille Synchronous, 37% on Asynchronous, and 15% on ALFWorld while maintaining comparable or lower computational cost.

Distribution-Calibrated Inference Time Compute for Thinking LLM-as-a-Judge

Hamid Dadkhahi, Firas Trabelsi, Parker Riley, Juraj Juraska, Mehdi Mirzazadeh
Thinking Large Language Models (LLMs) used as judges for pairwise preferences remain noisy at the single-sample level, and common aggregation rules (majority vote, soft self-consistency, or instruction-based self-aggregation) are inconsistent when ties are allowed. We study inference-time compute (ITC) for evaluators that generate n independent thinking--rating samples per item, and propose a principled, distribution-calibrated aggregation scheme. Our method models three-way preferences with a Bradley–Terry-Davidson formulation on rating counts, leveraging both polarity (margin among non-ties) and decisiveness (non-tie rate) to distinguish narrow margins from strong consensus. Across various evaluation benchmarks, our approach consistently reduces MAE and increases pairwise accuracy versus standard baselines, and when evaluated against human-consensus meta-labels, matches or exceeds individual human raters. These results show that carefully allocating ITC and aggregating with distribution-aware methods turns noisy individual model judgments into reliable ratings for evaluation.
****
A Single Layer to Explain Them All: Understanding Massive Values in Large Language Models
Zeru Shi, Zhenting Wang, Fan Yang, Qifan Wang, Ruixiang Tang
We investigate the origins of massive activations in large language models (LLMs) and identify a specific layer named the Massive Emergence Layer (ME Layer), that is consistently observed across model families, where massive activations first emerge and subsequently propagate to deeper layers through residual connections. We show that, within the ME Layer both the RMSNorm and the FFN parameters jointly contribute to the emergence of massive activations. Once formed, the massive activation token representation remains largely invariant across layers, reducing the diversity of hidden representations passed to the attention module. Motivated by this limitation, we propose a simple and effective method to reduce the rigidity of the massive activation token. Our approach consistently improves LLM performance across multiple tasks, including instruction following and math reasoning, in both training free and fine tuning settings. Moreover, we show that our method mitigates attention sinks by selectively weakening their influence, elucidating their origin at the hidden state level and shedding new light on principled mitigation strategies.
****
Self-Distillation Enables Continual Learning
Idan Shenfeld, Mehul Damani, Jonas Hübotter, Pulkit Agrawal
Continual learning, enabling models to acquire new skills and knowledge without degrading existing capabilities, remains a fundamental challenge for foundation models. While on-policy reinforcement learning can reduce forgetting, it requires explicit reward functions that are often unavailable. Learning from expert demonstrations, the primary alternative, is dominated by supervised fine-tuning (SFT), which is inherently off-policy. We introduce Self-Distillation Fine-Tuning (SDFT), a simple method that enables on-policy learning directly from demonstrations. SDFT leverages in-context learning by using a demonstration-conditioned model as its own teacher, generating on-policy training signals that preserve prior capabilities while acquiring new skills. Across skill learning and knowledge acquisition tasks, SDFT consistently outperforms SFT, achieving higher new-task accuracy while substantially reducing catastrophic forgetting. In sequential learning experiments, SDFT enables a single model to accumulate multiple skills over time without performance regression, establishing on-policy distillation as a practical path to continual learning from demonstrations.

Diving into Kronecker Adapters: Component Design Matters
Jiayu Bai, Danchen Yu, Zhenyu Liao, TianQi Hou, Feng Zhou, Robert C Qiu, Zenan Ling
Kronecker adapters have emerged as a promising approach for fine-tuning large-scale models, enabling high-rank updates through tunable component structures. However, existing work largely treats the component structure as a fixed or heuristic design choice, leaving the dimensions and number of Kronecker components unde

rexplored. In this paper, we identify component structure as a key factor governing the capacity of Kronecker adapters. We perform a fine-grained analysis of both the dimensions and number of Kronecker components.
In particular, we show that the alignment between Kronecker adapters and full fine-tuning depends on component configurations. Guided by these insights, we propose Component Designed Kronecker Adapters (CDKA). We further provide parameter-budget–aware configuration guidelines and a tailored training stabilization strategy for practical deployment. Experiments across various architectures and modalities demonstrate the effectiveness of CDKA. Code is available at \url{https://github.com/rainstonee/CDKA}.

LLM4Cov: Execution-Aware Agentic Learning for High-coverage Testbench Generation
Hejia Zhang, Zhongming Yu, Chia-Tung Ho, Haoxing Ren, Brucek Khailany, Jishen Zhao
Execution-aware LLM agents offer a promising paradigm for learning from tool feedback, but such feedback can be expensive and slow to obtain, making online reinforcement learning (RL) less practical in certain scenarios.
High-coverage hardware verification exemplifies this challenge due to its reliance on industrial simulators and non-differentiable execution signals.
We propose LLM4Cov, an offline agent-learning framework that models verification as single-step state transitions guided by deterministic evaluators.
Building on this formulation, we introduce execution-validated data curation, policy-aware agentic data synthesis, and worst-state-prioritized sampling to enable scalable learning under execution constraints.
We further curate a reality-aligned benchmark adapted from an existing verification suite through a revised evaluation protocol.
Using the proposed pipeline, a compact 4B-parameter model achieves 69.2\% pass rate and 90.4\% average coverage in CVDP-ECov under agentic evaluation, outperforming its teacher by 5.3\% and 10.5\%, demonstrating competitive performance against models an order of magnitude larger.

Bayesian Tensor Decomposition with Diffusion Model Prior
Zerui Tao, Qibin Zhao
Low-rank tensor decomposition (TD) is usually effective on clean, fully observed data, but it often degrades under severe missingness or noise. Low-rankness is itself a useful but limited structural prior, and additional handcrafted priors (e.g., sparsity or smoothness) still fall short of capturing the rich statistics of real-world data. To compensate for this weak inductive bias under heavy corruption, one would like to inject a learned, data-driven prior; however, the state-of-the-art diffusion models are not readily compatible with current TD and tractable posterior inference. To address these challenges, we introduce DiffBCP, a hybrid-prior Bayesian CP decomposition framework that couples a cumulative shrinkage process prior over the CP factors for automatic rank selection with an off-the-shelf pre-trained diffusion model as an implicit data prior on the reconstructed tensor. To make posterior inference tractable despite the coupling among the likelihood, low-rank constraint, and diffusion prior, we develop a split Gibbs sampler: CP factors admit conjugate updates, while the diffusion block is sampled via low-rank-guided denoising. A noise-adaptive coupling schedule further reduces sensitivity to hand-tuned annealing. Experiments on image inpainting and denoising, including high-resolution out-of-distribution images, show consistent gains over Bayesian, nonlinear, and plug-and-play TD baselines.
****

Operator Splitting with Hamilton-Jacobi-based Proximals
Nicholas Di, Eric Chi, Samy Wu Fung
Operator splitting algorithms are a cornerstone of modern first-order optimization, decomposing complex problems into simpler subproblems solved via proximal operators. However, most functions lack closed-form proximal operators, which has long restricted these methods to a narrow set of problems. Hamilton-Jacobi-based proximal operator (HJ-Prox) is a recent derivative-free Monte Carlo technique based on Hamilton-Jacobi PDE theory, that approximates proximal operators numeric

ally. In this work, we introduce a unified framework for operator splitting via HJ-Prox, which allows for deployment of operator splitting even when functions a re not proximable. We prove that replacing exact proximal steps with HJ-Prox in algorithms such as proximal point, proximal gradient descent, Douglas–Rachford s plitting, Davis–Yin splitting, and primal–dual hybrid gradient preserves converg ence guarantees under mild assumptions. Numerical experiments demonstrate HJ-Pro x is competitive and effective on a wide variety of statistical learning tasks.
****

MIND: Multi-rationale INtegrated Discriminative Reasoning Framework for Multi-mo dal Large Models

Chuang Yu, Jinmiao Zhao, Mingxuan Zhao, Yunpeng Liu, Xiujun Shu, Yuanhao Feng, B o Wang, Xiangyu Yue

Recently, multimodal large language models (MLLMs) have been widely applied to r easoning tasks. However, they suffer from limited multi-rationale semantic model ing, insufficient logical robustness, and susceptibility to misleading cues. The refore, we propose a Multi-rationale INtegrated Discriminative (MIND) reasoning framework, which is designed to endow MLLMs with human-like cognitive abilities of “Understand → Rethink → Correct”, and achieves a paradigm evolution from pass ive imitation-based reasoning to active discriminative reasoning. Specifically, we introduce a Rationale Augmentation and Discrimination (RAD) paradigm, which p rovides a unified and extensible data foundation. Meanwhile, we design a Progres sive Two-stage Correction Learning (P2CL) strategy. The first phase enhances mul ti-rationale positive learning, while the second phase enables active logic disc rimination and correction. In addition, to mitigate representation entanglement in the multi-rationale semantic space, we propose a Multi-rationale Contrastive Alignment (MCA) optimization strategy. Extensive experiments show that our MIND achieves SOTA performance on multiple public datasets. Our data and code are ava ilable at https://github.com/YuChuang1205/MIND.

On the Adversarial Robustness of Large Vision-Language Models under Visual Token Compression

Xinwei Zhang, Hangcheng Liu, Li Bai, Hao Wang, Qingqing Ye, Tianwei Zhang, Haibo Hu

Visual token compression is widely used to accelerate large vision-language mode ls (LVLMs) by pruning or merging visual tokens, yet its adversarial robustness r emains unexplored. We show that existing encoder-based attacks cannot fully disc lose the robustness vulnerabilities of compressed LVLMs, due to an optimization-inference mismatch: perturbations are optimized on the full-token representation , while inference is performed through a token-compression bottleneck. To addres s this gap, we propose the Compression-AliGnEd attack (CAGE), which aligns pertu rbation optimization with compression inference without assuming access to the d eployed compression mechanism or its token budget. CAGE combines (i) expected fe ature disruption, which concentrates distortion on tokens likely to survive acro ss plausible budgets, and (ii) rank distortion alignment, which actively aligns token distortions with rank scores to promote the retention of highly distorted evidence. Across diverse representative plug-and-play compression mechanisms and datasets, our results show that CAGEconsistently achieves lower robust accuracy than the baseline. This work highlights that robustness assessments ignoring co mpression can be overly optimistic, calling for compression-aware security evalu ation and defenses for efficient LVLMs.

Beyond Static Allocation: Dynamic Sensitivity-Aware Fine-Tuning for Vision Trans formers

Yuanyang Cao, Xichun Liu, Fuwei Zhang, Shangqi Deng, Ziyang Ren, Jianji Wang

Existing Parameter-Efficient Fine-Tuning (PEFT) methods are fundamentally constr ained by a static allocation paradigm, which overlooks the model's evolving opti mization priorities during training. To address this, we introduce Dynamic Adapt ive Fine-tuning (DAF), a novel framework that periodically evaluates and reconfi gures the trainable structure based on a context-aware decoupled sensitivity ana lysis. DAF employs a Rebuild-and-Refocus strategy to preserve learned knowledge

by freezing outdated modules while decisively reallocating the parameter budget to newly identified critical regions. Extensive experiments on challenging visio n benchmarks demonstrate that DAF significantly outperforms mainstream static PE FT methods and achieves superior performance and efficiency, particularly under extreme parameter budgets. Our work fundamentally challenges the static nature o f the field, offering a more intelligent and efficient paradigm for adapting lar ge pretrained models. The code is available at https://github.com/E-green11/DAF.
****
Depth-Progressive Monotonic Learning without Global Backpropagation
Chenhao Ye, Rongguang Ye, Yuchao Zhang, Ming Tang
Backpropagation (BP) remains the dominant training paradigm for deep neural netw orks, yet its reliance on global gradient propagation fundamentally induces upda te locking problem, enforcing strong inter-layer dependencies in parameter updat es. To address this limitation, we propose Depth-progressive Monotonic Learning (DMoL), a training scheme that assigns layer-wise local belief objectives and in crementally refines them across network depth, enabling unlocked parameter updat es. As a result, DMoL supports dynamic modification of network depth during trai ning, adapting to available compute and device resources while maintaining stabl e optimization. We provide theoretical guarantees that layer-wise local belief o bjectives improve monotonically with increasing depth and converge exponentially . Empirically, DMoL consistently matches or outperforms BP across diverse tasks, yielding a 4.3\% accuracy gain on CIFAR-100, mitigating over-smoothing in deep graph neural networks (+37.5\% on Cora), and reducing the final loss by over 35\ % in diffusion model training, highlighting its robustness and flexibility as an alternative to BP. The code is publicly available at: https://github.com/ychAlb ert/DMoL.
****
Quantifying Biases in LLM-as-a-Judge Evaluations
Magda Dubois, Harry Coppock, Mario Giulianelli, Ole Kristian Jorgensen, Timo Fle sch, Lennart Luettgau, Cozmin Ududec
The evaluation of large language models (LLMs) is increasingly performed by othe r LLMs, a setup commonly known as "LLM-as-a-judge", or autograders. While autogr aders offer a scalable alternative to human evaluation, they are not free from b iases (e.g., favouring longer outputs or generations from their own model family). Here we propose a statistical framework based on Bayesian generalised linear models (GLMs) that enables researchers to address their primary research questio ns (e.g., LLM capability or risk assessment), while simultaneously identifying, quantifying and mitigating various biases in their autograders. Our approach can be applied to various evaluation formats (e.g., absolute scores or pairwise pre ferences) and augments traditional metrics (e.g., inter-rater agreement) by prov iding precise uncertainty estimates and clarifying sources of disagreement betwe en graders. This framework also enables efficient counterfactual simulations wit hout costly re-evaluation (e.g., assessing agreement after removing systematic b iases). We demonstrate these capabilities through simulated examples, with all m ethods available in an open-source software package. Overall, we introduce a nov el framework for autograder evaluation which allows researchers to detect, quant ify and correct for various biases in a systematic way.

DV-World: Benchmarking Data Visualization Agents in Real-World Scenarios
Jinxiang Meng, Shaoping Huang, Fangyu Lei, Jingyu Guo, Haoxiang Liu, Jiahao Su, Sihan Wang, Yao Wang, Enrui Wang, Ye Yang, Hongze Chai, Jinming Lyu, Anbang Yu, Huangjing Zhang, Yitong Zhang, Yiming Huang, Zeyao Ma, Shizhu He, Jun Zhao, Kang Liu
Real-world data visualization (DV) requires native environmental grounding, cros s-platform evolution, and proactive intent alignment, yet existing benchmarks ar e often limited to code sandboxes, creation-only tasks, and fully specified inte nts.
We introduce DV-World, a 260-task benchmark for evaluating DV agents across prof essional visualization lifecycles.
DV-World covers three domains: DV-Sheet for native spreadsheet chart/dashboard c

reation and diagnostic repair; DV-Evolution for adapting reference visual artifacts to new data across programming paradigms; and DV-Interact for proactive intent alignment with a user simulator under ambiguous requirements.
Its hybrid evaluation combines \textit{Table-value Alignment} for numerical precision with rubric-based \textit{MLLM-as-a-Judge} for semantic-visual assessment.

Experiments show that state-of-the-art models achieve below 50\% overall performance, exposing major gaps in real-world DV capabilities.
DV-World provides a realistic testbed for developing DV agents suited to enterprise workflows.
Data and code are available at \url{dv-world-project.github.io}.
****
Follow-the-Perturbed-Leader for Decoupled Bandits: Best-of-Both-Worlds and Practicality
Chaiwon Kim, Jongyeong Lee, Min-hwan Oh
We study the decoupled multi-armed bandit problem, where the learner separately selects one arm for exploration and one, possibly different, arm for exploitation at each round.
In this setting, the loss of the explored arm is observed but not incurred, whereas the loss of the exploited arm is incurred without being observed.
We propose an efficient Follow-the-Perturbed-Leader (FTPL) policy that achieves Best-of-Both-Worlds (BOBW) guarantee with constant regret in the stochastic regime and optimal $\mathcal{O}(\sqrt{KT})$ regret in the adversarial regime.
A key feature of our method is that it completely avoids both the convex optimization required by prior BOBW policies and the resampling procedures typically used in FTPL bandit policies.
This allows FTPL to fully realize its computational efficiency advantages, leading to substantial reductions in computational cost.
We empirically confirm that our policy not only improves the runtime but also demonstrates superior regret performance in both regimes.
****
The Assistant Axis: Situating and Stabilizing the Default Persona of Language Models
Christina Lu, Jack Gallagher, Jonathan Michala, Kyle Fish, Jack Lindsey
Large language models can represent a variety of personas but typically default to a helpful Assistant identity cultivated during post-training. Across several different models, we find an “Assistant Axis" in their activation space, which captures the extent to which a model is operating in its default Assistant mode. Steering towards the Assistant direction reinforces helpful and harmless behavior; steering away increases the model’s tendency to identify as other entities. Measuring deviations along the Assistant Axis predicts “persona drift,” a phenomenon where models slip into exhibiting harmful or bizarre behaviors that are uncharacteristic of their typical persona. We find that persona drift is often driven by conversations demanding meta-reflection on the model’s processes or featuring emotionally vulnerable users. We show that restricting activations to a fixed region along the Assistant Axis can stabilize model behavior in these scenarios—and also in the face of adversarial persona-based jailbreaks. Our results suggest that post-training steers models toward a particular region of persona space but only loosely tethers them to it, motivating work on training and steering strategies that more deeply anchor models to a coherent persona.
****
GADA: Geometry-Aware Deformable Aggregation for Image-Based Gaussian Splatting
Siwoo Lim, Sunjae Yoon, Gwanhyeong Koo, Chang D. Yoo
Gaussian Splatting has achieved significant improvements by incorporating warping-based techniques. However, such methods suffer from pixel-level inaccuracies due to uncertain geometry. This uncertainty leads to spatial misalignments in the warped images, which disrupt residual learning used in warping-based methods and fundamentally limit the gains of correction, particularly on thin structures and high-frequency details. Driven by our insight that useful visual cues are not lost but locally preserved under slight displacement, we propose Geometry-Aware

Deformable Aggregation (GADA). This method introduces an iterative refinement module with deformable offsets to actively correct spatial misalignments and recover these displaced cues. Furthermore, to address the limitations of standard pipelines where visibility checks (i.e., thresholding) often discard valid pixels and multi-view warped image fusion relies on naive mean aggregation, our module is coupled with an implicit confidence weighting mechanism that selectively suppresses unreliable evidence. Consequently, our approach outperforms prior warping-based Gaussian Splatting, preserving high-frequency quality while achieving 2.13 times faster FPS.

Detecting Fluent Optimization-Based Adversarial Prompts via Sequential Entropy Changes

Mohammed Alshaalan, Miguel R. D. Rodrigues

Optimization-based adversarial suffixes can jailbreak aligned large language models (LLMs) while remaining fluent, weakening static and windowed perplexity-based detectors. We cast adversarial suffix detection as an *online change-point detection* problem over the token-level next-token entropy stream. Using the LLM system prompt to estimate a robust baseline, we standardize user-token entropies and apply a one-sided CUSUM statistic. The resulting detector, *CPD Online* (CPD), is model-agnostic, training-free, runs online, and localizes the adversarial suffix onset. On a benchmark of 1,012 optimization-based suffix attacks (GCG, AutoDAN, AdvPrompter, BEAST, AutoDAN-HGA) and 1,012 perplexity-controlled benign prompts, CPD improves F1 over the strongest windowed-perplexity baseline on all six open-weight chat models (LLaMA-2-7B/13B, Vicuna-7B/13B, Qwen2.5-7B/14B). On LLaMA-2-7B at the canonical CUSUM setting ($k=0$), CPD reaches AUROC 0.88 and F1 0.82. Beyond prompt-level detection, CPD concentrates 79.6% of its triggers inside the adversarial suffix, versus 17–46% for windowed perplexity. Finally, when used as a lightweight gate for LLaMA Guard, CPD reduces guard calls by 17–22% on a high-volume, benign-dominated deployment while preserving guard-level detection quality.

TestExplora: Benchmarking LLMs for Proactive Bug Discovery via Repository-Level Test Generation

Steven Liu, Jane Luo, Xin Zhang, Aofan Liu, Hao Liu, Jie Wu, Ziyang Huang, Yangyu Huang, Yu Kang, Scarlett Li

Given that Large Language Models (LLMs) are increasingly applied to automate software development, comprehensive software assurance spans three distinct goals: regression prevention, reactive reproduction, and proactive discovery. Current evaluations systematically overlook the third goal. Specifically, they either constrain models to a compliance trap by treating existing code as the ground truth for regression prevention, or rely on post-failure artifacts (e.g., issue reports) for reactive bug reproduction, failing to expose defects before they manifest as failures. To bridge this gap, we present TestExplora, a benchmark designed to evaluate LLMs as proactive testers within full-scale, realistic repository environments. Comprising 2,389 tasks across 482 repositories, TestExplora conceals all defect-related information, forcing models to uncover bugs by identifying discrepancies between implementation and documentation-derived intent—utilizing documentation as the reference oracle. Furthermore, to ensure sustainable evaluation and mitigate risks of data leakage in static datasets, we propose a continuous, time-aware data collection framework. Our evaluation reveals a significant capability gap: state-of-the-art models achieve a maximum Fail-to-Pass ($F2P$) rate of only 16.06%. Further analysis indicates that navigating complex cross-module interactions and leveraging agentic exploration are critical to advancing LLMs toward autonomous software quality assurance. Consistent with this, SWEAgent instantiated with GPT-5-mini achieves an $F2P$ of 17.27% and an $F2P@5$ of 29.7%, highlighting the effectiveness and promise of agentic exploration in proactive bug discovery tasks.

Active Exploring like a Pigeon: Reinforcing Spatial Reasoning via Agentic Vision-Language Models

Wei Deng, Xianlin Zhang, Mengshi Qi
Enabling Vision-Language Models (VLMs) to perform spatial reasoning remains chal
lenging.
Existing approaches treat VLMs as passive observers, which is difficult for real
-world applications.
Moreover, reinforcement learning methods rely on sparse rewards, limiting their
effectiveness for complex reasoning tasks.
Inspired by pigeons' building and exploiting cognitive maps for navigation, we p
ropose a novel agentic pipeline for spatial reasoning.
First, we introduce a new \emph{dynamic cognitive map} parameterizing scene layo
ut as object positions and orientations, serving as persistent memory for new ob
servations.
Second, we propose a novel \emph{Spatial Assertion Codes (SAC)}, Python expressi
ons programmatically describing spatial relationships.
By collaborating with the dynamic cognitive map, SAC enables verification of int
ermediate reasoning steps, providing dense reward signals.
We optimize the model via supervised and reinforcement finetuning.
Experiments on the MindCube benchmark demonstrate state-of-the-art performance w
ith \emph{80.5\%} overall accuracy, outperforming the best current method by \em
ph{29.5} accuracy points (a relative improvement of \emph{53.2\%}) on the challe
nging \textsc{Rotation} subset. Our code and data are open-sourced at \url{https
://github.com/dw-dengwei/active-spatial-reasoning.git}.

Practical Mechanism for Fault-Tolerant Spiking Neural Networks via Simple Input
Control Based on Learnable Fragmentation
Hyun-Jong Lee, Jae-Han Lim
Spiking Neural Networks (SNNs) are regarded as the third generation of neural ne
tworks, offering energy-efficient computing for neuromorphic devices. Despite th
is benefit, hardware-implemented SNNs are vulnerable to hardware faults, which s
everely degrade their performance. Previous approaches have required direct acce
ss to internal SNN circuits to modify weights or monitor internal states, limiti
ng their practicality. Improving robustness to hardware faults without such acce
ss remains challenging. To overcome this challenge, we propose a fault-tolerant
mechanism that operates only through input data control. Hardware faults reduce
the usable learning capacity of SNNs, resulting in a mismatch between the instan
taneous input load and the degraded network dynamics. Our mechanism mitigates th
is mismatch by dividing each input sample into multiple fragments, redistributin
g the input load via a learnable fragmentation strategy. The strategy learns tw
o key fragmentation components: 1) division boundaries and 2) the number of frag
ments. To our knowledge, this is the first mechanism to improve the fault tolera
nce of SNNs without accessing the internal circuits. Experimental results demons
trate that our mechanism consistently outperforms previous methods in various SN
N models, achieving these gains without direct access to internal circuits. Furt
hermore, we validate its effectiveness on SNNs implemented with a physical FPGA
platform, confirming its practicality.

Show, Don't Tell: Morphing Latent Reasoning into Image Generation
Harold Haodong Chen, Xinxiang Yin, Wen-Jie Shu, Hongfei Zhang, Zixin Zhang, Chen
fei Liao, Litao Guo, Qifeng Chen, Ying-Cong Chen
Text-to-image (T2I) generation has achieved remarkable progress, yet existing me
thods often lack the ability to dynamically reason and refine during generation-
-a hallmark of human creativity. Current reasoning-augmented paradigms mostly re
ly on explicit thought processes, where intermediate reasoning is decoded into d
iscrete text at fixed steps with frequent image decoding and re-encoding, leadin
g to inefficiencies, information loss, and cognitive mismatches. To bridge this
gap, we introduce **LatentMorph**, a novel framework that seamlessly integrates
implicit latent reasoning into the T2I generation process. At its core, LatentMo
rph introduces four lightweight components: (***i***) a **condenser** for summar
izing intermediate generation states into compact visual memory, (***ii***) a **
translator** for converting latent thoughts into actionable guidance, (***iii***

) a **shaper** for dynamically steering next image token predictions, and (***iv***) an RL-trained **invoker** for adaptively determining when to invoke reasoning. By performing reasoning entirely in continuous latent spaces, LatentMorph avoids the bottlenecks of explicit reasoning and enables more adaptive self-refinement. Extensive experiments demonstrate that LatentMorph **(I)** enhances the base model Janus-Pro by 16% on GenEval and 25% on T2I-CompBench; **(II)** outperforms explicit paradigms (*e.g.*, TwiG) by 15% and 11% on abstract reasoning tasks like WISE and IPV-Txt, **(III)** while reducing inference time by 44% and token consumption by 51%; and **(IV)** exhibits 71% cognitive alignment with human intuition on reasoning invocation.

Tree-Structured Orthonormal Decomposition of the Aitchison Simplex

Daisuke Yamada, Qijun Zhang, Travis Pence, Barbara B. Bendlin, Federico Rey, Vikas Singh

Compositional data---vectors encoding relative proportions---arise across scientific domains, including ecology, geochemistry, and genomics. The features in these data often come with known hierarchical structure (e.g., taxonomies, phylogenies, ontologies), yet existing methods either ignore this structure, discard the intrinsic Aitchison geometry, are designed for binary trees, or yield incomplete coordinate systems. We describe *PolyILR*, a canonical orthonormal decomposition of the Aitchison tangent space aligned with any tree topology. Our construction defines a weighted local geometry at each internal node capturing full branching structure, then lifts these to a global orthonormal basis where every coordinate corresponds to a specific tree location. On microbiome and single-cell benchmarks, PolyILR yields stable, interpretable features and enables inference at multiscale tree resolution. We also establish a novel theoretical connection to softmax classifiers, suggesting possible applications to probabilistic modeling.

****

GeoLoom: High-quality Geometric Diagram Generation from Textual Input

Xiaojing Wei, Ting Zhang, Wei He, Jingdong Wang, Hua Huang

High-quality geometric diagram generation presents both a challenge and an opportunity: it demands strict spatial accuracy while offering well-defined constraints to guide generation. Inspired by recent advances in geometry problem solving that employ formal languages and symbolic solvers for enhanced correctness and interpretability, we propose GeoLoom, a novel framework for text-to-diagram generation in geometric domains. GeoLoom comprises two core components: an autoformalization module that translates natural language into a specifically designed generation-oriented formal language GeoLingua, and a coordinate solver that maps formal constraints to precise coordinates using the efficient Monte Carlo optimization. To support this framework, we introduce GeoNF, a dataset aligning natural language geometric descriptions with formal GeoLingua descriptions. We further propose a constraint-based evaluation metric that quantifies structural deviation, offering mathematically grounded supervision for iterative refinement. Empirical results demonstrate that GeoLoom significantly outperforms state-of-the-art baselines in structural fidelity, providing a principled foundation for interpretable and scalable diagram generation.

MiniAppBench: Evaluating the Shift from Text to Interactive HTML Responses in LLM-Powered Assistants

Zuhao zhang, Chengyue Yu, Yuante Li, Chenyi Zhuang, Linjian Mo, Shuai Li

With the rapid advancement of Large Language Models (LLMs) in code generation, human-AI interaction is evolving from static text responses to dynamic, interactive HTML-based applications, which we term **MiniApps**. These applications require models to not only render visual interfaces but also construct customized interaction logic that adheres to real-world principles. However, existing benchmarks primarily focus on algorithmic correctness or static layout reconstruction, failing to capture the capabilities required for this new paradigm. To address this gap, we introduce **MiniAppBench**, the first comprehensive benchmark designed to evaluate principle-driven, interactive application generation. Sourced from a real-world application with **10M+** generations, MiniAppBench distills 500 t

asks across six domains (e.g., Games, Science, and Tools). Furthermore, to tackl
e the challenge of evaluating open-ended interactions where no single ground tru
th exists, we propose **MiniAppEval**, an agentic evaluation framework. Leveragi
ng browser automation, it performs human-like exploratory testing to systematica
lly assess applications across three dimensions: Intention, Static, and Dynamic.
 Our experiments reveal that current LLMs still face significant challenges in g
enerating high-quality MiniApps, while MiniAppEval demonstrates high alignment w
ith human judgment, establishing a reliable standard for future research. Our ho
mepage is available in https://miniappbench.github.io.

LLM Priors for ERM over Programs
Shivam Singhal, Priyadarsi Mishra, Eran Malach, Tomer Galanti
We study program-learning methods that are efficient in both samples and computa
tion. Classical learning theory suggests that when the target admits a short pro
gram description, for example a short piece of ``Python code'', it can be learne
d from few examples by ERM over the program class. However, this approach relies
 on enumerating candidate programs, which is typically exponential in the descri
ption length; gradient-based training avoids this explicit search but, for some
families of short programs, can require exponentially many samples to succeed. W
e propose \textsc{LLM-PV}, a propose-and-verify recipe that enables ERM-style se
lection over a discrete program class without exhaustive enumeration: a pretrain
ed LLM induces a proposal distribution over candidate programs, each proposal is
 executed and scored on a held-out validation set, and the best program is selec
ted, with no gradient updates or validation feedback used to adapt the sampling
distribution. Across algorithmic tasks including parity variants, pattern matchi
ng, and primality testing, \textsc{LLM-PV} often recovers the exact underlying r
ule from a small labeled set and generalizes far beyond the training sequence le
ngths, while SGD-trained transformers, fine-tuning, in-context learning, and cla
ssical ML baselines can fit the training data yet fail to generalize reliably. T
ogether, these results suggest that pretrained LLM priors can serve as effective
 search biases for ERM, narrowing the gap between statistical and computational
efficiency.

HVAE: Hyperbolic Variational Autoencoder For Flexible Knowledge Transfer Across
Multiple Domains
Xiaolei Liu, Binfeng Wang, Kaixin Gao, Shaoshuai Li
Cross-domain recommendation (CDR) serves as a pivotal solution to data sparsity
and cold-start problems by transferring knowledge across distinct domains. Howev
er, existing approaches predominately rely on Euclidean embedding spaces, which
suffer from a fundamental geometry-distribution mismatch: real-world user-item i
nteractions typically exhibit power-law distributions and latent hierarchical st
ructures that flat Euclidean spaces cannot accurately represent without signific
ant distortion. This geometric limitation not only compromises representation qu
ality but, more critically, hinders the effective disentanglement of domain-inva
riant user preferences from domain-specific interests, limiting transferability
in low-overlap scenarios. To bridge this gap, we introduce the Mixed-Curvature H
yperbolic Variational Auto-Encoder (HVAE), a principled framework that unifies k
nowledge extraction and transfer within a hyperbolic manifold. By leveraging the
 exponential expansion capacity of hyperbolic geometry, HVAE naturally accommoda
tes hierarchical data structures, enabling precise disentanglement of user inten
ts without the need for strict domain overlap constraints. Furthermore, we propo
se a rigorous hyperbolic Wasserstein barycenter mechanism to align invariant dis
tributions across heterogeneous domains. Extensive experiments on large-scale in
dustrial and public datasets demonstrate that HVAE achieves superior performance
, particularly in challenging scenarios with long-tail distributions and minimal
 domain overlap.

Single-Rollout Hidden-State Dynamics for Training-Free RLVR Data Selection
Jianghao Wu, Jianfei Cai, Weiqiang Wang, Jin Ye, Daniel F. Schmidt, Yasmeen Geor
ge

Reinforcement learning with verifiable rewards (RLVR) can yield large reasoning gains from very few training instances, yet its strong sensitivity to which instances are used makes data selection a central bottleneck. Most existing selection pipelines rely on training-time optimization signals and/or require access to verifiable rewards or ground-truth answers over large candidate pools, which is costly and often infeasible in specialized domains. We study RLVR data selection in a setting where selection must be performed before any RL training and without labels or reward evaluation on the full pool. We propose SHIFT, a one-shot, training-free selector based solely on inference-time hidden-state dynamics. For each candidate instance, SHIFT runs a single deterministic reasoning rollout and computes a reasoning-induced representation shift (RIRS) as the start-to-end hidden-state delta. SHIFT uses the RIRS magnitude as a lightweight proxy for instance utility and enforces coverage via a quality-weighted farthest-first CoreSet procedure in an RIRS-augmented feature space, producing compact subsets that scale to large unlabeled pools. Across mathematical reasoning and medical QA benchmarks under ultra-low budgets, SHIFT consistently outperforms training-free diversity and difficulty/uncertainty baselines, improving both in-domain accuracy and transfer to harder evaluation settings. Ablations show that RIRS-based coverage and quality-weighting contribute complementary gains, and analyses indicate that RIRS is not explained by simple input/output length statistics. Code is available at github.com/JianghaoWu/SHIFT.

FIDIA: Function-Informed Sequence Design via Inference-Aligned Policy Optimization

Minghan Li, Fengji Li, Yilin Tao, Yue Deng

Computational protein design typically employs a sequential workflow of structure generation followed by sequence (re)design. While structure generators can be explicitly conditioned on functional objectives, inverse folding models are constrained by their function-agnostic nature and sequence-structure degeneracy. More critically, the associated training objectives do not account for the *Best-of-N* (BoN) inference protocol, resulting in a fundamental training-inference misalignment. Here, we propose FIDIA, a reinforcement learning framework that enables **F**unction-**I**nformed sequence **D**esign via **I**nference-**A**ligned policy optimization. Specifically, FIDIA integrates functional constraints into composite rewards and explicitly optimize the induced policy under BoN toward high-fitness sequence regions. We achieve this via a grounded gradient estimator that directly maximizes the expected maximum reward. FIDIA consistently outperforms both standard and RL-optimized baselines in success rate and precision on a general motif scaffolding benchmark. Further experiments on realworld cases including vaccine and affinity-enhancing enzyme design validate FIDIA’s efficacy in complex therapeutic and biocatalytic contexts.

StreamFlow: Theory, Algorithm, and Implementation for High-Efficiency Rectified Flow Generation

Sen Fang, Hongbin Zhong, Yalin Feng, Yanxin Zhang, Dimitris N. Metaxas

New technologies such as Rectified Flow and Flow Matching have significantly improved the performance of generative models in the past two years, especially in terms of control accuracy, generation quality, and generation efficiency. However, due to some differences in its theory, design, and existing diffusion models, the existing acceleration methods cannot be directly applied to the Rectified Flow model. In this article, we have comprehensively implemented an overall acceleration pipeline from the aspects of theory, design, and reasoning strategies. This pipeline uses new methods such as batch processing with a new velocity field, vectorization of heterogeneous time-step batch processing, and dynamic TensorRT compilation for the new methods to comprehensively accelerate related models based on flow models. Currently, the existing public methods usually achieve an acceleration of 18%, while experiments have proved that our new method can accelerate the 512$\times$512 image generation speed to up to 611%, which is far beyond the current non-generalized acceleration methods. Project page at https://world-snapshot.github.io/StreamFlow/

Credible Information Subset Decomposition: An End-to-End Multi-fidelity Learning Model by Modeling Label Information
Sihan Wang, Wenjie Du, Yang Wang
In the AI4Chemistry scenario, utilizing heterogeneous data at different fidelity levels is a common and core issue. High-fidelity data is accurate but scarce, while low-fidelity data is abundant but biased. Traditional multi-fidelity methods typically identify cross-fidelity biases based on paired samples under different fidelity labels. However, due to the mismatch in dataset input distribution and the complexity of the biases themselves, these methods are difficult to implement in real-world scientific environments. To address this, we propose a trusted information subset decomposition framework that can efficiently utilize multi-fidelity data without requiring paired samples. Multi-fidelity label supervision is decomposed into three complementary subsets: a trusted information subset based on the absolute value of high-fidelity labels; a trusted subset that captures the reliability of the high-fidelity and medium-fidelity label intervals through adaptive constraints; and an ordered trusted subset representing the numerical relationships within the same fidelity level. These subsets are then integrated into a unified end-to-end model, enabling the reasonable utilization of medium- and low-fidelity information. Extensive experiments on various molecular and material property benchmarks demonstrate that our method consistently outperforms state-of-the-art multifidelity and singlefidelity baseline methods, and exhibits good robustness under real-world unpaired multifidelity conditions.

Causal Representation Learning with Optimal Compression and Complex Treatments
Wanting Liang, Haoang Chi, Zhiheng Zhang
Estimating Individual Treatment Effects (ITE) in multi-treatment scenarios faces two critical challenges: the Hyperparameter Selection Dilemma for balancing weights and the Curse of Dimensionality in computational scalability. This paper derives a novel multi-treatment generalization bound and proposes a theoretical estimator for the optimal balancing weight α, eliminating expensive heuristic tuning. We investigate three balancing strategies: Pairwise, One-vs-All (OVA), and Treatment Aggregation. While OVA achieves superior precision in low-dimensional settings, our proposed Treatment Aggregation ensures both accuracy and $\mathcal{O}(1)$ scalability as the treatment space expands. Furthermore, we extend our framework to a generative architecture, Multi-Treatment CausalEGM, which preserves the Wasserstein geodesic structure of the treatment manifold. Experiments on semi-synthetic and image datasets demonstrate that our approach significantly outperforms traditional models in estimation accuracy and efficiency, particularly in large-scale intervention scenarios.
****
HiST: A Hierarchical Sparse Transformer for Cross-Modal Spatial Transcriptomics Modeling
Weiyi Wu, Xinwen Xu, Xingjian Diao, Siting Li, Zhi Wei, Alma Andersson, Jiang Gui
Spatial transcriptomics (ST) links gene expression with tissue morphology but remains expensive and low-throughput, motivating surrogates that infer expression from routine histology.
Whole-slide H&E-to-ST inference pairs a gigapixel image with gene measurements at a sparse, irregular set of locations, making multiscale modeling challenging without incurring dense-grid overhead or quadratic token mixing.
We propose HiST, a hierarchical sparse transformer that treats measured locations as a lattice-indexed sparse field and builds a dyadic encoder--decoder directly on the active tissue footprint.
HiST combines sparse window attention for local geometric correspondence with resolution-changing operators for rapid multiscale context integration.
For a fixed window size, the dominant runtime and memory scale with the number of observed locations rather than the dense slide area.
To mitigate slide-specific acquisition variation, HiST adds a bottlenecked globa

l conditioning pathway via a \emph{slide calibration token} that summarizes slide-level context and conditions local representations.
On a multi-organ benchmark spanning diverse tissues and acquisition sources, HiST improves predictive performance over recent baselines while reducing runtime and peak memory.
****

DyCon: Dynamic Reasoning Control via Evolving Difficulty Modeling
Tengyao Tu, Yulin Li, Hui-Ling Zhen, Libo Qin, Zhoujun Wei, Jinghua Piao, Zhuotao Tian, Yong Li, Min Zhang
Recent advances in Large Reasoning Models (LRMs) demonstrate remarkable performance improvements by iteratively reflecting, exploring, and executing complex tasks, yet suffer from inefficiencies due to redundant reasoning, known as ``overthinking''.

Existing methods to mitigate this issue either rely on static difficulty estimates or require task-specific training, and thus fail to adapt to the dynamic complexity during reasoning.

In this work, we empirically show that the problem difficulty evolves dynamically throughout the reasoning process and is linearly encoded in the LRM’s step-level embeddings.

Building on this insight, we propose DyCon, a training-free framework that leverages latent step-level representations to explicitly model the evolving task difficulty, enabling the dynamic control of reasoning depth to mitigate the overthinking issue. Extensive experiments conducted on four models ranging from 4B to 32B, and across twelve benchmarks in math reasoning, general question answering, and coding tasks demonstrate that DyCon significantly enhances reasoning efficiency by reducing redundant steps without sacrificing accuracy or generalization. Project page and code are available at https://github.com/yu-lin-li/DyCon.

Stochastic Sparse Attention for Memory-Bound Inference
Kyle Lee, Corentin Delacour, Kevin Callahan-Coray, Kyle Jiang, Can Yaras, Samet Oymak, Tathagata Srimani, Kerem Yunus Camsari
Autoregressive decoding becomes bandwidth-limited at long contexts, as generating each token requires reading all n_k key and value vectors from KV cache. We present Stochastic Additive No-mulT Attention (SANTA), a method that sparsifies value-cache access by sampling $S \ll n_k$ indices from the post-softmax distribution and aggregates only those value rows. This yields an unbiased estimator of the post-softmax value aggregation while replacing value-stage multiply-accumulates with gather-and-add. We introduce stratified and systematic sampling to design variance-reduced, GPU-friendly variants. Evaluated on Llama-3.1-8B-Instruct at 32k-token contexts, S^{2}ANTA matches baseline accuracy while achieving up to $1.5\times$ decode-step attention-kernel speedup over FlashInfer and FlashDecoding on an NVIDIA RTX 6000 Ada. In batched long-context generation, these kernel gains translate to up to $1.25\times$ end-to-end decode-latency speedup. Finally, we propose Bernoulli qK^T sampling as a complementary technique to sparsify the score stage, reducing key-feature access through stochastic ternary queries. Both methods are complementary to upstream quantization, low-rank projection, KV-cache compression, and KV-cache selection methods. Together, they point toward sparse, multiplier-free, and energy-efficient inference. We open-source our kernels at: https://github.com/OPUSLab/SANTA.git
****

Divisiveness-Consistent Label Distribution Learning
Yunan Lu, Haitao Wu, Weiwei Li, Lei Yang, Xiuyi Jia
Label Distribution Learning (LDL) is an effective learning paradigm for predicting entire conditional label distributions, improving the trustworthiness of predictions in risk-sensitive tasks. Although previous LDL methods achieve satisfactory performance on conventional evaluation metrics, they generally overlook the divisiveness within label distributions, i.e., the propensity of label distribution to exhibit dissension between semantically opposing labels, which is an essential indicator of the practical decision risk. Therefore, we propose a divisiveness■consistent label distribution learning framework to quantify and preserve t

he divisiveness information. First, we formalize a divisiveness measure that sat isfies the axiomatic property of polarity monotonicity to quantify the divisiven ess information. Second, we theoretically demonstrate the inconsistency between conventional loss functions and divisiveness error. Besides, in order to address the adversarial gradient problem arising from directly minimizing the divisiven ess error, we propose a pairwise divisiveness loss as an unbiased estimator of t he original divisiveness error. Experiments confirm the effectiveness of the pro posed method.
****
Large Vision-Language Models Get Lost in Attention
Gongli Xi, Ye Tian, Mengyu Yang, Huahui Yi, Liang Lin, Xiaoshuai Hao, Kun Wang, Wendong Wang
Despite the rapid evolution of training paradigms, the decoder backbone of large vision--language models (LVLMs) remains fundamentally rooted in the residual-co nnection Transformer architecture. Therefore, deciphering the distinct roles of internal modules is critical for understanding model mechanics and guiding archi tectural optimization. While prior statistical approaches have provided valuable attribution-based insights, they often lack a unified theoretical basis. To bri dge this gap, we propose a unified framework grounded in *information theory and geometry* to quantify the **geometric and entropic nature** of residual updates . Applying this unified framework reveals a fundamental functional decoupling: * *Attention acts as a subspace-preserving operator** focused on reconfiguration, whereas **FFNs serve as subspace-expanding operators** driving semantic innovati on. Strikingly, further experiments demonstrate that replacing learned attention weights with predefined values (e.g., Gaussian noise) yields comparable or even superior performance across a majority of datasets relative to vanilla models. These results expose severe **misallocation and redundancy** in current mechanis ms, suggesting that state-of-the-art LVLMs effectively ``get lost in attention'' rather than efficiently leveraging visual context.

SafeSci: Safety Evaluation of Large Language Models in Science Domains and Beyon d
Xiangyang Zhu, Yuan Tian, Qi Jia, Kaiwei Zhang, Zicheng Zhang, Chunyi Li, Zijian Chen, Lu Sun, Kaiyuan Ji, Renrui Zhang, Wei Sun, Guangtao Zhai
The success of large language models (LLMs) in scientific domains has heightened safety concerns, prompting numerous benchmarks to evaluate their scientific saf ety. Existing benchmarks often suffer from limited risk coverage and a reliance on subjective evaluation. To address these problems, we introduce SafeSci, a com prehensive framework for safety evaluation and enhancement in scientific context s. SafeSci comprises SafeSciBench, a multi-disciplinary benchmark with 0.25M sam ples, and SafeSciTrain, a large-scale dataset containing 1.5M samples for safety enhancement. SafeSciBench distinguishes between safety knowledge and risk to co ver extensive scopes and employs objective metrics such as deterministically ans werable questions to mitigate evaluation bias. We evaluate 24 advanced LLMs and reveal critical vulnerabilities. We also observe that LLMs exhibit varying degre es of excessive refusal behaviors on safety-related issues. For safety enhanceme nt, we demonstrate that fine-tuning on SafeSciTrain significantly enhances the s afety alignment of LLMs. Finally, we argue that determining the safety of a scie ntific question should depend on the specific context, rather than universally c ategorizing it as safe or unsafe.
****
Memory-Efficient LLM Pretraining via Minimalist Optimizer Design
Athanasios Glentis, Jiaxiang Li, Andi Han, Mingyi Hong
Training large language models (LLMs) relies on adaptive optimizers such as Adam , which introduce extra operations and require significantly more memory to main tain first- and second-order moments than SGD. While recent works such as GaLore , Fira and APOLLO have proposed state-compressed memory-efficient variants, a f undamental question remains: *What are the minimum modifications to plain SGD ne eded to match state-of-the-art pretraining performance?* We systematically inves tigate this question using a bottom-up approach, and identify two simple yet hig

hly (memory- and compute-) efficient techniques: (1) column-wise gradient normal ization (normalizing the gradient along the output dimension), that boosts SGD p erformance without momentum; and (2) applying first-order momentum only to the o utput layer, where gradient variance is highest. Combining these two techniques lead to SCALE (Stochastic Column-normAlized Last-layer momEntum), a simple opti mizer for memory efficient pretraining. Across multiple models (60M–1B), SCALE m atches or exceeds the performance of Adam while using only 35–45% of the total m emory. It also consistently outperforms memory-efficient optimizers such as GaLo re, Fira and APOLLO, making it a strong candidate for large-scale pretraining un der memory constraints. For LLaMA 7B, SCALE outperforms the state-of-the-art me mory-efficient methods APOLLO and Muon in both perplexity and memory consumption . Code is available at https://github.com/OptimAI-Lab/Minimalist_LLM_Pretraining .

Hierarchical Image Tokenization for Multi-Scale Image Super Resolution

Isma Hadji, Enrique Sanchez, Adrian Bulat, Brais Martinez, Georgios Tzimiropoulo s

We introduce a multi-scale Image Super Resolution (ISR) method building on recen t advances in Visual Auto-Regressive (VAR) modeling. VAR models break image toke nization into additive, gradually increasing scales, using Residual Quantization (RQ), an approach that aligns perfectly with our target ISR task. Previous work s taking advantage of this synergy suffer from two main shortcomings. First, due to the limitations in RQ, they only generate images at a predefined fixed scale , failing to map intermediate outputs to the corresponding image scales. They al so rely on large backbones or a large corpus of annotated data to achieve better performance. To address both shortcomings, we introduce two novel components to the VAR training for ISR, aiming at increasing its flexibility and reducing its complexity. In particular, we introduce a) a **Hierarchical Image Tokenization (HIT)** approach that progressively represents images at different scales while enforcing token overlap across scales, and b) a **Direct Preference Optimization (DPO) regularization term** that, relying solely on the (LR,HR) pair, encourage s the transformer to produce the latter over the former. Our proposed HIT acts a s a strong inductive bias for the VAR training, resulting in a small model (300M params vs 1B params of VARSR), that achieves state-of-the-art results without e xternal training data, and that delivers multi-scale outputs with a single forwa rd pass.

TeamWork: Multivariate Time Series Anomaly Detection via Asymmetric Role-aware C hannel Modeling

Shiyan Hu, Tengxue Zhang, Jianxin Jin, Xiangfei Qiu, Bin Yang, Chenjuan Guo

Multivariate time series anomaly detection remains challenging as it requires th e joint modeling of variable relationships and temporal dependencies. Existing m ethods often struggle to balance channel relationship modeling and overlook the relative importance of different variables within multivariate time series. To a ddress this, we propose TeamWork, an asymmetric role-aware channel modeling fram ework that decouples variables into dominant and auxiliary roles according to th eir contributions to uncertainty reduction. Dominant variables drive system evol ution and their deviations more strongly disrupt normal patterns, while auxiliar y variables provide complementary cues. These variables with different roles are integrated through a role-aware gated interaction module. Moreover, point and s ubsequence anomalies can exist in multiple periodic systems, and the same anomal y type may behave differently across short- and long-period series. To capture s uch variations, we introduce a period-aware masked modeling mechanism. It employ s multiple specialized masking mechanisms spanning short to long periods to faci litate comprehensive temporal dependency learning. Extensive experiments on mult iple real-world datasets demonstrate that TeamWork achieves superior performance compared with state-of-the-art methods.

****

Var-JEPA: A Variational Formulation of the Joint-Embedding Predictive Architectu re – Bridging Predictive and Generative Self-Supervised Learning

Moritz Gögl, Christopher Yau
The Joint-Embedding Predictive Architecture (JEPA) is often seen as a non-genera tive alternative to likelihood-based self-supervised learning, emphasizing predi ction in representation space rather than reconstruction in observation space. W e argue that the resulting separation from probabilistic generative modeling is largely rhetorical rather than structural: the canonical JEPA design–coupled enc oders with a context-to-target predictor–mirrors the variational posteriors and learned conditional priors obtained when variational inference is applied to a p articular class of coupled latent-variable models, and standard JEPA can be view ed as a deterministic specialization in which regularization is imposed via arch itectural and training heuristics rather than an explicit likelihood. Building o n this view, we derive the *Variational JEPA* (Var-JEPA), which makes the latent generative structure explicit by optimizing a single Evidence Lower Bound (ELBO). This yields meaningful representations without ad-hoc anti-collapse regulariz ers and allows principled uncertainty quantification in the latent space. We ins tantiate the framework for tabular data (Var-T-JEPA) and achieve strong represen tation learning and downstream performance, improving over T-JEPA across real-wo rld tabular benchmarks while remaining competitive with strong raw-feature basel ines.

HypCL: Adapting CLIP in Hyperbolic Space for Continual Learning
Quan Cheng, Hao Yu, Da-Wei Zhou, Lijun Zhang
Recently, vision-language models (e.g., CLIP) have been increasingly adopted for continual learning to mitigate catastrophic forgetting. However, existing CLIP- based methods typically freeze the backbone to preserve pre-trained knowledge, w hich limits the model's ability to learn discriminative features for downstream tasks. In this paper, we introduce HypCL, a parameter-efficient framework that c ontinually adapts CLIP in hyperbolic space for continual learning. Our key insig ht is that the exponentially expanding capacity of hyperbolic geometry naturally accommodates the growing class space and promotes stronger inter-class separati on. Specifically, HypCL attaches task-specific adapters and composes their updat es sequentially in the Poincaré ball. To exploit the enhanced feature separabili ty of hyperbolic geometry, HypCL maintains visual prototypes computed from the a dapted features, which serve as stable anchors for calibrating predictions at in ference. Extensive experiments on standard class-incremental benchmarks demonstr ate that HypCL consistently outperforms existing CLIP-based continual learning m ethods.

Attn-QAT: 4-Bit Attention With Quantization-Aware Training
Peiyuan Zhang, Matthew Noto, Wenxuan Tan, Chengquan Jiang, Will Lin, Wei Zhou, H ao Zhang
Achieving reliable 4-bit attention is a prerequisite for end-to-end FP4 computat ion on emerging FP4-capable GPUs, yet attention remains the main obstacle due t o FP4's tiny dynamic range and attention's heavy-tailed activations. This paper presents the first systematic study of 4-bit quantization-aware training (QAT) f or attention. We find ``drop-in'' QAT -- naively combining an FP4 forward pass w ith high-precision Flash Attention (FA)-style backward pass -- leads to training instability.
We identify two key principles for stable FP4 attention: (1) matching low-precis ion recomputation of attention scores in the backward pass and (2) resolving imp licit precision assumptions in FA’s gradient calculation. Based on these insight s, we propose Attn-QAT and implement fused Triton kernels for training plus FP4 inference kernels. Across diffusion and language models, Attn-QAT recovers the quality drop from FP4 attention without explicit outlier-mitigation heuristics used in prior FP4 attention, and delivers up to a 1.5x speedup on an RTX 5090.

PASO: Step Parallel Stochastic Optimization
Jianrong Lu, Zhuoya Gu, Haobo Li, Zhiyu Zhu, Yechao Zhang, Jianhai Chen, Minghui Yang, Junwei Liu, Jian Wang, Qinming He, Hui LIU, Junhui Hou
This paper approaches the fundamental challenge of accelerating the inherently a

utoregressive nature of gradient descent (GD) like SGD and Adam through a dynami
c system perspective.
Specifically, we introduce a unified framework that recasts the autoregressive G
D process as solving a system of triangular nonlinear equations (TNEs), thereby
enabling \textit{step-parallel} training, where gradients for different GD steps
 are computed concurrently without sequential dependencies. Within this generic
framework, we establish that: (1) the TNE system admits a unique solution corres
ponding precisely to the autoregressive GD iterative trajectory; (2) solving th
e TNEs system guarantees convergence to the GD iterative trajectory in at most t
he equal iterations.
Building on these insights, we present \textit{PASO}, the first step-parallel op
timizer for accelerating a broad class of GD-based optimizers like SGD and Adam
.
Extensive experiments (\textit{e.g.}, Llama-3.2-1B and diffusion model) validate
 that PASO achieves up to \textbf{21}$\times$ reduction in GD steps and \textbf{
4.5}$\times$ speedup in wall-clock time, with no model quality loss.
Source code is available at: \url{https://github.com/Jianrong-Lu/PASO.git}.

AlgoTrace: Algorithmic Primitives and Compositional Geometry of Reasoning in Lan
guage Models
Samuel Lippl, Thomas Austin McGee, Kimberly Lopez, Ziwen Pan, Pierce Zhang, Salm
a Ziadi, Oliver Eberle, Ida Momennejad
How do inference time and latent computations enable large language models (LLMs
) to solve multi-step reasoning problems? We introduce AlgoTrace, a framework fo
r tracing and steering algorithmic operations in the model latent space for mult
i-step reasoning.
We operationalize primitives by clustering latent activations of the model when
solving four benchmarks: Traveling Salesperson Problem (TSP), 3SAT, AIME, and Gr
aph Navigation. We annotate the clusters using their corresponding tokens in the
 reasoning trace. We then apply function vector methods to extract primitive vec
tors as reusable compositional building blocks of reasoning. We find that a) inj
ecting a primitive vector into models (Phi, Qwen, Llama) elicits the associated
algorithmic operation in the reasoning trace, b) injecting primitives can steer
behavior across tasks, c) primitive vectors can be composed through algebraic op
erations, revealing a geometric logic in activation space, and d) a fine-tuned m
odel exhibits improved composition of primitives (Phi-4-Reasoning vs. Phi-4). Th
ese findings demonstrate that LLM reasoning can be understood as a walk through
algorithmic primitives in the latent space governed by compositional geometry. T
hese primitives transfer across tasks, and reasoning finetuning strengthens algo
rithmic generalization and composition across domains.

Towards Parameter-Free Temporal Difference Learning
Yunxiang LI, Mark Schmidt, Reza Babanezhad Harikandeh, Sharan Vaswani
Temporal difference (TD) learning is a fundamental algorithm for estimating valu
e functions in reinforcement learning. Recent finite-time analyses of TD with li
near function approximation quantify its theoretical convergence rate. However,
they often require setting the algorithm parameters using problem-dependent quan
tities that are difficult to estimate in practice --- such as the minimum eigenv
alue of the feature covariance (ω) or the mixing time of the underlying M
arkov chain (τ_mix). In addition, some analyses rely on nonstandard
and impractical modifications, exacerbating the gap between theory and practice.
 To address these limitations, we use an exponential step-size schedule with the
 standard TD(0) algorithm. We analyze the resulting method under two sampling re
gimes: independent and identically distributed (i.i.d.) sampling from the statio
nary distribution, and the more practical Markovian sampling along a single traj
ectory. In the i.i.d. setting, the proposed algorithm does not require the knowl
edge of problem-dependent quantities such as ω, and attains the optimal b
ias-variance trade-off for the last iterate. In the Markovian setting, we propos
e a regularized TD(0) algorithm with an exponential step-size schedule. The resu
lting algorithm achieves a comparable convergence rate to prior works, without r

equiring projections, iterate averaging, or knowledge of τ_mix or ω.

No More K-means: Single-Stage Sparse Coding for Efficient Multi-Vector Retrieval
Lixuan Guo, Yifei Wang, Tiansheng Wen, Aosong Feng, Stefanie Jegelka, Chenyu You
Multi-vector retrieval (MVR) models, exemplified by ColBERT, have established new benchmarks in retrieval accuracy by preserving fine-grained token-level interactions. However, this granularity imposes prohibitive storage and retrieval efficiency bottlenecks: to manage the immense memory footprint and computational overhead of billion-scale token vectors, state-of-the-art systems are forced to rely on aggressive dimension reduction and complex clustering (e.g., K-means). This compromise introduces two critical limitations: excessive indexing latency of clustering large-scale corpora and semantic information loss inherent to compression. In this paper, we propose Single-stage Sparse Retrieval (SSR}, a paradigm shift that replaces expensive clustering with efficient sparse coding. Instead of compressing features into low-dimensional dense vectors, we utilize Sparse Autoencoder (SAE) to project token embeddings into a high-dimensional but highly sparse representation. This transformation enables us to bypass vector clustering entirely and leverage inverted indexing for precise, high-throughput retrieval. Extensive experiments on the BEIR benchmark demonstrate that SSR achieves a "trifecta" of improvements: it reduces indexing time by 15x compared to ColBERTv2, halves retrieval latency, and simultaneously improves retrieval performance over leading baselines.
****
Graph Neural Networks Are Not Continuous Across Graph Resolutions
Christian Koke, Yuesong Shen, Abhishek Saroha, Marvin Eisenberger, Bastian Rieck, Michael M. Bronstein, Daniel Cremers
We show that contrary to conventional wisdom in the community, graph neural networks (GNNs) are not continuous with respect to all natural modes of graph convergence. As a result, GNNs may generate substantially different latent representations for graphs that are very similar. In particular they assign vastly different latent embeddings to graphs that represent the same underlying object at different resolution scales. We trace this failure of continuity back to a structural obstruction arising from commonly used information-propagation schemes. Building on this insight we then derive a principled modification to standard GNN architectures which equips models with continuity across scales. The proposed modification enables consistent integration of distinct resolutions and reliable generalization between them. We systematically validate our theoretical findings in a wide range of numerical experiments.

Reward Shaping Control Variates for Off-Policy Evaluation Under Sparse Rewards
Ritam Majumdar, Finale Doshi-Velez, Sonali Parbhoo
Off-policy evaluation (OPE) is essential for deploying reinforcement learning in safety-critical settings, yet existing estimators such as importance sampling and doubly robust (DR) often exhibit prohibitively high variance when rewards are sparse. In this work, we introduce Reward-Shaping Control Variates, a new family of unbiased estimators that leverage potential-based reward shaping to construct additional zero-mean control variates. We prove that shaped estimators always yields valid variance reduction, and that combining shaping-based and Q-based control variates strictly expands the variance-reduction subspace beyond DR and its minimax variant MRDR. Empirically, we provide a systematic regime map across synthetic chains, a cancer simulator, 5 single-stock and 1 multi-stock DOW-30 trading environments and an ICU-sepsis benchmark showing that shaping-based OPE consistently outperforms DR in sparse-reward settings, while a hybrid estimator achieves state-of-the-art performance across sparse, noisy, and misspecified environments. Our results highlight reward shaping as a powerful and interpretable tool for robust OPE, offering both theoretical guarantees and practical improvements in domains where standard estimators fail.

M-IDoL: Information Decomposition for Modality-Specific and Diverse Representati

on Learning in Medical Foundation Model
Yihang Liu, Longzhen Yang, Jiaxiong Yang, Ying Wen, Lianghua He, Heng Tao Shen
Medical foundation models (MFMs) aim to learn universal representations from mul timodal medical images that can generalize effectively to diverse downstream cli nical tasks.
However, most existing MFMs suffer from information ambiguity that blends multim odal representations in a single embedding space, leading to the degradation of modality specificity and diversity.
In this paper, we propose M-IDoL, a self-supervised ***M***FM that introduces ** *I***nformation ***D***ecomposition for multim***o***dal representation ***L***e arning via two objectives:
i) maximizing inter-modality entropy by dispersing multimodal representations in to separable Mixture-of-Experts (MoE) subspaces to achieve representation specif icity across modalities;
and ii) minimizing intra-modality uncertainty by performing fine-grained semanti c discrimination within each MoE subspace to enrich representation diversity per modality.
By pre-training on 1.15 million medical images, M-IDoL i) delivers superior gene ralization across 21 downstream clinical tasks, outperforming 20 foundation mode ls on five imaging modalities (e.g., X-ray, fundus, OCT, dermoscopy and patholog y), and ii) learns modality-specific and diverse representations, showing cleare r separation of feature clusters across modalities and finer-grained feature dis crimination within each modality.

Negative Sampling From the Ground Up: A Redesign for Recommendation
Yanbang Wang, Jon Kleinberg, Yanhong Wu
Negative sampling is an important yet challenging component in self-supervised g raph representation learning, particularly for recommendation systems where user -item interactions are modeled as bipartite graphs. Existing methods often rely on heuristics or human-specified principles to design negative sampling distribu tions. This potentially overlooks the usage of an underlying ``true'' negative d istribution, which we might be able to access as an oracle despite not knowing i ts exact form. In this work, we shift the focus from manually designing negative sampling distributions to a more principled method that approximates and levera ges the underlying true distribution from the ground up. We expand this idea in the analysis of two scenarios: (1) when the observed graph is an unbiased sampl e from the true distribution, and (2) when the observed graph is biased with par tially observable positive edges. The analysis result is the derivation of a sam pling strategy as the numerical approximation of a well-established learning obj ective. Our theoretical findings are also empirically validated, and our new sam pling methods achieve state-of-the-art performance on real-world datasets.
****

Skip a Layer or Loop It? Learning Program-of-Layers in LLMs
Ziyue Li, Yang Li, Tianyi Zhou
Large language models (LLMs) perform inference by following a fixed depth and or der, non-recurrent execution of all layers. We reveal the wide existence of trai ning-free, flexible, dynamic *program-of-layers (PoLar)*, where pretrained layer s can be packed as modules and then skipped or looped to form a customized progr am for each input. For most inputs, substantially shorter program executions can achieve the same or better accuracy, while incorrect predictions of the origina l LLM can be corrected by alternative programs with fewer layers. These observat ions indicate that inference admits multiple valid latent computations beyond th e standard forward pass. To efficiently achieve PoLar in practice, we propose a lightweight PoLar prediction network, which learns to generate execution program s that dynamically skip or repeat pretrained layers for each input. Experiments on mathematical reasoning benchmarks demonstrate that PoLar consistently improve s accuracy over standard inference and prior dynamic-depth methods, often while executing fewer layers, and that these gains persist under out-of-distribution e valuation. Our results suggest that fixed-depth execution captures only a narrow subset of an LLM’s latent reasoning capacity.

From Parameters to Feature Space: Task Arithmetic for Backdoor Mitigation in Model Merging
Zhenqian Zhu, Yamin Hu, Yiya Diao, Weixiang Li, Haodong Li, Wenjian Luo
Model merging (MM) has gained significant attention as a cost-effective approach to integrate multiple task-specific models into a unified model. However, recent work reveals that MM is highly susceptible to backdoor attacks. Existing defenses based on task arithmetic often fail to eliminate backdoors without substantially degrading clean-task performance, owing to their reliance on direct parameter-space editing. To address this gap, we propose Linear Feature Path Minimization (LFPM), a backdoor mitigation framework for model merging, which introduces an anti-backdoor task vector into the backdoored merged model. Unlike prior approaches, LFPM formulates the backdoor robustness of the merged model from a unified feature-space perspective under the Cross-Task Linearity (CTL) framework, which leverages the approximate linearity of features across tasks. This perspective guides the optimization of the anti-backdoor task to suppress backdoors while preserving clean-task performance. Furthermore, we introduce an effective optimization mechanism based on gradient accumulation and loss path-integral, ensuring robust backdoor suppression along the interpolation path. Extensive experiments demonstrate that LFPM consistently exhibits strong robustness against backdoor attacks in both full fine-tuning and Parameter-Efficient Fine-Tuning (PEFT) settings.
****
ConPress: Learning Efficient Reasoning from Multi-Question Contextual Pressure
Jie Deng, Shining Liang, Jun Li, Hongzhi Li, Yutao Xie
Large reasoning models (LRMs) typically solve reasoning-intensive tasks by generating long
chain-of-thought (CoT) traces, leading to substantial inference overhead.
We identify a reproducible inference-time phenomenon, termed \textbf{\emph{Self-Compression}}:
when multiple independent and answerable questions are presented within a single prompt,
the model spontaneously produces shorter reasoning traces for each question. This phenomenon arises from \emph{multi-question contextual pressure} during generation and consistently manifests across models and benchmarks. Building on this observation, we propose ConPress (Learning from Contextual Pressure, a lightweight self-supervised fine-tuning approach. ConPress constructs multi-question prompts to induce self-compression, samples the resulting model outputs, and parses and filters per-question traces to obtain concise yet correct
reasoning trajectories. These trajectories are directly used for supervised fine-tuning, internalizing compressed
reasoning behavior in single-question settings without external teachers, manual pruning, or reinforcement learning.
With only 8k fine-tuning examples, ConPress reduces reasoning token usage by 59\% on MATH500
and 33\% on AIME25, while maintaining competitive accuracy.
****
Non-Euclidean Gradient Descent Operates at the Edge of Stability
Rustem Islamov, Michael Crawshaw, Jeremy Cohen, Robert M. Gower
The Edge of Stability (EoS) is a phenomenon where the sharpness (largest eigenvalue) of the Hessian approaches and then hovers near the stability threshold $2/\eta$ during gradient descent (GD) with step size η. Despite (apparently) violating classical smoothness assumptions, EoS has been widely observed in deep learning, but its theoretical foundations remain incomplete. We provide an interpretation of EoS through the lens of Directional Smoothness [Mishkin et al., 2024]. This interpretation naturally extends to non-Euclidean norms, which we use to define generalized sharpness under an arbitrary norm. Our generalized sharpness measure includes previously studied vanilla GD and preconditioned GD as special cases, as well as methods for which EoS has not been studied, such as ℓ_{∞}-descent, Block CD, Spectral GD, and their normalized versions. Through

experiments on neural networks, we show that non-Euclidean GD with our generalized sharpness also exhibits progressive sharpening followed by oscillations around or above the threshold $2/\eta$. Practically, our framework provides a geometry-aware spectral diagnostic that can be applied across a broad class of non-Euclidean gradient methods.

Reward Under Attack: Analyzing the Robustness and Hackability of Process Reward Models
Rishabh Tiwari, Aditya Tomar, Udbhav Bamba, Monishwaran Maheswaran, Heng Yang, Michael W. Mahoney, Kurt Keutzer, Amir Gholami
Process Reward Models (PRMs) are rapidly becoming the backbone of LLM reasoning pipelines, yet we demonstrate that state-of-the-art PRMs are systematically exploitable under optimization pressure. We introduce a three-tiered diagnostic framework that applies increasing adversarial pressure to quantify these vulnerabilities. Static perturbation analysis uncovers a fluency-logic dissociation: high invariance to surface-level style changes (reward changes $<$0.1) yet inconsistent detection of logically corrupted reasoning, with different models failing on different attack types. Adversarial optimization demonstrates that gradient-based attacks inflate rewards on invalid trajectories, with reward landscapes exhibiting wide, exploitable peaks. RL-induced reward hacking exposes the critical failure mode: policies trained on AIME problems achieve near-perfect PRM rewards ($>$0.9) while ground-truth accuracy remains below 4\%, with 43\% of reward gains attributable to stylistic shortcuts. These findings reveal that current PRMs function as fluency detectors rather than reasoning verifiers, creating systematic blind spots that undermine their use as training signals. We release PRM-BiasBench and a diagnostic toolkit to enable robustness evaluation before deployment.
****
AMDP: Asynchronous Multi-Directional Pipeline Parallelism for Large-Scale Models Training
Ling Chen, Houming Wu, Wenjie Yu
Pipeline parallelism is essential for large-scale model training, but existing asynchronous approaches often degrade convergence due to parameter mismatch between forward and backward passes. We propose Asynchronous Multi-Directional Pipeline parallelism (AMDP) to mitigate this issue while sustaining high utilization. AMDP limits the first stage of each pipeline to process at most two minibatches before backpropagation, bounding the number of parameter updates between forward and backward passes. To alleviate the resulting pipeline bubbles, AMDP launches multiple concurrent pipelines and adapts their number according to pipeline depth. In addition, AMDP accumulates gradients across minibatches and applies them in a single update, ensuring that only a bounded number of minibatches experience parameter mismatch, limited to within one optimization step. Experiments on GPT- and BERT-style models demonstrate that AMDP significantly accelerates training while preserving convergence.
****
BFCL Audio: An Audio Function Calling Evaluation for Large Language Models
Huanzhi Mao, Aditya Ghai, Imra Dawoodani, Tony A Ginart, Shishir G Patil, John Emmons, Joseph E. Gonzalez
Audio agents are increasingly deployed to execute tools from spoken requests, yet audio tool use poses challenges beyond text-only function calling: perception errors (e.g., homophones, noise, disfluencies) can corrupt entities and arguments, and natural interactions often require clarification that changes the tool-calling protocol. We introduce BFCL Audio, a large-scale benchmark for audio function calling with 6.2K expert-verified tasks across two suites that mirror common deployments: BFCL Text Audio (pipelined $\text{ASR}\rightarrow\text{LLM}\rightarrow\text{tools}$ via transcripts) and BFCL True Audio (end-to-end $\text{audio-in}\rightarrow\text{tool calls}$). BFCL Audio includes controlled speech and acoustic perturbations (accent and speaking-rate variation, content disfluencies, and background noise) generated through a controllable audio synthesis/augmentation pipeline. We provide automatic grading for both function names and argument values using AST-based matching for single-turn calls and response/state-based me

trics for multi-turn interactions, enabling scalable evaluation without LLM judges. Across a broad set of models, we propose a failure-mode taxonomy and analyze which speech and noise factors most strongly impact tool-calling accuracy. We release the benchmark, evaluation harness, and audio pipeline to support research on reliable speech-based agents.
****
Adaptive Visual Autoregressive Acceleration via Dual-Linkage Entropy Analysis
Yu Zhang, Jingyi Liu, Feng Liu, Duoqian Miao, Qi Zhang, Kexue Fu, Changwei Wang, Longbing Cao
Visual AutoRegressive modeling (VAR) suffers from substantial computational cost due to the massive token count involved. Failing to account for the continuous variation in modeling, existing VAR token reduction methods face three key limitations: heuristic stage partition, non-adaptive schedules, and limited acceleration scope, thereby leaving significant acceleration potential untapped. Since entropy variation intrinsically reflects the transition of predictive uncertainty, it offers a principled measure to capture continuous modeling variation. Therefore, we propose NOVA, a training-free token reduction acceleration framework for VAR models via entropy analysis. NOVA adaptively determines the acceleration activation scale during inference by online identifying the inflection point of scale entropy growth. Through scale-linkage and layer-linkage ratio adjustment, NOVA dynamically computes distinct token reduction ratios for each scale and layer, pruning low-entropy tokens while reusing the cache derived from the residuals at the prior scale to accelerate inference and maintain generation quality. Extensive experiments and analyses validate NOVA as a simple yet effective training-free acceleration framework. Code is available.
****
ORBIT: A Prognostic World Model for Ocular Reasoning Based on Imagined Trajectories
Jiangtao Yan, Yanlin Qu, Yansheng Qiu, Shujian Gao, Wei Yu, Zheng Wang, Xiaodong Sun, Huixun Jia, Diping Song
The longitudinal management of blinding fundus diseases constitutes a Partially Observable Markov Decision Process (POMDP) necessitating a critical precision-risk trade-off between intervention and over-treatment, as true pathology is often obscured in static observations. However, existing paradigms fail to address this complexity. Traditional vision models remain uninterpretable and memoryless, and while Vision-Language Models (VLMs) excel in semantic understanding, they rely on unsafe open-loop text reasoning lacking the anatomical grounding essential for clinical safety.
Furthermore, robust learning is hindered by the scarcity of process supervision in sparse clinical records.
To bridge this gap, we introduce the Logic-Constrained Abductive Data Engine. Operating on a ``Propose-and-Verify'' paradigm, it validates MLLM-proposed biomarkers against clinical and temporal logic to reconstruct dense pathological states from sparse outcomes.
Building on this foundation, we propose ORBIT, the first ophthalmic Prognostic World Model. Uniquely, ORBIT employs counterfactual visual foresight to imagine anatomical futures under different treatments, anchoring decisions in Closed-Loop Anatomical Verification rather than linguistic probabilities.
Experiments demonstrate that ORBIT effectively captures disease evolution and establishes a new paradigm for human-in-the-loop longitudinal decision support and anatomically grounded treatment planning.

Dispersion Loss Counteracts Embedding Condensation and Improves Generalization in Small Language Models
Chen Liu, Xingzhi Sun, Xi Xiao, Alexandre Van Tassel, Ke Xu, Kristof Reimann, Danqi Liao, Mark Gerstein, Tianyang Wang, Xiao Wang, Smita Krishnaswamy
Large language models (LLMs) achieve remarkable performance through ever-increasing parameter counts, but scaling incurs steep computational costs. To better understand LLM scaling, we study representational differences between LLMs and their smaller counterparts, with the goal of replicating the representational quali

ties of larger models in smaller models. We observe a geometric phenomenon which we term $\textbf{embedding condensation}$, where token embeddings collapse into a narrow cone-like subspace in some language models. Through systematic analyses across multiple Transformer families, we show that small models such as $\texttt{GPT2}$ and $\texttt{Qwen3-0.6B}$ exhibit severe condensation, whereas larger models such as $\texttt{GPT2-xl}$ and $\texttt{Qwen3-32B}$ are more resistant to this phenomenon. Additional observations show that embedding condensation is not reliably mitigated by knowledge distillation from larger models. To fight against it, we formulate a dispersion loss that explicitly encourages embedding dispersion during training. Experiments demonstrate that it mitigates condensation, recovers dispersion patterns seen in larger models, and yields performance gains across 10 benchmarks. We believe this work offers a principled path toward improving smaller Transformers without additional parameters.

Pushing Forward Pareto Frontiers of Proactive Agents with Behavioral Agentic Optimization
Yihang Yao, Zhepeng Cen, Haohong Lin, Shiqi Liu, Zuxin Liu, Jiacheng Zhu, Zhang-Wei Hong, Laixi Shi, Ding Zhao
Proactive large language model (LLM) agents aim to actively plan, query, and interact over multiple turns, enabling efficient task completion beyond passive instruction following and making them essential for real-world, user-centric applications. Agentic reinforcement learning (RL) has recently emerged as a promising solution for training such agents in multi-turn settings, allowing interaction strategies to be learned from feedback. However, existing pipelines face a critical challenge in balancing task performance with user engagement, as passive agents can not efficiently adapt to users' intentions while overuse of human feedback reduces their satisfaction. To address this trade-off, we propose BAO, an agentic RL framework that combines behavior enhancement to enrich proactive reasoning and information-gathering capabilities with behavior regularization to suppress inefficient or redundant interactions and align agent behavior with user expectations. We evaluate BAO on multiple tasks from the UserRL benchmark suite, and demonstrate that it substantially outperforms RL baselines under controlled comparisons, while achieving comparable or even superior performance to frontier LLM agents, highlighting its effectiveness for training proactive, user-aligned LLM agents in complex multi-turn scenarios.

Large Language Models Develop Novel Social Biases Through Adaptive Exploration
Addison J. Wu, Ryan Liu, Xuechunzi Bai, Thomas L. Griffiths
As large language models (LLMs) are adopted into frameworks that grant them the capacity to make real decisions, it is increasingly important to ensure that they are unbiased. In this paper, we argue that the predominant approach of simply removing existing biases from models is not enough. Using a paradigm from the psychology literature, we demonstrate that LLMs can spontaneously develop novel social biases about artificial demographic groups even when no inherent differences exist. These biases result in highly stratified task allocations, which are less fair than assignments by human participants and are exacerbated by newer and larger models. In humans, emergent biases like these have been shown to result from exploration-exploitation trade-offs, where the decision-maker explores too little, allowing early observations to strongly influence impressions about entire demographic groups. To alleviate this effect, we examine a series of interventions targeting model inputs, problem structure, and explicit steering. We find that explicitly incentivizing exploration most robustly reduces stratification, highlighting the need for better multifaceted objectives to mitigate bias. These results reveal that LLMs are not merely passive mirrors of human social biases, but can actively create new ones from experience, raising urgent questions about how these systems will shape societies over time.

Geometry-Preserving Unsupervised Alignment for Heterogeneous Foundation Models
Shuwen Yu, Zhanxuan Hu, Yi Zhao, Yonghang Tai, Huafeng Li
Foundation models have driven rapid progress in computer vision, yet the two dom

inant paradigms, vision-language foundation models (VLMs) and vision-only founda tion models (VFMs), remain only partially compatible. VLMs offer language-ground ed semantic alignment but are often visually coarse, while VFMs learn discrimina tive perceptual geometry but lack semantic grounding. We propose **GPUA**, a *Ge ometry-Preserving Unsupervised Alignment* framework that integrates the compleme ntary strengths of VFMs and VLMs. Inspired by cross-lingual alignment, **GPUA** treats VFM features as a *visual language* and learns an *orthogonal* mapping th at translates the VFM space into the VLM semantic space, preserving geometry and narrowing the modality gap without labels or model parameter updates. **GPUA** is task-agnostic and requires only feature-level access to pretrained models. Ex periments across diverse benchmarks demonstrate improved cross-model compatibili ty and strong gains in downstream zero-shot recognition and segmentation with ne gligible overhead. Our code is available at: https://github.com/Yuteam14/GPUA.

How Far Ahead Do LLMs Plan? Uncovering the Latent Horizon in Chain-of-Thought Re asoning

Liyan Xu, Mo Yu, Fandong Meng, Jie Zhou

Chain-of-thought (CoT) reasoning has become a central mechanism for eliciting mu lti-step reasoning in Large Language Models (LLMs). Yet recent evidence presents a tension: hidden states appear to already encode future reasoning before CoT f ully unfolds, while explicit steps still remain crucial for tasks requiring comp ositional computation.

To deepen the understanding between LLM's internal states and its verbalized rea soning trajectories, we investigate the latent planning strength of LLMs, throug h our probing method, Tele-Lens, applying to hidden states across diverse task d omains.

Our empirical results indicate that LLMs exhibit a myopic horizon, primarily con ducting incremental transitions without precise global planning.

Leveraging this characteristic, we propose a hypothesis on enhancing uncertainty estimation of CoT, which we validate that a sparse set of pivot positions can e ffectively represent the uncertainty of the entire path.

We further underscore the significance of exploiting CoT dynamics, and demonstra te that automatic recognition of CoT bypass can be achieved without performance degradation.

Our code, data and models are released at https://github.com/lxucs/tele-lens.

Cross-Subject Modeling for Widefield Calcium Imaging via Atlas-Aligned Spatiotem poral Tokenization

Mohammad Hosseini, Eray Erturk, Saba Hashemi, Maryam M. Shanechi

Large-scale, multi-subject widefield calcium imaging provides unprecedented acce ss to brain-wide cortical dynamics. However, the high dimensionality, complex sp atiotemporal structure, and substantial task-irrelevant activity in widefield re cordings have largely restricted modeling efforts to single-session analyses, li miting scalability and generalization. While multi-subject pretrained models hav e been explored for some neural modalities, multi-subject models for widefield c alcium imaging have not yet been demonstrated; further, subject-invariant zero-s hot behavior decoding remains elusive for multi-subject models across neural mod alities more broadly. As a first step toward foundation modeling of widefield da ta, we introduce WiCAT, a multi-subject model that leverages self-supervised pre training to both outperform single-session models and enable zero-shot behavior decoding on unseen subjects. WiCAT introduces an atlas-grounded tokenization sch eme without session-specific components and learns globally shared spatiotempora l representations. Across multiple widefield datasets, the pretrained model supp orts lightweight downstream decoding, transfers across subjects, tasks, and data sets, and outperforms baseline models. Notably, the model also achieves robust z ero-shot continuous behavior decoding and left-out brain region reconstruction o n unseen subjects.

DiL: Discrete-anchored Representation Alignment for Semi-Supervised Continual Le arning

Nanyi Wang, Chaojie Chen, Zuoqi Tang, Jinxiang Lai, Xingcai Wu, Qi Wang
Leveraging the unlabeled stream is crucial yet challenging in Semi-Supervised Co ntinual Learning (SSCL) under continual class expansion.
Existing SSCL methods typically enforce dense pseudo-label consistency and indis criminate distillation on unlabeled data, which can reinforce errors and intensi fy base–novel interference.
To address these issues, we propose Discrete-anchored Incremental Learning (DiL) to ground continual updates on reliable discrete anchors that remain stable und er noisy pseudo-labels.
DiL introduces Discrete Contrastive Distillation (DCD), which discretizes the di stillation pathway and performs anchor-referenced selective distillation to curb error reinforcement.
Meanwhile, Class-Aware Channel-Chunked Encoding (CACE) learns channel-chunked re presentations and exploits the confusion matrix induced by the discrete anchors to separate novel from confusable base classes.
Extensive experiments on multiple datasets show that DiL achieves state-of-the-a rt performance across diverse SSCL protocols.

Balancing Understanding and Generation in Discrete Diffusion Models
Yue Liu, Yuzhong Zhao, Zheyong Xie, Qixiang Ye, Jianbin Jiao, Yao Hu, Shaosheng Cao, Yunfan Liu
In discrete generative modeling, two dominant paradigms demonstrate divergent ca pabilities: Masked Diffusion Language Models (MDLM) excel at semantic understand ing and zero-shot generalization, whereas Uniform-noise Diffusion Language Model s (UDLM) achieve strong few-step generation quality, yet neither attains balance d performance across both dimensions. To address this, we propose XDLM, which br idges the two paradigms via a stationary noise kernel. XDLM offers two key contr ibutions: it provides (1) a principled theoretical unification of MDLM and UDLM, recovering each paradigm as a special case; and (2) an alleviated memory bottle neck enabled by an algebraic simplification of the posterior probabilities. Expe riments demonstrate that XDLM advances the Pareto frontier between understanding capability and generation quality. Quantitatively, XDLM surpasses UDLM by 5.4 p oints on zero-shot text benchmarks and outperforms MDLM in few-step image genera tion (FID 54.1 vs. 80.8). When scaled to tune an 8B-parameter large language mo del, XDLM achieves 15.0 MBPP in just 32 steps, effectively doubling the baseline performance. Finally, analysis of training dynamics reveals XDLM’s superior pot ential for long-term scaling. Code is available at [https://github.com/MzeroMiko /XDLM](https://github.com/MzeroMiko/XDLM).

Improved Convergence Analysis of Topology Dependence in Decentralized SGD
Yuki Takezawa, Anastasia Koloskova, Sebastian U Stich
Decentralized SGD is a fundamental algorithm in decentralized learning, although the influence of an underlying network topology on its convergence behavior is not yet fully understood. Existing convergence analyses have shown that topologi es with a small spectral gap significantly deteriorate the convergence rate of D ecentralized SGD in both homogeneous and heterogeneous cases. However, many prio r papers have reported that indeed the choice of the topology has a significant experimental impact in the heterogeneous case, but has little experimental impac t on training behavior in the homogeneous case. In this paper, we present a tigh ter convergence analysis of Decentralized SGD, offering a more precise understan ding of how topologies affect the convergence rate than the prior analysis. Spec ifically, unlike existing convergence analyses that used only the spectral gap a s a property of the topology, our novel analysis shows that all eigenvalues of t he mixing matrix affect the convergence rate. Throughout the experiments, we car efully evaluated the convergence behavior of Decentralized SGD and demonstrated that our novel convergence analysis can more accurately describe the effect of t opology on the convergence rate.

Towards Scalable and Consistent 3D Editing
Ruihao Xia, Yang Tang, Pan Zhou

3D editing—the task of locally modifying the geometry or appearance of a 3D asset—has wide applications in immersive content creation, digital entertainment, and AR/VR. However, unlike 2D editing, it remains challenging due to the need for cross-view consistency, structural fidelity, and fine-grained controllability. Existing approaches are often slow, prone to geometric distortions, or dependent on manual and accurate 3D masks that are error-prone and impractical. To address these challenges, we advance both the data and model fronts. On the data side, we introduce 3DEditVerse, the largest paired 3D editing benchmark to date, comprising 116,309 high-quality training pairs and 1,500 curated test pairs. Built through complementary pipelines of pose-driven geometric edits and foundation model-guided appearance edits, 3DEditVerse ensures edit locality, multi-view consistency, and semantic alignment. On the model side, we propose 3DEditFormer, a 3D-structure-preserving transformer. By enhancing image-to-3D generation with dual-guidance attention and time-adaptive gating, 3DEditFormer disentangles editable regions from preserved structure, enabling precise and consistent edits without requiring auxiliary 3D masks. Extensive experiments demonstrate that our framework outperforms state-of-the-art baselines both quantitatively and qualitatively, establishing a new standard for practical and scalable 3D editing. Dataset and code are available at https://www.lv-lab.org/3DEditFormer/

From Interaction Trajectories to Prompt Rules: Credit Assignment for Multi-Agent Prompt Optimization

Bin Wu, Haoran Xu, Xiang Zhuang, Zonghao Chen, Zhu Li, Emine Yilmaz, Qiang Zhang

Large language model (LLM)-based multi-agent systems commonly rely on natural-language prompts to specify agent behavior, yet optimizing these prompts remains challenging when agent roles and interaction structures are fixed by design. In such systems, behaviors emerge over long, noisy interaction trajectories, making it difficult to determine which prompt components are responsible for success or failure. As a result, outcome-level feedback alone is insufficient, while existing prompt optimization methods typically rely on final task scores or global prompt rewrites, limiting their ability to exploit trajectory evidence or support the localized updates. We propose Trajectory-based Rule Credit Estimation (TRUCE), a framework for prompt optimization in multi-agent systems that explicitly addresses this credit assignment challenge. TRUCE performs trajectory-aware attribution by linking outcome feedback to informative sub-trajectories and translating the resulting credit signals into unit-level edits over prompt-defined behavioral rules. By preserving agent roles and interaction structures, TRUCE enables prompt refinement through localized updates aggregated across tasks. Experiments on multiple benchmarks demonstrate that TRUCE consistently improves task performance and efficiency over competitive baselines. Code is available at https://github.com/bingo-w/TRUCE.

Lavida-R1: Advancing Reasoning for Unified Multimodal Diffusion Language Models

Shufan Li, Yuchen Zhu, Kangning Liu, Zhe Lin, Yongxin Chen, Molei Tao, Aditya Grover, Jiuxiang Gu, Jason Kuen

Diffusion language models (dLLMs) recently emerged as a promising alternative to auto-regressive LLMs. The latest works further extended it to multimodal understanding and generation tasks. In this work, we propose LaViDa-R1, a multimodal, general-purpose reasoning dLLM. Unlike existing works that build reasoning dLLMs through task-specific reinforcement learning, LaViDa-R1 incorporates diverse multimodal understanding and generation tasks in a unified manner. In particular, LaViDa-R1 is built with a novel unified post-training framework that seamlessly integrates supervised finetuning (SFT) and multi-task reinforcement learning (RL). It employs several novel training techniques, including answer-forcing, tree search, and complementary likelihood estimation, to enhance effectiveness and scalability. Extensive experiments demonstrate LaViDa-R1's strong performance on a wide range of multimodal tasks, including visual math reasoning, reason-intensive grounding, and image editing.

Learning Context-Conditioned Predicate Semantics via Prototype Feedback

NamGyu Jung, Chang Choi
In scene graph generation, a central challenge is modeling polysemous predicates whose meanings shift across contexts. Prior approaches address this issue by decomposing predicates into multiple static prototypes or retrieving semantically similar exemplars. However, these strategies keep predicate representations static and cannot reorganize semantics to reflect image-specific evidence, leading to systematic confusions in ambiguous contexts. We propose **AlignG**, which learns context-conditioned predicate semantics via prototype feedback. AlignG infers context-conditioned predicate semantics from the relation candidates within each image and feeds the adapted semantics back to recalibrate relation representations. The learning objective anchors this adaptation to global semantic centers, preventing semantic drift while still allowing selective reorganization when the scene provides consistent relational cues. Experiments on VG-150 and GQA-200 show consistent improvements over state-of-the-art baselines, with F@100 improvements of +1.4 on VG-150 and +2.7 on GQA-200 under SGDet. We further visualize per-image prototype similarity shifts and observe coherent context-dependent reorganization where prototypes selectively merge or separate predicates according to scene evidence. The code is available at https://github.com/Namgyu97/AlignG-SGG.pytorch.

Disentangling Intent from Role: Adversarial Self-Play for Persona-Invariant Safety Alignment
Jiajia Li, Xiaoyu Wen, Shuyue Hu, Qiaosheng Zhang, Zhen Wang
The growing capabilities of large language models (LLMs) have driven their widespread deployment across diverse domains, even in potentially high-risk scenarios. Despite advances in safety alignment techniques, current models remain vulnerable to emerging *persona-based jailbreak attacks*. Existing research on persona-based jailbreak has primarily focused on attack iterations, yet it lacks systemic and mechanistic constraints on the defense side. To address this challenge, we propose Persona-Invariant Alignment (PIA), an adversarial self-play framework that achieves co-evolution through Persona Lineage Evolution (PLE) on the attack side and Persona-Invariant Consistency Learning (PICL) on the defense side. Theoretically, PICL is grounded in the *structural separation hypothesis*, using a unilateral KL-divergence constraint to enable the structural decoupling of safety decisions from persona context, thereby maintaining safe behavior under persona-based jailbreak attacks. Experimental results demonstrate that PLE efficiently explores high-risk persona spaces by leveraging lineage-based credit propagation. Meanwhile, the PICL defense method significantly reduces the Attack Success Rate (ASR) while preserving the model's general capability, thereby validating the superiority and robustness of this alignment paradigm. WARNING: This paper contains potentially offensive and harmful text.

Forgetting Whenever You Want: A Decentralized Continual Learning Framework with On-Demand Unlearning
Xiao Zhang, Zengzhe Chen, Mingyi Li, Jing Qiao, Fuzhen Zhuang, YUAN YUAN, Dongxiao Yu
Decentralized class continual learning refers to a paradigm where distributed clients continuously acquire new classes while retaining previously learned information without relying on a central server. With increasing emphasis on privacy preservation, there is a growing need for on-demand unlearning, introducing two key challenges: Historical Class Unlearning and Network-Wide Knowledge Entanglement. In this work, we propose a decentralized continual learning framework with on-demand unlearning (DCU), which is the first attempt at achieving class continual learning and arbitrary-time class unlearning in a distributed setting. Specifically, our proposed DCU comprises three main stages: prototypes extraction, prototype-guided continual learning, and unlearning with disposable prototypes. Firstly, the prototypes extraction mechanism is designed to capture the class-specific concepts as lightweight, disposable embeddings. Then, the synthetic data guided by these prototypes can be combined with real data to achieve incremental learning through distillation. Besides, synthetic samples with noisy label are use

d to guide the adjustment of the model's decision boundary, effectively erasing the influence of the target class while preserving other classes' knowledge. Ext ensive experiments conducted on two datasets demonstrate the effectiveness of ou r DCU in dynamic learning and target class unlearning.
****
Escaping the Verifier: Learning to Reason via Demonstrations
Locke Cai, Max Ryabinin, Ivan Provilkov
Training Large Language Models (LLMs) to reason often relies on Reinforcement Le arning (RL) with task-specific verifiers. However, many real-world reasoning-int ensive tasks lack verifiers, despite offering abundant expert demonstrations tha t remain under-utilized for reasoning-focused training. We introduce **RARO** (R elativistic Adversarial Reasoning Optimization), which learns strong reasoning c apabilities from expert demonstrations alone via **Inverse Reinforcement Learnin g**. Our method sets up an adversarial game between a **policy** and a **relativ istic critic**: the policy learns to mimic expert answers, while the critic aims to identify the expert among (expert, policy) answer pairs. Both the policy and the critic are trained jointly and continuously via RL, and we identify key sta bilization techniques required for robust learning. Empirically, RARO significan tly outperforms strong verifier-free baselines across all evaluation tasks: $+13 .7\%$ accuracy on Countdown (1.5B), +8.2\% on DeepMath (7B), and $+19.1\%$ w in-rate on Poetry Writing (7B) against expert poems. RARO also exhibits simila r robust scaling trends as RL with verifiers. These results demonstrate that RAR O effectively elicits strong reasoning performance from expert demonstrations al one, enabling robust reasoning learning even when task-specific verifiers are un available.

Robust Parallel Diffusion Sampling via Dynamic Jacobian Bandwidth
Zile Huang, Ser-Nam Lim
Recent years have witnessed significant progress in developing effective diffusi on models. Parallel sampling is a promising recent approach that reformulates th e sequential denoising process as solving a system of nonlinear equations, and i t can be combined with other acceleration techniques. However, current progress is limited by the trade-off between high fidelity and computational efficiency. This paper addresses the challenge of scaling to high-dimensional, multi-modal g eneration. Specifically, we present ROPA (Robust Parallel Diffusion Sampling), w hich takes into account the properties of the denoising process and solves the l inear system using adaptive local sparsity to achieve stable parallel sampling. Extensive experiments demonstrate ROPA’s effectiveness: it significantly acceler ates sampling across diverse image and video diffusion models, achieving up to $ 2.9\times$ speedup with eight core, an improvement of 20.8\% over baselines with out sacrificing sample quality. ROPA enables parallel sampling methods to provid e a solid foundation for real-time, high-fidelity diffusion generation.

On the Anisotropy of Score-Based Generative Models
Andreas Floros, Seyed-Mohsen Moosavi-Dezfooli, Pier Luigi Dragotti
We investigate the role of network architecture in shaping the inductive biases of modern score-based generative models. To this end, we introduce the Score Ani sotropy Directions (SADs), architecture-dependent directions that reveal how dif ferent networks preferentially capture data structure. Our analysis suggests tha t SADs form adaptive bases aligned with the architecture's output geometry, prov iding a principled way to predict generalization ability in score models prior t o training. Through both synthetic data and standard image benchmarks, we demons trate that SADs reliably capture fine-grained model behavior and correlate with downstream performance, as measured by Wasserstein metrics. Our work offers a ne w lens for explaining and predicting directional biases of generative models.

FOVI: A biologically-inspired foveated interface for deep vision models
Nicholas Blauch, George A. Alvarez, Talia Konkle
Human vision is foveated, with variable resolution peaking at the center of a la rge field of view; this reflects an efficient trade-off for active sensing, allo

wing eye-movements to bring different parts of the world into focus with other p
arts of the world in context. In contrast, most computer vision systems encode t
he visual world at a uniform resolution, raising challenges for processing full-
field high-resolution images efficiently. We propose a foveated vision interface
 (FOVI) based on the human retina and primary visual cortex (V1), that reformats
 a variable-resolution retina-like sensor array into a uniformly dense, V1-like
sensor manifold. Receptive fields are defined as k-nearest-neighborhoods (kNNs)
on the sensor manifold, enabling kNN-convolution via a novel kernel mapping tech
nique. We demonstrate two use cases: (1) an end-to-end kNN-convolutional archite
cture, and (2) a foveated adaptation of the DINOv3 ViT foundation model, leverag
ing low-rank adaptation (LoRA). These models provide competitive performance wit
h a fraction of the pixels and computational cost of full resolution non-foveate
d baselines, opening pathways for efficient and scalable active sensing for high
-resolution egocentric vision.
Code (https://github.com/nblauch/fovi) and pre-trained models (https://huggingfa
ce.co/fovi-pytorch) are available.

Boost the Identity-Preserving Embedding for Consistent Visual Generation
Zixun Xia, Kai Wang, Shuyu Guo, Boqian Li, jian Yang, Yaxing Wang
Text-to-image models have advanced high-fidelity content generation, but their i
nability to maintain subject consistency hampers realistic applications.
Existing training-based methods rely on heavy computation and large datasets; wh
ile training-free approaches demand excessive memory or complex auxiliary module
s.
In this paper, we first reveal a key property overlooked in prior works that the
 identity-relevant signals, termed Identity-Preserving Embeddings (*IPemb*), are
 implicitly encoded in textual embeddings of frame prompts. To address the consi
stent T2I generation with the *IPemb* embedding, we propose Boost Identity-Prese
rving Embedding (*BIPE*), a training-free yet plug-and-play framework that expli
citly extracts and enhances the *IPemb*.
Its core innovations are two complementary techniques:
First, Adaptive Singular-Value Rescaling (*adaSVR*) applies singular-value decom
position to the joint embedding matrix of all frame prompts, amplifying identity
-centric components while suppressing frame-specific noise.
Second, Union Key (*UniK*) further reinforces consistency by aligning the T2I ba
ckbone’s image-text attention across the entire generation sequence.
Experiments on the *ConsiStory+* benchmark demonstrate *BIPE* outperforms existi
ng methods in both qualitative and quantitative metrics. To address the gap in e
valuating a broader range of scenarios with diversified prompt templates, we int
roduce a *DiverStory* benchmark to further confirm our scalability.

Optimizing Network Simulation: Enhancing Performance Prediction Accuracy via Neu
ral Architecture Search
ShaoChen He, Zirui Zhuang, Haifeng Sun, Xiaoyuan Fu, Qi Qi, Lei Zhang, Jianxin L
iao, Jingyu Wang
Existing machine learning models for network simulation excel at predicting aver
age performance but, due to their reliance on mean squared error, systematically
 fail to capture the critical tail-latency and jitter that define modern network
 stability. This 'tail-blindness' renders them unreliable for latency-sensitive
systems. We bridge this gap by introducing Accurate Neural Architecture Search (
ANAS), a paradigm that automates the discovery of architectures for high-precisi
on, distribution-aware network simulation. ANAS corrects the evaluation inaccura
cies of weight-sharing NAS via a similarity-constrained search, employs a hybrid
 search space to model complex traffic, and uses a Wasserstein loss to optimize
for the entire delay distribution, not just its mean. Empirically, the ANAS-disc
overed architecture is holistically superior: it reduces overall validation loss
 by 25.8\% compared to DeepQueueNet, demonstrating strong average-case performan
ce, while simultaneously excelling at tail-sensitive metrics by lowering the nor
malized Wasserstein distance (W_n) by up to 69.8\%. This confirms its ability
to faithfully model a comprehensive performance spectrum, encompassing both aver

age and critical tail behaviors. The ANAS framework provides a practical methodology for automatically creating high-fidelity model of network devices, enabling more reliable validation of next-generation network protocols and algorithms.

Spatio-Temporal LLM: Reasoning about Environments and Actions
Haozhen Zheng, Beitong Tian, Mingyuan Wu, Zhenggang Tang, Klara Nahrstedt, Alex Schwing
Despite significant recent progress of Multimodal Large Language Models (MLLMs), current MLLMs are challenged by "spatio-temporal" prompts, i.e., prompts that refer to 1) the entirety of an environment encoded in a point cloud that the MLLM should consider; and simultaneously also refer to 2) actions that happened in part of the environment and are encoded in a short ego-centric video clip. However, such a holistic spatio-temporal understanding is important for agents operating in the real world. To address this challenge, we first develop a framework to collect a large-scale dataset. Using the collected "Reasoning about Environments and Actions" (REA) dataset, we show that recent MLLMs indeed struggle to correctly answer "spatio-temporal" prompts. Building on this dataset, we study two spatio-temporal LLM (STLLM) baselines: 1) STLLM-3D, which directly fuses point cloud, video, and text representations as inputs to the LLM; and 2) STLLM-Aligner, which aligns spatial context with video and text before LLM decoding. Both baselines aim to enhance spatial understanding of environments and temporal grounding of egocentric observations. On REA, the STLLM baselines outperform existing models, demonstrating the effectiveness of our designs.

SWE-Perf: Can Language Models Optimize Code Performance on Real-World Repositories?
Xinyi He, Qian Liu, Mingzhe Du, Lin Yan, ZhiJie Fan, Yiming Huang, Yin Zheng, Zejian Yuan, Zejun MA
Code performance optimization is paramount in real-world software engineering and critical for production-level systems. While Large Language Models (LLMs) have demonstrated impressive capabilities in code generation and bug fixing, their proficiency in enhancing code performance at the repository level remains largely unexplored. To address this gap, we introduce SWE-Perf, the first benchmark specifically designed to systematically evaluate LLMs on code performance optimization tasks within authentic repository contexts. SWE-Perf comprises 140 carefully curated instances, each derived from performance-improving pull requests from popular GitHub repositories. Each benchmark instance includes the relevant codebase, target functions, performance-related tests, expert-authored patches, and executable environments. Through a comprehensive evaluation of representative methods that span file-level and repo-level approaches (e.g., Agentless and OpenHands), we reveal a substantial capability gap between existing LLMs and expert-level optimization performance, highlighting critical research opportunities in this emerging field.
****
Scalable Kronecker-Factored Fisher Approximation for Neural Network Parameter Sensitivity
Viktoriia A. Chekalina, Daniil Moskovskiy, Tatyana Matveeva, Andrey Kuznetsov, Evgeny Frolov
The Fisher Information Matrix (FIM) provides a principled geometric framework for parameter sensitivity in neural networks, but directly computing and using the full FIM is infeasible in high-dimensional models.
As a result, most existing methods rely on diagonal approximations that discard important correlation structure.
We introduce Matrix-free Fisher Factorization (MFF), a GPU-tractable algorithm that captures both diagonal and off-diagonal dependencies without materializing the full matrix.
For post-training neural network layer compression, we prove that under Matrix-Variate Normal assumptions, MFF yields GFWSVD, a unique closed-form linear layer decomposition that optimally minimizes the expected second-order loss increase.
Experiments on controlled numerical benchmarks with large neural networks show t

hat GFWSVD achieves up to 50\% compression while matching or exceeding state-of-the-art diagonal and activation-based baselines across most tasks, and it reliably avoids collapse in dense architectures such as Llama 3.
Moreover, when used to initialize existing optimization pipelines (e.g., Dobi-SVD), GFWSVD better preserves accuracy at 40\% parameter reduction in regimes where standard methods substantially degrade. Together, these results position MFF and GFWSVD as foundational algorithmic primitives for scalable, second-order-aware neural network approximation and parameter sensitivity.
****
Trajectory-Level Speculative Decoding for Diffusion Language Models
Tianxiang Pan, Baitao Gong, Mo Guang, Hongwei Yong, Tianpeng Jiang, Yaqian Li, Zheng Cao, Kaiwen Long
Diffusion-based language models (dLLMs) enable parallel token generation through iterative denoising, but existing decoding strategies collapse to single-token generation under low confidence, severely limiting throughput. Unlike autoregressive models where speculative decoding operates on token sequences in a fixed left-to-right order, dLLMs require speculating over \emph{denoising trajectories}—sequences of multi-token updates with explicit positions and unmasking orders. We develop a trajectory-level speculative framework that constructs draft denoising trajectories via confidence-stratified tree exploration and verifies them through blockwise parallel evaluation with bidirectional attention masking. Our method further introduces inter-block speculation, exploiting diffusion models' bidirectional structure to perform cross-block lookahead. We formally characterize when this approach is exact and identify trajectory drift as the fundamental cost of increased parallelism. Building on Fast-dLLM's dual-cache infrastructure, our framework reduces denoising iterations by 30-40\% and increases tokens-per-step from 2.6 to 4.3, achieving 7-14$\times$ speedup over vanilla dLLMs and 1.3$\times$ over Fast-dLLM with less than 1\% accuracy change across reasoning and code benchmarks.
****
Just-In-Time Reinforcement Learning: Continual Learning in LLM Agents Without Gradient Updates
Yibo Li, Zijie Lin, Ailin Deng, Xuan Zhang, Yufei He, Shuo Ji, Tri Cao, Bryan Hooi
While Large Language Model (LLM) agents excel at general tasks, they inherently struggle with continual adaptation due to the frozen weights after deployment. Conventional reinforcement learning (RL) offers a solution but incurs prohibitive computational costs and the risk of catastrophic forgetting.

We introduce Just-In-Time Reinforcement Learning (JitRL), a training-free framework that enables test-time policy optimization without any gradient updates.

JitRL maintains a dynamic, non-parametric memory of experiences and retrieves relevant trajectories to estimate action advantages on-the-fly.

These estimates are then used to directly modulate the LLM's output logits.

We theoretically prove that this additive update rule is the exact closed-form solution to the KL-constrained policy optimization objective.

Extensive experiments on WebArena and Jericho demonstrate that JitRL establishes a new state-of-the-art among training-free methods.

Crucially, JitRL outperforms the performance of computationally expensive fine-tuning methods (e.g., WebRL) while reducing monetary costs by over 30 times, offering a scalable path for continual learning agents. The code is available at https://github.com/liushiliushi/JitRL.
****
Investigating Advanced Reasoning of Large Language Models via Black-Box Environment Interaction
Congchi Yin, Tianyi Wu, Yankai Shu, Alex Gu, Yun Han Wang, Jun Shao, xun jiang, Piji Li
Existing tasks fall short in evaluating reasoning ability of Large Language Models (LLMs) in an interactive, unknown environment. This deficiency leads to the isolated assessment of deductive, inductive, and abductive reasoning, neglecting

the integrated reasoning process that is indispensable for humans discovery of r
eal world.
We introduce a novel evaluation paradigm, black-box interaction, to tackle this
challenge.
A black-box is defined by a hidden function that maps a specific set of inputs t
o outputs. LLMs are required to unravel the hidden function behind the black-box
 by interacting with it in given exploration turns, and reasoning over observed
input-output pairs.
Leveraging this idea, we build the Oracle benchmark which comprises 6 types of b
lack-box task and 96 black-boxes. 19 modern LLMs are benchmarked. o3, a leading
LLM from OpenAI, ranks first in 5 of the 6 tasks, achieving over 70\% accuracy o
n most easy black-boxes. But it still struggles with some hard black-box tasks,
where its average performance drops below 40\%.
Further analysis indicates a universal difficulty among LLMs: They lack the high
-level planning capability to develop efficient and adaptive exploration strateg
ies for hypothesis refinement.
Code is available in https://github.com/lemonsis/Oracle_Benchmark.
****

Turbo Connection: Reasoning as Information Flow from Higher to Lower Layers
Tang Mohan, Sidi Lu
Complex problems, whether in math, logic, or planning, are solved by humans thro
ugh a sequence of steps where the result of one step informs the next. In this w
ork, we adopt the perspective that the reasoning power of Transformers is fundam
entally limited by a fixed maximum number of steps along any latent path of comp
utation. To address this, we introduce Turbo Connection (TurboConn), a novel arc
hitecture that overcomes the fixed-depth constraint by routing multiple residual
 connections from the higher-layer hidden states of each token t to the lower
layers of token $t+1$. Fine-tuning pre-trained LLMs with our method not only yie
lds accuracy gains of 0.9\% to over 10\% on benchmarks like GSM8K, Parity, and m
ulti-step arithmetic, but also demonstrates that the density of these backward c
onnections is critical; our dense interaction significantly outperforms "sparse"
 alternatives that only pass a single hidden state or vector. Notably, TurboConn
 can be integrated into pre-trained LLMs to overcome task-specific plateaus: whi
le a fine-tuned Qwen-3-1.7B achieves only 53.78\% on Parity, adding our architec
tural modification enables the model to reach 100\% accuracy, all without the ne
cessity to retrain the full model from scratch or sophisticated curriculum learn
ing. Our results provide strong empirical evidence that the depth of the computa
tional path is a key factor in reasoning ability, also offering a new mechanism
to enhance LLMs without significantly affecting generation latency.
****

VENOMREC: Cross-Modal Interactive Poisoning for Targeted Promotion in Multimodal
 LLM Recommender Systems
Guowei Guan, Yurong Hao, Jiaming Zhang, Tiantong Wu, Fuyao Zhang, Tianxiang Chen
, Longtao Huang, Cyril Leung, Wei Yang Bryan Lim
Multimodal large language models (MLLMs) are pushing recommender systems (RecSys
) toward content-grounded retrieval and ranking via cross-modal fusion.
We find that while cross-modal consensus often mitigates conventional poisoning
that manipulates interaction logs or perturbs a single modality, it also introdu
ces a new attack surface where synchronised multimodal poisoning can reliably st
eer fused representations along stable semantic directions during fine-tuning.
To characterise this threat, we formalise cross-modal interactive poisoning and
propose VENOMREC, which performs Exposure Alignment to identify high-exposure re
gions in the joint embedding space and Cross-modal Interactive Perturbation to c
raft attention-guided coupled token--patch edits.
Experiments on four real-world multimodal datasets demonstrate that VENOMREC con
sistently outperforms strong baselines,
achieving 0.73 mean ER@20 and improving over the strongest baseline by +0.52 abs
olute ER points on average, while maintaining comparable recommendation utility.
Code is available at https://github.com/GuoweiGuan666/VenomRec.

scDEBART: Predicting in silico Single-Cell Perturbation Responses via Large-Scale Differential Expression Learning
Jieun Sung, Wankyu Kim
Single-cell foundation models trained on millions of cells can learn gene expression patterns across diverse contexts. However, for predicting genetic perturbation effects they often underperform simple regression models. We hypothesize two potential limitations: targets defined on dropout-prone absolute expression, and pretraining objectives that reconstruct static co-expression rather than encoding how genes co-regulate under expression changes. We introduce $\textbf{scDEBART}$, a perturbation-specific pretraining framework that predicts log fold-changes (logFC) conditioned on basal expression, thereby learning how gene sets co-vary across expression-change contexts at scale. To obtain reliable estimates of expression change under technical sparsity, we compute logFC from scVI-denoised expression and restrict pretraining to genes with robust detection. Pretrained on 6.28 million expression-change profiles from 66.6 million human cells and fine-tuned on five Perturb-seq datasets, scDEBART achieves mean enrichment factor (EF) of 11.96, 4-7$\times$ higher than scGPT and GEARS (mean EF 1.74-2.99), and 71.4\% top-1 accuracy for reverse perturbation identification compared to near-zero accuracy for prior models. In cross-modal transfer to drug perturbations (SCIPLEX), the model shows dose-dependent improvement in directional alignment (cosine similarity 0.04→0.30) with above-random DEG enrichment (EF 2.91-4.32), suggesting partial transfer of learned regulatory patterns across modalities. Overall, these results indicate that large-scale pretraining on scVI-denoised expression-change profiles provides a useful inductive bias for perturbation prediction.
****
CSD: Content-aware Speculative Decoding for Efficient Image Generation
Mingcheng Wang, Junbo Qiao, Yunchen Li, Lingfu Jiang, Wei Li, Jie Hu, Jiao Xie, Zhou Yu, Xinghao Chen, Guixu Zhang, Shaohui Lin
Speculative decoding (SD) has emerged as a key solution to accelerate the inference of autoregressive models. However, in the field of image generation, it faces the challenge of low acceptance rates, and directly relaxing its criteria leads to degradation in image quality. In this paper, we propose a novel content-aware speculative decoding algorithm, termed CSD, which integrates an entropy-based probability relaxation mechanism with an optimal resampling strategy to enhance the inference efficiency for autoregressive image generation. By leveraging the informational uncertainty inherent in different regions of an image, CSD dynamically adjusts the acceptance probability of candidate tokens, increasing the acceptance rate in low-detail areas to accelerate generation. Moreover, a distribution alignment filter is introduced to ensure the output distribution to be aligned with the target model, which significantly improves the generative quality. Experiments conducted on Lumina-mGPT and Janus-Pro demonstrate that the superiority of the proposed CSD. Our source code is available at https://github.com/aderfebr/CSD.

Circle-RoPE: Cone-like Decoupled Rotary Positional Embedding for Vision-Language Models
Chengcheng Wang, Jianyuan Guo, Hongguang Li, Yuchuan Tian, Ying Nie, Chang Xu, Kai Han
Rotary Position Embedding (RoPE) is widely adopted in large language models, but when applied to vision-language models (VLMs) it couples text and image position indices and can introduce spurious cross-modal relative-position bias.

We propose *Per-Token Distance* (PTD) to quantify cross-modal positional disentanglement, and we prove that $\mathrm{PTD}=0$ is a sufficient condition to eliminate the geometric attention bias induced by RoPE.

Guided by this criterion, we introduce Circle-RoPE, which remaps 2D image-token coordinates onto an annulus orthogonal to the text position axis, yielding a cone-like geometry where each text token is equidistant to all image tokens while preserving intra-image spatial structure.

We further propose Alternating Geometry Encoding (AGE) to synergize complementary geometric priors by alternating the decoupled geometry of Circle-RoPE and th

e grid-based prior of standard RoPE across layers. This design ensures both rigorous cross-modal disentanglement and the preservation of fine-grained intra-image spatial structure, and experiments on diverse VLM backbones and multimodal benchmarks show consistent gains in spatial grounding and visual reasoning.
  The code is available at https://github.com/lose4578/CircleRoPE.

STABLE: Simulation-Ready Tabletop Layout Generation via a Semantics–Physics Dual System
Zhen Luo, Yixuan Yang, Xudong XU, Jinkun Hao, Zhaoyang Lyu, Feng Zheng, Jiangmiao Pang, Yanwei Fu
Generating simulation-ready tabletop scenes from task instructions is an intriguing and promising research direction in the field of Embodied AI.
However, existing task-to-scene generation methods rely exclusively on large language models (LLMs) to predict scene layouts, inevitably yielding object collisions or floating due to LLMs' inherent limitations in 3D spatial reasoning.
In this paper, we present \textbf{STABLE}, a semantics–physics dual-system tailored for simulation-ready tabletop scene generation.
STABLE consists of two complementary modules: (i) a \textbf{Semantic Reasoner}, a fine-tuned LLM trained on a structured tabletop scene dataset to generate coarse layouts from input task instructions, and (ii) a \textbf{Physics Corrector}, a physics-aware flow-based denoising model that outputs pose updates to refine layouts, which ensures the physical plausibility of scenes while preserves semantic alignment with task instructions.
STABLE adopts a progressive generation paradigm: by alternating between the Semantic Reasoner and Physics Corrector, it incrementally expands the scene from task-critical objects to background objects.
Experiments demonstrate that STABLE successfully generates simulation-ready tabletop scenes that strictly conform to task instructions and significantly enhances the physical validity of scenes over prior art.

Mitigating the Modality Gap in Vision–Language Models with Fractal Spectral Geometry
Zihan Zhou, Yang Zhou, Ruoming Jin, Pan He, Patrick Emami
Vision–language models such as CLIP embed images and text into a shared space, but still suffer from a modality gap, where image and text features cluster separately and nearest neighbors are dominated by same-modality rather than true cross-modal matches. Existing works alleviate the modality gap by strengthening cross-modal losses, post-processing embeddings or similarities, or imposing geometric regularization, but they primarily enforce global alignment and can distort local geometry, limiting gains in local ranking and zero-shot accuracy. We propose Fractal Spectral Alignment (FSAlign), which reduces the modality gap by shaping and matching the multi-scale geometry of image and text embeddings. By enforcing Ahlfors-regularity and sub-Gaussian heat kernel bounds, FSAlign constructs a shared fractal multi-scale structure for multiple modalities. This structure captures geometry across scales, from local neighborhoods to global structure, and ensures shared fractal spectral geometry across modalities. Based on this structure, we introduce a fractal spectral zeta score derived from multi-scale heat kernels and minimize the discrepancy between pairwise image–text samples to align their multi-scale neighborhoods. We theoretically demonstrate that FSAlign can guarantee the alignment of local spectral measures and global fractional Dirichlet energies.

CoEvol-NO: State and Coordinate Co-Evolution with an Error-Driven Predictor-Corrector Paradigm for Neural Operator Transformer
Jianqiao Zeng, Ruocheng Wang, Yanzhi Liu, Hao Xiong, Junchi Yan
Despite the fast progress in neural operator learning, long-sequence modeling still is a standing challenge whereby latent states have been introduced with techniques well derived. Diverging from existing methods that treat latent states as transient variables or decoupled representations, CoEvol-NO introduces a persistent state to establish a co-evolutionary framework, where the latent state and

mesh sequence are updated jointly and bidirectionally. Inspired by classical nu
merical methods, we model the layer-wise state evolution as a Predictor-Correcto
r (PC) process. Specifically, a "Predictor'' generates a tentative target, follo
wed by a "Corrector'' that refines the persistent state via an {error-driven upd
ate mechanism}. Furthermore, our theoretical analysis reveals that the widely us
ed \textit{direct substitution} and \textit{residual update} paradigms are essen
tially {first-order approximations} of this error-driven correction under differ
ent loss assumptions. We theoretically prove that CoEvol-NO achieves strict line
ar time complexity. Extensive experiments on five standard benchmarks and two la
rge-scale industrial design tasks demonstrate that CoEvol-NO consistently achiev
es state-of-the-art (SOTA) performance.

URS: A Unified Neural Routing Solver for Cross-Problem Zero-Shot Generalization
Changliang Zhou, Canhong Yu, Shunyu Yao, Xi Lin, Zhenkun Wang, Yu Zhou, Qingfu Z
hang
Multi-task neural routing solvers have emerged as a promising paradigm for their
ability to solve multiple vehicle routing problems (VRPs) using a single model.
However, existing neural solvers typically rely on predefined problem constrain
ts or require per-problem fine-tuning, which substantially limits their zero-sho
t generalization ability to unseen VRP variants. To address this critical bottle
neck, we propose URS, a unified neural routing solver that achieves zero-shot ge
neralization across a wide range of unseen VRPs with a single model. We propose
a unified data representation (UDR) that replaces problem enumeration with data
unification, thereby broadening the problem coverage and reducing reliance on do
main expertise. In addition, we introduce a mixed bias module (MBM) during encod
ing to improve node embeddings, which efficiently captures multiple priors inher
ent to various problems. On top of the UDR, we develop a problem-conditioned par
ameter generator to further improve zero-shot generalization. Extensive experime
nts show that URS consistently produces high-quality solutions for 110 VRP varia
nts (including 99 unseen variants) while demonstrating impressive scalability to
large-scale instances with up to 7000 nodes. To the best of our knowledge, URS
is the first neural solver to handle over 100 VRP variants with a single model.
Our code is available at https://github.com/CIAM-Group/URS.

NeuroCLUS: A Foundation Model with Functional Clustering for Intracranial Neural
Decoding
Hui Zheng, Haiteng Wang
Foundation models for intracranial neural recordings aim to learn generalizable
representations from large-scale unlabeled data. However, existing approaches re
ly on suboptimal tokenization schemes -- treating individual electrode channels
as independent tokens or aggregating them into a single brain-wide representatio
n -- which fail to capture the brain’s inherent functional modularity. We introd
uce NeuroCLUS, a foundation model that learns to represent neural activity throu
gh data-driven functional clusters. NeuroCLUS is built on a novel two-stage pre-
training framework. First, a spatial-temporal model learns a functional context
graph between channels via a functional context prediction task. Second, this gr
aph guides a soft clustering of channels into a set of learnable prototype token
s, enabling the transformer backbone to process coherent functional units rather
than raw channels. Evaluated across a diverse range of decoding paradigms -- in
cluding speech perception, speech production, and seizure detection -- NeuroCLUS
consistently achieves state-of-the-art performance. The discovered functional c
lusters align with established neurophysiology and offer enhanced interpretabili
ty. Our work demonstrates that explicitly modeling functional neural groupings s
ignificantly improves the efficiency, generalization, and interpretability of fo
undation models for intracranial decoding.

Positive-Unlabeled Learning with Extreme Scarcity of Labeled Positives
Yuanchao Dai, Ximing Li, Wei Wang, Changchun Li, Gang Niu, Masashi Sugiyama
Positive-Unlabeled (PU) learning is a weakly-supervised paradigm that trains a b
inary classifier from labeled positive and unlabeled instances. In PU risk estim

ation, the empirical risk consists of an unlabeled term and a positive term. In this paper, we observe that when labeled positives are scarce, the risk deviation is dominated by the generalization bound of the positive term, which is composed of a complexity term governed by Rademacher complexity and a concentration term governed by the uniform range bound, leading to estimator instability. Based on this observation, we theoretically derive the sufficient sample threshold, defined as the smallest number of labeled positives required to achieve a target excess risk with high probability, and reveal its explicit dependence on both components. Inspired by this insight, we propose ScalePU, which incorporates variance regularization to induce a restricted sub-hypothesis space with reduced Rademacher complexity, and geometric regularization to encourage compact clustering of positive samples with a tighter effective range. Theoretical analysis demonstrates that both mechanisms effectively lower the threshold through improvements to different components of the bound. Experiments on eight benchmark datasets validate the effectiveness of ScalePU, with significant improvements under extreme label scarcity.

Shortcut-Resistant CAM Distillation for Long-Tailed Recognition

Wenhai Wan, Teng Zhang, Shao-Yuan Li, Xinrui Wang, Qiang-Sheng Hua, Songcan Chen

Real-world datasets often follow a long-tailed distribution, making generalization to tail classes difficult. We revisit this problem through the lens of shortcut learning, where models prefer the easiest predictive cues (e.g., background or textures) over object-centric semantics, especially under scarce and biased supervision. We find that this tendency is amplified for tail classes: limited examples often share similar contexts, making non-semantic signals highly correlated and thus tempting shortcuts, whereas head classes with diverse appearances and environments encourage more stable object-focused representations. Motivated by this observation, we propose Shortcut-Resistant CAM Distillation (SRCD), a plug-and-play framework that transfers object-focused explanations from head to tail classes. SRCD operates in the Class Activation Map (CAM) space, where a CAM provides a class-specific spatial evidence map for a prediction. SRCD aggregates CAMs from a small set of head-class candidates into a shortcut-resistant teacher using an energy-model weighting based on coherence and concentration, and distills it to the tail-class CAM. We provide a theoretical analysis that quantifies shortcut reliance as shortcut-region evidence mass in CAM space and shows that SRCD suppresses tail shortcuts. Extensive experiments on long-tailed benchmarks consistently improve strong baselines. The code is available at \url{https://github.com/Haifeng3/SRCD}.

Orthogonal Model Merging

Sihan Yang, Kexuan Shi, Weiyang Liu

Merging finetuned Large Language Models (LLMs) has become increasingly important for integrating diverse capabilities into a single unified model. However, prevailing model merging methods rely on linear arithmetic in Euclidean space, which often destroys the intrinsic geometric properties of pretrained weights, such as hyperspherical energy. To address this, we propose Orthogonal Model Merging (OrthoMerge), a method that performs merging operations on the Riemannian manifold formed by the orthogonal group to preserve the geometric structure of the model's weights. By mapping task-specific orthogonal matrices learned by Orthogonal Finetuning (OFT) to the Lie algebra, OrthoMerge enables a principled yet efficient integration that takes into account both the direction and intensity of adaptations. In addition to directly leveraging orthogonal matrices obtained by OFT, we further extend this approach to general models finetuned with non-OFT methods (e.g., low-rank finetuning, full finetuning) via an Orthogonal-Residual Decoupling strategy. This technique extracts the orthogonal components of expert models by solving the orthogonal Procrustes problem, which are then merged on the manifold of the orthogonal group, while the remaining linear residuals are processed through standard additive merging. Extensive empirical results demonstrate the effectiveness of OrthoMerge in mitigating catastrophic forgetting and maintaining model performance across diverse tasks.

Towards Efficient and Expressive Offline RL via Flow-Anchored Noise-conditioned Q-Learning
Sungyoung Lee, Dohyeong Kim, Eshan Balachandar, Zelal Su Mustafaoglu, Keshav Pingali
We propose Flow-Anchored Noise-conditioned Q-Learning (FAN), a highly efficient and high-performing offline reinforcement learning (RL) algorithm. Recent work has shown that expressive flow policies and distributional critics improve offline RL performance, but at a high computational cost. Specifically, flow policies require iterative sampling to produce a single action, and distributional critics require computation over multiple samples (e.g., quantiles) to estimate value. To address these inefficiencies while maintaining high performance, we introduce FAN. Our method employs a behavior regularization technique that uses a single flow policy iteration and requires a single Gaussian noise sample for distributional critics. Our theoretical analysis of convergence and performance bounds demonstrates that these simplifications not only improve efficiency but also lead to superior task performance. Experiments on robotic manipulation and locomotion tasks demonstrate that FAN achieves state-of-the-art performance while significantly reducing both training and inference runtimes. We release our code at https://github.com/brianlsy98/FAN.
****
Learning Compressed Shape-Aware Molecular Representations for Virtual Screening
Robin Winter, Julian Cremer, Djork-Arné Clevert
Virtual screening of billion-scale molecular libraries based on 3D shape similarity remains
computationally prohibitive, requiring expensive conformational sampling and alignment,
as done by established tools like *ROCS*.
Here, we introduce *SAND* (**S**hape-**A**ware **N**eural
Descriptor), a method that can retrieve shape similar molecules from their 2D graph alone. Our
approach makes two key contributions: (1) a rank-preserving contrastive learning framework using
differentiable Spearman correlation that results into representations where similarity
strongly correlates with 3D molecular shape overlap (R=0.86), and (2) an end-to-end learned
quantization-aware training scheme that jointly optimizes the encoder with a two-level IVF-PQ
discretization step, achieving approximately $4\times$ better compression than post-hoc quantization at
equivalent retrieval quality. We demonstrate that *SAND* enables searching over 10
billion molecules in less than a second on a single GPU node - a speedup of $>10^{8}
    \times$ compared to traditional methods. We release open-source code and trained weights to facilitate
adoption.
****
Mitigating Plasticity Loss through Architectural Design in Continual Learning
Niklas Koeppe, Luiz Felipe Vecchietti, Dongqi Han, Dongsheng Li, Sang Wan Lee
Neural networks for continual reinforcement learning (CRL) often suffer from plasticity loss, i.e., a progressive decline in their ability to learn new tasks arising from increased representational drift (churn) and Neural Tangent Kernel (NTK) rank collapse. Current methods mitigating this problem involve algorithmic interventions such as regularization, resets, and optimization schedules. Here, we propose InterpLayers, a lightweight architectural solution that combines a fixed, parameter-free reference pathway with a learnable projection pathway using input-dependent interpolation weights. This structure makes InterpLayers orthogonal to existing algorithmic solutions. We show through theoretical analysis that

InterpLayers upper-bound the output variability, bound churn, and prevent a collapse of the NTK rank through continual non-zero rank contribution from the interpolation mechanism. Across different distributional shifts, including permutation, windowing, and expansion, InterpLayers outperform similar gated architectures and achieve similar performance as current state-of-the-art methods without the need for optimization-level intervention or the introduction of sensitive hyperparameters. Ablation studies highlight that these improvements are sustained when InterpLayers are combined with existing algorithmic methods for preventing plasticity loss. These results position InterpLayers as a simple, complementary solution for maintaining plasticity in CRL.

AdaNav: Adaptive Reasoning with Uncertainty for Vision-Language Navigation
Xin Ding, Jianyu Wei, Yifan Yang, Shiqi Jiang, Qianxi Zhang, Hao Wu, Fucheng Jia, Liang Mi, Yuxuan Yan, Weijun Wang, Yunxin Liu, Zhibo Chen, Ting Cao
Vision-Language Navigation (VLN) requires agents to follow natural language instructions by grounding them in sequential visual observations over long horizons. Explicit reasoning could enhance temporal consistency and perception–action alignment, but reasoning at fixed steps often leads to suboptimal performance and unnecessary computation. To address this, we propose AdaNav, an uncertainty-based adaptive reasoning framework for VLN. At its core is the Uncertainty-Adaptive Reasoning Block (UAR), a lightweight plugin that dynamically triggers reasoning. We introduce Action Entropy as a policy prior for UAR and progressively refine it through a Heuristics-to-RL training method, enabling agents to learn difficulty-aware reasoning policies under the strict data limitations of embodied tasks. Results show that with only 6K training samples, AdaNav achieves substantial gains over closed-source models trained on million-scale data, improving success rate by 20% on R2R val-unseen, 11.7% on RxR-CE, and 11.4% in real-world scenes.

HiMAP-Travel: Hierarchical Multi-Agent Planning for Long-Horizon Constrained Travel
The Viet Bui, Wenjun Li, Yong Liu
Sequential LLM agents fail on long-horizon planning with hard constraints like budgets and diversity requirements. As planning progresses and context grows, these agents drift from global constraints. We propose **HiMAP-Travel**, a hierarchical multi-agent framework that splits planning into strategic coordination and parallel day-level execution. A Coordinator allocates resources across days, while Day Executors plan independently in parallel. Three key mechanisms enable this: a transactional monitor enforcing budget and uniqueness constraints across parallel agents, a bargaining protocol allowing agents to reject infeasible sub-goals and trigger re-planning, and a single policy trained with GRPO that powers all agents through role conditioning.
On TravelPlanner, HiMAP-Travel with Qwen3-8B achieves 52.78% validation and 52.65% test Final Pass Rate (FPR). In a controlled comparison with identical model, training, and tools, it outperforms the sequential DeepTravel baseline by +8.67 pp. It also surpasses ATLAS by +17.65 pp and MTP by +10.0 pp. On FlexTravelBench multi-turn scenarios, it achieves 44.34% (2-turn) and 37.42% (3-turn) FPR while reducing latency 2.5$\times$ through parallelization.

HieraMAS: Optimizing Intra-Node LLM Mixtures and Inter-Node Topology for Multi-Agent Systems
Tianjun Yao, Zhaoyi Li, Zhiqiang Shen
Multi-agent systems (MAS) built on large language models (LLMs) have demonstrated remarkable performance across diverse tasks. Existing approaches optimize communication topology, role assignment, or LLM routing in isolation, while treating each agent as a monolithic unit—failing to exploit internal LLM mixtures that can enhance individual role capabilities. We propose **`HieraMAS`**, a hierarchical agent collaboration framework with intra-node LLM mixtures and inter-node communication topology. HieraAgent introduces *supernodes*, where each functional role comprises multiple heterogeneous LLMs in a propose-synthesis structure. The optimization of **`HieraMAS`** poses unique credit assignment challenges, as fin

al task performance heavily depends on LLM capabilities, potentially causing err
oneous reinforcement of suboptimal configurations. We address this via a two-sta
ge algorithm: (1) multi-level reward attribution providing fine-grained feedback
 at both node and system levels; and (2) graph classification treating topology
selection as a holistic task rather than per-edge optimization. Experiments on r
easoning and coding benchmarks demonstrate that **`HieraMAS`** significantly out
performs existing methods while achieving better cost-performance trade-offs.

Learning the Interaction Prior for Protein-Protein Interaction Prediction: A Mod
el-Agnostic Approach

Ziqi Gao, Chenyi Zi, Zijing Liu, Ziqiao Meng, Yu Li, Jia Li

Protein-protein interactions (PPIs) are fundamental to cellular function, diseas
e mechanisms, and drug discovery. Current learning-based PPI predictors focus on
 learning powerful protein representations but neglect designing specialized cla
ssification heads. They mainly rely on generic aggregating methods like concaten
ation or dot products, which lack biological insight. Motivated by the biologica
l "L3 rule", where multiple length-3 paths between a pair of proteins indicate t
heir interaction likelihood, our study addresses this gap by designing a biologi
cally informed PPI classifier. In this paper, we provide empirical evidence that
 popular PPI datasets strongly support the L3 rule. We propose an L3-path-regula
rized graph prompt learning method called L3-PPI, which can generate a prompt gr
aph with virtual L3 paths based on protein representations and controls the numb
er of paths. L3-PPI reformulates the classification of protein embedding pairs i
nto a graph-level classification task over the generated prompt graph. This ligh
tweight module seamlessly integrates with leading PPI predictors as a plug-and-p
lay component, injecting the interaction prior of complementarity to enhance per
formance. Extensive experiments show that L3-PPI achieves superior performance e
nhancements over state-of-the-art competitors.

Learning syntax without semantics: Disentangled tiny language models

Ezra Winston, J Zico Kolter

Language models acquire syntax and world knowledge together, entangling the two
in ways that limit efficiency and controllability. We show that syntax can be le
arned while suppressing semantic plausibility and world■knowledge cues, yielding
 more efficient and controllable models. We train tiny LMs on grammatical nonsen
se — syntactically well-formed text with semantic content ablated via constraine
d relexicalization (SAMBAL). Models trained on this data perform comparably to s
tandard pretraining on syntactic benchmarks (BLiMP, SyntaxGym) while scoring at
chance on world knowledge probes (EWoK). On targeted grammar-plausibility confli
ct probes, content-neutral models prefer grammaticality where standard models pr
efer plausibility, and their representations show more syntactic vs lexical alig
nment. On efficiency, disentanglement yields substantial sample and parameter ga
ins: in low■resource regimes, a 5M■parameter model matches a 30M■parameter basel
ine at the same data budget. On controllability, content-neutral models adapt ra
pidly to a new domain with minimal exposure, suggesting the feasibility of modul
ar post■hoc knowledge specialization.

RetrOrchestrator: A Multi-Step Retrosynthesis Agent Dynamically Orchestrating Si
ngle-Step Transition Models

Liao Chang, Luotian Yuan, Yiping Ke, Ying Wei

Multi-step retrosynthesis planning is a fundamental challenge in organic chemist
ry, defined by its enormous search space. Existing methods typically formulate i
t as a Markov Decision Process (MDP) with a fixed choice of transition model (i.
e., a single-step retrosynthesis model), and focus on improving *how to search*
through better policies and value functions.

However, *how the transition space itself is navigated* remains largely unexplor
ed.

This limitation is particularly urgent given our observation of pronounced *skil
l disparity* among single-step prediction models: different models exhibit subst
antially different performance across molecule states.

Motivated by this observation, we introduce RetrOrchestrator, an LLM-powered age
nt that explicitly accounts for model skill disparity by reframing retrosynthesi
s planning as a Partially Observable Markov Decision Process (POMDP).
By regarding each single-step prediction model as a tool, we further propose a s
caffold-aware reinforcement learning algorithm to optimize navigation policy wit
hin the transition space.
As a result, RetrOrchestrator jointly searches which molecule to expand and whic
h single-step model to apply for the molecule at the current step.
Empirically, RetrOrchestrator significantly outperforms static baselines on the
Retro*-190 benchmark, achieving a state-of-the-art 94.21% success rate (vs. 9.47
% off-the-shelf LLM and 82.63\% non-LLM state-dependent router), with 92.49% of
solved routes invoking two or more SSRs—evidence that the policy is not collapsi
ng to a single specialist or a static router.
The same gain persists on a larger out-of-distribution set (PDB-600), with RetrO
rchestrator Pareto-optimal in both wall-clock time and model-query count.
Code: https://github.com/ScottLiao920/verl-retro-agent.

TimeSeed: Effective Time Series Forecasting with Sparse Endogenous Variables
Zhaowang Wu, Kaixin Deng, Hua Yan
Time series forecasting has long relied on dense endogenous observations, yet in
 many real-world scenarios, such data is scarce or even absent. Existing approac
hes attempt to compensate with exogenous variables, but their reliance on incomp
lete endogenous histories makes them brittle under data scarcity. In this work,
we introduce sparse endogenous forecasting as a new setting, where exogenous seq
uences and only sparse endogenous observations are available. To tackle this pro
blem, we propose TimeSeed, a lightweight architecture that redefines sparse fore
casting as a context reconstruction task. By jointly exploiting the stability of
 exogenous sequences and the limited but informative endogenous signals, TimeSee
d reconstructs robust historical representations and transforms forecasting into
 a tractable sequence-based prediction problem. Remarkably, TimeSeed achieves th
is with a purely linear architecture using only 0.19M parameters, consistently o
utperforming state-of-the-art deep models on seven real-world benchmarks, with a
n average improvement of 13.01\% in MSE and 7.54\% in MAE. These results establi
sh sparse endogenous forecasting as a practical and promising paradigm, opening
a new direction for time series analysis under extreme data scarcity. Code is av
ailable at this repository: \url{https://anonymous.4open.science/r/Alistair-7}.

Pianist Transformer: Towards Expressive Piano Performance Rendering via Scalable
 Self-Supervised Pre-Training
Hong-Jie You, Jie-Jing Shao, Xiao-Wen Yang, Lin-Han Jia, Lan-Zhe Guo, Yu-Feng Li
Existing methods for expressive music performance rendering rely on supervised l
earning over small labeled datasets, which limits scaling of both data volume an
d model size, despite the availability of vast unlabeled music, as in vision and
 language. To address this gap, we introduce Pianist Transformer, with three key
 contributions: 1) introducing large-scale self-supervised learning into express
ive piano performance rendering through a unified Musical Instrument Digital Int
erface (MIDI) representation, enabling pre-training on 10B tokens of unlabeled M
IDI data; 2) an efficient asymmetric Transformer with note-level compression, su
bstantially improving training efficiency, memory usage, and inference speed for
 long-context music modeling; 3) a state-of-the-art rendering model with an edit
able workflow, achieving strong objective and subjective results and enabling in
tegration into real-world music production workflows. Overall, Pianist Transform
er outlines a scalable path toward human-like performance synthesis in the music
 domain. Code, audio samples, and model checkpoints are available on our project
 page: https://yhj137.github.io/pianist-transformer-demo/.

Rethinking Video Generation Model for the Embodied World
Yufan Deng, Zilin Pan, Hongyu Zhang, Xiaojie Li, Ruoqing Hu, Yufei Ding, Yiming
Zou, Yan Zeng, Daquan Zhou
While video generation holds promise for embodied intelligence, current video mo

dels struggle with physical realism, and progress is hindered by the lack of sta ndardized benchmarks. To address this gap, we introduce a comprehensive robotics benchmark, RBench, designed to evaluate robot-oriented video generation across five task domains and four distinct embodiments. By assessing task correctness a nd visual fidelity through reproducible metrics, our evaluation of 25 models rev eals significant deficiencies in generating physically realistic robot behaviors . Furthermore, the benchmark achieves a 0.96 Spearman correlation with human jud gment, validating its effectiveness. While RBench provides the necessary lens to identify these deficiencies, achieving physical realism requires moving beyond evaluation to address the critical shortage of high-quality training data. Drive n by these insights, we introduce a refined four-stage data pipeline, resulting in RoVid-X, the largest open-source robotic dataset for video generation with 4 million annotated video clips, covering thousands of tasks and enriched with phy sical property annotations. Extensive experiments demonstrate that finetuning on RoVid-X yields consistent performance gains. Collectively, this synergistic eco system of evaluation and data establishes a robust foundation for rigorous asses sment and scalable training of video models, accelerating the evolution of embod ied AI toward physical intelligence. The code and video demos are available in t he supplementary materials.

EVOLVING ROLLOUTS: Harnessing Historical Experience for Web Agent Evolution in R einforcement Learning

Sinuo Wang, WANG PIAOHONG, Tianrui Qin, Maojia Song, Qianben Chen, Qiexiang Wang , Gengze Zhou, Zeyu Zhang, He Zhu, Dingfeng Shi, Yutong Xie, Minghao Liu, Jiahen g Liu, Ge Zhang, Jiawei Ma, Yuchen Eleanor Jiang, Qi Wu, Wangchunshu Zhou

Agentic reinforcement learning (RL) for web search is prohibitively expensive du e to long context lengths and costly environment interactions, and this ineffici ency is further exacerbated by group-based optimization, which discards learning signals from entire rollout groups with zero reward variance. In this work, we propose EVOLVING ROLLOUTS, an RL framework for web-search agents that moves beyo nd episodic training and distills collected rollouts into in-context guidance fo r future policy behavior. By extracting the reward-labeled trajectories into str ategic experiences, our method augments standard parameter-space optimization wi th implicit context-space optimization guided by prior experience. This enables the agent to recover learning signals from zero-variance rollouts, thereby foste ring co-evolution between the policy and the experience repository. EVOLVING ROL LOUTS improves sample efficiency and task performance across representative web search benchmarks, with Qwen3-8B surpassing the much larger Qwen3-30B-A3B in ave rage performance across GAIA, xBench, and HLE, and Qwen3-4B attaining comparable results on GAIA and HLE.

The Hidden Risk: Membership Inference Attacks on Multimodal Federated Learning v ia Modality Imbalance

chang Ma, Jun Li, Kang Wei, Yipeng Zhou, Ming Ding, Yiyang Ni

Federated learning (FL) faces significant challenges from modality heterogeneity , which motivates multimodal federated learning (MFL) to leverage complementary modalities across decentralized clients for improved performance. However, moda lity imbalance introduces a new attack surface, making MFL more vulnerable to me mbership inference attacks (MIAs), an issue that remains largely unexplored. In this work, we present the first systematic study of MIAs against MFL and propose a modality-aware attack framework.

We show that multimodal models are inherently more susceptible to MIAs due to he terogeneous modality contributions, and existing attacks are suboptimal as they treat multimodal parameters as a whole.

By performing MIAs on individual modalities, we find that (i) attacking the domi nant modality achieves comparable accuracy with lower overhead, and (ii) differe nt modalities expose distinct membership patterns.

To identify members with different patterns, we propose a modality-aware framewo rk that exploits cross-modal performance gaps to adaptively select attack modali ties and calibrate inference results. Experiments on three datasets show our app

roach outperforms baselines across multiple metrics.

Compress then Merge: From Multiple LoRAs into One Low-Rank Adapter
Zhengbao He, Ruiqi Ding, Zhehao Huang, Ruikai Yang, Tao Li, Xiaolin Huang
Low-rank adaptation (LoRA) enables parameter-efficient specialization of foundation models, but the proliferation of task-specific adapters fragments capabilities across many adapters, complicating reuse and deployment.
We study the problem of **merging T LoRAs into a single rank-r LoRA**, thereby preserving the benefits of low-rank structure.
Existing Merge-then-Compress pipelines treat the rank constraint as an afterthought: they merge adapters in the full parameter space,
then compress the merged result to rank r via truncated SVD.
However, full-parameter merging may destroy the low-rank structure, making it difficult for subsequent compression to recover an effective rank-r LoRA.
We propose Compress-then-Merge (CtM), a reversed pipeline that enforces the rank-r bottleneck _before_ merging: CtM computes shared r-dimensional subspaces using only the LoRA weights to capture cross-adapter common structure, projects each adapter into the shared subspaces to obtain $r\times r$ coordinates, and then applies standard merging rules in this reduced space.
CtM guarantees a rank-r LoRA by construction, avoiding post-hoc truncation, and enables efficient computation in the core space spanned by concatenated LoRA factors.
Experiments across multiple models and tasks show that CtM consistently outperforms existing single-LoRA-output baselines while narrowing the performance gap to full-parameter merging methods.

Scalable Option Learning in High-Throughput Environments
Mikael Henaff, Scott Fujimoto, Michael Matthews, Michael Rabbat
Hierarchical reinforcement learning (RL) has the potential to enable effective decision-making over long timescales. Existing approaches, while promising, have yet to realize the benefits of large-scale training. In this work, we identify and solve several key challenges in scaling online hierarchical RL to high-throughput environments. We propose Scalable Option Learning (SOL), a highly scalable hierarchical policy gradient algorithm which achieves a ~35x higher throughput compared to existing hierarchical methods. To demonstrate SOL's performance and scalability, we train hierarchical agents using 30 billion frames of experience on the complex game of NetHack, significantly surpassing flat agents and demonstrating positive scaling trends. We also validate SOL on MiniHack and Mujoco environments, showcasing its general applicability.
****
Frequentist Consistency of Prior-Data Fitted Networks for Causal Inference
Valentyn Melnychuk, Vahid Balazadeh, Stefan Feuerriegel, Rahul G Krishnan
Foundation models based on prior-data fitted networks (PFNs) have shown strong empirical performance in causal inference by framing the task as an in-context learning problem. However, it is unclear whether PFN-based causal estimators provide uncertainty quantification that is consistent with classical frequentist estimators. In this work, we address this gap by analyzing the frequentist consistency of PFN-based estimators for the average treatment effect (ATE). (1) We show that existing PFNs, when interpreted as Bayesian ATE estimators, can exhibit prior-induced confounding bias: the prior is not asymptotically overwritten by data, which, in turn, prevents frequentist consistency. (2) As a remedy, we suggest employing a calibration procedure based on a one-step posterior correction (OSPC). We show that the OSPC helps to restore frequentist consistency and can yield a semi-parametric Bernstein-von Mises theorem for calibrated PFNs (i.e., both the calibrated PFN-based estimators and the classical semi-parametric efficient estimators converge in distribution with growing data size). (3) Finally, we implement OSPC through tailoring martingale posteriors on top of the PFNs. In this way, we are able to recover functional nuisance posteriors from PFNs, required by the OSPC. In multiple (semi-)synthetic experiments, PFNs calibrated with our martingale posterior OSPC produce ATE uncertainty that (i) asymptotically matches f

requentist uncertainty and (ii) is well calibrated in finite samples in comparis
on to other Bayesian ATE estimators.

MOD-SR: Unifying Multimodal Learning and Direct Optimization with Gradient-Guide
d Diffusion Model for Symbolic Regression
Chuyang Xiang, Yichen Wei, Junchi Yan
Symbolic regression (SR) aims to discover interpretable mathematical expressions
 from observed data.
While recent generative approaches have shown promise in treating SR as machine
translation or multimodal learning tasks using NN methods, they suffer from unco
ntrollable generation process and training-evaluation misalignment.
The training objectives (average cross-entropy loss on a token level across the
distribution of historical data) differ from the evaluation metric (fitting erro
r for every test data / complexity), necessitating extensive heuristic post-proc
essing.
On the other hand, direct optimization methods suffer from an exponential slowdo
wn as the dimensionality increases, non-differentiability and local optima traps
.
We propose **MOD-SR**, unifying multimodal distribution learning during training
 with direct optimization at inference time. This is achieved by modeling the ta
sk as $p(x_0 \mid \mathcal{D}, y^*)$ and employing gradient-guided diffusion in
embedding space, enhanced by contrastive learning and representation alignment.
Furthermore, we introduce DFEX, a fixed-depth tree relaxation method that ensure
s differentiability for effective gradient guidance during inference.
Experiments demonstrate that MOD-SR achieves superior performance on diverse ben
chmarks through a unified framework integrating distribution learning and optimi
zation. Our code is available at [https://github.com/KROX777/MOD-SR](https://git
hub.com/KROX777/MOD-SR).

ABSINT-AI: Agentic Heap Abstractions for Abstract Interpretation
Michael Wang, Kexin Pei, Armando Solar-Lezama
Static program analysis is a foundational technique in software engineering for
reasoning about program behavior. Traditional static analysis algorithms model p
rograms as logical systems with well-defined semantics, but rely on uniform, har
d-coded heap abstractions. This limits their precision and flexibility, especial
ly in dynamic languages like JavaScript, where heap structures are heterogeneous
 and difficult to analyze statically. In this work, we introduce ABSINT-AI, a la
nguage-model-guided static analysis framework that augments abstract interpretat
ion with adaptive, per-object heap abstractions for Javascript. This enables the
 analysis to leverage high-level cues, such as naming conventions and access pat
terns, without requiring brittle, hand-engineered heuristics. Importantly, the L
M agent operates within a bounded interface and never directly manipulates progr
am state, preserving the soundness guarantees of abstract interpretation. To eva
luate our approach, we focus on a soundness-critical task: determining whether o
bject property accesses may result in undefined or null dereferences. This task
directly models a common requirement in compiler optimizations, where proving th
at an access is safe enables the removal of dynamic checks or simplifies code mo
tion. On this task, ABSINT-AI reduces false positives by up to 34% compared to t
raditional static analyses with fixed heap abstractions, while preserving formal
 guarantees. Our ablations show that the LM’s ability to interact agentically wi
th the analysis environment is crucial, outperforming non-agentic LM predictions
 by 25%.

PatternKV: Flattening KV Representation Expands Quantization Headroom
Ji Zhang, Yiwei Li, Shaoxiong Feng, Peiwen Yuan, Xinglin Wang, Yueqi Zhang, Jiay
i Shi, Chuyi Tan, Boyuan Pan, Yao Hu, Kan Li
KV cache in autoregressive LLMs eliminates redundant recomputation but has emerg
ed as the dominant memory and bandwidth bottleneck during inference, notably wit
h long contexts and test-time scaling. KV quantization is a key lever for reduci
ng cache cost, but accuracy drops sharply as the native KV distribution lacks fl

atness and thus maintains a wide quantization range. Prior work focuses on isola ting outliers, which caps their error but fails to flatten the overall distribut ion, leaving performance fragile under low-bit settings. In this work, we show t hat the K cache maintains a stable, context-evolving structure, while the V cach e carries latent semantic regularities, with both contributing to the organizati on of vectors into shared patterns. Building on these insights, we propose **Pat ternKV**, a pattern-aligned residual quantization scheme. It mines representativ e pattern vectors online, aligns each KV vector to its nearest pattern, and quan tizes only the residual. This reshaping of the KV distribution flattens the quan tization target and narrows its range, thereby improving the fidelity of low-bit KV quantization. Across long-context and test-time scaling settings on multiple backbones, PatternKV delivers consistent 2-bit gains, incurs only a 0.08\% aver age 4-bit drop relative to FP16, and improves test-time scaling accuracy by 10\% on average. Compared with FP16, PatternKV further raises throughput by 1.5$\tim es$ and supports 1.25$\times$ larger batches.

Role-Level Inductive Bias for Cross-Task Generalization in Multi-Agent Reinforce ment Learning

Chang Yao, Youfang Lin, Shoucheng Song, Hao Wu, Shengkun Yang, Yuqing Ma, Kai Lv

Achieving cross-task generalization remains a critical challenge in Multi-Agent Reinforcement Learning (MARL), fundamentally relying on effective inductive bias es. However, existing entity-level biases often overlook collaborative patterns, whereas task-level biases lack sufficient coverage for novel scenarios. To addr ess this, we introduce a role-level inductive bias as an intermediate abstractio n that integrates entity-level flexibility with task-level inter-agent collabora tion. To instantiate this, we propose Gaussian-mixture-model-based Transferable Role discovery (GTR). Specifically, GTR constructs a structured role space to en sure diverse role assignment, further achieves role decoupling via regularizatio n, and ultimately utilizes these roles for efficient generalization. Empirical r esults demonstrate that GTR achieves superior zero-shot and few-shot transfer pe rformance on unseen tasks compared to state-of-the-art methods.

Enhanced Latent-Space Adversarial Training for Super-Resolution

Liangbin Xie, Zheyuan Li, Fanghua Yu, Xinqi Lin, Jun-hao Zhuang, Jinfan Hu, Jinj in Gu, Jiantao Zhou, Chao Dong

Real-world super-resolution (SR) at large upscaling factors (i.e., ≥ 4×) remains difficult due to complex real-image degradations. HYPIR, a leading diffusion-ba sed restoration model, performs strongly on many inputs, yet for a non-trivial p ortion of more challenging cases a single forward step does not fully recover fi ne-grained details. A naive two-stage cascade improves visual quality, but intro duces over-saturation, weak texture details, and high inference latency. To addr ess these issues, this paper proposes HYPIR++. It removes the degradation remova l encoder and noise augmentation modules to better preserve fidelity cues from l ow-quality inputs. Equipped with an optimized latent ConvNeXt and a latent patch discriminator, HYPIR++ supports latentspace adversarial learning for clearer de tails and more stable local structures. It further shortens text sequences and r eplaces full attention with sparse neighbor attention, enabling efficient highre solution inference without tiling. Experiments show that HYPIR++ improves percep tual quality and runs 1.71× faster than HYPIR on large-factor real-world SR

Geometry-Misalignment in Distributional Learning

Tao Wang, Xiaoting Zhong

Distributional learning problems optimize discrepancies between probability meas ures, including optimal transport or Sinkhorn divergence, yet are typically opti mized using Euclidean first-order methods in parameter space. We show this misma tch is structural rather than algorithmic. We introduce geometry-misalignment, a local condition number that measures distortion between Euclidean geometry and the intrinsic geometry induced by a distributional objective. For a broad class of problems, we establish lower bounds demonstrating that Euclidean first-order methods incur an unavoidable convergence slowdown proportional to misalignment,

even under intrinsic strong convexity and smoothness. We further prove geometry-aware preconditioned methods attain matching upper bounds independent of misalignment, yielding a sharp separation between Euclidean optimization and geometry-aware optimization. Beyond convergence rates, we show geometry-misalignment induces an optimization-dependent excess risk term under finite budgets, directly linking optimization geometry with statistical efficiency. We develop a geometry-calibrated optimization framework that estimates misalignment and selectively activates geometry-aware updates when necessary. Experiments on distribution matching for domain adaptation validate the theory, with improvements concentrated in high-misalignment regimes and negligible overhead.

Self-supervised Hierarchical Visual Reasoning with World Model
Yuanfei Xu, Lin Liu, Wengang Zhou, Mingxiao Feng, Houqiang Li
3D open-world environments with adversarial opponents remain a core challenge for reinforcement learning due to their vast state spaces.
Effective reasoning representations are essential in such settings. While existing self-supervised visual foresight reasoning approaches often suffer from multi-step error accumulation, many recent studies resort to injecting domain-specific knowledge for more stable guidance.
Our key insight is that the photorealistic fidelity of visual reasoning representations is secondary; what truly matters is providing informative, task-relevant signals.
To this end, we propose ResDreamer, a hierarchical world model in which each higher-level layer is trained to reconstruct the residuals of the layer below. This design enables progressive abstraction of increasingly sophisticated world dynamics and fosters the emergence of richer latent representations.
Drawing inspiration from the “Bitter Lesson,” ResDreamer trains its reasoning representations in a purely self-supervised manner. The higher-level residual representations are used to modulate lower-level predictions, allowing the world model to scale effectively with only linearly increasing cross-layer communication costs.
Experiments show that ResDreamer achieves state-of-the-art sample efficiency and parameter efficiency. This scalable hierarchical visual foresight reasoning architecture paves the way for more capable online RL agents in open-ended, dynamic environments.
****

DeltaEvolve: Accelerating Scientific Discovery through Momentum-Driven Evolution
Jiachen Jiang, Tianyu Ding, Zhihui Zhu
LLM–driven evolutionary systems have shown promise for automated science discovery, yet existing approaches such as AlphaEvolve rely on full-code histories that are context-inefficient and potentially provide weak evolutionary guidance. In this work, we first formalize the evolutionary agents as a general Expectation–Maximization framework, where the language model samples candidate programs (E-step) and the system updates the control context based on evaluation feedback (M-step). Under this view, constructing context via full-code snapshots constitutes a suboptimal M-step, as redundant implement details dilutes core algorithmic ideas, making it difficult to provide clear inspirations for evolution. To address this, we propose DeltaEvolve, a momentum-driven evolutionary framework that replaces full-code history with structured semantic delta capturing how and why modifications between successive nodes affect performance. As programs are often decomposable, semantic delta usually contains many effective components which are transferable and more informative to drive improvement. By organizing semantic delta through multi-level database and progressive disclosure mechanism, input tokens are further reduced. Empirical evaluations on tasks across diverse scientific domains show that our framework can discover better solution with less token consumption over full-code-based evolutionary agents.

When LLMs Develop Languages: Symbolic Communication for Efficient Multi-Agent Reasoning
Zhengqi Pei, Qingming Huang, Shuhui Wang

Chain-of-Thought (CoT) improves large language models (LLMs) on difficult reasoning tasks, but it often incurs long natural-language rationales that are poorly aligned with efficient machine reasoning.
We propose Communicative Language Symbolism Routing (CLSR), a test-time framework in which multiple LLM agents autonomously invent, evolve, and share compact Language Symbolism Frameworks (LSFs), while a latent-free router adaptively selects and composes these languages per query to optimize the accuracy--token trade-off.
Unlike prompt optimization that refines surface instructions, CLSR treats each LSF as a reusable symbolic protocol with compact symbols, usage rules, and a message-passing contract, and improves it through an evolutionary loop driven by correctness and token cost.
At inference time, the router may invoke a single low-cost LSF call, ensemble multiple LSFs, or execute a multi-round LSF composition protocol on harder queries.
Across challenging benchmarks, CLSR reduces latency-oriented generated token completion by $3\sim 6\times$ compared to standard CoT while maintaining accuracy.
We further derive an information-theoretic lower bound on token cost under arbitrary symbolism and show that, under an interpreter-realizability premise, multi-round LSF protocols conditionally subsume program-execution pipelines.

LORD-GoF: A Robust Online Detection Approach for LLM Watermarks in Sparse and Mixed Streams
Jiade Xu, Zhouping Li
Watermarking is crucial for identifying AI-generated text, however, existing detection methods often focus on offline settings and fail to control the online False Discovery Rate (oFDR) when applied to real-world streams where machine-generated content is sparse and mixed with human writing. To address this issue, in this paper, we propose LORD-GoF, a novel online detection framework that combines a Goodness-of-Fit (GoF) statistic with the Levels based On Recent Discovery (LORD) procedure. We prove that LORD-GoF approach can rigorously control the oFDR below a user-specified level by dynamically adjusting detection thresholds. Extensive experiments on watermarked text from Qwen-2.5-3B, Sheared-LLaMA-2.7B, and OPT-1.3B using both the Gumbel-Max and Inverse Transform watermarking schemes show that our method maintains statistical power comparable to offline benchmarks while successfully controlling the oFDR under complex, mixed streaming scenarios.

MORE: A Multilingual Document Parsing Benchmark and Evaluation
Long Xu, Binghong Wu, TingHao YU, Hao Feng, Zhenyu Huang, Haoqing Jiang, Yunhao Wang, Shuo Huang, feng zhang
Multilingual documents encapsulate rich regional cultures, scientific discoveries, and historical records. Parsing this content into structured, machine-readable formats is critical for unlocking global knowledge. However, existing benchmarks predominantly focus on high-resource languages like English and Chinese, creating an $\textit{evaluation blind spot}$ concerning model performance on other languages. While recent Vision-Language Models (VLMs) claim support for hundreds of languages, the lack of ground truth makes it impossible to empirically verify these capabilities. To bridge this gap, we introduce $\textbf{MORE}$, a large-scale benchmark designed for multilingual document parsing evaluation. MORE distinguishes itself through three key dimensions: (1) $\textbf{Unprecedented Scale}$: It covers $\textbf{149 languages}$, making it the most linguistically diverse benchmark to date; (2) $\textbf{Structural Complexity}$: Unlike previous works, it extends evaluation beyond plain text to include structural elements such as code blocks, tables, and catalogs; and (3) $\textbf{Data Authenticity}$: All samples are curated from real-world documents via a model-assisted, human-refined annotation pipeline. We evaluate state-of-the-art models using MORE, establishing new performance baselines for long-tail languages and validating the benchmark's effectiveness in diagnosing model capabilities in realistic, diverse scenarios. The MORE dataset will be available at https://github.com/zimoqingfeng/MORE.

TabSwift: An Efficient Tabular Foundation Model with Row-Wise Attention
Si-Yang Liu, Han-Jia Ye
Tabular foundation models, exemplified by TabPFN, perform prediction via in-context learning, inferring test labels directly from labeled training examples. They have demonstrated competitive performance, particularly on small-to-medium datasets. However, recent tabular foundation models often improve accuracy with increasingly complex architectures, incurring higher inference cost and limiting practical deployment.
In this work, we revisit the original TabPFN design and show that a lightweight row-wise attention–only backbone can remain highly competitive with two simple enhancements: a gated attention stabilization mechanism and a small set of learnable register tokens that provide global context and improve pretraining quality. The resulting model, TabSwift, supports both classification and regression, and is competitive with stronger tabular foundation models (e.g., TabPFN v2 and TabICL) while being more efficient at inference.
For latency-sensitive serving, we further introduce an adaptive layer-wise early-exit mechanism that dynamically adjusts inference depth per sample.
Overall, TabSwift enables efficient and anytime tabular in-context learning for practical deployments.
****
Every Step Counts: Decoding Trajectories as Authorship Fingerprints of dLLMs
Qi Li, Runpeng Yu, Haiquan Lu, Xinchao Wang
Discrete Diffusion Large Language Models (dLLMs) have recently emerged as a promising non-autoregressive paradigm, offering faster inference while achieving strong performance in code generation and mathematical reasoning tasks. In this work, we show that dLLMs' decoding mechanism not only improves utility but also enables effective model attribution: by analyzing a response's decoding trajectory, we can identify its source model and help mitigate risks from model misuse. A key challenge is the diversity of attribution scenarios, ranging from distinguishing different models to identifying different checkpoints or backups of the same model. To ensure broad applicability, we focus on two core questions: what information to extract from the decoding trajectory, and how to use it effectively. We first observe that per-step model confidence is ineffective, as the bidirectional nature of dLLMs causes mutual influence among decoded tokens, leading to highly redundant confidence signals that obscure structural information about decoding order and dependencies. To overcome this, we propose a novel information extraction scheme called the \textit{Directed Decoding Map (DDM)}, which captures structural relationships between decoding steps and reveals model-specific behaviors. Furthermore, to fully leverage the extracted structure, we propose \textit{Gaussian-Trajectory Attribution (GTA)}, which fits a cell-wise Gaussian distribution at each decoding position for each model and uses log-likelihood differences between trajectories as the attribution score. Extensive experiments across diverse models, datasets and different model access assumptions validate the effectiveness of our approach.

How (Not) to Hybridize Neural and Mechanistic Models for Epidemiological Forecasting
Yiqi Su, Ray Lee, Jiaming Cui, Naren Ramakrishnan
Epidemiological forecasting from surveillance data is a hard problem and hybridizing mechanistic compartmental models with neural models is a natural direction. The mechanistic structure helps keep trajectories epidemiologically plausible, while neural components can capture non-stationary, data-adaptive effects. In practice, however, many seemingly straightforward couplings fail under partial observability and continually shifting transmission dynamics driven by behavior, waning immunity, seasonality, and interventions. We catalog these failure modes and show that robust performance requires making non-stationarity explicit: we extract multi-scale structure from the observed infection series and use it as an interpretable control signal for a controlled neural ODE coupled to an epidemiological model. Concretely, we decompose infections into trend, seasonal, and residual components and use these signals to drive continuous-time latent dynamics wh

ile jointly forecasting and inferring time-varying transmission, recovery, and i
mmunity-loss rates. Across early outbreak and multi-wave regimes, our approach a
ttains the lowest RMSE on all five datasets (up to 57% reduction over the strong
est baseline), predicts the peak within one time step on four of five, and recov
ers time-varying epidemiological rates within ground-truth ranges, without relyi
ng on auxiliary covariates.

On the Intrinsic Limits of Transformer Image Embeddings in Non-Solvable Spatial
Reasoning
Siyi Lyu, Quan Liu, Feng Yan
Vision Transformers (ViTs) excel in semantic recognition but exhibit systematic
failures in spatial reasoning tasks such as mental rotation.
While often attributed to data scale, this work argues that the limitation arise
s from the intrinsic circuit complexity of the architecture.
By formalizing spatial understanding as a **Group Homomorphism Problem**—where l
atent embeddings preserve the algebraic structure of physical transformations ac
ting on images—we identify a fundamental computational bottleneck.
Specifically, for non-solvable groups (e.g., $\mathrm{SO}(3)$), maintaining such
 structure-preserving embeddings is lower-bounded by the Word Problem, which is
$\mathsf{NC^1}$-complete.
In contrast, constant-depth ViTs with polynomial precision are strictly bounded
by the complexity class $\mathsf{TC^0}$.
Under the standard conjecture $\mathsf{TC^0} \subsetneq \mathsf{NC^1}$, a **comp
lexity boundary** emerges: constant-depth architectures lack the logical depth r
equired to capture non-solvable spatial structures in a single forward pass.
To empirically validate this theoretical gap, we propose the **Latent Space Alge
bra (LSA)** benchmark, which reveals a significant degradation in ViT representa
tions as the compositional depth of non-solvable tasks increases.

FusionCell: Cross-Attentive Fusion of Layout Geometry and Netlist Topology for S
tandard-Cell Performance Prediction
Haoyi Zhang, Kairong Guo, Bojie Zhang, Yibo Lin, Runsheng Wang
Standard cells form the building blocks of digital circuits, so their delay and
power critically influence chip-level performance; yet characterization (can be
understood as evaluation of cell delay and power) still relies on slow simulatio
n sweeps, and many fast predictors ignore layout geometry, missing coupling and
layout-dependent effects. The challenge is to jointly represent layout geometry
and netlist topology so models capture fine-grained spatial details together wit
h structural connectivity for accurate performance prediction. We introduce \tex
tbf{FusionCell}, a dual-modality predictor that treats routed layout geometry an
d netlist topology as inputs and fuses them explicitly in a unified model. A Dei
T encoder processes three-layer routed layouts, while a graph transformer models
 heterogeneous device/net graphs. The modalities are integrated through a \textb
f{topology-guided} mechanism, where the netlist acts as a structural ``map'' to
actively query relevant physical regions in the layout for joint geometric and t
opological reasoning. We build a 7nm dataset based on the ASAP7 PDK with over 19
.5k cells spanning 149 types using automatic tools, targeting six metrics: signa
l rise/fall delay, transition, and power. Experimental results demonstrate that
\textbf{FusionCell} reduces regression error (average MAPE 0.92\%) and improves
Spearman/Kendall ranking over baselines, while accelerating the characterization
 process by orders of magnitude compared to circuit simulation.
****
Decomposing Out-of-Distribution Error in Conditional Flow Matching via Wasserste
in Geometry
Long HC Pham
Conditional flow matching has emerged as a powerful generative modeling framewor
k that learns a vector field to transport an initial distribution toward a targe
t data distribution. However, theoretical understanding of its out-of-distributi
on (OOD) performance under unseen conditions remains limited. In this work, we e
stablish a rigorous geometric formulation to decompose the source of generalizat

ion error. We treat the conditional task as a map from the condition space to th
e Wasserstein space and derive a generalization bound under a coarse embedding a
ssumption. The resulting decomposition separates OOD error into three tractable
components: *Interpolation Sparsity*, *Geometric Distortion*, and *In-Distributi
on Fit*. Our empirical evaluation confirms that this framework demonstrates thre
e key functions: (1) it acts as a diagnostic tool that tracks the dynamics of ge
neralization during training; (2) it identifies dataset-specific failure modes (
e.g., topological gaps, geometric instability); and (3) it enables mathematicall
y motivated interventions that yield predictable gains by minimizing specific te
rms.

Distributional Alignment Games for Answer-Level Fine-Tuning
Mehryar Mohri, Jon Schneider, Yifan Wu
We focus on the problem of \emph{Answer-Level Fine-Tuning} (ALFT), where the
goal is to optimize a language model based on the correctness or properties of
its final answers, rather than the specific reasoning traces used to produce
them. Directly optimizing answer-level objectives is computationally
intractable due to the need to marginalize over the vast space of latent
reasoning paths. To overcome this, we propose a general game-theoretical
framework that lifts the problem to a *Distributional Alignment Game*. We
formulate ALFT as a two-player game between a Policy (the generator) and a
Target (an auxiliary distribution). We prove that the Nash Equilibrium of this
game corresponds exactly to the solution of the original answer-level
optimization problem. This variational perspective transforms the intractable
marginalization problem into a tractable projection problem. We demonstrate
that this framework unifies recent approaches to diversity and
self-improvement (coherence) and provide efficient algorithms compatible with
Group Relative Policy Optimization (GRPO), such as
Coherence-GRPO, yielding significant complexity gains in
mathematical reasoning tasks.
****

Attribution-Guided and Coverage-Maximized Pruning for Structural MoE Compression
Yifu Ding, jiacheng wang, Ge Yang, Yongcheng Jing, Jinyang Guo, Xianglong Liu, D
acheng Tao
Mixture-of-Experts (MoE) models scale compute efficiently, yet they remain expen
sive to deploy due to substantial memory footprint and inference overhead. Prior
 methods mainly operate at the expert level, either removing whole experts or ra
nking experts by importance. However, such expert-wise decisions are too coarse
to identify redundancy, and often misallocate pruning budgets and limits compres
sion. This issue worsens in large MoEs with dynamic routing and heterogeneous ex
perts. To alleviate this dilemma, we for the first time observe that information
 in MoE experts is highly concentrated in a few channels, leaving substantial re
dundancy even in "high importance" experts. Accordingly, we propose a structural
 pruning framework tailored for MoEs, reforming the prune-ratio objective to max
imizing channel-score coverage via an efficient attribution-based approximation.
 Experiments on DeepSeek and Qwen MoEs retain accuracy under 50\% or 25\% prunin
g joinly with 4-bit quantization, reducing the memory footprint of Qwen3-30B-A3B
 by 5.27$\times$, and outperforming state-of-the-art baselines under diverse ben
chmarks.

Sharp Empirical Bernstein Inequalities for the Variance of Bounded Random Variab
les
Diego Martinez-Taboada, Aaditya Ramdas
We develop novel "empirical Bernstein" inequalities for the variance of bounded
random variables. Our inequalities hold under constant conditional variance and
mean, without further assumptions like independence or identical distribution of
 the random variables, making them suitable for sequential decision making conte
xts. The results are instantiated for both the batch setting (where the sample s
ize is fixed) and the sequential setting (where the sample size is a stopping ti
me). Our bounds are asymptotically "sharp": when the data are iid, our CI adapts

optimally to both unknown mean μ and unknown $\mathbb{V}[(X-\mu)^2]$, meaning that the first order term of our CI exactly matches that of the oracle Bernstein inequality which knows those quantities. We compare our results to a widely used (non-sharp) concentration inequality for the variance based on self-bounding random variables, showing both the theoretical gains and improved empirical performance of our approach. We finally extend our methods to work in any separable Hilbert space.
****
STORM: Segment, Track, and Object Re-Localization from a Single Image
Yu Deng, Teng Cao, Hikaru Shindo, Quentin Delfosse, Jiahong Xue, Kristian Kersting
Accurate 6D pose estimation and tracking are core capabilities for physical AI systems, yet real-world deployment remains brittle and labor-intensive.
Many pipelines rely on CAD models, manual masking, or per-object adaptation, and still fail under occlusion or fast motion without a principled way to recognize failure.
We propose STORM, a unified framework for reference-conditioned 6D tracking that can operate from a single reference image, with minimal manual input and improved robustness.
STORM combines: (i) Hierarchical Spatial Fusion Attention (HSFA), a task-driven reference-query fusion architecture that supports both single-reference and multi-reference conditioning and can optionally use vision-language semantic conditioning to resolve instance ambiguities; and (ii) a BCE-trained tracking verifier whose continuous compatibility logit is used as an energy-like score to detect drift and trigger automatic re-initialization.
Experiments on LM-O and YCB-Video show that STORM improves annotation-free pose tracking accuracy over strong baselines and recovers reliably from severe occlusions and rapid viewpoint changes with minimal overhead.
****
Clustering in Deep Stochastic Transformers
Lev Fedorov, Michael Eli Sander, Romuald Elie, Pierre Marion, Mathieu Lauriere
Transformers have revolutionized deep learning across various domains but understanding the precise token dynamics remains a theoretical challenge. Existing theories of deep Transformers with layer normalization typically predict that tokens cluster to a single point; however, these results rely on deterministic weight assumptions, which fail to capture the standard initialization scheme in Transformers.
In this work, we show that accounting for the intrinsic stochasticity of random initialization alters this picture. More precisely, we analyze deep Transformers where noise arises from the random initialization of value matrices. Under diffusion scaling and token-wise RMS normalization, we prove that, as the number of Transformer layers goes to infinity, the discrete token dynamics converge to an interacting-particle system on the sphere where tokens are driven by a *common* matrix-valued Brownian noise. In this limit, we show that initialization noise prevents the collapse to a single cluster predicted by deterministic models. For two tokens, we prove a phase transition governed by the interaction strength and the token dimension: unlike deterministic attention flows, antipodal configurations become attracting with positive probability. Numerical experiments confirm the predicted transition, reveal that antipodal formations persist for more than two tokens, and demonstrate that suppressing the intrinsic noise degrades accuracy.
****
Think Less, Act Early: Reinforced Latent Reasoning with Early Exit in Vision-Language-Action Models
Dianqiao Lei, Lianlei Shan
Existing Vision-Language-Action (VLA) models predominantly rely on explicit Chain-of-Thought (CoT) reasoning to bridge perception and action. While effective, this paradigm suffers from high computational costs and error propagation in multi-step tasks. In this paper, we propose Adaptive Variable Alignment VLA (AVA-VLA), a novel Latent Reasoning VLA framework that models reasoning as a sequence of

unobservable latent variables, bypassing the need for explicit text generation. However, latent trajectories are inherently susceptible to noise interference and misalignment with downstream objectives. To address this, we introduce a Reinforcement Learning-based Denoising mechanism that treats latent state generation as a sequential decision process, optimizing reasoning trajectories via task-level rewards. Furthermore, we incorporate an Early-Exit Strategy that adaptively terminates reasoning based on state confidence, enabling a dynamic trade-off between depth and efficiency. Extensive experiments on embodied decision benchmarks demonstrate that AVA-VLA significantly reduces inference latency while achieving superior stability and success rates compared to full-reasoning baselines.
****

LRAgent: Efficient KV Cache Sharing for Multi-LoRA LLM Agents
Hyesung Jeon, Hyeongju Ha, Jae-Joon Kim
Role specialization in multi-LLM agent systems is often realized via multi-LoRA, where agents share a pretrained backbone and differ only through lightweight adapters.
Despite sharing base model weights, each agent independently builds and stores its own KV cache for the same long, tool-augmented trajectories, incurring substantial memory and compute overhead.
Existing KV cache sharing methods largely overlook this multi-LoRA setting.
We observe that, across agents, cache differences are dominated by adapter outputs, while activations from the shared pretrained backbone remain highly similar.
Based on this observation, we propose LRAgent, a KV cache sharing framework for multi-LoRA agents that decomposes the cache into a shared base component from the pretrained weights and an adapter-dependent component from LoRA weights.
LRAgent reduces memory overhead by sharing the base component and storing the adapter component in its inherent low-rank form, and further reduces compute overhead, enabled by shared-A multi-LoRA architectures, by also sharing the low-rank cache and avoiding redundant computations for contexts already processed by other agents.
To efficiently reconstruct adapter contributions at runtime, we introduce Flash-LoRA-Attention, a kernel that reorders attention computation to avoid materializing the low-rank cache to full dimension.
LRAgent achieves throughput and time-to-first-token latency close to fully shared caching, while preserving accuracy near the non-shared caching baseline across agentic question-answering benchmarks.

Recursive Monte-Carlo Tree Search
Benjamin Howard, Keith Frankston
We introduce a recursive AlphaZero style Monte--Carlo tree search algorithm, "RMCTS". It first generates the search tree using prior policies, and then recursively re-estimates action values by using the regularized optimal posterior policies from ``Monte--Carlo tree search as regularized policy optimization'' (Grill et al., 2020) at each node of the search tree, starting from the leaves and working back up to the root. We find that RMCTS matches or exceeds the quality of AlphaZero's MCTS-UCB in a tiny fraction of the time.
****

Beyond Independent Genes: Learning Module-Inductive Representations for Single-Cell Gene Perturbation Prediction
Jiafa Ruan, Ruijie Quan, Xu Liyang, Zongxin Yang, Yi Yang
Predicting transcriptional responses to genetic perturbations is a central problem in functional genomics.
In practice, perturbation responses are rarely gene-independent but instead manifest as coordinated, program-level transcriptional changes among functionally related genes.
However, most existing methods do not explicitly model such coordination, due to gene-wise modeling paradigms and reliance on static biological priors that cannot capture dynamic program reorganization.
To address these limitations, we propose scBIG, a module-inductive perturbation prediction framework that explicitly models coordinated gene programs. scBIG ind

uces coherent gene programs from data via Gene-Relation Clustering, captures inter-program interactions through a Gene-Cluster-Aware Encoder, and preserves modular coordination using structure-aware alignment objectives. These structured representations are then modeled using conditional flow matching to enable flexible and generalizable perturbation prediction.
Extensive experiments on multiple single-cell perturbation benchmarks show that scBIG consistently outperforms state-of-the-art methods, particularly on unseen and combinatorial perturbation settings, achieving an average improvement of 6.7% over the strongest baselines. The code is available at https://github.com/ttruan2426-dot/scBIG.
****

Set-Coupled Guidance: Set-Level Coordination in Diffusion-Based Dataset Distillation
Ziang Gan, Qi Zhu, Libao Zhang
Diffusion models serve as generative priors for dataset distillation, yet existing pipelines rely on per-sample update rules that evolve each synthetic image independently, limiting their ability to optimize collective set-level objectives. We propose Set-Coupled Guidance (SCG), a plug-and-play auxiliary controller that shifts from per-image to group (IPC-at-once) sampling by injecting set-symmetric feedback at each diffusion step. SCG combines spectral set-point regulation, which aligns set-level statistics to real data via empirical characteristic function matching, with cooperative kernel coupling that stabilizes joint trajectories under noisy feedback. All computations operate on lightweight descriptors extracted from predicted clean latents, adding low overhead to the base method. We provide theoretical analysis including Lyapunov descent and input-to-state stability for distributional tracking. Experiments on ImageNette, ImageWoof, ImageNet-100 and ImageNet-1K show consistent accuracy gains across multiple diffusion-based baselines; code is available at \url{https://github.com/tade1s/SCG}.

A proximal ADMM for multiblock problems with block anti-upper triangular constraints
Zhanwang Deng, Yuqiu Su, Wen Huang
In this paper, we present the convergence analysis of the proximal Alternating Direction Method of Multipliers (ADMM) for problems with block anti-upper triangular constraints.
While the linear constraints can be treated separately, most analyses of ADMM and its variants predominantly regard the linear constraints as one. Hence, it relies on assumptions related to the entire constraint matrix, such as the full column rank. However, some problems with block anti-upper triangular constraints that can be solved by ADMM do not satisfy these assumptions. To fill this gap, a new assumption is proposed and used to guarantee the global convergence of the proximal ADMM for nonconvex problems.
In the strongly convex setting, we also prove the global convergence of the proximal ADMM and establish the linear convergence under four different scenarios. This work extends the theoretical understanding of the multi-block ADMM to more general cases with block anti-upper triangular constraints.
****

Bridging the Gap Between Average and Discounted TD Learning
Haoxing Tian, Zaiwei Chen, Ioannis Paschalidis, Alex Olshevsky
The analysis of Temporal Difference (TD) learning in the average-reward setting faces notable theoretical difficulties because the Bellman operator is not contractive with respect to any norm. This complicates standard analyses of stochastic updates that are effective in discounted settings. Although a considerable body of literature addresses these challenges, existing theoretical approaches come with limitations. We introduce a novel algorithm designed explicitly for policy evaluation in the average-reward setting, utilizing sampling from two Markovian trajectories. Our proposed method overcomes previous limitations by guaranteeing convergence to the unique solution of a properly defined projected Bellman equation. Notably, and in contrast to earlier work, our convergence analysis is uniformly applicable to both linear function approximation and tabular settings and

does not involve explicit dimension-dependent terms in its convergence bounds. These results align with what is known to hold in the discounted setting. Furthermore, our algorithm achieves improved dependence on the problem's condition number, reducing the sample complexity from quartic, as in prior literature, to quadratic scaling, and thus matching the efficiency seen in the discounted setting.
****

NaviAgent: Graph■Driven Bilevel Planning for Scalable Tool Orchestration
Yan Jiang, Hao Zhou, Lizhong Gu, Tianlong Li, Ruinan Jin, Wanqi Zhou, Ai Han
Large Language Models (LLMs) increasingly act as function call agents that invoke external tools to tackle tasks beyond their static knowledge. However, they typically invoke tools one at a time without a global view of task structure. As tools often depend on one another, this leads to error accumulation and poor scalability, particularly when scaling to hundreds or thousands of tools. To address these limitations, we propose NaviAgent, an explicit bilevel architecture that decouples task planning from tool execution through graph■based modeling of tool relations. At the planning level, the LLM■based agent decides whether to respond directly, clarify intent, or retrieve and execute a toolchain independent of inter■tool complexity. At the execution level, a Tool World Navigation Model (TWNM) encodes structural and behavioral relations among tools, steering the agent to compose scalable and robust invocation sequences. Incorporating feedback from real tool interactions, NaviAgent achieves closed■loop alignment between planning and execution, enabling adaptive navigation in large■scale tool ecosystems. Evaluations on API-Bank and ToolBench show consistent improvements in task success rate (TSR), with TWNM yielding an average gain of 13.1 points on complex tasks. Further tests on 50 real APIs across 7 domains show consistent gains of 4.3-12.0 points, with fewer steps and latency, demonstrating robust generalization under real-world dynamics.

VJEPA: Variational Joint Embedding Predictive Architectures as Probabilistic World Models
Yongchao Huang
Joint Embedding Predictive Architectures (JEPAs) avoid pixel reconstruction by predicting latent representations, but standard formulations remain deterministic and provide limited uncertainty estimates for planning and control. We introduce \emph{Variational JEPA (VJEPA)}, a probabilistic extension that learns predictive distributions over future latent states using a latent-space variational objective, without autoregressive observation likelihoods. We show that VJEPA links JEPA-style self-supervised learning to predictive state representations and Bayesian filtering, and that its latent variables can serve as sufficient information states for control when they preserve task-relevant predictive information. We also propose \emph{Bayesian JEPA (BJEPA)}, which combines a learned dynamics expert with modular prior experts through a Product of Experts, enabling constraint-aware prediction and zero-shot prior swapping. Experiments on Noisy-TV systems, nonlinear and image-based benchmarks, STL-10 with a ViT encoder, and DMC Cheetah-run show that predictive JEPA-family objectives are more robust to high-variance nuisance distractors than reconstruction-based world-model baselines. These results position probabilistic latent prediction as a principled framework for robust, uncertainty-aware, reconstruction-free world models.

Generalizing Stochastic Smoothing for Differentiation and Gradient Estimation
Felix Petersen, Christian Borgelt, Aashwin Ananda Mishra, Stefano Ermon
We address the problem of gradient estimation for stochastic differentiable relaxations of algorithms, operators, simulators, and other non-differentiable functions. Stochastic smoothing conventionally perturbs the input of a non-differentiable function with a differentiable density distribution with full support, smoothing it and enabling gradient estimation. Our theory starts at first principles to derive stochastic smoothing with reduced assumptions, without requiring a differentiable density nor full support, and presenting a general framework for relaxation and gradient estimation of non-differentiable black-box functions f. We develop variance reduction for gradient estimation from 3 orthogonal perspect

ives. Empirically, we benchmark 6 distributions and up to 24 variance reduction strategies for differentiable sorting and ranking, differentiable shortest-paths on graphs, differentiable rendering for pose estimation, as well as differentiable cryo-electron tomography simulations.

Bioacoustic Geolocation: Species Sounds as Geographic Signals
Mustafa Chasmai, Wuao Liu, Subhransu Maji, Grant Van Horn
Can we determine someone’s geographic location solely from the sounds they hear? Are acoustic signals enough to localize within a country, state, or even city? In this work, we tackle the challenge of global-scale audio geolocation, with a particular focus on wildlife and natural sounds. We posit that bioacoustic signals contain informative geolocation cues because of well-defined geographic ranges of species. To test this hypothesis, we benchmark image geolocation and soundscape mapping methods, design oracles and species-centric baselines, and propose a hybrid approach that combines species range prediction with retrieval-based geolocation. We further ask whether geolocation improves with species-diverse recordings and spatiotemporal aggregation across neighboring samples. Finally, we extend our study to multimodal geolocation with case studies from movies that combine both audio and visual content. Our results highlight the potential of incorporating bioacoustic signals into geospatial tasks, motivating future work on species recognition and audio geolocation.

InvGNN: Learning Invertible Node Representations on Graphs
Giannis Nikolentzos, Dimitrios Kelesis, Nikolaos Nakis
Over the past decade, Graph Neural Networks (GNNs) have become a standard tool for solving machine learning problems on graphs. While many aspects of GNNs have been studied in depth, including their efficiency and expressive power, the invertibility of these models has remained largely unexplored. Standard aggregation functions, such as the mean, max and sum operators, are not invertible, which limits their applicability in tasks requiring invertible transformations. In this work, we introduce an invertible GNN layer. By stacking multiple such layers, we construct fully invertible GNN models, which we refer to as InvGNNs. These models inherit the benefits of invertible neural networks, including low memory usage for deep architectures, exact likelihood computation, and generative modeling capabilities. We demonstrate that InvGNNs can match the expressive power of the 1-dimensional Weisfeiler-Leman algorithm, showing that invertibility does not compromise model expressiveness. On standard graph classification benchmarks, our model performs comparably to other well-established GNNs. Beyond classification, we demonstrate the potential of invertible layers through density estimation tasks, including outlier detection and node feature generation.

Plan, Decouple, Assimilate: Physics-Aware Object Insertion in Remote Sensing Imagery
Yingyan Hou, Xianchi Dong, Chao Ren, Wanxuan Lu, Zihan Wei, Hongfeng Yu, Yixiao Wang, Xian Sun
Object insertion has emerged as a promising augmentation paradigm for the label scarcity and long-tailed distributions in remote sensing, generating training samples by synthesizing target instances onto real backgrounds. However, existing methods suffer from three critical issues: (i) semantic placement inconsistency, (ii) radiometric inconsistency with illumination and atmospheric conditions, and (iii) textural discontinuity. To address these, we propose a physics-aware method, "Plan, Decouple, Assimilate" (PDA), for generating high-fidelity training samples. In the planning stage, the Planning (P) module automatically generates geometrically valid bounding boxes. In the generation stage, a dual-module design synthesizes the target instance: the Decoupling (D) module employs Asymmetric Spectral Adaptation to disentangle structural identity from environmental illumination, while the Assimilation (A) module uses Neighborhood-Aware Texture Assimilation to harmonize the local manifold. By integrating these modules, PDA enforces multi-level consistency from global geometry to local micro-textures. Extensive experiments verify that PDA outperforms state-of-the-art methods in generative

quality, reducing whole-image FID by 15.7% over the strongest baseline, and substantially improves downstream detection, boosting average mAP50 by +17.07 points over the real data.

SafeLab: An Interactive High-Fidelity Benchmark for Embodied Safety in Scientific Robotics
Fengshuo Bai, Yufeng Li, Ruihai Wu, Peishuo Wang, Yuhan Wang, Bernie Hao Zhu, Yuanfei Wang, Tawei Chou, Jing Gao, Runchuan Zhu, Ying Wen, Yaodong Yang, Yuanpei Chen
Scientific embodied agents could automate laboratory workflows, but laboratory success is trajectory-level: an agent must remain safe throughout execution, not merely reach a final goal. In benchtop settings a small pose, force, or tilt error can cause irreversible spillage or equipment damage, yet most robot benchmarks evaluate reversible, high-tolerance manipulation and imitation-trained policies receive no recovery signal for execution drift. We introduce SafeLab, a generative simulation benchmark that couples a verified generative engine, an automated expert for teleoperation-free demonstrations, and a safety-aware RL interface, with 63 calibrated laboratory assets, 64 tasks across 9 manipulation categories, and 6,400 expert trajectories. Across state-of-the-art policies, it reveals unsafe-but-successful trajectories—large gaps between task success and Safe Success Rate—most acutely in liquid handling, force-limited actuation, and bimanual glassware rearrangement. Bounded residual RL then learns execution-level corrections that raise the simulated Safe Success Rate by up to 43.0 percentage points without retraining the base policy. Finally, 50 open-loop physical replays show 86% agreement between simulated and observed safety outcomes, supporting SafeLab as a scalable platform for screening and training safer laboratory agents.

$\mathcal{O}(\log N)$ Latent Dimension Suffices for Universal Approximation of Permutation-invariant Function
Min ZHOU, Enming Liang, Minghua Chen
Learning permutation-invariant functions over sets of N elements, where the output is independent of the input ordering, is fundamental to many deep learning applications. While sum-decomposable architectures like DeepSets offer universal approximation for such functions, existing constructive bounds require a latent dimension of $\mathcal{O}(N)$, posing a significant scalability bottleneck. We break this barrier for *Wasserstein-stable* functions, i.e., those that are Lipschitz continuous with respect to the Wasserstein-1 metric on input distributions. We constructively prove that a latent dimension of $\mathcal{O}\left(C_D\varepsilon^{-(3D+4)}\log(N+\varepsilon^{-D})\right)$ suffices for uniform approximation as $ \varepsilon\to 0 $, where D is the element dimension and C_D is a constant depending only on D. We first discretize the input space into a finite net of measures with covering number polynomial in N. We then embed it via a multiscale Random Fourier Feature encoder that guarantees both Lipschitz stability and Hölder separation. Finally, we recover the target function via a McShane-extended Hölder decoder. This result advances the theoretical understanding of the expressivity and scalability of set-based neural architectures.

One Bug, Hundreds Behind: LLMs for Large-Scale Bug Discovery
Qiushi Wu, Yue Xiao, Dhilung Kirat, Kevin Eykholt, Jiyong Jang, Douglas Lee Schales
Recurring Pattern Bugs (RPBs) are defined as bugs where a single root cause appears repeatedly across multiple code segments. These bugs remain a persistent security threat even after individual instances are patched. Various static analyzers exist for finding specific bug patterns but require significant engineering effort and fail to generalize well beyond their predefined template, preventing them from detecting RPBs. To tackle RPBs, we introduce BugStone, a hybrid framework combining LLVM-based program analysis with Large Language Models to automate RPB detection. BugStone leverages a single patched instance to synthesize abstract error patterns and retrieves semantically similar bugs throughout the codebase. To evaluate BugStone, we create a ground truth dataset by analyzing over 1.9

K security bugs reports, on which BugStone achieves 92.2% precision and 79.1% p
airwise accuracy. We further validated BugStone through a large-scale real-world
 deployment. In the Linux kernel, BugStone identified over 22K potential issues;
 a manual audit of 400 samples confirmed 246 valid bugs, including invalid point
er dereferences, resource leaks, type errors, performance issues, and others. To
 evaluate the generalizability of BugStone, we further applied it to the top 100
 Python projects, discovering multiple critical command injection vulnerabilitie
s.

On the Epistemic Uncertainty of Overparametrized Neural Networks
David Rügamer
Epistemic uncertainty is often viewed as a reducible uncertainty that vanishes w
ith increasing data. This perspective implicitly assumes parameter identifiabili
ty and equates epistemic uncertainty with predictive variability. In overparamet
rized neural networks, however, model parameters are typically non-identifiable
due to symmetries and redundant representations. As a consequence, substantial p
arameter uncertainty can persist even when the underlying function is fully iden
tified. In this work, we analyze epistemic uncertainty through the lens of non-i
dentifiability and characterize both discrete and continuous sources of residual
 uncertainty. Focusing on one-hidden-layer ReLU networks, we thoroughly analyze
the resulting posterior structure and validate our theoretical insights through
empirical studies.

Mirror Descent Actor Critic via Bounded Advantage Learning
Ryo Iwaki
Regularization is a core component of recent Reinforcement Learning (RL) algorit
hms. Mirror Descent Value Iteration (MDVI) uses both Kullback-Leibler divergence
 and entropy as regularizers in its value and policy updates. Despite its empiri
cal success in discrete action domains and strong theoretical guarantees, the pe
rformance of KL-entropy-regularized methods does not surpass that of a strong en
tropy-only-regularized method in continuous action domains. In this study, we pr
opose Mirror Descent Actor Critic (MDAC) as an actor-critic style instantiation
of MDVI for continuous action domains, and show that its empirical performance i
s significantly boosted by bounding the actor's log-probability terms in the cri
tic's loss function, compared to a non-bounded naive instantiation. Further, we
relate MDAC to Advantage Learning by recalling that the actor's log-probability
is equal to the regularized advantage function in tabular cases, and theoretical
ly discuss when and why bounding the advantage terms is validated and beneficial
. We also empirically explore effective choices for the bounding functions, and
show that MDAC performs better than strong non-regularized and entropy-only-regu
larized methods with an appropriate choice of the bounding functions.

Latent Representation Alignment for Offline Goal-Conditioned Reinforcement Learn
ing
Hyungkyu Kang, Byeongchan Kim, Min-hwan Oh
Offline goal-conditioned reinforcement learning (GCRL) provides a practical fram
ework for obtaining goal-reaching policies from fixed datasets.
  However, learning a reliable goal-conditioned value function in long-horizon t
asks remains challenging.
  In this paper, we identify erroneous generalization in goal-conditioned value
functions as a fundamental bottleneck, and demonstrate that appropriate inductiv
e bias in the value function is crucial for addressing the bottleneck.
  Building on these findings, we propose Latent-Aligned Value Learning (LAVL), a
n offline GCRL algorithm that integrates latent-representation-based value gener
alization with hierarchical planning in a unified framework.
  Extensive numerical experiments on OGBench demonstrate that LAVL consistently
outperforms existing offline GCRL methods, achieving the highest performance on
20 out of 22 datasets.
  Notably, LAVL exhibits strong performance in long-horizon tasks and trajectory
 stitching datasets, where prior methods suffer significant performance degradat

ion.

Geometrically Constrained Outlier Synthesis
Daniil Karzanov, Marcin Detyniecki
Deep neural networks for image classification often exhibit overconfidence on ou t-of-distribution (OOD) samples. To address this, we introduce Geometrically Con strained Outlier Synthesis (GCOS), a training-time regularization framework aime d at improving OOD robustness during inference. GCOS addresses a limitation of p rior synthesis methods by generating virtual outliers in the hidden feature spac e that respect the learned manifold structure of in-distribution (ID) data. The synthesis proceeds in two stages: (i) a dominant-variance subspace extracted fro m the training features identifies geometrically informed, off-manifold directio ns; (ii) a conformally-inspired shell, defined by the empirical quantiles of a n onconformity score from a calibration set, adaptively controls the synthesis mag nitude to produce boundary samples. The shell ensures that generated outliers ar e neither trivially detectable nor indistinguishable from in-distribution data, facilitating smoother learning of robust features. This is combined with a contr astive regularization objective that promotes separability of ID and OOD samples in a chosen score space, such as Mahalanobis or energy-based. Experiments demon strate that GCOS outperforms state-of-the-art methods using standard energy-base d inference on near-OOD benchmarks, defined as tasks where outliers share the sa me semantic domain as in-distribution data. As an exploratory extension, the fra mework naturally transitions to conformal OOD inference, which translates uncert ainty scores into statistically valid p-values and enables thresholds with forma l error guarantees, providing a pathway toward more predictable and reliable OOD detection.

When Does Predictive Inverse Dynamics Outperform Behavior Cloning?
Lukas Schäfer, Pallavi Choudhury, Abdelhak Lemkhenter, Chris Lovett, Somjit Nath , Luis França, Matheus Ribeiro Furtado de Mendonça, Alex Lamb, Riashat Islam, Si ddhartha Sen, John Langford, Katja Hofmann, Sergio Valcarcel Macua
Behavior cloning (BC) is a practical offline imitation learning method, but it o ften fails when expert demonstrations are limited. Recent works have introduced a class of architectures named predictive inverse dynamics models (PIDM) that co mbine a future state predictor with an inverse dynamics model. While PIDM often outperforms BC, the reasons behind its benefits remain unclear. In this paper, w e provide a theoretical explanation: PIDM introduces a bias-variance tradeoff. W hile predicting the future state introduces bias, conditioning the IDM on the pr ediction can significantly reduce variance. We establish conditions for PIDM to achieve lower prediction error and higher sample efficiency than BC, with the ga p widening when additional data sources are available. We validate the theoretic al insights empirically in 2D navigation tasks, where BC requires up to five tim es (three times on average) more demonstrations than PIDM to reach comparable pe rformance. Results are also illustrated in a complex 3D environment in a modern video game with high-dimensional visual inputs and stochastic transitions, where BC requires over 66\% more samples than PIDM.

Newton-coupled Dual-Teacher Semi-supervised Learning Framework
Hongyang He, Xinyuan Song, Yan Zhong, Daizong Liu, Xuanyu Liu, Victor Sanchez
Most semi-supervised learning frameworks rely on a single teacher that transfers zero-order supervision through pseudo-labels, constraining the student to imita te categorical outputs without perceiving the loss geometry. This design often l eads to unstable optimization and limited generalization under scarce labels. We propose TTN (Two-Teachers Newton-guided Learning), a dual-teacher framework tha t integrates complementary supervision from MAE and DINOv3 and optimizes the stu dent through a Newton step update. The two teachers provide multi-scale structur al and semantic cues whose pseudo-labels and local Hessians are fused by confide nce weighting, forming a unified second-order supervision signal. The student up dates parameters preconditioned by the fused curvature, enabling stable converge nce and geometry-consistent learning. TTN consistently improves over existing si

ngle-teacher and consistency-based semi-supervised learning methods on ImageNet, CIFAR-10, SVHN, and STL-10, demonstrating that combining multi-view self-supervised teachers with curvature-guided optimization yields robust and efficient semi-supervised learning.

From Holo Pockets to Electron Density: GPT-style Drug Design with Density
Jiahao Chen, Letian Gao, Yanhao Zhu, Wenbiao zhou, Bing Su, Zhi John Lu, Bo Huang
Recent advances in generative modeling have enabled significant progress in structure-based drug design (SBDD). Existing methods typically condition molecule generation on empty binding pockets from holo complexes, overlooking informative components such as the filler (ligands and solvent). Here, we leverage low-resolution electron density (ED) derived from the filler as a physically grounded condition for \textit{de novo} drug design. We consider two types of ED—calculated and cryo-EM/X-ray—obtainable from computational or experimental sources, supporting unified pre-training and experimental integration. Compared with rigid pocket representations, experimental ED naturally captures conformational flexibility and provides a more faithful description of the binding environment. Based on this, we introduce EDMolGPT, a decoder-only autoregressive framework that generates molecules from low-resolution ED point clouds. By grounding generation in physically meaningful density signals, EDMolGPT mitigates structural bias and produces molecules with 3D conformations. Evaluations on 101 biological targets verify the effectiveness. Our project page: \url{https://jiahaochen1.github.io/EDMolGPT_Page/}.

Active Tabular Augmentation via Policy-Guided Diffusion Inpainting
Zheyu Zhang, Shuo Yang, Bardh Prenkaj, Gjergji Kasneci
Generative tabular augmentation is appealing in data-scarce domains, yet the prevailing focus on distributional fidelity does not reliably translate into better downstream models. We formalize a *fidelity-utility gap*: common generative objectives prioritize distributional plausibility, whereas augmentation succeeds only when injected samples reduce the current learner's held-out evaluation loss. This gap motivates learning not just how to generate, but what to generate and when to inject as training evolves. We propose TAP (Tabular Augmentation Policy), which couples diffusion inpainting with a lightweight, learner-conditioned policy to steer generation toward high-utility regions and controls safe injection via explicit gating and conservative windowed commitment. Under severe data scarcity, TAP consistently outperforms strong generative baselines on seven real-world datasets, improving classification accuracy by up to 15.6 percentage points and reducing regression RMSE by up to 32%.

Q-Flow: Stable and Expressive Reinforcement Learning with Flow-based Policy
JaeHyeok Doo, Byeongguk Jeon, Seonghyeon Ye, Kimin Lee, Minjoon Seo
There is growing interest in utilizing flow-based models as decision-making policies in reinforcement learning due to their high expressive capacity. However, effectively leveraging this expressivity for value maximization remains challenging, as naive gradient-based optimization requires backpropagating through numerical solvers and often leads to instability. Existing approaches typically address this issue by restricting the expressive capacity of flow-based policies, resulting in a trade-off between optimization stability and representational flexibility. To resolve this, we introduce **Q-Flow**, a framework that leverages the deterministic nature of flow dynamics to explicitly propagate terminal trajectory value to intermediate latent states along the policy-induced flow. This formulation enables stable policy optimization using intermediate value gradients without unrolling the numerical solver, effectively bridging the gap between stability and expressivity. We evaluate Q-Flow in the offline learning setting on the challenging OGBench suite, where it consistently outperforms state-of-the-art baselines by an average of *10.6* percentage points, while also enabling stable online adaptation within the same framework.
****

A recipe for scalable attention-based ML potentials: unlocking long-range accuracy with all-to-all node attention
Eric Qu, Brandon M. Wood, Aditi S. Krishnapriyan, Zachary Ward Ulissi
Machine-learning interatomic potentials (MLIPs) have advanced rapidly, with many top models relying on strong physics-based inductive bias. However, as models scale to larger systems like biomolecules and electrolytes, they struggle to accurately capture long-range (LR) interactions, leading current approaches to rely on explicit physics-based terms or components.
In this work, we propose AllScAIP, a straightforward, attention-based, and energy-conserving MLIP model that scales to O(100 million) training samples. It addresses the long-range challenge using an all-to-all node attention component that is purely data-driven. Extensive ablations reveal that in low-data/small-model regimes, inductive biases improve sample efficiency. However, as data and model size scale, these benefits diminish or even reverse, while all-to-all attention remains critical for capturing LR interactions. Our model achieves state-of-the-art energy/force accuracy on molecular systems (OMol25), while being competitive on materials (OMat24) and catalysts (OC20).
Furthermore, it enables stable, long-timescale MD simulations that accurately recover experimental observables, including density and heat of vaporization predictions.

Wait, Wait, Wait... Why Do Reasoning Models Loop?
Charilaos Pipis, Shivam Garg, Vasilis Kontonis, Vaishnavi Shrivastava, Akshay Krishnamurthy, Dimitris Papailiopoulos
Reasoning models (e.g., DeepSeek-R1) generate long chains of thought to solve harder problems, but they often loop, repeating the same text at low temperatures or with greedy decoding. We study why this happens and what role temperature plays. With open reasoning models, we find that looping is common at low temperature. Larger models tend to loop less, and distilled students loop significantly even when their teachers rarely do. This points to mismatches between the training distribution and the learned model, which we refer to as errors in learning, as a key cause. To understand how such errors cause loops, we introduce a synthetic graph reasoning task and demonstrate two mechanisms. First, risk aversion caused by hardness of learning: when the correct progress-making action is hard to learn but an easy cyclic action is available, the model puts relatively more probability on the cyclic action and gets stuck. Second, even when there is no hardness, Transformers show an inductive bias toward temporally correlated errors, so the same few actions keep being chosen and loops appear. Higher temperature reduces looping by promoting exploration, but it does not fix the errors in learning, so generations remain much longer than necessary at high temperature; in this sense, temperature is a stopgap rather than a holistic solution. We end with a discussion of training-time interventions aimed at directly reducing errors in learning.
****
Is Your Diffusion Sampler Actually Correct? A Sampler-Centric Evaluation of Discrete Diffusion Language Models
Luhan Tang, Longxuan Yu, Shaorong Zhang, Greg Ver Steeg
Discrete diffusion language models (dLLMs) provide a fast and flexible alternative to autoregressive models (ARMs) via iterative denoising with parallel updates. However, their evaluation is challenging: existing metrics conflate denoiser approximation error with sampler-induced error from the sampling dynamics, a problem that does not arise for ARMs whose autoregressive sampling exactly reflects the learned probability model. We introduce a sampler-centric oracle framework that replaces learned denoisers with an exact Hidden Markov Model posterior derived from a ground-truth Markov chain, isolating sampler-induced error in a controlled setting. We show that few-step discrete diffusion samplers are not distributionally correct even under an oracle denoiser, with transition-level mismatch that vanishes only as the number of steps approaches the sequence length. Moreover, improvements in negative log-likelihood (NLL), generative perplexity (GenPPL), or MAUVE do not imply correct sampling. Code is available at https://luhantang

.github.io/dllm_sampler/.

RAIGen: Rare Attribute Identification in Text-to-Image Generative Models
Silpa Vadakkeeveetil Sreelatha, Dan Wang, Serge Belongie, Muhammad Awais, Anjan Dutta
Text-to-image diffusion models achieve impressive generation quality but inherit and amplify training-data biases, skewing coverage of semantic attributes. Prior work addresses this in two ways. Closed-set approaches mitigate biases in predefined fairness categories (e.g., gender, race), assuming socially salient minority attributes are known a priori. Open-set approaches frame the task as bias identification, highlighting majority attributes that dominate outputs. Both overlook a complementary task: uncovering rare or minority features underrepresented in the data distribution (social, cultural, or stylistic) yet still encoded in model representations. We introduce RAIGen, the first framework, to our knowledge, for label-free rare-attribute discovery in diffusion models, requiring no predefined minority categories. RAIGen leverages Matryoshka Sparse Autoencoders and a novel minority metric combining neuron activation frequency with semantic distinctiveness to identify interpretable neurons whose top-activating images reveal underrepresented attributes. Experiments show RAIGen discovers attributes beyond fixed fairness categories in Stable Diffusion, scales to larger models such as SDXL, supports systematic auditing across architectures, and enables targeted amplification of rare attributes during generation. The project page is available at https://vssilpa.github.io/RAIGen_webpage/.

Branching Diffusion for Point Processes in Time and Space
Chao Yang, Wenjie Shen, Shuang Li
We propose a non-autoregressive branching diffusion model for generating spatio-temporal point processes.
Starting from a geometric principle---the Wasserstein-Fisher-Rao (WFR) gradient flow of a generalized KL divergence toward a simple reference intensity---we obtain a tractable forward noising mechanism with two interpretable components:
(i) a Langevin-type \emph{drift-diffusion} step that perturbs event locations and times, and
(ii) a \emph{birth-death branching} step that changes the event count via location-dependent thinning (deaths) and Poisson offspring replication (births).
We learn the reverse-time dynamics using a permutation-equivariant denoiser that predicts a drift field and a net-growth field, and we train it using an entropic-regularized unbalanced optimal transport (UOT), which naturally handles count mismatch between noisy and clean samples.
The resulting generator produces complete spatio-temporal event sets without autoregressive simulation or explicit intensity normalization.

Unveiling the Potential of Quantization with MXFP4: Strategies for Quantization Error Reduction
Jatin Chhugani, Geonhwa Jeong, Bor-Yiing Su, Yunjie Pan, Hanmei Yang, Aayush Ankit, Jiecao Yu, Summer Deng, Yunqing Chen, Nadathur Satish, Changkyu Kim
Large Language Models (LLMs) have intensified the need for low-precision formats for efficient inference. The Open Compute Project Microscaling (MX) standard is attractive due to its favorable hardware efficiency, but its 4-bit variant (MXFP4) lags behind NVIDIA’s NVFP4 in accuracy, limiting adoption. We introduce two software-only techniques, Overflow-Aware Scaling (OAS) and Macro Block Scaling (MBS), that improve MXFP4 quantization fidelity without requiring hardware changes. OAS reduces overall errors by increasing effective dynamic range under power-of-two block scaling, while MBS allocates higher-precision scaling at a coarser granularity to better preserve outliers. Across multiple LLMs and standard downstream benchmarks, OAS and MBS reduce the end-to-end accuracy gap between MXFP4 and NVFP4 from about 10% to below 1% on average, while incurring modest GEMM overhead (6.2% on average). These results re-establish MXFP4 as a practical alternative to NVFP4, enabling near-NVFP4 accuracy while retaining MX’s hardware-efficiency advantages (e.g., 12% relative area savings in tensor cores).

TwinWeaver: An LLM-Based Foundation Model Framework for Pan-Cancer Digital Twins
Nikita Makarov, Maria Bordukova, Lena Voith von Voithenberg, Estrella Pivel-Villanueva, Sabrina J Mielke, Jonathan Wickes, Hanchen Wang, Mingyu Derek Ma, Keunwoo Choi, Kyunghyun Cho, Stephen Ra, Raul Rodriguez-Esteban, Fabian Schmich, Michael Patrick Menden
Precision oncology requires forecasting clinical events and trajectories, yet modeling sparse, multi-modal clinical time series remains a critical challenge. We introduce TwinWeaver, an open-source framework that serializes longitudinal patient histories into text, enabling unified event prediction as well as forecasting with large language models, and use it to build Genie Digital Twin (GDT) on 93,054 patients across 20 cancer types.
In benchmarks, GDT significantly reduces forecasting errors, achieving a median Mean Absolute Scaled Error (MASE) of 0.87 compared to 0.97 for the strongest time-series baseline ($p<0.001$). Furthermore, GDT improves risk stratification, achieving an average concordance index (C-index) of 0.703 across survival, progression, and therapy switching tasks, surpassing the best baseline of 0.662. GDT also generalizes to out-of-distribution clinical trials, matching trained baselines at zero-shot and surpassing them with fine-tuning, achieving a median MASE of 0.75–0.88 and outperforming the strongest baseline in event prediction with an average C-index of 0.672 versus 0.648. Finally, TwinWeaver enables an interpretable clinical reasoning extension, providing a scalable and transparent foundation for longitudinal clinical modeling.

Probing the Geometry of Diffusion Models with the String Method
Elio Moreau, Florentin Coeurdoux, Grégoire Ferré, Eric Vanden-Eijnden
Understanding the geometry of learned distributions is fundamental to improving and interpreting diffusion models, yet systematic tools for exploring their landscape remain limited. Standard latent-space interpolations fail to respect the structure of the learned distribution, often traversing low-density regions. We introduce a framework based on the string method that computes continuous paths between samples by evolving curves under the learned score function. Operating on pretrained models without retraining, our approach interpolates between three regimes: pure generative transport, which yields continuous sample paths; gradient-dominated dynamics, which recover minimum energy paths (MEPs); and finite-temperature string dynamics, which compute principal curves---self-consistent paths that balance energy and entropy. We demonstrate that the choice of regime matters in practice. For image diffusion models, MEPs contain high-likelihood but unrealistic ``cartoon'' images, confirming prior observations that likelihood maxima appear unrealistic; principal curves instead yield realistic morphing sequences despite lower likelihood. For protein structure prediction, our method computes transition pathways between metastable conformers directly from models trained on static structures, yielding paths with physically plausible intermediates. Together, these results establish the string method as a principled tool for probing the modal structure of diffusion models---identifying modes, characterizing barriers, and mapping connectivity in complex learned distributions.

ETS: Energy-Guided Test-Time Scaling for Training-Free RL Alignment
Xiuyu Li, Jinkai Zhang, Mingyang Yi, Yu Li, Longqiang Wang, Yue Wang, Ju Fan
Reinforcement Learning (RL) post-training alignment for language models is effective, but also costly and unstable in practice, owing to its complicated training process. To address this, we propose a training-free inference method to sample directly from the optimal RL policy. The transition probability applied to Masked Language Modeling (MLM) consists of a reference policy model and an energy term. Based on this, our algorithm, Energy-Guided Test-Time Scaling (ETS), estimates the key energy term via online Monte Carlo, with a provable convergence rate. Moreover, to ensure practical efficiency, ETS leverages modern acceleration frameworks alongside tailored importance sampling estimators, substantially reducing inference latency while provably preserving sampling quality.
Experiments on MLM (including autoregressive models and diffusion language model

s) across reasoning, coding, and science benchmarks show that our ETS consistently improves generation quality, validating its effectiveness and design.
The code is available at https://github.com/sheriyuo/ETS.

Compute as Teacher: Turning Inference Compute Into Reference-Free Supervision
Dulhan Jayalath, Shashwat Goel, Thomas Foster, Parag Jain, Suchin Gururangan, Cheng Zhang, Anirudh Goyal, Alan Schelten
Where do learning signals come from when there is no ground truth in post-training? We show that inference compute itself can serve as supervision. By generating parallel rollouts and converting them into reference estimates, models can learn without human labels—critically, even in non-verifiable domains like healthcare guidance where no programmatic checker exists. We call this framework *Compute as Teacher (CaT)* and it turns inference-time compute from parallel rollouts into supervision for RL training. The framework has two components: (1) reference estimation which aggregates rollouts into a pseudo-reference answer, and (2) reward derivation which converts that pseudo-reference into RL rewards. For (1), we explore a simple method we call *synthesis*, but the framework admits any aggregator. For (2), we introduce self-proposed rubrics for non-verifiable domains. These are binary, auditable criteria generated from the pseudo-reference and scored by an LLM judge. On HealthBench, models trained with CaT match or exceed inference-time aggregation quality while using 9× less test-time compute. Here, CaT also competes with learning from expert physician annotations, yielding up to +30% relative improvement over the initial policy. The framework extends naturally to verifiable rewards, matching the best existing baselines on MATH-500 in test-time RL and demonstrating 'drop-in' versatility across both types of domains.

Randomized Advantage Transformation (RAT): Computing Natural Policy Gradients via Direct Backpropagation
Mingfei Sun
Natural policy gradients improve optimization by accounting for the geometry of distribution space, but their practical use is limited by the cost of estimating and inverting the Fisher matrix. We present Randomized Advantage Transformation (RAT), a method for estimating Tikhonov-regularized natural policy gradients via direct backpropagation. By applying the Woodbury formula, we reformulate the regularized natural gradient as vanilla policy gradients with a transformed advantage. RAT computes this transformation efficiently via randomized block Kaczmarz iterations on on-policy mini-batches, avoiding explicit Fisher construction, conjugate-gradient solvers, and architecture-specific approximations. We provide convergence guarantees for RAT and demonstrate empirically that it matches or exceeds established natural-gradient methods across continuous and visual control benchmarks, while remaining simple to implement and compatible with various architectures.

Hard labels sampled from sparse targets mislead rotation invariant algorithms
Avrajit Ghosh, Bin Yu, Manfred K Warmuth, Peter Bartlett
One of the most common machine learning setups is logistic regression. In many classification models, including neural networks, the final prediction is obtained by applying a logistic link function to a linear score. In binary logistic regression, the feedback can be either soft labels, corresponding to the true conditional probability of the data (as in distillation), or sampled hard labels (taking values ± 1). We point out a fundamental problem that arises even in a particularly favorable setting, where the goal is to learn a noise-free soft target of the form $\sigma(\mathbf{x}^{\top}\mathbf{w}^{\star})$. In the over-constrained case (i.e. the number of samples n exceeds the input dimension d) with examples $(\mathbf{x}_i,\sigma(\mathbf{x}_i^{\top}\mathbf{w}^{\star}))$, it is sufficient to recover $\mathbf{w}^{\star}$ and hence achieve the Bayes risk. However, we prove that when the examples are labeled by hard labels y_i sampled from the same conditional distribution $\sigma(\mathbf{x}_i^{\top}\mathbf{w}^{\star})$ and $\mathbf{w}^{\star}$ is s-sparse, then rotation-invariant algorithms are provably suboptimal: they incur an excess risk $\Omega\!\left(\frac{d-1}{n

}\right)$, while there are simple non-rotation invariant algorithms with excess risk $O(\frac{s\log d}{n})$. The simplest rotation invariant algorithm is gradient descent on the logistic loss (with early stopping). A simple non-rotation-invariant algorithm for sparse targets that achieves the above upper bounds uses gradient descent on the weights u_i,v_i, where now the linear weight w_i is reparameterized as u_iv_i.

TRACER: Trajectory Risk Aggregation for Critical Episodes in Agentic Reasoning
Sina Tayebati, Divake Kumar, Nastaran Darabi, Davide Ettori, Ranganath Krishnan, Amit Ranjan Trivedi
Estimating uncertainty for AI agents in real-world multi-turn tool-using interaction with humans is difficult because failures are often triggered by sparse critical episodes (e.g., looping, incoherent tool use, or user-agent miscoordination) even when local generation appears confident. Existing uncertainty proxies focus on single-shot text generation and therefore miss these trajectory-level breakdown signals. We introduce TRACER, a trajectory-level uncertainty metric for dual-control Tool-Agent-User interaction. TRACER combines content-aware surprisal with situational-awareness signals, semantic and lexical repetition, and tool-grounded coherence gaps, and aggregates them using a tail-focused risk functional with a MAX-composite step risk to surface decisive anomalies.
We evaluate TRACER on τ^2-bench (Barres et al., 2025) by predicting task failure and selective task execution. To this end, TRACER improves AUROC by up to 37.1\% and AUARC by up to 55\% over baselines, enabling earlier and more accurate detection of uncertainty in complex conversational tool-use settings. Our code base is available at: https://github.com/sinatayebati/agent-tracer.

ScaleMoE: Mixture-of-Experts for Scalable Continuous Control in Actor-Critic Reinforcement Learning
Yi Ma, Chenjun Xiao, Hongyao Tang, Yaodong Yang, Jinyi Liu, Jing Liang, Jiye Liang
Scaling network remains a bottleneck in deep reinforcement learning (RL): simply enlarging actor–critic networks destabilizes training and soon saturates performance. Although recent monolithic architectures such as SimBa and BRC have shown that carefully designed inductive biases can enable positive scaling up to a certain size, their improvements plateau soon as model parameters grow further. This work introduces ScaleMoE, a scalable RL architecture that integrates Mixture-of-Experts (MoE) modules into both the actor and critic of modern continuous control algorithms. Two complementary gating schemes are studied: output-level aggregation of per-expert policies and Q-functions, and feature-level fusion of expert representations before a shared head. We instantiate ScaleMoE on two representative monolithic RL baselines: the single-task method SimBa and the multi-task method BRC. Experiments across the DeepMind Control Suite, MetaWorld, and HumanoidBench show that progressively increasing the number of experts (up to 64) yields substantial improvements in returns, significantly outperforming monolithic networks of comparable or even greater parameter counts. Results demonstrate that ScaleMoE provides an efficient and effective scaling axis for deep RL in continuous control.

Joint Navigation and Manipulation Planning with 3D Interaction Chains
Keming Zhang, Sixian Zhang, Xinhang Song, Hongyu Wang, Yiyao Wang, Yingjie Wang, Shuqiang Jiang
Open-vocabulary mobile manipulation (OVMM) requires long-horizon navigation in unseen environments and object-centric manipulation. Most existing methods treat navigation and manipulation as separate stages, which can yield navigation endpoints that are poor for manipulation or manipulation-friendly poses that are globally inefficient.
We address this mismatch with 3D Interaction Chains (3D-IC), a unified framework that couples multi-stage navigation and manipulation planning. 3D-IC maintains a shared 3D feature map for both skills, generates stage-aligned interaction waypoints, and links them into candidate multi-stage chains. A hierarchical policy

then scores these chains by jointly considering feasibility (via VLM reasoning o
ver waypoint-centric 3D features) and transition cost, selecting the best trade-
off between success and path efficiency. The robot executes the next waypoint an
d replans as new observations arrive. Experiments in simulation and on a real St
retch 3 robot demonstrate consistent gains in both task success and trajectory e
fficiency.

Dynamic Programming for Epistemic Uncertainty in Markov Decision Processes
Axel Benyamine, Julien Grand-Clément, Marek Petrik, Michael I. Jordan, Alain Oli
viero Durmus
In this paper, we propose a general theory of ambiguity-averse MDPs, which treat
s the uncertain transition probabilities as random variables and evaluates a pol
icy via a risk measure applied to its random return. This ambiguity-averse MDP f
ramework unifies several models of MDPs with epistemic uncertainty for specific
choices of risk measures. We extend the concepts of value functions and Bellman
 operators to our setting. Based on these objects, we establish the consequences
 of dynamic programming principles in this framework (existence of stationary po
licies, value and policy iteration algorithms), and we completely characterize l
aw-invariant risk measures compatible with dynamic programming. Our work draws c
onnections among several variants of MDP models and fully delineates what is pos
sible under the dynamic programming paradigm and which risk measures require lea
ving it.

BPL: Generalizable Deepfake Detection via Bias-only Pair-aware Learning
Yuxiang Xu, Rundong He, Zhiyuan Yan, Yicong Dong, Zhongyi Han, Xiaoyan Wang, Yil
ong Yin
The detection of synthetic images has traditionally been framed as a binary clas
sification problem. However, we argue that this formulation overlooks a fundamen
tal structural property of generative datasets: synthetic images are not indepen
dent samples, but are implicitly paired with real images sharing the same semant
ic source. Existing methods treat real and fake images as independent instances,
 failing to capture generation-induced relational discrepancies in real–fake pai
rs. Moreover, models tend to rapidly overfit to seen fake patterns, leading to p
oor generalization to unseen ones. To overcome these challenges, we propose a no
vel detection framework that explicitly mines real–fake pairs by constructing so
urce-guided mappings or leveraging nearest-neighbor relationships in the CLIP em
bedding space. We then introduce pair-wise discrepancy learning that explicitly
enlarges generation-induced deviations and discrepancy inversion to mitigate ove
rfitting. Moreover, to preserve pretrained semantic representations while improv
ing generalization, we adopt a bias-only fine-tuning scheme that restricts model
 capacity during adaptation. Extensive experiments show that our approach achiev
es superior generalization across unseen fake patterns.

Normalizing Flows with Iterative Denoising
Tianrong Chen, Jiatao Gu, David Berthelot, Joshua M. Susskind, Shuangfei Zhai
Normalizing Flows (NFs) are a classical family of likelihood based methods that
have received revived attention. Recent efforts such as TARFlow have shown that
NFs are capable to achieving promising performance on image modeling tasks, maki
ng them promising alternatives to other methods such as diffusion models. In thi
s work, we further advance the state of Normalizing Flow generative models by in
troducing iterative TARFlow (iTARFlow). Unlike diffusion models, iTARFlow mainta
ins a fully end-to-end, likelihood-based objective during training. During sampl
ing, it performs autoregressive generation followed by an iterative denoising pr
ocedure inspired by diffusion-style methods. Through extensive experiments, We s
how that iTARFlow achieves competitive performance across ImageNet resolutions o
f 64, 128, and 256 pixels, demonstrating its potential as a strong generative mo
del and advances the frontier of Normalizing Flows. In addition, we analyze the
characteristic artifacts produced by iTARFlow, offering insights that may shed t
he light for future improvements.

Stabilizing In-Context Multi-Source Domain Adaptation for Biomedical Images Thro
ugh Controls
Ana Sanchez-Fernandez, Thomas Pinetz, Werner Zellinger, Günter Klambauer
Biomedical imaging data presents enormous potential for deep learning models to
predict invaluable properties, such as diseases and drug effects. However, unavo
idable alterations of the technical conditions cause *batch effects*: variations
 between groups of samples that are not due to any biological signal of interest
. Batch effects greatly hinder the generalization abilities of deep learning mod
els, preventing their practical use in the real world. Unsupervised Domain Adapt
ation (UDA) methods have been proposed to mitigate batch effects, but they usual
ly assume that the data is comprised of only one source domain and one target do
main, whereas biological datasets are comprised of multiple domains, both at tra
ining and at inference time. While Batch Normalization–based test-time and meta-
learning adaptation methods offer a promising mechanism for domain alignment, we
 show that existing approaches exhibit degraded performance under the usual infe
rence scenarios of small target batch sizes and label shift. We address these li
mitations by leveraging negative control samples, which are consistently present
 in every experimental batch in biological datasets, as stable context for adapt
ation. We propose CS-ARM-BN, a meta-learning BN adaptation method that uses cont
rols both during training and inference to stabilize domain statistics. We perfo
rm a suite of experiments of Mechanism-Of-Action (MoA) classification, a crucial
 task for drug discovery, on the large JUMP-CP imaging dataset. Our experiments
show that CS-ARM-BN substantially improves robustness to batch size and class di
stribution shifts, enabling practical use of deep learning models for biomedical
 images.

On the Limits of LLM Adaptability: Impact of Model-Internalized Priors on Annota
tion Task Performance
Etienne Casanova, Rafal Kocielnik, R. Michael Alvarez
Large Language Models (LLMs) are increasingly used for zero-shot annotation and
LLM-as-a-judge tasks, yet their reliability hinges on how model-internalized pri
ors interact with user-provided instructions. We investigate three dimensions of
 this interaction: (1) how an LLM's familiarity with data and task definitions a
ffects performance, (2) the extent to which additional information in prompts ca
n correct zero-shot errors (``decision stickiness''), and (3) model susceptibili
ty to misaligned task definitions. Through experiments on toxicity detection acr
oss diverse datasets (spanning social media, gaming, news, and forums) using bot
h dense and mixture-of-experts models, we find that nearly two-thirds of zero-sh
ot errors are resistant to correction, with an overall rescue rate (fraction of
initial errors corrected by prompting) of only 34.8\%. High-confidence errors pr
ove especially resistant to correction. When given misaligned definitions, LLMs
follow them while maintaining confidence levels unchanged from the aligned condi
tion. Crucially, we introduce Definition-Specific Familiarity (DSF), which measu
res alignment between a model's internal concept and the task definition. After
controlling for dataset-level confounds, DSF shows a positive association with m
odel performance (partial $r=+0.41$), while three distinct memorization metrics
(ROUGE-L, BERTScore, and embedding cosine similarity) all fail to show a positiv
e association. These findings show the limitations of prompt-based correction in
 annotation tasks, highlighting the importance of definition alignment over text
-level memorization.
****
Expectation Alignment of Language Models for Real-World User Expectations
Miaomiao Li, Yang Wang, Bin Liang, Shudong Liu, Zhiwei Zhang, Kam-Fai Wong
Large language models (LLMs) have demonstrated remarkable performance on standar
d benchmarks, yet it remains largely unexplored whether they truly meet user exp
ectations. Existing evaluation approaches, relying on model heuristics, expert r
ubrics, or user simulation, fail to capture the diversity and subtlety of real h
uman expectations, causing models to appear competent while misaligning with wha
t users actually seek. we present the first systematic study of user expectation
s in real-world LLM interactions, proposing a principled procedure to extract se

mantically rich expectations and introducing ExpectBench, a benchmark grounded i
n real user expectations. Analyses reveal that current LLMs struggle to satisfy
and anticipate what users hope to obtain, highlighting a fundamental source of m
isalignment.
Building on these observations, we propose LENS, a lightweight latent expectatio
n–aware response generation framework. LENS enables models to internalize user e
xpectations and generate better-aligned responses, consistently improving expect
ation satisfaction and underscoring the importance of explicitly modeling user e
xpectations for realistic human–AI alignment.

Semantic Granularity Navigation in Image Editing
Liangsi Lu, Minzhe Guo, Xuhang Chen, Yang Shi
Despite the generative capabilities of diffusion and flow models, real-image edi
ting remains constrained by a persistent trade-off between semantic editability
and structural fidelity. We trace a primary cause of this limitation to the impl
icit coupling of edit progress with model scale in existing paradigms. Under thi
s coupling, stronger edits typically require visiting noisier states, which spen
ds computation on destabilizing layout before the semantic change is well locali
zed. We introduce NaviEdit, a training-free inference-time controller that decou
ples edit progress from model scale traversal through a strict self-consistency
contract. NaviEdit operates at the rollout level and leaves the underlying pretr
ained model unchanged. It treats scale as a control input and reallocates a fixe
d step budget toward semantically responsive intermediate scales instead of dest
ructive high-noise regimes. Experiments show positive average gains across compa
tible editors and flow backbones, supporting decoupling as a portable inference-
time control principle.

Towards Effective Waste Segmentation for Automated Waste Recycling in Cluttered
Background
Mamoona Javaid, Mubashir Noman, Abdul Hannan, Shah Nawaz, Mustansar Fiaz, Sajid
Ghuffar
Rapid expansion of urban areas and population growth is causing an immense incre
ase in waste production, which demands the need for efficient and automated wast
e management.
In this scenario, automated waste recycling (AWR) using deep learning methods ca
n assist humans in optimal waste management.
Recent deep learning approaches for AWR provide promising waste segmentation per
formance, however, these methods rely on large backbone networks that are ineffi
cient for AWR systems and suffer from performance deterioration in cluttered sce
nes.
To this end, an optimal waste segmentation network is introduced which effective
ly utilizes the spatial domain to capture localized structural dependencies and
the spectral domain to efficiently extract global contextual relationships.
This cascaded design allows the network to progressively leverage both local and
 global representations across complementary domains to highlight the semantic i
nformation necessary for effective segmentation of various waste objects.
Furthermore, auxiliary feature enhancement module (AFEM) is introduced to enhanc
e the target objects' boundaries and blob amplification for better segmentation
in cluttered scenarios.
Extensive experimentation on ZeroWaste-aug, ZeroWaste-f and SpectralWaste datase
ts reveals the merits of the proposed method.

The Bridge-Garden Dilemma in LLM Distillation: Why Mixing Hard and Soft Labels W
orks
Guanghui Wang, Kaiwen Lv Kacuila, Zhiyong Yang, Zitai Wang, Jin-Wen Wu, Longtao
Huang, Qianqian Xu, Qingming Huang
Knowledge distillation (KD) transfers knowledge from a large teacher model to a
smaller student. In language modeling, the student is trained either on tokens s
ampled from the teacher (\textbf{hard labels}) or the teacher’s full next-token
distribution (\textbf{soft labels}). Despite soft labels appear strictly richer,

we find that mixing hard and soft labels consistently yields better results. Cr
ucially, we show that this gain cannot be explained by closer teacher matching d
uring training. Instead, it comes from reduced exposure bias---the mismatch betw
een training and inference distributions.
To explain this phenomenon, we introduce the Bridge–Garden Decomposition theory,
 which categorizes generation steps into two types: \textit{Bridges}, where the
next token must be \textit{exact}, and \textit{Gardens}, where it can be \textit
{flexible}. We show that hard-only KD excels in Bridges by avoiding risky deviat
ions, while soft-only KD preserves diversity in Gardens. A hybrid strategy hand
les both cases and, as a result, reduces exposure bias across the sequence.
Guided by this theory, we develop a family of Bridge--Garden hybrid supervision
methods that adaptively balance hard and soft labels. Across seven teacher--stud
ent pairs (including Qwen, Llama, Gemma, and DeepSeek) and benchmarks in reasoni
ng and coding, our approach outperforms divergence-based and on-policy KD baseli
nes while reducing training cost by \textbf{9.7$\times$}, enabling efficient mod
el compression.

SOLAR: Self-supervised Joint Learning for Symmetric Multimodal Retrieval
Wenjie Yang, Hang Yu, Yuyu Guo, Peng Di
In this work, we address the critical yet underexplored challenge of symmetric m
ultimodal-to-multimodal (MM2MM) retrieval, where queries and contexts are interc
hangeable. Existing universal multimodal retrieval works struggle with this task
, as they are constrained by the labeled asymmetric datasets used. We produce SO
LAR (Self-supervised jOint LeArning for symmetric multimodal Retrieval), a novel
 two-stage self-supervised framework that leverages readily available unlabeled
web-scale image-text pairs. Based on the observation that both semantic alignmen
t and discrepancies exist between two modalities, in the first stage, we learn t
he intersection mask of image-text pair, allowing us to align intersection while
 preserving semantic of difference. In the second stage, the learned mask is fur
ther utilized to construct positive and hardnegative samples via masking differe
nt parts of image/text, which enable us to conduct self-supervised multimodal em
bedding learning. Complementing this framework, we present a new benchmark featu
ring high-quality human-verified positive and hard-negative pairs to evaluate sy
mmetric MM2MM retrieval under realistic conditions, as well as the corresponding
 pipeline. Extensive experiments against ten SOTA methods show SOLAR surpasses t
he strongest supervised VLM by 7.08 points on this benchmark, with over 50x fewe
r model parameters and a 5x smaller embedding dimension. Code will be available
upon publication.

Eating for a Sustainable Planet: Personalized Sustainable Diet Recommendation vi
a Constraint-Aware Decision-Making Modeling
Ying Jin, Weiqing Min, Mingyu Huang, Shuqiang Jiang
A sustainable diet represents a multi-dimensional synergy among four essential p
illars: nutrition adequacy, economic affordability, cultural acceptability, and
environmental respect. Despite the prevalence of population-level sustainability
 modeling, practical implementation relies on effective individual-level adoptio
n. This transition is often hindered by inter-individual heterogeneity, posing a
 formidable challenge in aligning sustainable diet requirements with individual
preferences. To address this issue, we propose a personalized sustainable diet r
ecommendation model based on a constraint-aware decision-making mechanism, where
 sustainability is incorporated through learnable constraints rather than modele
d as user preferences. To systematically evaluate the proposed approach, we cons
truct a sustainable diet dataset named SusDiet with about 150k recipes, characte
rized by broad coverage of sustainability indicators across four dimensions. Exp
erimental results on this dataset show that our method promotes more sustainable
 choices without compromising individual preference. This work establishes a fra
mework for aligning individual dietary choices with planetary health, offering q
uantitative evidence to guide future sustainable diet interventions and policy-m
aking for sustainable development.

Asymmetric Contrastive Objectives for Efficient Phenotypic Screening
Luke Nightingale, Joseph Tuersley, Scott Warchal, Andrea Cairoli, Jacob Howes, Cameron Shand, Andrew J Powell, Darren V.S. Green, Amy Strange, Michael Howell
Phenotypic screening experiments produce many microscope images of cells under diverse perturbations, with biologically significant responses often subtle or difficult to identify visually. A central challenge is to extract image representations that distinguish activity from controls and group phenotypically similar perturbations. In this work we propose new adaptations of contrastive loss functions that incorporate experimental metadata as learned class vectors, and a geometrically inspired variant, called SPC, where class vectors are confined to the unit sphere and updated only by attractive terms (allowing more overlap of phenotypically similar classes). The approach is tested on two popular benchmarking datasets, BBBC021 and RxRx3-core; and we also evaluate performance on uncurated screens of HaCaT cells to gauge effectiveness in a realistic use-case scenario. We find we outperform prior methods across the three datasets and on a wide array of metrics measuring phenotype grouping, biological recall, drug-target interaction and mechanism-of-action inference. We also show we maintain this improved performance compared to models over 10x larger in parameter count, and that SPC can be used as an effective fine-tuning technique. The method is easy to implement and is well suited to settings with limited data or compute resources.
****
Few-Shot Design Optimization by Exploiting Auxiliary Information
Arjun Mani, Carl Vondrick, Richard Zemel
Many real-world design problems involve optimizing an expensive black-box function $f(x)$, for which Bayesian Optimization is a sample-efficient framework. However, while the basic black-box setting returns a scalar reward, real-world experiments often generate a wealth of useful information. We introduce a new setting where an experiment generates high-dimensional auxiliary information $h(x)$ along with $f(x)$; moreover, a history of relevant, previously-solved tasks is available for accelerating optimization. We develop a novel method based on a neural model which predicts $f(x)$ for unseen designs given a few-shot context containing observations of $h(x)$. We evaluate our method on two challenging domains, robotic hardware design and hyperparameter tuning. On both domains, our method achieves improved few-shot prediction and faster design optimization, outperforming several multi-task optimization methods.
****
On Information Self-Locking in Reinforcement Learning for Active Reasoning of LLM agents
Deyu Zou, Yongqiang Chen, Fan Feng, Mufei Li, Pan Li, Yu Gong, James Cheng
Reinforcement learning (RL) has become a de
facto paradigm for building LLM-based agents
that act, interact, and reason over extended task
horizons. However, in active reasoning where
agents must elicit new observations through interaction with the environment to solve the task,
we find that outcome-based RL can induce a systematic failure mode which we call information
self-locking (SeL): agents fail both to elicit informative feedback and to internalize obtained evidence. To understand the issue, we trace agentic
behaviors into two coupled capabilities: Action
Selection (AS), which determines observation
streams, and Belief Tracking (BT), which updates
the agent’s internal task understanding. Theoretical and empirical analyses reveal a bidirectional
bottleneck that leads to SeL: weak BT obscures
the credit of informative actions, while weak AS
deprives BT of useful evidence. This coupling
weakens the learning signal for both capabilities
and leads to SeL. To mitigate this issue, we propose AREW, a simple yet effective Advantage Reweighting method that uses easy-to-obtain directional critiques to

reallocate credit within trajectories. Extensive experiments across 9 agentic tasks of varying complexity show that AREW significantly mitigates SeL, yielding up to 60-point
gains in final performance. Code is available at
https://github.com/unimpor/T3.
****
NITP: Next Implicit Token Prediction for LLM Pre-training
Xiangdong Zhang, Debing Zhang, Shaofeng Zhang, Xiaohan Qin, Yu Cheng, Junchi Yan
Standard Next-Token Prediction (NTP) supervises language models solely through discrete labels in the output logit space.
We argue that this sparse, one-hot supervision leaves the latent representation space under-constrained, allowing hidden states to drift into degenerate and anisotropic configurations that limit generalization.
To address this issue, we propose Next Implicit Token Prediction (NITP), which augments discrete prediction with dense, continuous supervision directly in the representation space.
NITP requires the model to predict the implicit semantic content of the next token, using shallow-layer representations from the same model as stable self-supervised targets.
Theoretically, we show that NITP regularizes the optimization landscape by mitigating under-constrained degrees of freedom and enforcing a compact, structured representation geometry.
Empirically, across dense and MoE models ranging from 0.5B to 9B parameters, NITP consistently {improves downstream performance with negligible computational overhead}. Notably, on the 9B MoE model, NITP achieves a 5.7\% absolute improvement on MMLU-Pro,
along with gains of 6.4\% on C3 and 4.3\% on CommonsenseQA, with $\sim$2\% additional training FLOPs and no additional inference cost. Our implementation is available at https://github.com/aHapBean/NITP.
****
Nonparametric Data Attribution for Diffusion Models
Yutian Zhao, Chao Du, Xiaosen Zheng, Tianyu Pang, Min Lin
Data attribution for generative models seeks to quantify the influence of individual training examples on model outputs. Existing methods for diffusion models typically require access to model gradients or retraining, limiting their applicability in proprietary or large-scale settings. We propose a *nonparametric* attribution method that operates directly on data, measuring influence via patch-level similarity between generated and training images. Our approach is grounded in the analytical form of the optimal score function, extends naturally to multiscale representations, and remains computationally efficient through convolution-based acceleration. In addition to producing spatially interpretable attributions, our framework uncovers patch-level correspondences between training data and generated outputs. Experiments show that NDA substantially outperforms existing nonparametric baselines and achieves the best attribution performance among the evaluated methods that do not use target-model parameters or gradients.
****
Training LLM Agents to Empower Humans
Evan Ellis, Vivek Myers, Jens Tuyls, Sergey Levine, Anca Dragan, Benjamin Eysenbach
Assistive agents should not only take actions on behalf of a human, but also step out of the way and cede control when there are important decisions to be made. However, current methods for building assistive agents, whether via mimicking expert humans or via RL finetuning on an inferred reward, often encourage agents to complete tasks on their own rather than truly assisting the human achieve her objectives. We propose a new approach to tuning assistive language models based on maximizing the human's empowerment, their ability to effect desired changes in the environment. Our empowerment-maximizing method, Empower, only requires offline examples of human-written text, providing a self-supervised method for fine-tuning language models to better assist humans. To study the efficacy of our approach, we conducted an 18-person user study comparing our empowerment assistan

t with a strong baseline. Participants preferred our assistant 78% of the time (p=0.015), with a 31% higher acceptance rate. With this empowerment objective, we provide a framework for useful aligned AI agents without the need for human fee dback or verifiable rewards.
****
HieraScaffold: Learning Compact Hierarchical Representations for Scalable 4D LiD AR Generation
Zijie Wu, Na Zhao
Outdoor LiDAR generation has shown strong potential for autonomous driving and l arge-scale 3D perception. However, existing approaches remain computationally in tensive and primarily static, lacking explicit modeling of temporal dynamics. Th is limitation weakens spatiotemporal coherence and reduces the realism of 4D LiD AR generation.
We propose a hierarchical recoupling generation framework that explicitly disent angles and reconstructs large-scale geometry and motion within a unified hierarc hical structure. First, we design a multi-resolution feature scaffold that predi cts time-correlated unsigned distance fields and spatial gradients, enabling hie rarchical decomposition of 4D dynamics into static and motion-varying components . Next, to achieve compact yet expressive modeling, we introduce a neural contou rlet representation that prunes redundant scaffolds into minimal directional bas es, efficiently capturing essential geometric and motion cues. Finally, we progr essively re-couple these hierarchical components to generate realistic and tempo rally coherent 4D LiDAR data.
Extensive experiments demonstrate that our method outperforms baselines in both quality and consistency, achieving 3.3\%, 25.0\%, 17.8\% improvements in FRD, MM D, and JSD, respectively, over the strong competitors, LiDMs and RangeLDM.

STT-LLM: Structural-Temporal Tokenization for Adapting LLMs to Longitudinal Clin ical Profiles
Maxx Richard Rahman, Mostafa Hammouda, Wolfgang Maass
Large Language Models have shown strong generalization across natural language t asks but remain underexplored for longitudinal clinical profiles. In sports anti -doping, biological profiles are analyzed to support early detection of prohibit ed substance use and identification of anomalous biological patterns, both of wh ich require joint modeling of temporal dynamics and metabolic relationships. We propose STT-LLM, a structural-temporal tokenization framework that adapts LLMs t o longitudinal clinical analysis without modifying their backbone architectures. STT-LLM constructs biologically grounded structural-temporal embeddings and tra nsforms them into LLM-compatible tokens via specialized tokenizers that explicit ly encode pathway structure and temporal evolution. We evaluate STT-LLM on real- world longitudinal datasets from athletes, showing consistent improvements over native LLM tokenization strategies in sequence prediction and anomaly detection. In addition, we present a case study where STT-LLM provides contextual reasonin g that aligns more closely with expert assessments compared to baseline models. These results highlight tokenization as a key bottleneck and opportunity for ada pting LLMs to clinical data.
****
Exact Unlearning in Reinforcement Learning
Thanh Nguyen-Tang, Raman Arora
We formulate the problem of \emph{exact unlearning} in reinforcement learning, w here the goal is to design an efficient framework that enables the removal of an y user’s data upon deletion request, i.e., the online learner’s output after unl earning be \emph{indistinguishable} from what would have been produced had the d eleted user never interacted with the learner. For any $\rho >0$, we show that t here exists a reinforcement learning (RL) algorithm that is ρ-TV-stable and supports an exact unlearning procedure whose expected computational cost is onl y a $\rho \sqrt{\ln T}$ fraction of the computational cost of retraining from sc ratch. We construct such a ρ-TV-stable RL algorithm for tabular Markov deci sion processes (MDPs), which achieves a regret bound of $\mathcal{O}(H^2 \sqrt{ SAT} + H^3 S^2 A + {H^{2.5} S^2 A}/{\rho})$, where S, A, H, and T denote the

number of states, the number of actions, the episode horizon, and the number of episodes, respectively. We also establish a lower bound of $\Omega(H\sqrt{SAT}+{SAH}/{\rho})$ for ρ-TV-stable RL algorithms, showing that our algorithm is nearly minimax optimal.
****

PrivGate: Steering Contextual Integrity in LLMs via Latent Space Geometry
Runshan Hu, Yukun Dong, Yingying Huangfu, Ruohan Zhao, Yi Xie, Tieyan Li
Securing Contextual Integrity (CI) is critical for privacy-preserving Large Language Model (LLM) agent execution. However, existing agents struggle to balance the agility of direct generation against the prohibitive latency of CI-constrained thinking. To address this, we propose PrivGate, a framework that selectively invokes explicit reasoning based on internal privacy signals. Our approach is grounded in the discovery of a privacy manifold, where models linearly encode privacy sensitivity within their residual streams, even during non-compliant generation. Leveraging this structure, PrivGate employs Latent Gating, a training-free mechanism that requires no fine-tuning of the base LLM and triggers explicit reasoning only when high latent risk is detected, thereby optimizing the efficiency-privacy trade-off by minimizing unnecessary compute. On the contextual PrivacyLens benchmark, PrivGate maintains consistently high performance in out-of-distribution risk identification, validating the generalizability of the discovered manifold. End-to-end evaluations show that PrivGate achieves a 62.6% average relative reduction in privacy leakage with 15.9% token overhead, offering a practical pathway to reconcile rigorous CI requirements with the performance demands of LLM agents.

The benefits of full data shuffle, now with optimal I/O cost: k-wise independence and matrix transposition to the rescue
Peyman Afshani, Rezaul Chowdhury, Mayank Goswami, Jens Kristian Refsgaard Schou, Francesco Silvestri, Mariafiore Tognon
It is known that RandomShuffle, the without replacement version of Stochastic Gradient Descent (SGD), converges faster than with replacement SGD. However, RandomShuffle requires uniformly performing a random permutation of the input sequence, which is known to have high I/O complexity due to data movement across the memory hierarchy. In this paper, we propose a shuffling algorithm with a linear I/O complexity that generates almost-uniformly random permutations with rigorous mathematical guarantees. Specifically, we show that the shuffling algorithm can generate 2-wise independent permutations. Furthermore, we can extend to k-wise independence with a small error in the probability distribution, if the fast memory has at least k memory blocks. These results allow us to reach the same expected theoretical convergence as RandomShuffle while achieving optimal linear I/O cost.

Semantic Impact–Driven Visual Scheduling in Vision-Language Models
Xuan Wang, Yilin Liu, Fangxiang Feng, Caixia Yuan, Huixing Jiang, Xiaojie Wang
Vision-Language Models (VLMs) suffer from high inference latency due to long visual sequences. To enable efficient, on-demand utilization of visual information, we argue that visual necessity should be assessed by its semantic impact on the output distribution, rather than inferred from intermediate interaction signals such as attention weights. We propose a training-free framework based on token embedding subspace decomposition, which we term a prediction-conditioned Semantic Lens. Specifically, at fixed decoding intervals, we perform QR decomposition on the Top-K candidate token embeddings to construct an orthogonal semantic basis. We then introduce Semantic IImpact–Driven Visual Scheduling (SIVS), which measures how visual inputs impact model predictions by projecting visual-induced hidden-state variations onto this semantic lens. SIVS provides a geometrically grounded, impact-driven criterion for dynamic visual KV scheduling. Empirical results demonstrate that SIVS achieves ~87% visual KV compression while maintaining over 99% of model performance.

DARTS: Distribution-Aware Active Rollout Trajectory Shaping for Accelerating LLM

Reinforcement Learning
Yujie Wang, Siwei Chen, Longzan Luo, Xinyi Liu, Xupeng Miao, Fangcheng Fu, Bin CUI
Reinforcement Learning (RL) has become pivotal for improving model capabilities yet suffers from rollout efficiency bottlenecks due to the long-tail response length distribution. While existing works mitigate the impact of long tails via prompt-level tail scheduling, we focus on the root source of inefficiency: the distribution itself. Specifically, we characterize the long-tail distribution at a finer granularity, identifying intra-prompt long tails, and revealing that they frequently consist of ineffective verbosity. To address this, we propose a novel paradigm of active distribution shaping to shape the rollout distribution towards conciseness and certainty, thereby fundamentally resolving tail-induced overheads. We achieve this through a distribution-aware trajectory sampling mechanism, which selects trajectories from a redundant exploration space for each prompt, and an adaptive redundancy allocation scheme to maximize both shaping effectiveness and system efficiency. Experiments demonstrate significant acceleration over state-of-the-art systems by up to 1.77$\times$ without compromising model performance.
****
Sequential Group Composition: A Window into the Mechanics of Deep Learning
Giovanni Luca Marchetti, Daniel Kunin, Adele Myers, Francisco Acosta, Nina Miolane
How do neural networks trained over sequences acquire the ability to perform structured operations, such as arithmetic, geometric, and algorithmic computation? To gain insight into this question, we introduce the sequential group composition task. In this task, networks receive a sequence of elements from a finite group encoded in a real vector space and must predict their cumulative product. This task can be order-sensitive and cannot be solved by a linear model. Our analysis isolates the roles of the group structure, encoding statistics, and sequence length in shaping learning. We prove that two-layer networks from vanishing initialization learn this task one irreducible representation of the group at a time in an order determined by the Fourier statistics of the encoding. To perfectly learn the task, these networks require a hidden width exponential in the sequence length k. In contrast, we construct deeper architectures that exploit associativity to dramatically improve this scaling: recurrent neural networks can compose elements sequentially in k steps, while multilayer networks can compose adjacent pairs in parallel in $\log k$ layers. Overall, the sequential group composition task offers a tractable window into the mechanics of deep learning.

Revisiting Asymmetries in Black-box Link Stealing against Graph Neural Networks
Paul Agbaje, Habeeb Olufowobi
Graph Neural Networks (GNNs) are increasingly deployed on sensitive relational data, from social networks to healthcare records. However, their outputs can leak private graph structure, enabling link-stealing attacks that infer whether a connection between two entities existed in the training graph. While prior work demonstrates high average performance for such attacks, privacy is fundamentally a worst-case property, not an average one. The key question is whether an adversary can reliably compromise even a small set of critical links under strict precision constraints. We revisit posterior-only link-stealing attacks in a strict black-box setting and show that they remain effective at extremely low false-positive rates, revealing tail-risk vulnerabilities that current evaluations overlook. We further find that intra-class vulnerabilities are suppressed by geometric bottlenecks that collapse discriminative directions in posterior space. Building on this insight, we propose a geometry-aware reconditioning method that reshapes intra-class distances, substantially improving separability without harming reliability. Across multiple real-world graphs and GNNs, this diagnostic correction achieves up to $2\times$ higher success on intra-class pairs than generic attacks, redefining link-privacy evaluation as a tail-risk problem and revealing that posterior leakage remains substantially under-measured in current GNN deployments.

FoundObj: Self-supervised Foundation Models as Rewards for Label-free 3D Object Segmentation
Zihui Zhang, Zhixuan Sun, Yafei YANG, Jinxi Li, Jiahao Chen, Bo Yang
We address the challenging task of 3D object segmentation in complex scene point clouds without relying on any scene-level human annotations during training. Existing methods are typically constrained to identifying simple objects, primarily due to insufficient object priors in the learning process. In this paper, we present FoundObj, a novel framework featuring a superpoint-based object discovery agent that incrementally merges suitable neighboring superpoints, guided by our innovative semantic and geometric reward modules. These modules synergistically leverage semantic and geometric priors from self-supervised 2D/3D foundation models, providing complementary feedback to the object discovery agent and enabling robust identification of multi-class objects through reinforcement learning. Extensive experiments on diverse benchmarks demonstrate that our approach consistently outperforms existing baselines.
Notably, our method exhibits strong generalization in zero-shot and long-tail scenarios, underscoring its potential for scalable, label-free 3D object segmentation.
Code is available at https://github.com/vLAR-group/FoundObj

CapBencher: Give Your LLM Benchmark a Built-in Alarm for Test-Set Overfitting
Takashi Ishida, Thanawat Lodkaew, Ikko Yamane
Publishing a large language model (LLM) benchmark (especially its ground-truth answers) on the Internet risks contaminating future LLMs and enabling evaluation gaming: it may be unintentionally (or intentionally) used to train or select a model, or exploited to overfit and hack leaderboards when labels are accessible. A common mitigation is to keep the benchmark private and let participants submit their models or predictions to the organizers, but this still permits test-set overfitting through feedback loops. To overcome this issue, we propose CapBencher, a way to publish benchmarks without fully disclosing the ground-truth answers, while preserving open evaluation of LLMs. The main idea is to reduce the best possible accuracy, i.e., Bayes accuracy, by injecting randomness to the answers by preparing several logically correct answers, and only include one of them as the solution in the benchmark. Not only does this obscure the ground-truth answers, but it also offers a test for leakage or gaming: since even fully capable models should not surpass the Bayes accuracy, any model that does is a strong signal. We show theoretically and empirically that CapBencher accurately detects test-set overfitting across diverse benchmarks, models, training methodologies, and scenarios.
****
HSMAD: Heterophily-Driven Spectral and Manifold Learning for Graph Anomaly Detection
Chen Zhu, Yaying Zhang
Graph anomaly detection (GAD) is a fundamental task in graph learning. However, most existing methods rely on the homophily assumption, which posits that connected nodes tend to share the same labels. This assumption often fails in the presence of edge heterophily, leading to degraded performance. We first observe that down-weighting heterophilic edges, relative to the original or randomly weighted graphs, results in a more concentrated spectral energy distribution, thereby facilitating the learning of discriminative spectral representations. Moreover, existing methods typically embed graphs in Euclidean spaces, neglecting the importance of heterophily in manifold spaces. Motivated by these observations, we propose HSMAD, a novel framework for GAD. It consists of two key components: the Heterophily-Weighted Spectral Filtering module, which reconstructs the Laplacian using heterophily-based edge weighting for spectral filtering, and the Heterophily-Routed Manifold Update module, which routes neighborhood messages to the appropriate manifold for node feature updates, enabling curvature-adaptive representation learning. These spectral and geometric representations are jointly leveraged for anomaly detection. Extensive experiments on six real-world datasets show t

hat HSMAD achieves state-of-the-art performance across the average F1-Macro, AUROC, AUPRC, and G-Mean. Specifically, the average F1-Macro score improves by 2.66% over the best-performing method.

SimpleMem: Efficient Lifelong Memory for LLM Agents
Jiaqi Liu, Yaofeng Su, Peng Xia, Siwei Han, Zeyu Zheng, Cihang Xie, Mingyu Ding, Huaxiu Yao
To support long-term interaction in complex environments, LLM agents require memory systems that manage historical experiences. Existing approaches either retain full interaction histories via passive context extension, leading to substantial redundancy, or rely on iterative reasoning to filter noise, incurring high token costs. To address this challenge, we introduce SimpleMem, an efficient memory framework based on semantic lossless compression. We propose a three-stage pipeline designed to maximize information density and token utilization: (1) Semantic Structured Compression, which distills unstructured interactions into compact, multi-view indexed memory units; (2) Online Semantic Synthesis, an intra-session process that instantly integrates related context into unified abstract representations to eliminate redundancy; and (3) Intent-Aware Retrieval Planning, which infers search intent to dynamically determine retrieval scope and construct precise context efficiently. Experiments on benchmark datasets show that our method consistently outperforms baseline approaches in accuracy, retrieval efficiency, and inference cost, achieving an average F1 improvement of 26.4% in LoCoMo while reducing inference-time token consumption by up to 30×, demonstrating a superior balance between performance and efficiency. Code is available at https://github.com/aiming-lab/SimpleMem.

PathwayLLM: Explainable Clinical Trajectory Modeling with Structured Pathways for Sepsis Prediction
Zhengqiu Yu, Yueping Ding, Xiangrong Liu
Patient-level sepsis prediction requires models that track clinical deterioration over time and integrate heterogeneous structured evidence from electronic health records. We present PathwayLLM, a trajectory-based framework that grounds prediction on temporal signals, graph-structured evidence, and pathway-level clinical information derived from statistical dependency discovery. PathwayLLM follows a three-stage design. First, each observation window is encoded from multiple structured views, including physiological measurements, temporal dynamics, a heterogeneous patient-diagnosis-medication graph, and dependency-derived pathway signals. Second, these representations are injected into a pretrained language model as auxiliary contextual embeddings so that risk prediction and evidence-conditioned explanations can be learned jointly. Third, a Clinical Trajectory LSTM with Deterioration Attention aggregates window-level representations to highlight critical deterioration points and produce patient-level risk scores. On MIMIC-IV (15,410 ICU patients; 8.45% sepsis prevalence), PathwayLLM achieves AUROC 0.891 and AUPRC 0.724, outperforming strong time-series and pretrained baselines. External validation on eICU achieves AUROC 0.842 zero-shot and 0.867 after light fine-tuning. Ablation studies indicate that trajectory aggregation and structured clinical signals are key contributors, and clinician review suggests coherent, interpretable, and clinically relevant explanations.

Density-Guided Robust Counterfactual Explanations on Tabular Data under Model Multiplicity
Jun Tan, Qing Guo, Zicheng Xu, Jinglin Li, QI Fang, Ning Gui
Counterfactual explanations (CEs) are essential for actionable recourse, yet their reliability is often compromised in low-density regions, where classifiers exhibit high variance. Unlike existing methods that rely on expensive ensemble intersections to define stability, we propose DensityFlow, a generative framework that constructs robust CEs by adhering to the high-confidence data manifold. Specifically, we model the counterfactual generation as continuous-time dynamics parameterized by Neural ODE, guided by a differentiable density score to actively avoid uncertain, low-density areas. This density score is learned via Noise Contr

astive Estimation, effectively leveraging a $(K{+}1)$-way discriminator to estim
ate density ratios. For black-box settings, we introduce a local proxy distillat
ion mechanism that aligns a lightweight surrogate with the target model strictly
 within the trajectory of CE generation, enabling efficient gradient-based optim
ization with minimal queries. Experiments demonstrate that \textit{DensityFlow}
achieves superior validity under model multiplicity while significantly reducing
 query costs compared to ensemble-based baselines. Our implementation is availab
le at \url{https://github.com/G-AILab/DensityFlow}.

Breaking the Self-Confirming Loop: Diagnosing and Mitigating Systemic Reward Bia
s in Self-Rewarding RL

Chuyi Tan, Peiwen Yuan, Xinglin Wang, Yiwei Li, Shaoxiong Feng, Yueqi Zhang, Jia
yi Shi, Ji Zhang, Boyuan Pan, Yao Hu, Kan Li

Reinforcement learning with verifiable rewards (RLVR) efficiently scales the rea
soning ability of large language models (LLMs) but is bottlenecked by scarce la
beled data. Reinforcement learning with intrinsic rewards (RLIR) offers a scalab
le alternative via self-rewarding, yet often suffers from instability and inferi
or performance. We trace this gap to a systemic bias in confidence-coupled self-
rewarding: the model tends to over-reward high-confidence mistakes, forming a \t
extbf{self-confirming loop}. We quantify this feedback-loop bias with three metr
ics: reward noise magnitude (ρ_{noise}), policy–reward coupling ($\r
ho_{\text{selfbias}}$), and over-/under-reward skew (ρ_{symbias}). O
ur analyses show a compounding effect where strong coupling amplifies confidence
-conditioned errors and drives a drift toward over-reward, leading to instabilit
y and a lower performance ceiling. To mitigate this, we propose reinforcement le
arning with ensembled rewards (\textbf{RLER}), which aggregates diverse models w
ith adaptive reward interpolation and disagreement-aware rollout selection to re
duce coupling and suppress over-reward drift. Extensive experiments show that RL
ER improves by 6.2\% over the best RLIR baseline and is within 3.6\% of RLVR, wh
ile exhibiting stable scaling on unlabeled samples.
****

CryoACE: An Atom-centric Framework for Accurate and Automated Model Building in
Cryo-EM

Minzhang Li, LI Mingrui, Weichen Qin, Qihe Chen, Sixian Shen, Yuan Pei, Jiakai Z
hang, Jingyi Yu

Protein automodeling from cryo-EM density maps faces unique challenges in enforc
ing physicochemical validity and managing conformational heterogeneity. Current
solvers are often limited to static predictions or require computationally inten
sive heuristic searches. We present CryoACE, an end-to-end framework that recons
tructs precise atomic graphs for both homogeneous and heterogeneous structures.
Our method features two key innovations: an atom-centric reconstruction paradigm
, where density features are sampled directly at atomic coordinates and iterativ
ely recycled to refine structures—replacing expensive voxel convolutions for eff
icient multimodal fusion—and a training-free guidance mechanism that leverages p
redicted local resolution priors to resolve dynamic ambiguity. Validated on a ne
wly constructed high-quality dataset, CryoACE significantly outperforms existing
 baselines on static benchmarks and, for the first time, unveils atomic-level dy
namic conformations on complex real-world datasets like EMPIAR-10345 without rel
ying on pre-built static structures. We release our code, model weights, and dat
aset to facilitate future research.

Convex Dataset Valuation for Post-Training

Siqi Zeng, Christopher Jung, Rui Li, Zhe Kang, Ming Li, Nima Noorshams, Zhigang
Wang, Fuchun Peng, Han Zhao, Xue Feng

Improving LLM performance on downstream tasks sometimes requires leveraging
auxiliary datasets during post-training. In practice, however, developers face
constraints on compute, labeling, and licensing costs that preclude using all
available data, necessitating principled dataset-level selection. These
constraints are increasingly shaped by dataset marketplaces, where data
acquisition is governed by budgets and negotiation. We study dataset valuation a

s a subset selection problem during LLM post-training.
Our goal is to identify and weight auxiliary datasets so as to maximize target task performance given constrained budgets. We first show that commonly used gradient
alignment scores provide a reasonable yet incomplete valuation signal, as they ignore
redundancy among datasets. To address this, we propose a
scalable convex dataset-level valuation method based on kernel mean matching (KMM) in gradient
space, which jointly accounts for alignment with the target task and redundancy across auxiliary datasets.
Through extensive experiments across diverse post-training
settings and tasks, we show that our approach
consistently outperforms existing valuation baselines, achieving
stronger performance with low computational overhead. Our results position dataset valuation as a practical decision tool for post-training data selection in market-constrained large language model settings.

Making Models Unmergeable via Scaling-Sensitive Loss Landscape
Minwoo Jang, Hoyoung Kim, Jabin Koo, Jungseul Ok
The rise of model hubs has made it easier to access reusable model components, making model merging a practical tool for combining capabilities. Yet, this modularity also creates a *governance gap*: downstream users can recompose released weights into unauthorized mixtures that bypass safety alignment or licensing terms. Because existing defenses are largely post-hoc and architecture-specific, they provide inconsistent protection across diverse architectures and release formats in practice. To close this gap, we propose Trap^{2}, an architecture-agnostic protection framework that encodes protection into updates during fine-tuning, regardless of whether they are released as adapters or full models. Instead of relying on architecture-dependent approaches, Trap^{2} uses weight re-scaling as a simple proxy for the merging process. It keeps released weights effective in standalone use, but degrades them under re-scaling that often arises in merging, undermining unauthorized recomposition.
****

SparseOpt: Addressing Normalization-induced Gradient Skew in Sparse Training
Mohammed Adnan, Rohan Jain, Tom Jacobs, Ekansh Sharma, Rahul G Krishnan, Rebekka Burkholz, Yani Ioannou
Dynamic Sparse Training (DST) methods train neural networks by maintaining sparsity while dynamically adapting the network topology. Despite the promise of reduced computation, DST methods converge significantly slower than dense training, often requiring comparable training time to achieve similar accuracy. We demonstrate both analytically and empirically that Batch Normalization (BN) adversely affects sparse training, and propose SparseOpt — a sparsity-aware optimizer — to address this. Experiments on ResNet models across CIFAR-100 and ImageNet demonstrate consistently faster convergence and improved generalization with our proposed method. Our work highlights the limitations of current normalization layers in sparse training and provides the first systematic study of the interaction between Batch Normalization, sparse layers, and DST, taking a significant step toward making DST practically competitive with dense training.
****

InfoFlow KV: Information-Flow-Aware KV Recomputation for Long Context
Xin Teng, Canyu Zhang, Shaoyi Zheng, Danyang Zhuo, Tianyi Zhou, Shenji Wan
Retrieval-augmented generation (RAG) for long-context question answering is bottlenecked by inference-time prefilling over large retrieved contexts. A common strategy is to precompute key–value (KV) caches for individual documents and selectively recompute a small subset of tokens to restore global causal dependencies, but existing methods rely on heuristics or representation discrepancies without modeling whether selected tokens can effectively influence generation. We cast selective KV recomputation as an information flow problem and show that a simple attention-norm signal from the query reliably identifies tokens that are both s

emantically relevant and structurally positioned to propagate information, when computed under an inference-consistent RoPE geometry. We therefore reconstruct global positional assignments for retrieved chunks and introduce an information-flow–guided chunk reordering strategy. Experiments on Large Language Model and Vision-Language Model benchmarks demonstrate consistent gains over prior methods under comparable latency.
****

CLASP: Online learning algorithms for Convex Losses And Squared Penalties
Ricardo N. Ferreira, Joao Xavier, Claudia Soares
Addressing Constrained Online Convex Optimization (COCO), we introduce CLASP (Convex Losses And Squared Penalties), a framework that minimizes cumulative loss together with squared constraint violations. We propose two variants of CLASP, CLASP-I and CLASP-F, allowing for a joint or separate handling of the static decision set and the time-varying constraints, a decoupling flexibility that affords simpler implementations when projections onto the static decision set are easy. Our theoretical analysis departs from prior work by fully leveraging the variety of \emph{cutter operators}, and contraction properties such as the strongly quasi-nonexpansiveness, a proof strategy not previously applied in this setting. For convex losses, both CLASP algorithms achieve regret $O\left(T^{\max\\{\beta,1-\beta\\}}\right)$ and cumulative squared penalty $O\left(T^{\\{1-\beta\\}}\right)$ for any $\beta \in (0,1)$. Most importantly, for strongly convex problems, we provide the first logarithmic guarantees on both regret and cumulative squared penalty: In the strongly convex case, both CLASP algorithms guarantee that the regret is upper bounded by $O(\log T)$ and the cumulative squared penalty is also upper bounded by $O(\log T)$.

Deep Learning of Compositional Targets with Hierarchical Spectral Methods
Hugo Tabanelli, Yatin Dandi, Luca Pesce, Florent Krzakala
Why depth yields a genuine computational advantage over shallow methods remains a central open question in learning theory. We study this question in a controlled high-dimensional Gaussian setting, focusing on compositional target functions. We analyze their learnability using an explicit three-layer fitting model trained via layer-wise spectral estimators. Although the target is globally a high-degree polynomial, its compositional structure allows learning to proceed in stages: an intermediate representation reveals structure that is inaccessible at the input level. This reduces learning to simpler spectral estimation problems, well studied in the context of multi-index models, whereas any shallow estimator must resolve all components simultaneously. Our analysis relies on Gaussian universality, leading to sharp separations in sample complexity between two and three-layer learning strategies.
****

Beyond Correctness: Distance-Based Social Dynamics of Multi-Agent Debate
Seungwoong Ha, Melanie Mitchell
Multi-agent debate (MAD) systems are often evaluated using binary correctness or peer agreement, yet such evaluations obscure how individual agents revise their answers during social interaction. We study the microscopic dynamics of answer revision in large language models (LLMs) using ConceptARC, a 2D grid-reasoning benchmark that admits quantitative distance measures between candidate solutions. By exposing a target model to controlled configurations of peer answers, we analyze how the likelihood and direction of revision depend on both social context and the distance between answers and the ground truth. We find that agents are more likely to revise when their answers are farther from the correct solution, and that revisions of incorrect answers exhibit a systematic contraction toward the ground truth, even when the final answer remains incorrect. Conversely, correct answers can be overturned by social pressure, particularly when wrong peers are near-correct. Together, these results show that multi-agent interaction induces structured, distance-aware movements in solution space that are invisible under binary correctness, clarifying when social reasoning leads to improvement, stability, or gradual regression in solution quality.
****

Bio-Inspired Self-Supervised Learning for Wrist-worn Accelerometer Data
Prithviraj Tarale, Kiet Chu, Abhishek Varghese, Kai-Chun Liu, Maxwell A Xu, Mohit Iyyer, Sunghoon Lee
Wearable accelerometers enable large-scale health monitoring, yet learning robust human-activity representations has been constrained by scarce labeled data. While self-supervised learning offers a remedy, existing methods treat sensor streams as unstructured time series, overlooking the underlying biological structure of human movement, a factor we argue is critical for effective Human Activity Recognition (HAR). We introduce a novel tokenization strategy grounded in the *submovement theory* of motor control, which posits that continuous wrist motion is composed of elementary basis functions called submovements. We define our token as the *movement segment*, a computationally tractable unit of motion composed of a finite sequence of submovements. By pretraining a Transformer encoder via masked reconstruction of these tokens, we shift the learning focus from local waveform morphology to high-level structural and temporal organization. Pretrained on the NHANES corpus ($\approx$ 28k hours; $\approx$ 11k participants), our representations outperform strong wearable SSL baselines across six subject-disjoint HAR benchmarks. Code and pretrained weights are available at https://prithvitarale.github.io/biopm-site/.
****
OPIC: Enhancing Language Model Merging via Optimizing In-Context Capability
Jie He, Weidong Bao, Chao Chen, Zhengyi Zhong, Shuai Zhang, Ji Wang
Task-vector–based model merging enables low-cost, training-free multi-task learning for large language models, but suffers from severe performance degradation due to task conflict. Prior mitigation strategies largely rely on validation data for costly hyperparameter tuning, limiting both interpretability and practicality.
We therefore propose OPIC, an evolutionary optimization–based model merging framework. Our preliminary experiments reveal that the degradation of In-Context Learning (ICL) capabilities is a primary driver of task conflict. Motivated by this insight, we formulate model merging as an optimization problem with ICL preservation as the objective. OPIC introduces a hierarchical refinement operators and optimizes it using self-generated data, effectively eliminating the reliance on external validation sets.
Experimental results demonstrate that OPIC achieves an average performance retention of 80.73%, outperforming SOTA methods and improving by up to 11.1% over recent validation-free approaches. In addition, OPIC is compatible with existing merging pipelines, offering a new alternative solution for deploying without validation dependencies. Code is available at: https://anonymous.4open.science/r/OPIC-CFFE.
****
Long-Context Modeling with Dynamic Hierarchical Sparse Attention for Memory-Constrained LLM Inference
Siheng Xiong, Joe Zou, Faramarz Fekri, Yae Jee Cho
The quadratic cost of attention limits the scalability of long-context LLMs, especially under limited hardware memory budgets. While attention is often sparse, existing static sparse methods cannot adapt to task- or input-dependent variations, and recent dynamic approaches rely on predefined templates or heuristics that may sacrifice generality. We propose Dynamic Hierarchical Sparse Attention (DHSA), a data-driven framework that predicts attention sparsity online while keeping the LLM backbone frozen. DHSA performs hierarchical routing by estimating importance at the chunk level and propagating it to token-level interactions, preserving causally important dependencies while enabling efficient sparsification. Across Needle-in-a-Haystack test, LongBench and RULER, DHSA maintains near-dense accuracy in highly sparse regimes, achieving 12--20% relative accuracy gains over Block Sparse Attention at comparable prefill cost. With a memory-efficient tiled backend, DHSA delivers up to $10\times$ prefill speedup at 128K context length. On LLaMA-3.1-8B (4-bit), DHSA scales to 100K context on a single 24GB GPU, where dense attention fails. We provide complementary GPU and CPU backends, enabling DHSA to run across diverse hardware environments and multiple open-weight mod

el families. These results demonstrate DHSA as an efficient and adaptable soluti on for memory-constrained long-context LLM inference. Code is available at: http s://github.com/xiongsiheng/DHSA.
****

Contrastive Spectral Rectification: Test-Time Defense towards Zero-shot Adversar ial Robustness of CLIP
Sen Nie, Jie Zhang, Zhuo Wang, Shiguang Shan, Xilin CHEN
Vision-language models (VLMs) such as CLIP have demonstrated remarkable zero-sho t generalization, yet remain highly vulnerable to adversarial examples (AEs). Wh ile test-time defenses are promising, existing methods fail to provide sufficien t robustness against strong attacks and are often hampered by high inference lat ency and task-specific applicability. To address these limitations, we start by investigating the intrinsic properties of AEs, which reveals that AEs exhibit se vere feature inconsistency under progressive frequency attenuation. We further a ttribute this to the model's inherent spectral bias. Leveraging this insight, we propose an efficient test-time defense named Contrastive Spectral Rectification (CSR). CSR optimizes a rectification perturbation to realign the input with the natural manifold under a spectral-guided contrastive objective, which is applie d input-adaptively. Extensive experiments across 16 classification benchmarks de monstrate that CSR outperforms the SOTA by an average of 18.1% against strong AP GD with modest inference overhead. Furthermore, CSR exhibits broad applicability across diverse visual tasks. Code is available at https://github.com/Summu77/CS R.
****

Margin-Adaptive Confidence Ranking for Reliable LLM Judgement
Gaojie Jin, Yong Tao, Lijia Yu, Tianjin Huang
Jung et al. (2025) introduce a hypothesis testing framework for guaranteeing agr eement between large language models (LLMs) and human judgments, relying on the assumption that the model’s estimated confidence is monotonic with respect to hu man-disagreement risk.
In practice, however, this assumption may be violated, and the generalization be havior of the confidence estimator is not explicitly analyzed.
We mitigate these issues by learning a dedicated confidence estimator instead of relying on heuristic confidence signals.
Our approach leverages simulated annotator diversity and a margin-based ranking formulation to explicitly model how confidently an LLM distinguishes between hum an-agreement and human-disagreement cases.
We further derive generalization guarantees for this estimator, revealing a marg in-dependent trade-off that informs the design of an adaptive estimator training procedure.
When integrated into fixed-sequence testing, the learned confidence estimator yi elds improved ranking accuracy and empirically strengthens the monotonic relatio nship between confidence and disagreement risk, leading to higher success rates in satisfying target agreement levels across multiple datasets and judge models.

Contrastive Diffusion Alignment: Learning Structured Latents for Controllable Ge neration
Ruchi Sandilya, Sumaira Perez, Charles Lynch, Lindsay Victoria, Benjamin Zebley, Derrick Matthew Buchanan, Mahendra T. Bhati, Nolan Williams, Timothy Spellman, FAITH M. GUNNING, Conor Liston, Logan Grosenick
Diffusion models excel at generation, but their latent spaces are high dimension al and not explicitly organized for interpretation or control. We introduce ConD A (Contrastive Diffusion Alignment), a plug-and-play geometry layer that applies contrastive learning to pretrained diffusion latents using auxiliary variables (e.g., time, stimulation parameters, facial action units). ConDA learns a low-di mensional embedding whose directions align with underlying dynamical factors, co nsistent with recent contrastive learning results on structured and disentangled representations. In this embedding, simple nonlinear trajectories support smoot h interpolation, extrapolation, and counterfactual editing while rendering remai ns in the original diffusion space. ConDA separates editing and rendering by lif

ting embedding trajectories back to diffusion latents with a neighborhood-preserving kNN decoder and is robust across inversion solvers. Across fluid dynamics, neural calcium imaging, therapeutic neurostimulation, facial expression dynamics, and monkey motor cortex activity, ConDA yields more interpretable and controllable latent structure than linear traversals and conditioning-based baselines, indicating that diffusion latents encode dynamics-relevant structure that can be exploited by an explicit contrastive geometry layer.

Knowing Who, Not How Much: Learning-Augmented Mechanisms for Consumer Utility Maximization

Kira Goldner, Divyarthi Mohan, Thodoris Tsilivis

We study consumer utility maximization in an online random-order model where strategic agents arrive sequentially. To circumvent strong impossibility results for utility maximization, we turn to the framework of learning-augmented mechanism design. Crucially, we show that the types of predictions commonly used in learning-augmented mechanism design (such as predictions of agent values or the optimal value) are not useful for utility maximization, where payments are directly at odds with the objective. Instead, we identify that a qualitatively different kind of prediction suffices: the identity of the highest-valued agent. First, we provide a deterministic truthful mechanism for our online setting by adapting offline randomized techniques. Then, we augment our mechanism with predictions. When the predictions are correct, we achieve a constant approximation to the optimal solution under full information (consistency), and even when predictions are arbitrarily bad, we guarantee a constant approximation to the best implementable solution (robustness).

Cost-aware Stopping for Bayesian Optimization

Qian Xie, Linda Cai, Alexander Terenin, Peter I. Frazier, Ziv Scully

In automated machine learning, scientific discovery, and other applications of Bayesian optimization, deciding when to stop evaluating expensive black-box functions in a cost-aware manner is an important but underexplored practical consideration. A natural performance metric for this purpose is the *cost-adjusted simple regret*, which explicitly captures the trade-off between solution quality and cumulative evaluation cost. Existing stopping rules for Bayesian optimization are either heuristic, or are theoretically grounded but designed to optimize simple regret without accounting for evaluation costs; as a result, they provide no guarantees against unnecessary evaluations when costs are high. We propose a *principled cost-aware stopping rule* for Bayesian optimization that adapts to varying evaluation costs without heuristic tuning. Our rule is grounded in a theoretical connection to state-of-the-art cost-aware acquisition functions, namely the Pandora's Box Gittins Index (PBGI) and log expected improvement per cost (LogEIPC). When paired with either acquisition function, we prove that the resulting policy satisfies a theoretical guarantee bounding the expected cost-adjusted simple regret. Across synthetic tasks and empirical benchmarks including hyperparameter optimization and neural architecture size search, pairing our stopping rule with PBGI or LogEIPC usually matches or outperforms other acquisition-function--stopping-rule pairs in terms of cost-adjusted simple regret.

Benchmarking and Evolving Reason-Reflect-Rectify for Reflective Visual Generation

Junjie Wang, Xinghua Lou, Xiangtai Li, Ye Tian, Keyu Chen, Yulin Li, Bin Kang, Guangcan Mai, Yanwei Li, Zhuotao Tian, Liqiang Nie

Text-to-Image (T2I) models and Unified Multimodal Models (UMMs) have achieved remarkable progress in visual generation.

However, their reliance on a single-pass generation paradigm limits their ability to handle complex prompts requiring iterative refinement. To enable multi-round Reflective Visual Generation (RVG), we formalize the *Reason--Reflect--Rectify* (R^3) loop as a core framework and introduce R^3-Bench, a benchmark of over 600 expert-annotated instances that quantifies iterative reasoning and rectification capabilities.

Evaluation on R^3-Bench reveals a critical gap: while state-of-the-art models can identify generation errors, they fail to generate actionable rectification i nstructions.
To bridge this gap, we propose R^3-Refiner, a dual-stage framework leveraging Group Relative Policy Optimization (GRPO) and a Hierarchical Reward Mechanism (H RM) to better align rectification with reflective reasoning.
Experiments show that R^3-Refiner achieves significant improvements on R^3-B ench (+12.0% in Reflective Verdict Score, +9.0% in Rectification Score),
and can be seamlessly integrated with various MLLMs to enhance the generation qu ality of different T2I models on GenEval++ and T2I-CompBench.
Code is available at https://github.com/xiaomoguhz/R3-Bench.

Random Process Flow Matching: Generative Implicit Representations of Multivariat e Random Fields

Julien Lalanne, David Picard, Lionel Boillot, Lina-María GUAYACÁN-CARRILLO, Leon Barens, Jean-Michel Pereira

Generative modeling provides a powerful framework for learning data distribution s. These models initially relied on probabilistic methods such as Gaussian Proce sses (GP) for uncertainty-aware predictions and shifted towards larger trainable models to learn more complex distributions. In this work, we introduce *Random Process (RP) Flow*, a Flow Matching-based framework that represents the vector f ield as a neural implicit function. Unlike modern generative methods, our settin g involves a single observed field, from which only sparse measurements are avai lable. RP Flow uses Random Fourier Features to learn an implicit signal represen tation that can be queried at any arbitrary location from a limited set of obser vations, while encoding uncertainty through ensemble sampling. We propose constr ucting a Bayesian posterior by GP regression in the source space to generate hig h-quality samples. Our empirical results demonstrate that this framework generat es realistic samples along with calibrated uncertainty estimates, even under cha llenging conditions such as high frequency, high sparsity, or high dimensionalit y. These findings position RP Flow as a milestone towards generative models for reconstruction tasks where data is scarce and uncertainty must remain traceable.

Query-Based Asymmetric Modeling with Decoupled Input–Output Rates for Speech Res toration

Ui-Hyeop Shin, Jaehyun Ko, Woocheol Jeong, Hyung-Min Park

Speech restoration aims to recover clean speech from degraded recordings affecte d by noise, reverberation, bandwidth reduction, or other distortions, where inpu t and output sampling rates may differ. Existing approaches typically assume mat ched input--output rates and apply redundant resampling, limiting native multi-r ate processing. We formulate this gap as the extended sampling-frequency-indepen dent (xSFI) setting, where a model must operate under decoupled input--output ra tes, and propose TF-Restormer, a query-based xSFI modeling framework. The model encodes only the observed input band and synthesizes the unobserved high-frequen cy band through extension queries with band-partitioned cross-attention, yieldin g an asymmetric encoder--decoder that allocates capacity to analysis while keepi ng synthesis lightweight. Trained with a perceptual loss, a scaled log-spectral loss, and adversarial supervision via an SFI-STFT discriminator, TF-Restormer at tains balanced fidelity--perceptual quality as a single unified model, without r edundant resampling across denoising, dereverberation, bandwidth extension, and combined-distortion benchmarks under multiple sampling rates.

UB-SMoE: Universally Balanced Sparse Mixture-of-Experts for Resource-adaptive Fe derated Fine-tuning of Foundation Models

Van-Tuan Tran, Hong-Hanh Nguyen-Le, Marco Ruffini, Merim Dzaferagic

Heterogeneous LoRA-rank methods address system heterogeneity in federated fine-t uning of foundation models by assigning client-specific ranks based on computati onal capabilities. However, these methods achieve only marginal computational sa vings, as dense feed-forward computations dominate. Sparse Mixture-of-Experts (S MoE) provides a promising alternative through conditional computation, yet we id

entify that its naive application to heterogeneous federated settings introduces two critical discordances: (i) expert utilization imbalance and (ii) non-differentiability of Top-K routing. Our convergence analysis demonstrates that these discordances lead to degraded convergence, particularly for resource-constrained clients. To address these challenges, we propose Universally Balanced Sparse Mixture-of-Experts (UB-SMoE), which introduces Dynamic Modulated Routing (DMR) to rebalance expert utilization, and Universal Pseudo-Gradient (PG) to reconstruct learning signals for non-activated experts. These mechanisms form a self-reinforcing cycle that maintains expert viability across heterogeneous clients. Experiments on benchmarks show that UB-SMoE achieves up to 45.0% computational reduction on low-resource clients while improving their performance by $8.7 \times$ compared to existing heterogeneous LoRA-rank methods.

Probing Cross-modal Information Hubs in Audio-Visual LLMs

Jihoo Jung, Chaeyoung Jung, Ji-Hoon Kim, Joon Son Chung

Audio-visual large language models (AVLLMs) have recently emerged as a powerful architecture capable of jointly reasoning over audio, visual, and textual modalities. In AVLLMs, the bidirectional interaction between audio and video modalities introduces intricate processing dynamics, necessitating a deeper understanding of their internal mechanisms. However, unlike extensively studied text-only or large vision language models, the internal workings of AVLLMs remain largely unexplored. In this paper, we focus on cross-modal information flow between audio and visual modalities in AVLLMs, investigating where information derived from one modality is encoded within the token representations of the other modality. Through an analysis of multiple recent AVLLMs, we uncover two common findings. First, AVLLMs primarily encode integrated audio-visual information in sink tokens. Second, sink tokens do not uniformly hold cross-modal information. Instead, a distinct subset of sink tokens, which we term cross-modal sink tokens, specializes in storing such information.

Based on these findings, we further propose a simple training-free hallucination mitigation method by encouraging reliance on integrated cross-modal information within cross-modal sink tokens. Our code is available at https://github.com/kaistmm/crossmodal-hub.

Langevin Rollout Optimization for Modelic Reinforcement Learning

Tianyi Zhang, Likun Wang, Guojian Zhan, Feihong Zhang, Yang Guan, Yao Lyu, Shengbo Eben Li

Planning-driven model-based (modelic) reinforcement learning has achieved impressive success in continuous control tasks but predominantly relies on zero-order optimizers like Model Predictive Path Integral (MPPI).

While robust for global exploration, MPPI updates actions solely through sampling and neglects the smooth return gradients inherent in structured dynamics that guide fine-grained search.

To complement MPPI’s robustness with gradient-guided precision, we first propose \textbf{La}ngevin \textbf{R}ollout \textbf{O}ptimization (LaRO), which leverages return gradients to refine actions via Langevin dynamics, achieving reliable local convergence without sacrificing multimodal exploration.

This is supported by a score-augmented world model that jointly learns dynamics and a score function within a unified latent space, facilitating efficient and accurate gradient estimation for real-time planning.

Second, we combine MPPI and LaRO through a simple yet effective choice mechanism, termed \textbf{M}aximum \textbf{L}ook-\textbf{A}head \textbf{P}lanning (MLAP).

Finally, we instantiate MLAP within the latest BOOM algorithm, replacing its MPPI-only planner and yielding BOOM-L. Empirical results on the DeepMind Control Suite and Humanoid Bench demonstrate that BOOM-L consistently outperforms strong baselines in both sample efficiency and final performance.

Dual-stage Contrastive Learning-enhanced Multi-view Variational Clustering

Yanxi Liu, Yipin Hu, Fangxi Liu, Yanwei Yu, Lei Meng, Yongyong Chen, Guoqing Chao

Multi-view clustering aims to obtain a consensus clustering by integrating compl
ementary and consistent information from multiple views. However, two critical c
hallenges still exist in variational methods: (1) view heterogeneity and noise o
ften make fusion unreliable; (2) ambiguous posteriors and misassigned boundary
samples impact the clustering performance. To address these issues, we propose D
ual-stage Contrastive Learning-enhanced Multi-view Variational Clustering (DCL-M
VC), which integrates contrastive learning into both the fusion and representati
on stages. Firstly, at the fusion stage, we introduce a fusion-then-attention me
chanism to capture cross-view interactions and learn view-level attention weight
s for building a unified and reliable fused representation, and further introduc
e instance-level contrastive learning to enforce cross-view alignment at the ins
tance level. Secondly, we focus on boundary samples with uncertain posteriors an
d refine their cluster assignments by using cluster-center contrastive loss to e
nlarge inter-cluster margins, while leveraging prototypical contrastive learning
 with a confidence-aware curriculum to promote intra-cluster compactness at the
representation stage. Extensive experiments on six real-world datasets demonstra
te consistent improvements over strong baselines and validate the contribution o
f each component.

Conformal Calibration Transfer

Achref Doula

Conformal prediction converts point predictions into set-valued predictions with
 coverage guarantees under exchangeability between calibration and deployment da
ta. We study *conformal calibration transfer*, where this requirement fails beca
use labeled calibration is available only in a source space, while prediction se
ts are needed in a target space linked to the source through *unlabeled paired*
observations (e.g., paired modalities or sensor changes).

We propose Transported Conformal Calibration (TCC): we transport labeled source
calibration into the target space using the paired data, and then correct residu
al post-transport mismatch using only unlabeled target inputs. We instantiate th
is correction with two complementary methods: **TCC-KS**, which uses a label-fre
e uncertainty surrogate to detect mismatch and adjust calibration conservatively
, and **weighted-TCC**, which reweights transported calibration toward the targe
t domain for improved efficiency when weights are stable. We provide finite-samp
le target-domain coverage guarantees that adapt to an observable measure of mism
atch. Across CIFAR-100-C, Tiny-ImageNet-C, and SEN12MS, we show reliable target-
domain coverage transfer without labeled target calibration data, with label-fre
e diagnostics that predict when correction is needed.

From Parameters to Data: A Task-Parameter-Guided Fine-Tuning Pipeline for Effici
ent LLM Alignment

Hao Chen, Qi Zhang, Liyao Li, Zhanming Shen, Wentao Ye, Lirong Gao, NINGTAO WANG
, Xing Fu, Xiaoyu Shen, Junbo Zhao

Adapting Large Language Models (LLMs) to specialized domains typically incurs hi
gh data and computational overhead. While prior efficiency efforts have largely
treated data selection and parameter-efficient fine-tuning as isolated processes
, our empirical analysis suggests they may be intrinsically coupled. We posit th
e Strong Map Hypothesis: a sparse subset of attention heads plays a dominant rol
e in task-specific adaptation, acting as keys that unlock specific data patterns
. Building on this observation, we propose From Parameters to Data (P2D), a unif
ied framework that leverages these task-sensitive attention heads as a dual comp
ass for both sample mining and structural pruning. To rigorously quantify the to
tal pipeline cost, we introduce the Alignment Efficiency Ratio (AER) metric for
both selection latency and training time. Mechanistically, P2D identifies critic
al heads via a lightweight proxy and uses them as a functional filter to curate
high-affinity data, establishing a synergistic pipeline. Empirically, by updatin
g merely 10% of attention heads on 10% of the data, P2D achieves an 8.3 pp perfo
rmance gain over strong baselines and delivers a 7.0x end-to-end time speedup. T
hese results validate that precise parameter-data synchronization eliminates red
undancy, offering a new paradigm for efficient alignment.

Reinforcement Fine-Tuning Naturally Mitigates Forgetting in Continual Post-Train ing
Song Lai, Haohan Zhao, Rong Feng, Changyi Ma, Wenzhuo Liu, Hongbo Zhao, Xi Lin, Dong Yi, Qingfu Zhang, Hongbin Liu, Gaofeng Meng, Fei Zhu
Continual post-training (CPT) is a popular and effective technique for adapting foundation models like multimodal large language models to ever-evolving downstr eam tasks. While existing research primarily focuses on methods like data replay , model expansion, or parameter regularization, the fundamental role of the lear ning paradigm remains largely unexplored. This paper presents a comparative anal ysis of two core post-training paradigms: supervised fine-tuning (SFT) and reinf orcement fine-tuning (RFT), investigating their respective impacts on knowledge retention during CPT. Our experiments are conducted across multiple multimodal t asks, utilizing Qwen2.5-VL-7B-Instruct as the base model. The investigation yiel ds two significant findings: (1) When continuously learning on downstream tasks, SFT leads to catastrophic forgetting of previously learned tasks. In contrast, RFT inherently preserves prior knowledge and achieves performance comparable to multi-task training. (2) RFT successfully protects and even enhances the model's general knowledge on standard benchmarks, while SFT degrades general model capa bilities severely. Further analysis reveals that this stability is not primarily due to explicit mechanisms like KL penalty or chain-of-thought reasoning. We in vestigate RFT's learning dynamics and find that its selective update mechanism i nherently prevents interference with established knowledge. Based on this insigh t, we propose a rollout-based instance filtering algorithm (RIF-RFT) that enhanc es the training efficiency of RFT by focusing on learnable samples. Our comprehe nsive study demonstrates the superiority of RFT as a robust paradigm for continu al post-training.

Pushing the Limits of Block Rotations in Post-Training Quantization
Sai Sanjeet, Ian Colbert, Pablo Monteagudo-Lago, Giuseppe Franco, Yaman Umuroglu , Nicholas J. Fraser
Recent post-training quantization (PTQ) methods have adopted block rotations to diffuse outliers prior to rounding. While this reduces the overhead of online fu ll-vector rotations, the effect of block structure on outlier suppression remain s poorly understood. To fill this gap, we present the first systematic, non-asym ptotic analysis of outlier suppression for block Hadamard rotations. Our analysi s reveals that outlier suppression is fundamentally limited by the geometry of t he input vector. In particular, in the deterministic worst case, post-rotation o utliers are minimized when the pre-rotation ℓ_1 norm mass is evenly distrib uted across blocks. Guided by these insights, we introduce PeRQ (Permute, Rotate , then Quantize), a PTQ framework that redistributes activation mass via permuta tions prior to rotation. We propose a greedy mass diffusion algorithm to calibra te permutations by equalizing the expected blockwise ℓ_1 norms. To avoid ad ding inference overhead, we identify permutation-equivariant regions in transfor mer architectures to merge these permutations into model weights before deployme nt. Experiments show that PeRQ consistently improves accuracy across all block s izes, recovering up to 90% of the full-vector rotation perplexity when quantizin g Llama3 1B to INT4 with block size 16, compared to 46% without permutations.

LLMs as Noisy Channels: A Shannon Perspective on Model Capacity and Scaling Laws
Xu Ouyang, Deyi Liu, Yuhang Cai, Jing Liu, Yuan Yang, Chen Zheng, Thomas Hartvig sen, Yiyuan Ma
Existing scaling laws for Large Language Models (LLMs), predominantly monotonic power laws, fail to explain emerging non-monotonic phenomena such as *catastroph ic overtraining* and *quantization-induced degradation*, where performance deter iorates despite increased compute.

We propose the Shannon Scaling Law, a unified theoretical framework that models LLM training as information transmission over a noisy channel, grounded in the S hannon–Hartley theorem. By mapping model parameters to channel bandwidth and tra

ining tokens to signal power, our formulation explicitly captures the interactio n between learning signal and intrinsic noise. This perspective reveals a fundam ental Shannon capacity for LLMs: scaling model size or data without preserving a sufficient signal-to-noise ratio (SNR) inevitably amplifies noise, inducing a t ransition from monotonic improvement to U-shaped performance degradation.

We validate our theory through experiments on Pythia and OLMo2 under perturbatio ns, including Gaussian noise, quantization and supervised fine-tuning on math, Q A and code tasks. The Shannon Scaling Law consistently outperforms classical sca ling laws and recent perturbation-aware laws, achieving strong R^2 scores and accurately capturing loss basins missed by prior approaches. It also extrapolate s: fitted on $\leq$6.9B Pythia models with $\leq$180B tokens, it predicts the un seen 12B model up to 307B tokens at pooled $R^2{=}0.847$, while monotonic baseli nes collapse.

Trajectory-Aware Spiking DiTs Conversion via Membrane Potential Error-Feedback
Haoran Fang, Tianxing Man, Xingchen Li, Wanli Shi, Jinjie Fang, Bin Gu
Diffusion Transformers (DiTs) have achieved state-of-the-art generative performa nce, yet their iterative denoising process remains computationally expensive and energy-intensive. Spiking Neural Networks (SNNs) offer a promising neuromorphic alternative for energy efficiency; however, the non-differentiable nature of sp iking neurons makes direct training difficult, positioning ANN-to-SNN conversion as a more practical, training-free solution. In this paper, we identify a criti cal challenge unique to converting DiTs: standard fixed-scale spiking neurons fa il to accommodate the highly dynamic activation ranges inherent across denoising steps. This mismatch leads to cumulative errors that significantly degrade gen eration fidelity. To resolve this, we propose a novel conversion framework featu ring Multi-Threshold (MT) neurons and a Membrane Potential Error-Feedback (MPEF) mechanism. MT neurons expand the expressive capacity of discrete spikes by empl oying a multi-level firing strategy. Concurrently, MPEF exploits the temporal co rrelation between successive denoising steps to recycle residual membrane potent ial, effectively compensating for information loss and mitigating distribution s hifts without retraining. Extensive experiments on ImageNet demonstrate that our framework achieves competitive generative quality with superior energy efficien cy, establishing a new performance benchmark for spiking Diffusion Transformers.

GKD-Recruiter: Jointly Modeling Social and Task Heterogeneity for Spatial Crowds ourcing via Graph Knowledge Distillation
Yucen Gao, Zhemeng Yu, Zhuoran Li, Jianxiong Guo, Xiaofeng Gao
Social recruitment offers a solution to worker scarcity in Spatial Crowdsourcing (SC) but faces challenges that are often ignored in traditional Influence Maxim ization. First, task heterogeneity arising from offline execution constraints br eaks the interest-implies-participation assumption, as social influence often fa ils to translate into physical presence. Second, finite task demand creates a sa turation trap, a non-submodular setting in which utility drops sharply to zero o nce demand is met. To bridge these gaps, we propose GKD-Recruiter, a Task-Aware framework designed to maximize Effective Task Satisfaction (ETS). We explicitly model the complex worker-task affinity via a heterogeneous graph and capture dir ectional social influence using a novel Influential GAT. To robustly fuse these distinct signals, we introduce a Graph Knowledge Distillation mechanism. Further more, we employ Rainbow DQN to navigate the non-submodular combinatorial search space, avoiding the local optima that trap greedy heuristics. Extensive experime nts on real-world datasets demonstrate that GKD-Recruiter significantly outperfo rms state-of-the-art baselines in both solution quality and inference efficiency . The code is available at https://github.com/GaoYucen/GKD-Recruiter.

MADE: Benchmark Environments for Closed-Loop Materials Discovery
Shreshth A Malik, Tiarnan Doherty, Panagiotis Tigas, Muhammed Razzak, S Roberts, Aron Walsh, Yarin Gal
Existing benchmarks for computational materials discovery primarily evaluate sta

tic predictive tasks or isolated computational sub-tasks. While valuable, these evaluations neglect the inherently iterative and adaptive nature of scientific discovery. We introduce **MA**terials **D**iscovery **E**nvironments (**MADE**), a novel framework for benchmarking end-to-end autonomous materials discovery pipelines. MADE simulates closed loop discovery campaigns in which an agent or algorithm proposes, evaluates, and refines candidate materials under a constrained oracle budget, capturing the sequential and resource-limited nature of real discovery workflows. We formalize discovery as a search for thermodynamically stable compounds relative to a given convex hull, and evaluate efficacy and efficiency via comparison to baseline algorithms. The framework is flexible; users can compose discovery agents from interchangeable components such as generative models, filters, and planners, enabling the study of arbitrary workflows ranging from fixed pipelines to agentic systems. We demonstrate this by conducting systematic experiments across a diverse range of systems and algorithms, finding that adaptive planning becomes more important to discovery efficiency as the search space scales.

SEER: Transformer-based Robust Time Series Forecasting via Automated Patch Enhancement and Replacement

Xiangfei Qiu, Xvyuan Liu, Tianen Shen, Xingjian Wu, Hanyin Cheng, Bin Yang, Jilin Hu

Time series forecasting is important in many fields that require accurate predictions for decision-making. Patching techniques, commonly used and effective in time series modeling, help capture temporal dependencies by dividing the data into patches. However, existing patch-based methods fail to dynamically select patches and typically use all patches during the prediction process. In real-world time series, there are often low-quality issues during data collection, such as missing values, distribution shifts, anomalies and white noise, which may cause some patches to contain low-quality information, negatively impacting the prediction results. To address this issue, this study proposes a robust time series forecasting framework called $\textbf{SEER}$. Firstly, we propose an $\textit{Augmented Embedding Module}$, which improves patch-wise representations using a Mixture-of-Experts~(MoE) architecture and obtains series-wise token representations through a channel-adaptive perception mechanism. Secondly, we introduce a $\textit{Learnable Patch Replacement Module}$, which enhances forecasting robustness and model accuracy through a two-stage process: 1) a dynamic filtering mechanism eliminates negative patch-wise tokens; 2) a replaced attention module substitutes the identified low-quality patches with global series-wise token, further refining their representations through a causal attention mechanism. Comprehensive experimental results demonstrate the SOTA performance of SEER.

RevealLayer: Disentangling Hidden and Visible Layers via Occlusion-Aware Image Decomposition

Binhao Wang, Shihao Zhao, Bo Cheng, Qiuyu Ji, Yuhang Ma, Liebucha Wu, Shanyuan Liu, Dawei Leng, Yuhui Yin

Recent diffusion-based approaches have made substantial progress in image layer decomposition.
However, accurately decomposing complex natural images remains challenging due to difficulties in occlusion completion, robust layer disentanglement, and precise foreground boundaries. Moreover, the scarcity of high-quality multi-layer natural image datasets limits advancement.
To address these challenges, we propose **RevealLayer**, a diffusion-based framework that decomposes an RGB image into multiple RGBA layers, enabling precise layer separation and reliable recovery of occluded content in natural images.
RevealLayer incorporates three key components: (1) a **Region-Aware Attention** module to disentangle hidden and visible layers; (2) an **Occlusion-Guided Adapter** to leverage contextual information to enhance overlapping regions; and (3) a **composite loss** to enforce sharp alpha boundaries and suppress residual artifacts.
To support training and evaluation, we introduce **RevealLayer-100K**, a high-qu

ality multi-layer natural image constructed through a collaboration between auto
mated algorithms and human annotation, and further establish **RevealLayerBench*
* for benchmarking layer decomposition in general natural scenes.
Extensive experiments demonstrate that RevealLayer consistently outperforms exis
ting approaches in layer decomposition.

TreePO: Enhancing Policy Efficacy and Inference Efficiency with Tree Modeling
Yizhi LI, Qingshui Gu, Zhoufutu Wen, Ziniu Li, Ruibin Yuan, Tianshun Xing, Shuyu
e Guo, Tuney Zheng, Xin Zhou, Xingwei Qu, Wangchunshu Zhou, Zheng Zhang, Wei She
n, Wei Xue, Qian Liu, Chenghua Lin, Jian Yang, Ge Zhang, Wenhao Huang
Recent advancements in aligning large language models via reinforcement learning
 have achieved remarkable gains in solving complex reasoning problems, but at th
e cost of expensive on-policy rollouts and limited exploration of diverse reason
ing paths. In this work, we introduce TreePO, involving a self-guided rollout al
gorithm that views sequence generation as a tree-structured searching process. C
omposed of dynamic tree sampling policy and fixed-length segment decoding, TreeP
O leverages local uncertainty to warrant additional branches. By amortizing comp
utation across common prefixes and pruning low-value paths early, TreePO essenti
ally reduces the per-update compute burden while preserving or enhancing explora
tion diversity. Key contributions include: (1) a segment-wise sampling algorithm
 that alleviates the KV cache burden through contiguous segments and spawns new
branches along with an early-stop mechanism; (2) a tree-based segment-level adva
ntage estimation that considers both global and local proximal policy optimizati
on. and (3) analysis on the effectiveness of probability and quality-driven dyna
mic divergence and fallback strategy. We empirically validate the performance ga
in of TreePO on a set reasoning benchmarks and the efficiency saving of GPU hour
s from 22% up to 43% of the sampling design for the trained models, meanwhile sh
owing up to 40% reduction at trajectory-level and 35% at token-level sampling co
mpute for the existing models. While offering a free lunch of inference efficien
cy, TreePO reveals a practical path toward scaling RL-based post-training with f
ewer samples and less compute.

REST: Diffusion-based Real-time End-to-end Streaming Talking Head Generation via
 ID-Context Caching and Asynchronous Streaming Distillation
Haotian Wang, Yuzhe Weng, Jun Du, Haoran Xu, Xiaoyan Wu, Shan He, Bing Yin, Cong
 Liu, Qingfeng Liu
Diffusion models have significantly advanced the field of talking head generatio
n (THG). However, slow inference speeds and prevalent non-autoregressive paradig
ms severely constrain the application of diffusion-based THG models. In this stu
dy, we propose REST, a pioneering diffusion-based, real-time, end-to-end streami
ng audio-driven talking head generation framework. To support real-time end-to-e
nd generation, a compact video latent space is first learned through a spatiotem
poral variational autoencoder with a high compression ratio. Additionally, to en
able semi-autoregressive streaming within the compact video latent space, we int
roduce an ID-Context Cache mechanism, which integrates ID-Sink and Context-Cache
 principles into key-value caching for maintaining identity consistency and temp
oral coherence during long-term streaming generation. Furthermore, an Asynchrono
us Streaming Distillation (ASD) strategy is proposed to mitigate error accumulat
ion and enhance temporal consistency in streaming generation, leveraging a non-s
treaming teacher with an asynchronous noise schedule to supervise the streaming
 student. REST bridges the gap between autoregressive and diffusion-based approac
hes, achieving a breakthrough in efficiency for applications requiring real-time
 THG. Experimental results demonstrate that REST outperforms state-of-the-art me
thods in both generation speed and overall performance.

The Expert Strikes Back: Interpreting Mixture-of-Experts Language Models at Expe
rt Level
Jeremy Herbst, Stefan Wermter, Jae Hee Lee
Mixture-of-Experts (MoE) architectures have become the dominant choice for scali
ng Large Language Models (LLMs), activating only a subset of parameters per toke

n. While MoE architectures are primarily adopted for computational efficiency, it remains an open question whether their sparsity makes them inherently easier to interpret than dense feed-forward networks (FFNs). We compare MoE experts and dense FFNs using k-sparse probing and find that expert neurons are consistently less polysemantic, with the gap widening as routing becomes sparser. This suggests that sparsity pressures both individual neurons and entire experts toward monosemanticity. Leveraging this finding, we _zoom out_ from the neuron to the expert level as a more effective unit of analysis. We validate this approach by automatically interpreting hundreds of experts. This analysis allows us to resolve the debate on specialization: experts are neither broad domain specialists (e.g., biology) nor simple token-level processors. Instead, they function as fine-grained task experts, specializing in linguistic operations or semantic tasks (e.g., closing brackets in LaTeX). Our findings suggest that MoEs are inherently interpretable at the expert level, providing a clearer path toward large-scale model interpretability. Code is available at: https://github.com/jerryy33/MoE_analysis.

Conformal Thinking: Risk Control for Reasoning on a Compute Budget

Xi Wang, Anushri Suresh, Alvin Zhang, Rishi More, William Jurayj, Mehrdad Farajtabar, Daniel Khashabi, Eric Nalisnick

Reasoning Large Language Models (LLMs) enable test-time scaling, with dataset-level accuracy improving as the token budget increases,
motivating adaptive reasoning---spending tokens when they improve reliability and stopping early when additional computation is unlikely to help.
However, setting the token budget, as well as the threshold for adaptive reasoning, is a practical challenge that entails a fundamental risk-accuracy trade-off. We re-frame the budget setting problem as risk control, limiting the error rate while minimizing compute.
Our framework introduces an upper threshold that stops reasoning when the model is confident (risking incorrect output) and a novel parametric \emph{lower} threshold that preemptively stops unsolvable instances (risking premature stoppage). Given a target risk and a validation set, we use distribution-free risk control to optimally specify these stopping mechanisms.
Empirical results across diverse reasoning tasks and models demonstrate the effectiveness of our risk control approach, demonstrating computational efficiency gains from the lower threshold and ensemble stopping mechanisms, all while adhering to the user-specified risk target.

Sample Complexity Bounds for Robust Mean Estimation with Mean-Shift Contamination

Ilias Diakonikolas, Giannis Iakovidis, Daniel Kane, Sihan Liu

We study the basic task of mean estimation in the presence of mean-shift contamination. In the mean-shift contamination model, an adversary is allowed to replace a small constant fraction of the clean samples by samples drawn from arbitrarily shifted versions of the base distribution. Prior work characterized the sample complexity of this task for the special cases of the Gaussian and Laplace distributions. Specifically, it was shown that consistent estimation is possible in these cases, a property that is provably impossible in Huber's contamination model. An open question posed in earlier work was to determine the sample complexity of mean estimation in the mean-shift
contamination model for general base distributions. In this work, we study and essentially resolve this open question. Specifically, we show that, under mild spectral conditions on the characteristic function of the (potentially multivariate) base distribution, there exists a sample-efficient algorithm that estimates the target mean to any desired accuracy. We complement our upper bound with a qualitatively matching sample complexity lower bound. Our techniques make critical use of Fourier analysis, and in particular introduce the notion of a Fourier witness as an essential ingredient of our upper and lower bounds.

ANCHOR: Abductive Network Construction with Hierarchical Orchestration for Relia

ble Probability Inference in Large Language Models
Wentao Qiu, Guanran Luo, Zhongquan Jian, Jingqi Gao, Meihong Wang, Qingqiang Wu
A central challenge in large-scale decision-making under incomplete information is estimating reliable probabilities. Recent approaches use Large Language Models (LLMs) to generate explanatory factors and coarse-grained probability estimates, which are then refined by a Naïve Bayes model over factor combinations. However, sparse factor spaces often yield ''unknown'' predictions, while expanding factors increases noise and spurious correlations, weakening conditional independence and degrading reliability. To address these limitations, we propose Anchor, an aggregated Bayesian inference framework over a hierarchical factor space. It constructs dense factor hierarchies through iterative generation and clustering, maps contexts via hierarchical retrieval and refinement, and augments Naïve Bayes with a Causal Bayesian Network to model latent factor dependencies. Experiments show that Anchor markedly reduces ''unknown'' predictions and produces more reliable probability estimates than direct LLM baselines, achieving state-of-the-art performance while significantly reducing time and token overhead.
****
Post-Training with Policy Gradients: Optimality and the Base Model Barrier
Alireza Mousavi-Hosseini, Murat A Erdogdu
We study post-training linear autoregressive models with outcome and process rewards. Given a context x, the model must predict the response $y \in \mathcal{Y}^N$, a sequence of length N that satisfies a γ margin condition, an extension of the standard separability to sequences.
We prove that on test samples where the base model achieves a non-trivial likelihood α, a variant of policy gradient (PG) can achieve likelihood $1 - \varepsilon$ with an essentially minimax optimal number of reward queries $\tilde{\mathcal{O}}((\alpha^{-1} + \varepsilon^{-1})/\gamma^2)$.
However, a barrier arises for going beyond the support of the base model.
We prove that the overall expected error after post-training with outcome rewards is governed by a property of the base model called the *Likelihood Quantile* (LQ), and that variants of PG, while minimax optimal, may require a number of reward queries exponential in N to go beyond this support, regardless of the pre-training algorithm.
To overcome this barrier, we study post-training with a process reward model, and demonstrate how PG variants in this setting avoid the curse of dimensionality in N via dependence on a token-level LQ.
Along the way, we prove that under the margin condition, SGD with adaptive learning rate (LR) achieves a near optimal test error for statistical learning, and PG with adaptive LR achieves a near optimal number of mistakes for online learning while being computationally efficient whenever possible, both of which may be of independent interest.

Discriminative Attribute Graph Clustering Through Topology-Guided Contrastive Learning
Ling Ding, Zhizhi Yu, Cuiying Huo
Deep attribute graph clustering aims to learn discriminative node representations by leveraging both node attributes and graph topology to partition nodes into distinct clusters. Although substantial progress has been made in attribute-graph clustering in recent years, two key challenges remain: noisy edges in the original adjacency matrix degrade the quality of information propagation, and redundant feature information across different feature views hampers the learning of discriminative representations. To address these issues, we propose a self-supervised attribute graph clustering method based on topological reconstruction and correlation decorrelation. First, we reconstruct the graph topology by computing intersections between k-nearest neighbors and the original adjacency relationships, while simultaneously leveraging global semantic information from K-means clustering to filter out noisy nodes. This reconstructed topology effectively mitigates information redundancy during feature aggregation in Graph Neural Networks. Second, unlike existing augmentation-based contrastive methods, we treat the feature representations from an auto-encoder (AE) and a graph auto-encoder (GAE) a

s two complementary natural views. We then apply mutual information minimization and a decorrelation constraint to suppress redundant information between views, yielding more discriminative node representations. Extensive experiments on four widely-used graph datasets—ACM, DBLP, CITE, and AMAP—demonstrate that our method consistently outperforms six state-of-the-art baselines.
****
SegPVSG: Panoptic Video Scene Graph Generation via Temporal Focusing and Generative Augmentation
YiKai Li, Quhui Ke, Jinglin Liang, Zhi-Yuan Zhang, Zhidi Lin, Shuangping Huang
Panoptic Video Scene Graph Generation (PVSG) aims to identify relations between pixel-level entities in a video, serving as a novel paradigm for structured video parsing. However, this task faces two key challenges. First, the interactions between entities are temporally fragmented and sparse, meaning videos are dominated by irrelevant content with limited salient information. Second, the distribution of relations exhibits a significant long-tailed pattern, making models struggle to perform well on tail categories with insufficient data. To address these issues, we propose SegPVSG, an innovative, temporal-segment-aware PVSG framework consisting of two key components: TempFocusNet (TFN) and Relation-centric Generative Video Augmentation (RGVA) module. TFN is a localization-then-recognition network that improves PVSG performance by explicitly localizing and focusing on salient segments before relation recognition. Meanwhile, RGVA is a novel augmentation module that generates realistic, context-consistent video segments for rare relations and coherently inserts them into original videos. Our method outperforms prior methods by +3.53 mR@20 and +5.9 mR@50, demonstrating its effectiveness.
The code is available at https://github.com/ticatt/SegPVSG.

A unified theory of feature learning in RNNs and DNNs
Jan Philipp Bauer, Kirsten Fischer, Moritz Helias, Agostina Palmigiano
Recurrent and deep neural networks (RNNs/DNNs) are cornerstone architectures in machine learning. Remarkably, RNNs differ from DNNs only by weight sharing, as can be shown through unrolling in time. How does this structural similarity fit with the distinct functional properties these networks exhibit? To address this question, we here develop a unified mean-field theory for RNNs and DNNs in terms of representational kernels, describing fully trained networks in the feature learning (μP) regime. This theory casts training as Bayesian inference over sequences and patterns, directly revealing the functional implications induced by the RNNs' weight sharing. In DNN-typical tasks, we identify a phase transition when the learning signal overcomes the noise due to randomness in the weights: below this threshold, RNNs and DNNs behave identically; above it, only RNNs develop correlated representations across timesteps. For sequential tasks, the RNNs' weight sharing furthermore induces an inductive bias that aids generalization by interpolating unobserved time steps. Overall, our theory offers a way to connect architectural structure to functional biases.

A Positive Case for Faithfulness: Explanations Help Predict Model Behavior
Harry Mayne, Justin Singh Kang, Dewi Sid William Gould, Kannan Ramchandran, Adam Mahdi, Noah Y. Siegel
LLM self-explanations are often presented as a promising tool for AI oversight, yet their faithfulness to the model's true reasoning process is poorly understood. Existing faithfulness metrics have critical limitations, typically relying on identifying unfaithfulness via adversarial prompting or detecting reasoning errors. These methods overlook the predictive value of explanations. We introduce *Normalized Simulatability Gain* (NSG), a general and scalable metric based on the idea that a faithful explanation should allow an observer to learn a model's decision-making criteria, and thus better predict its behavior on related inputs. We evaluate 18 frontier proprietary and open-weight models, e.g., Gemini 3, GPT-5.2, and Claude 4.5, on 7,000 counterfactuals from popular datasets covering health, business, and ethics. We find self-explanations substantially improve prediction of model behavior (11-37% NSG). Self-explanations also provide more predi

ctive information than explanations generated by external models, even when thos
e models are stronger. This implies an advantage from self-knowledge that extern
al explanation methods cannot replicate. Our approach also reveals that, across
models, 5-15% of self-explanations are egregiously misleading. Despite their imp
erfections, we show a positive case for self-explanations: they encode informati
on that helps predict model behavior.

Class-Grouped Normalized Momentum and Faster Hyperparameter Exploration to Tackl
e Class Imbalance in Federated Learning
Haemin Park, Diego Klabjan, Martin W. Braun, Xiuqi Li, Balakrishnan Ananthanaray
anan
Class imbalance poses a critical challenge in federated learning (FL), where und
errepresented classes suffer from poor predictive performance yet cannot be addr
essed by standard centralized techniques due to privacy and heterogeneity constr
aints. We propose FedCGNM (Federated Class-Grouped Normalized Momentum), a clien
t-side optimizer in FL that partitions classes into a small number of groups bas
ed on minimum within-group variance, maintains a momentum per group, normalizes
each group momentum to unit length, and uses the summation of the normalized gro
up momentums as an update direction. This design both equalizes gradient magnitu
de across majority and minority groups and mitigates the noise inherent in rare-
class gradients. We further provide a theoretical convergence analysis explicitl
y accounting for time-varying resampling-rates. Additionally, to efficiently opt
imize these rates in small-client regimes, we introduce FedHOO, an X-armed-bandi
t (XAB) based algorithm that exploits federated parallelism that evaluates many
combinations of two candidate rates per client at linear cost. Empirical evaluat
ion on four public long-tailed benchmarks and a proprietary chip-defect dataset
demonstrates that FedCGNM consistently outperforms baselines, with FedHOO yieldi
ng further gains in small-scale federations.
****
CodeTaste: Can LLMs Generate Human-Level Code Refactorings?
Alex Thillen, Niels Mündler, Veselin Raychev, Martin Vechev
LLM coding agents can generate working code, but their solutions often accumulat
e complexity, duplication, and architectural debt. Human developers address such
 issues through refactoring: behavior-preserving program transformations that im
prove structure and maintainability. We investigate whether agents (i) can execu
te refactorings reliably and (ii) identify the refactorings that human developer
s actually chose in real codebases.
To this end, we construct CodeTaste, a benchmark mined from large multi-file ope
n-source refactorings. To score solutions, we combine repository test suites tha
t measure functional correctness with tailored static checks that verify removal
 of undesired and introduction of desired code patterns using dataflow reasoning
.
Our results show a clear gap: agents perform well at implementing refactorings t
hat are specified in detail, but often fail to discover the human refactoring ch
oices when given a focus area for changes. A propose-then-implement decompositio
n improves alignment, and selecting the best-aligned proposal before implementat
ion can yield further gains. CodeTaste provides an evaluation target and a poten
tial preference signal for aligning coding agents with human refactoring decisio
ns in realistic codebases. We release the benchmark, leaderboard, and code.

TelecomTS: A Multi-Modal Observability Dataset for Time Series and Language Anal
ysis
Austin Feng, Andreas Varvarigos, Ioannis Panitsas, Daniela Fernandez, Jinbiao We
i, Yuwei Guo, Jialin Chen, Ali Maatouk, Leandros Tassiulas, Rex Ying
Modern enterprises generate vast streams of time series metrics when monitoring
complex systems, known as observability data. Unlike conventional time series fr
om domains such as climate, observability data are zero-inflated, highly stochas
tic, and exhibit minimal temporal structure. Despite their importance, observabi
lity datasets remain underrepresented in public benchmarks due to proprietary re
strictions and privacy concerns. Existing datasets are often anonymized and norm

alized, removing scale information and limiting their use for tasks such as anom aly detection, root cause analysis, and multi-modal reasoning. To address this g ap, we introduce TelecomTS, a large-scale observability dataset derived from a 5 G telecommunications network. TelecomTS features heterogeneous, de-anonymized co variates with explicit absolute scale information and provides a diverse suite o f downstream tasks, including anomaly detection, root cause analysis, and multi- modal question-answering. Benchmarking state-of-the-art time series, language, r easoning, and multi-modal foundation models reveals that existing approaches str uggle with the abrupt, noisy, and high-variance dynamics characteristic of obser vability data. Our experiments further underscore the importance of preserving c ovariates' absolute scale, emphasizing the need for foundation time series model s that natively leverage scale information for practical real-world observabilit y applications. The code is available at: \url{https://github.com/Ali-maatouk/Te lecomTS}.

Optimal Fair Aggregation of Crowdsourced Noisy Labels using Demographic Parity C onstraints

Gabriel Singer, Samuel Gruffaz, Olivier VO VAN, Nicolas Vayatis, Argyris Kaloger atos

As acquiring reliable ground-truth labels is usually costly, or infeasible, crow dsourcing and aggregation of noisy human annotations is a common alternative. Ag gregating subjective labels, though, may amplify individual biases, particularly regarding sensitive features, raising fairness concerns. Nonetheless, fairness in crowdsourced aggregation remains largely unexplored, with no existing converg ence guarantees and only limited post-processing approaches for enforcing $\vare psilon$-fairness under demographic parity. We address this gap by analyzing the fairness of crowdsourced aggregation methods within the ε-fairness framework, for Majority Vote and Optimal Bayesian aggregation. In the small-crow d regime, we derive an upper bound on the fairness gap of Majority Vote in terms of the fairness gaps of the individual annotators. We further show that the fai rness gap of the aggregated consensus converges exponentially fast to that of th e ground-truth under interpretable conditions. Since ground-truth itself may sti ll be unfair, we generalize a state-of-the-art multiclass fairness post-processi ng algorithm from the continuous to the discrete setting, which enforces strict demographic parity constraints on any aggregation rule. Experiments on syntheti c and real datasets demonstrate the effectiveness of our approach and corroborat e the theoretical insights.

Rethinking Genomic Modeling Through Optical Character Recognition

Hongxin Xiang, Pengsen Ma, Yunkang Cao, Di Yu, Haowen Chen, Xinyu Yang, xiangxia ng Zeng

Recent genomic foundation models largely adopt large language model architecture s that treat DNA as a one-dimensional token sequence. However, exhaustive sequen tial reading is structurally misaligned with sparse and discontinuous genomic se mantics, leading to wasted computation on low-information background and prevent ing understanding-driven compression for long contexts. Here, we present Optical DNA, a vision-based framework that reframes genomic modeling as Optical Characte r Recognition (OCR)-style document understanding. OpticalDNA renders DNA into st ructured visual layouts and trains an OCR-capable vision--language model with a \emph{visual DNA encoder} and a \emph{document decoder}, where the encoder produ ces compact, reconstructible visual tokens for high-fidelity compression. Buildi ng on this representation, OpticalDNA defines prompt-conditioned objectives over core genomic primitives—reading, region grounding, subsequence retrieval, and m asked span completion—thereby learning layout-aware DNA representations that ret ain fine-grained genomic information under a reduced effective token budget. Acr oss diverse genomic benchmarks, OpticalDNA consistently outperforms recent basel ines; on sequences up to 450k bases, it achieves the best overall performance wi th nearly $20\times$ fewer effective tokens, and surpasses models with up to $98 5\times$ more activated parameters while tuning only 256k \emph{trainable} param eters.

****
Covariance Volume Maximization for Embodied Latent Exploration in Deep Reinforcement Learning
Yiming Wang, Yiheng Zhang, Kaiyan Zhao, Xingjie Zuo, Xingyu Liu, Xuetao Li, Furui Liu, Bo An, Leong Hou U
Efficient exploration remains a key challenge in deep reinforcement learning, especially for embodied agents operating in realistic environments with high-dimensional observations and complex dynamics. Recent latent exploration methods define bonuses in a learned latent space, but often struggle in these settings where (i) representations can be
noisy or policy-dependent, and (ii) common strategies such as randomized latent objectives or fixed directional spanning are brittle and fail to improve global coverage. We propose Covariance Volume Maximization (CVM), a coverage-driven latent exploration framework with two key components. First, we learn a behavioral state encoder using a *policy-mixture* objective to reduce representation drift under rapidly changing exploration policies, yielding stable and behaviorally meaningful latent displacements. Second, CVM rewards each transition by its exact increase in the log-determinant of the covariance of recent latent displacements, explicitly expanding the explored region and prioritizing under-covered directions. This objective coincides with the classical *D-optimal* design criterion, providing an information-efficiency justification. Extensive experiments on embodied navigation and manipulation tasks demonstrate that CVM substantially improves exploration efficiency and robustness, and scales effectively to different environments.

Seeing Without Understanding: Disentangling Perception, Reasoning, and Simulation in VLM Gameplay
Dingyang Jin, Jiawei He, Calvin Lo, Steven Hu, Ryan Rad
While Vision-Language Models (VLMs) excel on static visual benchmarks, they consistently underperform in game-based reasoning, yet existing evaluations conflate failures in perception, rule comprehension, and reasoning. We propose a two-stage diagnostic framework that decomposes VLM performance into testable components: controlled perception tests isolating visual encoding, and a diagnostic matrix with a six-level rule complexity ladder evaluated in both explicit verification and predictive simulation modes. Experimenting with six state-of-the-art VLMs reveals three failure patterns: (1) coordinated spatial drift, where off-by-one localization errors among adjacent pieces share the same shift direction at 1.5-$1.9\times$ the rate expected under spatial independence; (2) perception-reasoning dissociation, where models correctly verify board states but fail to apply rules—at complex constraint levels, perception remains relatively stable while reasoning accuracy plummets, with even the best-performing model capped at 75%; and (3) a simulation gap, with performance dropping by up to 27 points when predicting future states versus verifying observed outcomes. These limitations persist across model scales and are not resolved by scaling, text-only input, or structured prompting. Code and data are available at https://github.com/chillibeaver/PRS-Diag.
****
Certified Robustness under Heterogeneous Perturbations via Hybrid Randomized Smoothing
Blaise Delattre, Hengyu WU, Paul Caillon, Wei Yang Bryan Lim, Yang Cao
Randomized smoothing provides strong, model-agnostic robustness certificates, but
existing guarantees are limited to single modalities, treating continuous and
discrete inputs in isolation.
This limitation becomes critical in multimodal models, where decisions depend on
cross-modal semantics and adversaries can jointly perturb heterogeneous inputs,
rendering unimodal certificates insufficient.

We introduce a unified randomized smoothing framework for mixed discrete--continuous
inputs based on an analytically tractable Neyman--Pearson formulation of the joint
worst-case problem.
By analyzing the joint likelihood ordering induced by factorized discrete and
continuous noise, our approach yields a closed-form, one-dimensional certificate
that strictly generalizes both Gaussian (image-only) and discrete (text-only)
randomized smoothing.
We validate the framework on multimodal safety filtering, providing, to our
knowledge, the first model-agnostic Neyman--Pearson certificate for joint
discrete-token and continuous-image perturbations in interaction-dependent
text--image safety filtering.
****

VideoGPA: Distilling Geometry Priors for 3D-Consistent Video Generation
Hongyang Du, Junjie Ye, Xiaoyan Cong, Runhao Li, Jingcheng Ni, Aman Agarwal, Zeqi Zhou, Zekun Li, Randall Balestriero, Yue Wang
While recent video diffusion models (VDMs) produce visually impressive results, they fundamentally struggle to maintain 3D structural consistency, often resulting in object deformation or spatial drift. We hypothesize that these failures arise because standard denoising objectives lack explicit incentives for geometric coherence. To address this, we introduce VideoGPA (Video Geometric Preference Alignment), a data-efficient self-supervised framework that leverages a geometry foundation model to automatically derive dense preference signals that guide VDMs via Direct Preference Optimization (DPO). This approach effectively steers the generative distribution toward inherent 3D consistency without requiring human annotations. VideoGPA significantly enhances temporal stability, geometric plausibility, and motion coherence using minimal preference pairs, consistently outperforming state-of-the-art baselines in extensive experiments.
****

SAEs-BrainMap: Unveiling the Emergence of Specialized Concepts in Deep Models via a Brain Alignment
Ziming Mao, Jia Xu, Wenxuan Pan, Mufan Xue, Yaochu Jin, Guoyuan Yang
Understanding the internal mechanisms of deep neural networks remains a significant challenge, particularly in elucidating how generic visual concepts emerge within latent spaces. In this work, we propose SAEs-BrainMap, a novel framework that utilizes human brain activation patterns from the ventral visual pathway as objective probes to guide the identification of features decomposed by Sparse Autoencoders (SAEs). Our quantitative and qualitative empirical results demonstrate a robust representational alignment between sparse model features and biological Regions of Interests (ROIs), confirming the feasibility of utilizing brain signals to characterize model functionality. By leveraging this alignment, we trace the hierarchical trajectory of generic concepts cross layers and utilize the brain's hierarchical structure to visualize the model's global processing flow, providing novel insights into model interpretability. Our code is available at [this repository](https://github.com/Matzohe/SAEs-BrainMap).

EnsembleVLA: Ensemble Learning for Vision-Language Action Models
Mingchen Song, Xiang Deng, Jie Wei, Dongmei Jiang, Liqiang Nie, Weili Guan
Diverse Vision-language-action (VLA) models have been proposed and demonstrated remarkable capabilities in robotic manipulation. However, how to effectively ensemble VLAs to further enhance performance remains largely unexplored, as conventional ensemble techniques designed for discriminative tasks cannot be directly applied to generative action policies with high-dimensional, multimodal distributions. To address this challenge, we propose EnsembleVLA, an energy-based framework that enables principled ensemble of diverse VLA models. We establish a unified theoretical framework showing that both diffusion-based and flow-based VLA mod

els can be formulated as energy-based models, where additive energy combination naturally induces policy composition at the distribution level. This theoretical foundation enables multiple pre-trained policies to be seamlessly aggregated into a stronger ensemble policy. Building upon this compositional framework, EnsembleVLA further incorporates learnable composition weights for dynamic policy balancing, coupled with a confidence-aware gating mechanism that adaptively modulates bounded residual corrections, collectively ensuring stable and robust task execution. Extensive experiments demonstrate that EnsembleVLA achieves competitive performance across various tasks in both simulated and real-world environments.

MotiMotion: Motion-Controlled Video Generation with Visual Reasoning
Lee Hsin-Ying, Hanwen Jiang, Yiqun Mei, Jing Shi, Ming-Hsuan Yang, Zhixin Shu
Current motion-controlled image-to-video generation models rigidly follow user-provided trajectories that are often sparse, imprecise, and causally incomplete. Such reliance often yields unnatural or implausible outcomes, especially by missing secondary causal consequences.
To address this, we introduce MotiMotion, a novel framework that reformulates motion control as a reasoning-then-generation problem.
To encourage causally grounded and commonsense-consistent interactions, we leverage a training-free vision-language reasoner to refine image-space coordinates of primary trajectories and to hallucinate plausible secondary motions.
To further improve motion naturalness, we propose a confidence-aware control scheme that modulates guidance strength, enabling the model to closely follow high-confidence plans while correcting artifacts under low-confidence inputs with its internal generative priors.
To support systematic evaluation, we curate a new image-to-video benchmark, MotiBench, consisting of interaction-centric scenes where new events are triggered by motion.
Both VLM-based evaluation and a human study on MotiBench demonstrate that MotiMotion produces videos with more plausible object behaviors and interaction, and is preferred over existing approaches.

Efficient Hallucination Detection for LLMs Using Uncertainty-Aware Attention Heads
Artem Vazhentsev, Lyudmila Rvanova, Gleb Kuzmin, Ekaterina Fadeeva, Ivan Lazichny, Alexander Panchenko, Maxim Panov, Mrinmaya Sachan, Preslav Nakov, Timothy Baldwin, Artem Shelmanov
While large language models (LLMs) have become highly capable, they remain prone to factual inaccuracies, commonly referred to as "hallucinations." Uncertainty quantification (UQ) offers a promising way to mitigate this issue, but most existing methods are computationally intensive and/or require supervision. In this work, we propose Recurrent Attention-based Uncertainty Quantification (RAUQ), an unsupervised and efficient framework for identifying hallucinations. The method leverages an observation about transformer attention behavior: when incorrect information is generated, certain "uncertainty-aware" attention heads tend to reduce their focus on preceding tokens. RAUQ automatically detects these attention heads and combines their activation patterns with token-level confidence measures in a recurrent scheme, producing a sequence-level uncertainty estimate in just a single forward pass. Through experiments on twelve datasets spanning question answering, summarization, and translation across nine different LLMs, we show that RAUQ consistently outperforms state-of-the-art UQ baselines. Importantly, it incurs minimal overhead, requiring less than 1% additional computation.
Since it requires neither labeled data nor extensive parameter tuning, RAUQ serves as a lightweight, plug-and-play solution for real-time hallucination detection in white-box LLMs.
****

What is Missing? Explaining Neurons Activated by Absent Concepts
Robin Hesse, Simone Schaub-Meyer, Janina Hesse, Bernt Schiele, Stefan Roth
Explainable artificial intelligence (XAI) aims to provide human-interpretable insights into the behavior of deep neural networks (DNNs), typically by estimating

a simplified causal structure of the model. In existing work, this causal structure often includes relationships where the presence of a concept is associated with a strong activation of a neuron. For example, attribution methods primarily identify input pixels that contribute most to a prediction, and feature visualization methods reveal inputs that cause high activation of a target neuron – the former implicitly assuming that the relevant information resides in the input, and the latter that neurons encode the presence of concepts. However, a largely overlooked type of causal relationship is that of encoded absences, where the absence of a concept increases neural activation. In this work, we show that such missing but relevant concepts are common and that mainstream XAI methods struggle to reveal them when applied in their standard form. To address this, we propose two simple extensions to attribution and feature visualization techniques that uncover encoded absences. Across experiments, we show how mainstream XAI methods can be used to reveal and explain encoded absences, how ImageNet models exploit them, and that debiasing can be improved when considering them.

Reward Modeling from Natural Language Human Feedback

Zongqi Wang, Rui Wang, Yuchuan Wu, Yiyao Yu, Pinyi Zhang, Shaoning Sun, Yujiu Yang, Yongbin Li

Reinforcement Learning with Verifiable Reward (RLVR) on preference data has become the mainstream approach for training Generative Reward Models (GRMs). Typically, GRMs generate reasoning chains ending with critiques and preference labels, with RLVR using label correctness as the training reward. However, we demonstrate that such binary classification tasks make GRMs susceptible to guessing correct outcomes without sound critiques, introducing noise into the reward signal and impairing learning effectiveness. To address this, we propose Reward Modeling from Natural Language Human Feedback (RM-NLHF), which leverages natural language feedback to obtain process reward signals. Specifically, we compute the similarity between GRM-generated and human critiques as the process reward, providing more accurate signals than outcome-only supervision. Considering that human critiques are difficult to scale, we introduce MetaRM which learns to predict process reward from datasets with human critiques and generalizes to data without them. Experiments on multiple benchmarks demonstrate that RM-NLHF consistently outperforms state-of-the-art models trained with outcome reward, confirming the superiority of natural language over binary feedback. Our code is publicly available at https://github.com/Tongyi-ConvAI/Qwen-Character/tree/main/Character-GenRM-NLHF.

WestWorld: A Knowledge-Encoded Scalable Trajectory World Model for Diverse Robotic Systems

Yuchen Wang, Jiangtao Kong, Sizhe Wei, Xiaochang Li, Haohong Lin, Hongjue Zhao, Tianyi Zhou, Lu Gan, Huajie Shao

Trajectory world models play a crucial role in robotic dynamics learning, planning, and control. While recent works have explored trajectory world models for diverse robotic systems, they struggle to scale to a large number of distinct system dynamics and overlook domain knowledge of physical structures. To address these limitations, we introduce *WestWorld*, a kno**W**ledge-**E**ncoded **S**calable **T**rajectory **World** model for diverse robotic systems. To tackle the scalability challenge, we propose a novel system-aware Mixture-of-Experts (Sys-MoE) that dynamically combines and routes specialized experts for different robotic systems via a learnable system embedding. To further enhance zero-shot generalization, we incorporate domain knowledge of robot physical structures by introducing a structural embedding that aligns trajectory representations with morphological information. After pretraining on 89 complex environments spanning diverse morphologies across both simulation and real-world settings, *WestWorld* achieves significant improvements over competitive baselines in zero- and few-shot trajectory prediction. Additionally, it shows strong scalability across a wide range of robotic environments and significantly improves performance on downstream model-based control for different robots. Finally, we deploy our model on a real-world Unitree Go1, where it demonstrates stable locomotion performance. The code is available at https://github.com/511205787/WestWorld.

****

Behavioral Mode Discovery for Fine-tuning Multimodal Generative Policies

Alberta Longhini, David Emukpere, Jean-Michel Renders, Seungsu Kim

We address the problem of fine-tuning pre-trained generative policies with reinforcement learning (RL) while preserving the multimodality of their action distributions. Existing methods for RL fine-tuning of generative policies (e.g., diffusion policies) improve task performance but often collapse diverse behaviors into a single reward-maximizing mode. To mitigate this issue, we propose an unsupervised mode discovery framework that uncovers latent behavioral modes within generative policies. The discovered modes enable the use of mutual information as an intrinsic reward, regularizing RL fine-tuning to enhance task success while maintaining behavioral diversity. Experiments on robotic manipulation tasks demonstrate that our method consistently outperforms conventional fine-tuning approaches, achieving higher success rates and preserving richer multimodal action distributions.

Know Thyself, Know Thy User: Intrinsic Dual-Perspective Reasoning for Role-Playing LLMs

Haotong Sun, Jianye Xie, Bocheng Xu, Yinghui Jiang

As role-playing Large Language Models (LLMs) become central to personalized AI, they face a fundamental challenge: balancing character authenticity with user satisfaction. Prior dual-process and dual-perspective approaches address this through prompt-level conditioning, auxiliary modules, or inference-time reflection---realizing duality externally rather than within the core attention mechanism. We introduce the KnowSelf-KnowOther Transformer (KSKT), which embeds dual-perspective reasoning directly into the generation process via dual-stream factorized attention that processes self-understanding and other-understanding through separate streams. This intrinsic integration enables token-level dynamic balance rather than post-hoc reconciliation. On CharacterBench, KSKT achieves 6.2% overall improvement over Qwen3-4B-Thinking. On SOTOPIA, KSKT improves Relationship by 19.3% over the base model---the dimension requiring explicit self-other coordination. These results establish intrinsic dual-perspective reasoning as an effective architectural principle for role-playing systems.

Learning Reward–Cost Balance in Safe RL via Score-Based World Models

Yuetian Wang, Dianxi Shi, Yuanze Wang, Huanhuan Yang, Shiming Song, Chunping Qiu

Safe reinforcement learning (Safe RL) seeks to optimize long-term performance while ensuring adherence to safety constraints. However, most existing approaches address safety in a simplified manner, typically by linearly combining rewards and costs, which provides limited guidance when safety and performance interact in complex, nonlinear ways. We present USB-RL (Unsupervised Score-Balanced Reinforcement Learning), a model-based framework that learns implicit safety–performance preferences directly from experience. Our approach infers a monotone partial-order score through unsupervised pairwise comparisons of long-horizon outcomes, capturing nuanced trade-offs without relying on manually tuned cost weights. The learned score guides model-based policy optimization by dynamically balancing safety and performance, enabling flexible and adaptive multi-step planning in imagination-based control. Across diverse safety benchmarks, USB-RL achieves strong returns while substantially reducing safety violations, demonstrating stable and interpretable safety–performance trade-offs.

Dual Quaternion SE(3) Synchronization with Recovery Guarantees

Jianing Zhao, Linglingzhi Zhu, Anthony Man-Cho So

Synchronization over the special Euclidean group $\mathrm{SE}(3)$ aims to recover absolute poses from noisy pairwise relative transformations and is a core primitive in robotics and 3D vision. Standard approaches often require multi-step heuristic procedures to recover valid poses, which are difficult to analyze and typically lack theoretical guarantees. This paper adopts a dual quaternion representation and formulates $\mathrm{SE}(3)$ synchronization directly over the unit dual quaternion. A two-stage algorithm is developed: A spectral initializer compu

ted via the power method on a Hermitian dual quaternion measurement matrix, foll
owed by a dual quaternion generalized power method (DQGPM) that enforces feasibi
lity through per-iteration projection. The estimation error bounds are establish
ed for spectral estimators, and DQGPM is shown to admits a finite-iteration erro
r bound and achieves linear error contraction up to an explicit noise-dependent
threshold. Experiments on synthetic benchmarks and real-world multi-scan point-s
et registration demonstrate that the proposed pipeline improves both accuracy an
d efficiency over representative matrix-based methods.
****

Planar Symmetric Pattern Generation

Ning Lin, Luxi Chen, Huaguan Chen, Jiacheng Cen, Chongxuan Li, Wenbing Huang, Ha
o Sun

Generating objects with specific symmetries is essential in various real-world s
cenarios. However, adapting existing 2D continuous representations to enforce pl
anar group symmetry remains a challenge, as the transformation of non-reflective
group elements may disrupt continuity. To overcome this limitation, we propose
a symmetrization framework for arbitrary planar groups. Our method transforms an
y 2D continuous representation into a symmetric one while preserving continuity.
We provide the mathematical formulation of this representation, demonstrate its
approximation capability for symmetric functions, and detail the construction m
ethodology. We validate our approach through three visual design tasks (pattern
design, paper-cutting design and stylized topology design) and one material desi
gn task. Experiments confirm that our representation enables effective symmetry
control and demonstrate its broader applicability.
****

TT-Sparse: Learning Sparse Rule Models with Differentiable Truth Tables

Hans Farrell Soegeng, Sarthak Ketanbhai Modi, Thomas Peyrin

Interpretable machine learning is essential in high-stakes domains where decisio
n-making requires accountability, transparency, and trust. While rule-based mode
ls offer global and exact interpretability, learning rule sets that simultaneous
ly achieve high predictive performance and low, human-understandable complexity
remains challenging. To address this, we introduce TT-Sparse, a flexible neural
building block that leverages differentiable truth tables as nodes to learn spar
se, effective connections. A key contribution of our approach is a new soft TopK
operator with straight-through estimation for learning discrete, cardinality-co
nstrained feature selection in an end-to-end differentiable manner. Crucially, t
he forward pass remains sparse, enabling each node (and the entire model) to be
transformed exactly into compact, globally interpretable DNF/CNF Boolean formula
s via Quine--McCluskey minimization. Extensive empirical results across 28 datas
ets spanning binary, multiclass, and regression tasks show that the learned spar
se rules exhibit superior predictive performance with lower complexity compared
to existing state-of-the-art methods.
****

Language as a Wave Phenomenon: Semantic Phase Locking and Interference in Neural
Networks

Alper YILDIRIM, ■brahim Yüceda■

In standard Transformer architectures, semantic importance is often conflated wi
th activation magnitude, obscuring the geometric structure of latent representat
ions. To disentangle these factors, we introduce PRISM, a complex-valued archite
cture designed to isolate the computational role of phase. By enforcing a strict
unit-norm constraint ($|z| = 1$) and replacing attention with gated harmonic conv
olutions, the model is encouraged to utilize subtractive interference in the fre
quency domain to suppress noise, rather than relying on magnitude-based gating.
We utilize this constrained regime to study a hybrid architecture—fusing phase-b
ased routing with standard attention—which achieves improved parameter efficienc
y and representation quality compared to baselines in our evaluated settings. Me
chanistically, interventional ablations indicate that the model carries substant
ial task-relevant information in phase: preserving phase largely maintains perfo
rmance, whereas disrupting phase causes severe degradation. Together, these resu
lts suggest that phase-based spectral interference is a usable computational mec

hanism for neural sequence modeling at the evaluated scale.
****
DeepImageSearch: Benchmarking Multimodal Agents for Context-Aware Image Retrieval in Visual Histories
Chenlong Deng, Mengjie Deng, Junjie Wu, Dun Zeng, Teng Wang, Qingsong Xie, Jiadeng Huang, Shengjie Ma, Changwang Zhang, Zhaoxiang Wang, Jun Wang, Yutao Zhu, Zhicheng Dou
Existing multimodal retrieval systems excel at semantic matching but implicitly assume that query-image relevance can be measured in isolation. This paradigm overlooks the rich dependencies inherent in realistic visual streams, where information is distributed across temporal sequences rather than confined to single snapshots. To bridge this gap, we introduce DeepImageSearch, a novel agentic paradigm that reformulates image retrieval as an autonomous exploration task. Models must plan and perform multi-step reasoning over raw visual histories to locate targets based on implicit contextual cues. We construct DISBench, a challenging benchmark built on interconnected visual data. To address the scalability challenge of creating context-dependent queries, we propose a human-model collaborative pipeline that employs vision-language models to mine latent spatiotemporal associations, effectively offloading intensive context discovery before human verification. Furthermore, we build a robust baseline using a modular agent framework equipped with fine-grained tools and a dual-memory system for long-horizon navigation. Extensive experiments demonstrate that DISBench poses significant challenges to state-of-the-art models, highlighting the necessity of incorporating agentic reasoning into next-generation retrieval systems.
****
Weights to Code: Extracting Interpretable Algorithms from the Discrete Transformer
Yifan Zhang, Wei Bi, Kechi Zhang, Dongming Jin, Jie Fu, Zhi Jin
Algorithm extraction aims to synthesize executable programs directly from models trained on algorithmic tasks, enabling *de novo* recovery of executable mechanisms from weights without relying on human-written target programs.
However, applying this paradigm to Transformer is complicated by representation entanglement (e.g., superposition), where features encoded in overlapping directions substantially hinder the recovery of symbolic expressions.
We propose the Discrete Transformer, an architecture explicitly designed to bridge the gap between continuous representations and discrete symbolic logic.
By injecting discreteness through temperature-annealed sampling, our framework effectively leverages hypothesis testing and symbolic regression to extract human-readable programs.
Empirically, the Discrete Transformer achieves performance comparable to the RNN-based MIPS baseline on shared discrete tasks, while broadening extraction to tasks with continuous-valued intermediate computations.
Finally, we show that architectural inductive biases provide fine-grained control over synthesized programs, establishing the Discrete Transformer as a controllable testbed for algorithm extraction and Transformer interpretability.
****
Learning Disentangled Multi-Agent World Model for Decentralized Control
Di Xue, Jing Jiang, Shaowei Zhang, Wenhao Guo, Lei Yuan, Zongzhang Zhang, Yang Yu
World models enable learning policies via latent imagination, offering benefits such as history compression and sample efficiency.
The primary challenge in applying world models to multi-agent tasks is that modeling multi-agent dynamics in latent space requires integrating information from different agents, often creating spurious correlations between their latent states.
Existing methods either reconstruct the observation for each agent or employ communication to maintain correlation during execution, failing to learn disentangled latent states that are crucial for effective decentralized control.
To address this, we present the Disentangled Multi-Agent World Model (DMAWM). It facilitates learning decentralized policies in the latent space through a novel

architecture comprising independent agent modules and a shared environment module.
During real-environment execution, agent modules independently process local information to form a factorized latent representation.
The environment module is then trained to mirror the factorized structure generated by the agent modules, effectively disentangling individual latent states from the interaction dynamics.
Consequently, imaginary rollouts generated by the environment module more faithfully simulate decentralized execution dynamics, facilitating the transfer of policies from imagination to decentralized execution.
Empirically, DMAWM outperforms existing model-based and model-free approaches in convergence speed and final performance, with additional visualization demonstrating its efficacy in capturing agent interactions.

Asymmetric Prompt Weighting for Reinforcement Learning with Verifiable Rewards
Reinhard Heckel, Mahdi Soltanolkotabi, Christos Thrampoulidis
Reinforcement learning with verifiable rewards has driven recent advances in LLM post-training, in particular for reasoning. Policy optimization algorithms generate a number of responses for a given prompt and then effectively weight the corresponding gradients depending on the rewards. The most popular algorithms including GRPO, DAPO, and RLOO focus on ambiguous prompts, i.e., prompts with intermediate success probability, while downgrading gradients with very easy and very hard prompts. In this paper, we consider asymmetric prompt weightings that assign higher weights to prompts with low, or even zero, empirical success probability. We find that asymmetric weighting particularly benefits from-scratch RL (as in R1-Zero), where training traverses a wide accuracy range, and less so in post-SFT RL where the model already starts at high accuracy. We also provide theory that characterizes prompt weights which minimize the time needed to raise success probability from an initial level to a target accuracy under a fixed update budget. In low-success regimes, where informative responses are rare and response cost dominates, these optimal weights become asymmetric, upweighting low success probabilities and thereby accelerating effective-time convergence.

Conformal Prediction for Early Stopping in Mixed Integer Optimization
Stefan Clarke, Bartolomeo Stellato
Mixed-integer optimization solvers often find optimal solutions early in the search, yet spend the majority of computation time proving optimality. We exploit this by learning when to terminate solvers early on distributions of similar problem instances. Our method trains a neural network to estimate the true optimality gap from the solver state, then uses conformal prediction to calibrate a stopping threshold with rigorous probabilistic guarantees on solution quality. On six problem families from the Distributional MIPLIB library, our method reduces solve time by over 60% while guaranteeing 0.1%-optimal solutions with 95% probability for new instances drawn from the same distribution.

Weak-to-Strong Generalization via Bregman Bias–Variance Decomposition
Gengze Xu, Wei Yao, Ziqiao Wang, Yong Liu
Weak-to-strong generalization (W2SG) is the phenomenon in which a powerful student model, trained on labels produced by a weaker teacher, ultimately outperforms the teacher on the target task. In this work, we theoretically investigate how W2SG can arise via a generalized bias–variance decomposition under Bregman divergence. We show that the expected population risk gap between the student and the teacher is characterized by the expected misfit between the two models. Unlike earlier misfit-based analyses, our theory removes several restrictive assumptions, e.g., it does not require the student hypothesis class to be convex.
Our results indicate that W2SG is more likely when the student effectively approximates the teacher's posterior mean. Specializing to squared loss, we provide a sufficient condition (illustrated through a concrete example) under which the student converges to its posterior mean teacher; in particular, increasing the student model size can ensure this convergence. For cross-entropy loss, our analy

sis further suggests that lowering the entropy of the student's predictive distr
ibution can promote W2SG. We also find that the reverse cross-entropy, unlike th
e standard forward cross-entropy, is less sensitive to the teacher's predictive
uncertainty. Finally, we verify these theoretical insights empirically and demon
strate that incorporating reverse cross-entropy consistently improves student pe
rformance.

STEP: Warm-Started Visuomotor Policies with Spatiotemporal Consistency Predictio
n

Jinhao Li, Yuxuan Cong, Yingqiao Wang, Hao Xia, Shan Huang, Yijia Zhang, Ningyi
Xu, Guohao Dai

Diffusion policies have recently emerged as a powerful paradigm for visuomotor c
ontrol in robotic manipulation due to their ability to model the distribution of
 action sequences and capture multimodality. However, iterative denoising leads
to substantial inference latency, limiting control frequency in real-time closed
-loop systems. Existing acceleration methods either reduce sampling steps, bypas
s diffusion through direct prediction, or reuse past actions, but often struggle
 to jointly preserve action quality and achieve consistently low latency.
In this work, we propose **STEP**, a lightweight spatiotemporal consistency pred
iction mechanism to construct high-quality warm-start actions that are both dist
ributionally close to the target action and temporally consistent, without compr
omising the generative capability of the original diffusion policy.
Then, we propose a velocity-aware perturbation injection mechanism that adaptive
ly modulates actuation excitation based on temporal action variation to prevent
execution stall especially for real-world tasks.
We further provide a theoretical analysis showing that the proposed prediction i
nduces a locally contractive mapping, ensuring convergence of action errors duri
ng diffusion refinement.
Extensive evaluations on nine simulated benchmarks and two real-world tasks show
 that STEP with 2 steps can achieve an average 21.6\% and 27.5\% higher success
rate than BRIDGER and DDIM on the RoboMimic benchmark and real-world tasks, resp
ectively.
The code is available at https://github.com/Kimho666/STEP.

GRASP: Graph Reasoning via Agentic Solving and Probing of LLMs

Xiaojun Guo, Mingxue Tian, Chenheng Zhang, Xiaohan Wang, Jiajun Chai, Guojun Yin
, Wei Lin, Yifei Wang, Yisen Wang

Integrating graph knowledge into Large Language Models (LLMs) via passive repres
entation faces critical bottlenecks: limited context windows, unreliable numeric
al computation, and structural hallucinations. To solve this, we propose **GRASP
** (**G**raph **R**easoning via **A**gentic **S**olving and **P**robing), shifti
ng the paradigm from passive ingestion to proactive agentic exploration. By inte
rleaving Neighbor Retrieval for on-demand probing with Code Interpreter as a det
erministic solver, GRASP enables LLMs to autonomously navigate and compute over
complex topologies. We employ a staged reinforcement learning strategy (GRPO) th
at transitions from visible tuning to a structure-blind environment, forcing the
 agent to develop genuine topological awareness. Evaluated on multi-domain graph
 reasoning benchmarks, our 4B model achieves a 53.06% average performance boost,
 surpassing SOTA baselines like DeepSeek-V3.2 and successfully generalizing to u
nseen tasks, with high potential for tackling sampling on million-node graphs an
d solving Hard-level LeetCode graph problems. Our implementation is open-sourced
 at https://github.com/PKU-ML/GRASP, with models hosted on Huggingface collectio
n https://huggingface.co/collections/PKU-ML/grasp.

Structured Diffusion Bridges: Inductive Bias for Denoising Diffusion Bridges

Eitan Kosman, Gabriele Serussi, Chaim Baskin

Modality translation is inherently under-constrained, as multiple cross-modal ma
ppings may yield the same marginals. Recent work has shown that diffusion bridge
s are effective for this task. However, most existing approaches rely on fully p
aired datasets, thereby imposing a single data-driven constraint. We propose a d

iffusion-bridge framework that characterizes the space of admissible solutions a
nd restricts it via alignment constraints, treating paired supervision as an opt
ional heuristic rather than a prerequisite. We validate our method on synthetic
and real modality translation benchmarks across unpaired, semi-paired, and paire
d regimes, showing consistent performance across supervision levels. Notably, it
 achieves near fully-paired quality with a substantial relaxation in pairing req
uirements, and remaining applicable in the unpaired regime. These results highli
ght diffusion bridges as a flexible foundation for modality translation beyond f
ully paired data.

Learning to Reconfigure: Configuration-Control Co-optimization of Reconfigurable
 Robots for Heterogeneous Locomotion
Xiaoyu Xiong, Kehan Liu, Huiyi Yan, Shengjie Wang, Yang Gao, Tao Du
Traditional robot co-design approaches typically converge to one configuration,
which do not explore the flexibility from reconfiguration on heterogeneous envir
onments. On the other hand, existing designs for reconfigurable robots require h
uman-designed configurations. We present Learning to Reconfigure, a holistic pip
eline for configuration-control co-optimization of reconfigurable robots in hete
rogeneous locomotion tasks consisting of several sub-tasks. Our pipeline propose
s low-level specialized primitives with a high-level scheduler. To jointly optim
ize configuration design and control, our primitives employ a multi-tail archite
cture that disentangles these distinct objectives. Building on this, the schedul
er learns to dynamically switch configurations based on global task progress. We
 evaluate our pipeline on locomotion tasks across walking, flying, and swimming,
 and compare with the state-of-the-art baselines, including single-robot control
 and multi-morphology co-optimization algorithms. Quantitative results based on
traversal progress show that our pipeline outperforms single-robot baselines by
5.95x average progress. Compared with the reconfiguration-free design given by t
he co-design algorithms, our robots also exhibit 9.81x progress on average. Thes
e results highlight the critical role of configuration adaptation in achieving v
ersatile robotic autonomy in complex worlds.

LLM-Guided Communication for Cooperative Multi-Agent Reinforcement Learning
Sangjun Bae, Yisak Park, Sanghyeon Lee, Seungyul Han
Communication is a key component in multi-agent reinforcement learning (MARL) fo
r mitigating partial observability, yet prior approaches often rely on inefficie
nt information exchange or fail to transmit sufficient state information. To add
ress this, we propose LLM-driven Multi-Agent Communication (LMAC), which leverag
es an LLM's reasoning capability to design a communication protocol that enables
 all agents to reconstruct the underlying state as accurately and uniformly as p
ossible. LMAC iteratively refines the protocol using an explicit state-awareness
 criterion, improving state recovery while narrowing differences in agents' know
ledge. Experiments on diverse MARL benchmarks show that LMAC improves state reco
nstruction across agents and yields substantial performance gains over prior com
munication baselines.

An In-Depth Study on Deep Learning Model Cloning
Bin Hu, Xiancong Pan, Dongjin Yu, Tianyi Hu
Artificial intelligence has achieved remarkable breakthroughs in fields such as
text, image, and video analysis, with deep learning serving as the mainstream pa
radigm. Trained deep learning models can be integrated into various applications
 either through fine-tuning or without any modification. While this practice pro
motes the advancement of artificial intelligence, it also raises concerns regard
ing intellectual property protection and information security risks. Therefore,
it is necessary to propose relevant methods to measure the similarity between mo
dels. Existing code clone detection techniques are insufficient to address this
issue. In this paper, we provide the first definition of model cloning and desig
n a method for model similarity detection. The framework characterizes model top
ology at the structural level based on normalized computational graphs, and at t
he weight level, it employs a method that does not require explicit parameter al

ignment to measure the statistical similarity of weight parameters. Experiments on a synthetic model clone benchmark dataset and real-world open-source models demonstrate that the proposed method can accurately detect similar models. This method provides a unified and extensible quantitative foundation for model lineage analysis, model retrieval, and intellectual property protection of models.

Task-Aware Mechanism: Hybrid MoE Vision Tower Towards Holistic Video Understanding
Qishen Yin, Tanghui Jia, Peng Jin, Li Hao, Juntong Wu, Guanlin Lu, Li Yuan
Should an LVLM use the same video processing pipeline for \emph{comprehending the main idea of a 2-hour movie} and \emph{counting the birds appearing in a 15-second clip}? We present Task-Aware Mechanism (TAM), a hybrid-gated Mixture-of-Experts (MoE) vision tower that adapts frame count and resolution to the user query and video length. TAM introduces a compact 0.1B text-only \emph{Inductor} trained on our TA-116K dataset to infer task types, enabling task-aware visual budgeting and routing: a soft-gated MoE vision encoder for stability, and hard-gated resolution-specific projectors/pipelines for efficient specialization. The explicit budget also separates task classification from downstream visual-language reasoning, making routing decisions easier to inspect and helping diagnose when fixed visual pipelines under-sample temporal or spatial evidence. Built on Qwen2-7B, TallVA-8B-A7B achieves state-of-the-art performance among models with comparable LLMs on most video benchmarks and remains competitive against stronger-LLM baselines, showing that task-aware visual budgeting makes video understanding more holistic.

Particles Don’t Care About Z: Towards Scaling Entropy Estimation of Unnormalized Densities
Safa Messaoud, Skander Charni, Elaa Bouazza, Ali Pourghasemi Fatideh, Halima Bensmail
Computing the differential entropy of distributions known only up to a normalization constant is a fundamental challenge with broad theoretical and practical significance. While variational inference is highly scalable for density approximation from samples, its application to unnormalized densities remains under-explored due to the difficulty of constructing variational distributions that exploit the structure of the unnormalized density and are simultaneously expressive, tractable, efficiently samplable. Recently, Messaoud et al. (ICLR 24) introduced _P-SVGD_, a Stein variational inference method for this setting. We show, however, that \textit{P-SVGD} fails to scale to high dimensions due to incorrect invertibility assumptions, omission of a critical trace-of-Hessian term, and unstable divergence-control heuristics. We propose _MET-SVGD_, a principled extension of _P-SVGD_ that provides a general framework for stable _SVGD_ hyperparameter selection with global invertibility and convergence guarantees. Empirically, _MET-SVGD_ achieves up to $12\times$ and $16\times$ lower entropy estimation error than _P-SVGD_ and existing _SVGD_ baselines, respectively. On CIFAR-10 energy-based image generation, it improves FID by 80.4% and yields $64\times$ higher training stability. In maximum-entropy reinforcement learning, it achieves up to 16% higher returns than _P-SVGD_. Code is available at https://shorturl.at/fTG0G.

V-LynX: Token Interface Alignment for Video+X LLMs
Jungin Park, Jiyoung Lee, Kwanghoon Sohn
This study introduces an intriguing phenomenon in Video LLMs: rather than merely translating frames into textual embeddings, Video LLMs establish a continuous manifold, token interface, allowing visual tokens to operate as standalone entities within the architecture.

Exploiting this discovery, we propose V-LynX, a scalable framework that integrates novel modalities into Video LLMs by repurposing the internalized interface.

Departing from conventional paradigms that necessitate heavy modality-specific encoders or paired supervision, V-LynX employs a lightweight auxiliary pathway in parallel with the frozen vision encoder.

Our method integrates new sensory inputs with intrinsic video priors by aligning both attention responses and statistical distributions using unpaired unimodal data sets.

This ensures manifold compatibility while preserving the integrity of the Video LLMs.

Extensive benchmarks demonstrate that V-LynX achieves SOTA and efficiency across audio-visual QA, 3D reasoning, high-frame-rate, and multi-view video understanding. The code is available at https://github.com/park-jungin/lynx.

Telescope: Improving Zero Shot Detection of LLM Generated Content By Measuring Token Repetition Probability

Christopher Nassif, Joshua F. Cooper

Distinguishing Large Language Model (LLM) generated text from human writing is a critical and difficult challenge. While LLMs are trained to write like humans, we hypothesize that this training leaves an indelible mark. LLMs develop a particularly strong aversion to token repetition very early in training. This bias persists as a ``Vestigial Heuristic'' (a developmental artifact) that is activated in LLM-generated text, separating LLM from human writing. To probe this phenomenon, we introduce Telescope Perplexity, a metric that evaluates the token repetition of the model, $P(s_i | s_{1:i})$. Our empirical investigation reveals that the Telescope Perplexity signature emerges early in pre-training, and Telescope Perplexity empirically enables highly effective zero-shot LLM detection. We show state-of-the-art or competitive performance across diverse datasets (including modern evaluation sets we introduce), reference models, and perturbation schemes with greater efficiency than other methods.

Beyond Euclidean Clipping: Overcoming Exploration Collapse in LLM RL via Riemannian Isometric Policy Optimization

Zhicheng Cai, Xinyuan Guo, Hanlin Wu, Mingxuan Wang, Wei-Ying Ma, Ya-Qin Zhang, Hao Zhou

Reinforcement learning (RL) has become a dominant paradigm for enhancing LLMs' reasoning capabilities.

However, RL algorithms with PPO-Clip are inherently limited by exploration collapse.

Subsequent works remain primarily heuristic and fail to identify the essential cause of PPO-Clip’s failure.

This work reveals the fundamental flaw of PPO-Clip: it implicitly measures policy discrepancy using Euclidean metric, which is theoretically inconsistent with the intrinsic geometry on the policy Riemannian manifold. This geometric mismatch results in overly conservative updates in low-probability regions while aggressive in high-probability regions, ultimately collapsing exploration.

To correct this geometric flaw, we propose Riemannian Isometric Policy Optimization (RIPO), which guarantees isometric policy updates on the Riemannian manifold, effectively balancing exploration and exploitation.

We further show that RIPO achieves a favorable bias-variance trade-off, which stabilizes optimization.

Extensive experiments demonstrate that RIPO significantly surpasses existing LLM RL algorithms across seven competition-level benchmarks (up to 60% improvement over GRPO on AIME24).

VBA: Vector Bundle Attention for Intrinsically Geometric Representation Learning

Shenglei Fang, Xianfang Sun, You Zhou

Learning from geometrically structured data is central to applications in biology, physics, and computer vision. In many tasks, meaningful comparisons depend on how features are aligned in space. Graph Neural Networks capture local structure but are constrained by message passing. Transformers model long-range dependencies but largely ignore geometry. We introduce the Vector Bundle Attention Transformer (VBA-Transformer), a framework that redefines attention as an intrinsic geometric operator. Each token couples a base manifold coordinate with a fiber feature vector, following vector bundle theory. A principled parallel transport me

chanism aligns fiber features across local coordinate systems before similarity is computed. This embeds geometry directly into the attention operator. Unlike p rior methods that inject geometry as an external bias or positional encoding, VB A integrates geometry natively inside attention. On challenging single-cell RNA sequencing benchmarks, VBA achieves state-of-the-art accuracy, outperforming Tra nsformer baselines by over 3--5\%. On spatial transcriptomics, it demonstrates s uperior clustering performance. On 3D point clouds, it achieves competitive accu racy, validating broad generalization across domains. Beyond empirical gains, we provide theoretical analysis of invariance and perturbation stability. We also demonstrate robust transport behavior empirically. Together, these results estab lish intrinsic geometric alignment as a powerful principle for scalable represen tation learning.

****

Toward Scalable and Valid Conditional Independence Testing with Spectral Represe ntations

Alek Fröhlich, Vladimir R Kostic, Karim Lounici, Daniel Perazzo, Daniel Guimarãe s Tiezzi, Massimiliano Pontil

Conditional independence (CI) is central to causal inference, feature selection, and graphical modeling, yet it is untestable in many settings without additiona l assumptions. Existing CI tests often rely on restrictive structural conditions , limiting their validity. Kernel methods using partial covariance operators off er a more principled approach but suffer from limited adaptivity and scalability . In this work, we explore whether representation learning can help address thes e limitations. Specifically, we focus on representations derived from the singul ar value decomposition of partial covariance operators and use them to construct a simple test statistic. We also introduce a bi-level contrastive algorithm to learn these representations. Our theory links representation learning error to t est performance and establishes asymptotic validity and power guarantees. Experi ments on real and synthetic data suggest that this approach offers a principled and statistically grounded path toward scalable CI testing, bridging kernel-base d theory with modern representation learning.

Convex Distance Operator Transport: A Convex and Geometry-Preserving Formulation

Junhyoung Chung, Euijong Song, Won Hwa Kim, Gunwoong Park

We introduce Convex Distance Operator Transport (CDOT), the first convex optimal transport framework that aligns distributions across heterogeneous domains by j ointly preserving feature correspondence and intrinsic geometric structure. Spec ifically, CDOT employs an operator-based regularization that aligns aggregated d istance structures by introducing distance and conditional expectation operators . Consequently, the proposed regularization improves the robustness to local geo metric variations. We further prove that the resulting CDOT discrepancy is a val id pseudometric on the space of attributed compact metric-measure spaces. In add ition, we characterize the relationship between CDOT and Gromov--Wasserstien (GW) through a new notion of dispersion gap, formally elucidating the geometric sou rce of non-convexity in GW compared to the convexity of CDOT. In the finite-samp le regime, we derive a non-asymptotic risk bound decomposed into optimization an d statistical errors, establishing risk consistency under a globally convergent Frank--Wolfe algorithm. Experiments on synthetic point clouds, brain connectomes , and graph classification benchmarks demonstrate better performance over existi ng methods, with stable and reliable behavior in practice.

Evaluating LLMs When They Do Not Know the Answer: Statistical Evaluation of Math ematical Reasoning via Comparative Signals

Zihan Dong, Zhixian Zhang, Yang Zhou, Can Jin, Ruijia Wu, Linjun Zhang

Evaluating mathematical reasoning in LLMs is constrained by limited benchmark si zes and inherent model stochasticity, yielding high-variance accuracy estimates and unstable rankings across platforms. On difficult problems, an LLM may fail t o produce a correct final answer, yet still provide reliable pairwise comparison signals indicating which of two candidate solutions is better. We leverage this observation to design a statistically efficient evaluation framework that combi

nes standard labeled outcomes with pairwise comparison signals obtained by havin g models judge auxiliary reasoning chains. Treating these comparison signals as control variates, we develop a semiparametric estimator based on the efficient i nfluence function (EIF) for the setting where auxiliary reasoning chains are obs erved. This yields a one-step estimator that achieves the semiparametric efficie ncy bound, guarantees strict variance reduction over naive sample averaging, and admits asymptotic normality for principled uncertainty quantification. Across s imulations, our one-step estimator substantially improves ranking accuracy, with gains increasing as model output noise grows. Experiments on GPQA Diamond, AIME 2025, and GSM8K further demonstrate more precise performance estimation and mor e reliable model rankings, especially in small-sample regimes where conventional evaluation is pretty unstable.

****

Covariance estimation using Markov chain Monte Carlo

Yunbum Kook, Matthew Shunshi Zhang

We investigate the complexity of covariance matrix estimation for Gibbs distribu tions based on dependent samples from a Markov chain. We show that when $π$ sati sfies a Poincaré inequality and the chain possesses a spectral gap, we can achie ve similar sample complexity using MCMC as compared to an estimator constructed using i.i.d. samples, with potentially much better query complexity. As an appli cation of our methods, we show improvements for the query complexity in both con strained and unconstrained settings for concrete instances of MCMC. In particula r, we provide guarantees regarding isotropic rounding procedures for sampling un iformly on convex bodies.

****

Why ReLU? A Bit-Model Dichotomy for Deep Network Training

Ilan Doron-Arad, Elchanan Mossel

Theoretical analyses of Empirical Risk Minimization (ERM) are standardly framed within the Real-RAM model of computation. In this setting, training even simple neural networks is known to be $\exists \mathbb{R}$-complete - a complexity clas s believed to be harder than NP, characterizing the difficulty of solving system s of polynomial inequalities over the real numbers. However, this algebraic fram ework diverges from the reality of digital computation with finite-precision har dware. In this work, we analyze the theoretical complexity of ERM under a realis tic bit-level model (ERM-bit), where network parameters and inputs are constrain ed to be rational numbers with polynomially bounded bit-lengths. Under this mode l, we reveal a sharp dichotomy in tractability governed by the activation functi on: for deep networks with any polynomial activation with rational coefficients and degree at least 2, deciding ERM-bit is #P-hard, determining the sign of a single partial derivative is unlikely to be in BPP, and deciding a specific bit in the gradient is #P-hard. In contrast, for piecewise-linear activations such a s ReLU, precision requirements remain manageable: ERM-bit is in NP, indeed NP-co mplete, and standard backpropagation runs in polynomial time, showing that finit e-precision constraints are not merely implementation details but fundamental de terminants of learnability.

GRPO is Secretly a Process Reward Model

Michael Sullivan, Alexander Koller

Process reward models (PRMs) allow for fine-grained credit assignment in reinfor cement learning (RL), and seemingly contrast with outcome reward models (ORMs), which assign a single reward to an entire trajectory. However, we provide theore tical proof in this work that the Group Relative Policy Optimization (GRPO) RL a lgorithm equipped with an ORM is in fact equivalent to a PRM-aware RL objective equipped with a non-trivial, Monte-Carlo-based PRM (given mild assumptions). Lev eraging the framework of GRPO-as-a-PRM, we identify a flaw in the GRPO objective that interacts with imbalanced process steps and rewards to hinder both explora tion and exploitation (under different conditions). We propose a simple modifica tion to the algorithm to mitigate this defect (λ-GRPO), and show that LL Ms tuned with λ-GRPO outperform LLMs tuned with standard GRPO on downstr eam reasoning tasks$\textemdash$and reach peak performance more rapidly. These r

esults show that we can leverage the hidden, built-in PRM structure within the v anilla GRPO algorithm to boost model performance without employing an explicit P RM, and with a negligible impact on training time and cost.

Stop the Flip-Flop: Context-Preserving Verification for Fast Revocable Diffusion Decoding

Yanzheng Xiang, Lan Wei, Yizhen Yao, Qinglin Zhu, Hanqi Yan, Chen Jin, Philip Al exander Teare, Dandan Zhang, Lin Gui, Amrutha Saseendran, Yulan He

Parallel diffusion decoding can accelerate diffusion language model inference by unmasking multiple tokens per step, but aggressive parallelism often harms qual ity. Revocable decoding mitigates this by rechecking earlier tokens, yet we obse rve that existing verification schemes frequently trigger flip-flop oscillations , where tokens are remasked and later restored unchanged. This behaviour slows i nference in two ways: remasking verified positions weakens the conditioning cont ext for parallel drafting, and repeated remask cycles consume the revision budge t with little net progress. We propose COVER (Cache Override Verification for Ef ficient Revision), which performs leave-one-out verification and stable drafting within a single forward pass. COVER constructs two attention views via KV cache override: selected seeds are masked for verification, while their cached key va lue states are injected for all other queries to preserve contextual information , with a closed form diagonal correction preventing self leakage at the seed pos itions. COVER further prioritises seeds using a stability aware score that balan ces uncertainty, downstream influence, and cache drift, and it adapts the number of verified seeds per step. Across benchmarks, COVER markedly reduces unnecessa ry revisions and yields faster decoding while preserving output quality.

Revisiting OOD Generalization in Programmatic RL

Amirhossein Rajabpour, Kiarash Aghakasiri, Sandra Zilles, Levi Lelis

Programmatic policies are often reported to generalize better than neural polici es in reinforcement learning (RL) benchmarks. We revisit some of these claims an d show that much of the observed gap arises from uncontrolled experimental facto rs rather than intrinsic representational reasons. Re-evaluating three core benc hmarks used in influential papers---TORCS, Karel, and Parking---we find that neu ral policies, when trained with a few modifications, such as sparse observations and cautious intrinsic reward functions, can match or exceed the out-of-distrib ution (OOD) generalization of programmatic policies. We argue that a representat ion enables OOD generalization if (i) the policy space it induces includes a gen eralizing policy and (ii) the search algorithm can find it. The neural and progr ammatic policies in prior work are comparable in OOD generalization because the domain-specific languages used induce policy spaces similar to those of neural n etworks, and our modifications help the gradient search find generalizing soluti ons. By disentangling representational factors from experimental confounds, we a dvance our understanding of what makes a representation succeed or fail at OOD g eneralization.
****

Advantage Weighted Matching: Aligning RL with Pretraining in Diffusion Models

Shuchen Xue, Chongjian GE, Shilong Zhang, Yichen Li, Zhi-Ming Ma

Reinforcement Learning (RL) has emerged as a central paradigm for advancing Larg e Language Models (LLMs), where both pre-training and RL post-training stages ar e grounded in the same log-likelihood formulation. In contrast, recent RL approa ches for diffusion models, most notably Denoising Diffusion Policy Optimization (DDPO), optimize an objective different from the pretraining objectives--score/f low matching loss.

In this work, we establish a novel theoretical analysis: DDPO is an implicit for m of score/flow matching with noisy targets, which increases variance and slows convergence. Building on this analysis, we introduce \textbf{Advantage Weighted Matching (AWM)}, a policy-gradient method for diffusion. It uses the score/flow-matching loss and reweights each sample by its advantage. In effect, AWM raises the influence of high-reward samples and suppresses low-reward ones while keepin g the modeling objective identical to pretraining.

This simple yet effective design yields substantial benefits: on the GenEval, OCR, and PickScore benchmarks, AWM delivers up to a $\mathbf{34}\times$ speedup over Flow-GRPO (which builds on DDPO), when applied to Stable Diffusion 3.5 Medium and FLUX, without compromising generation quality. Code is available at \url{https://github.com/scxue/advantage_weighted_matching}.

Cross-Modal Semantic Decoupling and Transfer for Text-to-Visible-Infrared Person Re-Identification
Ziang Zhang, Bin Yang, Mang Ye
Text-to-Image Person Re-Identification (TI-ReID) retrieves visible pedestrian images using text queries. Yet in low-light or nighttime settings, visible images lack sufficient identity details, while infrared images effectively capture pedestrian contours and textures. To enable all-day surveillance, we propose a dual cross-modal retrieval task called Text-to-Visible-Infrared Re-Identification (TVI-ReID) and construct corresponding tri-modal datasets. Compared to TI-ReID, TVI-ReID faces two key challenges: (1) **complex hybrid discrepancies** in dual cross-modal retrieval from three modalities, and (2) **semantic inconsistency** between pretraining and downstream tasks. To address these issues, we propose a Cross-Modal Semantic Decoupling and Transfer (CSDT) framework. CSDT constructs color-related and color-irrelevant feature subspaces via Semantic Decoupling Learning (SDL) to align shared semantics across text and dual image modalities, reducing hybrid discrepancies. Moreover, Semantic Distribution Transfer (SDT) adapts pretrained text-visible alignment to text-infrared matching. Extensive experiments on tri-modal datasets show our approach outperforms existing state-of-the-art TI-ReID methods.

BrainJanus: A Unified Model for Understanding and Generation across Brain, Vision, and Language
Haitao Wu, Qirui Zhang, Zhouheng Yao, Shangquan Sun, Qihao Zheng, Mianxin Liu, Chi Zhang, Wanli Ouyang, Chunfeng Song, Changqing Zhang, Jiamin Wu
Modeling the bidirectional correspondence between external sensory stimuli and internal neural activity has emerged as a critical frontier in neuroscience. However, existing approaches predominantly treat brain encoding and decoding as isolated tasks, relying heavily on unimodal alignment and external priors while overlooking the brain's intrinsic nature as a multimodal integration system. To address these limitations, we propose BrainJanus, the first unified brain model that integrates brain, vision, and language within a single framework. Specifically, we introduce a Unified Brain Tokenizer to quantize continuous neural dynamics into discrete tokens aligned with visual and linguistic representations in a shared Omni space. Building on this, we utilize an All-in-One autoregressive architecture that leverages next-token prediction to enable seamless any-to-any generation, which encompasses image-to-brain and text-to-brain encoding, and brain-to-image and brain-to-text decoding. Extensive experiments demonstrate that BrainJanus achieves superior performance across diverse benchmarks. Furthermore, our framework exhibits zero-shot generalization and preserves interpretable biological topography, highlighting its potential as a general-purpose brain modeling paradigm. The code is available at \href{https://github.com/HaitaoWuTJU/BrainJanus}{GitHub}.

IBMA: Information Bottleneck-Based Multimodal Alignment
Yancheng Wang, Zeyu Dong, Dongfang Sun, Alvin C Silva, Teresa Wu, Yingzhen Yang
Multimodal learning aims to integrate information from heterogeneous data sources to improve representation quality and downstream task performance. A key challenge lies in aligning modality-specific representations while suppressing modality-dependent noise and redundancy. The Information Bottleneck (IB) principle provides a principled framework for learning task-relevant representations. Existing multimodal IB methods primarily apply the IB principle to fused multimodal representation and rely on restrictive distributional assumptions, such as Gaussian latent priors induced by variational autoencoders, which may not hold in practice.

In this paper, we propose Information Bottleneck–based Multimodal Alignment (IBMA), a novel multimodal learning framework that enforces the IB principle for both the fused multimodal representation and modality-specific representations. IBMA introduces modality-specific representation alignment that guides each modality-specific encoder to learn informative and task-relevant representations aligned with the complementary modality, thereby enhancing cross-modal semantic consistency. Moreover, we derive a novel, efficient, and distribution-free variational upper bound for the IB loss that avoids unrealistic assumptions on latent feature distributions and is readily optimized using standard stochastic gradient descent. Extensive experiments demonstrate that IBMA achieves superior performance compared to existing multimodal learning methods, validating the effectiveness of modality-specific representation alignment. The code for IBMA is available at https://github.com/Statistical-Deep-Learning/IBMA.

TabMGP: Martingale Posterior with TabPFN

Kenyon Ng, Edwin Fong, David Tyler Frazier, Jeremias Knoblauch, Susan Wei

Bayesian inference provides principled uncertainty quantification but is often limited by the challenges of prior and likelihood elicitation. The martingale posterior (MGP) (Fong et al., 2023) offers an alternative by replacing these requirements with a predictive rule. In addition, the MGP focuses inference on parameters defined through a loss function. This framework is especially resonant in the era of foundation transformers; practitioners increasingly leverage models like TabPFN for their state-of-the-art capabilities, yet often require epistemic uncertainty for a scientific estimand θ that need not parameterise the implicit latent model. The MGP provides a mechanism to recover these posterior distributions. We introduce TabMGP, an MGP built on TabPFN for tabular data. TabMGP produces credible sets with near-nominal coverage and often outperforms both hand crafted MGP constructions and standard Bayesian baselines.

PolarDepth: Monocular Transparent Object Depth from Polar-Physics Priors

Wen Dong, Haiyang Mei, Yinglian Ji, Zijun Zhang, Wenyuan Zhang, Pengwei Luo, Bo Dong, Shengfeng He, Xin Yang

Depth estimation for transparent objects remains a fundamental challenge, as RGB-based cues often fail in regions affected by refraction and light transmission. Polarization provides physically grounded information related to surface orientation and material properties, offering reliable geometric cues even in the absence of texture. In this work, we introduce PolarDepth, a monocular framework that incorporates both RGB and polarization inputs, including the degree and angle of linear polarization (DoLP and AoLP), to estimate dense depth and localize transparent regions. PolarDepth injects polarization-derived physical priors by estimating the refractive index, zenith angle, and azimuth angle from polarization measurements and embedding them into an implicit geometric representation that constrains depth inference in ambiguous transparent regions. To support model development and evaluation, we introduce PTOD, a dataset with synchronized RGB, polarization, and depth data and manually annotated transparent region masks. Experimental results demonstrate that PolarDepth achieves state-of-the-art performance in transparent object depth estimation. The findings highlight the effectiveness of embedding polarization-derived physical priors into learned representations for robust perception in complex visual environments.

Looking Locally: Object-Centric Vision Transformers as Foundation Models for Efficient Segmentation

Manuel Traub, Martin V. Butz

Current state-of-the-art segmentation models encode entire images before focusing on specific objects. This wastes computational resources. We introduce FLIP (Fovea-Like Input Patching), a parameter-efficient vision model that realizes object segmentation through biologically-inspired top-down attention. FLIP selectively samples multi-resolution patches centered on objects of interest from the input. As a result, it allocates high-resolution processing to object centers while maintaining coarser peripheral context. This off-grid, scale-invariant design e

nables FLIP to outperform META's Segment Anything models (SAM, SAM2 and fast var iants) by large margins: With more than 440 $ \times$ fewer parameters, FLIP-Tin y (0.51M parameters) reaches a mean IoU of 79.90\% while SAM2-L reaches 75.87\% IoU (224.45M parameters). FLIP-Large even achieves 83.26\% mean IoU (96.6M param eters), still running about $2 \times$ faster than SAM2-L. We evaluate on six be nchmarks in total. In five established benchmarks (Hypersim, KITTI-360, OpenImag es, COCO, LVIS) FLIP consistently outperforms SAM and various variants of it. In our novel ObjaScale dataset, which stress-tests scale invariance with objects r anging from 0.0001\% up to 25\% of the image area, we show that FLIP segments ev en very small objects accurately, where existing models fail severely. FLIP open s new possibilities for real-time, object-centric vision and offers much higher energy efficiency. We believe that FLIP can act as a powerful foundation model, as it is very well-suited to track objects over time, for example, when being in tegrated into slot-based scene segmentation architectures.

Condition Number Based Low-Bit Quantization for Image Super-Resolution
Kai Liu, Dehui Wang, Zhiteng Li, Zheng Chen, Yong Guo, Linghe Kong
Low-bit model quantization for image super-resolution (SR) is a longstanding tas k that is renowned for its surprising compression and acceleration ability. Howe ver, accuracy degradation is inevitable when compressing the full-precision (FP) model to ultra-low bit widths ($2\sim4$ bits). Experimentally, we observe that the degradation of quantization is mainly attributed to the quantization of acti vation instead of model weights. Considering that the activation quantization er ror is hard to minimize, minimizing the impact of the error emerges as a good ch oice, which is described by the condition number. Therefore, we propose CondiQua nt, a condition number-based low-bit post-training quantization for image super- resolution. Specifically, we formulate the quantization error of activation as t he condition number of weight metrics. By decoupling the representation ability and the quantization sensitivity, we design an efficient proximal gradient desce nt algorithm to iteratively minimize the condition number and maintain the outpu t. With comprehensive experiments, we demonstrate that CondiQuant outperforms ex isting state-of-the-art post-training quantization methods in accuracy without c omputation overhead and gains the theoretically optimal compression ratio in mod el parameters. Our code will be released soon.

No Retraining at Edge: Efficient Resource-Aware Mixed-Precision Quantization via Federated Supernet Learning
Lianbo Ma, Yonghui Su, Nan Li, Xingwei Wang
Federated learning (FL) enables collaborative training across distributed edge d evices, but deploying lightweight models in dynamic edge environments remains ch allenging. Existing methods typically require retraining whenever device resourc e constraints change, resulting in excessive computational overhead. We propose DFMPQ, a dynamic federated mixed-precision quantization framework that enables r etraining-free deployment at the edge. DFMPQ trains a weight-sharing mixed-preci sion supernet via FL, which jointly represents diverse bit-width configurations. After training, resource-aware quantized subnets can be derived on demand to sa tisfy heterogeneous and time-varying resource constraints without additional opt imization. Optimizing such a supernet in federated settings is difficult due to optimization interference among heterogeneous bit-widths and the coupling of qua ntization noise with non-IID data. DFMPQ addresses these issues through semantic -aware training and aggregation mechanisms that stabilize supernet optimization. In addition, a sensitivity-guided greedy search strategy is adopted to efficien tly identify suitable quantization configurations under given resource budgets. Extensive experiments on multiple datasets and network architectures demonstrate that DFMPQ achieves competitive accuracy with significantly reduced computation al cost, enabling efficient deployment for dynamic edge computing environments.

Differentially Private Geodesic Regression
Aditya Kulkarni, Carlos J Soto
In statistical applications it has become increasingly common to encounter data

structures that live on non-linear spaces such as manifolds. For data living on such non-linear spaces geodesic regression emerged as a natural extension of linear regression where the response variable lives on a Riemannian manifold. The parameters of geodesic regression capture the relationship of sensitive data, and hence, one should consider the privacy protection practices of said parameters. We consider releasing Differentially Private (DP) parameters of geodesic regression via the K-Norm Gradient (KNG) mechanism for Riemannian manifolds. We derive theoretical bounds for the sensitivity of the parameters showing they are tied to their respective Jacobi fields and hence the curvature of the space. We demonstrate the efficacy of our methodology on the sphere, $S_2\subset\mathbb{R}^3$, the space of symmetric positive definite matrices, and Kendall's planar shape space. Our methodology is general to any Riemannian manifold, and thus it is suitable for data in domains such as medical imaging and computer vision.

Interpretable Neural ODEs for Gene Regulatory Network Discovery under Perturbations
Zaikang Lin, Sei Chang, Aaron Zweig, Minseo Kang, Fabian J Theis, Elham Azizi, David A. Knowles
Modern high-throughput biological datasets containing thousands of perturbations enable large-scale discovery of causal graphs that represent regulatory interactions between genes. Differentiable causal graphical models and regression-based methods have been developed to infer gene regulatory networks (GRNs) from interventional datasets. However, existing approaches fail to capture the non-linear dynamics of biological processes such as cellular differentiation. To address this limitation, we propose $\textit{PerturbODE}$, a novel framework that employs interpretable neural ordinary differential equations (neural ODEs) to model cell state trajectories under perturbations and derive the underlying causal GRN from the neural ODE parameters, enabling downstream simulation of unseen genetic interventions. The GRN is encoded via a single-hidden-layer feedforward network, implicitly grouping genes into interpretable co-regulated modules. We demonstrate PerturbODE's efficacy in GRN inference and extension to perturbation response prediction across both simulated and real overexpression datasets.

AgentVocab: Structure-Aware Vocabulary Adaptation for Efficient LLM Agents
Kai Bian, Haosi Mo, Xuebo Liu, Shuangyong Song, Jing Li, Yongxiang Li, Min Zhang, Xuelong Li
Recent large language models (LLMs) have demonstrated strong capabilities across challenging tasks, enabling their widespread adoption in agentic systems that interact with external tools. In such deployments, however, LLMs are typically trained with general-purpose tokenizers designed for broad language coverage, while their usage is dominated by narrow, structured tool-calling interactions. This training–deployment mismatch leads to inefficient tokenization, where repetitive structural patterns and frequent semantic units in function calls are fragmented into long sequences of low-level tokens, increasing decoding overhead. To address this gap, we introduce $\textbf{AgentVocab}$, a structure-aware vocabulary adaptation framework for efficient LLM agents. AgentVocab derives specialized vocabulary entries from real tool-calling traces and adapts the model vocabulary to better reflect structural and semantic regularities, without task-specific schema engineering. Experiments on τ-bench and τ^2-bench show that AgentVocab preserves tool-calling performance while reducing latency relative to the vanilla baseline by 17.7\% and 19.5\%, respectively. Our approach is orthogonal to existing fine-tuning and agent-training methods and integrates seamlessly into standard agent pipelines. Source code and models will be available at https://github.com/Starry-159/AgentVocab.

VELR: Efficient Video Reward Feedback via Ensemble Latent Reward Models
Liyu Zhang, Kehan Li, Tao Zhou, Zeyi Huang, Chao Li, Jiming Chen
Reward feedback learning (ReFL) is effective for both text-to-image (T2I) and text-to-video (T2V) generation with image reward models (RMs). However, image RMs are misaligned with temporal objectives of T2V, motivating ReFL with video rewar

d models. Nevertheless, directly deploying video RMs is impractical due to their large parameter size and the prohibitive cost of memory. To address this, we propose VELR: an efficient framework that employs ensemble latent reward models (LRMs) to predict rewards directly in latent space, bypassing expensive backpropagation through VAE decoders and video RMs. Specifically, we introduce the ensemble technique for the LRM, which enhances capacity, quantifies uncertainty, and mitigates reward hacking. VELR achieves a reduction of up to 150GB in memory, requiring as little as 12.4% of the memory compared to standard ReFL. Experiments on OpenSora-1.2, CogVideoX-1.5, and Wan-2.1 with large-scale video RMs demonstrate that VELR achieves comparable performance as standard ReFL and enables efficient and robust video RM-based ReFL at scales previously unattainable.

Sentinel-VLA: A Metacognitive VLA Model with Active Status Monitoring for Dynamic Reasoning and Error Recovery

Wenhao Li, Xiu Su, Dan Niu, Yichao Cao, Hongyan Xu, Zhe Qu, Lei Fan, Shan You, Chang Xu

Vision-language-action (VLA) models have advanced the field of embodied manipulation by harnessing broad world knowledge and strong generalization. However, current VLA models still face several key challenges, including limited reasoning capability, lack of status monitoring, and difficulty in self-correction. In this paper, we introduce \textbf{Sentinel-VLA}, a metacognitive VLA model equipped with an active ``sentinel'' module to monitor real-time execution status. Only when necessary, such as during initial planning or upon detecting an error, the model triggers a dynamic reasoning or formulate error recovery solutions. This on-demand reasoning mechanism ensures robust decision-making while minimizing computational overhead. Notably, all training data (spanning 44 tasks and over 2.6 million transitions) is automatically generated and annotated through our designed pipeline. We also propose the Self-Evolving Continual Learning (SECL) algorithm, which allows Sentinel-VLA to identify its capability boundaries and automatically collect data for expansion, paired with Orthogonal Continual Adapter (OC-Adapter) to constrain parameter updates to an orthogonal space, thereby preventing catastrophic forgetting. Real-world experiments demonstrate that Sentinel-VLA boosts the task success rate by over 30\% compared to the SOTA model, PI0. We will open-source all the code, weights, and data generation pipeline.

Divide and Conquer: Reliable Multi-View Evidential Learning for Deepfake Detection

Xiaolu Kang, Zhongyuan Wang, Jikang Cheng, Baojin Huang, Zhanhe Lei, Gang Wu, Qin Zou, Qian Wang

With the evolution of generative models, deepfakes have achieved near-perfect semantic realism, leaving forensic traces only in subtle structural anomalies. However, existing single-view paradigms often fail to generalize, as dominant semantic features overwhelm subtle artifact cues within entangled representations. This imbalance leads to overconfident yet brittle predictions—a phenomenon we term the Semantic Masking Effect.

To address this challenge, we propose a reliable framework called Divide-and-Conquer Multi-View Evidential Learning (DiCoME) for Deepfake Detection.

In the "Divide'' phase, we employ Geometric View Purification to decompose the entangled representation space through principled geometric projection. This process suppresses semantic interference within artifact-sensitive representations, forming the foundation for decorrelated yet complementary semantic and artifact views.

In the "Conquer'' phase, we leverage Uncertainty-Aware Evidential Learning to synthesize these distinct views. By explicitly modeling the "epistemic conflict'' between semantic and artifact cues, this mechanism provides calibrated uncertainty estimates instead of forcing rigid deterministic decisions.

Extensive experiments across multiple benchmarks demonstrate that our method consistently outperforms existing approaches in generalization performance, while providing reliable uncertainty estimation for trustworthy deepfake detection.

Code is available at https://github.com/kxl0825/DiCoME.git.

Recursive Models for Long-Horizon Reasoning
Chenxiao Yang, Nathan Srebro, Zhiyuan Li
Modern language models reason within bounded context, an inherent constraint tha t poses a fundamental barrier to long-horizon reasoning. We identify recursion a s a core principle for overcoming this barrier, and propose recursive models as a minimal realization, where the model can recursively invoke itself to solve su btasks in isolated contexts. We prove that any computable problem admits a recur sive decomposition of reasoning in which each subtask requires only exponentiall y smaller active context than standard autoregressive models; this strictly surp asses any context management approach confined to a single sequence, such as sum marization. We further generalize our framework to modern agentic systems with a rbitrary context processing and control flows, and prove that recursive models c an achieve optimal power within this broader class. Experimentally, we train a 3 B model to reason recursively and evaluate on Boolean satisfiability, a task req uiring long-horizon combinatorial search, where it significantly outperforms fro ntier LLMs.

Revisiting Zeroth-Order Hessian Approximation: A Single-Step Policy Optimization Lens
Junbin Qiu, Zhaowei Hong, Renzhe Xu, Yao Shu
Accurate Zeroth-Order (ZO) Hessian estimation is a cornerstone of derivative-fre e methods, essential for tasks such as bilevel optimization, Bayesian inference, and uncertainty quantification.
However, obtaining a complete suite of low-variance estimators for the Hessian a nd its inverse in high-dimensional settings remains a significant challenge.
To address this, we propose a unified framework that reinterprets ZO Hessian app roximation through the lens of single-step Policy Optimization (PO).
This perspective establishes a theoretical equivalence between general ZO Hessia n estimators and the Hessian of a smoothed PO objective, unifying distinct class ical randomized estimators as specific instances of baseline selection.
Building on this foundation, we introduce ZoVH, a comprehensive suite of varianc e-reduced estimators for the full Hessian matrix, its regularized inverse, and t he bias-corrected inverse Hessian-gradient product.
ZoVH leverages two key techniques: (1) a unique optimal baseline derived to prov ably minimize variance, and (2) a query reuse strategy that incorporates histori cal function queries to enhance sample efficiency without inflating costs.
Our rigorous theoretical analysis confirms the unbiasedness of the Hessian estim ator, validates the variance optimality of our baseline, provides error bounds f or the entire ZoVH suite, and establishes convergence guarantees for the resulti ng curvature-aware ZO algorithm.
Extensive empirical results validate our theoretical findings, demonstrating tha t ZoVH achieves superior estimation accuracy and convergence performance in real -world applications.

Probabilistic Retrofitting of Learned Simulators
Cristiana Diaconu, Miles Cranmer, Richard E. Turner, Tanya Marwah, Payel Mukhopa dhyay
Dominant approaches for modelling Partial Differential Equations (PDEs) rely on deterministic predictions, yet many physical systems of interest are inherently chaotic and uncertain. While training probabilistic models from scratch is possi ble, it is computationally expensive and fails to leverage the significant resou rces already invested in high-performing deterministic backbones. In this work, we adopt a training-efficient strategy to transform pre-trained deterministic mo dels into probabilistic ones via retrofitting with a proper scoring rule: the Co ntinuous Ranked Probability Score (CRPS). Crucially, this approach is architectu re-agnostic: it applies the same adaptation mechanism across distinct model back bones with minimal code modifications. The method proves highly effective across different scales of pre-training: for models trained on single dynamical system s, we achieve $20–54\%$ reductions in rollout CRPS and up to 30% improvements

in variance-normalised RMSE (VRMSE) relative to compute-matched deterministic fine-tuning. We further validate our approach on a PDE foundation model, trained on multiple systems and retrofitted on the dataset of interest, to show that our probabilistic adaptation yields an improvement of up to 40% in CRPS and up to 15% in VRMSE compared to deterministic fine-tuning. Validated across diverse architectures and dynamics, our results show that probabilistic PDE modelling need not require retraining from scratch, but can be unlocked from existing deterministic backbones with modest additional training cost.

Riemannian Dueling Optimization

Yuxuan Ren, Abhishek Roy, Shiqian Ma

Dueling optimization considers optimizing an objective with access to only a comparison oracle of the objective function. It finds important applications in emerging fields such as recommendation systems and robotics. Existing works on dueling optimization mainly focused on unconstrained problems in the Euclidean space. In this work, we study dueling optimization over Riemannian manifolds, which covers important applications that cannot be solved by existing dueling optimization algorithms. In particular, we propose a Riemannian Dueling Normalized Gradient Descent (RDNGD) method and establish its iteration complexity when the objective function is geodesically L-smooth or geodesically (strongly) convex. We also propose a projection-free algorithm, named Riemannian Dueling Frank–Wolfe (RDFW) method, to deal with the situation where projection is prohibited. We establish the iteration and oracle complexities for RDFW. We illustrate the effectiveness of the proposed algorithms through numerical experiments on both synthetic and real applications.

ParEVO: Synthesizing Code for Irregular Data: High-Performance Parallelism through Agentic Evolution

Liu Yang, Zeyu Nie, Andrew Liu, Ruomu Zou, Deniz Alt■nbüken, Amir Yazdanbakhsh, Quanquan C. Liu

Parallelizing code for **irregular data structures** (sparse graphs, unbalanced trees, non-uniform meshes) is notoriously hard, and current LLMs fail catastrophically on such tasks, generating code riddled with race conditions, deadlocks, and poor scaling. We address this with **ParEVO**, a framework for synthesizing high-performance parallel algorithms for irregular data, built on three contributions: the **Parlay-Instruct Corpus** of 13,820 tasks generated via a "Critic-Refine" pipeline that filters for empirically performant uses of Work-Span primitives; specialized **DeepSeek**, **Qwen**, and **Gemini** models fine-tuned to the semantics of the ParlayLib library; and an **Evolutionary Coding Agent (ECA)** that repairs the "last mile" of correctness using compiler and profiler feedback. On the ParEval benchmark, ParEVO achieves an average **107x speedup** and a **13.6x speedup** on highly complex irregular graph problems, outperforming commercial models like GPT-5-Thinking and Gemini-3-Pro, while matching expert *human-written* baselines and reaching up to a **4.1x speedup** on kernels such as Maximal Independent Set. This demonstrates that AI-driven agents can effectively navigate the complex landscape of high-performance computing. Source code and datasets are available at https://github.com/WildAlg/ParEVO.

World Guidance: World Modeling in Condition Space for Action Generation

Yue Su, Sijin Chen, Haixin Shi, Mingyu Liu, Zhengshen Zhang, Ningyuan Huang, Weiheng Zhong, Zhengbang Zhu, Yuxiao Liu, Xihui Liu

Leveraging future observation modeling to facilitate action generation presents a promising avenue for enhancing the capabilities of Vision-Language-Action (VLA) models.

However, existing approaches struggle to strike a balance between maintaining efficient, predictable future representations and preserving sufficient fine-grained information to guide precise action generation.

To address this limitation, we propose WoG (World Guidance), a framework that maps future observations into compact conditions by injecting them into the action inference pipeline.

The VLA is then trained to simultaneously predict these compressed conditions al
ongside future actions, thereby achieving effective world modeling within the co
ndition space for action inference.
We demonstrate that modeling and predicting this condition space not only facili
tates fine-grained action generation but also exhibits superior generalization c
apabilities. Moreover, it learns effectively from substantial human manipulation
 videos.
Extensive experiments across both simulation and real-world environments validat
e that WoG significantly outperforms existing methods based on future prediction
. Project page is available at: https://selen-suyue.github.io/WoGNet/.

Benchmarking and Improving Fine-Grained Text-to-Image Alignment via Paired Reinf
orcement Learning
Kaihang Pan, Wendong Bu, Yuruo Wu, Kai Shen, Yang Wu, Yun Zhu, Zehan Wang, Yunfe
i Li, Hang Zhao, Juncheng Li, Siliang Tang
While recent autoregressive models have achieved text-to-image generation perfor
mance comparable to diffusion models, they significantly struggle with fine-grai
ned semantic alignment. To rigorously evaluate this limitation, we introduce Del
taBench, a benchmark featuring paired prompts with subtle fine-grained differenc
es, which reveals that existing models fail to achieve precise control over visu
al tokens. To bridge this gap, we propose FocusDiff, a comprehensive framework t
hat enhances alignment by learning from subtle differences in similar text-image
 pairs. Specifically, we construct FocusDiff-Data, a large-scale dataset of pair
ed samples derived from image editing tasks to capture localized semantic shifts
. Furthermore, we introduce Pair-GRPO, an improved reinforcement learning algori
thm that extends GRPO to paired samples. Extensive experiments demonstrate that
our approach outperforms most prior prominent methods on both DeltaBench and exi
sting benchmarks.
****

Revisiting Padded Transformer Expressivity: Which Architectural Choices Matter a
nd Which Don't
Anej Svete, William Merrill, Ryan Cotterell, Ashish Sabharwal
Recent work describes what transformers can and cannot compute through connectio
ns to boolean circuits, but existing results lack exact characterizations and ar
e sensitive to modeling choices.
Padded transformers---to whose input filler symbols such as ``...'' are appended
---emerge as a useful gadget for establishing equivalences to circuit classes by
 providing polynomial space for adaptive parallel computation.
However, only a limited set of padded transformer idealizations has been studied
, leaving open how robustly these equivalences hold under changes to attention t
ype, model width, and uniformity.
We find that, under practical assumptions, padded transformers are surprisingly
robust to all of these, and identify numeric precision and model depth as the ma
in factors affecting expressivity.
Concretely, we prove that polynomially padded L-uniform constant-precis
ion transformers are equivalent to L-uniform AC^0, while growing-precis
ion ones achieve L-uniform TC^0 regardless of width.
Furthermore, looping enables sequential processing analogous to circuits: $\log^
d N$-looped constant-precision transformers reach FO-uniform AC^d, and
growing-precision ones reach FO-uniform TC^d.
Interestingly, growing width or precision beyond logarithmic does not increase e
xpressivity, and all our results hold for both softmax and average hard attentio
n transformers.

Origo: Interpretable Multi-physics PDE Foundation Model through Neural Operator
Splitting
Li Sun, Hongbo Lv, Zhikai Jiang, Zhongtian Sun, Lanxu Yang, Philip S. Yu
Partial Differential Equations (PDEs) play a fundamental role in scientific comp
uting, and recent efforts have sought to extend the success of foundation models
 to PDE solving. However, multi-physics PDE pre-training faces the unique challe

nge of disentangling dynamic heterogeneity to learn universal, elementary patter
ns that generalize to new PDEs. Additionally, cross-physics transfer lacks a the
oretical framework for interpretability—specifically, understanding which pre-tr
ained operator knowledge is effectively transferred to target PDEs. To bridge th
ese gaps, we introduce the theory of neural operator splitting, which decomposes
 PDE evolution into a modulated global spectral operator and sparse local consti
tutive mechanisms. A key innovation is Origo, which provides a neural operator b
ank that enables the identification of operator-level generalization patterns. E
xtensive experiments demonstrate strong zero-shot generalization and mechanism-l
evel interpretability on unseen PDEs.

HiPPO Zoo: Explicit Memory Mechanisms for Interpretable State Space Models
Jack Goffinet, Casey Hanks, David Carlson
Representing the past in a compressed, efficient, and informative manner is a ce
ntral problem for systems trained on sequential data. The \textit{HiPPO} framewo
rk, originally proposed by Gu \& Dao et al., provides a principled approach to s
equential compression by projecting signals onto orthogonal polynomial (OP) base
s via structured linear ordinary differential equations. Subsequent works have e
mbedded these dynamics in state space models (SSMs), where HiPPO structure serve
s as an initialization. Nonlinear successors of these SSM methods such as Mamba
are state-of-the-art for many tasks with long-range dependencies, but the mechan
isms by which they represent and prioritize history remain largely implicit. In
this work, we revisit the HiPPO framework with the goal of making these mechanis
ms explicit. We show how polynomial representations of history can be extended t
o support capabilities of modern SSMs such as adaptive memory allocation and ass
ociative memory, while retaining direct interpretability in the OP basis. We int
roduce a unified framework comprising five such extensions, which we collectivel
y refer to as a ``HiPPO zoo.'' Each extension exposes a specific modeling capabi
lity through an explicit, interpretable modification of the HiPPO framework. The
 resulting models adapt their memory online and train in streaming settings with
 efficient updates. We illustrate the behaviors and modeling advantages of these
 extensions through a range of synthetic sequence modeling tasks, demonstrating
that capabilities typically associated with modern SSMs can be realized through
explicit, interpretable polynomial memory structures.
****

DecAEvolve: Decompose, Adapt, and Evolve for Effective LLM-based Scientific Equa
tion Discovery
Pouya Behzadifar, Parshin Shojaee, Sanchit Kabra, Kazem Meidani, Chandan K. Redd
y
Finding mathematical relations underlying natural phenomena is a fundamental tas
k in scientific discovery. Recent advances in evolutionary search with Large Lan
guage Models (LLMs) show great promise by leveraging their embedded scientific k
nowledge. However, discovering governing equations remains challenging due to va
st combinatorial hypothesis spaces with exponentially many possible relations. E
xisting LLM-based approaches treat LLMs as static hypothesis generators unaware
of the observed scientific system, leading to suboptimal and inefficient explora
tion that over-relies on internal priors. To address this, we introduce Decompos
e, Adapt, and Evolve (DecAEvolve), a framework that combines granular feedback f
rom symbolic term decomposition with LLM refinement through reinforcement learni
ng fine-tuning. DecAEvolve unifies symbolic decomposition with test-time RL adap
tation, enabling adaptive rather than static hypothesis generation. Our experime
nts across diverse scientific benchmarks demonstrate that DecAEvolve significant
ly improves both the accuracy of discovered equations and the efficiency of the
discovery process, reducing error by up to an order of magnitude compared to sta
te-of-the-art baselines.

G^{2}RPO: Geometric GRPO; Escaping LLM's Reasoning Rut to Break Accuracy--Entro
py Trade-off
Ali Rad, Khashayar Filom, Darioush Keivan, Peyman Mohajerin Esfahani, Ehsan Kama
linejad

Reinforcement learning with verifiable rewards (RLVR) is a cornerstone of post-training for large reasoning models, yet widely used algorithms such as Group Relative Policy Optimization (GRPO) often exhibit \textbf{diversity collapse}.
We provide a geometric diagnosis by formalizing GRPO as a dynamical flow on the probability simplex. Under a mode-based coarse-graining of rollouts, we show that GRPO induces a \textbf{collision field} over correct modes, monotonically pushing towards simplex vertices and thus yielding a \textbf{winner-take-all} regime.
To address this systematically, we introduce \textbf{G^{2}RPO (Geometric GRPO)}, which reshapes RLVR via principled \textbf{vector-field editing}. Concretely, we intervene at the advantage level by adding granularity bonuses inversely proportional to mode probabilities, encouraging underrepresented correct modes. The bonus has a natural geometric interpretation, and its potential performance side effects can be mitigated, thereby avoiding the usual accuracy--diversity trade-off.
In experiments with 7B and 14B models trained on a math reasoning task and evaluated on \textbf{AIME 2024/2025}, GRPO loses up to \textbf{57\%} of active correct modes. In contrast, G^{2}RPO increases active correct-mode coverage by \textbf{172\%--205\%}, reduces concentration on any single correct mode, prevents the late-stage \emph{entropy crash}, and improves \texttt{pass@1} by \textbf{+1.4} to \textbf{+7.9} points relative to GRPO.
Overall, diversity is not merely a regularizer but a \textbf{geometric property} to be controlled to improve the model without trapping it in a single dominant strategy.
****

LLM-based Embeddings: Attention Values Encode Sentence Semantics Better Than Hidden States
Yeqin Zhang, Yunfei Wang, Chen Jiaxuan, Ke Qin, Yizheng Zhao, Cam-Tu Nguyen
Sentence representations are foundational to many Natural Language Processing (NLP) applications. While recent methods leverage Large Language Models (LLMs) to derive sentence representations, most rely on final-layer hidden states, which are optimized for next-token prediction and thus often fail to capture global, sentence-level semantics.
This paper introduces a novel perspective, demonstrating that attention value vectors capture sentence semantics more effectively than hidden states. We propose *Value Aggregation (VA)*, a simple method that pools token values across multiple layers and token indices. In a training-free setting, VA outperforms other LLM-based embeddings, even matches or surpasses the ensemble-based MetaEOL. Furthermore, we demonstrate that when paired with suitable prompts, the layer attention outputs can be interpreted as aligned weighted value vectors. Specifically, the attention scores of the last token function as the weights, while the output projection matrix (W_O) aligns these weighted value vectors with the common space of the LLM residual stream. This refined method, termed *Aligned Weighted VA (AlignedWVA)*, achieves state-of-the-art performance among training-free LLM-based embeddings, outperforming the high-cost MetaEOL by a substantial margin. Finally, we highlight the potential of obtaining strong LLM embedding models through fine-tuning Value Aggregation.
****

Swift-SVD: Theoretical Optimality Meets Practical Efficiency in Low-Rank LLM Compression
Ruoling Qi, Yirui Liu, Xuaner Wu, Xiangyu Wang, Ming Li, Chen Chen, Jian Chen, Yin Chen, Qizhen Weng
The deployment of Large Language Models is constrained by the memory and bandwidth demands of static weights and dynamic Key-Value cache. SVD-based compression provides a hardware-friendly solution to reduce these costs. However, existing methods suffer from two key limitations: some are suboptimal in reconstruction error, while others are theoretically optimal but practically inefficient. In this paper, we propose Swift-SVD, an activation-aware, closed-form compression framework that simultaneously guarantees theoretical optimum, practical efficiency and numerical stability. Swift-SVD incrementally aggregates covariance of output

activations given a batch of inputs and performs a single eigenvalue decompositi
on after aggregation, enabling training-free, fast, and optimal layer-wise low-r
ank approximation. We employ effective rank to analyze local layer-wise compress
ibility and design a dynamic rank allocation strategy that jointly accounts for
local reconstruction loss and end-to-end layer importance. Extensive experiments
 across six LLMs and eight datasets demonstrate that Swift-SVD outperforms state
-of-the-art baselines, achieving optimal compression accuracy while delivering 3
–70$\times$ speedups in end-to-end compression time. Our code is available at ht
tps://github.com/hiahei/Swift-SVD.

Early Decisions Matter: Proximity Bias and Initial Trajectory Shaping in Non-Aut
oregressive Diffusion Language Models
Jiyeon Kim, Sungik Choi, Yongrae Jo, Moontae Lee, Minjoon Seo
Diffusion-based language models(dLLMs) have emerged as a promising alternative t
o autoregressive language models, offering the potential for parallel token gene
ration and bidirectional context modeling. However, harnessing this flexibility
for fully non-autoregressive decoding remains an open question, particularly for
 reasoning and planning tasks. In this work, we investigate non-autoregressive d
ecoding in dLLMs by systematically analyzing its inference dynamics along the te
mporal axis. Specifically, we uncover an inherent failure modes in confidence-ba
sed non-autoregressive generation stem from a strong proximity bias—the denoisin
g order tends to concentrate on spatially adjacent tokens. This local dependency
 leads to spatial error propagation, rendering the entire trajectory critically
contingent on the initial unmasking position. Leveraging this insight, we presen
t a minimal-intervention approach that guides early token selection, employing a
 lightweight planner and end-of-sequence temperature annealing. We thoroughly ev
aluate our method on various reasoning and planning tasks and observe substantia
l overall improvement over existing heuristic baselines without significant comp
utational overhead.

Time-PEFT: Temporal and Multichannel Complexity-Based Fine-Tuning for Time-Serie
s Foundation Models
Jihye Na, Patara Trirat, Chanyoung Park, Jae-Gil Lee
Recent studies have attempted to fine-tune time-series foundation models to enha
nce a target dataset's forecasting performance. However, these approaches procee
d without a clear criterion for identifying complex datasets that require fine-t
uning due to performance degradation in zero-shot forecasting. To distinguish da
tasets that are more challenging than standard benchmarks, we introduce data-dri
ven temporal complexity and multichannel complexity. *Temporal complexity* captu
res the difficulty of identifying distinct patterns by quantifying spectral entr
opy in the frequency domain, while *multichannel complexity* captures cross-chan
nel information flow that can impact predictive uncertainty. These metrics serve
 as *effective proxies for performance gains* achievable through fine-tuning. Ba
sed on the two metrics, we develop *Time-PEFT*, a parameter-efficient fine-tunin
g framework that incorporates a frequency adapter for top-k filtering and a ch
annel adapter for multichannel modeling. With the base variant of MOMENT as a ba
ckbone, *Time-PEFT* improves performance by up to 38\% over LoRA on complex data
sets.

Beyond Tokens: Enhancing RTL Quality Estimation via Structural Graph Learning
Yi Liu, Hongji Zhang, Yiwen Wang, Dimitris Tsaras, Lei Chen, Mingxuan Yuan, Qian
g Xu
Estimating the quality of register transfer level (RTL) designs is crucial in th
e electronic design automation (EDA) workflow, as it enables instant feedback on
 key performance metrics like area and delay without the need for time-consuming
 logic synthesis. While recent approaches have leveraged large language models (
LLMs) to derive embeddings from RTL code and achieved promising results, they ov
erlook the structural semantics essential for accurate quality estimation. In co
ntrast, the control data flow graph (CDFG) view exposes the design's structural
characteristics more explicitly, offering richer cues for representation learnin

g. In this work, we introduce StructRTL, a novel structure-aware graph self-supe
rvised learning framework for improved RTL design quality estimation. By learnin
g structure-informed representations from CDFGs, StructRTL significantly outperf
orms prior art on various quality estimation tasks. To further boost performance
, we incorporate a knowledge distillation strategy that transfers low-level insi
ghts from post-mapping netlists into the CDFG-based predictor. Experimental resu
lts demonstrate that StructRTL establishes new state-of-the-art results, highlig
hting the effectiveness of combining structural learning with cross-stage superv
ision.

FormAct: Agentic Source Editing for Rich-Format Document Generation
Eugene J. Yu, Xingxing Zhang, Yuan Xia, Tao Ge, Xun Wang, FNU Kartik, Vishwas Su
ryanarayanan, Cheng Yang, Amanda Jiang, Jiayu Ding, Xiangyu Wong, Tengchao Lv, L
ei Cui, Si-Qing Chen, Furu Wei, Sujian Li
Rich-format documents are essential for everyday operations yet costly to author
, motivating the need for automated generation to enhance productivity. To this
end, we present FormAct, an agentic system that generates professional rich-form
at documents from scratch. FormAct operates on an HTML source representation and
 performs iterative source refinement with an *editing agent* that invokes a sui
te of tools, including a syntax-aware source editor and a template retriever, an
d a *review agent* that critiques rendered pages to guide refinement. Additional
ly, we incorporate edit-triggered context compression to maintain a bounded work
ing context and keep multi-round editing efficient. To support development and e
valuation, we introduce RichDocBench for end-to-end generation, and RichDocFuzz
to evaluate formatting-error recognition for reviewer agents. Through extensive
automated evaluation and blind human-preference studies, we show that FormAct co
nsistently outperforms strong baselines, including Codex-CLI, with particularly
strong improvements in generating error-free, professional rich-format documents
.

AutoNumerics-Zero: Automated Discovery of State-of-the-Art Mathematical Function
s
Esteban Real, Mirko Rossini, Connal de Souza, Manav Garg, Moritz Firsching, Quoc
 V Le, Yao Chen, Akhil Verghese, Ekin Dogus Cubuk, David H. Park
Transcendental functions, such as the exponential, are central to scientific com
puting, yet they cannot be natively calculated by digital hardware. Instead, com
puters must approximate these functions by combining basic operations, such as $
\{+, -, \times, \div\}$, using methods like Taylor series. These methods were de
veloped over centuries by mathematicians, who focused on approaches that could a
ttain arbitrary accuracy. However, computers can handle most applications by usi
ng only finite-precision types, like *float32*, where any accuracy beyond the ty
pe's precision is effectively discarded. We explore, therefore, whether forgoing
 arbitrary accuracy can lead to the discovery of more efficient approximations.
The evolutionary method of symbolic regression is particularly suitable, as it c
an search for arbitrary operation combinations and can optimize non-differentiab
le objectives, such as the number of operations used. Our results show that evol
ution can discover computer programs that outperform established methods in this
 setting, despite having no prior mathematical knowledge beyond the calculation
of the basic operations. Starting from empty code, symbolic regression construct
s programs representing novel mathematical expressions. In particular, we discov
ered a 10-operation program that approximates the exponential function to 14 sig
nificant figures, exceeding the accuracy of previously known approximations of t
his size by more than 6 orders of magnitude.
****

OTora: A Unified Red Teaming Framework for Reasoning-Level Denial-of-Service in
LLM Agents
Xinyu Li, Ronghui Mu, Lin Li, Tianjin Huang, Gaojie Jin
Large Language Models (LLMs) are increasingly deployed as autonomous agents that
 execute tool-augmented, multi-step tasks, where latency is a critical factor fo
r real-world applications. Yet an overlooked threat is Reasoning-Level Denial-of

-Service (R-DoS), in which an attacker preserves task correctness but degrades availability by inflating an agent’s reasoning depth or tool-use budget.
We introduce OTora, the first unified, two-stage red-teaming framework for instantiating R-DoS attacks. Stage I optimizes an adversarial trigger that induces targeted tool invocations using insertion-aware scoring and dynamic target co-evolution, supporting both black-box and white-box settings. Stage II generates agent-aware reasoning payloads via an ICL-guided genetic search that amplifies overthinking while maintaining correct task outcomes.
Across WebShop, Email, and OS agents built on multiple backbone models such as LLaMA-70B and GPT-OSS-120B, OTora achieves up to 10× increases in reasoning tokens and order-of-magnitude latency slowdowns, all while preserving near-baseline task accuracy. Finally, we discuss mitigation strategies for detecting and constraining abnormal reasoning and latency spikes.
****

Abstraction Induces the Brain Alignment of Language and Speech Models
Emily Cheng, Aditya R. Vaidya, Richard Antonello
Research has repeatedly demonstrated that intermediate hidden states extracted from large language models and speech audio models predict measured brain response to natural language stimuli. Yet, very little is known about the representation properties that enable this high prediction performance. Why is it the intermediate layers, and not the output layers, that are most effective for this unique and highly general transfer task? We give evidence that the correspondence between speech and language models and the brain derives from shared meaning abstraction and not their next-word prediction properties. In particular, models construct higher-order linguistic features in their middle layers, cued by a peak in the layerwise *intrinsic dimension*, a measure of feature complexity. We show that a layer's intrinsic dimension strongly predicts how well it explains fMRI and ECoG signals; that the relation between intrinsic dimension and brain predictivity arises over model pre-training; and finetuning models to better predict the brain causally increases both representations' intrinsic dimension and their semantic content. Results suggest that semantic richness, high intrinsic dimension, and brain predictivity mirror each other, and that the key driver of model-brain similarity is *rich meaning abstraction* of the inputs, where language modeling is a task sufficiently complex (but perhaps not the only) to require it.
****

Revenue Guarantees of No-Swap-Regret Dynamics in First Price Auctions
Anders Bo Ipsen, Stratis Skoulakis
We study the revenue of approximate correlated equilibrium in discrete first price auctions - the set of allowable bids is $\mathcal{B} = \{0, 1/k, \dots, 1 - 1/k, 1\}$ for some $k \in \mathbb{N}$. We show that the revenue of any ϵ-\textit{approximate} correlated equilibrium is at least $v_2 - \Theta(1/k)- \Theta(\epsilon k^2)$, where $v_2 \geq 0$ is the second-highest valuation. Our results establish the first polynomial convergence rates on the revenue generated by no-swap regret bidders in first-price auctions.
For instance, if bidders admit the optimal swap regret of $\mathcal{O}(\sqrt{k T})$, then the time-averaged revenue is at least $v_2 - \Theta(1/k) - \Theta(\epsilon)$ after $\mathcal{O}(k^5/\epsilon^2)$ rounds.
****

PinTok: Tokenizers Deserve Dedicated Pinned CPU-Compute and Memory
Sean Choi, Myungheon Chin, Ernest K. Ryu
Tokenization is the first point of contact between large language models (LLMs) and text data, yet it has not been viewed by many as a component of LLMs worth accelerating. During inference, tokenizers typically rely on simple dictionary lookups and are executed on CPUs as standard processes. This approach, however, introduces significant overhead from scheduling delays, core selection, data copying, and other system-level costs. These inefficiencies become problematic in latency-sensitive applications such as embedding, small language models, and agentic AI. In this paper, we present the Pinned Tokenizer (PinTok), a novel tokenizer architecture that reduces redundant hardware, operating system, and networking overhead through three key innovations: core and memory pinning, scheduling and

context switch avoidance, and duplicate network packet copy and processing avoidance. Our implementation of PinTok can serve as a drop-in replacement for existing tokenizer deployments, delivering latency reductions of up to 95% (average), 97% (P50), 94% (P90), and 87% (P99) along with throughput improvements of up to 2,084%.

Behavior-Invariant Task Representation Learning with Transformer-based World Models for Offline Meta-Reinforcement Learning

Fuyuan Qian, Menglong Zhang, Song Wang, Quanying Liu

Offline meta-reinforcement learning leverages static datasets to enable agents to generalize to unseen environments by combining offline efficiency with meta-learning adaptability, yet it faces key challenges from context and policy distribution shifts. These issues hinder agents from adapting to online environments, and are further exacerbated under sparse-reward settings. As a result, agents often become trapped in an inherent pattern dilemma, failing to achieve robust generalization. In this work, we propose a novel framework that integrates information-theoretic task representation learning with a Transformer-based stochastic world model. Our approach extracts task-defining latent variables that are invariant to behavior policy, thereby effectively mitigating the context distribution shift. To further handle policy shift and model exploitation, we apply a conservative value penalty to imagination-based rollouts, preventing the policy from exploiting model inaccuracies while maintaining robust adaptation. Extensive evaluations demonstrate that our method outperforms state-of-the-art approaches, with superior stability and generalization under out-of-distribution and sparse-reward settings.

Softsign: Smooth Sign in Your Optimizer For Better Parameter Heterogeneity Handling

Dmitrii Feoktistov, Timofey Belinsky, Andrey Veprikov, Amir Zainullin, Aleksandr Beznosikov

Sign-based and LMO-inspired optimizers have recently attracted substantial attention in deep learning due to their strong performance and low memory footprint. However, their fixed-magnitude updates can hurt terminal convergence: they decouple update mechanisms from gradient magnitudes and fail to account for parameter heterogeneity, often leading to oscillation rather than convergence. We propose SoftSignum, a smooth relaxation of sign-based optimization that replaces the hard sign map with a temperature-controlled soft-sign transformation, enabling a parameter-wise transition from sign-like updates to magnitude-sensitive SGD-like steps. We complement it with an adaptive quantile-based temperature schedule and extend the same principle to matrix-valued optimizers, obtaining SoftMuon. We also develop a generalized geometry-relaxation framework based on strongly convex regularizers and Fenchel conjugates, proving convergence in stochastic non-convex setting. Experiments on diverse deep learning tasks, including LLM pretraining, show that SoftSignum and SoftMuon consistently improve over their hard sign-based counterparts and standard AdamW.

On the Spectral Unreachability of Brain Graph Learning

Jiaming Zhuo, Shuai Zhai, Ziyi Ma, Kun Fu, Chuan Wang, Di Jin, Zhen Wang, Xiaochun Cao, Huazhu Fu, Liang Yang

Brain network classification is pivotal for diagnosing neurological disorders, yet identifying interpretable functional biomarkers fundamentally relies on precise parcellation. Unfortunately, conventional deep graph encoders applied to brain networks suffer from a critical theoretical limitation termed Spectral Unreachability. Through graph spectral analysis, this paper demonstrates that standard coupled encoder-pooling architectures inevitably oversmooth node representations, corrupting the high-frequency topological signals strictly required to delineate sharp module boundaries. To provide a structural remedy, the Hierarchical Spectral Parcellation Network (HiSP-Net) is proposed, which structurally decouples partition learning from feature smoothing via a project-then-align paradigm. Specifically, HiSP-Net maps representations directly into a partition space using a

topology-agnostic projection block to preserve all-frequency details, while a Topology-Aware Alignment regularizer subsequently enforces spatial coherence. Extensive evaluations demonstrate that HiSP-Net consistently outperforms state-of-the-art baselines in classification, while successfully extracting stable and structurally coherent functional biomarkers. Source code is available at https://github.com/Kevin-916/HiSP-Net-demo/.
****

SpikeCLR: Self-Supervised Contrastive Learning for Visual Representations with Spiking Neural Networks
Chengwei Zhou, Gourav Datta
Spiking Neural Networks (SNNs) offer a promising alternative to traditional artificial neural networks by leveraging sparse, event-driven computation that closely mimics biological neurons. When deployed on neuromorphic hardware, SNNs enable substantial energy savings due to their temporal and asynchronous processing. However, training SNNs remains fundamentally difficult because the non-differentiable nature of spike generation breaks the bidirectional gradient flow required in modern self-supervised learning (SSL) frameworks. In this work, we introduce the first fully SSL framework for SNNs that scales to large-scale visual tasks without requiring labeled fine-tuning. Our method leverages intrinsic spike-time dynamics by aligning representations across time steps and augmented views. To address gradient mismatch during surrogate training, we propose the MixedLIF neuron model, which combines a spiking path with an antiderivative-based surrogate path during training to stabilize optimization, while retaining a fully spiking and energy-efficient architecture at inference. We also introduce two temporal objectives, Cross Temporal Loss and Boundary Temporal Loss, that align multi-time-step outputs to improve learning efficiency. Our approach achieves competitive performance across both ResNet- and Vision Transformer-based SNNs on both static and neuromorphic datasets. Our approach further generalizes through transfer learning from ImageNet-1K to downstream tasks. Notably, our self-supervised SNNs match or exceed the performance of some non-spiking SSL models, demonstrating both representational strength and energy efficiency.
****

REViT: Roto-reflection Equivariant Convolutional Vision Transformer
Sheir A. Zaheer, Alexander C. Holston, Chan Y. Park
In this paper, we propose a discrete roto-reflection group equivariant vision transformer with convolutional attention. Roto-reflection equivariant networks preserve the rotational, flip and positional symmetry in feature maps, making them useful for tasks where orientation of the inputs is relevant to the model outputs. In image classification and object detection, most of the studies on roto-reflection equivariant models have focused on using convolutional neural networks rather than vision transformers. In this paper, we examine the challenges involved in achieving equivariance in vision transformers, and we propose a simpler way to implement a discretized roto-reflection group equivariant vision transformer. The experimental results demonstrate that our approach outperforms the existing approaches for developing discrete roto-reflection group equivariant neural networks for image classification.

VocSim A Training-free Benchmark for Zero-shot Content Identity in Single-source Audio
Maris Basha, Anja T Zai, Sabine Stoll, Richard Hahnloser
General-purpose audio representations aim to map acoustically variable instances of the same event to nearby points, resolving content identity in a zero-shot setting. Unlike supervised classification benchmarks that measure adaptability via parameter updates, we introduce VocSim, a training-free benchmark probing the intrinsic geometric alignment of frozen embeddings, with no parameters updated and no labels used (a label-free PCA whitening is fit per subset to correct anisotropy). VocSim aggregates 125k single-source clips from 19 corpora spanning human speech, animal vocalizations, and environmental sounds, isolating content representation from source separation (polyphonic mixtures are out of scope). We evaluate embeddings with Precision@k for local purity and the Global Separation Rat

e (GSR) for point-wise class separation, calibrated by lift over an empirical pe
rmutation baseline. A simple pipeline of frozen Whisper features, time–frequency
 pooling, and label-free PCA yields strong zero-shot performance with stable GSR
 rankings across domains (Kendall's $\tau = 0.60$). However, on blind low-resource sp
eech (Shipibo-Conibo, Chintang), local retrieval collapses while remaining above
 chance, exposing a cross-lingual speech generalization gap. As external validat
ion, our top embeddings predict avian perceptual similarity, improve bioacoustic
 classification, and achieve state-of-the-art on the HEAR benchmark. We release
data, code, and a public leaderboard.

Shifting the Breaking Point of Flow Matching for Multi-Instance Editing
Carmine Zaccagnino, Fabio Quattrini, Enis Simsar, Marta Tintore Gazulla, Rita Cu
cchiara, Alessio Tonioni, Silvia Cascianelli
Flow matching models have recently emerged as an efficient alternative to diffus
ion, especially for text-guided image generation and editing, offering faster in
ference through continuous-time dynamics. However, existing flow-based editors p
redominantly support global or single-instruction edits and struggle with multi-
instance scenarios, where multiple parts of a reference input must be edited ind
ependently without semantic interference. We identify this limitation as a conse
quence of globally conditioned velocity fields and joint attention mechanisms, w
hich entangle concurrent edits. To address this issue, we introduce Instance-Dis
entangled Attention, a mechanism that partitions joint attention operations, enf
orcing binding between instance-specific textual instructions and spatial region
s during velocity field estimation.
We evaluate our approach on both natural image editing and a newly introduced be
nchmark of text-dense infographics with region-level editing instructions. Exper
imental results demonstrate that our approach promotes edit disentanglement and
 locality while preserving global output coherence, enabling single-pass, instanc
e-level editing.

Star Elastic: Many-in-One Reasoning LLMs with Efficient Budget Control
Ali Taghibakhshi, Ruisi Cai, Saurav Muralidharan, Sharath Turuvekere Sreenivas,
Ameya Sunil Mahabaleshwarkar, Marcin Chochowski, Akhiad Bercovich, Ran Zilberste
in, Ran El-Yaniv, Yonatan Geifman, Daniel Korzekwa, Yoshi Suhara, Oluwatobi Olab
iyi, Ashwath Aithal, Nima Tajbakhsh, Pavlo Molchanov
Training a family of large language models (LLMs), either from scratch or via it
erative compression, is prohibitively expensive and inefficient, requiring separ
ate training runs for each model in the family. In this paper, we introduce Star
 Elastic, a novel LLM post-training method that adds N nested submodels to a giv
en parent reasoning model using the compute of one run (Nx savings) via a single
 post-training job. Beyond reducing training costs, Star Elastic also addresses
a fundamental limitation in efficient reasoning: the rigidity of static architec
tures, which forces the allocation of constant resources regardless of token dif
ficulty. By unlocking elastic budget control, Star Elastic enables a novel appro
ach that uses different submodels for each reasoning phase (thinking and answeri
ng). Star Elastic supports (1) nesting along the SSM, embedding channel, MoE and
 FFN axes, (2) learning nested submodels via an end-to-end trainable router, and
 (3) curriculum-based knowledge distillation. We apply Star Elastic to the NVIDI
A Nemotron Nano models; in particular, we demonstrate its effectiveness on hybri
d MoE architectures with Nemotron Nano v3 (30B/3.6A), generating 23B (2.8A) and
12B (2.0A) variants with 160B training tokens. For Nemotron Nano v2 (12B), we pr
oduce 9B and 6B nested models using only 110B training tokens, achieving a 360x
reduction versus training from scratch and a 7x reduction over state-of-the-art
compression methods. All nested models match or outperform independently trained
 baselines of comparable size. Crucially, elastic budget control advances the ac
curacy--latency Pareto frontier, achieving up to 16% higher accuracy and 1.9x lo
wer latency via dynamic per-phase model selection.
****

Training Language Model Agents to Find Vulnerabilities with CTF-Dojo
Terry Yue Zhuo, Dingmin Wang, Hantian Ding, Varun Kumar, Zijian Wang

Large language models (LLMs) have demonstrated exceptional capabilities when tra
ined within executable runtime environments, notably excelling at software engin
eering tasks through verified feedback loops. Yet, scalable and generalizable ex
ecution-grounded environments remain scarce, limiting progress in training more
capable ML agents. We introduce CTF-Dojo, the first large-scale executable runti
me tailored for training LLMs with verifiable feedback, featuring 658 fully func
tional Capture-The-Flag (CTF)-style challenges containerized in Docker with guar
anteed reproducibility. To enable rapid scaling without manual intervention, we
develop CTF-Forge, an automated pipeline that transforms publicly available arti
facts into ready-to-use execution environments in minutes, eliminating weeks of
expert configuration traditionally required. We trained LLM-based agents on just
 486 high-quality, execution-verified trajectories from CTF-Dojo, achieving up t
o 11.6% absolute gains over strong baselines across three competitive benchmarks
: InterCode-CTF, NYU CTF Bench, and Cybench. Our best-performing 32B model reach
es 31.9% Pass@1, establishing a new open-weight state-of-the-art that rivals fro
ntier models like DeepSeek-V3-0324 and Gemini-2.5-Flash. By framing CTF-style ta
sks as a benchmark for executable-agent learning, CTF-Dojo demonstrates that exe
cution-grounded training signals are not only effective but pivotal in advancing
 high-performance ML agents without dependence on costly proprietary systems.

Hierarchical Retrieval at Scale: Bridging Interpretability and Efficiency
Shubham Gupta, Zichao Li, Tianyi Chen, Cem Subakan, Siva Reddy, Perouz Taslakian
, Valentina Zantedeschi
Information retrieval is a core component of many intelligent systems as it enab
les conditioning of outputs on new and large-scale datasets. While effective, th
e standard practice of encoding data into high-dimensional representations for s
imilarity search entails large memory and compute footprints, and also makes it
hard to inspect the inner workings of the system. Hierarchical retrieval methods
 offer an interpretable alternative by organizing data at multiple granular leve
ls, yet do not match the efficiency and performance of flat retrieval approaches
. In this paper, we propose Retreever, a tree-based method that makes hierarchic
al retrieval viable at scale by directly optimizing its structure for retrieval
performance while naturally providing transparency through meaningful semantic g
roupings. Our method offers the flexibility to balance cost and utility by index
ing data using representations from any tree level. We show that Retreever deliv
ers strong coarse (intermediate levels) and fine representations (terminal level
), while achieving the highest retrieval accuracy at the lowest latency among hi
erarchical methods. These results demonstrate that this family of techniques is
viable in practical applications.
****

Test-Time Graph Search for Goal-Conditioned Reinforcement Learning
Evgenii Opryshko, Junwei Quan, Claas A Voelcker, Yilun Du, Igor Gilitschenski
Offline goal-conditioned reinforcement learning (GCRL) often struggles with long
-horizon tasks, where errors in value estimation accumulate and produce unreliab
le policies. It is typically assumed that effective long-term planning is infeas
ible without specialized training. In contrast, our work demonstrates that exist
ing GCRL policies can complete long-horizon tasks when combined with a lightweig
ht, training-free planning wrapper. We find that standard goal-conditioned value
 functions encode locally consistent geometric structure sufficient for planning
. Our approach, Test-Time Graph Search (TTGS), constructs a graph over the offli
ne dataset and employs an adaptive subgoal selection strategy. To address unreli
able value estimates during shortest-path search, we propose a novel mechanism t
hat softly penalizes long-distance transitions. Our method incurs negligible com
putational overhead and requires no additional supervision or parameter updates.
 On the OGBench benchmark, TTGS significantly boosts success rates across multip
le base learners and tasks, with primary gains on challenging long-horizon locom
otion tasks where some success rates are improved from near-zero to over 90\%, o
ften matching or outperforming methods that require complex auxiliary training.
Code and videos can be found at https://ktolnos.github.io/ttgs.

Diff-MN: Diffusion Parameterized MoE-NCDE for Continuous Time Series Generation with Irregular Observations

Xu Zhang, Junwei Deng, Chang Xu, Hao Li, Jiang Bian

Time series generation (TSG) is widely used across domains, yet most existing methods assume regular sampling and fixed output resolutions. These assumptions are often violated in practice, where observations are irregular and sparse, while downstream applications require continuous and high-resolution TS. Although Neural Controlled Differential Equation (NCDE) is promising for modeling irregular TS, it is constrained by a single dynamics function, tightly coupled optimization, and limited ability to adapt learned dynamics to newly generated samples from the generative model.

We propose Diff-MN, a continuous TSG framework that enhances NCDE with a Mixture-of-Experts (MoE) dynamics function and a decoupled architectural design for dynamics-focused training. To further enable NCDE to generalize to newly generated samples, Diff-MN employs a diffusion model to parameterize the NCDE temporal dynamics parameters (MoE weights), i.e.,
jointly learn the distribution of TS data and MoE weights. This design allows sample-specific NCDE parameters to be generated for continuous TS generation. Experiments on ten public and synthetic datasets demonstrate that Diff-MN consistently outperforms strong baselines on both irregular-to-regular and irregular-to-continuous TSG tasks. The code is available at the link \url{https://github.com/microsoft/TimeCraft/tree/main/Diff-MN}.

****

The Geometric Reasoner: Manifold-Informed Latent Foresight Search for Long-Context Reasoning

Ren Zhuang, Ben Wang, Shuifa Sun

Scaling test-time compute enhances long chain-of-thought (CoT) reasoning, yet existing approaches face a fundamental trade-off between computational cost and coverage quality: either incurring high training expense or yielding redundant trajectories. We introduce The Geometric Reasoner (TGR), a training-free framework that performs manifold-informed latent foresight search under strict memory bounds. At each chunk boundary, TGR scores candidate latent anchors via a lightweight look-ahead estimate combined with soft geometric regularizers that encourage smooth trajectories and diverse exploration. Chunk-wise KV cache resets keep memory linear in chunk length. On challenging math and code benchmarks, TGR improves robust trajectory coverage, measured by the area under the Pass@k curve (AUC), by up to 13 points on Qwen3-8B, with negligible overhead of about 1.1--1.3$\times$.

Noisy Pairwise-Comparison Random Search for Smooth Nonconvex Optimization

Taha EL BAKKALI EL KADI, Rayane Bouftini, Qiuyi Zhang, Omar Saadi

We study smooth nonconvex optimization using only noisy pairwise comparisons, without access to gradients or function values.

We propose Noisy-Comparison Random Search (NCRS), a simple direct-search method that samples random directions and performs accept/reject updates from comparison feedback.

Under a low-dimensional active-subspace structure, NCRS adapts to the intrinsic dimension $k\le d$ rather than the ambient dimension d.

For a uniform-margin comparison oracle with advantage p, NCRS achieves ϵ-first-order stationarity with comparison complexity
$\mathcal{O}(k/(p^2\epsilon^2))$.

We also introduce a gap-dependent confidence model, where comparison reliability decreases as the objective-value gap between the two candidates becomes small, and analyze a confidence-weighted voting variant of NCRS.

For this oracle, the method achieves ϵ-first-order stationarity with total comparison complexity
$\mathcal{O}(k^2/\epsilon^4)$.

These results provide intrinsic-dimension convergence guarantees for noisy comparison-based random search in smooth nonconvex optimization.

GenCircuit-RL: Reinforcement Learning from Hierarchical Verification for Genetic Circuit Design
Noah Flynn
Designing genetic circuits, which are biological systems capable of programmed behaviors within living cells, remains a laborious, expert-driven process despite decades of progress in synthetic biology. We introduce GenCircuit-RL, a reinforcement learning framework that trains language models to reason about genetic circuit design through code generation, where models produce Python code using PySBOL to construct circuits in the standardized Synthetic Biology Open Language (SBOL) format. Our approach addresses the challenge of sparse feedback in biological design through hierarchical verification rewards that decompose correctness into five levels, from code execution through structural validity to functional behavior, providing dense learning signal while multiplicative dependencies prevent reward hacking. We contribute SynBio-Reason, a benchmark of approximately 4,753 circuits spanning six canonical circuit types and nine tasks from code repair to de novo design, with held-out biological parts enabling rigorous out-of-distribution evaluation. A four-stage curriculum progressively shifts optimization pressure from basic code generation toward functional correctness, enabling models to acquire compositional reasoning capabilities incrementally. Our framework demonstrates that hierarchical verification combined with curriculum learning enables compact language models to generate functionally correct genetic circuits, including generalization to novel biological parts and rediscovery of canonical designs from synthetic biology literature.
****
Beyond Perplexity: UTF-8 Validity in Byte-aware Language Models
Sangwhan Moon, Daisuke Oba, Youmi Ma, Tatsuya Hiraoka, Naoaki Okazaki
Byte-level tokenization enables language models to handle any Unicode input, but models can generate invalid UTF-8 sequences when encountering rare or unseen characters. We investigate the relationship between training scale and UTF-8 generation reliability with a 355M parameter model trained on 80B tokens from a balanced multilingual corpus of English, Japanese, Korean, and Chinese. We introduce multiple evaluation protocols that isolate UTF-8 structural validity from language modeling. UTF-8 validity convergence lags perplexity by a
roughly a factor of two: perplexity stabilizes after 2.1B tokens, but UTF-8 validity requires 4.2B tokens. In context-free generation, rare characters achieve higher structural validity than common characters, suggesting over-specialization of frequent character representations. Through experiments, we observed that reliable UTF-8 generation is a distinct capability requiring evaluation beyond perplexity.
****
On the Origin of Neural Scaling Laws: from Random Graphs to Natural Language
Maissam Barkeshli, Alberto Alfarano, Andrey Gromov
Scaling laws have played a major role in modern AI, providing predictive power over how model performance will improve with increasing resources. This has spurred intense interest in their origin, with a common suggestion being that they arise from power laws already present in the data. Here we study scaling laws for transformers trained to predict random walks on graphs with tunable complexity. We show that this simplified setting already yields scaling laws even in the absence of power laws in the data correlations. We further consider dialing down the complexity of language by training on sequences sampled from increasingly simplified generative language models, from 4,2,1-layer transformer language models down to language bigrams, revealing a monotonic evolution of the scaling exponents. Our results also include scaling laws obtained from training on random walks on random graphs drawn from Erdös-Renyi and scale-free Barabási-Albert ensembles. Finally, we revisit scaling laws for language modeling, demonstrating that several essential results can be reproduced using 2 layer transformers with context length of 100, demonstrate an alternative method for obtaining compute optimal curves, and provide preliminary evidence that maximal update parameterization may be more parameter efficient than standard parameterization.

AlphaGRPO: Unlocking Self-Reflective Multimodal Generation in Unified Multimodal Models via Decompositional Verifiable Reward
Runhui Huang, Jie Wu, Rui Yang, Zhe Liu, Hengshuang Zhao
In this paper, we propose **AlphaGRPO**, a novel framework that applies Group Relative Policy Optimization (GRPO) to AR-Diffusion Unified Multimodal Models (UMMs)
to enhance multimodal generation capabilities without relying on external knowledge injection. Our approach unlocks the model's intrinsic potential to perform advanced reasoning tasks: Reasoning Text-to-Image Generation,
where the model actively infers implicit user intents, and Self-Reflective Refinement, where it autonomously diagnoses and corrects misalignments in generated outputs.
To address the challenge of providing stable supervision for real-world multimodal generation, we introduce the Decompositional Verifiable Reward (**DVReward**).
Unlike holistic scalar rewards, DVReward utilizes an LLM to decompose complex user requests into atomic, verifiable semantic and quality questions,
which are then evaluated by a general MLLM to provide reliable and interpretable feedback. Extensive experiments demonstrate that AlphaGRPO yields robust improvements across multimodal generation benchmarks,
including GenEval, TIIF-Bench, DPG-Bench and WISE, while also achieving significant gains in editing tasks on GEdit without training on editing tasks.
These results validate that our self-reflective reinforcement approach effectively leverages inherent understanding to guide high-fidelity generation.
****
Robust Stochastic Gradient Posterior Sampling with Lattice Based Discretisation
Zier Mensch, Lars Holdijk, Samuel Duffield, Maxwell Aifer, Patrick J. Coles, Max Welling, Miranda C. N. Cheng
Stochastic-gradient MCMC methods enable scalable Bayesian posterior sampling but often suffer from sensitivity to minibatch size and gradient noise. To address this, we propose Stochastic Gradient Lattice Random Walk (SGLRW), an extension of the Lattice Random Walk discretisation. Unlike conventional Stochastic Gradient Langevin Dynamics (SGLD), SGLRW introduces stochastic noise only through the off-diagonal elements of the update covariance; this yields greater robustness to minibatch size while retaining asymptotic correctness. Furthermore, as a comparison we analyse a natural analogue of SGLD utilising gradient clipping. Experimental validation on Bayesian regression and classification demonstrates that SGLRW remains stable in regimes where SGLD fails, including in the presence of heavy-tailed gradient noise, and matches or improves predictive performance.

Revisiting Coding-Based Approaches to Overcome the Curse of Dimensionality in Learning-Based Watermarking
Yupeng Qiu, Han Fang, Ee-Chien Chang
Deep learning–based watermarking has substantially improved robustness to real-world noise, but its performance degrades as the payload dimension increases. In contrast, coding-based methods such as quantization index modulation (QIM) do not suffer from this curse of dimensionality, although they are less robust to real-world noise. To leverage the strengths of both approaches, we propose OrthoMark, a framework that decouples robust feature extraction from message encoding. OrthoMark first learns a distortion-invariant feature representation using a deep robust feature extractor, and then performs watermark encoding and decoding in this feature domain using coding-based methods. Extensive experiments demonstrate that OrthoMark significantly improves the trade-off among visual quality, robustness, and capacity compared to prior deep watermarking methods, with particularly large gains in the high capacity regime, effectively overcoming the curse of dimensionality. Our code is available at \url{https://github.com/QQiuyp/OrthoMark}.

Networked Information Aggregation for Binary Classification
Mohammadhossein Bateni, Zahra Hadizadeh, MohammadTaghi Hajiaghayi, Mahdi JafariR

aviz, Shayan Taherijam
We study networked binary classification on a directed acyclic graph (DAG), where each agent observes only a subset of the feature coordinates. Agents act sequentially along the DAG: each receives logits from its parents, augments its local features with these logits, fits a logistic predictor by minimizing binary cross-entropy (BCE), and forwards its logit to its outgoing neighbors. We ask whether this sequential distributed protocol achieves information aggregation: can a downstream agent attain small excess loss compared to the best logistic predictor with access to all features? This question was studied for linear regression under squared loss by Kearns, Roth, and Ryu (2026). Extending their guarantees to classification is nontrivial because their squared-loss tools do not directly transfer to BCE with a logistic link. We analyze the resulting sequential logit-passing protocol and prove an excess-loss upper bound of $O(M/\sqrt{D})$ on depth-D paths satisfying the M coverage condition, namely that every contiguous block of M agents collectively observes all features. We also prove complementary hard instances with excess loss at least $\Omega(k/D)$, where k is the feature dimension. Together, these results show that network depth is a fundamental bottleneck for information aggregation in networked logistic regression.

LATO: 3D Mesh Flow Matching with Structured TOpology Preserving LAtents
Tianhao Zhao, Youjia Zhang, Hang Long, Jinshen Zhang, Wenbing Li, Yang Yang, Gongbo Zhang, Jozef Hladký, Matthias Nießner, Wei Yang
In this paper, we introduce LATO, a novel topology-preserving latent representation that enables scalable, flow matching-based synthesis of explicit 3D meshes. LATO represents a mesh as a Vertex Displacement Field (VDF) anchored on surface, incorporating a sparse voxel Variational Autoencoder (VAE) to compress this explicit signal into a structured, topology-aware voxel latent. To decapsulate the mesh, the VAE decoder progressively subdivides and prunes latent voxels to instantiate precise vertex locations. In the end, a dedicated connection head queries the voxel latent to predict edge connectivity between vertex pairs directly, allowing mesh topology to be recovered without isosurface extraction or heuristic meshing.
For generative modeling, LATO adopts a two-stage flow matching process, first synthesizing the structure voxels and subsequently refining the voxel-wise topology features. Compared to prior isosurface/triangle-based diffusion models and autoregressive generation approaches, LATO generates meshes with complex geometry, well-formed topology while being highly efficient in inference.

Preference-based Antibody Expression Ranking: Scaling with Large-scale Weak Supervision
Josh Qixuan Sun, Morteza Babaie, Wenyang hou, Mark Crowley, David Young
Antibody expression ranking is a critical task in antibody design, yet its modeling is severely hindered by the scarcity of labeled experimental data. To address this, we propose a unified preference-based learning framework that integrates scarce quantitative expression data with large-scale weak positive supervision from immunization data. We adapt Direct Preference Optimization (DPO) to protein language models by introducing a union-masked log-likelihood approximation and IMGT-based alignment, enabling efficient training on variable-length sequences. Evaluating on a diverse internal dataset of 1254 labeled sequences and 4 million unlabeled camelid-derived antibodies, we show that our method consistently outperforms baselines on most metrics. Our results demonstrate that preference learning can effectively learn from weak supervision, providing a scalable solution for antibody expressibility optimization in data-constrained settings. Project page: https://kisoji-biotechnology-inc.github.io/Preference-Expression-Ranking/.

Counterfactual Residual Data Augmentation for Regression
Hossein Mohebbi, Oliver Schulte, Ke Li, Pascal Poupart
Data-driven modeling in real-world regression tasks often suffers from limited training samples, high collection costs, and noisy observations. Inspired by the impact of data augmentation in vision and language, we propose a novel Counterfa

ctual Residual Data Augmentation (CRDA) technique for tabular regression. Our ke y insight is that once a regressor has modeled the systematic component of the d ata, the remaining noise can be viewed as an invariant residual that remains sta ble under small perturbations of carefully selected features. We exploit this re sidual invariance to generate new, yet realistic, training samples, effectively expanding the dataset without requiring additional real data. Our method is mode l-agnostic and readily applicable to various types of regressors. In experiments across datasets from a variety of benchmark repositories, on average, CRDA redu ces an MLP Regressor's MSE by 22.9% and an XGBoost Regressor's MSE by 6.4%. When compared to existing state-of-the-art data generators and augmentation techniqu es, CRDA consistently outperforms in MSE reduction. By adding principled counter factual variations to the training data, our method offers a simple and efficien t remedy for noise-prone, small-sample regression settings.

UFO: Chain-of-Evaluation for Omni-Condition Alignment in Multi-Modal Image Gener ation

Danning Zhang, Yijing Lin, Shuhan Zhuang, Mengqi Huang, Shaojin Wu, Shancheng Fa ng, Zhendong Mao

Multi-modal image generation, particularly subject-driven customization, has gar nered growing attention in recent years. Despite the rapid advancement of genera tive models, their evaluation remains largely lagging. Existing methods, whether embedding-based or Multi-modal Large Language Model (MLLM)-based, evaluate alig nment with each modal condition in isolation, which contradicts the simultaneous condition alignment objective of multi-modal image generation, leading to poor consistency with human judgments. To address this challenge, we propose \textbf{ UFO}, the first \textbf{U}ni\textbf{F}ied framework for \textbf{O}mni-condition alignment simultaneous evaluation. Specifically, UFO introduces a novel Atomized Chain-of-Evaluation paradigm, \emph{i.e.}, it first decomposes omni-condition a lignment into a sequential chain of fine-grained, disentangled Atomic Evaluation Units (AEUs), categorizes them into distinct modality-relevance classes, and th en employs general or dedicated functional calls for accurate verification of di fferent AEU types. Experimental results demonstrate that UFO achieves the highes t correlation with human evaluation preferences, delivering an average improveme nt of 15.25\%. Furthermore, we present UFO-Bench, a dedicated benchmark designed to holistically evaluate the performance of existing customization models under the diverse mutual interactions of textual and visual conditions.

Conf-Gen: Conformal Uncertainty Quantification for Generative Models

Gabriel Loaiza-Ganem, Kevin Zhang, Wei Cui, Marc T. Law, Kin Kwan Leung

Conformal prediction (CP) and its extension, conformal risk control (CRC), are e stablished frameworks for quantifying uncertainty in supervised machine learning through formal guarantees. However, recent breakthroughs in artificial intellig ence (AI) have been driven by unsupervised generative models, such as large lang uage models (LLMs) and image generators, which are not directly compatible with CP or CRC. In this work we introduce conformal generation (Conf-Gen), a general framework adapting CRC to generative tasks while relaxing its theoretical assump tions. Conf-Gen unifies and generalizes previous attempts to apply CP to LLMs, a nd extends conformal methodology to entirely new domains. We demonstrate the fle xibility of Conf-Gen through some novel applications, including obtaining confor mal guarantees on: image generators producing non-memorized images, conversation al AI systems having asked enough clarifying questions, and the output of AI age nts being correct.

Fast Byte Latent Transformer

Julie Kallini, Artidoro Pagnoni, Tomasz Limisiewicz, Gargi Ghosh, Luke Zettlemoy er, Christopher Potts, Xiaochuang Han, Srini Iyer

Recent byte-level language models (LMs) match the performance of token-level mod els without relying on subword vocabularies, yet their utility is limited by slo w, byte-by-byte autoregressive generation. We address this bottleneck in the Byt e Latent Transformer (BLT) through new training and generation techniques. First

, we introduce **BLT Diffusion (BLT-D)**, a new model and our fastest BLT varian t, trained with an auxiliary block-wise diffusion objective alongside the standa rd next-byte prediction loss. This enables an inference procedure that generates multiple bytes in parallel per decoding step, substantially reducing the number of forward passes required to generate a sequence. Second, we propose two exten sions inspired by speculative decoding that trade some of this speed for higher generation quality: **BLT Self-speculation (BLT-S)**, in which BLT's local decod er continues generating past its normal patch boundaries to draft bytes, which a re then verified with a single full-model forward pass; and **BLT Diffusion+Veri fication (BLT-DV)**, which augments BLT-D with an autoregressive verification st ep after diffusion-based generation. All methods may achieve an estimated memory -bandwidth cost over 50\% lower than BLT on generation tasks. Each approach offe rs its own unique advantages, together removing key barriers to the practical us e of byte-level LMs.

On the Generalization Gap in Self-Evolving Language Model Reasoning

Zhenting Qi, Susanna Maria Baby, Stefanie Anna Baby, Kan Yuan, Andrew Tomkins, T u Vu, Da-Cheng Juan, Cyrus Rashtchian

Recent work suggests that large language models (LLMs) can improve through self- evolution (SE), using supervision signals generated by the model itself. In this work, we ask: under a strict closed-loop setup, where the SE algorithm has acce ss only to an unlabeled prompt set and a base model, how close can internally ge nerated supervision come to oracle-supervised training? We analyze four represen tative strategies in a unified offline self-evolution framework, including singl e-round verification, multi-turn revision with feedback, iterative training, and curriculum learning. Our primary experiments use Knights and Knaves (KK) logica l reasoning tasks, which provide deterministic solutions, controlled difficulty levels, and a clean testbed for easy-to-hard generalization. We first show that SE consistently improves over the base model, but plateaus after excessive train ing compute is invested, and eventually still leaves a non trivial gap to oracle supervision. We find that multi-turn critic-revision with large models could re ach strong self-evolution performance, where Gemma 12B nearly matches oracle-sup ervised training. Beyond KK, we also evaluate SE on real-world reasoning benchma rks, where gains are also modest. Overall, our results characterize when closed- loop SE can help, and show how internally generated supervision remains insuffic ient under this minimal formulation.

AlgoVeri: An Aligned Benchmark for Verified Code Generation on Classical Algorit hms

Haoyu Zhao, Ziran Yang, Jiawei Li, Mike He, Zenan Li, Chi Jin, Venugopal Veerava lli, Aarti Gupta, Sanjeev Arora

Vericoding refers to the generation of formally verified code from rigorous spec ifications. Recent AI models show promise in vericoding, but a unified methodolo gy for cross-paradigm evaluation is lacking. Existing benchmarks test only an in dividual language/tool (e.g., Dafny, Verus, and Lean) and each covers very diffe rent tasks, so the performance numbers are not directly comparable. We address t his gap with AlgoVeri, a benchmark that evaluates vericoding of 77 classical a lgorithms in each of Dafny, Verus, and Lean. By enforcing identical functional c ontracts, AlgoVeri reveals critical capability gaps in current models. While fro ntier models achieve tractable success in Dafny (40.3\% for Gemini-3 Flash), w here high-level abstractions and SMT automation simplify the workflow, performan ce collapses under the systems-level memory constraints of Verus (24.7\%) and the explicit proof construction required by Lean (7.8\%). Beyond aggregate met rics, we uncover a sharp divergence in test-time compute dynamics: Gemini-3 effe ctively utilizes iterative repair to boost performance (e.g., tripling pass rate s in Dafny), whereas GPT-OSS saturates early. Finally, our error analysis shows that language design affects the refinement trajectory: while Dafny allows model s to focus on logical correctness, Verus and Lean trap models in persistent synt actic and semantic barriers.

Noise-corrected GRPO: From Noisy Rewards to Unbiased Gradients
Omar El mansouri, Fathinah Asma Izzati, Mohamed El Amine Seddik, Salem Lahlou
Reinforcement learning from human feedback (RLHF) or verifiable rewards (RLVR), the standard paradigm for aligning LLMs or building recent SOTA reasoning models , is highly sensitive to noise from inconsistent or erroneous rewards. Yet, the interaction between such noise and widely used group-based policy optimization m ethods remains underexplored. We introduce a noise-robust Group Relative Policy Optimization (GRPO) and Done Right GRPO (Dr.GRPO) framework that explicitly mode ls reward corruption as Bernoulli noise. Our method applies noise correction aft er estimating reward flip probabilities to debias the learning signal, yielding unbiased gradient estimates. Theoretical analysis shows that group-based methods inherently mitigate individual-level noise, and our correction strategy amplifi es this robustness. Empirically, we observe consistent improvements across math and code tasks when applying our noise correction to standard reward model usage , with particular gains of up to 6.7 percentage points in accuracy on math tasks and 1.5 on code tasks under realistic reward model conditions. This work bridge s label-noise correction from supervised learning with modern RLHF, offering bot h theoretical insights and a practical algorithm for noisy real-world deployment .

SSA: Sparse Sparse Attention by Aligning Full and Sparse Attention Outputs in Fe ature Space
Zhenyi Shen, Junru Lu, Lin Gui, Jiazheng Li, Yulan He, di yin, Xing Sun
Sparse attention reduces the quadratic complexity of full self-attention but fac es two challenges: (1) an attention gap, where applying sparse attention to full -attention-trained models causes performance degradation due to train-inference distribution mismatch, and (2) a capability gap, where models trained purely wit h sparse attention lack complete gradient flow, preventing them from matching fu ll-attention performance. We propose SSA (Sparse Sparse Attention), a training f ramework that integrates both sparse and full attention with bidirectional atten tion-output alignment. We prove that the approximation error scales linearly wit h the attention mass dropped under sparse attention, and show that SSA's alignme nt objective substantially reduces this quantity compared to baselines. Experime nts demonstrate that SSA achieves state-of-the-art performance under both infere nce modes, adapts smoothly to varying sparsity budgets, and demonstrates superio r long-context capabilities. Code is available at https://github.com/zhenyi4/ssa .

No More, No Less: Least-Privilege Language Models
Paulius Rauba, Dominykas Seputis, Patrikas Vanagas, Mihaela van der Schaar
Least privilege is a core security principle: grant each request only the minimu m access needed to achieve its goal.
Deployed language models almost never follow it, instead being exposed through a single API endpoint that serves all users and requests.
This gap exists not because least privilege would be unhelpful—deployments would benefit greatly from reducing unnecessary capability exposure.
The real obstacle is definitional and mechanistic: what does "access" mean insid e a language model, and how can we enforce it without retraining or deploying mu ltiple models?
We take inspiration from least privilege in computer systems and define a class of models called *least-privilege language models*, where privilege is *reachabl e internal computation* during the forward pass.
In this view, lowering privilege literally shrinks the model's accessible functi on class (as opposed to denying access via learned policies).
We formalize deployment-time control as a monitor--allocator--enforcer stack, se parating (i) request-time signals, (ii) a decision rule that allocates privilege , and (iii) an inference-time mechanism that selects privilege.
We then propose *Nested Least-Privilege Networks*, a shape-preserving, rank-inde xed intervention that provides a smooth, reversible control knob.
We show that this knob yields policy-usable privilege--utility frontiers and ena

bles selective suppression of targeted capabilities with limited collateral degr
adation across various policies.
Most importantly, we see this as a defense of a completely new deployment paradi
gm which challenges the premise that we can only have output-level control of la
nguage models.

Are Large Reasoning Models Interruptible?
Tsung-Han Wu, Mihran Miroyan, David M. Chan, Trevor Darrell, Narges Norouzi, Jos
eph E. Gonzalez
Real-world applications of Large Reasoning Models (LRMs) often require reasoning
 about changing prompts or environments. In this work, we challenge the frozen w
orld assumption and evaluate LRM robustness under two realistic dynamic scenario
s: interruptions, which test the accuracy of model responses under budget-constr
ained outputs, and dynamic context, which tests model adaptation to in-flight ch
anges. Across mathematics and programming benchmarks that require long-form reas
oning, static evaluations consistently overestimate robustness: even state-of-th
e-art LRMs, which achieve high accuracy in static settings, can fail unpredictab
ly when interrupted or exposed to changing context, with performance dropping by
 up to 60\% when updates are introduced late in the reasoning process. Our analy
sis further reveals several novel failure modes, including reasoning leakage, wh
ere models fold the reasoning into their final answer when interrupted; panic, w
here under time pressure models abandon reasoning entirely and return incorrect
answers; and self-doubt, where performance degrades when trying to incorporate u
pdated information. The project page is at https://dynamic-lm.github.io

G^{2}TAM: Geometry Grounded Track Anything Model
Chenming Zhu, Peizhou Cao, Jingli Lin, Wenbo Hu, Yunlong Ran, Jiangmiao Pang, Ta
i Wang, Xihui Liu
Human spatial understanding arises from jointly perceiving geometry and semantic
s, enabling consistent object identification and localization across viewpoints
and time. Current video segmentation models depend on explicit object appearance
 memory banks for instance tracking, yet they remain vulnerable to large viewpoi
nt changes and long-term occlusions. Leveraging the spatial consistency afforded
 by modern feed-forward 3D reconstruction models, we propose the Geometry Ground
ed Tracking Anything Model (G^{2}TAM), a unified framework for promptable instan
ce tracking in 3D using only unordered RGB images or videos. G^{2}TAM employs sp
atially aligned geometric representations as implicit memory, ensuring stable in
stance identity and localization across frames and views. At its core is a cross
-modal spatial encoder that integrates visual and textual prompts into a shared
geometric space, enabling end-to-end spatial reconstruction and instance-consist
ent mask prediction. To support training and evaluation, we construct InsTrack,
a large-scale dataset with a dedicated validation split for benchmarking. Extens
ive experiments show that G^{2}TAM delivers strong cross-view consistency, promp
table instance spatial tracking, video object segmentation, and spatial reconstr
uction, establishing a foundation for interactive, geometry-grounded spatial rea
soning.
****
OptProver: Bridging Olympiad and Optimization through Continual Training in Form
al Theorem Proving
Chenyi Li, Yanchen Nie, Zhenyu Ming, Gong Zhang, Kun Yuan, Zaiwen Wen
Recent advances in formal theorem proving have focused on Olympiad-level mathema
tics, leaving undergraduate domains largely unexplored. Optimization, fundamenta
l to machine learning, operations research, and scientific computing, remains un
derserved by existing provers. Its reliance on domain-specific formalisms (conve
xity, optimality conditions, and algorithmic analysis) creates significant distr
ibution shift, making naive domain transfer ineffective. We present OptProver, a
 trained model that achieves robust transfer from Olympiad to undergraduate opti
mization. Starting from a strong Olympiad-level prover, our pipeline mitigates d
istribution shift through two key innovations. First, we employ large-scale opti
mization-focused data curation via expert iteration. Second, we introduce a spec

ialized preference learning objective that integrates perplexity-weighted optimi
zation with a mechanism to penalize valid but non-progressing proof steps. This
not only addresses distribution shifts but also guides the search toward efficie
nt trajectories. To enable rigorous evaluation, we construct a novel benchmark i
n Lean 4 focused on optimization. On this benchmark, OptProver achieves state-of
-the-art Pass@1 and Pass@32 among comparably sized models while maintaining comp
etitive performance on general theorem-proving tasks, demonstrating effective do
main transfer without catastrophic forgetting.

OOVDet: Low-Density Prior Learning for Zero-Shot Out-of-Vocabulary Object Detect
ion
Binyi Su, chenghao huang, Haiyong Chen
Zero-shot out-of-vocabulary detection (ZS-OOVD) aims to accurately recognize obj
ects of in-vocabulary (IV) categories provided at zero-shot inference, while sim
ultaneously rejecting undefined ones (out-of-vocabulary, OOV) that lack correspo
nding category prompts.
However, previous methods tend to overfit IV classes, resulting in undefined OOV
 objects being confidently misclassified as semantically similar IV categories.
To mitigate this issue, this paper proposes a zero-shot OOV detector (OOVDet), a
 novel framework that effectively detects predefined classes while reliably reje
cting undefined ones in zero-shot scenes. Specifically, due to the model’s lack
of prior knowledge about the distribution of OOV data, we synthesize region-leve
l OOV prompts by sampling from the low-likelihood regions of the class-condition
al Gaussian distributions in the hidden space, motivated by the assumption that
unknown semantics are more likely to emerge in low-density areas of the latent s
pace. For OOV images, we further propose a Dirichlet-based gradient attribution
mechanism to mine pseudo-OOV image samples, where the attribution gradients are
interpreted as Dirichlet evidence to estimate prediction uncertainty, and sample
s with high uncertainty are selected as pseudo-OOV images. Building on these syn
thesized OOV prompts and pseudo-OOV images, we construct the OOV decision bounda
ry through a low-density prior constraint, which regularizes the optimization o
f OOV classes using Gaussian kernel density estimation in accordance with the ab
ove assumption.
 Experimental results show that our method significantly improves the OOV detect
ion performance in zero-shot scenes. The code is available at \url{https://githu
b.com/binyisu/OOVDet}.

Episodic Memory-Guided Controllable Experience Synthesis for Reinforcement Learn
ing
Xiao Ma, Tian Li, Wu-Jun Li
In real-world scenarios, data collection for reinforcement learning (RL) is ofte
n constrained by safety concerns and high costs, resulting in limited data avail
ability. Diffusion models (DMs) have recently demonstrated remarkable capabiliti
es in capturing complex distributions, making data augmentation a promising appr
oach. However, existing DM-based data augmentation methods still suffer from the
 limited quality of synthesized data for downstream RL tasks. To overcome this l
imitation, we propose a novel method called episodic memory-guided controllable
experience synthesizer (EMCES). EMCES incorporates an episodic memory-based cont
rollable DM with informative yet concise conditions constructed by episodic memo
ry (EM). To guide the synthesis toward high-quality data, we propose an EM-prior
itized condition sampling strategy that leverages EM-based temporal-difference e
rrors to focus generation on data most helpful for RL. Furthermore, we introduce
 a hashing-based state representation for EM to improve its efficiency and furth
er boost the quality of synthetic data. To the best of our knowledge, EMCES is t
he first work to incorporate EM into controllable DMs and to leverage EM for gui
ding data synthesis in RL. Experimental results across multiple environments dem
onstrate that EMCES significantly improves the quality of the synthetic data, th
ereby improving the performance of several state-of-the-art RL algorithms. In pa
rticular, the hashing-based state representation can reduce storage cost by abou
t 8000-fold and reduce time cost by 25.5-fold, without degrading the normalized

score.
****
Q-SAM: Unlocking Sharpness-Aware Minimization for Generalization in Offline Rein forcement Learning
Da Wang, Yi Ma, Ting Guo, Lin Li, Wei Wei, Jiye Liang
Generalization remains a central challenge in offline reinforcement learning (RL), where policies are trained solely from static datasets and must perform relia bly under distribution shift. While most existing offline RL methods focus on re ducing training loss using standard optimizers such as Adam, the role of loss la ndscape geometry $-$ particularly sharpness $-$ has received little attention. S harpness-Aware Minimization (SAM) has recently shown strong generalization benef its in supervised learning by favoring flatter minima. However, directly applyin g SAM to offline RL is non-trivial: unlike supervised settings with ground-truth labels, offline RL relies on bootstrapped targets, making sharpness estimation noisy and often destabilizing optimization. In this paper, we revisit offline RL from an optimization perspective and investigate how sharpness-aware optimizati on can be made effective in this setting. We propose Q bound weighted SAM (Q-SAM), a robust and scalable framework that treats sharpness as a weighted objective and selectively prioritizes samples that are most suitable for sharpness-aware optimization based on Q bounds. By aligning the SAM objective with the character istics of bootstrapped value estimation, Q-SAM amplifies the benefits of sharpne ss minimization while preserving training stability. Extensive experiments on st andard offline RL benchmarks demonstrate that Q-SAM consistently improves genera lization performance across diverse datasets and algorithms. Our results highlig ht the importance of loss sharpness in offline RL and suggest optimizer design a s a promising direction for developing more robust offline RL methods.

Toward Identifiable Sparse Autoencoders
Walter Nelson, Theofanis Karaletsos, Francesco Locatello
Recently, sparse autoencoders (SAEs) have emerged as an attractive tool for inte rpreting and interacting with representations in practical neural networks. Whil e it is common empirical folklore, we also show theoretically that SAEs are high ly unstable: different training runs are likely to produce different concept dic tionaries and sparse codes. We characterize the model properties that hinder the stability of real-world SAEs, and address each of these problems through minima l changes to the architecture and training procedure. Together, these changes yi eld two versions of an **i**dentifiable SAE (iSAE), a variant of the standard To pK SAE with lower reconstruction error and improved stability. We explain this i mprovement theoretically by connecting SAEs with traditional dictionary learning approaches, and show that the dictionaries learned in practice satisfy an appro ximate restricted isometry condition, rendering the corresponding sparse codes i n those models near-identifiable.
****

Quantifying the noise sensitivity of the Wasserstein metric for images
Erik Lager, Gilles Mordant, Amit Moscovich
Wasserstein metrics are increasingly adopted as similarity scores for images. We consider the sensitivity of Wasserstein metrics with respect to pixel-wise addi tive noise when the images are treated as discrete measures on the pixel grid. W e derive finite-sample expectation bounds for a Gaussian noise model. Among othe r results, we prove that the error in the signed 2-Wasserstein distance scales w ith the square root of the noise standard deviation. This is favorable compared to the Euclidean metric that scales linearly, and thus provides a theoretical ba sis for the benefits of optimal transport distances in noisy settings. We presen t experiments that support our theoretical findings and point to a peculiar phen omenon where increasing the level of noise can decrease the Wasserstein distance .
A case study on cryo-electron microscopy images demonstrates that the Wasserstei n metric can capture the geometry of the data manifold in high noise settings ev en when the Euclidean metric fails.

Hermes: An Evidence-Driven Agentic Framework for Trustworthy and Explainable AI-Generated Video Detection
Shuaibo Li, Pengfei HAO, Hongtao Wu, Jianfeng Dong, Ping Li, Xiaohong Liu, Lei Z hu
Recent advances in generative video models have blurred the boundary between rea l and synthetic content, raising urgent concerns about digital authenticity. Mul timodal large language models (MLLMs) are appealing for AI-generated video (AIGV) detection due to their broad perceptual and reasoning capabilities; however, e xisting MLLM-based detectors still suffer from hallucination and unstable reason ing, leading to high false-alarm rates and generic, non-verifiable explanations. To address these issues, we propose Hermes, an evidence-driven agentic framework for trustworthy and explainable AIGV detection. Hermes realizes three key capab ilities: (1) Adaptive Instance-Conditioned Detection Strategy Planning, (2) Evid ence-Centric Reasoning and Verification, and (3) Graph-Grounded Evidence Deliber ation. Specifically, Hermes uses instance-conditioned retrieval-augmented genera tion to analyze each video and retrieve authenticity-verification knowledge for composing a tailored detection strategy. It then constructs a verifiable Evidenc e Reasoning Graph (ERG) to keep reasoning grounded in concrete video evidence an d reduce attention drift. Finally, multi-agent deliberation audits and refines t he ERG to reconcile conflicting evidence and improve reliability.
With these capabilities and a library of forensic tools, Hermes enables structur ed, verifiable, and interpretable decision-making. Extensive experiments show th at Hermes achieves state-of-the-art performance while producing auditable explan ations for trustworthy video forensics.

On the Coordination of Value-Maximizing Bidders
Yanru Guan, Jiahao Zhang, Zhe Feng, Tao Lin
While the auto-bidding literature predominantly considers independent bidding, we investigate the coordination problem among multiple auto-bidders in online advertising platforms. Two motivating scenarios are: collaborative bidding among multiple bidders managed by a third-party bidding agent, and strategic bid selection for multiple ad campaigns managed by a single advertiser. We formalize this coordination problem as a theoretical model and investigate the coordination mechanism where only the highest-value bidder competes with outside bidders, while other coordinated bidders refrain from competing. We demonstrate that such a coordination mechanism dominates independent bidding, improving both Return-on-Spend (RoS) compliance and the total value accrued for the participating auto-bidders or ad campaigns, for a broad class of auto-bidding algorithms. Additionally, our simulations on synthetic and real-world datasets support the theoretical result that coordination outperforms independent bidding. These findings highlight both the theoretical potential and the practical robustness of coordinated auto-bidding in online auctions.
****
LiMuon: Light and Fast Muon Optimizer for Large Models
Feihu Huang, Yuning Luo, Songcan Chen
Large models recently are widely applied in machine learning, so efficient training of large models has received widespread attention. More recently, the useful Muon optimizer is specifically designed for matrix-structured parameters of large models. Although some works have begun to study the Muon optimizer, the existing Muon and its variants still suffer from high sample complexity or high memory for large models. To fill this gap, we propose a light and fast Muon (LiMuon) optimizer for training large models, which builds on the momentum-based variance reduced technique and randomized Singular Value Decomposition (SVD). In particular, our LiMuon simultaneously has a lower memory and lower sample complexity than the Muon and its variants. Moreover, we prove that our LiMuon with lower memory has a lower sample complexity of $O(\epsilon^{-3})$ for finding an ϵ-stationary solution of non-convex stochastic optimization under the generalized smoothness condition. To further narrow practice and theory gap, we also prove that our LiMuon with Newton-Schulz steps has a lower sample complexity than the Muon with Newton-Schulz steps. Numerical experimental results on training Mamba-130M, Qwen2.5-0.5B and ViT models demonstrate effectiveness of our LiMuon.

Unbiased Reward Modeling from Implicit Feedback for LLM Alignment
Hao Wang, Haocheng Yang, Licheng Pan, Zhichao Chen, Xiaoxi Li, Yinuo Wang, Lei Shen, Yuan Lu, Haoxuan Li, Zhouchen Lin
Despite the success of reinforcement learning from human feedback (RLHF), existing reward modeling methods largely rely on explicit feedback, which is costly to collect and difficult to scale. This work studies implicit reward modeling, learning reward models from implicit user feedback, such as clicks, copies and skips. While scalable and cost-effective, implicit feedback poses two key challenges: (1) It lacks definitive negative samples, which makes standard positive-negative classification methods inapplicable; (2) It suffers from selection bias, where responses have heterogeneous propensities to elicit feedback, which further obscures definitive negative samples. To address these challenges, we propose ImplicitRM, which learns unbiased reward models from implicit feedback. It stratifies training samples into four latent groups using a stratification model and derives a likelihood-maximization objective that is theoretically unbiased, thereby addressing both challenges. Experiments across diverse LLM backbones and benchmark datasets validate that ImplicitRM learns accurate reward models from implicit feedback and improves performance on downstream RLHF tasks.

SGMD: Score Gradient Matching Distillation for Few-Step Video Diffusion Distillation
Zhuguanyu Wu, Ruihao Gong, Yang Yong, Yushi Huang, Xiangyu Fan, Lei Yang, Dahua

Lin, Xianglong Liu
Distribution Matching Distillation (DMD) is a widely used paradigm for accelerating inference in few-step video diffusion models. However, DMD-style training faces a structural bottleneck: the student-side auxiliary score network (the fake score) must closely track a continuously evolving generator. Updating the fake score too frequently increases training cost and can over-emphasize inner-loop tracking, while infrequent updates lead to tracking lag that destabilizes training and degrades generation consistency. To address this issue, we propose \textbf{Score Gradient Matching Distillation (SGMD)}. SGMD adopts a fake-score perspective by directly optimizing the fake score toward the teacher, while using teacher stop-gradient Fisher as a stable distribution-matching objective. We provide a gradient analysis that motivates this objective choice under ideal tracking. Building on this, SGMD introduces a pair of dual potentials: negative-residual (NR) for outer-loop correction and residual-contraction (RC) for inner-loop tracking. Empirically, compared to DMD, SGMD achieves an approximately $\sim 3\times$ training speedup and substantially improves motion dynamics for 4-step distilled models while preserving temporal consistency.

BEAR: Dissecting Embodied Abilities in Multimodal Language Models through Skill-level Evaluation and Diagnosis
Yu Qi, Haibo Zhao, Ziyu Guo, Siyuan Ma, Ziyan Chen, Yaokun Han, Renrui Zhang, Zitiantao Lin, Yizhe Zhu, Shiji Xin, Yijian Huang, Boce Hu, Kai Cheng, Jiayi Zhang, Peiheng Wang, jiazheng liu, Wenqing Wang, Yiran Qin, Haojie Huang, Lawson L.S. Wong
Understanding the capability bottlenecks of embodied multimodal large language models (MLLMs) is crucial for improvement. However, existing embodied benchmarks fail to provide actionable insights because they focus on task-level evaluation rather than discovering capability bottlenecks. To address this, we introduce BEAR, where we divide embodied tasks into 14 atomic skills for skill-level evaluation. BEAR comprises 4,469 interleaved image–video–text entries across 14 skills in 6 categories, ranging from low-level perception to high-level planning. We evaluate 20 MLLMs on BEAR under a hierarchical skill-level diagnosis framework and discover that (1) perceptual capabilities are major bottlenecks behind reasoning failures, and (2) models fail due to unstable spatiotemporal modeling which remain unexposed in previous benchmarks. Furthermore, building on these insights, we propose BEAR-Agent, a multimodal conversable agent that augments MLLMs with visual and spatial tools. It substantially enhances MLLMs’ performance across skills, yielding a relative improvement of 17.5% on GPT-5 on BEAR and outperform baselines by a large margin in both simulation and real-robot experiments across models. We provide our project website at https://bear-official66.github.io/.

Excited Pfaffians: Generalized Neural Wave Functions Across Structure and State
Nicholas Gao, Till Grutschus, Frank Noe, Stephan Günnemann
Neural-network wave functions in Variational Monte Carlo (VMC) have achieved great success in accurately representing both ground and excited states. However, achieving sufficient numerical accuracy in state overlaps requires increasing the number of Monte Carlo samples, and consequently the computational cost, with the number of states. We present a nearly constant sample-size approach, Multi-State Importance Sampling (MSIS), that leverages samples from all states to estimate pairwise overlap. To efficiently evaluate all states for all samples, we introduce Excited Pfaffians. Inspired by Hartree-Fock, this architecture represents many states within a single neural network. Excited Pfaffians also serve as generalized wave functions, allowing a single model to represent multi-state potential energy surfaces. On the carbon dimer, we match the $\mathcal{O}(N_s^4)$-scaling natural excited states while training $>200\times$ faster and modeling 50\% more states. Our favorable scaling enables us to be the first to use neural networks to find all distinct energy levels of the beryllium atom. Finally, we demonstrate that a single wave function can represent excited states across various molecules.

CADFit: Precise Mesh-to-CAD Program Generation with Hybrid Optimization
Ghadi Nehme, Eamon Whalen, Faez Ahmed
Despite recent progress, recovering parametric CAD construction sequences from g eometric input, such as meshes or point clouds, is a key challenge for design an d manufacturing, as existing CAD reconstruction and generation methods are large ly restricted to difficult-to-edit formats like meshes or Breps or editable simp le sketch-and-extrude pipelines and low-complexity datasets. We introduce CADFit , a hybrid optimization-based CAD reconstruction framework that recovers complex , editable CAD construction sequences from meshes by incrementally fitting and v alidating parametric operations using geometric feedback. Our approach is distin guished by formulating reconstruction as an IoU-driven optimization over structu red CAD programs and supporting a rich set of operations, including extrusions, revolutions, fillets, and chamfers. Experiments on multiple CAD benchmarks show that CADFit outperforms state-of-the-art mesh-to-CAD methods in volumetric Inter section-over-Union and Chamfer Distance, while substantially reducing the Invali d Ratio of reconstructed CAD programs, particularly for complex designs. We furt her present a multimodal pipeline that enables end-to-end reconstruction of CAD construction sequences from images by combining image-based geometry reconstruct ion with CADFit. By enabling accurate reconstruction of higher-complexity CAD mo dels, CADFit provides a practical foundation for generating richer datasets and advancing future learning-based approaches to CAD reverse engineering. The code is available at: https://github.com/ghadinehme/CADFit.

Efficient Learning of Deep State Space Models via Importance Smoothing
John-Joseph Brady, Nikolas Nüsken, Yunpeng Li
Latent state space systems are ubiquitous in statistical modelling, arising natu rally when time series are observed through noisy measurements. However, trainin g deep state space models (DSSMs) at scale remains difficult. Two largely distin ct strategies have emerged for training DSSMs. The first, auto-encoding DSSMs, t rains generative models by optimising a variational lower bound. The second back propagates through the outputs of classical sequential Monte Carlo (SMC) algorit hms. Such approaches can train DSSMs for both discriminative and generative task s, but their inherently sequential forward passes scale poorly on modern hardwar e. We propose \emph{parallel variational Monte Carlo} (PVMC), a new training met hod that bridges these paradigms and robustly trains DSSMs for both discriminati ve and generative tasks. Across a set of benchmark experiments, PVMC matches or exceeds state-of-the-art performance while training $10\times$ faster than the f astest competing SMC-based approach.

PSG-Nav: Probabilistic Scene Graph Navigation via Multiverse Decision Making
Rufeng Chen, Yue Chang, Xiaqiang Tang, Hechang Chen, Sihong Xie
Open-vocabulary navigation requires embodied agents to manage significant percep tion uncertainty stemming from semantic ambiguity and model errors.

However, most existing works settle for local optimal deterministic approach es, depriving complex navigation decision-making over multiple composite possibi lities that are critical for globally better solutions.

In this paper, we propose Probabilistic Scene Graph Navigation (PSG-Nav), wh ich constructs a 3D Probabilistic Scene Graph that uses full semantic categorica l distributions to account for perception uncertainty.

To efficiently use the local distributions to compose and reason about the o ptimal navigation landmarks, we propose Multiverse Decision to sample multiple m ost likely world settings from the joint distribution, and evaluate navigation l andmarks based on the compatibility between landmarks and multiverses.

To mitigate false positives due to epistemic uncertainty in open-vocabulary navigation, we introduce the Evidential Experience Calibrator, which enables onl ine lifelong adaptation by cross-validating detections against memories of past successes and failures.

Extensive experiments on widely-used benchmarks MP3D, HM3D, and HSSD demonst rate that PSG-Nav establishes new state-of-the-art results, achieving Success Ra tes of 66.1%, 44.8%, and 67.9%, respectively.

Code is available at: https://psg-nav.github.io

Trading Complexity for Expressivity Through Structured Generalized Linear Token Mixing
Erwan Fagnou, Paul Caillon, Blaise Delattre, Alexandre Allauzen
Token mixing layers play a key role in how language models can learn and generate long-range dependencies. Their efficiency relies on the necessary trade-off between decoding speed and the memory requirements, along with the cache size. Considering causal generation, this paper explores new trade-offs thanks to a unified framework which separates two crucial features: (i) the direct influence of inputs on outputs in one generation step; (ii) the recurrent propagation of information through past outputs.

This framework encompasses major architectures such as attention and state-space models, but also generalizes the recurrence equations by allowing each state to depend on multiple past states rather than only the immediate predecessor. By introducing structure, we design new recurrence patterns that provably achieve the desired complexity, while providing theoretical insights on their expressivity -- trading runtime for expressivity in a principled way. Empirical validation is performed on synthetic tasks, along with language modeling. Together, these results provide a unified toolkit for the understanding and design of efficient and expressive token mixers across model families.
****
MineDraft: A Framework for Batch Parallel Speculative Decoding
Zhenwei Tang, Arun Verma, Zijian Zhou, Zhaoxuan Wu, Alok Prakash, Daniela Rus, Bryan Kian Hsiang Low
Speculative decoding (SD) accelerates large language model inference by using a smaller draft model to propose draft tokens that are subsequently verified by a larger target model. However, the performance of standard SD is often limited by the strictly sequential execution of these drafting and verification stages. To address this, this paper proposes MineDraft, a batch parallel speculative decoding (PSD) framework designed to effectively hide drafting latency by overlapping it with verification. Our theoretical analysis shows that PSD is substantially more efficient than standard SD. MineDraft realizes the PSD through a novel batch-parallel design that maintains two batches of requests, overlapping drafting for one batch with verification for the other. Our experimental results show significant improvements of MineDraft in both throughput (up to 75%) and end-to-end latency (up to 39%) over standard SD. Furthermore, we have implemented MineDraft as a plugin for vLLM, demonstrating its practicality for production-ready inference systems. The code is publicly available in the [MineDraft GitHub repository](https://github.com/electron-shaders/MineDraft).

Contrastive Weak-to-Strong Generalization
Houcheng Jiang, Junfeng Fang, Jiaxin Wu, Tianyu Zhang, Chen Gao, Xiang Wang, Xiangnan He, Yang Deng
Weak-to-strong generalization provides a promising paradigm for scaling large language models (LLMs) by training stronger models on samples from aligned weaker ones, without requiring human feedback or explicit reward modeling. However, its robustness and generalization are hindered by the noise and biases in weak-model outputs, which limit its applicability in practice. To address this challenge, we leverage implicit rewards, which approximate explicit rewards through log-likelihood ratios, and reveal their structural equivalence with Contrastive Decoding (CD), a decoding strategy shown to reduce noise in LLM generation. Building on this connection, we propose \textbf{Contrastive Weak-to-Strong Generalization (ConG)}, a framework that employs contrastive decoding between pre- and post-alignment weak models to generate higher-quality samples. This approach enables mor

e reliable capability transfer, denoising, and improved robustness, substantiall y mitigating the limitations of traditional weak-to-strong methods. Empirical re sults across different model families confirm consistent improvements, demonstra ting the generality and effectiveness of ConG. Taken together, our findings high light the potential of ConG to advance weak-to-strong generalization and provide a promising pathway toward AGI. Our code is available at: \url{https://github.c om/jianghoucheng/ConG}

ADEPT: RL-Aligned Agentic Decoding of Emotion via Evidence Probing Tools — From Consensus Learning to Ambiguity-Driven Emotion Reasoning
Esther Sun, Bo-Hao Su, Abinay Reddy Naini, Shinji Watanabe, Carlos Busso
Speech Large Language Models (SLLMs) enable high-level emotion reasoning, but of ten produce ungrounded, text-biased judgments without verifiable acoustic eviden ce. In contrast, SSL encoders such as WavLM yield strong acoustic representation s yet remain opaque discriminative models that offer limited interpretability. T o bridge this gap, we introduce the Agentic Decoding of Emotion via Probing Tool s (ADEPT) framework, which reframes emotion recognition as a multi-turn inquiry process rather than a single-pass prediction. ADEPT transforms an SLLM into an a gent that maintains an evolving candidate set and adaptively invokes dedicated s emantic and acoustic probing tools within a structured pipeline of candidate gen eration, evidence collection, and adjudication. Crucially, ADEPT enables a parad igm shift from consensus learning to ambiguity-driven emotion reasoning. Since h uman affect exhibits complexity and co-occurrence of emotions, we leverage minor ity annotations as informative signals instead of discarding them as noise. Fina lly, we integrate Group Relative Policy Optimization (GRPO) with the Evidence Tr ust Gate to explicitly couple tool-usage behaviors with prediction quality and e nforce evidence-based reasoning. Experiments demonstrate that ADEPT improves in most cases the primary emotion accuracy while substantially improving minor emot ion characterization, producing explanations grounded in auditable evidence.
****
Once-for-All: Scalable Simultaneous Forecasting via Equilibrium State Estimation
Beinan Xu, Andy Song, Jiti Gao, Feng Liu
We introduce Equilibrium State Estimation (ESE), a novel paradigm for simultaneo us prediction, where multiple interacting systems require separate yet coordinat ed forecasts. Such scenarios often arise in real-world such as economics and hea lthcare modeling. Unlike existing approaches that predict one system at a time, ESE forecasts all systems in a single pass. It first estimates the equilibrium state across systems, then generates holistic forecasts based on the difference between the current state and the estimated equilibrium. Extensive experiments on synthetic and real-world datasets, including currency exchange and COVID-19 spread modeling, demonstrate that ESE is at least as accurate as state-of-the-ar t (SOTA) methods while being significantly faster. In addition, ESE integrates seamlessly with conventional predictors, combining their accuracy with its excep tional efficiency and delivering a 10–70× speedup. With linear-time complexity, ESE scales far better than SOTA methods as the number of systems increases. More over, it remains accurate under diverse perturbations, establishing ESE as a fas t, generalizable, robust, and scalable multi-prediction method.

Video-o3: Native Interleaved Clue Seeking for Long Video Multi-Hop Reasoning
Xiangyu Zeng, Zhiqiu Zhang, Yuhan Zhu, Xinhao Li, Zikang Wang, Changlian Ma, Qin gyu Zhang, Zizheng Huang, Kun Ouyang, Tianxiang Jiang, Ziang Yan, Yi Wang, Hongj ie Zhang, Yali Wang, Limin Wang
Existing multimodal large language models for long-video understanding predomina ntly rely on uniform sampling and single-turn inference, limiting their ability to identify sparse yet critical evidence amid extensive redundancy. We introduce Video-o3, a novel framework that supports iterative discovery of salient visual clues, fine-grained inspection of key segments, and adaptive termination once s ufficient evidence is acquired. Technically, we address two core challenges in i nterleaved tool invocation. First, to mitigate attention dispersion induced by t he heterogeneity of reasoning and tool-calling, we propose Task-Decoupled Attent

ion Masking, which isolates per-step concentration while preserving shared globa l context. Second, to control context length growth in multi-turn interactions, we introduce a Verifiable Trajectory-Guided Reward that balances exploration cov erage with reasoning efficiency. To support training at scale, we further develo p a data synthesis pipeline and construct Seeker-173K, comprising 173K high-qual ity tool-interaction trajectories for effective supervised and reinforcement lea rning. Extensive experiments show that Video-o3 substantially outperforms state- of-the-art methods, achieving 72.1% accuracy on MLVU and 46.5% on Video-Holmes. These results demonstrate Video-o3's strong multi-hop evidence-seeking and reaso ning capabilities, and validate the effectiveness of native tool invocation in l ong-video scenarios.

Skewness-Robust Causal Discovery in Location-Scale Noise Models
Daniel Klippert, Alexander Marx
To distinguish Markov equivalent graphs in causal discovery, it is necessary to restrict the structural causal model. A flexible class of models that is general and identifiable in most cases are location-scale noise models (LSNMs), in whic h the effect Y is modeled based on its causes $\boldsymbol{X}$ as $Y = f(\bold symbol{X}) + g(\boldsymbol{X})N$.
To facilitate the estimation of these models, a prominent assumption is that t he noise variable N follows a symmetric distribution.
We show that when N is a skewed random variable,
which is likely in real-world domains, such approaches drop in performance.
To address this limitation, we propose SkewD, a likelihood-based method for ca usal discovery under LSNMs
with skewed noise, employing a combination of heuristic search and expectation conditional maximization for parameter estimation. SkewD extends the usual norm al distribution framework to the skew-normal setting,
enabling reliable inference under symmetric and skewed noise. While our main f ocus is on bivariate cause-effect inference, we further showcase how SkewD can b e extended to the multivariate setting.

Measuring Agents in Production
Melissa Pan, Negar Arabzadeh, Riccardo Cogo, Yuxuan Zhu, Alexander Xiong, Lakshy a A Agrawal, Huanzhi Mao, Emma Shen, Sid Pallerla, Liana Patel, Shu Liu, Tiannen g Shi, Xiaoyuan Liu, Jared Quincy Davis, Emmanuele Lacavalla, Alessandro Basile, Shuyi Yang, Paul Castro, Daniel Kang, Koushik Sen, Dawn Song, Joseph E. Gonzale z, Ion Stoica, Matei Zaharia, Marquita Ellis
LLM-based agents already operate in production across many industries, yet we la ck an understanding of what technical methods make deployments successful.
We present the first systematic study of **M**easuring **A**gents in **P**roduct ion, MAP, using first-hand data from agent developers. We conducted 20 case stud ies via in-depth interviews and surveyed 86 deployed systems practitioners acros s 26 domains.
We investigate why organizations build agents, how they build them, how they eva luate them, and their top development challenges.
Our study finds that production agents are built using simple, controllable appr oaches:
68% execute at most 10 steps before human intervention, 70% rely on prompting of f-the-shelf models instead of weight tuning, and 74% depend primarily on human e valuation.
Reliability (consistent correct behavior over time) remains the top development challenge, which practitioners currently address through systems-level design.
MAP documents the current state of production agents, providing the research com munity with visibility into deployment realities and underexplored research aven ues.

Approximation Error Upper and Lower Bounds for Hölder Class with Transformers
Xin He, Yuling Jiao, Xiliang Lu, Jerry Zhijian Yang
We explore the expressive power of Transformers by establishing precise approxim

ation error upper and lower bounds for Hölder class. Specifically, a new approximation upper bound is derived for the standard Transformer architecture equipped with Softmax operators, ReLU activation functions, and residual connections. We prove that a Transformer network composed of at most $\mathcal{O}(\varepsilon^{-{d_{0}}/{\alpha}})$ blocks can approximate any bounded Hölder function with d_{0}-dimensional input and smoothness $\alpha\in(0,1]$ under any accuracy $\varepsilon>0$. In the case of approximation lower bounds, leveraging the VC-dimension upper bound, we are the first to rigorously prove that Transformers demand for at least $\Omega(\varepsilon^{-{d_{0}}/({4\alpha})})$ blocks to achieve the ε approximation accuracy. As a final step, we extend the derived results for standard Transformers to a general regression task and establish the corresponding excess risk rates demonstrating Transformers' empirical effectiveness in real-world settings.

Metric—Phase Fields: Decoupling Distance and Sign for Thin-Structure Reconstruction from Unoriented Point Clouds

Jiayi Kong, Xuhui Chen, Chen Zong, Fei Hou, Junhui Hou, Wenping Wang, Ying He

Neural Signed Distance Functions (SDFs) excel at reconstructing watertight manifolds but fail on thin structures and open boundaries due to strict inside—outside constraints. Conversely, Unsigned Distance Fields (UDFs) accommodate general geometries but suffer from gradient singularities at the zero-level set, hindering optimization and extraction.

We introduce Metric—Phase Fields (MPFs), a decoupled implicit representation that separates metric proximity from topological phase. Given an unoriented point cloud, MPFs learn (i) an unsigned metric field r and (ii) a smooth phase field θ, for which we derive a bounded phase indicator $P=\tanh(\beta\theta)$ that provides soft inside—outside cues where they are meaningful. We couple the two fields via a gated-metric formulation with a residual phase injection to obtain a signed implicit function with stable near-surface gradients. The phase coefficient β is learnable, allowing MPFs to adaptively control the sharpness of the phase transition and the degree of saturation of the soft sign indicator. Experiments on both synthetic and scanned thin-shell and thin-plate shapes demonstrate that MPFs preserve thin and layered structures more faithfully than recent SDF-based methods, while also enabling more robust training and more reliable surface extraction than UDF-based approaches. Check out [MPFs-GitHub](https://github.com/JIAYI-Scarlett/ICML2026-MPF) for source code and test models.

PINNfluence: Interpreting PINNs through Influence Functions

Aleksander Krasowski, Jonas Naujoks, Moritz Weckbecker, Galip Ümit Yolcu, Thomas Wiegand, Sebastian Lapuschkin, Wojciech Samek, René Pascal Klausen

Physics-informed neural networks (PINNs) have emerged as a powerful deep learning approach for solving partial differential equations (PDEs) in the physical sciences, yet their behavior remains largely opaque and is typically understood through failure mode analyses rather than explicit interpretability.

To address this issue, we introduce PINNfluence, a training data attribution framework for interpreting PINNs based on influence functions.

By extending influence functions to composite physics-informed training objectives, we enable fine-grained attribution between predictions, loss components, and training data points.

Through benchmark experiments across various PDEs, we demonstrate that influence patterns provide granular diagnostics that distinguish structural characteristics across well-trained and poorly-trained PINNs.

PINNfluence thus opens a new avenue for understanding and improving the reliability of PINNs through the lens of their data.

Optimizing Agentic Reasoning with Retrieval via Synthetic Semantic Information Gain Reward

Senkang Hu, Yong Dai, Yuzhi Zhao, Yihang Tao, Yu Guo, Zhengru Fang, Sam Kwong, Yuguang Fang

Agentic reasoning enables large reasoning models (LRMs) to dynamically acquire e

xternal knowledge, yet optimizing the retrieval process remains challenging due to the lack of dense, principled reward signals. In this paper, we introduce *InfoReasoner*, a unified framework that incentivizes effective information seeking via a *synthetic semantic information gain reward*. Theoretically, we redefine information gain as uncertainty reduction over the model's belief states, establishing key properties including non-negativity, telescoping additivity, and channel monotonicity. Practically, to enable scalable optimization without manual intermediate retrieval annotations, we instantiate this principle as a semantic information gain reward computed from the model's output distributions using *semantic clustering via bidirectional textual entailment*. This training reward provides dense credit for retrieval steps while remaining anchored to final-answer correctness, enabling efficient training via Group Relative Policy Optimization (GRPO). Experiments on seven question-answering benchmarks, MATH500, and WebDetective show consistent gains over strong retrieval-augmented baselines, supporting our dense semantic information gain as a practical training signal for agentic retrieval.

HDTree: Generative Modeling of Cellular Hierarchies for Robust Lineage Inference

Zelin Zang, WenZhe Li, Yongjie Xu, Chang Yu, Changxi Chi, Jingbo Zhou, Zhen Lei, Stan Z. Li

In single-cell research, tracing and analyzing high-throughput single-cell differentiation trajectories is crucial for understanding biological processes. Key to this is the robust modeling of hierarchical structures that govern cellular development. Traditional methods face limitations in computational cost, performance, and stability. VAE-based approaches have made strides but still require branch-specific network modules, limiting their scalability and stability, while often suffering from posterior collapse.To overcome these challenges, we introduce HDTree, a generative modeling framework designed for robust lineage inference. HDTree captures tree relationships within a hierarchical latent space using a unified hierarchical codebook and employs a quantized diffusion process to model continuous cell state transitions. By aligning the generative process with the Waddington landscape, this method not only improves stability and scalability but also enhances the biological plausibility of inferred lineages. HDTree's effectiveness is demonstrated through comparisons on both general-purpose and single-cell datasets, where it outperforms existing methods in lineage inference accuracy, reconstruction quality, and hierarchical consistency. These contributions enable accurate and efficient modeling of cellular differentiation paths, offering reliable insights for biological discovery.

****

Don't Force the Fit: Bounded Log-Likelihood Loss for Enhanced Reasoning in Large Language Models

Feng Zhao, Hong Zhang, Yu Yang, Ruilin Zhao, Guandong Xu

Supervised fine-tuning (SFT) is central to aligning large language models (LLMs) with instruction following and task-specific reasoning. Despite its success, SFT optimizes token-level likelihoods under the implicit assumption that strictly fitting all tokens in expert demonstrations induces the desired downstream behavior. However, in reasoning tasks where correctness is defined by logical validity or final outcomes rather than exact token realizations, this assumption can lead to optimization misalignment. We empirically observe that low-probability tokens in reasoning demonstrations often correspond to realization-specific or stylistic variations, and that reducing their influence during training consistently improves generalization on reasoning benchmarks. Motivated by this insight, we propose the *Bounded Log-Likelihood Loss* (BLL-Loss), a simple and parameter-free alternative to standard likelihood training that bounds gradient contributions from low-probability tokens while preserving conventional optimization behavior. We provide theoretical insights and extensive empirical results demonstrating that BLL-Loss improves reasoning generalization across diverse model scales and challenging benchmarks.

NeuroMamba: A Universal Spatiotemporal Module for Robust Perception in Degraded

Sensory Streams
Jinfeng Li, Huijia Song, Xiangyue Hu, HanLiang Zhou, Jiahui Zhang, Xinpeng Jiang, Fangli Guan, Bin Lin, Dingran Dong, Liqi Yan, Pan Li
In open-world intelligent systems, processing continuous sensory streams disrupted by heterogeneous degradation sources presents a fundamental challenge: reconciling the inherent tension between observational completeness and reconstruction fidelity. Methods that prioritize completeness by bridging long-term occlusions often introduce spurious artifacts, while approaches that focus on aggressive noise suppression inevitably disrupt temporal continuity and erase valid structures. To address this challenge, we propose NeuroMamba, a universal plug-and-play module that enhances spatiotemporal consistency in degraded streams. NeuroMamba tackles the dual objectives through two synergistic components. First, we introduce a regional Hybrid Spatiotemporal Rectification (HSR) module, which leverages Mamba-based inertial modeling of linear complexity to recover short-horizon temporal dependencies and infer missing modalities under partial observability. Second, we design a Spiking Confidence Gate (SCG) that enforces reconstruction fidelity under occupancy-guided supervision. Implemented as a hard-thresholding spiking gate unit based on leaky integrate-and-fire (LIF) neurons, SCG distinguishes valid geometric features from sensor noise based on accumulated temporal evidence. Extensive experiments on the nuScenes robustness benchmark demonstrate that NeuroMamba effectively reconciles the trade-off between completeness and fidelity, outperforming the performance of existing approaches in restoring high-fidelity spatiotemporal features from severely incomplete and degraded observations.
****
Causal Modeling of Selection in Evolution
Haoyue Dai, Zeyu Tang, Peter Spirtes, Kun Zhang
Understanding potential selection in data is crucial for causal discovery; we argue that "selection" in common narratives takes two forms, which we term _static_ and _evolutionary_ selection, respectively. Static selection refers to a one-shot filtering process where observed data consist of a _subset_ of the population of interest, as in survey volunteer bias. Evolutionary selection, in contrast, operates through repeated rounds of differential fitness in reproduction, where observed data constitute the latest _generation_ shaped by a historical trajectory, as in immune adaptation, antibiotic resistance, and social norm emergence. Existing methods largely conflate these two forms and rely on an identical graphical model of selection. We show that this model is valid for static settings but fails to characterize data under evolution, yielding false discovery results. To address this, we introduce a new model that specifically characterizes evolutionary selection, and develop a sound and complete procedure for identifying such models from data across one or multiple environments or generations. Experimental results validate the method's ability to uncover the relevant mechanisms underlying evolution from data.
****
When to Memorize and When to Stop: Gated Recurrent Memory for Long-Context Reasoning
Leheng Sheng, Zhang Yongtao, Wenchang Ma, Yaorui Shi, Ting Huang, Xiang Wang, An Zhang, Ke Shen, Tat-Seng Chua
While reasoning over long context is crucial for various real-world applications, it remains challenging for large language models (LLMs) as they suffer from performance degradation as the context length grows.
Recent work MemAgent has tried to tackle this by processing context chunk-by-chunk in an RNN-like loop and updating a textual memory for final answering.
However, this naive recurrent memory update faces two crucial drawbacks:
(i) memory can quickly explode because it can update indiscriminately, even on evidence-free chunks;
and (ii) the loop lacks an exit mechanism, leading to unnecessary computation after even sufficient evidence is collected.
To address these issues, we propose GRU-Mem, which incorporates two text-controlled gates for more stable and efficient long-context reasoning.
Specifically, in GRU-Mem, the memory only updates when the update gate is open a

nd the recurrent loop will exit immediately once the exit gate is open.
To endow the model with such capabilities, we introduce two reward signals r^{update} and r^{exit} within end-to-end RL, rewarding the correct updating and exiting behaviors respectively.
Experiments on various long-context reasoning tasks demonstrate the effectiveness and efficiency of GRU-Mem, which generally outperforms the vanilla MemAgent with up to 400\% times inference speed acceleration.

Neuromem: A Granular Decomposition of the Streaming Lifecycle in External Memory for LLMs
Ruicheng Zhang, Xinyi Li, Tianyi Xu, Shuhao Zhang, Xiaofei Liao, Hai Jin
Most evaluations of External Memory Module assume a static setting: memory is built offline and queried at a fixed state. In practice, memory is streaming: new facts arrive continuously, insertions interleave with retrievals, and the memory state evolves while the model is serving queries. In this regime, accuracy and cost are governed by the full memory lifecycle, which encompasses the ingestion, maintenance, retrieval, and integration of information into generation. We present Neuromem, a scalable testbed that benchmarks External Memory Module under an interleaved insertion-and-retrieval protocol and decomposes its lifecycle into five dimensions including memory data structure, normalization strategy, consolidation policy, query formulation strategy, and context integration mechanism. Using three representative datasets LoCoMo, LONGMEMEVAL, and MemAgentBench, Neuromem evaluates interchangeable variants within a shared serving stack, reporting token-level F1 and insertion/retrieval latency.Overall, we observe that performance typically degrades as memory grows across rounds, and time-related queries remain the most challenging category. The memory data structure largely determines the attainable quality frontier, while aggressive compression and generative integration mechanisms mostly shift cost between insertion and retrieval with limited accuracy gain.
****

Who Transfers Safety? Identifying and Targeting Cross-Lingual Shared Safety Neurons
Xianhui Zhang, Chengyu Xie, Linxia Zhu, Yonghui Yang, Weixiang Zhao, Zifeng Cheng, Cong Wang, Fei Shen, Tat-Seng Chua
Multilingual safety remains significantly imbalanced, leaving non-high-resource (NHR) languages vulnerable compared to robust high-resource (HR) ones. Moreover, the neural mechanisms driving safety alignment remain unclear despite observed cross-lingual representation transfer.In this paper, we find that LLMs contain a set of cross-lingual shared safety neurons (SS-Neurons), a remarkably small yet critical neuronal subset that jointly regulates safety behavior across languages. We first identify monolingual safety neurons (MS-Neurons) and validate their causal role in safety refusal behavior through targeted activation and suppression. Our cross-lingual analyses then identify SS-Neurons as the subset of MS-Neurons shared between HR and NHR languages, serving as a bridge to transfer safety capabilities from HR to NHR domains. We observe that suppressing these neurons causes concurrent safety drops across NHR languages, whereas reinforcing them improves cross-lingual defensive consistency. Building on these insights, we propose a simple neuron-oriented training strategy that targets SS-Neurons based on language resource distribution and model architecture. Experiments demonstrate that fine-tuning this tiny neuronal subset outperforms state-of-the-art methods, significantly enhancing NHR safety while maintaining the model's general capabilities.

AOEB: Benchmarking Agent-Oriented Multimodal Embeddings
Xin Zhang, Jiaxin Xu, mengjia zhou, Xinping Zhao, Yinghui Li, di yin, Xing Sun, Meishan Zhang, Baotian Hu, Wenjie Li, Min Zhang
LLM agents powered by retrieval and RAG are increasingly prevalent across research and applications. Embedding models play a critical role in these systems, particularly in embedding-based retrieval. However, current benchmarks for embeddings remain focused on general-purpose scenarios, which may fail to align well wit

h the diverse and evolving needs of agentic applications. To close this gap, we introduce Agent-Oriented Embedding Benchmark (AOEB), a comprehensive evaluation suite dedicated to agent-centric retrieval for embedding models. AOEB is characterized by two key features: (1) Multi-Task, covering five essential capabilities for retrieval in LLM agents, including code, tool, reasoning, and memory retrieval; and (2) Multi-Modal, providing evaluation with both textual and visual data for each task category. We evaluate representative embedding models on AOEB and observe that they exhibit distinct strengths across different agent-oriented retrieval tasks. By curating AOEB, we aim to promote a move toward more practically oriented directions within the embedding community and foster further progress.

ReasonEdit: Editing Vision--Language Models using Human Reasoning

Jiaxing Qiu, Kaihua Hou, Roxana Daneshjou, Ahmed Alaa, Thomas Hartvigsen

Model editing aims to correct errors in large, pretrained models without altering their unrelated behaviors. While some recent works have edited vision–language models (VLMs), no existing editors tackle reasoning-heavy tasks, which typically require humans and models to reason about images. We therefore propose ReasonEdit, the first VLM editor to let users explain their reasoning during editing, introducing a new, practical model editing setup. ReasonEdit continuously stores human reasoning in a codebook, and retrieves only relevant facts during inference using a novel topology-balanced multimodal embedding method inspired by network science. Across four VLMs on multiple rationale-based visual question answering datasets, ReasonEdit achieves state-of-the-art editing performance, ultimately showing that using human reasoning during editing greatly improves edit generalization.

AdamO: A Collapse-Suppressed Optimizer for Offline RL

Nan Qiao, Sheng Yue, Shuning Wang, Ju Ren

Offline reinforcement learning (RL) can fail spectacularly when bootstrapped temporal-difference (TD) updates amplify their own errors, driving the critic toward extreme and unusable Q-values.

A key counterintuitive insight of this work is that collapse is not only a property of the backup rule or network architecture: the optimizer alone can directly trigger or suppress instability.

From a control-theoretic viewpoint, we model offline TD learning as a feedback system and analyze Adam-based critic updates.

This yields a necessary and sufficient condition for stability: training is stable if and only if the spectral radius of the update dynamics is strictly below one.

Further analysis reveals that standard Adam updates can inadvertently distort the parameter geometry, necessitating explicit orthogonality constraints to prevent TD error amplification.

To this end, we propose AdamO, an Adam-based optimizer with a decoupled orthogonality correction regulated by a strict task-alignment budget.

We prove that this design theoretically guarantees worst-case task safety and preserves Adam’s continuous-time dissipative dynamics.

Empirically, AdamO is plug-and-play across diverse offline RL baselines, improving stability and returns across a broad suite of benchmarks.

SWE-MiniSandbox: Container-Free Reinforcement Learning for Building Software Engineering Agents

Danlong Yuan, Wei Wu, Zhengren Wang, Xueliang Zhao, Huishuai Zhang, Dongyan Zhao

Reinforcement learning (RL) has become a key paradigm for training software engineering (SWE) agents, yet its practical accessibility and scalability is often constrained by container-based execution frameworks used for environment isolation. As the number of task instances increases, pre-cached container images introduce substantial storage overhead, limiting large-scale training under limited container resources, and excludes users without container management privileges. We introduce SWE-MiniSandbox, a lightweight, container-free method that enables sc

alable RL training of SWE agents without sacrificing isolation. Instead of relyi ng on per-instance containers, SWE-MiniSandbox executes each task in an isolated workspace backed by kernel-level mechanisms, substantially reducing system over head. It leverages lightweight environment pre-caching techniques to eliminate t he need for bulky container images.
As a result, our approach lowers disk usage to approximately 5\% of that require d by container-based pipelines and reduces environment preparation time to about 25\% of the container baseline. Empirical results demonstrate that SWE-MiniSand box achieves evaluation performance comparable to standard container-based pipel ines. Consequently, by removing the dependency on heavy container infrastructure , SWE-MiniSandbox offers a practical and accessible foundation for scaling RL-ba sed SWE agents, particularly in resource-constrained research environments.

DecomPose: Disentangling Cross-Category Optimization Contention for Category-Lev el 6D Object Pose Estimation

Yifan Gao, Lu Zou, Zhangjin Huang, Guoping Wang

Category-level 6D object pose estimation is typically formulated as a multi-cate gory joint learning problem with fully shared model parameters. However, pronoun ced geometric heterogeneity across categories entangles incompatible optimizatio n signals in shared modules, resulting in gradient conflicts and negative transf er during training. To address this challenge, we first introduce gradient-based diagnostics to quantify module-level cross-category contention. Building on res ults of diagnostics, we propose DecomPose, a difficulty-aware decomposition fram ework that mitigates optimization contention via: (1) difficulty-aware gradient decoupling, which groups categories using a data-driven difficulty proxy and rou tes each instance to a group-specific correspondence branch to isolate incompati ble updates; and (2) stability-driven asymmetric branching, which assigns higher -capacity branches to structurally simple categories as stable optimization anch ors while constraining complex categories with lightweight branches to suppress noisy updates and alleviate negative transfer. Extensive experiments on REAL275, CAMERA25, and HouseCat6D demonstrate that DecomPose effectively reduces cross-c ategory optimization contention and delivers superior pose estimation performanc e across multiple benchmarks.

Modeling Covariate Transition for Efficient Estimation of Longitudinal Treatment Effects in Randomized Experiments

Naoki Chihara, Tatsushi Oka, Yasuko Matsubara, Yasushi Sakurai, Shota Yasui

We present a regression-adjustment framework designed for the estimation of long itudinal treatment effects in randomized experiments under static regimes. While regression-adjustment methods are useful for variance reduction in randomized e xperiments by using pre-treatment covariates, they usually focus only on average effects, from which we cannot obtain valuable insights into when the effects ap pear and how long they continue. To address this issue, we consider intermediate outcomes and evolving post-treatment covariates over time, and we represent suc h dynamic trajectories using transition kernels. Furthermore, we establish the a symptotic normality and the semiparametric efficiency bound for our estimator, e nabling more powerful statistical inference. Simulation studies and empirical an alysis using A/B test data from a streaming platform in Japan show the practical advantages of our method.

Spatial Priors via Space Filling Curves for Small and Limited Data Vision Transf ormers

Leyla Naz Candogan, Arshia Afzal, Pol Puigdemont, Volkan Cevher

Though Vision Transformers (ViTs) have become the dominant backbone in many comp uter vision tasks, due to permutation equivariance, their attention mechanism la cks explicit spatial inductive biases. This become particularly important in two settings: when model capacity is small or training data is limited. Inspired by the attention masking strategies in Linear Transformers and the scanning patter ns of Vision SSMs, we introduce VIOLIN, a lightweight masked attention mechanism that encodes spatial structure within attention via Space Filling Curves (SFCs)

with less than 0.0015% extra parameters and negligible computational overhead. VIOLIN scans the image using multiple SFCs to construct curve-specific decay masks, which are then combined and multiplied with the attention matrix. Across a wide range of evaluations, VIOLIN consistently improves performance. In limited data regimes such as fine-tuning on VTAB-1K, it boosts accuracy across all task groups and by up to 8.7% on the tasks where spatial information is essential. It can be combined with parameter-efficient fine-tuning methods such as LoRA to further increase the performance. Beyond fine-tuning, VIOLIN improves various small scale ViT architectures (e.g., DeiT, DINO) during pretraining on ImageNet-1K. Additionally, on pixel-level CIFAR-100 training, a task that is highly dependent on location information, VIOLIN increases accuracy by up to 7.2%. Overall, VIOLIN provides a computationally efficient yet effective way to inject spatial inductive bias into ViTs, especially benefiting small models and limited data settings.

MACD: Model-Aware Contrastive Decoding via Counterfactual Data for Video-LLMs

Qixin Xiao, Kun Zhou

Video language models (Video-LLMs) are prone to hallucinations, generating plausible but ungrounded content when visual evidence is weak, ambiguous, or biased. Existing methods, such as contrastive decoding (CD), rely on random perturbations to construct contrastive data for hallucination mitigation, but often fail to target the visual cues that drive hallucination or align with model weaknesses. We propose Model-Aware Counterfactual Data based Contrastive Decoding (MACD), an inference strategy that combines model-guided counterfactual construction with contrastive decoding. MACD uses the Video-LLM's own feedback to identify object regions most responsible for hallucination, generating targeted object-level counterfactual inputs rather than arbitrary frame or temporal modifications. These counterfactual inputs are integrated into CD to enforce evidence-grounded token selection during decoding. Experiments on EventHallusion, MVBench, Perception-test, and Video-MME show that MACD consistently reduces hallucination while maintaining or improving task accuracy across diverse Video-LLMs, including Qwen and InternVL, with especially strong gains in scenarios involving small, occluded, or co-occurring objects.

Momentum Further Constrains Sharpness at the Edge of Stochastic Stability

Arseniy Andreyev, Advikar Ananthkumar, Marc Walden, Tomaso Poggio, Pierfrancesco Beneventano

Recent work suggests that (stochastic) gradient descent self-organizes near the instability boundary, shaping both optimization and the solutions found. Momentum and mini-batch gradients are widely used in practical deep learning optimization, but it remains unclear whether they operate in a comparable regime of instability. We demonstrate that SGD with momentum exhibits an Edge of Stochastic Stability (EoSS)-like regime with \textit{batch-size--dependent behavior} that cannot be explained by a single momentum-adjusted stability threshold. Batch Sharpness (the expected directional mini-batch curvature) stabilizes in two distinct regimes: at small batch sizes it converges to a lower plateau $2(1-\beta)/\eta$, reflecting amplification of stochastic fluctuations by momentum and favoring flatter regions than vanilla SGD; at large batch sizes it converges to a higher plateau $2(1+\beta)/\eta$, where momentum recovers its classical stabilizing effect and favors sharper regions consistent with full-batch dynamics. We further show this aligns with linear stability thresholds and we discuss the implications on hyperparameters tuning and coupling.

Reliable Neighborhood-Aware Multi-View Outlier Detection

Huijie Ma, Haoyuan Xin, Lei Meng, Guanzhou Ke, Yongyong Chen, Guoqing Chao

In recent years, multi-view outlier detection (MVOD) has gained increasing attention, with the primary objective of recovering the underlying structure of normal data from outlier-contaminated multi-view datasets. However, this objective is hindered by two fundamental challenges:(i) outlier propagation, (ii) scale discrepancy.

To address these issues, we propose RNAMOD (Reliable Neighborhood-Aware Multi-View Outlier Detection), which introduces the concept of reliability and constructs a reliable neighborhood structure to avoid outlier propagation. We introduce a leave-one-out directional consensus mechanism to align cross-view neighborhood structures while preventing scale discrepancy by aligning geometric directions that remain invariant to scaling.
Extensive experiments on six benchmark datasets demonstrate that RNAMOD consistently outperforms state-of-the-art methods.

Efficient Training-Free Multi-Token Prediction via Embedding-Space Probing
Raghavv Goel, Mukul Gagrani, Mingu Lee, Christopher Lott
Large Language Models (LLMs) possess latent multi-token prediction (MTP) abilities despite being trained only for next-token generation. We introduce ESP (Embedding-Space Probing), a simple and training-free MTP method that probes an LLM using on-the-fly mask tokens drawn from its embedding space, enabling parallel future-token prediction without modifying weights or relying on draft models.
ESP constructs a speculative token tree by sampling Top-K candidates from mask-token logits and applies a lightweight pruning rule to retain high-probability continuations. During generation, predictions are verified in parallel, yielding lossless decoding while significantly reducing model calls and increasing token throughput.
ESP consistently outperforms existing training-free baselines, improving acceptance length by 7–11% over Lookahead Decoding on LLaMA3 and 7–8% on Qwen3, and increasing throughput by up to 15–19% over the strongest baseline.
Finally, we provide theoretical insight and empirical evidence showing that decoder layers naturally align mask-token representations with next-token states, enabling accurate multi-step prediction without retraining or auxiliary models.

How Does the Lagrangian Guide Safe Reinforcement Learning through Diffusion Models?
Xiaoyuan Cheng, Wenxuan Yuan, Boyang Li, Yuanchao Xu, Yiming Yang, Hao Liang, Bei Peng, Robert Loftin, Zhuo Sun, Yukun Hu
Diffusion policy sampling enables reinforcement learning (RL) to represent multimodal action distributions beyond suboptimal unimodal Gaussian policies. However, existing diffusion-based RL methods primarily focus on offline setting for reward maximization, with limited consideration of safety in online settings. To address this gap, we propose Augmented Lagrangian-Guided Diffusion (ALGD), a novel algorithm for off-policy safe RL. By revisiting optimization theory and energy-based modeling, we show that the instability of primal–dual methods arises from the non-convex Lagrangian landscape. In diffusion-based safe RL, the Lagrangian can be interpreted as an energy function guiding the denoising dynamics; counter-intuitively, direct usage destabilizes both policy generation and training. ALGD resolves this issue by introducing an augmented Lagrangian that locally convexifies the energy landscape, yielding a stabilized policy generation and training, without altering the distribution of optimal policy. Theoretical analysis and extensive experiments demonstrate that ALGD is both theoretically grounded and empirically effective, achieving strong and stable performance across diverse environments.

DGG-HMR: Multi-Person Human Mesh Recovery with Depth-Guided Geometric Anchoring
Yanjie Li, Le Hui, Yali Peng, Shigang Liu
Multi-person human mesh recovery (HMR) from a single image is inherently ill-posed, as multiple 3D poses can produce identical 2D projections due to depth ambiguity. Most existing methods implicitly regress 3D translation from image features, which often leads to unreliable depth estimation. To address this issue, we propose a depth-guided multi-person HMR framework that explicitly models instance-level depth cues and integrates them into mesh recovery. Specifically, we first introduce an instance-aware depth estimator to predict per-person pelvis depths that serve as explicit 3D anchors, thereby decoupling depth estimation from mesh regression.

Then, we design a geometry-anchored refinement decoder that uses these anchors to initialize each instance within a plausible 3D neighborhood, stabilizing mesh refinement under joint 2D-3D supervision. Finally, we adopt a single-stage joint training strategy to coordinate depth estimation and mesh recovery in a unified framework. Extensive experiments on multiple benchmarks demonstrate that our method achieves state-of-the-art performance in both mesh reconstruction accuracy and depth ordering.

Deep networks learn to parse uniform-depth context-free languages from local statistics
Jack T. Parley, Francesco Cagnetta, Matthieu Wyart
Understanding how the structure of language can be learned from sentences alone is a central question in both cognitive science and machine learning. Studies of the internal representations of Large Language Models (LLMs) support their ability to parse text when predicting the next word, while representing semantic notions independently of surface form. Yet, which data statistics make these feats possible, and how much data is required, remain largely unknown. Probabilistic context-free grammars (PCFGs) provide a tractable testbed for studying these questions. However, prior work has focused either on the post-hoc characterization of the parsing-like algorithms used by trained networks; or on the learnability of PCFGs with fixed syntax, where parsing is unnecessary. Here, we *(i)* introduce a tunable class of PCFGs in which both the degree of ambiguity and the correlation structure across scales can be controlled; *(ii)* provide a learning mechanism---an inference algorithm inspired by the structure of deep convolutional networks---that links learnability and sample complexity to specific language statistics; and *(iii)* validate our predictions empirically across deep convolutional and transformer-based architectures. Overall, we propose a unifying framework where correlations at different scales lift local ambiguities, enabling the emergence of hierarchical representations of the data.

dgMARK: Decoding-Guided Watermarking for Diffusion Language Models
Pyo Min Hong, Albert No
We propose dgMARK, a decoding-guided watermarking method for discrete diffusion language models (dLLMs). Unlike autoregressive models, dLLMs can generate tokens in arbitrary order. While an ideal conditional predictor would be invariant to this order, practical dLLMs exhibit strong sensitivity to the unmasking order, creating a new channel for watermarking. dgMARK steers the unmasking order toward positions whose high-reward candidate tokens satisfy a simple parity constraint induced by a binary hash, without explicitly reweighting the model’s learned probabilities. The method is plug-and-play with common decoding strategies (e.g., confidence, entropy, and margin-based ordering) and can be strengthened with a one-step lookahead variant. Watermarks are detected via elevated parity-matching statistics, and a sliding-window detector ensures robustness under post-editing operations including insertion, deletion, substitution, and paraphrasing. Project website: https://dgmark-watermarking.github.io

Neural Vector Lyapunov–Razumikhin Certificates for Delayed Interconnected Systems
Jingyuan Zhou, Yuexuan Wang, Kaidi Yang
Ensuring scalable input-to-state stability (sISS) is critical for the safety and reliability of large-scale interconnected systems, especially in the presence of communication delays. While learning-based controllers can achieve strong empirical performance, their black-box nature makes it difficult to provide formal and scalable stability guarantees. To address this gap, we propose a framework to synthesize and verify neural vector Lyapunov-Razumikhin certificates for discrete-time delayed interconnected systems.
Our contributions are three-fold. First, we establish a sufficient condition for discrete-time sISS via vector Lyapunov-Razumikhin functions, which enables certification for large-scale delayed interconnected systems. Second, we develop a scalable synthesis and verification framework that learns the neural certificates

and verifies the certificates on reachability-constrained delay domains with scalability analysis. Third, we validate our approach on mixed-autonomy platoons, drone formations, and microgrids against multiple baselines, showing improved verification efficiency with competitive control performance.

Bayesian Gated Non-Negative Contrastive Learning
Peng Cui, Jiahao Zhang, Lijie Hu
While Contrastive Learning (CL) has revolutionized self-supervised representation learning, its latent representations remain highly entangled and opaque, limiting their interpretability in safety-critical applications. We identify that a fundamental cause of this entanglement is the reliance on deterministic similarity measures, which treat all feature dimensions equally. In compositional scenes, this creates an Optimization Conflict: common background features, such as, "blue sky", are encouraged to align in positive pairs but simultaneously repelled in negative pairs, causing gradient oscillations that hinder precise semantic disentanglement. To address this, we propose **BayesNCL** (Bayesian Gated Non-Negative Contrastive Learning). Unlike standard approaches, BayesNCL introduces a probabilistic gating mechanism that dynamically filters out task-irrelevant, high-frequency common features while selectively retaining discriminative semantics. By formalizing feature selection as a variational inference problem with a sparse Bernoulli prior, our method effectively resolves the optimization conflict. Empirical experimental results on Imagenet-100 demonstrate that BayesNCL achieves a remarkable 142.1\% improvement in semantic consistency compared to state-of-the-art baselines, yielding highly interpretable representations without compromising downstream task performance. Code is available at https://github.com/Cui-Peng-624/BayesNCL.

Editable Proof Sketch for Automated Theorem Proving
Zikai Xiao, Hanzheng Wang, Meng-Hao Guo, Shi-min Hu, Shing-Tung Yau
As large language models (LLMs) improve in mathematical reasoning and formal understanding, a promising approach for automated theorem proving (ATP) is to enable LLMs construct proof sketches, which plan a high-level proof strategy and decompose complex theorems into independently provable subgoals. However, most existing proof sketches are immutable. As a result, any revision typically requires rebuilding the entire sketch, which discards already proved subgoals and bring additional cost. In this paper, we address this limitation by introducing EditableSketch, an editable proof-sketch structure that supports in-place edits for error correction and further subgoal decomposition while preserving previously proved subgoals. Building on EditableSketch, we introduce SketchRefine, a proof-generation framework for ATP by iteratively refining proof sketches through localized, incremental edits. Experiments show that our method not only reduces the cost of the proof process, but also achieves superior performance. For example, our method realizes 76.0% pass rate on FormalMath-Lite (+14.1\% vs. DeepSeek-Prover-V2-671B). Meanwhile, compared with Hilbert, our method significantly reduces token overhead while achieving comparable performance.
****
Dual-branch Robust Unlearnable Examples
Xianlong Wang, Hangtao Zhang, Wenbo Pan, Ziqi Zhou, Changsong Jiang, Li Zeng, Xiaohua Jia
Unlearnable examples (UEs) aim to compromise model training by injecting imperceptible perturbations to clean samples.
However, existing UE schemes exhibit limited robustness against advanced defenses due to their heuristic design or narrowly scoped domain perturbations. To address this, we propose DUNE, a Dual-branch UNlearnable Ensemble perturbation optimization approach. Specifically, DUNE separately optimizes perturbations in the spatial and color domains to establish the mapping between perturbations and shift-induced labels. This design extends the perturbation domain to increase noise intensity for improving robustness and drives the models to learn perturbation-oriented features with degraded generalization, thereby achieving unlearnability. To strengthen DUNE's performance, we further propose an unlearnability-en

hancing ensemble strategy that aggregates diverse pre-trained models during the dual-branch optimization. Extensive experiments on benchmark datasets CIFAR-10 and ImageNet verify that DUNE's robustness outperforms 12 SOTA UE schemes under 7 mainstream defenses, yielding a lower average test accuracy of 14.95% to 50.82%.
